The first was that of an eminent merchant with numerous family connections, 65 years of age, a *bon vivant*, well known as a hospitable host as well as a genial guest. I am at his bedside in consultation with his ordinary medical attendant. He is semi-comatose; he has been so for twelve hours. His friends have been summoned from different parts of the country in the expectation of his death. There is general anasarca, some oppression of breathing, but a fair pulse, regular in its beat, 78 per minute; there is an aortic murmur with the first sound of the heart, but not very loud. The patient was able to be roused if spoken to loudly, and then dimly understanding what was said to him, but lapsing again into stupor; the eyes responded equally to light, and contracted to a point, equally dilating again on its removal; the conjunctivæ were turgid, the skin dry and felt hot, but the temperature, as taken in the mouth, showed that it was below normal, namely, 97.8°. The urine was very albuminous; the bowels had been freely relieved, indeed there had been slight relaxation for some time previously to the onset of his semi-coma. He had complained of feeling faint when the bowels acted; had for some days taken freely of stimulants, principally champagne and brandy, and since the previous day had swallowed about twenty-four ounces of the latter. He had passed at least three pints of water in the preceding twenty-four hours, and it was dribbling away slightly into the bed at the time of my visit. A catheter was introduced into the bladder and a portion drawn off, which was seen to contain about a quarter albumen after boiling. The comatose condition did not appear to me to be caused by uræmia, as there had been no arrest of urinary secretion, but the contrary, and there had been also relaxed bowels. The faintness was not caused by any serious heart embarrassment, for that organ, though probably fatty, and with aortic valves imperfect in consequence, as I supposed, of atheroma, was doing its duty. I came to the conclusion that the coma was rather the sequence of alcoholism than that of uræmic poisoning. I advised the cessation of the brandy treatment, which had really been pressed by the friends and nurses rather than the doctor, because it had been advised some time previously by an eminent London physician. I advised the administration of ammonia in its place, in minute quantities, with liq. potassæ, also in small doses. I urged the continuance of intestinal evacuations by means of assafoetida injections with small quantities of turpentine, and suggested a milk diet only. The following day the coma had lessened. It disappeared in forty-eight hours, and symptoms of gout manifested themselves a few days afterwards in the hands and elbows, whilst the respiratory difficulty diminished. The patient made a fair recovery in a few days from the imminent danger in which he was placed, and the anasarca lessened. He had however too much gout in his kidney, and atheroma in his aorta, to become convalescent; though he lived for four years after the time at which he was being rapidly poisoned by alcohol. The belief that the coma was due to the brandy, and not to the presence of uræmic poisoning, was thoroughly established by the result. Fortunately the kidneys did not immediately resent the excessive intrusion of the stimulant, for they continued to act freely, though the water was albuminous as long as he continued under my observation; the general dropsy declined, the aortic insufficiency however was not improved, and he remained for a long time incapable of exertion, though he did recover so much as to be able to take his place at the dinner-table again, and ultimately fell a victim to the renewal of his social habits of life, and a return to the pleasures of the after-dinner wine.

In this case, as in some others which I have met with, the aortic insufficiency has seemed to me to have been dangerously added to by the alcohol; and that in such cases, especially when there is gouty habit with albuminous urine, it seems to produce its comatose tendencies more rapidly than in other people, and in such cases I believe that all alcoholic stimulants should be rigorously withheld. This patient had been advised to take gin, by an eminent London physician, and for some weeks before the time at which I saw him had taken something like a pint a day, in the place of the port and brandy to which he was addicted. He could not or would not continue an abstaining course, for he preferred his port wine and obliviousness to discomfort and continuance in the flesh, though I am certain he would have lived some time longer if he had followed on the other tack, and even might have had a chance of recovery if he would have continued his absti-

¹ A paper read to the British Medical Temperance Association, Tuesday, February 21st, 1888.

nence, and have avoided those causes which tended to produce atheroma; for a kind of gluttony was indulged in, as well as a liking for wine.

The second case is altogether different in character, but quite as marked.

It is that of a young student who is working at his college; he comes home in consequence of inability to continue his mental labour, and with a feverish attack. He becomes ill, and I see in him what is considered to be the fifth day of an attack of typhoid fever. He is restless, has severe headache; his eyes are brilliant, and pupils somewhat inactive to the stimulus of light; his skin pale, and temperament leucophlegmatic. He has not slept much for some week or two, and talked a little at random on the preceding night. His pulse 102, running and thready; temperature 102.4° ; tongue very moist, but little furred, and slightly swollen. He is not particularly thirsty. There is some tympanites; skin dry; bowels confined. He had vomiting for a day or two at the first commencement of fever, but the sickness is gone, and he does not care for food, though he enjoys cold drinks. The urine somewhat scanty, high-coloured, but loaded with lithates, and non-albuminous. I regarded it as one of those cases of typhoid in which cerebral symptoms were likely to develop very rapidly, in consequence of the brain having been over-excited and not purifying itself from the consequences of its work. Every case of this kind which I have met with which had been treated with stimulants had died, sometimes after violent and continuous delirium, leading in subsultus and unconsciousness for twenty-four hours or more before death.

I advised, therefore, that all alcoholic beverages should be laid aside, and the case treated with salines, bromide of potassium, and milk; whilst we should relieve the loaded bowels by gentle aperients, and watch for complications. The heart sounds were normal, but there were some mucous râles in the chest, which were uncomfortable at so early a stage of the fever.

The case, after two or three days of suspense, ran a satisfactory course; the bowels were relieved by slight laxatives, the restlessness subsided, fair sleep was obtained, the characteristic rash came out about the ninth to the fourteenth day, with slight diarrhoea; the tumid abdomen subsided, the tongue lost its swollen character, and on the nineteenth day (when I saw him for the third time) was clean. The temperature 99.8° , the skin acting freely, and the appetite becoming more keen, so much so that I said to the mother, "In two or three days you will be altogether out of the wood." Two days afterwards I had a telegram, saying, "Come as quick as possible: my boy is dying." I went that afternoon. One of his medical attendants met me at the station, and said at once, "I don't know what has produced the condition, but it is comatose. He was very excited yesterday, wanted to get up and go out, insisted upon doing various things, was violent in the night, and to-day has been unconscious since 10 A.M." (this was at 4 P.M.). I found him as reported; the conjunctivæ were turgid, and non-resistant when the finger was placed on them, the pupils were contracted to a point, the skin was hot and dry, the face flushed, and the patient took no notice whatever of those about him, but the pulse was full and steady (88), not like to that of a dying man, the heart-sounds normal, the breathing steady, but inclined to stertor. The bowels had acted freely two or three times the day before, and there had been a free secretion of urine, and it continued free from albumen. The temperature had been taken several times since my visit two days before. The same night it sank to 98.4° . In the night it was 98° only, yesterday it sank to 97.6° , then in the evening it was 96.8° , and now I find it 96.2° . The medical attendants had viewed this fall of temperature with some alarm, and, acting upon an implied consent to the administration of alcohol, had allowed him to have champagne the day before, with the natural result of a still lower temperature. Since last night he had had eight ounces of brandy in addition to the half bottle of champagne which he had insisted upon having, and which fact the nurses had not communicated to the medical men in attendance. The error arose from my inadvertent consent to his urgent entreaty that he should be allowed a little claret and water on the occasion of my third visit. He had had that claret and water; it gave him a restless night, reduced his temperature below the normal standard, and, from a mistaken idea that alcohol would elevate the temperature, it was administered more freely the next day. The restlessness and excitement were increased; those symptoms were looked upon as reasons for increasing the dose of the stimulant, until at length its narcotising properties

were forthcoming. Perhaps he might have slept off the effects, and have recovered in spite of the treatment, which then in that case would have been regarded as the cause of the recovery. Having carefully considered all the points with his medical attendants in another room, I came to the conclusion that the coma was caused by his so-called remedies. I went back to his bedroom, and giving him a good shake, called out quite loudly, "H—, old boy, how are you?" He heard me, and opening his eyes looked at me with a tipsy leer, said, "Oh! is it you?" and lapsed again into insensibility. I was quite satisfied as to the condition, but felt myself on the horns of a dilemma. However, I asked his medical attendants to leave me to get out of the difficulty without casting any reflection upon their treatment, having pointed out to them the real state of the case. It was my duty to restore the patient, not to make reflections. I saw the mother downstairs; I told her that of course there was jeopardy, but that I thought the danger more apparent than real; that we should discontinue the stimulants which had been given, as not being efficient enough to meet the severity of the case, and that I proposed to give him a more powerful remedy—a single drop of the strongest liquor ammonia every half hour. I advised that he should be made to swallow as much liquid as could be managed in the form of tea and milk and potass water, and with external appliances I hoped to find tomorrow that he had recovered his consciousness, and that he would be restored to her as I had promised on my preceding visit.

There was no idea on the part of the parents as to the error that the nurses, rather than the doctor (for there were two experienced women in charge of the case), had committed, and I had the pleasure the next day of finding my anticipation correct; the coma was gone, headache and *malaise* alone remained, the temperature had risen to 98.4° , there was slight tumidity over the abdomen, the bowels had not acted, but the tongue was moist, a little whiter than normal. He had slept, however, for some half-an-hour at a time after several small doses of bromide of potassium, and two days afterwards was sitting up in bed, and suffering from nothing but a ravenous appetite and general debility.

I have brought these typical cases to your notice for the purpose of showing that one must not always assume that the symptoms in the case are those of the disease which you are called upon to treat. You must ask yourselves whether they are masked by previous treatment; patients and their friends will treat themselves before the doctor is sent for, and in cases in which a consultation is sought for, either at the instance of the medical attendant or of the patient's friends, the former may have exhibited larger doses of powerful remedies than he is aware of, and the symptoms of the remedy may be masking the character of the disease. I have seen this in at least two cases in which belladonna had been given in excess. Narcotics and stimulants are the most usual medicines which have been prescribed, especially the latter. The reduced temperature, the moderately quick pulse, the contracted pupil, the flushed conjunctivæ, the dry skin, and the headache, may all be added to or produced by the remedy used; and may therefore mask the disease and cause erroneous views as to nature, prognosis, and necessary treatment. We can only act upon the information afforded, and if deceived, either wilfully or by ignorance, it is the patient who suffers as well as the reputation of the physician who is consulted.

I am satisfied that it is far better to allow disease to run its course in a natural way, and to pilot the case through the blood-storms which the disease may be setting up, rather than by rendering the nervous system less sensitive to the influences of disease by deadening the activity of those nerves, and whilst so deadened allowing disease to establish itself, and so organic change may take place, never to be entirely removed. This appears to me to be the effect of the alcoholic treatment of disease. It is better for the patient to endure the discomfort, and ultimately get quite well, than to be comforted, as it is called, by the use of intoxicating liquor, and so allow real disease to gain a standpoint, instead of treating upset which arises from the functional disturbance caused by the determination of natural laws to assert their predominance, and so to lead to a perfect cure.

MR. P. MILLS has been appointed Librarian to Guy's Hospital. The Bootle Town Council have increased the salary of Mr. Robert J. Sprakeling, the medical officer of health, from £100 to £120 per annum.

ABSTRACTS OF THE MILROY LECTURES ON SOME GENERAL CONDITIONS WITH REGARD TO EPIDEMICS.

Delivered at the Royal College of Physicians of London,
February and March, 1888.

By ROBERT LAWSON, L.R.C.S.ED.,
Inspector-General (Retired) Army.

LECTURE IV.—CHOLERA.

Clinical Resemblances between Malignant and Summer Cholera.

—The lecturer first observed that similar difference of opinion as to the mode in which cholera was propagated existed, as in the case of yellow fever; one party holding that it was highly contagious and always transmitted from man to man, the other that it was devoid of contagion, and depended on local causes. He considered that cholera occurred under two forms, cholera nostras, or summer cholera, and Asiatic, Indian, or, as he preferred to call it, malignant cholera. Cholera nostras appeared every summer to a limited extent; malignant cholera, in temperate climates, as an epidemic advancing over new ground in successive years. Though typical cases of the former could be readily distinguished, sporadic cases were met with presenting the characters of the malignant disease so completely that if observed during an epidemic of the latter, they would be accepted without hesitation as typical examples of it. Such cases sometimes occurred in small groups, but were not invasive, and for this reason, and because they cannot be affiliated to a previous case, those who hold the theory of contagion do not admit them to be examples of malignant disease.

Epidemics without Importation.—Epidemics had, however, occurred where the most careful investigation by experienced observers had entirely failed to establish any history of communication. An instance of this was, he considered, afforded by the outbreak at Southampton and Theydon Bois in 1865 when impartially studied. The circumstances were investigated by the late Dr. Parkes, whose summing up, with regard to the epidemic at the former place, was: "The origin of an unknown epidemic influence, alone or concurring with local conditions, presents formidable difficulties, even if we cannot quite reject it. The origin by importation is deficient in precision of evidence." Another instance was that of the epidemic which commenced in New Orleans in 1873, and extended up the valleys of the Mississippi, Ohio, and Missouri. The Board of Health at New Orleans, after most minute examination of every circumstance connected with the shipping, came to the conclusion that it had not been imported, and Surgeon Van Buren Hubbard, United States Army, who had made an investigation for the Government, stated that it had "been found utterly impossible to establish the arrival of individuals who were personally affected with cholera." The outbreak of cholera without importation being admitted, it could not be maintained in other instances where an outbreak had been preceded by the importation of cases of cholera, that the epidemic was produced by them unless local causes could be excluded.

Epidemiological Relations of Malignant and Summer Cholera.—Cholera nostras was not a disease depending on the warmth of summer, or the abundance of fruit. The English, the Scotch, and the French returns, when examined for sufficiently long periods, showed that the frequency and fatality of cholera nostras rose as the country was approached by the epidemic malignant disease, and fell again as it passed on. The military returns taught the same lesson for other parts of the world. There therefore appeared to be the same kind of connection between cholera nostras and malignant cholera, as between benign plague and plague.

Cholera in India.—Recent investigations had rendered it doubtful whether the district of Bengal, which the late Dr. Bryden had described as the endemic area, was the only one which existed even in India. Dr. Bryden had concluded that the spread of the disease from that area was governed by the meteorological conditions prevailing at the time, the *materies morbi* being airborne; he was further led to infer that this *materies* existed in two forms, one in which its pathogenic properties were fully developed, the other in which these properties were only potential. This potential *materies* was often deposited far in advance

of the epidemic, and took twelve or fourteen days to develop under favourable circumstances; but at the end of the cholera season might remain dormant for months, until the return of that season when, like other forms of vegetation, it would develop its potential pathogenic properties.

Cholera at Sea.—From the examination of cases of cholera occurring on board coolie ships, and on certain islands and sea-coasts in the Indian Ocean, it appeared that the choleric factor was active from 1872 to 1874, over the sea from Sumatra to the south-west as far as Mauritius, while over the greater part of Hindustan it was inoperative, and the disease had almost disappeared. This frequency of cholera over the sea ceased suddenly in 1875, and coincidentally the epidemic spread over Hindustan from Cape Comorin to Lahore; Ceylon being affected before the mainland, a most unusual sequence.

The lecturer had collected a large number of notices of outbreaks on board ship in the Atlantic and Indian Oceans; they show that the choleric influence, when it exists, is widely diffused in the south-western part of the Indian Ocean, and that there was a prevalence of choleric diarrhoea and sporadic cases of cholera in Cape Colony and Natal some months before epidemic cholera appeared nearer the equator. Special reference was made to the cases of the *New York*, from Havre to New York, with German emigrants, and of the *Swanton*, from the same port to New Orleans, also with German emigrants (1848). Cholera broke out on board both vessels. After relating the particulars of these outbreaks, the lecturer said: "The question arising out of these occurrences at the time was, How did the passengers in these ships contract cholera in the middle of the Atlantic? One body of epidemiologists said the cause of the disease had been brought from Germany in clothing, and was communicated to those who wore it, after being unpacked, on November 24th. Though the narrative is wanting in many particulars as to localities and dates we should look for now before coming to a conclusion on the subject, it might have been accepted then had the *New York* only been affected; but it was quite inapplicable to the *Swanton*, which had not had cold weather on the 24th, nor any overhauling of chests for warm clothing. Another body of epidemiologists, seeing that a change of wind to the south-east took place with both ships before cholera appeared, were of opinion something must have been conveyed by the wind to cause the disease in both, but where it came from they were unable to indicate."

The Influence of Winds.—The remark of the captain of the *Swanton* that it was "more like artificially heated air than anything else," affords a clue to the mystery that now enables it to be explained. Anyone who has experienced a "hot wind" will see at once this is what he described; but as a hot wind always originates over arid land, how could such a wind have been experienced from the south-east at the place where the *Swanton* was, from which a south-easterly line would pass through the South Atlantic clear of all land? The wind was really from the desert in North Africa. In November, when the north-east trade wind is being re-established over the northern Atlantic, it reaches to 60° north; and about long. 30° west and lat. 20° north at this season winds are frequently experienced of the character described by the captain of the *Swanton*, and, in addition, often bearing red dust in such quantity as to cover the sails and rigging of passing vessels, leaving no doubt as to where they originated, and illustrating their transporting powers. Such a current of air which did not come to the surface of the sea, but continued to flow at some elevation above it, would retain its peculiarities for a long time; it would pass to the inner limit of the trade wind, about 6° north at this season, and then, rising in the atmosphere as the air of the trade does, will then double back to the north-west, becoming a south-east wind, and would reach the *Swanton* as such as described above. In November, 1848, when these occurrences took place, there had been cholera in Egypt and along the north coast of Africa, and with a moderate velocity of twenty miles an hour, the wind might have transported emanations from that to the *Swanton* in from ten to twelve days; and, if to her, there is nothing unreasonable in the inference that it was capable of transporting them to the continent of America itself, which really seems to have taken place on many occasions.

An Air-borne Miasm.—This transport of the exciting cause of cholera by a current, at some elevation in the atmosphere, and separated from the earth's surface by a thick stratum of air which may either be motionless, or forming a current flowing, it may be,

in a different direction, plays a frequent part in connection with the manifestation of that disease. In reading accounts of the circumstances preceding the occurrence of isolated outbreaks in India, one is struck by the frequency with which these immediately follow a thunder storm, or a heavy fall of rain, or even a dust storm, all of which bring a portion of the higher strata to the ground, and with that, of course, whatever material it may contain; this sequence is quite as remarkable at the elevated mountain stations as in the plains, and, as was the case at Peshawar in 1862, this was repeated no less than four times between July 7th and November 3rd, causing a distinct outbreak of cholera on each occasion.

Ships as Infective Areas.—Ships behaved towards cholera in much the same way as towards yellow fever. In some cases, even when crew or passengers have gone on board infected with cholera, the disease ceases after a few days at sea. In other cases the ship became a focus for cholera, so that not only those on board, but also others who came within range of the emanations from her contracted the disease. This had taken place only in crowded emigrant ships, and in them the steerage passengers alone were affected. An example was afforded by the *England* in 1866; out of 1,059 steerage passengers from 280 to 300 died, but none of the cabin passengers were attacked.

HISTOLOGICAL MEMORANDA.

THE "PAL-EXNER" METHOD OF STAINING SECTIONS OF THE CENTRAL NERVOUS SYSTEM.

THIS, like the "Pal-Weigert" method described in the *JOURNAL* of March 10th, is a new and valuable modification of an older method. As taught and practised in the laboratory of the Pathological Institute in Vienna, the method is as follows:—

The fresh brain or other nerve tissue to be examined is divided into small cubes or pieces and hardened for two days in a watery solution of osmic acid, which latter must be changed at least twice. The hardened tissue is then washed carefully in water, and dipped for about two seconds into absolute alcohol. It is then embedded in wax mass or celloidin, and sections from the block are cut by a Rivet-Leyser or other microtome direct into glycerine. From the glycerine the sections are transferred to water and thoroughly washed, and then they are dipped into a one-fourth per cent. watery solution of potassic permanganate for from ten to fifteen seconds to differentiate them. They are further decolorised in "Pal's solution" (oxalic acid and potassic sulphide of each 1 part, and distilled water 200 parts). The sections may now, after being washed in water, be stained further in safranin or picrocarmine, the process being completed by dehydration in absolute alcohol, clearing in creasote, and mounting in Canada balsam.

One great advantage this method presents is that, while retaining all the value of the original osmic acid method of Professor Exner, it enables the sections so prepared to be kept for future reference. From personal experience I consider it a distinct advance, and likely to prove of great service in further investigations on the minute histology and pathology of the nervous system.

For further details regarding this method I may refer to Dr. J. Pal's original and excellent paper read before the Imperial and Royal Society of Physicians in Vienna, in which he describes his modifications of the methods of Professors Exner and Weigert.

London, W.

JOHN J. REDFERN, M.A., M.D.

OBSTETRIC MEMORANDA.

STOPPAGE OF HÆMORRHAGE IN A CASE OF PLACENTA PRÆVIA BY THE EARLY APPLICATION OF FORCEPS.

I THINK the following case may be of interest. On my arrival I found Mrs. S. in labour with her seventh child, and almost moribund from hæmorrhage. On examination by the vagina the os was found about the size of a five-shilling piece, and completely occluded by the placenta, which was adherent all round excepting anteriorly, where the membranes could be reached. Having ruptured the membranes and partially detached the placenta, I waited a little time, in the hope that the hæmorrhage would cease, but, being disappointed, I determined to apply the forceps, fearing

version would cause instant death. This was accomplished much more easily than was anticipated, and I had the satisfaction of finding that slight traction controlled the hæmorrhage. I continued to apply sufficient traction for this purpose for three hours, during which time I fed the patient with egg, milk, and brandy. At the end of this time the patient showed signs of rallying, and there was a return of uterine contraction. The child was born in about half an hour, and the patient made a good recovery.

G. H. WARREN THOMAS,
Teignmouth, Devon. L.R.C.P.Lond., M.R.C.S.

CLINICAL MEMORANDA.

SCARLET FEVER IN A SUCKLING MOTHER.

A FEW weeks ago I attended a lady who had been confined about six weeks, and who had a copious scarlet fever rash on her chest, abdomen, etc., at the time that I first saw her. She had nursed her baby up to within a few hours of my seeing her, although she had felt ill, sore throat, vomiting, etc., and was struck with the fact that the milk, which had been abundant, had failed rapidly after she first began to feel ill. There had been a case of scarlet fever in the same house a few weeks previously. Both patients went through the usual period of "peeling," and recovered perfectly. The child showed no signs of the fever, and was merely a little upset by the sudden weaning that was, of course, necessary.

The patient's breasts were quite flaccid, and, apparently, little or no milk was secreted after the first onset of the disease, nor did it return when the first few days of fever were over.

The entire immunity of the child and the rapid disappearance of the lacteal secretion are, I think, worthy of record, although I am aware that such cases have been frequently published before.

Clifton. BARCLAY J. BARON, M.B. Edin.

HOW DO ROUND WORMS CAUSE CONVULSIONS?

IT is well known how often round worms cause convulsions, and even death. The way in which they act, however, does not seem to be clearly understood. Eichberg (*JOURNAL*, October 31st, 1885, p. 842) mentions cerebral effusion, but in a case recorded by me (*JOURNAL*, January 9th, 1886, p. 66) I found the brain perfectly healthy. The following case seems to suggest a more mechanical explanation.

On January 21st, 1888, I was summoned by the police to view the body of A. B., aged 13 months, who had died suddenly. At 9 the evening before, she was attacked with short quick breathing. She continued in the same state all night, and died at 10 the next morning. There was no vomiting. The necropsy showed the ascending colon twisted on its long axis about four inches beyond the valve. Above the constriction caused by the twist the bowel was distended with flatus, the mucous membrane reddened, and the solitary follicles very prominent. There was a considerable faecal accumulation in the cæcum above the twist, but the rest of the large intestine was nearly void, except of some flatus. On dividing the peritoneum over the ascending colon, the bowel revealed its normal calibre. There were a few round worms in the small intestine, and one in the stomach. The other viscera were healthy.

The next day, January 22nd, the cousin of the deceased, aged 3 years, was brought to me with precisely similar symptoms, namely, short quick breathing and apparent unconsciousness. It was passing round worms. Under castor oil and santolin the symptoms vanished in two days.

It seems fair to suppose, from the necropsy, that the symptoms in the first case were reflex and due to the twist of the colon, and that this was caused by movements of the worm or worms. Whether there was the same mechanical condition in the second case, followed by untwisting of the bowel is, of course, a question.

BEAVER RAKE, M.D. Lond.,
Government Medical Officer, Trinidad.

A CASE OF MYXEDEMA.

E. M., aged 31, but looking ten years older, who used to be a domestic servant, has been ill for about five years or a little more. She had rheumatic fever about nine or ten years ago, and was told that she had "cardiac dropsy"—that is, her present illness. The swelling was the first thing noticed; it began first in her hands, and after some time in the face around the eyes. She used to menstruate regularly up to the time the swelling commenced, but has not done so since. There is no history of any

mental or nervous shock, nor of any other assignable cause. She never suffered from menorrhagia or such uterine hæmorrhage, nor were her periods too profuse; and she has never had "whites." Her bowels act regularly, but she is subject to severe attacks of diarrhoea, which occur, she says, about once a month. She frequently suffers from indigestion, with headache and giddiness. Her urine was never dark-coloured, nor had she ever to get up at night too frequently to make water. She never feels too cold, though her hands occasionally get cold. She says her vision was dim at the beginning of her illness, but is now normal. From the commencement of her illness she has decidedly noticed herself becoming very slow and heavy in all movements and actions, and very readily fatigued. Her memory and intelligence seemed very fair. Her appearance is very striking. The face is large, broad, waxy, and pale, like that of chronic Bright's disease. Swelling is marked in both eyelids, and especially in the upper; the mouth is large and the lips swollen; the lower lip is of a purple colour. The cheeks are not flushed. Her eyelashes and eyebrows are normal, her hair coarse and shaggy, and abundant. Her tongue is large and flabby. Her speech is deliberate and somewhat slow, but quite distinct. The front upper incisors are gone, and the lower ones decayed and loose. Her hands are broad and much swollen, both the fingers and the backs being much swollen, but not pitting on pressure. Her feet are even more swollen, so that she cannot get shoes to fit her, and has to wear stockings and cloths around them. Her belly was enlarged some years ago, but is not much so now. The nose is much swollen, especially at the ale, which are of a purple colour. The ears are very large and swollen. The swelling came on gradually, and gravitation does not seem to have any effect on it, nor is it altered at night or morning, being always about the same. The heart-sounds are weak, but normal, and the impulse feeble. The pulse is 108; the temperature normal. Sensation is good and not delayed. The knee-jerk seemed absent on both sides. There was no clonus. There was decided occasional rotatory nystagmus. The specific gravity of the urine was 1,024; no albumen with heat, nitric or picric acid tests. The optic discs and retinæ were normal, but the retinal arteries were tortuous at either end of the disc.

FRED. TRESILIAN, M.D.

REPORTS

OF

HOSPITAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN, IRELAND, AND THE COLONIES.

ST. MARY'S HOSPITAL.

EXTENSIVE CARBUNCLES TREATED BY ERASION: RAPID CONVALESCENCE.

(Under the care of EDMUND OWEN, F.R.C.S.)

[Reported by Mr. R. H. COLE, Dresser.]

THE patient was a thin, unhappy-looking man, aged 55, a carpenter by trade. He had been out of work for some time, and had not had enough to eat. He was admitted on December 9th last for carbuncles over each shoulder-blade. They had been developing for about three weeks, the right sore being about four days older than the left. The long diameter of the right sore was five inches, and beyond that limit the skin was undermined; in the depths of the sore was a large slough bathed in offensive pus. The left sore was rather larger than the right, but the slough was more adherent, and more covered by bridges of dusky skin. The man was utterly prostrated; the urine, specific gravity 1009, contained neither albumen nor sugar.

Mr. Owen at once ordered his removal to the theatre, where, after having been administered, Mr. Callender, the house-surgeon, set to work to remove the sloughs and to scrape out the sores; there was hardly any bleeding during the operation; no vessel had to be tied. The undermined skin was trimmed, and divided by adiating incisions, so that it might not retain discharges, and the revic under it was thoroughly cleaned out with Volkmann's spoon. The surfaces were then washed with the mercuric solution 1 in 1,000, dusted with iodoform, and covered with moist perchloride gauze and with bulky pads of blue wool. Brandy and other tonics were subsequently prescribed, and the man made a rapid

convalescence. From the day after the operation he began to pick up, and was soon a different man.

REMARKS BY MR. OWEN.—Some months ago I read, but I regret to say that I do not remember where, some remarks upon the treatment of carbuncle by erosion, and I determined to make trial of the method on the first opportunity. But when I saw this prostrate carpenter with his two large carbuncles, and heard how he had been out of work and unable to get sufficient food, I wondered if he could offer a fair test for the method. However, I determined to try it, and was afterwards extremely glad that I did so. Hearing that my colleague, Mr. Page, is publishing a clinical lecture upon the subject, I thought that I might report this solitary case under its shadow, rather than wait for further experiences of my own.

Anthrax is, in its pathology, closely allied to certain cases of acute osteitis or periostitis, in which inflammatory distension of capillaries determines the death of a portion of bone; in the child, possibly, of the entire diaphysis. In anthrax, the dead tissue is called slough; in necrosis, it is called sequestrum. In recent years the surgeon has been constantly on the alert to separate the dead bone from the living, and so to diminish the risk of secondary abscess and pyæmia, to improve the chance of reproduction of new bone, and to shorten the course of the disease. He has even gone so far as to give a new name to a disease, "acute necrosis," so as to justify, as it were, if justification be needed, his surgical attack. Necrosis, however, should not be considered a pathological entity, but rather as a result of disease. In removing a piece of dead (?) bone before a line of demarcation can be seen, there is always a risk of taking away too much or too little tissue. But in the treatment of carbuncle by scalpel, forceps, and spoon, this risk is absent; the surgeon sees exactly where the grey slough borders on the living tissue. I apprehend that within a few days after the occurrence of the acute inflammation, there would be little difficulty in determining the limits of the slough; and I regret that I did not see this patient at the beginning of his illness, for, after making the free crucial incision which is so necessary for the relief of tension and pain, I would, there and then, have been prepared to separate the slough and clean out the cavity. I think there is less likelihood of harm from too early interference in the case of anthrax than in "acute necrosis;" and I am strongly of opinion that the radical treatment of the former condition is a distinct advance. It is a great matter to be able to convert a septic and a painful mass into an aseptic and a painless one; and the removal of the decomposing slough, at the earliest possible moment, must be the means of shortening the natural process of the disease by several weeks. The sudden and rapid improvement of this patient immediately after the operation was a thing to be remembered.

GOVERNMENT LUNATIC ASYLUM, MADRAS.

A CASE OF CYSTICERCUS CELLULOSE OF BRAIN.

(Under the care of Surgeon H. ARMSTRONG.)

A NATIVE coolie, named Lonala Yenavado, aged 23, was sent as a criminal lunatic from Nellore Gaol on September 18th, 1887.

Surgeon-Major Price had the patient under observation in gaol, at Nellore, and reported the case as one of chronic dementia, the history and antecedents of the man being unknown.

On admission into the asylum he was observed to be a harmless imbecile, in a fairly well-nourished condition, weighing 128 lbs., suffering from right hemiplegia, and unable to give any account of himself. There was no change in his condition until October 9th, when he had an epileptic fit, which passed off soon. The following day he had three fits of the *petit mal* type, and then an interval of seven days without any. On October 18th a very severe fit was followed by shorter ones of increasing intensity, ten being counted in one hour. Surgeon Armstrong ordered him santonine and castor oil, which brought away a number of round worms. Bromide of potassium was also administered, but the fits continued daily, and on October 30th he became comatose, and died in the evening.

A *post-mortem* examination revealed the presence of active inflammation of the membranes at the base of the brain, the dura mater being very adherent to the cerebrum, and the surface of the cerebrum and cerebellum studded over with small cysts. On making a section into the brain, cysts were found in the ventricles, and in the grey or cortical structure. One was found in the left ventricle of the heart, and two on the pleura of the right lung, the other organs being healthy and free from cysts.

The cysts, on examination, were found to contain a minute worm, which under the microscope proved to be *Cysticercus cellulosa*—a specimen of which was exhibited under the microscope at the meeting of the South Indian Branch, November 4th, 1887, at Madras.

REMARKS.—The case is of interest chiefly on account of the rarity of *Cysticercus cellulosa* about Madras, and it is to be regretted that the history of the patient is unknown.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, MARCH 20TH, 1888.

Sir JAMES PAGET, Bart., F.R.C.S., F.R.S., President, in the Chair.

Osteitis Deformans.—Specimens from a case of osteitis deformans were shown by Dr. J. F. GOODHART. The patient was an ostler, aged 65. His head was enormous, his body slight. He had been ill for four months. For fifteen years his head had been growing larger; it had gained two inches and a half in circumference in the last year. The head was enormously large and bossy; the bones of the limbs were curved. On examination after death, the skull, clavicles, vertebrae, and ilia were all found thickened and rarefied. The long bones were bent, but not otherwise diseased. In the liver were fleshy, probably cancerous, tubera, and the glands in the fissure were large. The pleura contained some nodules of growth. The spleen was enlarged, resembling the "hardbake" spleen of Hodgkin's disease; the growths in this organ were probably lymphomatous. The association of Hodgkin's disease with osteitis deformans was curious and unusual, and illustrated the inveterate tendency to cell growth in osteitis deformans. He combated the theory that osteitis deformans was a local disease, and urged that the occurrence of rarefying osteitis agreed as well with the theory of tumour.—Mr. EVE asked whether in this case there was any evidence of general calcareous degeneration. In one instance which he had seen, calcification of arteries and ligaments had occurred.—Mr. CLUTTON said that he grounded his argument in favour of the view that the disease was a variety of osteitis on the fact that in his case the bone was elongated. If the theory of cancer was true, there ought to have been more cases of the association of osteitis deformans with cancer.—Dr. HADDEN thought it probable that in some of the cases there was hypertrophy of bones and of soft tissues. In the disease described in France under the name of "acromégalie," there was a very extensive bony enlargement confined to the hands and feet.—The PRESIDENT said that "acromégalie" was a widely different disease; it did not affect the long bones nor produce bending. There was a remarkable enlargement of the bones of the face, hands, and feet, which overgrew, but the relations of the parts were maintained. The number of cases in which cancer was associated with osteitis deformans was more considerable than Mr. Clutton had said. Still, he thought the association accidental, for he had watched many cases for years where osteitis deformans was well marked and yet cancer had not ensued.—Dr. SAMUEL WILKS said that Dr. Fagge had described a case of "acromégalie," though he had not thought it necessary to give the condition a name; in that case there was a tumour in the brain.—Dr. SYDNEY COPLAND mentioned the case of a man who had been seen by the President and Professor Virchow; the face and hands were enormously enlarged; this was five or six years ago. Professor Virchow had not seen a case of the kind, but recalled an instance mentioned in a Swiss journal.—Dr. GOODHART said there was no calcification. He thought that Mr. Clutton had underrated the frequency with which osteitis deformans was associated with cancer; in his own experience half the cases of osteitis deformans also suffered from cancer.

Furrows on Nails.—Dr. WILKS showed drawings of furrows on the nails in a man aged 50. On August 2nd, 1887, he sailed for America, and was very sea-sick for three days. He then completely recovered, and so remained until he sailed for home on October 1st, 1887, and was ill again for three days. Two furrows subsequently appeared on his nails, which exactly corresponded with the dates of the sea-sickness. He had described the production of these furrows in a paper published about twenty years ago. As to the exact pathological meaning of this arrest of growth he felt somewhat uncertain. Several curious cases had been communi-

cated to him. Mr. Wagstaffe had described to him the case of a man whose arm was kept in a splint for some time, and the furrows had affected one side only. A correspondent, twenty years ago, had mentioned the case of a lady in whom the young hairs of the head lost their pigment whenever she had an illness. It was said that the number of calves a cow had could be told by counting the rings on the horns, one ring being produced for each calf.—Mr. BLAND SUTTON said that a gentleman who had studied the appearance of wild birds had told him that after a severe winter the feathers were stunted, and that if birds kept in confinement were badly fed the feathers were stunted and ill-shaped when they appeared after the next moult.—Mr. BULL said that the number of calves a cow had could be told by the number of rings on the horns; this was so well known that the rings were filed down by dishonest drovers.—Mr. SEDGWICK mentioned a family in which marked transverse ridges formed across the nails of the females at about the age of 52.—Mr. STEPHEN PAGET asked whether the hair in left-handed people did not grow faster on the left than on the right side.—Mr. BOWLBY said that nerve-injury was also followed by deformity of the nails. He had called attention to this in a paper on injuries to the nerve, and Dr. WEI MITCHELL had figured a very marked case.—The PRESIDENT said that in his own person he had observed that every severe illness was followed by a furrow. The case from which the photograph shown by Dr. Wilks was taken was valuable because it showed how short an attack of illness might produce the furrow.—I reply, Dr. WILKS said that he had made some inquiry about the teeth, and had found some evidence that the teeth might be grooved in the same sort of way.

An Exostosis.—Mr. BLAND SUTTON exhibited a specimen which had been sent to him by Dr. Rundle, of Truro, who described it as "resembling an ossified bird's head." Dr. Rundle was quite sure it was not artificial, as the source from whence he received it was above suspicion. The specimen was an osteoma connected with the fin-ray of a fish, probably *Ephippus*. Tumours of this nature connected with fin-rays of this species of fish were first described by William Bell (the original specimen is preserved in the museum of the Royal College of Surgeons), in a paper communicated to the Royal Society in 1793. The College museum also contained scores of these tumours, nearly all of which were Hunterian. The tumours were very characteristic; they were situated at the end of a fin-ray, and on section the ray could be clearly defined as runs through the tumour. Its exterior was smooth, hard, and ivory. Articulating with it by means of a shackle-joint was one, but usually two, smaller rays. Cuvier stated that these bones were common in osteological collections; they were brought home by travellers who had eaten of these fish, and then preserved the bones as curiosities. Mr. Sutton was not aware that any explanation of this curious condition had been offered. Bell stated, in his original description of this fish, that it was frequently caught at Bencoolen, and several other parts of the west coasts of Sumatra. Many of the bones have tumours; in the first fish Bell saw I thought they were exostoses arising from disease, but, on dissecting a second, found the corresponding bones had exactly similar tumours, and the fishermen informed him that they were always found on this fish.

Experimental Observations on Lupus.—Mr. EVE stated the chief facts for and against the theory that lupus is a local tuberculo- The tubercular theory had been opposed by Kaposi, Schwimmer and others. Schwimmer had urged that while the inoculation guinea-pigs with lupus caused general tuberculo- lupus, as such had never been produced in animals. Leloin failed to inoculate rabbits with lupus. The author had in two instances (the first ear in 1886) succeeded in producing a lupoid ulceration of the ear rabbits by inserting portions of the diseased tissue under the skin. A spreading ulcer covered with a dry scab formed, and similar ulcers developed at a distance from the primary one. Cicatrization took place after some weeks; and on killing the fish animal no visceral lesions were found. He had inoculated rabbits from other cases, but only small, quickly healing ulcers or abscesses had been set up. Passing lupus through the guinea-pig in one instance, did not increase its virulence. The production of lupus, as such, in animals was another point in favour of its being a modified tuberculo- of the skin. Three specimens of lupus a tuberculo- of the hand were shown, to illustrate the close relation of these processes. Specimen 1 was a raised plaque on the dorsum of the hand of a boy with spinal caries. It was not ulcerated, and had remained unchanged for some months. The microscope showed merely a formation of granulation tissue in

corium. The disease of the skin was probably secondary to that of the spine. Specimen 2 was a nodule removed from the palm by Mr. Bryant. It had microscopically the structure of reticular tubercle. The patient, aged 26, observed a growth four years before; this was removed two years and a half later, and subsequently the nodule shown appeared. Specimen 3, an old preparation from the College museum, was originally described as probably epithelioma. Recent examination showed distinct tubercles with giant cells in the corium, and a marked papillary thickening of the cuticle. No history was obtainable. This was probably a case of tuberculosis verrucosa cutis, a similar condition being described as lupus verrucosus.—Mr. CLUTTON mentioned some cases in which there was an association between lupus vulgaris of the nose and an ulcerative affection of the mouth, larynx, and even of the lungs; he related one case in which the patient died of phthisis; tubercular ulceration first occurred, and then lupus vulgaris of the nose.—Mr. GOLDING BIRD mentioned a case of tubercle of the tendon of the extensor carpi ulnaris, and suggested that this might probably have been the way in which the tumour on the back of the hand mentioned by Mr. Eve had originated; but Mr. EVE said that the subcutaneous tissue was not affected.

Sarcoma of the Urinary Bladder.—Mr. D'ARCY POWER showed a bladder containing a large sarcomatous tumour. The cavity of the organ was obliterated, except at its upper part, by the new growth, which infiltrated the anterior and lateral walls as well as the fundus. The portion of the growth which occupied the cavity of the bladder was a tuberous and cauliflower-like mass. The rectum had become involved by its extension backwards, and near the anus the tumour actually projected into the cavity of the bowel. The projecting portion, however, had broken down, and a fistulous passage was established between the bladder and the rectum. The preparation was obtained from a man aged 64, who had suffered from hæmaturia for eighteen months. The growth was partially removed by median cystotomy and dilatation of the prostate; but as it continued to increase in size, and micturition became difficult and painful, the bladder was punctured above the pubes. Microscopic examination showed the growth to be a typical mixed-celled sarcoma. Mr. Power drew attention to the alleged rarity of this form of vesical tumour, but stated that the museum of St. Bartholomew's was particularly rich in examples of it, for he was enabled to produce four other specimens, of which one appeared to be an alveolar sarcoma. In addition to those cases, there were two preparations of vesical sarcoma in the Hunterian Museum, one in the museum of Guy's Hospital, and one in the Middlesex Hospital.—Mr. HURRY FENWICK brought forward statistics of fifty cases of sarcoma of the urinary bladder. He showed that the cases fell into two groups: sarcomata of childhood before 5 years of age, and sarcomata of old age after 50. Each age seemed to possess especial characteristics. In children the growths were generally pedunculated. This was rare in after life, 10 per cent. only possessing pedicles. In childhood the growths were multiple, and affected the trigone and inferior zone of the bladder. In after years the growth was found to be usually single, and affected the posterior wall immediately behind the ureters. Mr. Fenwick submitted that the myxomata and sarcomata of childhood had been greatly confused.—Mr. GOLDING BIRD showed a specimen of round-celled sarcoma of the bladder recently removed by suprapubic cystotomy from a woman aged 55.

Disease of Adrenals without Bronzing.—Dr. COLLIER showed the right suprarenal capsule of a woman, aged 36, who had been ill or nine months with exhaustion and vomiting. She was anæmic, but well nourished, and not bronzed in any part; the pulse was extremely weak. While in the Radcliffe Infirmary, the most characteristic feature was the extremely languid condition in which he lay in bed. The patient died suddenly. Both suprarenal capsules were enlarged; the right capsule was entirely caseous, the left was reduced to a small sac containing cheesy material. The history showed that the suprarenal capsules had been diseased for at least nine or ten months, which rendered the absence of pigmentation the more remarkable.—Dr. WILKS said that asthenia and discoloration were the two main symptoms recognised by Addison, who was, however, aware that if death occurred at an early stage there might be no pigmentation.—Dr. COUPLAND said that in a few cases tubercle bacilli had been found.

Card Specimens.—Mr. FENWICK: Tumour of Urinary Bladder.—Mr. TARGETT (for Dr. FRY): 1. Cystadenoma of Thyroid. 2. Optic Aneurysm. 3. Isolated Fracture of the Base of the Skull.—Dr. F. T. PEARSE: Advanced Surgical Kidney.—Dr. M.

MURRAY: Cystic Disease of Kidneys.—Dr. ANGEL MONEY: Multiple Sarcoma of Dura Mater and Calvaria; Secondary to Suprarenal Sarcoma.—Dr. PENROSE: Vegetation on Mitral and Aortic Valves; Gap in first part of Aorta with Vegetations.

MEDICAL SOCIETY OF LONDON.

MONDAY, MARCH 19TH, 1888.

J. KNOWSLEY THORNTON, M.B., C.M., Vice-President, in the Chair.

On the Successful Treatment of "Hammer Toe" by the Subcutaneous Division of the Lateral Ligaments.—Mr. W. ADAMS read a paper on this subject, in which he observed that this contraction with deformity, which usually affected the second toe, was essentially an hereditary affection, often traceable through two or three generations. It was never caused by short or narrow boots, although this might aggravate the affection. In a slight degree the tendency to "hammer toe" was often traceable at five years of age, and the contraction steadily increased, but seldom became confirmed till the age of 15. He then alluded to the observations brought before the Pathological Society (December 21st, 1886) by Mr. SHATTOCK, who had dissected two "hammer toes" recently amputated, and had found that the deformity essentially depended upon a contracted condition of the lateral ligaments, and not upon contraction of the flexor tendons. In reference to treatment, Mr. Adams then described an operation which he had successfully practised for many years, essentially consisting in the subcutaneous division of the lateral ligaments. After having observed the failure of tenotomy to cure this contraction, he had adopted the method of dividing the lateral ligaments, and the correctness of this conclusion was now confirmed by Mr. SHATTOCK'S dissection. Immediate extension was adopted after the operation, and the toe retained in position by a metal splint for three or four weeks. Mr. W. Anderson had made a valuable contribution to the treatment of this affection, and had suggested a new operation of excising the head of the first phalanx, which he had successfully performed. This operation, which was described in the *Transactions of the Clinical Society*, vol. xx, p. 248, would be applicable to cases which could not be treated by the subcutaneous operation, and would supersede the necessity of amputation, which had generally been adopted in severe cases.—After some remarks from Mr. KNOWSLEY THORNTON, Mr. W. ANDERSON said that Mr. Adams's remarks had confirmed his own observations. He congratulated Mr. Adams on the good results of the division of the lateral ligaments, but he thought that the operation might not prove so simple in less experienced hands. The operation involving the removal of the head of the first phalanx had the advantage of giving a permanent result, which was not quite certain in division of the ligaments. He pointed out the similarity of this affection to that described by Mr. DAVIES COLLEY as *hallux flexus*. It always occurred during the period of active growth, but while "hammer toe" occurred indifferently in both sexes, *hallux flexus* had only occurred in males.—Mr. SHATTOCK observed that the etiology and pathology of these cases were obscure. He questioned the share accorded to the lateral ligaments in its production, and pointed out its analogy with the "claw hand" of Duchenne's paralysis. He suggested that a careful examination of the interossei might give a clue to the causation.—Mr. NOBLE SMITH said that he operated on the principle of dividing whatever tissue seemed to resist the replacement, and the results had been very satisfactory.—Mr. WALSHAM showed a dissection which he had been enabled to make of a case of "hammer toe," which pointed to the deformity being caused, in part at least, by the glenoid ligament. He observed that Dr. STEVENSON had been unable to detect any fault in the interossei by electrical tests. He was of opinion that the deformity was due to pressure from boots, etc. He doubted whether the lateral ligaments could be divided without opening the joint.—Mr. BERNARD PITTS thought that the majority of these cases were due to mechanical causes, and mentioned the case of a lad who had well-marked "hammer-toe" on one foot and an incipient one on the other foot, which, however, ceased to exist when the boot was taken off.—Mr. WALTER PYE said that they were agreed that the flexor tendons were not at fault. He alluded to the very strong hereditary tendency and to the corn which formed and favoured the secondary changes.—Mr. LENNOX BROWNE suggested that the hereditary theory was rather far fetched; he asked whether the heredity might not be in the bootmakers rather than in the patients.—Mr. ADAMS, in reply, paid a high tribute to the labours of Mr. Ander-

son and Mr. Shattock in this direction. He insisted upon the necessity for at least three weeks' after-treatment.

Extirpation of Goutre.—Dr. BOREL, after alluding to the geographical distribution of hypertrophy and cystic degeneration of goutre, mentioned that it was common in elderly dogs, being attributable, probably, to the large amount of lime they assimilated from a diet of cooked bones. The endemic disease in Switzerland had been made to disappear by drainage in some instances. He alluded to the undoubted regulating function of the thyroid over the cerebral circulation. In animals simultaneous extirpation of the spleen and thyroid caused death, though either could be removed separately with impunity. He referred to the observations of Kocher, of Berne, on cretinism following removal of the thyroid in very young people, the danger being less after puberty. He objected to interstitial injection of iodine, and attached but little importance to compression, shampooing, etc. Puncture might relieve cyst formations, but was useless in real hypertrophy. Operation in persons of advanced years was to be deprecated on account of the difficulty of arresting the hæmorrhage. He explained his method of operating, and mentioned that in cases of *goutres plongeants* (retrosternal struma), it might be necessary to dissect down to the arch of the aorta, enucleation being done with the fingers and scalpel handle. The operation might be one of urgency or merely of expediency. Cerebral disturbance and dysphagia, more or less ephemeral, might follow the operation, but he had never seen myxœdema follow. He illustrated the kind of mental disturbance which sometimes resulted by the history of three cases. The dangers were (1) entry of air into the veins, (2) primary arterial hæmorrhage and (3) asphyxia from compression of the softened trachea. He spoke of twenty-two cases in which he had performed extirpation.—Mr. KNOWSLEY THORNTON said that he was comforted on learning that a thyroidectomy had taken as long as five hours and a half, and involved two hundred ligatures. He had once passed three hours in removing a kidney and had thought it long.—Mr. LENNOX BROWNE said that the enormous *goutres* spoken of by Dr. Borel were really unknown in this country. He claimed priority in removal of the gland for Dr. Heron Watson, though the earlier operations were small compared to Dr. Borel's achievements. He thought the distinctions made between the so-called different varieties of thyroid tumours were more or less arbitrary. His experience of the seton was that the relief was not permanent. He had had six cases which he had treated by removal of the middle portion of the gland, and of the isthmus if enlarged. He never recommended recourse to operation for purely "cosmetic" purposes, nor unless there were serious symptoms.—Dr. KESER asked Dr. Borel whether he had had any experience of enucleation of the tumours without removing the gland itself.—Mr. BERNARD PITTS mentioned two cases, in one of which he had prevented imminent death from asphyxia by slitting open the tumour, and in the other, after having with difficulty performed tracheotomy, he had removed the whole gland with comparative ease. The latter patient, however, succumbed to cellulitis.

PATHOLOGICAL SOCIETY OF MANCHESTER.

WEDNESDAY, MARCH 14TH, 1888.

A. W. STOCKS, M.R.C.S., President, in the Chair.

Exostosis of the Orbit Associated with Cerebral Tumour.—Dr. PETER YATES showed a specimen of exostosis of the orbit, causing extreme proptosis of the left eyeball, with which was associated a cerebral tumour of myxomatous character. The exostosis occupied the position of the roof of the orbit, and had probably commenced in the frontal sinus. The bony growth encroached on the cranial cavity to the extent of about one inch, was very irregular, nodulated, and hard in texture. At the most prominent portion the dura mater was adherent, and attached to the latter by a pedicle, was a large, yellowish, gelatinous, lobulated, and flesh-like tumour with a distinct capsule. This growth was completely imbedded in the substance of the frontal lobe of the brain, and was easily shelled out. The cavity communicated behind with the lateral ventricle. During life there was a history of slight epileptiform seizures, but there was no loss of power or sensation, no vomiting, and absolutely no pain. The vision in the left eye was $\frac{1}{2}$ Jäger, that of the right being normal.

Abnormality of the Kidney.—Dr. A. M. PATERSON showed a preparation in which the right kidney was displaced, lying in the angle between the common iliac vessels, on the fourth and fifth lumbar vertebræ, and projecting downwards over the promontory

of the sacrum. The hilum was placed anteriorly, and from it the ureter passed downwards, a large vein upwards to the inferior vena cava. The left kidney was normal in position. Its hilum was placed in front also, and the pelvis of the ureter, lying on the anterior surface of the organ, was extremely large. The arteries to both kidneys were abnormal in number and mode of origin. The right kidney was supplied by four, and the left kidney by five vessels. The testicles and their vessels, and the suprarenal capsules were normal.

Renal Calculi.—Mr. SOUTHAM showed the kidneys of a man, aged 23 years. The orifice of the right ureter was blocked by a small calculus, and the gland was converted into a multilocular cyst full of pus. The left kidney was free from any traces of suppuration; its pelvis was much dilated and contained five calculi, three of which were of large size, weighing $5\frac{1}{2}$ ounces.

An Unusual Form of Uterine Polypus.—Dr. R. B. WILD showed a telangiectatic uterine polypus from the cervix, consisting of dilated vascular loops filled with blood-corpuscles; a loose connective tissue stroma with extravasated blood, and a few islands of glandular epithelial cells. The polypus was the cause of severe menorrhagia, and the microscopic structure explained the occurrence of hæmorrhage, quite out of proportion to the size of the tumour.

Sarcoma of the Pleura.—Dr. R. B. WILD showed a preparation consisting of nodular growths in the pleura, varying in size from a millet seed to a penny, and consisting of round and spindle cells, with a vascular zone between the normal pleura and the new growth.

MANCHESTER MEDICAL SOCIETY.

WEDNESDAY, MARCH 7TH, 1888.

JULIUS DRESCHFELD, M.D., F.R.C.P., President, in the Chair.

Trephining for Epilepsy.—Dr. HUTTON and Mr. WRIGHT showed a boy, aged 11, who suffered for nearly three years from epilepsy, which at first affected the limbs equally, but during the last few weeks had been mainly right sided, and accompanied by marked aphasia, with rapidly developing loss of mental power. A trephine two inches and a half in diameter was used, and the dura mater reflected. Exploration of the brain to the depth of an inch in various directions revealed nothing abnormal. The dura was stitched up, and the bone replaced after being cut into small pieces. Recovery from the operation followed without a bad symptom, but the mental condition remained unchanged, and the fits returned in a few days, though with less violence.

New Instruments, etc.—Dr. MULES showed (1) an instrument for the introduction of the artificial vitreous; (2) a series of drawings of rare ocular tumours.

Rupture of Kidney.—Dr. MULES also mentioned a case of rupture of the kidney through the capsule by direct violence, in which, with a large tumour in the flank, and considerable hæmorrhage from the urethra, recovery progressed uninterruptedly under the influence of complete rest and careful diet.

Tropho-Neurosis.—Dr. HUTTON showed a case of tropho-neurosis in a girl aged 9, which commenced as a gangrenous sore on the forefinger, and was followed three years and a half later by atrophy of the limb and sloughing of the skin over parts exposed to pressure, and general suppuration among the tissues of the left arm and hand.

Mitral Disease.—Dr. STELL read a paper on the auscultatory signs of mitral obstruction and regurgitation.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

THURSDAY, MARCH 1ST, 1888.

E. NOBLE EDWARDS, M.R.C.S., Vice-President, in the Chair.

Skin Diseases.—Dr. MACKEY showed (1) a case of steatorrhea affecting one cheek in a young woman; (2) a case of erythema rheumaticum (?) of three months' duration, affecting the face and arms, in a cook, who had had two attacks of acute rheumatism.

Some Remarks on Spinal Caries and its Results.—Dr. F. PALEY read a paper in which he said the disease was generally due to the scrofulous or tubercular taint, with frequently a blood exciting cause. The children of agricultural labourers, thought, were especially liable to this disease. The pathology was described as first a low form of osteitis, with marked tendency to the caseation and breaking down of the inflammatory exudation, and with it of the rarefied cancellous structure of the vertebral bodies. These changes were shown to commence chiefly

the epiphyses of the bodies in close contiguity to the cartilages. The chief results were angular curvature, abscess and pressure on the spinal cord. The situation of caries, whether towards the back or front of the body, was the chief agent in determining pressure on the cord or a psoas or dorsal abscess. The agent of pressure on the cord was generally the thickened spinal dura mater. The diagnosis of early caries before curvature was exceedingly difficult. The author related the case of a woman, aged 41, which had been diagnosed as hysterical, but which a year afterwards was found to be caries, and resulted in fatal pressure on the cord. The author laid down some points of distinction between caries and the hysterical and irritable species. He considered that ankle-clonus, if well marked, was always a sign of organic lesion, and was never produced by hysteria. The prognosis of caries itself, as far as life was concerned, was considered to be good. The prognosis of abscess was bad, whilst that of pressure on the cord was regarded as very favourable, a case of complete recovery in about a year being narrated. As regards treatment, Sayre's jackets, with good food and tonics, were recommended. Abscesses should be opened early and drained under antiseptic precautions.—Mr. JENNER VERRALL remarked on the difficulty of diagnosis in many of these cases, and of determining whether rest or exercise should be employed.—Mr. ARTHUR DODD mentioned a case of death from dislocation of the spine in the cervical region from disease.—Dr. ADOLPHUS RICHARDSON referred to a case of hysteria in which, in opposition to Dr. Paley's view, ankle-clonus existed.—Dr. BLACK thought that none of the classical signs of spinal caries were reliable; he referred with favour to the plan of tapping the abscess close to the spine, and if possible removing sequestra.—Mr. SANDERSON recommended Davy's hammock method of applying the plaster-of-Paris jacket.—Dr. UTHOFF and Mr. GORDON DILL also took part in the discussion.—Dr. PALEY, replying, spoke in favour of Davy's method of applying the jacket.

Treatment of Laryngeal Phthisis and Abscess of the Antrum.—Mr. CRESSWELL BABER read a paper on some recent methods of treating these diseases. He gave particulars of Rosenberg's treatment of laryngeal phthisis by means of injections into the larynx of a 20 per cent. solution of menthol in olive oil, combined with inhalations of the same drug. He also referred to the treatment of this disease by lactic and chromic acids, but recommended the menthol treatment for trial on account of its painlessness. In the treatment of abscess of the antrum, which he remarked might exist without any external symptoms beyond unilateral fetid purulent discharge, he mentioned the means of diagnosis and the different methods of opening this cavity, namely, through the middle meatus, through the inferior meatus, and through an alveolus, giving the preference to the latter if it were impossible to obtain an entrance through the normal opening of the antrum.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

THURSDAY, MARCH 8TH, 1888.

LAWSON TAIT, F.R.C.S., President, in the Chair.

Alcoholic Paralysis.—Dr. SÜCKLING read a paper on alcoholic paralysis.

The Treatment of Perforation of Gastric Ulcer.—Mr. J. W. TAYLOR and Dr. STACKY WILSON read a paper on this subject.

Multiple Peripheral Neuritis.—Dr. SÜCKLING showed a boy, aged 14, suffering from multiple peripheral neuritis. He had worked in lead and zinc for eighteen months. A few weeks before the onset of his illness he had changed his occupation to that of stamping bolts, and while at this heavy work weakness gradually came on. On admission he complained of weakness in his hands and feet, all of which were "dropped," power of extension being lost. There was much weakness in the other muscles of the extremities. Anæsthesia was well marked in all four extremities, but was not complete, and extended only a few inches from the wrist and ankle-joints; the knee-jerk was abolished on both sides; the calf muscles were tender on palpation. Faradic irritability was diminished, but the reaction of degeneration was not present. There was no blue line on the gums, nor had there been colic or constipation. The bladder and rectum were unaffected. Dr. Suckling considered that exposure to cold and hard work had been the exciting causes, but that his having worked on lead had predisposed to the affection.

Cancer of the Pancreas.—Mr. JORDAN LLOYD showed a specimen of cancer of the head of the pancreas, which had compressed the pancreatic and common bile ducts. The pancreatic bile duct was

dilated to a diameter of half an inch, and the gland was full of cysts varying in size from a pea to a pigeon's egg. The common bile duct and the hepatic ducts would admit an index finger. The gall-bladder was enormously distended. The patient was a woman nearly 80 years old, and had suffered during six months from pain in the abdomen and emaciation without jaundice. Cholecystotomy had been performed for the relief of painful distension of the gall-bladder.

Ossifying Enchondroma.—Mr. MARSH showed a typical specimen of ossifying enchondroma, the size of a large orange, removed a fortnight ago from the femur of a youth, aged 18. The growth was first noticed nine years previously, and its origin put down to a blow received a short time before; it had grown slowly ever since, without pain, but latterly its size caused inconvenience, and when knocked it was painful. The tumour was attached to the inner and anterior surface of the femur, four inches from the lower end, by a hard osseous pedicle. It was removed by longitudinal incisions on either side, and the pedicle sawn through with a chain saw. Dry boracic dressings were used, and primary union obtained except along the track of the drainage-tubes. Prior to the operation there was one-sixth to a quarter of albumen present, a sequel of scarlet fever. Since the operation this had entirely disappeared.

CAMBRIDGE MEDICAL SOCIETY.

FRIDAY, FEBRUARY 3RD, 1888.

E. CARVER, F.R.C.S., President, in the Chair.

Election of Officers.—It was proposed by Dr. GROVE and seconded by Dr. EASBY that Mr. STEAR, of Saffron Walden, be elected President for the ensuing year. This was carried unanimously. Mr. Wherry was elected Vice-President, and Mr. Laurence Humphry was re-elected Honorary Treasurer and Secretary for the year. Mr. Francis was re-elected Co-Secretary.

Cases of Erysipelas.—Professor HUMPHRY related the case of a woman who was admitted into Addenbrooke's Hospital suffering from cellulitis of the forearm. Before admission she had a sore thumb, and had been recently washing some dirty rags from a case of erysipelas. Soon after her admission the cellulitis subsided, and a girl lying in the next bed with necrosis on the popliteal aspect of the tibia developed erysipelas in the thigh. Both these cases were removed to another ward and isolated. The first case shortly afterwards had erysipelas in the forearm. Subsequently a woman at the end of the ward, with an ulcerated leg, developed erysipelas. The cases were all of a mild type. The treatment pursued had been lint soaked in bichloride of mercury (1 to 1,000) and placed on the margin of the spreading line of erysipelas and a few inches beyond. The cases appeared to be benefited by the treatment, but a girl admitted with erysipelas of the face got on equally well without treatment. Professor Humphry referred to the more recent views of the presence of micrococci in erysipelas; he was doubtful as to the particular efficiency of any modes of treatment in ordinary cases.—Dr. LATHAM, Mr. CARTER, and others took part in the discussion.

Sarcoma of Lung.—Mr. GRIFFITHS read the notes of a case which was admitted into Addenbrooke's Hospital under Dr. Bradbury on January 21st. A man, aged 58, had been ill for one year with cough and wasting. On admission there was marked dyspnoea, and cyanosis, and swelling of the eyelids; expectoration mucopurulent. The physical signs were absence of movement of the left side of the chest, absolute dulness and feeble respiration, hyper-resonance and rhonchal sounds over right side. Microscopic examination of the sputum showed only pus cells. A needle was introduced into the chest, but no fluid withdrawn. The diagnosis was made of malignant disease of the lung. The right hand became very oedematous, also the face; but the superficial veins were not distended. After several severe attacks of dyspnoea he died on January 30th. On *post-mortem* examination the pericardial sac was found to contain two to three ounces of straw-coloured fluid. Projecting into it from the left side was a firm, somewhat irregular tumour, pushing the pericardium in front of it; and this tumour was continuous with a firm, solid mass in connection with the base of the heart at the back of the left auricle. On section of the left lung, a firm, fleshy growth was found, occupying the root of the lung, and extending by irregular processes along the course of the bronchi and larger vessels. Above it embraced the lower half of the arch of the aorta and compressed it somewhat. The branches of the pulmonary vessels were also completely surrounded and compressed, but there was no ulceration. Here and

there in the section there were the skeletons of bronchi (cartilage) completely surrounded, and their lumen was absolutely obliterated by the new growth. The left bronchus was greatly narrowed, but there was no ulceration into it. Posteriorly, the growth projected on either side of the œsophagus, causing partial compression, and on passing one's finger into the lumen of the œsophagus there was a distinct constriction. There were no secondary growths.

Glaucoma caused by Melanotic Sarcoma of the Eyeball.—Mr. WHERRY showed an eyeball, which, on section, discovered a black growth the size of a raisin, which, growing from the choroid, had stripped off the retina. The pigment cells, under the microscope, were those common in melanotic sarcoma. The eye was removed from a lady, aged 70, who had the symptoms of glaucoma in the left eye. The patient had symptoms three weeks before seeking advice. About five years previously she had been told that she had an incipient cataract. The sight had failed gradually and painlessly. The other eye was in good condition and with good vision. Six days after the operation, a black swelling, as big as an egg, came suddenly on the left side of the lower jaw; it was soft, painless, and uniformly purple-black in colour. It was taken to be a growth; but in a few days its colour faded at the margins, and it decreased to half the size, appearing like an ecchymosis. There was, after a fortnight, a dark, almost black, patch of skin, about the size of a penny. The patient had recovered well from the operation, and was in good health.

Intussusception of the Bowel with Diverticulum.—Mr. A. INGLE showed a specimen of intussusception with diverticulum of the ileum. A child, 5 months old, was attacked with pain, vomiting and on the second day. Bloody mucus was passed from the anus on the third and fourth days; tympanites and hicough followed, and the child sank and died on the fifth day. At no time could any tumour be discovered in the abdomen, nor had there been any pain on palpation. The parents refused to allow any operative interference. After death the intussusception, which was of the common variety (at the ileo-cæcal valve) was found just below the stomach, the diverticulum being two or three inches higher up the ileum. Mr. Ingle asked if the symptoms would have warranted insufflation, and if it had been employed, how, in the absence of any sausage-shaped tumour, one would have known when it had been carried far enough? He raised the question, whether the diverticulum could have in any way acted as the cause of intussusception?—Professor HUMPHRY replied that he thought insufflation might justly have been used. He considered it hardly likely that the diverticulum could have had anything to do with the intussusception.

MIDLAND MEDICAL SOCIETY.

WEDNESDAY, MARCH 7TH, 1888.

W. ROSS JORDAN, M.R.C.S. Eng., President, in the Chair.

Non-union after Osteotomy.—Mr. MARSH exhibited a boy, aged 7, with non-union of the tibia after osteotomy for anterior curvature of that bone. The boy had been operated on four years ago in a provincial hospital; he wore a plaster case for a month after his return home, union having taken place. Eighteen months ago, the deformity still existing (a relapse had probably taken place) he was again operated upon, this time at home by the local medical practitioner. There was a good deal of suppuration after the operation, the wound healing slowly, but no history of necrosis. The boy ultimately got about with the aid of crutches, and wearing a boot with an iron upright. The parents discovered the non-union three months ago, and last week brought him to the Queen's Hospital, Birmingham. The left leg was one inch and a-half shorter than the right, and the muscles wasted from disuse. At the site of the osteotomy, about two inches below the middle of the tibia, there was slight over-riding of the divided ends, the lower being anterior, somewhat atrophied and connected with the upper by fibrous tissue, free movement in any direction being only restrained by the fibula. This latter bone was hypertrophied and curved anteriorly in its lower half, and just above the malleolus was an indication of an old transverse fracture with close fibrous union. Mr. Marsh commented on the rarity of non-union of bones in children, and considered that in this case it was due to local causes, probably imperfect fixation and interference with the medullary artery, and not to constitutional taint, there being no marked diathesis.

Suture of Median Nerve.—Mr. MARSH exhibited a successful case of suture of the median nerve, over eighteen weeks' having

elapsed since its division. The patient, a woman, aged 23, severely cut her right wrist with a pane of glass on October 5th, 1887. The hemorrhage was profuse, and the ulnar artery was ligatured some days afterwards for a recurrence of this. The median nerve was not seen at the time. The wound suppurated and healed slowly. Sensation was lost over the palm of the hand, and over both anterior and posterior surfaces of the thumb and the two adjacent fingers, and partly over the radial side of the ring finger. Trophic changes in the skin and nails, with troublesome ulceration of the tip of the index and radial side of middle fingers ensued, the hand being cold and useless. She was admitted to the Queen's Hospital on February 8th, and the nerve sutured the next day. The proximal end was drawn to the ulnar side of tendon of palmaris longus, was large and bulbous, and joined at an angle by a thin band of fibrous tissue to the atrophied distal end, the annular ligament requiring division to expose the latter. The ends were refreshed, placed in good position by stretching the nerve a little, and flexing the wrist, and joined by three fine cat-gut sutures. Dry boracic dressings were used, and primary union of the wound obtained. Fifteen days after the operation the patient noticed that the thumb and fingers "began to feel different," and two days after this there was a return of sensation over the palm and the carpal ends of the thumb and middle finger. This area had slowly increased up to the present date (twenty-seven days after), the index finger alone remaining without sensation, the fibres supplying this digit probably not having yet united. With this exception there was a marked improvement in the nutrition of the skin and nails. The hand was warmer, much more useful, and complete recovery was only a matter of time.

Suppurative Phlebitis of Uterine Veins.—Mr. BARLING showed a specimen taken from the body of a woman aged 40, who died fourteen days after a miscarriage, having suffered from symptoms of peritonitis for eleven days. Three days before death it was found that she had a strangulated femoral hernia, which was relieved by operation, with temporary diminution of her symptoms. The post-mortem examination showed pelvic peritonitis, evidently extending from the right side of the uterus; and when this organ was divided pus was found in some of the veins on the right side, the suppuration having extended in two places to the tissue of the uterus, producing abscesses the size of a nut lying immediately beneath the peritoneum. The strangulated intestine had recovered from its constriction.

Sarcoma of Ovary.—Mr. T. W. TAYLOR showed a specimen removed by him from a patient in the Women's Hospital. The specimen had been examined and prepared by Mr. Bland Sutton, and was, in his opinion, of exceptional interest. The patient made a good recovery from the operation, and had remained well since.

Shortening of Forearm following an Accident.—Mr. AUGERSTON CLAY showed a boy aged 14, who had injured his forearm six years ago by falling off a cart. It was treated then as a sprain, and after three weeks was apparently well. Three weeks ago he again hurt his arm, and the shortening was discovered. The wrist was much wider than the other, and the hand was pushed over to the radial side by the increased length of the ulna, which was exceptionally prominent and slightly bowed.

Signatures of the late Dr. John Ash.—Mr. WRIGHT WILSON showed three old documents bearing the signature of Dr. John Ash, the founder of the General Hospital.

Sarcoma of Kidney.—Mr. LAWSON TAIT showed a large sarcomatous kidney which he had recently removed.

Congenital Heart-disease.—Dr. SIMON showed a case of congenital heart-disease in a boy aged 13.

Brassfounders' Ague.—Dr. SIMON read a paper on Brassfounders' Ague.

The Movable Dwellings Bill which Mr. George Smith, of Coalville, is promoting for the purpose of bringing gipsy, van, and other travelling children under educational and sanitary influences, will be introduced into the House of Commons in a few days by Mr. Burt, and will be backed by Dr. Cameron, Mr. T. M. Healy, Mr. Penrose Fitzgerald, and Mr. Hozier. There is reason to hope that the Government will give it their support, and Lord Derby has written of it in terms of approval.

PRESENTATION.—Mr. Marshall, the Senior House-Surgeon of the Huddersfield Infirmary, has, on the occasion of his severing his connection with that institution, been presented with a handsome stationery cabinet with silver mounts and salver, some useful medical works, and other souvenirs.

REVIEWS AND NOTICES.

THE ELEMENTS OF PHYSIOLOGICAL PSYCHOLOGY. By GEORGE T. LADD, Professor of Philosophy in Yale University. Pp. xii, 696. London: Longmans, Green and Co. 1887.

THIS admirable work by Professor LADD deserves a hearty welcome from the English public as the first book of sufficient extent of subject-matter and depth of thought to take the place in American and English literature that has been held since 1874 in both Germany and France by Wundt's *Grundzüge der Physiologischen Psychologie*. It is "a treatise on the activities and nature of the mind from the physical and experimental point of view," as Professor Ladd phrases it; and it is even more than that, for Professor Ladd does not hesitate in the third part, and that not the least weightily and valuable, to face the ultimate difficulties and to speak plainly "on the nature of the mind" from a standpoint which is not experimental, but introspective. He has been known widely hitherto as the translator of Lotze's *Diätate*, and though he does not follow Lotze on all points, it is easy to see that he has felt the full force of his influence. The greatest struggle of thinkers since thought began has been to transcend the duality of mind and matter, and no victory has as yet been achieved which the world will consent to receive as decisive. The advance of the present age, as has been well said, has been to reduce the general problem of mind and matter to the particular problem of mind and brain. In furtherance of any future attempts at advance, it is, in the first place, necessary that an adequate statement of the ever-growing data of the nervous mechanism should be provided before the correlations of the nervous mechanism and the mind can be profitably discussed. These data and this discussion occupy the first two parts of Professor Ladd's book. The third part, "On the Nature of Mind," might perhaps have been more logically introduced before the second; for on the conclusions as to its nature must be based the premisses for its correlations.

The description of the nervous mechanism, which occupies with the preface the first 236 pages, is one for which all serious students must be sincerely grateful. It is a most clear and accurate account of the elements of the nervous system, their combinations, functions, and development, and a description, more in detail, of the organs of sense—of taste, of touch, of smell, of sight, and of hearing. In his treatment of all these points he does not profess to bring forward any new personal research, but he states fresh conclusions reached in special departments by Helmholtz, Flüger, Schiff, Hitzig, Ferrier, and many others in brief language which, in its clear discrimination, carries part of the proof of its authority.

The desire to bring this large and constantly enlarging physiological field within a single survey has led him to decline very wisely the more detailed examination of such tempting by-paths as the cerebral localisation of speech, and the psychological inferences which may be drawn from its abnormalities. Such a subject might, perhaps, be more appropriate to Professor Max Müller as helping to illustrate the actions of a state where there is probably science of thought without a science of words. Professor Ladd shows a prudent inclination not to limit too narrowly the localisation of such a complex matter as speech, and not to follow the expression and understanding of articulate language too essential a part in thought when he writes (p. 292): "The literal meaning of the statements made by Broca—such as that this part of the brain is 'the seat of the faculty of articulate language'—is, however, not simply inappropriate to the facts, it is even absurd. There is no one 'faculty' of language which can, in any possible meaning of the word, be regarded as having its 'seat,' or locality, confined to some particular region of the brain. Speech involves, in a very complicated and large way, all the faculties. Strictly speaking, then, it cannot be located, with all its attendant operations of self-conscious, rational mind, in any one cerebral area. It is that the phenomena of aphasia show some special connection of certain cerebral centres with the complex process of apprehending and expressing articulate language seems entitled to credit as an induction based on a wide range of facts."

Turning to the consideration of the mind, Professor Ladd is far too skilled a psychologist not to be well aware that there is no easy short cut for the reason to bring it honestly to materialism, and no easy satisfaction for most men in what may seem a logically impregnable idealism. He realises that mind is self-con-

scious, and is in that respect unique. "If the question is further pressed as the physical basis for the activities of self-consciousness, no answer can be given or even suggested. From its very nature that marvellous verifying *actus* of mind in which it recognises itself as the subject of its own states, and also recognises the states as its own, can have no analogous or corresponding material substratum. It is impossible to specify any physiological process representing this verifying *actus*; it is even impossible to imagine how the description of any such process could be brought into intelligible relation with this unique mental power" (p. 545). He recognises that the problem of the freedom of the will has received no adequate solution, and, as briefly as is courteous, dismisses such recent materialistic formulæ of determinism as M. Luys has put forward when he says that thinking of an object by our will is an illusion; "and the object is only forced upon us by the cunning conjuror, the brain, because the cell territory where that object resides has been previously set vibrating in the brain." That is to controvert "a plain and universal dictum of consciousness by his private and unverifiable hypothesis on a question of cerebral physiology where experts and novices are alike ignorant."

He at first passes by as out of his province the more subtle hypothesis of modern phenomenalism, "A third view which regards both the so-called 'brain' and the so-called 'mind' as merely phenomenal aspects of some one reality that is like neither, but manifests itself in both;" (p. 588); and when he returns to reconsider it later (p. 655), he seems to esteem this "double-faced unity" as overthrown, because we have no answer to the question, "Why does it manifest itself both as physical motion and as mental states?" Nevertheless, his own inclinations seem to leave him no choice but dualism of mind and matter, of which each half is mind-with-matter and matter with mind, a dualism from which Lotze has hardly saved himself.

In speaking of such a book it would be straining criticism too far to dwell on phrases like "visor angle," which fall strangely on the English ear, or to complain of some of the smaller points of omission. Still, in speaking on sound we should have been glad to see Lord Rayleigh's great work mentioned, and on the larger issues of the physico-psychical problems some of those many original articles and pamphlets from Dr. Hughlings Jackson's pen, of which perhaps the most easily accessible results are contained in the Croonian Lectures for 1884.

Among the additions in England, which are perhaps almost too recent to be incorporated, we may reckon on the physiological side Mr. Victor Horsley's experiments on the brain, and on the psychological side Mr. James Ward's article on Psychology in the *Encyclopædia Britannica*, which practically amounts to a treatise.

In his introductory chapter Mr. Ladd has told us with excellent distinctness that "no attempt will be made to describe and discuss any of the phenomena which may be classed as abnormal or as consisting (so far as they are psychical) as so-called 'disturbances of consciousness,' except when reference to such abnormal phenomena is necessary in order to explain those which are normal or ordinary. The phenomena of insanity, delirium, hypnotism, somnambulism, ecstasy, mind-reading, spiritualism, or even sleep and dreaming will therefore be definitely excluded" (p. 8).

He has kept accurately to the prudent lines he has laid down for himself in this book, and we may hope that he may be induced to go on with a firm grasp of his first principles and a wide view of his field to deal with some of the puzzling questions of abnormalities which may be found to throw here and there a gleam of very vivid light on the true character of the natural man.

DE L'EPILEPSIE JACKSONIENNE. Par le Dr. E. ROLLAND, Médecin des Asiles "John Bost" de Laforêt. Paris: Aux Bureaux du Progrès Médical. 1888.

THE form of epilepsy associated with the name of our great neurologist, Dr. Hughlings Jackson, has a literature which is singularly scattered, and Dr. ROLLAND has done the profession a great service in collecting what has been written of the disorder in the work before us. We cordially agree with the remark of Dr. Arnozan, in his introduction to the book, "that the author has done right to publish his work." It is almost entirely a compilation, but of such a kind as to be an exceedingly valuable help to all who are working at nervous disease, or are desirous of reading a complete account of unilateral or cortical epilepsy.

A summary of the anatomy and physiology of the cerebral convulsions is followed by a chapter upon the History of Jacksonian Epilepsy. Here it is shown that, while Dr. Hughlings Jackson was the first to study the disorder completely and to trace it to its organic cause, it was nevertheless known, even in the time of Hippocrates. The chapter upon the Symptomatology, is properly very minute and comprehensive. The first case is reported in the graphic language of Dr. Hughlings Jackson himself, as communicated to the author, and already published in English. We may quote the following as interesting to our readers, although, as will be seen, it is only a repetition of Dr. Jackson's views: "In Cases of Hemispasm, 1. If the attack commences in the face, it is always the upper limb which is affected in the first place, and the lower limb afterwards. 2. If the attack commences in the arm, the convulsions ascend along the arm, next affect the face, and finally descend the leg. 3. If the attack begins in the foot, it ascends the length of the leg, then descends the arm. This last rule appears to have numerous exceptions; in this mode of commencement the face is rarely attacked by convulsions, and if attacked, is affected last." A case under the author's personal observation is reported with great care, and an account of the *post-mortem* examination given.

The anatomical relationships of the disease are deduced from *post-mortem* records of 109 cases, including three from the author's own experience. In the chapter on Treatment, the recent methods of operative procedures receive due description, and a very full account of Professor Horsley's work is given.

There are no new ideas in the book, but it is an excellent work, and will be warmly welcomed.

NOTES ON BOOKS.

Alassio: "a Pearl of the Riviera." By Dr. JOSEPH SCHNEER. 12mo. Pp. 80. (London: Trübner and Co. 1888.)—Dr. Schneer gives us a pleasing account of Alassio, of its past history and present beauties, and also describes the many excursions that can be made from it. His booklet may be of interest to those who are already settled at Alassio; but it supplies no medical information beyond a few meteorological tables; it does not give a hint as to the medical resources of the place, or of the accommodation it offers to visitors. It is really not a guide, for it offers no facts that would help physician or patient who thought of selecting Alassio as a health resort. There is not a word to characterise the place, or show in what respects it agrees with or differs from other stations along that coast.

The Hospital Prayer-book, containing Prayers for Daily and Occasional Use, also a Short Form of Public Service for Lay-readers in Hospitals, with a few Remarks on conducting the Same. Arranged by EDWARD JOHN WARING, C.I.E., M.D., F.R.C.P. Second Edition. Revised and corrected. (London: J. and A. Churchill. 1888.)—Those who are not already acquainted with this volume will gain an adequate notion of its aim from the full title transcribed above. The prayers are arranged for use morning and evening for a week; the short service is founded upon the liturgy of the Church of England. To this second edition some hymns have been added, and the service and many of the prayers have been abbreviated. The preparation and revision of the volume has evidently been a labour of love for Dr. Waring, who may be congratulated on having completed his task in a way which leaves nothing to be desired.

REPORTS AND ANALYSES

AND

DESCRIPTIONS OF NEW INVENTIONS,

IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

FLORADOR.

(Prepared by the Florador Food Company.)

This is an excellent preparation, consisting mainly of granulated wheat of the very finest description. Its composition, chemically, is that of good wheat flour, the albuminoids amounting to 12 per

cent. The main features which distinguish it from other wheat preparations are the mode of granulation adopted, which prevents the flourer, when boiled, from gelatinising into a structureless paste, and the purity of its flavour. When properly boiled it furnishes not only a very good food for young children, but is a capital basis for milk puddings and custards. Children will appreciate the addition to their dietary.

MALTINE AND COD LIVER OIL.

It has long been known that some patients who are unable to tolerate the purest and most carefully prepared cod liver oil can readily digest and assimilate it when mixed or combined with maltine and malt extract. Since this fact was first observed a number of preparations of the two have been placed before the public; some are good, but many are either bad or indifferent.

The maltine and cod liver oil made by the Maltine Manufacturing Company, of Hart Street, Bloomsbury, is certainly one of the best preparations of the kind we have met with. The admixture is complete and permanent, and the consistence is very convenient, being about that of ordinary treacle, so that the liquid readily flows from the bottle. As regards taste, that of the cod liver oil is almost entirely concealed, and what suspicion there is of it is not at all unpleasant. The therapeutic value of good combinations of cod liver oil and malt extract has been so thoroughly recognised, and is so well known, that it is not necessary to enter into this part of the subject, but we can recommend that prepared by the Maltine Manufacturing Company on the ground of its perfect admixture, the ease with which it is assimilated, the good quality of the cod liver oil, and the value in diastase of the maltine.

NEURIN.

This is an effervescent beverage manufactured by Mr. J. F. Edebury, of Wrexham. It is perfectly clear and colourless, and is put up in bottles of the size of pint champagnes. It is non-phosphated, but ten grains of mixed bromides are contained in each bottle. When poured out the liquid is remarkably bright and effervesces briskly. The taste of the bromides is almost entirely masked, and, in fact, the sensation left on the palate after drinking the beverage is an entirely pleasant one. "Neurin" is likely to be useful in those cases in which small and repeated doses of bromides are indicated. The dose is stated to be half a tumblerful when required either alone or with wine.

LIQ. PODOPHYLLIN ET PEPSIN (HOCKIN).

We have previously commented favourably on several preparations manufactured by Messrs. Hockin, Wilson and Co., of Duke Street, Manchester Square, and the preparation now before us is no exception to the general excellence of those already examined by us. It is a clear, dark-coloured solution, and mixes perfectly without precipitation with water and aqueous solutions, such as infusions, etc., as well as with alcoholic and ethereal liquids. It may be employed with advantage in doses of one fluid drachm in cases in which there is deficiency of gastric secretion associated with constipation and insufficient secretion of bile.

SALIX NIGRA CORDIAL (CHRISTY).

SALIX NIGRA, the black or pussy willow, is a tree indigenous to the United States of America, but is found more especially along the streams towards the south. It is stated to be a powerful sexual sedative, similar, in fact, to the bromides in its action, but without having any depressing effect.

It is also said to be useful in ovarian hyperæsthesia, dysmenorrhœa, and uterine neuralgia. Prostatorrhœa and involuntary seminal emissions are stated to be lessened by its use, and it is credited with possessing tonic and antiperiodic properties. It has been reported upon favourably in this country by Dr. J. Hutchison, of Glasgow, and Mr. Hurry Fenwick, of the London Hos- pital.

The fluid extract is the preparation ordinarily used, but this has a very rough and astringent taste, which is very persistent. To obviate this Messrs. Christy and Co., of 25, Lime Street, E.C., have introduced a salix nigra cordial, made so that one tablespoonful is equivalent to one fluid drachm of Christy's fluid extract of salix nigra. The preparation is elegant and palatable, and the disagreeable taste of salix nigra is hardly perceptible. Patients who might object to the fluid extract would, in all probability, readily take Christy's cordial. The dose is from half to one tablespoonful

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1888.

SUBSCRIPTIONS to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the West Central District Office, High Holborn.

The British Medical Journal.

SATURDAY, MARCH 24TH, 1888.

THE LOCAL GOVERNMENT BILL.

THERE can be no doubt that the Bill for the reform of the local government of this country, which was introduced by Mr. Ritchie in the House of Commons on Monday, is by far the most comprehensive measure of the kind which has been yet framed by any ministry, Conservative or Liberal. The broad principles of the measure will probably meet with very general acceptance, and they need not, therefore, be discussed in these columns at any length. The establishment of an intermediate authority between the central government and local boards has been an admitted necessity for the last fifteen years; and although one or two attempts have been made in this direction, no adequate scheme has heretofore been proposed. That the elaborate apparatus of the Local Government Board and Parliament should have to be set in motion for the everyday concerns of local authorities is ridiculous and wasteful; and to the establishment of County Boards probably few will be found to object.

The discussion of the particular proposals of the Government is, however, rendered impossible by the unaccountable postponement of the appearance of the Bill itself until after Easter. Unless the rumours as to the dissensions in the Cabinet on this subject have much greater foundation than usual, the Ministry must have made up its mind some time ago as to the details of the measure; and it is impossible, without seeing the text of the various clauses, to follow Mr. Ritchie's necessarily complicated analysis of the Bill with any degree of surety.

As to the County Councils themselves, there is but little ambiguity. Justice is to be administered as at present by the Court of Quarter Sessions, but almost every other kind of county business is to be turned over to Boards which are to be elected by popular vote. These Boards will administer county rates and financial business, bridges, lunatic asylums, reformatory and industrial schools, the granting of licences for music and dancing, the sale of alcoholic liquors, the registration of voters, and the administration of the Acts of Parliament relating to explosives, contagious diseases of animals, food and drugs, weights and measures, main roads, etc. At all events for the present, the area which each Council will supervise will be co-terminous with the existing county divisions; and we shall

therefore see the anomaly of Rutlandshire having for its administration an apparatus as elaborate as Warwickshire.

County Councils will be made up of members elected on the same franchise as municipal corporations are at present, such members to sit for three years. In addition to the elected members, there will be a species of aldermen, who will be elected by the Council and will sit for six years. The ten largest boroughs of England will each have a separate County Council to itself, and London, moreover, will have a Council of its own, which is to supersede and extinguish the Metropolitan Board of Works.

The proposals of Mr. Ritchie as to the manner in which the primary local authorities will act under the county authorities are, however, much less clear. So far as we gather from his speech, it is still proposed to have two kinds of primary areas, namely, urban districts, which will be the "existing and future municipal boroughs and local boards and rural districts," and rural districts. It is not clear whether any place which happens now to have a local board will be permitted to maintain its separate organisation, or whether the county authority will map out the county afresh, so as to redress the anomalies which at present exist. Whatever may be the proposals of the Government on this head, we think that it is above all things essential that the sanitary areas of the country should be thoroughly recast. They have grown up upon no sort of system, and if they are perpetuated, endless difficulties will arise in the future.

However much the Bill might have been watered down, Mr. Ritchie would, in any case, have had to confront a formidable phalanx of opposition. It is to be regretted, therefore, that the Government have not seen their way to go a step further, and to unify all the local authorities which now exist; so that there may be one local authority, and one only, exercising jurisdiction over a particular area. It is worth while in this connection to point out that nearly all the existing authorities are of modern growth, so that no halo of sanctity yet surrounds any one of them. No doubt the Government were wise in not attempting to hack about the present counties, which have associations of well nigh a thousand years clinging to them. But the Poor Law Union is a creation of only fifty years ago, which for the first half of its existence had no common life growing up round about it. Local Boards are barely twenty years old, rural sanitary boards only fifteen years old, and School Boards only a year or so older. These manifold, intricate, and irrational organisations ought clearly to be amalgamated and co-ordinated. Yet we find Mr. Ritchie proposing to leave the poor law unions and the poor law guardians absolutely untouched. This, in our view, is the weakest part of his proposals. John Stuart Mill has, with his usual clearness, very well expressed what ought to be held in view with regard to local administration. He says, in his *Considerations of Representative Government*, that "in each local circumscription there should be but one elected body for all local business, not different bodies for different parts of it. The local, like the national Parliament, has for its proper business to consider the interest of the locality

as a whole composed of parts, all of which must be adapted to one another."

All the efforts of sanitary and local government reform have been directed towards this unification of area and functions, and it seems to us a distinct flaw in the Government proposals that the administration of the relief of the poor should be divorced altogether from the other parts of local administration.

Probably one reason why Mr. Ritchie has proposed not to touch this matter is his anxiety "not to overload the machine at starting;" but it is obvious that unless the question is grappled with in a comprehensive spirit, we shall have a repetition of the constant tinkering at reform which have been the bane of the local administration of the country for the last generation.

The only purely medical point which is brought out in Mr. Ritchie's speech is the proposal to suppress the grants in aid of medical officers of health and inspectors of nuisances now given by the Local Government Board under the Public Health Acts. These grants were originally instituted by Mr. Stansfield in 1872 as a kind of bribe to local authorities to accept the supervision of the Local Government Board over the appointment of these officers. But it has never worked well, and is, like many other grants in aid, an anomaly which an occasion like the present affords a useful opportunity for suppressing. In lieu of the grants in aid the Government intend to hand over to the local authorities the receipts from licences for the sale of intoxicating liquors and various other licences, roughly amounting to £3,000,000. They propose also to grant what is described as "a substantial contribution from personalty" amounting to £1,800,000. This may very possibly mean that the Government are intending to make the inhabited house duty, which amounts to about that sum, a local instead of an imperial tax. As Mr. Ernest Hart observed in his address on Local Government delivered to the Sanitary Congress at Leicester in 1885, there would be great advantage in the substitution of the various grants in aid by "a tax like the house tax, which is incomparably a more legitimate source of local revenue than the appointment of a local sanitary officer, for example, is a matter for imperial subsidy."

So far as can be seen at present the licensing part of the Bill is that upon which the chief opposition will turn. Happily a discussion on this point is beyond our province, and we may be permitted to hope that the criticism as to the powers of the proposed County Councils with regard to licences will not wreck the other and more urgent parts of the Bill. Nothing can well be more anomalous and wasteful than our present system, and both parties must put forth a strong effort to make at least a start in Local Government reform, even if it be necessary to postpone some important sections of the question for another year.

THE PRESIDENCY OF THE COLLEGE OF PHYSICIANS.

The forthcoming election to the Presidency of the Royal College of Physicians will be regarded by the profession generally

and the well-wishers of the College with more than usual interest. In Sir William Jenner the College loses a President of conspicuous ability, great firmness of character, and large social influence and interest in public business. It would at any time be difficult to fill the place of a man of so much professional and social eminence and unselfish earnestness of purpose, and possessing so decided a power of guidance in public affairs. It is peculiarly difficult at the present moment, when the College is involved in public transactions of great moment to its own future, and to the prospects of medical education and graduation in the metropolis.

Not many years have passed since the College of Physicians took up a new position in relation to the profession, and by creating a great class of Licentiates assumed new and enlarged duties and responsibilities to the profession and to the State, and this greatly magnified its office. The effect of this tardy but wise proceeding was to infuse new life into the College, to replenish its then scanty exchequer, and to place it in the front rank of the large and active professional forces of the day. That step was not taken without the usual opposition from the elder and more conservative elements of the College, and its chief author, Dr. Quain, may to-day be heartily congratulated on the foresight and ability with which he led the College on that great occasion into a path which has been one of prosperity, power, and enlarged usefulness. At this moment, and as a natural consequence of its developed professional relations, and its large duties to the great class of Licentiates whom it welcomes from all the metropolitan and provincial schools, it finds itself called upon to assist in making some provision for the more ready graduation of its candidates, and for opening to them facilities for the title of doctor of medicine which are granted on equitable and not too onerous conditions to the students of other great centres of medical education in Great Britain and Ireland.

A Royal Commission is about to sit on the various schemes and counter-schemes proposed. The College of Physicians will play a large part, not only in the proceedings before the Commission, but also in the subsequent negotiations which will follow its report—the latter being probably the more difficult and delicate task. The present position of the College is one which will require of its President, not only the possession of eminent business qualities, but the habit of dealing with public questions and public men, tact, knowledge of the affairs of the College, and of the other professional bodies which will take a friendly or an unfriendly part in the future negotiations. Many eminent physicians have neither the experience, nor the social influence, nor the clearness of intelligence, nor the presidential faculty which are needed for the good guidance of affairs in this peculiarly important period in the history of the College. It is contrary to our custom, and would infringe the peculiarly reticent traditions of the College, if we were even vaguely to indicate the names of those who are spoken of as likely to find their names in the lists voted on Monday next at Trafalgar Square, or to discuss, from however

impersonal a point of view, their respective public records; but we feel justified in expressing the opinion that there has rarely been an occasion in the history of any public body when the best interests concerned require a more careful weighing of the proved fitness of the candidate for the trying public duties of the office, or one on which it is more important that individual likes or dislikes or minor considerations of a personal or irrelevant kind should be more decidedly put aside. We have indicated what will, we think, be generally recognised as the qualities needed at this time, and the character of the public record which should command the support of the Fellows. The College should, out of its rich personal resources, have little difficulty in making a selection which will answer to the necessities of the occasion.

MEDICAL APPOINTMENTS AND POLITICAL INFLUENCES.

CONSEQUENT on the promotion of Dr. F. X. Maccabe to the Local Government Board, Dr. G. B. O'Farrell has been appointed medical member of the Prisons Board, Ireland. The salary is £800 a year, and as the duties of inspecting reformatory and industrial schools are temporarily added, the annual income from both offices will be about £1,000.

We have no objection to make to Dr. O'Farrell on any personal grounds. He has had three years' service as a Local Government Board Inspector, and before his appointment to that service he enjoyed a large private practice. He is a gentleman of considerable ability, and he has fulfilled the promise which he gave in a distinguished university career. But there his claims end, and we are not surprised to hear that grave dissatisfaction exists as to the appointment. In writing on the subject of the public medical service last week, we referred to the great weight which personal influence has in the filling of offices, and to the necessity that exists for more discrimination on the part of the Government officials who are entrusted with patronage. Here is a case of distinct hardship. The whole affair was "managed." Dr. O'Farrell was a candidate for the Local Government Board Commissionership. He had most powerful friends, but as he could not be given the best thing he was given the next best—he was made member of the Prisons Board *vice* Dr. Maccabe. No vacancy was declared, and even the chance of a vacancy was not known until the appointment was declared.

Dr. O'Farrell has no special knowledge of prison work—he never, we are informed, held a prison appointment—and it is not a pleasant thing to hear it openly stated that he owes his good fortune to the friendship of a Parliamentary official. In Ireland there is a large body of medical men employed in the prison service. They have to perform arduous duties, especially in these times; they are badly paid, and they not unnaturally look forward to winning the only prize open to them. There are plenty of them who are men of marked ability: they are trained in the work; but twice in succession they have been passed over in the interest of outsiders. When Mr. Forster was Chief Secretary

the prison medical officers were promised payment for the increased duties; but his successor and the Treasury repudiated any liability, and declined to pay. They are compelled to provide substitutes at their own cost, even when absent on official duty. To find themselves "dished" in this cool way, in addition to suffering other wrongs, is rather hard for their human nature. Were Dr. O'Farrell's abilities even far superior to those of all or any of the prison medical officers—which it is not derogatory to him to say they are not—his appointment to the Prisons Board would be no less an insult to the prison surgeons of Ireland, and would be no less marked by the smartness of a political job. No one for a moment thinks that such appointments shall of necessity be vested in the service always to the exclusion of others. But, *ceteris paribus*, promotion ought to be retained in a department, and not given outside of it. We do not wish to give the least pain to Dr. O'Farrell, who is a most popular officer and a cultivated gentleman, nor do we blame him for having taken advantage of any special circumstances to secure the position. But we do blame the system which in all political parties tolerates this kind of thing. Public appointments—the more valuable they are, the better—seem to be fair game with both sides to bestow upon their friends, and we can only hope that repeated protests may in the end serve to break down what has become a public scandal.

THE CLIFTON LUNACY CASE.

THE case tried at Bristol this week and last is an instance serving admirably for illustration of the liabilities incurred, under the present lunacy laws, by medical men and others who are in any way concerned in the confinement of persons as being of unsound mind. In another column will be found an abstract of the case, as reported in *The Times*. The plaintiff brought an action to recover damages against two medical men for negligently and improperly certifying her to be insane, and libel in the statement in their certificates that she was insane; and also against the Mother Superior of a convent for trespass and slander in connection with the acts of placing her in temporary confinement, and eventually under care and control. The jury found for the defendants; and, waiving all the matters of fact with regard to which there was any conflict of evidence, it is difficult to see how the jury could well have arrived at any other conclusion. As reported, the plaintiff in cross-examination, stated that on one occasion, leaving the convent and taking a ticket for London, she left the train at Swindon, went to a wood and lay down, intending to wait there for death, but changed her mind and went to a hotel instead; that in her opinion, all along, the real reason why the nuns had combined to get her shut up was that they falsely considered her a person of immoral character; and that she had broken ornaments and glass when in the asylum because she was determined to give as much trouble as possible, being convinced that she was not to be released. Add to this the plaintiff's letter, produced in court, and written to the Commissioners in Lunacy, in which she described herself as being almost perpetually in a state of

trance, "or, as they say, under the influence of some supernatural power," and while in that state as having made herself out to be a bad character by means of signs and words of which she only understood the import after they were made and uttered, which signs and words were uttered independently of her actual will and knowledge: and stated that there was no kind of insult or humiliation to which she had not been subjected during the preceding nine months. And this comprises only part of the letter. Further it was in evidence that from time to time the plaintiff had been visited and seen by Visiting Justices and Commissioners in Lunacy, who approved of her detention. These facts form a body of striking evidence, and may be considered quite irrespectively of the testimony of the medical defendants who signed the certificates of unsoundness of mind and quite irrespectively of the evidence of the medical men under whose care the plaintiff was in different asylums.

The numerous actions taken against medical men for having signed certificates of unsoundness of mind, or against those who have to do with placing persons in public or private asylums are more than sufficient to establish the necessity for some more reasonably protective clauses in the future lunacy law. At present, anyone concerned in placing persons as of unsound mind under care and control is liable to a series of actions at law, no matter how carefully or properly he or she may have acted in the matter; may be subjected to these actions long after the event, and no matter how unreal or factitious the grievance alleged, or how thoroughly the attack may break down, and may be left to bear, not merely the annoyance and loss of time, but also, perhaps, his or her own heavy costs, irrecoverable from an impecunious plaintiff.

It is to be hoped that in its final form the coming lunacy legislation will vastly improve this state of affairs.

THE Croonian Lectures at the Royal College of Physicians will be given by Dr. Donald MacAlister at 5 P.M. on Tuesdays and Thursdays, June 14th, 19th, 21st, 26th, 28th. The subject, as already announced, is "Antipyretics."

MR. THOMAS BRYANT, whose appointment as surgeon to Guy's Hospital lapses from efflux of time in May next, will then retire, the governors having at a recent meeting of their court accepted his resignation. Guy's men far and wide will regret the severance of Mr. Bryant from the teaching staff of the hospital, in which he has held a prominent place for nearly thirty-one years. For fourteen years he was assistant-surgeon; for seventeen years surgeon; and for the last seven years of that time he has been senior surgeon. Mr. Bryant has also held the Lectureship in Surgery for thirteen years.

CORONERS.

A BILL introduced by Lord Halsbury proposes to take away the appointment of coroners from the freeholders in counties and the council in boroughs, and to vest it in the Lord Chancellor. Another provision extends the jurisdiction of coroners to cases of fire. An inquiry as to a fire would, however, only be held at the request of the Metropolitan Board within its area, or of the borough council in a borough, or of a county magistrate elsewhere. Provision is also made for the revision of the remuneration given to coroners; and power is given to the Queen to fix by Order in Council the area of a coroner's jurisdiction in a county.

THE AITKEN PORTRAIT FUND.

WE are asked by the treasurer to the Aitken Portrait Fund to intimate to the subscribers that the portrait of Sir William Aitken will be on view at the studio of the artist, Mr. W. R. Symonds, Art Studios, Holland Park Road, W., on March 31st and April 1st, between the hours of 3 and 6 P.M. The picture will be shown to subscribers and their friends on presenting their cards.

PULMONARY PHTHISIS.

THE *Revue de Thérapeutique* of December 15th, 1887, published a lecture delivered by Dr. Vibert at the Paris Morgue, in which he stated that among 200 necropsies which he had made on persons who had died a violent death, he had in as many as 20 per cent. found evidence of old tubercular lesions in the lungs, which had healed.

THE QUEEN'S NURSING FUND.

At a meeting held at Grosvenor House on March 15th, it was formally proposed by the Countess of Strafford, seconded by Mrs. W. E. Gladstone, and adopted, that £70,000 of the Women's Jubilee Fund—which had reached a total of £84,116—should be transferred to the trustees nominated by Her Majesty of the proposed Nursing Fund. Also that, after a sum of £10,900 had been retained for the statue in Windsor Park and contingent purposes, and after the purchase with the surplus of a personal ornament to be worn by the Queen, and any other payments, any balance remaining should go to the Nursing Fund.

A NEW DEVICE IN ELECTROLYSIS.

DR. A. B. CARPENTER announces in the *Cleveland Medical Gazette* a plan for applying electricity to the treatment of fibroid tumours of the uterus without troubling oneself about batteries. He says it is difficult to keep jar-cells and dynamos in working order, so he simply turns on the electric current from a street wire of the incandescent lighting system. He has had connections made in his office with the Edison incandescent circuit, and, by means of an ingeniously constructed rheostat circuit, the current is reduced so as to be scarcely perceptible. By means of a delicate instrument the current is accurately measured while passing through the patient's body. A switch-board is made use of, whereby the current can be increased from a fraction of a milli-ampère to the highest tolerant dose. The apparatus is absolutely safe, as the entire voltage of the wire can be handled with impunity.

INQUESTS AND CHILD MURDER.

THE lax manner in which some coroners fulfil their duties has long been notorious, but we doubt whether a more striking illustration has ever been afforded of this than is shown by a recent occurrence at Brixton. The body of a newly-born female infant was discovered, with the head nearly severed from the trunk. The East Surrey coroner held an inquest, which for its perfunctory character is not equalled by any similar inquiry that we can remember. A policeman deposed to having received the body from the man who found it, and to having taken it to the Brixton Police Station, where it was seen and examined by Dr. Knight, the divisional surgeon to the police. The opinion of the latter that the head had been nearly severed from the body as by some sharp instrument, and that the child had not been attended to at birth in any manner, was duly given to the jury at secondhand by the policeman; and beyond the evidence of the finding of the body, they had nothing else upon which to found their verdict. This was to the effect that the child was found dead with its throat cut, but that they had no proof as to whether it had had a separate existence. If the jury had said that no attempt had been made to obtain any evidence as to this last point, the verdict in this respect would, at any rate, have been true; it is an

equivocation, to say the least of it, to say there is no proof of any particular point without making an investigation. But the first part of their verdict is even more objectionable, for they said the child was found dead, which must imply, as the correspondent who has drawn our attention to the case pointed out, that the child had been living at some previous time. The jury had no right to assume that the child had ever lived, for there is, as is well known, a presumption in law in all cases of this kind that the child was stillborn, and, therefore, in the absence of any evidence to the contrary, the finding of the jury violated a well recognised rule. It is not the first time by any means that we have had to complain of the way inquests are conducted in this district.

MARCH DRAWING-ROOMS.

MR. PUNCH, in his playful wisdom, has lately aimed his shafts, not a day too soon, at the system which must be held responsible for the woeful miseries endured by those who, at seasons like the present, desire loyally to show their dutiful allegiance to the Throne. Whensoever conventionalism is allowed, at the risk of health and of human life, to usurp the place of common sense, it is clearly the duty of the medical profession to let its voice be heard. When fair daughters of Eve, in so-called full dress, ingeniously display to the utmost their shapely arms and backs and busts; when, with the help of the *modiste* and the *undressmaker*, they approach as nearly to the nude as may be; when the young and beautiful, after a brief season of gaslight gaiety, are seen to be careworn and haggard; when matrons, beautified with feathers and paint, complacently smile at the sight of their daughters thus victimised; when modesty is thus shocked and common sense outraged, then we come to know that we are in the halls of modern fashion and enjoyment. Is the medical profession justified in witnessing such vagaries of human judgment without protest? Perchance the counsel of the wise, if properly directed, might yet succeed in coming to the rescue of long-suffering and half-clothed humanity.

WAVES OF TEMPERANCE.

IN a recent address, Dr. T. D. Crothers referred to the various temperance revivals in America and England as physiological cyclones. Enthusiasts believed on each occasion that the power and influence of alcohol were destroyed for ever. Yet as each wave of enthusiasm receded, it was seen that intemperance flourished apace. The same ebb and flow of the tide of temperance is still witnessed. As the whirlwind of revolution clears the air and prepares the way for the advance of truth, all these revivals and missions have directed the attention of the thoughtful to the study of the whole subject. The voice of science is beginning to teach that inebriety is a disease, and must be treated accordingly. Four medical societies and one quarterly journal are devoted exclusively to the study of the laws which govern inebriety. This increasing recognition of the disease aspect of intemperance is only the re-affirmation of a truth urged centuries ago, but the times were not then propitious for its reception and growth.

PAUPER NURSING.

A QUESTION put by Mr. Pedder at a recent meeting of the Holborn Board of Guardians elicited the reply that at the Highgate Infirmary there were fifteen wards, with an average of seventy-five patients in each, whose nightly wants were ministered to by one nurse for two wards. A member hereupon volunteered the statement that there were helpless patients in one of the wards who had not been fed or washed for four days. This a Mr. Miller emphatically denied. Mr. Pedder further said that two patients died in one ward within twenty minutes of each other, so they could have had but little attention from one nurse. The clerk

said that for the fifteen wards there were eight "charge" nurses, eighteen assistant nurses, and two temporary nurses. It was resolved to consider as to appointing more assistance. Mr. Jacobs called attention to Gray's Inn Road Infirmary, where he said there were 122 lunatics, imbeciles, and sick in seven wards, and cared for by only three nurses. Only one nurse was in charge of the whole number during the night. This also was referred to the Committee.

A CENSURE ON A MIDWIFE.

IN the case which has occurred at Birkenhead, we have another instance of a midwife endeavouring to perform an obstetric operation, about which she could have known very little, and for the performance of which she proved herself utterly incapable. Of course it is well known that anyone may legally perform any operation, no matter how difficult or important it may be. If, however, he or she fails to prove that the operation has been performed with competent skill, then an action may be brought against the offender. It is evident in this case that competent skill was not exercised, the midwife having failed to remove the whole of the adherent placenta; the coroner had therefore good grounds for censure, and the midwife may be thankful for the good fortune which permitted her to escape with so slight a penalty. Once more the necessity for legislation for the examination and registration of midwives is brought before us. An excellent Bill is already in existence, and generally approved and adopted. The action of Parliament alone is required. In the mean time the lives of mothers are daily sacrificed by ignorant and self-sufficient women, who undertake the duties of a calling requiring careful training and guarantees of efficiency. Public safety demands the attention of our legislators to put an end to this disgraceful scandal.

MEDICAL WITNESSES AT ASSIZE TRIALS.

A CORRESPONDENT informs us that great improvement took place at the last Liverpool Assizes which are just concluded in the arrangements made for the medical witnesses. After the cases had been before the grand jury, the witnesses were told on what day the case would be taken, and that it would be unnecessary for them to attend during the intervening time; thus the medical witnesses were enabled to return and make provision for the appointed day, and, as a rule, their case was taken on the appointed day. In one case the medical witness would have had to attend from day to day for ten days under the old arrangement, whereas he only attended three days, namely, the day for the grand jury and the day appointed and the following day; this was a convenience to himself, for otherwise he would have been ten days from his practice, and it was a saving to the country in fees in this particular instance of seven guineas. Evidently the action taken by the British Medical Association and, in the first instance by the Lancashire and Cheshire Branch, has borne some fruit, and what should be next done is to try and obtain adequate remuneration for the medical witness either in the form of a sliding scale according to experience and standing in the profession, or a fee of not less than two guineas a day. "Surely," adds our correspondent, "there are none who will allow that a guinea is adequate remuneration for a witness who has to leave his practice and go twenty miles to the assize town."

FURROWS ON THE FINGER NAILS.

NEARLY twenty years ago Dr. Wilks directed attention to the fact that a transverse furrow appeared on the nails of the hand after a serious illness. Medical literature has since then contained a few references to the subject; he again brought the subject before the Pathological Society at its meeting on March 20th, and related a remarkable case (see p. 664). In that case the

furrow was produced in a 'gentleman in robust health by three days' sea-sickness. Mr. W. W. Wagstaff, whose enforced withdrawal from notive work is a matter of so much regret, addressed a note to Dr. Wilks, containing the following interesting observations: He pointed out that the furrow was at first, when near the lunula, shallow, and difficult to identify, but that when it reached the middle of the nail, it was distinct, and often, especially in nails with longitudinal ridges, dotted. The furrow reached the middle of the nail about three months after an illness, but moved onwards towards the free end at different rates in various cases, the rate increasing as the free edge was approached. As a rule all the finger nails were affected, but in some only the right hand showed the mark, and in others only special fingers, the ring finger most often escaping entirely. Mr. Wagstaff also stated that the furrows could be produced by a local cause, and mentioned a case in which the left hand was injured by a rocket stick, which fractured the metacarpal bone of the index finger, and the arm and hand remained in splints for a month; the left hand only showed the transverse furrows, but on all the fingers.

AN EPIDEMIC OF INFLUENZA FOLLOWING MEASLES IN ST. HELENA.

THE following particulars of an outbreak of influenza in the island of St. Helena, which assumed an epidemic form in January of the present year, has been furnished us by the colonial surgeon, Mr. F. S. Watson. He is inclined to attribute its severe character to the lowered condition of the people after a severe epidemic of measles which prevailed in the island from May to October, 1887, when it is estimated that, out of a population of about 5,500, from 3,500 to 4,000 suffered. Eight deaths only occurred, caused by pneumonia and bronchitis; the prostration was nevertheless very great, it being necessary to keep adults on the sick list for an average of about one month. The symptoms of the influenza were a definite chill going on to rigors, and ending in profuse perspiration. The chill commenced usually in the evening, and the sweating about six hours after, followed by pains in the forehead, orbits, and chest, and accompanied by a dry hacking cough and aching in the limbs. The temperature varied during the chill from 105° to 101° F., and afterwards was about 100° F. There was no coryza. The disease lasted about four days, and ended in bronchial catarrh or bronchitis, the latter being usual in delicate or old subjects. One attack was a preventive against a second. The epidemic lasted about a month, during which time Mr. Watson treated about 1,000 cases, with 3 deaths from pneumonia and bronchitis. Coming so closely after measles, it has considerably lowered the physical powers of the inhabitants, and it is thought, will increase the mortality, especially among infants, for several years to come. An interesting feature of this epidemic was that, though the disease attacked nearly the whole population without reference to European descent, those who had lived on the island but a short time escaped. Influenza colds are usual in St. Helena at that time of the year, and Mr. Watson asks: "Might not the disease have taken on the form of epidemic influenza due to the lowered condition of the people after the epidemic of measles?" A similar epidemic of influenza occurred in the island twenty years ago, and epidemics of measles in 1807 and 1843, which, Mr. Watson points out, followed the usual course amongst isolated communities, the first epidemic being very severe, but modifying the succeeding ones.

SMALL-POX IN LEEDS.

THE question whether the insanitary state of a residence, coupled with dirty surroundings, could have any share in the production of small-pox, was referred to by Dr. Goldie at a recent meeting of the Yorkshire Association of Medical Officers of Health. Every speaker considered a distinct negative reply must be given to

such a question, an opinion with which we are entirely in accord. What the origin of small-pox is no one knows, but notwithstanding the statements of anti-vaccinationists, there is not a particle of evidence to show that it is caused by a local insanitary condition. Dr. Buchanan has clearly shown that the poorer half of the vaccinated community in London had actually less mortality from small-pox among its children than the richer half (*vide* Eleventh Annual Report of the Local Government Board, supplement containing the report of the Medical Officer for 1881), and necessarily the poorer half are more exposed to such conditions as those mentioned. The difference is, indeed, due to the greater protection afforded by vaccination as performed at public stations.

THE EPSOM COLLEGE BIENNIAL FESTIVAL.

A PRELIMINARY list of subscriptions and donations on the occasion of the biennial festival of the Royal Medical Benevolent College is published in our advertising columns (p. 47) this week, and it will be seen that the amount received already exceeds £450. As we stated last week, so many gentlemen have already signified their intention to be present that the list will shortly have to be closed. A complete list of stewards will be published next week, and intending donors should communicate without delay with Mr. R. Freeman, the Secretary, at the offices of the College, 37, Soho Square, W.

PARASITES IN FISH.

A WRITER in *La Nature* tells us that, amongst the more recent discoveries of scientific research is that of the presence of parasites in fish. Of these tiny eel-like creatures ten kinds are recognised in the fish of the Mediterranean Sea, the Atlantic and Indian Oceans. They are generally found in some hollow part of the fish's body, the cavities of the starfish's respiratory organs being a very favourite abode. Sometimes, however, they attach themselves to a part of the fish where life is not so easy a matter for them; for instance, they have been found in a pearl-oyster, buried in a curl of the shell. These parasites do not endanger the life of the fish on which they live, as they feed on the microscopic organisms which are washed into the cavities of the fish by the sea-water—eating their messmates, as Van Beneden says.

CONGENITAL FACIAL PARALYSIS.

DR. B. H. STEPHAN, of Zaandam, publishes in the *Weekblad* of the Dutch *Tijdschrift voor Geneeskunde* an account of a rare case of congenital facial paralysis, the explanation of which is very obscure. The subject was a woman to whom her mother had given birth before the arrival of the medical man, the labour having of course been a simple and not a prolonged one. It was very soon noticed that the two sides of the face were different in appearance, the left being "like a mask," in striking contrast to the right, which was "full of expression." The condition remained unchanged as she grew up. When seen by Dr. Stephan, the pupils were equal, and reacted equally to light. There was but little difficulty in eating or drinking, owing to practice. Sensation was equal on the two sides. The hearing was, however, somewhat dull on the left side. No difference could be detected in the tympanic membranes. Dr. Stephan, on looking up the subject in medical literature, was unable to find any description of a precisely similar case. Professor Hensch, who mentions the existence of congenital facial paralysis in his lectures on the diseases of children, on being communicated with, replied that he had scarcely ever seen a case reported, and that he did not know of any description which had been published. Dr. Stephan believes that there are three forms of congenital facial paralysis, two of which are transient and depend on the application of forceps or the pressure of a tumour, etc., during a prolonged labour, and a third, of which his own case is perhaps the only described instance, where the paralysis is permanent, and where it may, as

he suggests, depend upon necrosis, the main apparent difference between this and the other two forms being the affection of the hearing, which may, he believes, be an indication of the permanent character of the paralysis, its existence in any case being sufficient to cause the practitioner to give a guarded prognosis.

TÆNIA AND CYSTICERCUS.

DR. GAVOY endeavoured to prove, in a communication read last year before the Académie des Sciences, that the cysticercus cellulose found in measy pork is not the larva of the common tapeworm, *tœnia solium*. His argument is chiefly based on the fact that the hooklets of the *tœnia* measure 160 micro-millimètres, whilst the hooklets of the cysticercus are from 180 to 200 micro-millimètres in length. Dr. Gavoy admits that the head of the cysticercus which is found in the human brain is identical with that of the *tœnia solium* expelled from the human intestines. He further notes that the Arabs and Algerian Jews, who never eat pork, are subject to tapeworm. Dr. Raphael Blanchard, in a letter recently published in the *Progrès Médical*, disputes the correctness of Dr. Gavoy's theory. Dr. Blanchard observes that Aloys Humbert, Küchenmeister, Leuckart, Hollenbach, and Heller, have all separately proved by experiment that the cysticercus of measy pork becomes the *tœnia solium* of man when the diseased pork is eaten by human subjects. The question of the length of the hooklets is, in Dr. Blanchard's opinion, of no value, as it is a matter of individual variation. Lastly, he shows that the *tœnia* of the Arabs is not the scolex or adult of the cysticercus of measy pork, but the scolex of a larval form found in beef—in fact it is the *tœnia saginata*.

PHLEGMASIA DOLENS AND ŒDEMA OF INFANTS.

DR. LÉON DUMAS, Professor of Clinical Obstetrics and Gynaecology, Montpellier, has recently contributed to the *Annales de Gynécologie et d'Obstétrique* a paper on the Probable Identity of the Œdema of New-born Children and Phlegmasia Alba Dolens. He concludes that this Œdema is but one symptom of phlegmasia dolens developed in the course of the first few days after birth. Its causes, though very varied, are essentially of the same nature as in the adult, and may be divided into predisposing and determining. The principal determining cause is the incomplete establishment of respiration, including pathological and other obstacles which that function may encounter before arriving at its perfect stage of efficiency. The symptoms of phlegmasia are the same in the new-born infant as in the adult, allowing for certain modifications in relation to the special physiology of the first days of life after birth. There is likewise the same pathological anatomy in both cases; but in the child the venous thrombosis is more often situated in the inferior vena cava. The treatment should be alike in both cases, and the same dangers are to be feared in the infant and in the adult, though the relative lesser vitality of the new-born child must always render the prognosis less favourable in its case than when its mother is similarly attacked. All the precautions by which impediments to the establishment of perfect respiration are overcome, including the avoidance of hasty and immediate ligation of the umbilical cord, together constitute the true prophylaxis against the affection in question.

DEXTROCARDIA.

A CASE of right-sided position of the heart was recently shown to the Vienna K. K. Gesellschaft der Aerzte, by Dr. A. Grass. The patient, a young woman, aged 20, was badly developed, and complained much of dyspnoea and giddiness. There had been some improvement of late years. The pulsations of the heart on the right side of the sternum were noted at birth, and there had always been some cyanosis and feeling of coldness. There was no cardiac dulness on the left side; on the right it began at the

fourth rib, extending inwards to the right sternal border, and downwards, being lost in the liver dulness. Auscultation revealed in the second left intercostal space a distinct systolic murmur, and there was a loud diastolic sound. The murmur was heard in both carotids. The pulse was very small, but otherwise normal. The abdominal organs were normally situated. The diagnosis made was pure dextrocardia and congenital pulmonary stenosis, without malposition of the viscera in general. Von Bamberger concurred in the diagnosis, and remarked that Professor Schrötter had lately stated that no single case of pure dextrocardia had ever been proved, whereas all anatomists of great experience, for example, Rokitànsky, Friedberg, Förster, etc., had mentioned such cases, and he himself had seen two. The murmur was due to congenital stenosis, for the acquired kind was extremely rare, though he and Dittrich had described such a case (due to a kick of a horse). The loud second sound excluded the aorta as its origin. He thought also that the great vessels were not transposed; the case had gone on too favourably for that supposition. Professor Kundrat said that the great vessels might be transposed, the position of the septum to some extent correcting the malposition.

GUAIACOL IN PHTHISIS.

PROFESSOR FRÄNKEL, who has repeatedly advocated the use of creasote in the treatment of phthisis, now recommends guaiacol as the effective constituent of creasote. The good effects of the latter are, Fränkel thinks after nine years' experience of its effects in phthisis, unmistakable in a strictly defined class of cases. If used promiscuously in this disease, its good effects are distinctly evident in 16 or 20 out of 400 or 500 cases, and are due not to destruction of the bacillus tuberculosis, but to its favourable influence on the digestion. It has long been known that creasote is a mixture of different substances, and last summer Professor Penzoldt remarked that guaiacol appeared to be its strict therapeutical constituent. Since then Dr. Sahli, of Berné, has reported on the clinical uses of guaiacol, and Professor Fränkel has been using it since the beginning of the year in the following mixture, which suits admirably—guaiacol, 13.5; tinct. gent., 80; sp. vini rect., 250; vini xerici, q. s. ad colat. 1,000—a dessert spoonful in a wineglassful of water two or three times a day. This mixture is superior to gelatine capsules or tolu balsam. Sommerbrodt's praise of creasote is hardly justified by facts. Fränkel remarks on this point that his own patients were nearly all hospital patients carefully investigated, only nine being private patients, whereas Sommerbrodt speaks of five thousand private patients, but without giving details. In due time creasote (or rather, for the future, guaiacol) will take its proper place.

GERMAN GYNÆCOLOGICAL ASSOCIATION.

THE *Centralblatt für Gynäkologie* announces that the Second Congress of the Deutsche Gesellschaft für Gynäkologie will be held on May 24th, 25th, and 26th, in the Frauenklinik of the University of Halle. The sittings will be held from 9 to 12 and from 2 to 4 on each day. Patients whom members of the Association desire to exhibit will be lodged, after due notice, in the wards of the Frauenklinik. Notice of papers and demonstrations must be sent to Professor Kaltenbach on or before April 20th.

SCOTLAND.

MEDICAL OFFICERSHIP OF HEALTH, ABERDEEN. On Monday the Aberdeen Town Council appointed Dr. Matthew Hay, Professor of Medical Jurisprudence, Aberdeen University, to be Medical Officer of Health for the City of Aberdeen.

SMALL-POX IN SCOTLAND.

A FEW sporadic cases of small-pox continue to occur in Scotland. Two such have been observed in Inverkeithing, Fifeshire, where a large number of the workers at the Forth Bridge are congregated. The contractors for the bridge and the local authority have provided suitable accommodation for other cases, should such occur.

INFECTIOUS DISEASES IN EDINBURGH.

DR. LITTLEJOHN'S report for February stated that, during the month, 1,212 cases of infectious disease were reported, as compared with 768 in the same month last year, 468 in 1886, and 222 in 1885. The large increase is due to the epidemic of measles which was and is still raging, there having been 1,106 cases of measles alone, the remaining cases being typhoid fever, diphtheria, and scarlatina. The fatal cases were 4 of diphtheria and 1 of scarlatina. The cases in the City Hospital at the end of the month were 123, 63 adults and 60 children; during the month 112 patients had been admitted, 155 were discharged, and 4 died. At the meeting of the Public Health Committee, an application from the Admiralty was read, asking permission of the local authority to send cases of infectious disease occurring on board gunboats arriving at Leith and Granton to the City Hospital in Edinburgh, but the public health authorities have been obliged to refuse the application, as on various occasions lately the hospital has been barely large enough for their own uses.

IRELAND.

TIPPERARY UNION.

THE medical officer of this workhouse has directed the attention of the guardians to the want of hospital accommodation. He states that either additional accommodation must be provided or fever tickets of admission should not be issued for the next two months. There is, however, a large ward not in connection with the hospital which might be fitted up for the treatment of the non-infectious diseases of children. A committee of the guardians has been appointed to report upon the matter.

THE VACANT LOCAL GOVERNMENT BOARD INSPECTORSHIP.

THE vacancy caused by the transfer of Dr. G. P. O'Farrell from the Local Government Service to the Prisons Board has brought forward many candidates. The salary begins at £500 a year, and rises to £700, in addition to travelling allowances. Of the candidates, the following may be mentioned: Dr. Hepburn, Surgeon to the Meath Hospital, Dublin; Dr. Albert Mouillot, of Gorey; Dr. Usher, Dundrum.

CORK MEDICAL PROTECTION ASSOCIATION.

A GENERAL meeting of this society was held on March 17th, to consider the recent correspondence with the Local Government Board in reference to Dr. Magner's case. There were present Dr. Stephen O'Sullivan, President, in the chair; Drs. O'Flynn, Crenn, Harding, W. A. Cummins, Giusani, Daly, Tuohy, W. J. Cummins, Magner, Power, Donovan, Tanner, Burke, Golding, Sandford, Grattan, Cotter, Corby, Atkins, Ryan, etc. The following resolution was passed: "Resolved—That this Association, apart from any personal or party sympathy with Dr. Magner, feels that one of its members has been subjected to extremely harsh treatment, inasmuch as his offence being no dereliction of professional duty, but a political misdemeanour for which he suffered the lawful penalty, he has, in addition, been visited with professional ruin by practically the same authorities. We feel it to be unreasonable that the punishment allotted by the law should be deemed insufficient,

and resent the fact that use has been made of the professional position of the offender to increase his punishment a hundredfold, and make him the scapegoat to bear extra penalties from which others have immunity. Further, we feel that the prospect of being suddenly ousted from their position for a fault utterly unconnected with personal character or professional duties is likely to deter men of ability and independence seeking service as poor-law officers—as in this case no previous intimation had been given of the light in which such offences would be regarded. And further that, as our petition to the Local Government Board (asking what we considered simple justice) has met with a refusal, we now appeal to the medical profession through the United Kingdom to support us in our effort to have him reinstated, and we feel confident that meanwhile no member of this honourable body will accept his position under the circumstances."

HOUSE OF INDUSTRY HOSPITALS.

AT a meeting of the guardians of the North Dublin district, last week, the over-crowded state of the house was mentioned. Dr. J. Kenny reported that seventy-one inmates had to sleep on the floor. After some discussion, the clerk was directed to write to the Chief Secretary, inquiring on what terms the adjacent hospitals could be acquired by the Board. It is not, however, likely that these hospitals will be handed over in the manner desired. The question of closing them is only part of a very much larger one which involves the continuance of the Government grants as a whole, and many interests are involved. The Government are not at present inclined to take up the recommendations of the Hospital Commission. The Chief Secretary's answer will, however, be awaited with some anxiety.

THE MEDICAL COMMISSIONERSHIP OF THE LOCAL GOVERNMENT BOARD.

THE announcement which we were able to make in the JOURNAL of March 17th, regarding the successor of the late Dr. Croker King, was correct. Dr. F. X. Maccabe has been appointed Medical Commissioner of the Local Government Board. Without in any way depreciating other candidates, it is generally conceded that the Government have in this case acted wisely, and no better occupant of the office could be found. Dr. Maccabe has lived an official medical life. He began life as a dispensary medical officer under the Poor Law; then became medical superintendent of the Waterford Lunatic Asylum (1865); was promoted to the charge of the Dundrum Criminal Lunatic Asylum in 1872; next passed into the local government service as inspector (1876); and from this, in 1885, to the Prisons Board as medical member of that body. He has served also, with Sir R. Rawlinson, as a member of a Royal Commission to inquire into the causes of the Dublin death-rate. It will, therefore, be seen that Dr. Maccabe has not only had very great departmental experience, but that he has been a "marked" man in the most agreeable sense; and it is satisfactory to be able to say that his further promotion meets with the approval not only of the public but of the profession.

A LEGAL VIEW OF THE LUNACY BILL.

THE following notes by a lawyer who has had special experience in lunacy laws will show how the present Bill is viewed by a legal mind.

The Lunacy Bill now before Parliament was read three last session in the Lords, once in the Commons, and then was withdrawn in the usual massacre of innocents. It has been read twice in the Lords this session. Very little discussion in Parliament has been its fate hitherto.

The Bill contains many amendments of the old lunacy law, chiefly suggested by lunacy officials before the Committee of the Commons in 1878, but its chief feature is, as the Lord Chancellor

tated a short time ago in the House of Lords, the introduction of the necessity for a judicial decision before reception of a private lunatic into an asylum for cure and treatment. There are also, somewhat in mockery of the loud outcry of a certain section of the community against all private asylums, certain provisions in the Bill to exclude any rivalry with the present licensees of such houses on the part of other would-be-licensees, whereby the former are, beyond all doubt, assisted.

It is noteworthy that the Committee of 1878 could not discover single case of improper reception, did not recommend any such judicial decision," and deprecated legislative interference with private asylums, thinking it best to leave the question of their revival or gradual extinction to the decision of the public in their future choice between private and other institutions.

A few words upon the judicial decision. That decision, if not a mockery, must proceed upon legal evidence taken from both sides, and must be upon a full inquiry. Is the excitement of that inquiry calculated to promote speedy mental recovery of a patient? Will it not at least delay treatment which all admit should be early in view to any recovery? Will it not necessarily add to the cost of treatment? Will it meet the general desire for privacy in the care and treatment of lunatic relations? There are other, perhaps minor, matters for consideration. Are the most eminent medical experts in lunacy likely to be witnesses at these inquiries? If so, at what cost? Will it be well that the medical witnesses should be persons having little experience in lunacy? Will an inquiry before a magistrate, possibly adjourned, not facilitate the escape of lunatics from all treatment, and enable them often to commit an outrage on society, or injure or ruin themselves? Will not the cost or difficulty, or publicity, of the inquiry induce many to place their insane relatives in illegal and landestine charge here, or send them abroad? There are now those who thus act, and the penalty inflicted on the guilty, when prosecuted, is nominal.

It may be said in reply to these remarks, that there is a provision for an "urgency order." Yes; that is a provision imported from Scotland, where the magisterial order, which follows it, is, in practice, ministerial, the lunatic being rarely ever seen by the sheriff. The "urgency order" enables a person to be received temporarily on a single medical certificate. Is that an improvement on our present requirement of two medical certificates? Even a temporary detention may be ruinous to a sane man; and the Scotch practice of sheriffs indicates plainly enough what the "judicial decision" here will be. That decision will be simply ministerial, yet will shield the petitioner from all that responsibility which is now so heavy, and which is the chief check against improper reception, and it will substitute no other responsibility whatever, save that of the magistrate, and he can only be responsible for actually malicious conduct.

Is this legislation in favour of the liberty of the subject? What the present mischief which calls for remedy? Is it not a well-known fact that while the Committee could not discover a single instance of improper reception under the order of a private individual, several cases occur yearly of admissions into public asylums of pauper patients sane, though ordered in as insane by magistrates who have seen and examined them.

In addition to the above remarks on the Bill, its other provisions suggest much unfavourable comment. The framers of the Bill have evidently not been experts in lunacy; official suggestions have been mixed up with other undigested and indigestible matters, and even the heroic features of the Bill are ill drawn. It may be doubtful whether magistrates will be found in every district to undertake the duties cast upon them; certainly some will be wholly incompetent to discharge these duties unless they abdicate decision to the medical practitioners called in, which, if, as we are so greatly mistaken, the course now taken by many magistrates to deal with pauper lunatics, and perhaps they could adopt no other course.

It is earnestly to be hoped that "Irishry" will not smother all discussion on this Bill. Is it too late to ask whether the imprisonment of a person charged with crime is on all fours with the confinement of an individual for treatment of mental malady?

IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.

THE eleventh annual meeting of the association was held at 49, Berners Street, London, on March 17th (St. Patrick's Day), when Sir Thomas Crawford, K.C.B., resigned the presidential chair to Professor Alexander Macalister, M.D., F.R.S. Among the other members present were Deputy Surgeon-General George Saunders, C.B., Professor Mapother, M.D., Dr. Maenaughton Jones, Brigade-Surgeon W. Alexander, M.D., Surgeon-Major Boileau, M.D., Dr. H. H. Phillips, Dr. T. Gilbert-Smith, Dr. W. H. White, and the Hon. Secretaries, Drs. Stewart and Abraham.

The annual report announced a steady increase in the number of members, the total now on the roll being 514, as against 466 on St. Patrick's Day, 1887, notwithstanding the loss of four members by death and four by resignation. Much satisfaction was expressed at the success of Sir Thomas Crawford in inducing the British Medical Association at its annual meeting last August in Dublin to pass a resolution condemnatory of monopoly in hospital appointments. The Council is now in communication with the Irish qualifying bodies, and hopes, with their aid, in time to remove some of the disabilities at present affecting Irish degrees and qualifications in England.

The treasurer's accounts showed a balance in favour of the Association of £154 6s. 5d.

On the nomination of the Council, Dr. Richard Fegan, Blackheath, was appointed president-elect. Brigade-Surgeon W. Alexander was re-elected honorary treasurer. The following were elected by ballot as the twelve non-official members of Council for 1888-89, namely, Sir Thomas Crawford, K.C.B.; Dr. J. Nicholas Dick, C.B.; Henry Fitz Gibbon, Dublin; H. Singer Gabbett, Eastbourne; J. Hill Gibson, Douglas Lithgow, Richard Heath, St. Leonards; Maenaughton Jones; H. H. E. Phillips, Reading; T. Gilbert-Smith, W. Dickson Smyth, R.N.; and W. H. White.

A very hearty vote of thanks to the retiring President was passed by acclamation; it was proposed by Dr. Gilbert-Smith, and seconded by Deputy Surgeon-General Saunders, C.B., who said that the regularity of Sir Thomas Crawford's attendance at the numerous meetings during the past year, notwithstanding his many public duties, proved what a warm interest he took in the Association. His value as a leader was markedly shown in Dublin, where he had exhibited great ability in the way he put forward the arguments against the exclusion of Irish graduates and diplomats from English hospital appointments.

Deputy Inspector-General Lloyd, R.N., and Dr. W. H. Cullimore were elected honorary auditors.

The annual dinner took place the same evening at the Holborn Restaurant—the President, Professor Macalister, in the chair—when seventy-three members and guests were present, including Professor Corfield, M.D., Dr. Donkin, Sir George E. Paget, K.C.B., Dr. J. Nicholas Dick, C.B., R.N., Dr. Steet, and several ladies. The usual loyal toasts were duly honoured. The toast of the evening, "Success to the Irish Medical Schools' and Graduates' Association," was proposed by Professor Corfield, who said that without such associations many most intimate friends in their student days would become complete strangers to one another, so far at least as personal recognition was concerned. Dr. Maenaughton Jones, in reply, said that good fellowship was certain to be promoted by a society such as theirs. In their list of members could be found now the name of every teacher of note in the Irish medical schools. The President had said that, having become the second largest medical society in the three kingdoms, they were an acknowledged medical power in the land. This power it behoved all those eligible for membership, but not yet enrolled, to increase by joining their ranks and bringing up the total on their list to a thousand members. Sir George Paget, in proposing "The Medical Departments of the Public Services," alluded to the fact that the Association had now on its Council the two Directors-General—a fact of which Irishmen might well be proud. The toast was responded to by Sir Thomas Crawford and Dr. J. Nicholas Dick, C.B., R.N. "The Health of the Guests" was proposed by the President, who said they were to have had Professor Curnow with them, and also that distinguished Irishman, the President of the Royal Society, Professor Gabriel Stokes, but both those gentlemen had been prevented at the last moment from fulfilling their engagements. The toast was responded to by Dr. Donkin. The proceedings were interspersed by Irish melodies, rendered by Messrs. Groome and Martin and Dr. W. H. Bourke.

A VALUABLE horse belonging to Mr. Holden, of Nenby Hall, or Clitheroe, died last week from hydrophobia. The disease is supposed to be assuming serious proportions in the district. Two horses, three cows, and a large number of dogs are reported to have been attacked, and the latter have had to be destroyed.

ASSOCIATION INTELLIGENCE.

COUNCIL. NOTICE OF MEETING.

A MEETING of the Council will be held at the Offices of the Association, No. 429, Strand (corner of Agar Street), London, on Wednesday, the 18th day of April next, at 2 o'clock in the afternoon.

FRANCIS FOWKE, *General Secretary.*

March 15th, 1888.

NOTICE OF QUARTERLY MEETINGS FOR 1888. ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Meetings of the Council will be held on April 18th, July 18th, and October 17th, 1888. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before each meeting, namely, March 28th, June 27th, September 26th, and December 28th, 1888.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No member can be elected by a Branch Council unless his name has been inserted in the circular summoning the meeting at which he seeks election.

FRANCIS FOWKE, *General Secretary.*

COLLECTIVE INVESTIGATION OF DISEASE.

THE Report upon the CONNECTION OF DISEASE WITH HABITS OF INTEMPERANCE, which was presented to the Section of Medicine in the Annual Meeting of 1887 will shortly be published in the JOURNAL.

Reports upon the two remaining inquiries, namely, that into DIPHTHERIA, and that into the GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES, are in preparation, and will be published as soon as ready.

The following inquiry only of the first series remains open, namely, that on THE ETIOLOGY OF PHTHISIS.

A fresh inquiry into the ORIGIN AND MODE OF PROPAGATION OF EPIDEMICS OF DIPHTHERIA has been issued.

Memoranda upon these subjects, and forms for recording observations, may be had on application to the Secretary of the Collective Investigation Committee, 429, Strand, W.C.

BRANCH MEETINGS TO BE HELD.

SURREYSHIRE AND MID-WALES BRANCH.—The next meeting of the Branch will be held at the Salep Infirmary, on Tuesday, March 27th, at 3 P.M. Mr. W. Eldowes in the chair. Gentlemen wishing to exhibit or read notes of cases, or to bring forward subjects for discussion, are requested to communicate with the honorary secretary, EDWARD CURETON, Shrewsbury.

SOUTH WALES AND MONMOUTHSHIRE BRANCH.—The spring meeting of this Branch will be held at Pontypridd about the second or third week in April. Members wishing to read papers, etc., are requested to send titles to either of the Honorary Secretaries by the end of March, in order that they may be inserted in the circulars.—ALFRED SREEN, M.D., Cardiff; D. ARTHUR DAVIES, M.B., Swansea, Honorary Secretaries.

METROPOLITAN COUNTIES BRANCH: NORTH LONDON DISTRICT.—The next meeting of this district will be held at the North West Hospital, Kentish Town Road, on the evening of Wednesday, March 28th, at 8.30, when A. E. Durham, F.R.C.S., President of the Branch, will take the chair. Some interesting cases in the hospital will be exhibited. Dr. Hood will read a paper on Empyema following Pneumonia; or Clinical Notes on Membranous Sore Throat. The new committee of this district will assemble at 3 P.M. All members of the profession are welcome to attend.—GEORGE HENTY, M.D., Honorary Secretary, 30, Camden Road, N.

METROPOLITAN COUNTIES BRANCH: EAST LONDON AND SOUTH ESSEX DISTRICT.—The next meeting will be held on Thursday, April 19th, at the Hackney Town Hall, at 8.30 P.M. The chair will be taken by F. M. Corcor, Esq. A paper on the Surgery of Abscess will be read by Howard Marsh, Esq. Visitors will be welcome.—J. W. HUNT, 101, Queen's Road, Dalston, Honorary Secretary.

WEST SOMERSET BRANCH.—The spring meeting will be held at the Railway Hotel, Taunton, on Thursday, April 12th, at 5 P.M. Dinner at 5.30 P.M. The subject settled by the Council to be discussed after dinner is Bone Setting. Mr. W. J. Pennv, Assistant-Surgeon to the Bristol General Hospital, and Demonstrator of Anatomy to the Bristol Medical School, has kindly promised to come and open the discussion. The election of representative of the Branch on the

Council of the Association for the ensuing year will take place at this meeting.—W. M. KELLY, M.D., Taunton, Honorary Secretary.

SOUTH-EASTERN BRANCH: WEST KENT DISTRICT.—The next meeting of this District will take place on Friday, April 27th, at the Hospital, Gravesend. R. J. Bryden, Esq., in the chair. Gentlemen desirous of reading papers or exhibiting specimens are requested to inform the Honorary Secretary of the District not later than April 8th. Further particulars will be duly announced.—A. W. NANKIVELL, F.R.C.S., St. Bartholomew's Hospital, Chatham, Honorary Secretary.

SOUTH-EASTERN BRANCH: WEST SURREY DISTRICT.—The next meeting will be held at the Red Lion Hotel, Dorking, on Thursday, March 28th, at 1 P.M. C. W. Chaldecott, Esq., of Dorking, in the chair. Dinner at 6 P.M., charge 7s., exclusive of wine. The following papers, etc., are promised:—Mr. A. E. Barker: A paper on Two Successful Cases of Cerebral Suppuration, due to Ear Disease. Mr. A. A. Napper: Some Cases of Gunshot Injuries.—A. ARTHUR NAPPER, Broad Oak, Cranleigh, Honorary Secretary.

NORTH OF ENGLAND BRANCH.—The spring meeting will be held at the Infirmary, Sunderland, on Wednesday, April 25th, at 3 P.M. Members intending to read papers or show specimens are requested to communicate at once with the secretary. The dinner after the meeting will take place at the Queen's Hotel, at 5 o'clock. The following papers are already promised.—Dr. Bole: A Case of Congenital Fistula of the Stomach, Cured by Operation. Dr. Coler: On the Treatment of Effusion into the Pleura in Children. Dr. Mears: On Ambulance Work. Dr. Oliver: Notes on an Unusual Case of Haematuria.—G. E. WILLIAMSON, F.R.C.S., 22, Eldon Square, Newcastle-on-Tyne, Honorary Secretary.

NORTH OF IRELAND BRANCH.—A general meeting of this Branch will be held in the Royal Hospital, Belfast, on Thursday, April 19th, at 11 A.M. Gentlemen who wish to bring any business before the meeting will kindly communicate as early as convenient with JOHN W. BYERS, M.D., Lower Crescent, Belfast, Honorary Secretary.

OXFORD AND DISTRICT BRANCH.—The next meeting will be held at the Radcliffe Infirmary, Oxford, on Friday, April 27th, at 3 P.M. Notice of papers to be read must be sent to W. Lewis Morgan, 42, Broad Street, Oxford, on or before April 18th. A dinner will be provided for those members who signify their intention to dine to the Secretary two days before the meeting.—S. D. DARBISHIRE and W. LEWIS MORGAN, Honorary Secretaries.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT.
The spring meeting of the above district was held at the Cottage Hospital, Ashford, on March 15th. Dr. WILKS in the chair.
Next Meeting.—Dr. Parsons, of Dover, was elected chairman for the annual meeting of the District, to be held at Canterbury in May next.

Representative on Council.—Dr. Parsons was again unanimously nominated to serve on the Council of the Association.

Abdominal Section.—Mr. COLVILLE read notes of two cases of abdominal section, the first being one of acute strangulation of the small bowel, with symptoms nearly all masked; the operation was performed late, the patient dying soon after it; the bowel had ulcerated. The second case was one of retroperitoneal abscess. The abdomen was opened, and after separating the matted intestines, the abscess cavity gave way, this was washed out, and a drainage-tube put in; the patient made a rapid and complete recovery. In both cases repeated doses of castor-oil and salts had been given.—Dr. T. EASTES, Dr. JOYCE, Dr. MARSHALL, Mr. WHITEHEAD REID, and Dr. BOWLES took part in the discussion.

Apoplexy.—Dr. BOWLES read a paper on two cases of apoplexy and one simulating apoplexy, in which he spoke of the difficulty of diagnosing many cases of apoplexy, and thought that vascular section should be more often performed than it was at present.

Two Cases of Delirium Tremens and One Case of Alcohol Paralysis.—Dr. WILKS read a paper on this subject. One of the cases of delirium tremens was successfully treated by the cold douche after treatment by ordinary remedies of morphine, chloral etc., had failed.

Cases that Unexpectedly Get Well, with some Remarks on Prognosis.—Dr. TYSON drew attention to the great length of time that many people lived when placed under fair conditions, in good workable health, though suffering with chronic organic diseases.

Cases.—At the close of the meeting, Mr. COOPER WILKINSO showed cases of surgical interest.

Dinner.—There were twenty-four members and friends present fourteen of whom afterwards dined at the Saracen's Head, under the presidency of Dr. Wilks.

STAFFORDSHIRE BRANCH.

THE second general meeting of the present season was held at the London and North Western Hotel, Stafford, on Thursday, February 23rd, 1888. The President, Mr. W. D. SPANTON, was in the chair and there were twenty-five members present.

New Members.—The following gentlemen were elected members of the Branch: Mr. Horace Hartley, Stone; Mr. A. E. Taylor

County Asylum, Stafford; Mr. C. E. Strickland, Kids-grove; Mr. James Scott, H.M. Prison, Stafford; Mr. A. K. Holt, North Staffordshire Infirmary; Mr. V. J. Magrane, The Leys, Darlaston; Mr. G. Bower, Macclesfield, Cheshire; Dr. Stirling Christie, Aston Hill Asylum, Stafford.

Communications.—1. Mr. F. M. BLUMER showed a girl, aged 13, admitted into the Staffordshire Infirmary, July, 1887, suffering from a sprained ankle. Soon after the joint suppurated, and was opened and drained; finally the lower epiphysis and diaphysis of the tibia necrosed, and were eventually removed, the recovery afterwards being steady and uninterrupted.—2. Mr. F. M. BLUMER showed a child with a joint in the middle of each clavicle. The abnormality was hereditary.—3. Mr. F. M. BLUMER showed the bones of a boy's arm, amputated at the shoulder-joint, showing disease of the radio-ulnar articulation, and elbow-joint and extensive caries of both epiphyses of the humerus.—4. Dr. E. T. TYLLECOTE showed a testicle removed from a man, aged 48, and weighing 19½ ounces. The disease was round-celled sarcoma. Recovery was rapid.—5. Mr. SPANTON exhibited several calculi from the sacculated bladder of a man, aged 51. The first was removed by lithotripsy, and the others by lateral lithotomy once, and median lithotomy twice, followed by complete recovery.—6. Mr. SPANTON showed both ovaries and Fallopian tubes removed by abdominal section, for prolapsed cystic and adherent ovaries, followed by rapid recovery.—7. Mr. SPANTON exhibited photographs of a case of molluscum contagiosum, treated chiefly by incision.—8. Mr. VINCENT JACKSON showed a uric acid calculus weighing fifty-one grains, removed by suprapubic lithotomy, from a man aged 57. The calculus, which was flask-shaped, was tightly lodged in a diverticulum, on the left side of the base of the bladder at its junction with the posterior wall, and its removal was with some little difficulty effected by means of the left forefinger, and a small vesical scoop. The removal of the stone had previously been attempted by lithotripsy, and by median and lateral perineal lithotomy.

Papers.—The following papers were read: 1. Dr. C. ORTON: Treatment of Rheumatic Fever.—2. Mr. F. M. BLUMER: Notes of a Case of Litholapaxy in a boy, aged 5½ years.—3. Mr. SPANTON: A Case of Retention of Urine due to Retroversion of the Uterus.

BATH AND BRISTOL BRANCH: ORDINARY MEETING.

The fourth ordinary meeting of the session was held at the Museum and Library, Bristol, on Wednesday, February 29th, G. F. BURDER, M.D., President, in the chair. There were present forty-nine members and two visitors.

New Members.—The following gentlemen were elected: J. Wilding, M.B., Bristol; A. L. Marshall, M.B., Bath.

Cases.—The following cases were exhibited: 1. By Dr. C. A. WIGAN: Pseudo-Hypertrophic Paralysis.—2. By Dr. J. MICHELL CLARKE: Infantile Hemiplegia (without atrophy), three cases. Infantile Paraplegia (with atrophy). Infantile Paralysis of Muscles, passing from Spine to Scapula.—3. By Dr. E. MARKHAM SKERRITT: Advanced Bulbar Paralysis; Complete Special and General Hemianæsthesia in a Male. Mr. CROSS, and Drs. SHAW and HARRISON made observations on these cases.

Papers.—The following communications were also made: 1. By Dr. C. P. COOMBS: On Splenic Leukæmia; Drs. SPENDER, MARKHAM SKERRITT, and CLARKE, took part in the discussion that followed.—2. By Mr. N. C. DOBSON: A Case of Hydatid Cyst of the Omentum; Dr. PROWSE and Mr. BARCLAY made some observations on this case.—3. By Mr. W. J. PENNY: A Case of Acute Intestinal Obstruction, with early operation and successful result. Drs. NEWNHAM and COOMBS commented upon this communication.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

Resection of Wrist.—Ill-Effects of Antipyrin.—Erythrophlein.—Sulphur in Diphtheria.—Congress on Tuberculosis.—Hypodermic Injection of Iron.

I. VERNEUIL opened the fifth annual meeting of the Congrès français de Chirurgie on March 12th. M. Ollier, of Lyons, spoke on resection of the wrist which, according to him, had of late been practised much more frequently than formerly. In 1870

only 70 cases were recorded whereas in 1886 there were 170 cases. M. Ollier, who has himself practised it forty or fifty times, only referred to orthopædic resections performed in cases of ankylosis. To preserve the functions of the part, a larger section of bone than was necessary for immediate cure must be resected; the digital and carpal tendons must be preserved, also those acting on the wrist. The movements of the thumb might be preserved. The joint being supported by these tendons, the fingers could be extended and bent more powerfully; thus patients had been able to straighten their fingers with dumb-bells of 8, 10, and 18 kilogrammes. In two cases of late resection, M. Ollier remarked the formation between the extremities of bone of an osteo-fibrous pad, scattered through which were osseous nodules.

At a recent meeting of the Académie de Médecine, M. Germain Sée denied the report circulated in the lay press that on account of the disagreeable effects sometimes produced by antipyrin, the Académie had condemned that substance as a therapeutic agent. He stated that these accidents were comparatively rare, and were of a mild and transient nature, and that if medical men in such cases would abstain from rashly administering atropine, which often caused symptoms of poisoning, the ill effects of antipyrin would soon disappear, and recovery would ensue in the course of two or three days. M. Sée read a letter from M. Daremberg, in which that gentleman stated that he had obtained good results with antipyrin in patients suffering from migraine and tuberculosis. M. Hardy remarked that, although he had found antipyrin generally gave good results, he had met with patients who proved refractory to its action. In certain cases it caused vomiting or signs of cerebral depression, amnesia, syncope, etc., consequently he did not consider this remedy so marvellous as it was generally held to be. He also warned medical men to be prudent in prescribing acetanilide, and related a case in which it had caused sudden death after the eighth administration of a one-gramme dose. M. Dujardin-Beaumez believed this to be a mere coincidence, and the case an exceptional one, but M. Hardy maintained that the extraordinary rapidity with which coldness and rigidity had set in caused him to attribute it to acetanilide. M. Brouardel regarded it as more probably due to defective renal elimination, and added that it was very essential that the state of the kidneys should be ascertained before administering this drug. MM. Gautier and Laborde were of opinion that the presence of aniline or any other impurity in the substance might account for many accidents, and that chemists ought not to be allowed to dispense it without prescription. M. Laborde had, under M. Houdé's direction, caused a dimethoxyquinizine preparation to be made, and it invariably caused a sudden rise of temperature at the onset from $\frac{1}{2}^{\circ}$ to $\frac{3}{4}^{\circ}$ of a degree Centigrade, followed by a corresponding fall after a longer or shorter period of time. This thermic action of antipyrin might be utilised experimentally with chemical reagents, such as perchloride of iron or nitrous acid as a test of the purity of the product. Locally, in hypodermic injections, the mere contact of the substance with the tissues, especially the muscular tissues, exerts on these a more or less marked irritating influence according to the dose.

At a recent meeting of the Academy of Medicine, M. Panas communicated the results of experiments with erythrophlein, which he had tried on human eyes, and on those of the lower animals. He states that this substance has a positive anæsthetic effect, which lasts longer than that of cocaine. He considers it objectionable, however, on account of the violent pain and inflammation which it causes. M. Panas prefers cocaine, and condemns erythrophlein in ophthalmic surgery; he had used it in treating granulations and granular pampus, but the results were not satisfactory.

M. Schnyder claims unfailing good results from local applications of flower of sulphur and doses of chlorate of potash in diphtheria. The sulphur is insufflated over the part of the throat which is covered with false membranes. In mild cases four insufflations a day are sufficient; in grave cases they should be repeated every two hours. The sulphur should also be applied to the nasal cavities if they are filled with diphtheritic membrane.

The Congress to be held in Paris for the purpose of discussing the question of tuberculosis observed in man and in the lower animals will be held from the 25th to the 31st July. The following questions will be discussed: The dangers caused by the consumption of meat and milk obtained from tuberculous animals, and the preventive measures to be taken? Which are the human races

and species of the lower animals most especially predisposed to contract tuberculosis? What are the channels by which the tuberculous virus is introduced into the animal economy and propagated? The early diagnosis of tuberculosis in man and the lower animals. M. René Serraud has recently published a book (*Du Diagnostic Précoce de la Tuberculose chez l'Homme*. J. B. Baillière, 1888) in which many of these subjects are treated, especially the question of the early recognition of phthisis. He states that patients who later on are attacked by pulmonary phthisis always present marked pharyngo-laryngeal symptoms, such as anaemia of the pharyngeal mucous membrane; imperfect apposition of the vocal cords, owing to atony of the adductor muscles; localised congestion of the mucous membrane covering the arytenoid cartilages, resulting in a swollen condition of this region. These three symptoms can exist separately or simultaneously; the presence of one indicates the possibility of future pulmonary phthisis, the three together are a certain sign that it is impending.

M. G. Ludovic Hirschfeld has lately discussed the question of hypodermic injection of ferruginous compounds, in a thesis for the Doctor's degree. After a short review of the various works which have appeared on this subject since 1872, when Professor Rosenthal, of Vienna, first employed iron preparations in hypodermic injections, the author proceeds to describe his own experiments at the Hôpital Cochin. His observations have led him to conclude that the method of administering iron preparations by means of hypodermic injections is excessively painful to the patient, and inefficient in its result. In defending the system of administering iron compounds internally, M. Hirschfeld quotes the opinion of Professor Hayem, who states that he has hardly ever met with a patient who could not take iron salts. M. Hirschfeld has closely studied his subject, and the result is a work of considerable interest and merit.

Erythrophloïn as a Local Anæsthetic.—Removal of Tumour from the Bladder.—Co-existence of Syphilis and Cancer.

DR. LEWIN'S report on the extraordinarily good effects of erythrophloïn as a local anæsthetic has induced several investigators in Austria and Hungary to make a series of experiments with this substance. The general opinion seems not to be in favour of the statements made by the Berlin observer. Professor von Reuss, of Vienna, has made a series of experiments on the eye, and reports as follows:—On the instillation of a 0.05 per cent. solution of erythrophloïn into the eyes of patients suffering from trachoma, the sensibility of the cornea and the ocular conjunctiva became impaired; this condition became still more pronounced during the ensuing half hour, but complete anæsthesia could not be obtained. Applications of solution of sulphate of copper and nitrate of silver to the eye were felt just as much as on the other eye (which had not been anæsthetised). Neither subjective disturbances nor any objective signs of irritation could be observed after the instillation of the erythrophloïn. In a patient in whom iritis had just completed its course, almost complete anæsthesia of the cornea was produced after thirty minutes; after about eight hours the patient was seized with severe pains in the eye, and ciliary injection could be seen after twenty-four hours. In a case of chronic iritis, anæsthesia did not come on for an hour, and did not begin till forty-five minutes after the application of erythrophloïn. Professor von Reuss next tried a 0.25 per cent. solution. After the instillation of from two to four drops of this strength, a disagreeable sensation in the eye was felt in some cases, and in others burning and pricking pains, as well as contraction of the eyelids and redness of the conjunctiva, supervened. In a lad aged 15, who had to be treated with the galvano-cautery for ulceration of the cornea, the pain caused by the erythrophloïn was so severe that the patient wept. The decrease of sensibility in most of the cases was first noticed fifteen minutes after instillation. After forty-five minutes there was anæsthesia to contact with a smooth piece of wood, but slight scraping with a piece of paper was still felt. This condition lasted for two hours, but a certain degree of impaired sensibility could still be noticed after twenty-four hours. In the case of a patient with leucoma of the cornea, who had already once been tattooed under cocaine, anæsthesia seemed to be present twenty-five minutes after the application of erythrophloïn; but he felt the punctures so much that a second instillation of erythrophloïn had to be resorted to. When tattooing was performed after forty-five minutes, the punctures

were still more felt than they had been under cocaine. In a case of "pannus trachomatous" only slight diminution of sensibility of the cornea could be produced; and in the case of ulcer of the cornea referred to above cocaine had to be resorted to for the application of the galvano-cautery. Among the changes which the eye underwent in these cases, dimness of the cornea was found to be regularly present. Dimness of vision came on after about two hours and increased until the evening, the erythrophloïn having been applied in the morning; the eye was irritated, there was lachrymation in some cases, pressing and pricking pains were felt during the evening. The other symptoms, such as redness of the conjunctiva, ciliary injection, etc., which had been observed after the instillation of the 0.05 per cent. solutions, were noticed to be present now in a much higher degree. As the $\frac{1}{4}$ per cent. solution of erythrophloïn had proved to be too strong, the author, in a third series of experiments, used a 0.125 per cent. solution. The first instillation of this strength was not attended with any trouble whatever. After twenty-five minutes the sensibility began to decrease, but after an hour there was no longer any diminution of sensibility. The cornea remained clear. A second instillation of the same solution on the same patient was followed by pricking pains and symptoms of irritation of the eye. Fifteen minutes later anæsthesia came on, which increased to such a degree that the patient had but little sensation. On examination of the eye six hours later the cornea was cloudy, but did not show any trace of stripes. In the evening, (nine hours after the instillation) severe pricking pains supervened, which lasted for three hours, and finally disappeared, together with the dimness of vision. After twenty-seven hours the eye had resumed its normal appearance, but the sensibility of the cornea was still slightly impaired. Dilatation or narrowing of the pupil was never observed, and its mobility as well as the accommodation of the eye did not undergo any change. Summarising the results of his experiments with erythrophloïn on the eye, Professor von Reuss states that the sensibility of the normal human cornea becomes impaired by it to a different degree in different individuals, but that the anæsthesia is never so complete as that produced by cocaine; its duration, however, was longer. The weak solutions (0.05 to 0.125 per cent.) when applied once did not produce any disturbance, but neither did they cause sufficient diminution of sensibility. The repeated instillation of such solutions, as well as a single application of a $\frac{1}{4}$ per cent. solution, were, however, always more or less attended with severe pain and corneal opacity. I may add that Docens Dr. Königstein, of Vienna, who had undertaken a number of experiments with erythrophloïn on the eye, testing its effect on the eye of animals and the normal and diseased eye of man, has come to the conclusion that erythrophloïn will not find a place in eye surgery. Professor Kaposi, who has made experiments with erythrophloïn on seventeen cases of diseases of the skin, in the dermatological clinic of the General Hospital, arrives at the following conclusions: Subcutaneous injections of erythrophloïn on man produce local anæsthesia. The dose which was required to obtain this effect varied in his cases from 0.0025 to 0.01 or 0.02 grammes. Anæsthesia was not produced until fifteen minutes after injection, but a certain amount of diminution of sensibility could sometimes be observed after a shorter interval of time. The anæsthesia as well as the diminished sensibility lasted from one to three hours. The anæsthesia affected only a small middle zone of the area into which the injections had been made. The large marginal area was paræsthetic, and sometimes showed anæsthetic and paræsthetic points diffusely mixed with each other. The analgesia was often more complete than the anæsthesia, as the sensibility of touch was hardly ever quite absent. Symptoms of local irritation were observed after the very smallest doses such as 2.5 milligrammes, and were always present on the application of doses of from one to two centigrammes. These symptoms were characterised by burning sensations in the area of injection, and severe shooting pains, which lasted for many hours, and even one or two days. The objective symptoms were redness, swelling, and increase of temperature in the area of injection, and elevation of the skin in the form of pomphus. General toxic symptoms supervened after from a quarter of an hour to one hour when a dose of two centigrammes was used. These symptoms consisted in giddiness, dilatation of the pupils, impaired and retarded action of the heart and the pulse, as well as in accelerated and shallow respiration. Nausea and vomiting were also observed in some cases; all these symptoms lasted for

several hours. In Professor Kaposi's opinion, erythrophlein cannot be recommended as a local anæsthetic for practical purposes. He even believes that, owing to its general toxic effects, and owing to the fact that the toxic dose differs but little from that which is required for producing local anæsthesia (0.02—0.01—0.005 grammes), the use of erythrophlein should be discouraged.

Professor Antal brought before the same Society a patient from whom he had removed, in June of last year, a papilloma situated at the fundus of the bladder by a modified "high operation." The wound healed by first intention, and the patient recovered. In six months after operation hæmaturia again came on, and the patient also stated that in December he noticed that small "bits of flesh" passed with the urine. In January, 1888, the patient was again admitted under Professor Antal, who found, on cystoscopic examination, that a pedunculated tumour with a nodular surface, and situated on a swollen and relaxed mucous membrane, was present near the opening of the bladder. The examination further showed that at the place from which the tumour had been removed a year previously there was only a white patch; hence there was no recurrence of the first growth. He introduced a straight forceps through the urethra into the bladder, and succeeded in tearing off the tumour, together with the pedicle. The parts of the tumour which had been thus torn off were in part removed by the forceps and in part by the catheter. Repeating these manipulations several times, the whole growth was got away. Microscopical examination of the tumour showed that it was a "papilloma fimbriatum" (Thompson). The case was interesting from the etiological point of view, as the patient had suffered from gonorrhœa and inflammation of the neck of the bladder, and the causal connection of this condition with the development of the tumour could not be doubted. Moreover, this was the first case, within the knowledge of Professor Antal, in which the male urethra was used for the removal of a tumour.

At a recent meeting of the Wiener Medizinisches Doctoren-Collegium, Professor Edward Lang, of Vienna, read a paper on the Co-existence of Syphilis and Cancer. But little attention had been hitherto directed to the fact that syphilis sometimes formed the predisposing soil for the development of cancer, or that both diseases might be combined with each other. Setting aside some observations of comparatively little value which had been made by ancient authors on this subject, it was especially Hutchinson and Langenbeck, who, before Professor Lang, had directed attention to the simultaneous occurrence of syphilis and carcinoma. The speaker had observed such a combination four times. The first case was that of a patient who had been admitted in 1883 under his care when he was at Innsbruck. Besides an old-standing iritis and other symptoms of syphilis, he was suffering from serpiginous and gummatous ulcerations on the nose, the cheek, and the angles of the eye. Most of the ulcers healed under antisyphilitic treatment, except one, which gradually changed its character and assumed the form of an "ulcus rodens," that is, a flat carcinoma of the skin. The patient was transferred to the surgical clinic, where he underwent an operation, and microscopical examination proved the simultaneous existence of both syphilis and carcinoma. The second case was that of a patient aged 46, who had previously been treated for recent syphilis by Professor Lang. There were syphilitic infiltrations of the floor of the mouth and under the tongue, and, moreover, various syphilitic infiltrations over the occipital bone and the body. All these lesions subsided under the influence of a common antisyphilitic treatment except the infiltrations of the floor of the mouth, which became transformed into cancer. The third case was that of a man aged about 30, who presented a syphilitic ulcer on the under lip. The ulcer disappeared under antisyphilitic treatment, but relapse and transformation into carcinoma occurred a year later. In all these cases the correctness of the diagnosis was proved by the anatomical examination. The fourth case was shown to the Society. The patient had extensive scars, ulcerations as well as infiltrations on the forehead, loss of the entire nose, loss of substance on the upper lip, ulceration and perforation of the hard palate, perforation of the soft palate, and cicatricial retraction of the uvula. On admission of the patient to the clinic of Professor Lang, in the middle of January last, some of the ulcerations were covered with a white tallowy mass, which led Professor Lang to suggest the presence of a combination of syphilis with carcinoma. The microscopical examination, however, revealed only the presence of pus corpuscles and products of decomposition. The infiltrations on the right side of the forehead after on slightly diminished, but from four to five weeks later a

vegetation on the anterior end of the ulceration of the hard palate appeared, the character of which was incompatible with that of syphilitic ulceration. A part of this vegetation was excised, and the microscopical examination of it, which was made by Professor Weichselbaum, showed that it was "epithelial carcinoma."

Hairpins in the Female Bladder.—*Bacterio-chemistry of Tavel's Bacillus Strumitis.*—*Pigments of Green Pus.*—*Idiosyncrasy of Quinine.*

PROFESSOR AUGUSTE REVERDIN has recently published (in the *Revue Médicale de la Suisse Romande*, January, 1888, p. 33) a paper on hairpins in the female bladder. In less than three years he has met with four cases of the kind, which are remarkable, not only for their purely surgical interest, but from the fact that in only one of them was any secret made of the cause of the mishap. One of the patients, a married lady, aged 22, mother of a boy 10 months old, sought his help on the sixth day after the accident. Without the slightest hesitation or shame she stated that she had been in the habit of masturbating in that way ever since her school days. Her husband, a school teacher of thirteen years' standing, who was present, did not seem in the least surprised or shocked at this confession. Another patient, an unmarried woman, aged 42, a clergyman's servant, came on account of "her having apparently something (*quelque chose*) in the bladder." After the *quelque chose* (in the shape of a hairpin) had been extracted on the spot, the patient, on leaving Dr. Reverdin's house, advised his maidservant "never to go to bed without having previously removed all pins from your hair, otherwise some *triste accident* may so easily happen." A third patient, an English girl aged 17, said she had some time previously introduced six darning-needles into her rectum and two hairpins into her bladder; the former disappeared altogether, but the latter were found amongst the fragments of a vesical calculus which measured full 6 centimètres in diameter, and was removed by lithotripsy. According to the patient's own statement she had previously consulted two "professors," who, after due examination, had recommended her exercise and iron. The fourth patient was a diminutive girl aged 12, who openly confessed that whilst she had intended to introduce a hairpin into her vulva, the pin had slipped from her fingers and disappeared somewhere; she had at once taken another pin, which had followed the same way. Both were found in, and extracted from, her bladder. Commenting on this "epidemic" of hairpins in the bladder, Dr. Reverdin says that "masturbation in that way is practised by women much more frequently than is generally supposed." The hairpin is so often used for the purpose simply because it is always within reach of every woman. Some use it to titillate the clitoris; others put it up the vagina, or at least intend to do so, but sometimes, owing to their ignorance of anatomy, accidentally introduce it into the urethra instead. Others again—probably a minority suffering from some perverted sexual sensations—intentionally push the hairpin into the urethra. The slipping of the hairpin into the bladder is attributed by Professor Reverdin to a combination of several causes, namely, the weight of the pin, the spasmodic contraction of an irritated urethra, and temporary unconsciousness of the woman from excitement. The method of extraction must necessarily vary according to the peculiarities of the individual case. In cases of long standing, when a stone has formed around the foreign body, lithotripsy must be performed; but when the surgeon finds only hairpins, with or without incrustations, the best and simplest method will be to extract the foreign body by means of a pair of fine, slender, straight forceps introduced through the undilated urethra and guided by a finger in the vagina. The first point in such cases is to ascertain the exact position of the pin. If it is lying with the bent end towards the urethra, there is nothing easier than to seize and pull it out. When the pin lies in any other position, "version" of the pin should first be performed by gentle manipulation, so as to get the bent end forward. In the first of the cases just related a superficial incision into the urethra proved to be necessary in order to disentangle one of the pin's legs, the patient having previously applied to a midwife for surgical help.

M. James Kunz has recently carried out some interesting bacterio-chemical investigations in Professor von Nencki's laboratory at Berne. One series of researches was undertaken on the chemical products of Tavel's bacillus strumitis cultivated in a

slightly alkaline jelly with grape sugar. The gaseous bodies developed by the microbe were found to consist solely of pure carbonic acid. A marked acid reaction of the cultivation medium proved to be dependent on the presence of free ordinary fermentative lactic acid. Analysis by Brieger's method revealed, also, slight traces of a ptomaine.

Another group of M. Kunz's experiments related to the colouring matters of green pus. Having examined numerous pure cultures of the microbe of the pus, he was able to establish the fact that, side by side with pyocyanin and pyoxanthose (the colouring matters of blue pus), a third (still undescribed) pigment was present, which was characterised by a beautiful green fluorescence under direct rays of light. It was soluble only in water and diluted alcohol. M. Kunz has named this new body "pyofluorescin."

At a meeting of the Société Médicale du Valais, Dr. Ducrey read a paper on idiosyncrasy to quinine. In one of his patients, a gentleman, aged 60, even small doses of the drug (such as fifty centigrammes taken in a period of twelve hours) invariably caused a severe erythematous rash over the forehead, eyelids, and infra-orbital regions, followed by slight desquamation. The author met, also, several instances of purpura hæmorrhagica caused by the internal use of the remedy. He thinks that such clinical facts unmistakably point to a "real and special action of the quina preparations on the vasomotors of the skin."

GLASGOW.

[FROM OUR OWN CORRESPONDENT.]

Mysterious Epidemic in Glasgow.—Typhus Fever and Small-pox in Glasgow.—Pleuro-pneumonia in Scotland.—Combe Lectures to Teachers.

DR. RUSSELL'S report on the outbreak of an epidemic of a remarkable character, which occurred in St. Mary's Roman Catholic Industrial School for Males in the east end of Glasgow, has been published this week. The history and character of the outbreak are briefly as follows: On the evening of March 2nd one of the boys complained of headache, and was sent to bed in his dormitory. He rose as usual next morning at 6, and made his bed, but was observed to be staggering, and was sent to the sickroom, where he died two hours later. On March 3rd another boy complained of headache, and was sent to the sickroom and put under treatment. He became delirious on March 5th, and died at 4 A.M. These deaths were reported to the Procurator Fiscal, as the medical man could not characterise them, but he permitted the interment without a *post-mortem* examination. On March 7th another boy complained of sickness and headache; he became comatose, and died within four hours. On the morning of the 8th, a fourth boy was found to be unconscious when the other boys were called shortly before 6, and he died in about half an hour. Grouped around these fatal cases nineteen boys were more or less ill. On this day (March 8th) Dr. Russell's aid was sought. He found the sick boys all with more or less febrile temperature; and several had symptoms of pneumonia in various stages, but the disease was of a kind quite new to him, and evidently not poisoning in a criminal sense. He immediately transferred twelve of the most serious cases to a separate ward in Belvidere. On March 10th three fresh cases were removed, and on the 11th two more, and up to the 16th an additional five cases had been removed to Belvidere; of these five, two were girls employed in the kitchen. The total number removed to Belvidere is thus twenty-two. Two more cases have occurred since March 16th, one on the 17th and another on the 18th. There have been, however, no more fatal cases, and there is, according to Dr. Russell, no immediate prospect of further loss of life. Of the 205 inmates of the institution, there had been in all fifty-six cases of illness or alleged illness. Now as to the nature of the disease. It was new to Dr. Russell. He procured the assistance of Dr. Coats, and on the afternoon of March 8th, the day he was summoned, a careful *post-mortem* examination was made. The general result showed that they had to deal with a febrile disease, arising from some blood poison, which, even in the short illness of the boys whose bodies were examined, had produced local changes suggestive of some alliance to the specific poison of enteric fever. Dr. Coats is engaged in microscopical investigation, in the hope of elucidating the problem, and with the same view Mr. Maylard is conducting a bacteriological inquiry. The characters of the illness are as follows. The onset is sudden,

generally with vomiting. Almost immediately after a hearty meal a boy may complain of headache and lateral pain, and look depressed, and be tottering on his limbs. The first temperature taken may be already 103° or 104°. A drowsy tendency is generally evident. The specific poison may kill within three or four hours of the first declaration of illness. If the patient resists the first assault, in a number of cases pneumonia, either single or double, is developed, but a pure febrile state, with high ranges and irregular intermissions, may ensue. At no time is there diarrhœa: In a few cases the fever passes off, sometimes in a few hours, with deep sleep and it may be perspiration, and the patient is well; but in all there is an increase of temperature, however short. In searching for the cause of this puzzling outbreak, Dr. Russell found anything connected with the food excluded by the circumstance that the girls and boys are fed with the same food, distributed from a common store, cooked in the same kitchen, and eaten in the same dining hall. Yet, up to the date of the report, only boys were attacked, though the disease was not confined to any class of boys or any one dormitory. Examination has, however, been made into the source and quality of the food and of the milk. No pleuro-pneumonia existed at any of the farms from which milk was obtained. The drains are also being examined. Dr. Russell has no information of any similar disease in any part of the town, and has not yet discovered anything similar on record. He points out, however, that the local authority has had repeated experiences of this particular institution, which call for urgent representation in the proper quarter of its entire unsuitableness for the purposes of an industrial school. Within a few years outbreaks of typhus and scarlet fever and small-pox have occurred within it, causing loss of life, and costing the local authority large sums of money. It is situated in the centre of a manufacturing district of the city, and a graveyard, still in occasional use, is its only free space. The building is defective in structure and accommodation, especially on the boys' side. There are not sufficient sickrooms, and there is no mortuary. The boys' lavatory is cold, damp, and unwholesome looking, without hot water at the taps. Every part of the house is filled to the limit of its capacity, and the moment sickness of any kind appears, there is no possibility of separating the well from the sick, and disaster is inevitable. A test of the drains, made since the report was issued, disclosed some defects in the soil-pipes within the house. In the washing-house there was a serious escape, and in the lavatory were six choked bell-traps. The Health Committee of the city have instructed that the report be forwarded to the Secretary for Scotland, with the request that immediate steps be taken to obtain the discontinuance of the school on its present site.

The number of cases of typhus fever registered in Glasgow during the last fortnight was the same as the preceding two weeks, 17. There were also 22 cases of enteric fever, and 16 undefined, including those removed from the Roman Catholic Industrial School. One genuine case of small-pox had been found, the first since January, 1886. The patient was stoker of a steamer, which left Santander on February 16th. He sickened on the 22nd of that month, and reached Glasgow on the 25th. The disease was happily recognised by a practitioner on the 27th, and the patient's removal to Belvidere was effected.

A large and influential deputation waited on the President of the Council at the Privy Council offices, on March 19th, to urge the necessity of the Government undertaking an investigation into the nature and treatment of pleuro-pneumonia in cattle. The deputation represented twenty-nine different local authorities. It was stated that since 1874 there had been an annual increase of the disease in Scotland, there being 239 outbreaks in 1887, while in 1884 there were only fifty-five. In 1887 the expense for compensation had amounted to over £34,000. In Lanarkshire alone since February, 1887, there had been spent in compensation almost £19,000, while the whole of the previous expenditure from 1872 to 1887 had been under half that figure. In reply, Lord Cranbrook promised a very careful inquiry, though he could not undertake to promise a Royal Commission. The value of inoculation is naturally one of the chief questions which the deputation wished to be carefully investigated.

Dr. Andrew Wilson begins his annual course of free Combe Lectures on physiology to teachers in Glasgow on April 3rd. His subject this year is the Physiology of Motion and Nutrition. The course will extend to fifteen lectures. A limited number of tickets will be granted to members of the general public desirous of attending.

CORRESPONDENCE.

TREATMENT OF UTERINE FIBROIDS BY ELECTROLYSIS.

SIR,—I did not intend to take part in the discussion on the so-called "Apostoli method" of treating diseases of the uterus (including fibro-myoma), because I have never tried it, and being a gynecologist, do not intend to, as I think it may more properly be left to the obstetric physician. A very brief and misleading report of the remarks I made in a discussion at the meeting of the West London Médico-Chirurgical Society on March 2nd seems, however, necessitate some exposition of my real views on this subject.

1. I think the whole discussion premature, because we know that fibro-myomata are most uncertain in their habits of growth and retrogression when left entirely to themselves, the most surprising alterations taking place in periods of three, six, or twelve months. Such alterations are still more common if the patients are carefully handled as to diet, alcohol, rest at the periods, and special medicines.

2. Nothing which has yet been published by Apostoli or his followers is inconsistent with these natural, or slightly aided, changes, and the results obtained are probably as much due to the rest and care while under treatment, powerfully aided by the effect on the nervous system of confident hope of cure, as to the specific action of electricity.

3. No results can have any scientific value till the cure is proved by a sufficient interval of health for at least twelve months after the treatment has ceased.

4. We do not yet fully appreciate the dangers of the method. I know of one case in which rapidly fatal pyæmia followed a very few applications in the hands of one experienced in the use of the method. The journals tell us of narrow escapes, and even of such careful manipulators as the Keiths record a serious case of cellulitis, of which the gravity is not lessened by attributing it to the carelessness of the patient.

5. I would ask the profession not to be carried away by the enthusiasm of anyone in a revival of this kind, but to wait patiently for definite results, confirmed by sufficiently long intervals.

Let those who believe in the new "panacea" work for a year or two, and then show us their cured patients, *i.e.*, if they then have any to show.

The above was intended for last week's JOURNAL, but was misdirected. It contains all the information I can give Dr. Inglis Parsons, the details of the fatal case were given to me by the family medical attendant of the patient. I trust that the profession will in due time have the full particulars from the operator.—I am, etc.,
J. KNOWSLEY THORNTON.

22, Portman Street, W., March 20th, 1888.

"THE ABORTIVE TREATMENT OF SYPHILIS."

SIR,—I was much interested in reading the valuable article under the above heading in the JOURNAL of February 25th, as it exactly coincides with what has been my experience for some years past in the treatment of syphilis, with this exception: that instead of grey powder in 1-grain doses three times a day, I have been using liquor hydrarg. perchlor. in doses varying from half to a drachm three times a day, accompanied by an inunction of gnetum hydrarg., well rubbed into the affected glands every alternate night (in cases where mercury is not well tolerated when given internally), until we have satisfactory evidence that the constitution is affected, directing and continuing our treatment in such a watchful manner that neither salivation nor any vicious effect of the drug is produced. We thus gain a result by the early administration of mercury which fully justifies us in thinking that the disease has been so checked or "aborted" that neither the so-called secondary symptoms are entirely absent, or appear in such a mild form as to leave little doubt (when contrasted with those cases in which mercury has been withheld) as to the specific efficacy of the drug.

I am not aware if the beneficial practice of mercurial inunction directly into the affected glands has been pointed out in any of the textbooks. Certainly I have found the treatment in certain cases attended with very happy results, and now never hesitate in treating my patients on mercury, internally or by inunction, and I do not feel obliged to diagnose the primary lesion to be a true syphilitic one; in any case in which there may be a rational doubt as to the nature of the sore.

It is interesting to note that at Fürth, where the manufacture of mirrors is extensively carried on, Professor Kussmaul could not find an instance of a worker in mercury contracting syphilis, while under the influence of the drug.—I am, etc.,

J. CARTER BATTERSBY, M.B.,
Dublin, March 14th. Surgeon Army Medical Staff.

SIR,—May I be allowed to make a few remarks about the word "abortive" as applied to the successful treatment of disease? It is now frequently used in this way both in our own country and abroad, but surely it cannot be logically correct. If a man tries various means to combat an ailment, and he fails, one says that all his efforts proved abortive, that is to say, ineffectual. Now, this is exactly what is not meant by those who advocate the "abortive treatment" of erysipelas, syphilis, etc. Their object is to render the disease itself abortive. If the surgeon's aim be to exterminate or to eliminate from the system a morbid poison, such as syphilis, why not call the treatment "exterminative" or "eliminative?" I do not find either of these words in dictionaries, but they may be quite legitimately formed from their root-verbs.—I am, etc.,

JAMES DIXON.
Dorking, February 29th.

CONSULTATION WITH HOMŒOPATHS.

SIR,—Dr. Needham's contention, in his letter published in the JOURNAL of March 17th, is perfectly just, namely, that at the meeting of the Gloucestershire Branch on February 21st, "the question as to the right of holding consultations with homœopaths was not settled so far as the county of Gloucester was concerned." No resolution was put to the meeting. There was simply a discussion as to the present position of homœopaths, and nothing more.

The meeting, though certainly not a large one, was by no means insignificant, and Gloucester itself was very fully represented.

For myself, I may be allowed to say that I am an utter disbeliever in the tenets of homœopathy, but I should be glad if some basis of agreement could be found which would put an end to a schism which is alike injurious to the science of therapeutics and to the best interests of the profession. This was the view I took of the question at the Gloucester meeting, and it seemed to meet with the approval of all who were present, with the exception of my friends Drs. Bond and Needham. I will only add that I acted on the principle of the old Greek philosopher; who said, "τοῦτο μέγιστος ἐστὶ τεχνητὸ ἀγαθὸ ποιεῖν τὰ κακά."—I am, etc.,

ANDREW S. CURRIE.
The Moorlands, Lydney, Gloucestershire, March 21st.

THERAPEUTICS WITHOUT ALCOHOL.

SIR,—The Board of Management of the London Temperance Hospital desire me to offer, in their name, some comments upon the sub-leader in the JOURNAL, entitled "Therapeutics without Alcohol." It is there stated that this hospital has been in existence above twelve years (in reality above fourteen), and that "the annual report for 1886-7 may be studied with advantage, in order to compare the results with those of other hospitals." I would ask whether the comparison should not have been made with the series of reports during the whole period, and not with the report of one single year's results? It is somewhat strange that though copies of the annual reports have been supplied to the medical journals, and also reports of the medical and surgical cases for the three years, 1883-4-5, your criticism should be confined to the Registrar's report for a single year. You observe: "In the surgical department the results have been satisfactory, so far as one is enabled to judge from mere figures, but turning to the medical cases we may restrict examinations to one or two groups of diseases with advantage." If the results of the surgical operations were "very satisfactory," why add the words, "so far as one is enabled to judge from mere figures," seeing that the cases are set forth with every necessary explanation? And it cannot be overlooked that it is in regard to such cases, where great loss of strength inevitably occurs, that the supposed value of alcohol is most frequently and firmly insisted upon. The article goes on to observe that the four cases of typhoid fever all proved fatal, though the subjects were young persons, and comprised three abstainers. Would the writer recommend that young people should not be abstainers; or would he insinuate that the abstinence of the three had anything to do with the fatal result?

"The treatment," it is said, "was the same as elsewhere, and the only difference consisted in the non-exhibition of alcohol."

Is it, then, a scientific inference that the absence of the alcohol was the cause of these deaths? Do patients never die to whom alcohol is administered; and is there never in any hospital what is called, for want of a better name, a run of bad luck? If the writer had consulted the thirteenth annual report, he would have seen that out of sixty-eight cases of typhoid fever, treated up to April 30th, 1886, only seven had proved fatal; and that out of these seven, two were complicated by double pneumonia, one by cirrhosis of liver, one by ovarian cyst, and one by peritonitis and perforation. Will it be pretended that the use of alcohol in these fatal cases would have been attended with the saving of life; and was not the recovery in sixty-one cases "very satisfactory?" I may add that the total in-patients admitted down to April 30th, 1887, were 4,160, and that the deaths were 240, the rate of mortality thus being 5.8. Since the erection of the new buildings in the Hampstead Road, this rate has, for obvious reasons, increased, and was 8.4 per cent. for the year ending April 30th, 1887.

You commend the plan upon which the Registrar's report has been drawn up—a plan settled by the Medical Committee, and approved by the Board. We are not afraid of the fullest publicity, and members of the profession are ever welcome as visitors to the hospital. All that we claim, and have a right to claim, is that our results should be fairly considered, and that we should not be subjected to a style of criticism from which other hospitals are exempt. We rejoice to know that in all other hospitals the consumption of alcohol has diminished, and is diminishing, with advantage to the patients; and as our visiting staff are authorised to prescribe alcohol whenever they deem it needful, its non-exhibition cannot be ascribed to any fanatical adherence to an abstract theory. Those who can recall the days when the free brandy and port wine practice of Dr. Todd carried captive the great body of medical practitioners, and resulted in the loss of numberless lives, may congratulate both patients and doctors upon the present more enlightened method of treatment; and we look to the medical profession for an intelligent appreciation of an institution which is submitting the supposed value of alcohol in special cases to a really scientific examination.—I am, etc.,

DAWSON BURNS, D.D.

Honorary Secretary London Temperance Hospital,
Hampstead Road, N.W., March 17th.

MENSTRUATION AFTER HYSTERECTOMY.

SIR,—The somewhat fierce discussions which have taken place during the last few years on the treatment of uterine myoma will have at least two satisfactory results. The first is already accomplished. This consists in the disestablishment of the belief, which was until a very short time ago prevalent throughout the profession, that the disease was one which had no great clinical significance, and might generally be let alone. The second is that it is leading to the reconsideration of the notions concerning the relations of ovulation and menstruation as cause and effect. So long ago as 1843 Dr. Ritchie wrote a book in which, to my mind, the ovular theory of menstruation was completely destroyed. Since then Kesteven, Reeves-Jackson, De Sinéty, Malassez, and a host of others have completely confirmed Ritchie's original observation.

All the clinical facts with which I am acquainted yield further proof that ovulation and menstruation have no association with one another as cause and effect. The occurrence of menstruation after hysterectomy has long been to me a very familiar phenomenon, and I have under observation one patient from whom I removed the whole of the uterus, as nearly as it can be removed in supravaginal hysterectomy, both tubes, and both ovaries nearly six years ago; and that patient has menstruated every month during the whole of that time. In another case where, three years and a half ago, I removed a pregnant uterus about the fifth month, on account of two large ovarian tumours of the nature of soft sarcoma, the uterus being infiltrated with nodules of a similar growth in large numbers, I, of course, removed everything I possibly could. That patient had a metrostasis after the operation. Menstruation appeared at the end of twenty-three or twenty-four days, and she has since menstruated with as much regularity as ever she did in her life, and all the phenomena of its appearance in this case are still identical with those of the normal process. Whatever these clinical facts may lead us to as conclusions in the future, it is per-

fectly certain that they established Ritchie's conclusion, that the ovular theory of menstruation is absolutely untenable.—I am,
etc.,

LAWSON TAIT.

7, The Crescent, Birmingham, March 17th.

THE DEFICIENT SUPERVISION OF MEDICAL STUDENTS.

SIR,—I write to ask you if there is any law by which a medical student can be saved from the clutches of pawnbrokers. It appears to me that the matter requires looking into, when a mere lad of eighteen years is able to hand in to a pawnbroker the whole of his medical books, microscope, dissecting case, etc., all of which have been bought by the hardly-earned money of his father, and which are the actual working tools of a student. Surely there should be some restraint placed upon the facilities of pledging by minors. When I was a student there used to be considerable care displayed that students should be fit before going in for their examinations, and in fact they were not permitted to do so unless up to a certain standard, the credit of the hospital being so jealously guarded. But times are changed, and in one hospital at least it appears that as long as a student's fees are paid he may either work or go to the devil. Again, if he has led a life of idleness for twelve months, not even having been signed up for his dissections, surely his friends ought to be warned, and not allowed to pay the next year's fees in blind ignorance. Once more, I protest that it was not my duty as a father to discover from an outsider that card-playing was carried on within the hospital walls (I do not refer to the dressers' rooms). I therefore take it that there must be a great want of supervision where it is needed over first year's men. I can only sign myself

A DISTRESSED PARENT.

* * A pawnbroker commits an offence, for which he is liable to be summarily punished, if he takes an article in from a person appearing to be under the age of twelve years. If the pledger is over that age, but a minor, the pawnbroker might in some cases be obliged to restore the property pawned, on its being shown that the minor had no authority to pledge it. The authorities of hospitals and other educational establishments ought undoubtedly to look after the youths whose fees they take. At some, we believe most, schools a certain amount of supervision is exercised. If the authorities neglect to do so, they incur a grave moral responsibility.

THE SUPERIOR LONGEVITY OF TEETOTALLERS.

SIR,—The valuable statistics cited in the JOURNAL of March 17th show very conclusively that total abstinence from alcoholic drinks is most conducive to longevity and to absence from acute and chronic diseases. I have for many years past felt certain that the medical men of this country when in possession of the results of the statistics of those of our London insurance companies which separate teetotalers from non-teetotalers will range themselves and their families in the ranks of the total abstainers, for nothing can be more clearly proved by the figures you quote than the safety—and, more than that, the great advantage—of leaving off beer, wine, and spirits as a part of diet. In France and Germany no such information exists, and consequently there are very few teetotal medical practitioners. Here the number of such is rapidly increasing, and I am certain that few changes could do so much good to the community as the conversion of practitioners to teetotalism.—I am, etc.,

London, March 17th.

C. R. DRYSDALE, M.D.

CASE OF LYMPHADENOSIS.

SIR,—In an account of the meeting of the Clinical Society of Manchester, published in the JOURNAL of March 17th, p. 594, it is mentioned that I showed a rickety child with great enlargement of spleen and liver, and it would appear from the report that I associated the rickets and the enlargement in the relation of cause and effect. This, however, is not the fact. I showed the child as a case of lymphadenosis, and contended that, although the enlargement of the above-mentioned organs coincided with rickets, it was not due to that disease, but to infiltration of a malignant character. My experience of rickets leads me to the opinion that as a rule the spleen is not perceptibly enlarged, and is never very much so, and that it is still more rare to find the liver affected.—I am, etc.,

T. C. RALTON.

32, St. Ann Street, Manchester.

THE Duke of Devonshire has been elected President of the Chesterfield and North Derbyshire Hospital for the ensuing year.

NAVAL AND MILITARY MEDICAL SERVICES.

CHANGES OF STATION.

THE following changes of station among the officers of the Medical Staff of the Army have been officially notified as having taken place during the past month:—

	From	To
Deputy-Surg.-Gen. C. G. Irwin, M.B.	Bermuda	Edinburgh.
" F. W. Wade	Chatham	Bermuda.
Brigade-Surgeon J. Y. Donaldson, M.D.	Shorncliffe	Madras.
" W. Graves	Portsmouth	Bombay.
" S. E. Mausell	Woolwich	Jamaica.
" R. P. Ferguson	Madras	Shorncliffe.
" G. Perry	Coldstream Gds.	Brig. Foot Gds.
Surgeon-Major J. R. Murray, M.D.	Portsmouth	Hilsea.
" J. Barker	Bengal	Chatham.
" J. Maturin	"	Woolwich.
" J. Riddick	Winchester	Portsmouth.
" G. Corry	York	Sheffield.
" B. W. Fowler	Trinidad	Barbadoes.
" P. A. Hayes	Portland	Portsmouth.
Surgeon E. O. Reynolds	Trowbridge	Bengal.
" A. W. Carleton, M.B.	Athlone	Dublin.
" H. C. Kirkpatrick, M.D.	Netley	Shorncliffe.
" A. C. J. R. Lundy, M.B.	"	Woolwich.
" J. Tidbury, M.D.	Devonport	Trowbridge.
" W. P. Feltham	Netley	Newry.
" C. Seymour, M.B.	"	Aldershot.
" C. B. Hill	"	Portsmouth.
" O. Todd, M.B.	"	Colchester.
" A. O. Geoghegan, M.D.	"	Woolwich.
" W. R. Henderson, M.D.	Cork	Mitchelstown.
" A. M. Kavanagh	Netley	Woolwich.
" A. H. Burlton	Brighton	Canterbury.
" M. W. Kerin	Netley	Cork.
" J. G. W. Crofts	Ashton-n-Lyne	Fleetwood.
" A. J. Struthers, M.B.	Edinburgh	Glasgow.
" H. J. R. Moberly	Golden Hill Fort	Winchester.
" E. Butt	Armagh	Belfast.
" S. Townsend, M.D.	Cork	Queenstown.
" R. Haselden	Gosport	Portsmouth.
" C. A. P. Mitchell, M.D.	Edinburgh	Leith Fort.
" F. A. B. Daly, M.B.	Dublin	Belfast.
" J. Macnachie	Gosport	Golden Hill Fort
" J. R. Yourdi, M.B.	Bengal	Queenstown.
" G. T. Trewan, M.B.	Gosport	Portsmouth.
" J. W. Beatty, M.D.	Newcastle.	Sunderland.
" G. H. Younge	Bengal	Cork.
" J. M. Langhlin, M.D.	"	Dublin.
" W. L. Reade	Horfield	Clifton.
" W. Dick, M.B.	Bradford	Salford.
" S. F. Longhead, M.D.	Malta	Belfast.
" H. J. Wyatt	Dublin	Curragh.
" G. B. Russell, M.B.	Cahir	Fermoy.
" H. Mitchell	Portsmouth	Marchwood.
" J. R. Forrest	Colchester	Gt. Yarmouth.
" J. S. Green, M.B.	Dublin	Fermoy.
" J. J. O'Donnell, M.B.	Barbadoes	Trinidad.
" D. M. Greig, M.B.	Leith Fort	Edinburgh.
" H. A. Cummins, M.B.	Queenstown	Bengal.
" R. E. Kelly, M.D.	Mitchelstown	Madras.
" J. F. Donegan	Plymouth	"
" J. Donaldson	Belfast	"
" G. Bent	Sheerness	Bengal.
" G. H. Barefoot	York	"
" F. R. Newland, M.B.	Dublin	"
" C. W. Allport, M.D.	Cork	"
" J. J. Russell, M.B.	Fermoy	"
" A. B. Hinde	Portsmouth	Gosport.
" J. W. Ceckerill	Dover	Brighton.
" J. Ritchie, M.B.	Wrexham	Lancaster.
" S. Macdonald, M.B.	Edinburgh	Piershill.
" G. A. Wade, M.B.	Portsmouth	Gosport.
" W. P. G. Graham, M.B.	"	"
" G. F. Alexander, M.B.	Leith Fort	Edinburgh.
" E. M. Woods, M.B.	Portsmouth	Parkhurst
" G. T. Rawnsley	Dover	Shorncliffe.
" J. Glavin	Warley	Culchester.
" R. Crofts	Sierra Leone	Cape Coast Castle
Quartermaster D. Lackey	Egypt	Netley.

A SLIGHT TO SURGEONS IN INDIA.

MEDICAL STAFF writes: The offensive circular issued by the Military Secretary to the Viceroy, relative to the gold aiguillette worn by Honorary Surgeons to His Excellency, is not only an insult and indignity offered to honourable and gallant men, but to the entire medical profession to which they belong. It ought surely to be brought to the notice of the House of Commons. It is not a matter of mere sentiment and gold lace, but one of simple justice and honourable treatment in the public service.

RIGHT OF RETIREMENT AFTER TWENTY YEARS.

DISAPPOINTED SURGEON, Medical Staff, writes: If the right to retire after twenty years' full pay service is cancelled, a very gross breach of contract will be perpetrated on those medical officers who have entered the service on the terms of the Warrant of 1879. These men will have been secured on false promises. The pen will be drawn through the very best point in that warrant. Surely it is not contemplated to make changes retrospective?

THE NAVY.

SURGEON F. W. STERICKER has been appointed to the *Cockatrice*; and Surgeon G. H. MILNES to the *Starling*.

THE MEDICAL STAFF.

SURGEON-MAJOR D. C. W. HEATHER, having applied to retire before January 1st, 1888, is now granted the honorary rank of Brigade-Surgeon, and Quartermaster J. M. JOHNSON, is granted the honorary rank of Major.

Surgeon-Major A. MORPHEW, who has been serving in Bengal since the beginning of 1884, has been detailed to proceed to England in H.M.S. *Crocodile*, which was to leave Bombay on March 17th.

Brigade-Surgeon W. J. WILSON, M.D., serving in the Bombay command, is directed to proceed to England pending retirement from the service.

Brigade-Surgeon R. WATERS, serving in Beogal, is placed in administrative medical charge of the Allahabad division during the absence on furlough of Deputy Surgeon-General E. H. ROBERTS.

Inspector-General THOMAS DAVID HUME died at Gladstone House, Southsea, on March 16th, in the 80th year of his age. He entered the Army Medical Service as Hospital Assistant, October 26th, 1826; became Assistant-Surgeon, October 11th, 1827; Surgeon, July 2nd, 1841; Surgeon-Major, November 26th, 1852; Deputy Inspector-General, June 29th, 1855; and Inspector-General, December 31st, 1862; he was placed on half-pay, October 1st, 1865. Inspector-General Hume served at the siege of Sebastopol, and was Principal Medical Officer of the 3rd Division during the winter of 1855, and afterwards of the 4th Division until the end of the war. (He received the medal with clasp, the 5th class of the order of the Medjidie, and the Turkish Medal.)

THE INDIAN MEDICAL SERVICE.

DEPUTY SURGEON-GENERAL J. PINKERTON, M.D., Bombay Establishment, is promoted to be Surgeon-General vice Surgeon-General W. J. Moore, C.I.E., retired. Surgeon-General Pinkerton entered the service as Assistant-Surgeon August 4th, 1855, and attained the rank of Deputy Surgeon-General May 1st, 1883. He was engaged in the Persian campaign in 1856-7.

Surgeon-Major D. A. PATTERSON, M.D., Bombay Establishment, is appointed Secretary to the Surgeon-General H.M.'s forces in Bombay, vice Brigade-Surgeon F. S. Turnbull, M.D., who has been appointed Deputy Surgeon-General, and posted to the Sind District.

Surgeon F. C. REEVES, Madras Establishment, whose services have been placed by the Government of India at the disposal of the Chief Commissioner of the Central Provinces, is posted to the Betul District as Civil Surgeon.

Surgeon A. H. JACOB, Madras Establishment, doing duty in the Eastern District, is posted to the Burmah Division, vice Surgeon W. H. Karney.

Surgeon-Major J. S. WILKINS, Bombay Establishment, officiating in medical charge 21st Native Infantry, is directed to act as Presidency Surgeon to the Second District in addition to his other duties during the absence of Brigade-Surgeon E. H. R. Langley.

The undermentioned gentlemen have obtained leave of absence for the periods specified:—Surgeon-Major J. C. FULLERTON, Bengal Establishment, Agency Surgeon, Beloochistan, for one year and 213 days on private affairs; Surgeon-Major P. F. O'CONNOR, Bengal Establishment, Medical Officer to the Native Cavalry, for one year; Surgeon D. F. BARRY, Bengal Establishment, 15th Native Cavalry, for one year on private affairs; Surgeon-Major J. DAVIDSON, M.B., Bombay Establishment, in medical charge of Bombay Sappers and Miners, for two years on private affairs.

Surgeon J. A. CLARK, late of the Bengal Establishment, died at Park Circus, Ayr, on the 4th instant.

THE YEOMANRY AND VOLUNTEERS.

SURGEON C. H. GAMBLE, of the Royal North Devon Yeomanry, has resigned his commission, which bore date May 21st, 1867; he is granted the honorary rank of Surgeon-Major, and is permitted to retain his uniform.

Mr. JAMES MOIR is appointed Acting Surgeon to the 2nd Volunteer Battalion Royal Scots Fusiliers (formerly the 2nd Ayrshire).

Acting-Surgeon J. H. DAVIES, of the 2nd Volunteer Battalion Welsh Regiment (late the 1st Glamorgan), is promoted to be Surgeon to the same corps.

Surgeon R. ROBERTSON, M.D., and Acting-Surgeon F. G. TOOKER, M.D., of the 19th Lancashire (Liverpool Press Guard) have resigned their commissions; that of the former was dated October 16th, 1872, that of the latter April 18th, 1885.

Acting-Surgeon D. C. SMITH, of the 2nd Volunteer Battalion Norfolk Regiment (late the 2nd Norfolk) has resigned his appointment, which was dated December 11th, 1886.

Mr. J. E. LANE, M.D., has been appointed Acting-Surgeon to the 3rd Volunteer Battalion East Surrey Regiment (otherwise known as the 5th Surrey Volunteers).

THE ALEXANDER MEMORIAL PRIZE.

THIS prize of £50 and a gold medal of the value of £10 has been awarded to Surgeon Robert Hammill Firth, F.R.C.S. Eng., Medical Staff, for the best essay on "The Relations between the Food and Work of the British Soldier." The subject for the next competition is, "The Use of Drugs in the Treatment of Disease in the Army; the Principles on which Medicines should be selected so as to meet the Requirements of Field Service." The competition is limited to executive medical officers of the army on full pay. All essays to reach the President of the Committee on or before December 31st, 1890. The conditions of competition will be found in our advertising columns.

SURGEON-GENERAL MOORE, C.I.E., who has vacated his appointment and severed his connection with the Bombay Presidency, has, on the eve of his departure, met with a singularly appropriate and almost unprecedented recognition at the hands of the medical officers and subordinates in Bombay; over whom he presided as the head of the department for nearly three years. A

subscription has been started in the Civil Medical Department to obtain a bust and portrait of Dr. Moore, the balance, if any, to be used for providing a medical prize or scholarship in his name. A few weeks ago a dinner was given in his honour by the members of the medical service at Poonah; and a similar entertainment was given more recently in Bombay. The committee of the Bombay Medical Union have forwarded a letter expressing their regret at his departure.

MEDICO-LEGAL AND MEDICO-ETHICAL.

MASON v. DRS. MARSHALL AND SHAW, AND OTHERS.

This action was tried before Mr. Justice Field, and occupied three days. Fortunately it ended favourably for the medical men. A victory in such cases is only one step better than a defeat. Worry and expense are inevitable.

Medically the case appears to have been plain enough. A young lady developed ideas of suspicion, and fancied people turned against her; she had hallucinations, and refused food. These symptoms induced her to avoid her friends, and caused them to fear that she would commit suicide. Medical men were called in, who, without fee or reward, signed certificates under which she was sent to an asylum. She was transferred to two other asylums, and was seen by commissioners and visitors; at the end of over two years she was removed from asylum care, and a year later took these proceedings against the medical men who signed the certificates. The action, so far as it interests us, asserted malice and conspiracy, as well as negligence, against the medical men; but the first two pleas were withdrawn, and the question of negligence alone remained to be tried.

There are some noteworthy points in the proceedings at the trial to which we shall refer. First, the power of attacking medical men through certificates which were accepted as sufficient by the Commissioners in Lunacy. Certificates must, especially when signed in the earlier stages of insanity, or when signed for "suspicious" or profoundly melancholic patients, contain inferences as much as simple facts. We never understood that certificates must be more than evidence of insanity of a kind requiring special detention. They cannot be exhaustive. Medical men have, in the interests of society, to run risks enough in signing certificates, and do not expect to find enemies in their own profession. We regret that two medical men at the trial gave evidence for the plaintiff in this case, one of whom is reported to have said "he had seen the defendants' certificates, and he was of opinion that a reasonable man would not have signed a certificate of insanity on the facts observed by themselves or reported to them."

The other medical man declined to go so far as to say "that rambling, incoherent conversations, refusal to answer questions, and vague statements of ill-usage" were sufficient to justify the certificates; and thus, though called to curse, he involuntarily was forced to bless. Such symptoms might cover acute mania or weak-mindedness, with suspicion of the worst form.

The general evidence of the trial was conclusive. The judge on several occasions endeavoured to get the plaintiff to reconsider her conduct, but it was fought to the bitter end. We quote parts of the judge's summing-up. "It was most important that insanity should be taken in its incipient stage, when alone there was a possibility that by proper treatment the patient might be cured." "Again, with regard to medical men, if it were to come to this that no respectable medical man would put his hand to a certificate it would be a most unfortunate thing for patients themselves. No doctor was bound to act, but, if he acted, he undertook a duty and was responsible for any breach of it." "As to the mode of procedure in the case, his lordship said the doctor's general duty was to take proper care and skill, and it was alleged they had not done that. There was no suggestion of any particular act of negligence; the whole case was that their inquiry and investigation were insufficient." "The only evidence as to the alleged negligence was contained in the plaintiff's own account of the interviews with the doctors. Certain of the acts reported to the doctors and mentioned in their certificates were not denied." "They had the views of experts, and they had, what was more important, the conduct of certain persons whose duty it was to examine the certificates, and to act or refuse to act upon them, and those five or six gentlemen, having examined and acted upon

the certificates, the jury would consider whether they were sufficient or not."

His lordship left these, among other questions, to the jury. "Did (1) Dr. Marshall or (2) Dr. Shaw sign his certificate without due care?" Answer of the jury, "No."

"Were the conduct, behaviour, and appearance of the plaintiff at the times in question such as to induce the defendants, or any and which of them, to believe, and did they honestly and bona fide believe that she was a person of unsound mind and a fit and proper person to be taken charge of and detained under care and treatment, and were the acts complained of done by the defendants acting honestly on such belief?"—"Yes."

"Was the plaintiff at the times in question of unsound mind and a proper person to be taken charge of and detained under care and treatment?"—"Yes."

The conclusion of the case is so far satisfactory, and we are glad to find Mr. Justice Field more alive to the importance of medical evidence than was suspected after some recent judicial decisions involving such evidence.

The exceptional question submitted by "Beds" is one for his own consideration. At the same time, it may be judicious to note that we cannot regard the idea otherwise than as objectionable and repellent.

DECEASED PATIENTS.

F.R.C.S.—Fees due to medical men for attendance during illness, whether the last or not, rank as simple contract debts. If the estate is unable to pay in full, they are entitled to no priority. There may be cases in which such fees have been paid without objection, but no court would give a medical man preference over other creditors in respect of such fees.

MEDICO-PARLIAMENTARY.

HOUSE OF LORDS.—Monday, March 19th.

Scotch Universities Bill.—The Marquis of LOTHIAN presented a Bill for the better administration and endowment of the universities of Scotland.—The Bill was read a first time.

Tuesday, March 20th.

Lunacy Acts Amendment Bill.—On the report of amendments to this Bill, EARL SPENCER moved the following amendment:

Where an agreement has been entered into, or shall hereafter be entered into, between the committee of visitors for any county appointed to provide an asylum for the pauper lunatics of the said county and the committee of visitors appointed to provide an asylum for the pauper lunatics of any borough, for the lodging, maintenance, medicine, clothing, and care in the said county asylum for each pauper lunatic not wholly chargeable to the said borough, then all money payable or to be paid under the said agreement for all charges (except lodging) for the pauper lunatics so belonging to the said borough (notwithstanding any Act of Parliament to the contrary) be paid in the following way, namely, the guardians of the union shall pay to the treasurer of the said asylum for each pauper lunatic within the said borough (and not wholly chargeable thereto) the same sum as shall from time to time be charged for each pauper lunatic in the lunatic asylum belonging to the said county, and the difference between that sum and the total sum to be paid under the said agreement by the said committee of justices for the said borough for each borough pauper lunatic as before mentioned, shall be a charge upon the borough rates, and paid by the treasurer of the said borough to the treasurer of the said asylum.

—Lord BALFOUR of BURLINGHAM said the amendment not only would not make any alteration in the law, but it would not meet all cases which were now provided for. He thought that the noble earl had overlooked the Act of 30 and 31 Victoria, which dealt with this question.—The amendment was withdrawn and the report was received.

HOUSE OF COMMONS.—Friday, March 16th.

Sick Leave Allowances.—Sir WALTER FOSTER asked the Under-Secretary of State for India whether an executive officer of the Medical Staff in India, who officiated for less than one month as Deputy Surgeon-General, in the absence of the Deputy Surgeon-General on sick leave or furlough, received no allowances for the period, although he performed the duties in addition to his other duties; whether, in such an instance, the half-staff of the appointment reverted to the State; whether the acting officer would be held pecuniarily liable in the event of loss of stores or other mistakes; and, whether officers officiating on the military (combatant) staff, in a similar way, drew the half-staff for the broken periods; and, if so, why the difference was made in the case of medical officers.—Sir J. GOSSET said: No reply has yet been received to the despatch on the subject of sick-leave allowance, which was addressed to the Government of India in July last. The Secretary of State will call the attention of the Government of India to the delay which has taken place.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

THE TRUE DEATH-RATES OF LONDON SANITARY DISTRICTS DURING 1887.

In the accompanying table will be found summarised the vital and mortal statistics for 1887 of the forty sanitary districts of the metropolis. Quarterly summaries of these statistics have already appeared in these columns. The mortality figures in the table relate to the deaths of persons' actually belonging to the respective sanitary districts, and are the result of a complete system of distribution of the deaths occurring in the public institutions of London among the various sanitary districts in which the patients had previously resided. By this means the precise number of deaths of persons belonging to the different sanitary districts is known, as all deaths occurring in institutions of persons who had previously resided in another sanitary district have been excluded from the total deaths in the district in which the institution is situated, and credited to the districts from which they came. By this means alone can reliable data be secured upon which to calculate trustworthy rates of mortality.

The births registered in London during the year 1887 were 133,075, equal to an annual rate of 31.7 per 1,000 of the population, estimated at 4,216,192 persons. The London birth-rate has steadily declined, year by year, since 1876, when it was 35.9 per 1,000, and was lower during the year under notice than in any

year since 1849, when it was also 31.7 per 1,000. In the various sanitary districts the birth-rates showed the usual wide variations, owing to the differences in the age and sex distributions of their populations. In those districts containing an undue proportion of unmarried females, chiefly domestic servants, such as Kensington, St. George Hanover Square, St. James Westminster, and Hampstead, the birth-rates are exceptionally low; while in Fulham, St. Luke's, most of the East districts, and Southwark, where the population consists largely of young married persons, the birth-rates show a marked excess.

The 81,113 deaths registered in London during the year under notice were equal to an annual rate of 19.3 per 1,000 of the estimated population, which was lower than in any year since the present system of civil registration was established in 1837. During the past seven years of the current decade, the mean death-rate in London has been only 20.4 per 1,000, while it was equal to 24.4 in the ten years 1861-70, and to 22.5 in 1871-80. The recent marked decline in the London death-rate is to some extent due to the decline in the birth-rate, which materially diminishes the proportion of young children in the population. The lowest rates of mortality among the forty sanitary districts during 1887 were 13.0 in Hampstead, 14.3 in Plumstead, 15.2 in Kensington, 15.9 in Paddington, and 16.0 in Hackney. In the other districts the rates ranged upwards to 27.0 in St. George Southwark, 28.3 in Holborn, 28.5 in St. Saviour Southwark, and 28.7 in St. George-in-the-East. During the year under notice 12,627 deaths were referred to the principal zymotic diseases in London; of these, 3,762 resulted from diarrhoea, 2,928 from whooping-cough, 2,893 from measles, 1,431 from scarlet fever, 951

Analysis of the Vital and Mortal Statistics of the Sanitary Districts of the Metropolis, after Complete Distribution of Deaths occurring in Public Institutions, during the Year 1887.

from diphtheria, 653 from different forms of fever (including 587 from enteric fever, 48 from ill-defined forms of continued fever, and 18 from typhus), and 9 from small-pox. These 12,627 deaths were equal to an annual rate of 3.0 per 1,000, which, though slightly exceeding the rate in 1886, was considerably below the average rate in the preceding ten years 1877-86. The zymotic death-rate during the year 1887 in the various sanitary districts did not exceed 2.0 per 1,000 in London City, Hampstead, Paddington, Lewisham, St. James Westminster, Plumstead, and St. George Hanover Square; while it was equal to 4.2 in Mile End Old Town and in Bermondsey, 4.6 in Fulham, 4.7 in Stepney, 4.8 in St. Saviour Southwark, 5.2 in St. George-in-the-East, and 5.3 in St. George Southwark. Compared with the preceding year, the fatality of small-pox, "fever," and diarrhoea showed a slight decline, while that of each of the other zymotic diseases showed an increase. The mortality from scarlet fever, which last year considerably exceeded that recorded in either of the two previous years, was yet below the average for the ten preceding years 1877-86. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals, which had been 496 at the commencement of the year 1887, had risen to 2,600 at the end of November, after which it declined, and was 2,041 at the end of the year. The admissions, which had been 531, 475, and 688 in the first three quarters of the year, rose to 2,187 during the last three months of 1887. Measles showed the highest proportional fatality in Hammersmith, Chelsea, Fulham, St. George Southwark, Stepney, and St. George-in-the-East; scarlet fever in Fulham, St. Giles, Lambeth, Rotherhithe, Bermondsey, and Newington; diphtheria in Westminster, Lambeth, Hammersmith, and St. Giles; whooping-cough in Shoreditch, Newington, Stepney, and Mile End Old Town; "fever" in Shoreditch, Bethnal Green, St. George-in-the-East, Chelsea, and St. Luke's; and diarrhoea in Clerkenwell, Stepney, Mile End Old Town, Whitechapel, and St. Saviour Southwark. Only 9 deaths were referred to small-pox in the metropolis during the whole of 1887, the lowest number on record; of these, 4 belonged to South London, 2 to West, 2 to East, and 1 to Central London. Sixty-three small-pox patients were under treatment during the year under notice in the Metropolitan Asylums Hospitals, of whom 30 were admitted during the last three months of the year.

Infant mortality in London during 1887, measured by the proportion of deaths under one year of age to births registered, was equal to 158 per 1,000, against an average rate of 152 in the preceding ten years 1877-86. While the rate of infant mortality did not exceed 107 per 1,000 in Hampstead, 110 in Plumstead, 126 in Paddington and in Lewisham, and 138 in Marylebone, it ranged upwards in the other sanitary districts to 202 in Strand, 215 in Stepney, 225 in St. Martin-in-the-Fields, 228 in Holborn, and 270 in St. Olave Southwark.

HEALTH OF ENGLISH TOWNS.—During the week ending Saturday, March 17th, 5,560 births and 3,656 deaths were registered in the twenty-eight large English towns, including London, which have an estimated population of 9,398,273 persons. The annual rate of mortality per 1,000 living in these towns, which had been 21.5 and 23.3 in the two preceding weeks, declined again to 20.3 during the week under notice. The rates in the several towns ranged from 12.8 in Leicester, 15.5 in Hull, 16.0 in Wolverhampton, and 16.5 in Birmingham, to 26.2 in Norwich, 27.4 in Cardiff, 27.8 in Preston, and 31.6 in Blackburn. The mean death-rate in the twenty-seven provincial towns was 20.9 per 1,000, and exceeded by 0.8 the rate recorded in London, which was only 20.1 per 1,000. The 3,656 deaths registered during the week under notice in the twenty-eight towns included 363 which were referred to the principal zymotic diseases, against 366 and 442 in the two preceding weeks; of these, 148 resulted from whooping-cough, 49 from scarlet fever, 46 from measles, 33 from diphtheria, 33 from "fever" (principally enteric), 30 from diarrhoea, and 24 from small-pox. These 363 deaths were equal to an annual rate of 2.0 per 1,000; in London the zymotic death-rate was 2.2, while in the twenty-seven provincial towns it averaged 1.8 per 1,000, and ranged from 0.0 in Halifax and 0.5 in Birkenhead and in Hull, to 3.9 in Blackburn, 4.1 in Sheffield, and 7.4 in Plymouth. Measles caused the highest proportional fatality in Nottingham and Plymouth; scarlet fever in Oldham and Blackburn; whooping-cough in Brighton, Blackburn, Salford, and Norwich; and "fever" in Cardiff and Derby. The 33 deaths from diphtheria in the twenty-eight towns included 22 in London and 2 in Manchester. Of the 24 fatal cases of small-pox recorded during the week under notice,

18 occurred in Sheffield, 2 in Bristol, 2 in Manchester, and 2 in Huddersfield. The Metropolitan Asylums Hospitals contained 17 small-pox patients on Saturday, March 17th, of whom 6 had been admitted during the week. These hospitals, also contained 1,160 scarlet fever patients on the same date, against 1,295 and 1,201 in the two preceding weeks; there were 94 admissions during the week. The death-rate from diseases of the respiratory organs in London was equal to 5.6 per 1,000, and was below the average.

HEALTH OF SCOTCH TOWNS.—In the eight principal Scotch towns, 760 births and 531 deaths were registered during the week ending Saturday, March 17th. The annual rate of mortality, which had increased from 22.6 to 24.2 per 1,000 in the three preceding weeks, declined again to 21.0 during the week under notice, but exceeded by 0.7 per 1,000 the mean rate during the same period in the twenty-eight large English towns. Among these Scotch towns, the lowest rates were recorded in Greenock and Aberdeen, and the highest in Paisley and Glasgow. The 531 deaths in these towns during the week under notice included 47 which were referred to the principal zymotic diseases, equal to an annual rate of 1.9 per 1,000, which almost corresponded with the mean zymotic death-rate during the same period in the large English towns. The highest zymotic rates were recorded in Leith and Glasgow. The largest proportional fatality of measles occurred in Edinburgh, and of whooping-cough in Glasgow. Five deaths from diphtheria were recorded in Glasgow. The mortality from diseases of the respiratory organs in these Scotch towns was equal to 5.6 per 1,000, and corresponded with the rate from the same diseases in London.

HEALTH OF IRISH TOWNS.—During the week ending Saturday, March 17th, the deaths registered in the sixteen principal town-districts of Ireland were equal to an annual rate of 29.4 per 1,000. The lowest rates were recorded in Newry and Kilkenny, and the highest in Lisburn and Londonderry. The death-rate from the principal zymotic diseases in these towns averaged 3.5 per 1,000, and was highest in Lurgan and Lisburn. The 190 deaths registered in Dublin during the week under notice were equal to an annual rate of 29.0 per 1,000, which showed a further decline from the rates in recent weeks. The 190 deaths included 19 from the principal zymotic diseases (equal to an annual rate of 2.8 per 1,000), of which 8 were referred to different forms of "fever," 5 to measles, 3 to scarlet fever, 2 to diarrhoea, and 1 to diphtheria.

DAMAGES FOR DEFECTIVE HOUSE DRAINS.

A CASE of some hygienic and public importance came last week before Mr. Commissioner Kerr in the City of London Court. Two ladies sought to recover £25, damages sustained by them by reason of the defendant's misrepresentations as to the state of the drainage at the house occupied by them as tenants at a rental of £90 a year. It was stated for the plaintiffs that a distinct assurance was given either by the defendant or his agent that the drains were in perfect order; but soon after the plaintiffs entered into possession they discovered that the drains were defective. Some repairs were made, and then came a plague of rats, as many as twenty-two having been killed in a fewer number of days. When complaint of this was made to the agent, he philosophically replied that "they would go away in due course." It was also stated that as the result of the insanitary state of the house the plaintiffs' boarders became ill and left, and the plaintiffs had suffered loss to the extent of the sum claimed.

Mr. Commissioner Kerr recognised the claim, and gave judgment for the plaintiffs for £10, with costs on the higher scale.

EXHAUSTION AND DESTRUCTION OF SEWER-GAS BY MEANS OF A STRONG AND DESTRUCTIVE HEAT.

MR. SPENCER HURLBUTT (Fulham Union Infirmary, Hammersmith, W.), writes with reference to Dr. Russell's report on the action of Keeling's sewer-gas exhausters and destructors, at Baling (JOURNAL, March 17th, p. 618):—"Professor Wanklyn's report of the action of this apparatus contains the following paragraph:—"A consumption of one cubic foot of coal gas in the destructor effect the extraction of 500 cubic feet of air from the sewers." The point of vital importance appears to me to be contained in the concluding paragraph of your valuable article, namely:—"A definite extraction of foul sewer-air, in stagnant conditions of weather, and regardless of external temperature, in the air of hospital wards can be definitely extracted and purified at the rate of say, 10,000 cubic feet per hour, night and day, by such means as Keeling's exhauster and destructor, and if the sewer-air of such institutions can be prevented from being discharged into the atmosphere and consumption of only a cubic feet of coal gas per twenty-four hours, by the consumption of only a cubic feet of coal gas per hour, it appears to me to be not only rational but imperative, that such means and safeguards should be employed."

WORKHOUSE INQUESTS.

Dr. T. MARSDEN (The Square, Bridgwater) writes: I have held the appointment of medical officer (non-resident) to the Bridgwater Workhouse for about six years. During this period I have received the usual fee for attendance and evidence at inquests held at the workhouse, but at the last inquest, a short time ago, was informed by the coroner that under the Coroners' Act, Section 23, Sub-section 2, of Act 50 and 51 Vict., he, the coroner, was under the impression he could no longer grant a fee, on the ground that a workhouse came within the meaning of the Act referred to. As this ruling would do away with all workhouse inquest fees for the future, I would gladly have the opinion of other medical officers as to the right course to pursue. I have stated the facts to the Local Government Board, under whom I hold the appointment, and am informed that as the matter is not one in which the Board have any jurisdiction, they are not prepared to express any opinion on the question submitted.

My intention is to sue for the amount in the county court, but I wish to be strengthened by the knowledge that the workhouse medical officers have not been withheld similar fees.

* * * It is not advisable to sue in the county court, as the case would be decided against our correspondent. Some coroners still continue to give the fee, though they are not legally compelled to do so.

HOSPITAL AND DISPENSARY MANAGEMENT.

PROPOSED HOSPITAL FOR LUNATICS.

Dr. WHITCOMBE, the superintendent of the Winson Green Asylum, has recommended that a separate hospital for the insane should be erected by the Birmingham Town Council. He is convinced that the medical treatment of the insane in asylums scarcely deserves the name—nay, more, he maintains that recent cases are injured by their admission into a lunatic asylum as at present constituted. Were this plan adopted, he prophesies that 60, instead of 40, per cent. of the cases admitted would be cured. We admire Dr. Whitcombe's enthusiasm, and we sincerely hope that his proposal will be adopted. We are not, however, so sanguine as he is in regard to the increased number of recoveries which will take place. We think he will discover what many have discovered before him—that an enormous proportion of cases are associated from the beginning with such a degree of mental degeneration or insane inheritance that anything like 60 per cent. of recoveries is impossible. If it be otherwise, if this high percentage is attainable, we are strongly of opinion that there is no good reason why it should not be attained in existing well-constructed asylums, officered as they are by properly qualified medical men. Every accommodation is provided, enormous sums are spent upon the proper construction of these institutions; baths, and, indeed, every appliance that the superintendent demands are granted by the authorities.

It has long been the boast of England that everything is done to facilitate the treatment of the insane in county asylums. Several years ago Dr. Bucknill wrote that the idea of medical treatment seemed to have been given up in asylums for the insane, and he cast no blame on their construction or the surroundings of the patients. The scepticism with which so many superintendents meet the suggestion of definite medical treatment suited to the individual case is, no doubt, sufficiently depressing; but seeing that it exists in spite of all the advantages at the command of asylum physicians to which we refer, we are at a loss to see how it would be succeeded by faith in medical treatment by the establishment of hospitals such as Dr. Whitcombe proposes. They exist ready in Germany in several university towns, but they end in simply resembling the ward for recent or destructive patients in an English county asylum. We believe that the results of treatment are no better than they would be under the judicious treatment of a capable superintendent of the Winson Green Asylum, under his present conditions. If such is the fact, we regard the frequent exclamation of county asylum superintendents, that they would receive a great many more patients if they had only had a separate building on the hospital system, as the painful cry of despair rather than a scientific opinion justified by any facts attainable where the experiment has been tried. By all means, however, let Dr. Whitcombe's prophecy be put to the test, and, should it be fulfilled, we shall have great pleasure in recording the fact.

In this connection we may note that a new hospital is to be erected near the Montrose Asylum, which is to accommodate fifty patients of each sex. The cost of this building will be about £3,000. There is to be a resident medical officer whose "entire duty" is to use the conventional language of the hopeful and confident framers of asylum rules, is to be "devoted to the treatment of patients in the hospital." The object of this building is not the same as that proposed by Dr. Whitcombe. It is, properly speaking, an infirmary, and is intended for those patients who are

suffering from acute illness, the feeble, and the paralytic, and, in short, all cases requiring medical care. Dr. Howden, the superintendent for many years of the Montrose Asylum, has no doubt advised the architect in every detail of this establishment, and nothing appears to be wanting in the appliances down to the smallest detail, judging from a description given in the *Dundee Advertiser*, March 17th, in which an elevation of the hospital is given. It is a handsome structure.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST.

THE report of this hospital records the noteworthy fact that in two years the Total Abstinence Sons of the Phoenix had collected and paid into the funds £300, and that the Mile End Working Men's Society had enrolled seven of its members as life-governors, at a cost of seventy guineas. Like most of the other great hospital charities, this institution is in great need of funds.

CASTLEBAR LUNATIC ASYLUM.

THE resident medical superintendent in his annual report draws attention to the necessity for additional accommodation in this asylum. In consequence of having no day room accommodation, classification is out of the question; besides, the sleeping accommodation is entirely short of the requirements. In November, 1886, fever broke out and forty patients were attacked, the cause of the outbreak being apparently due to overcrowding, and the patients sleeping in a vitiated atmosphere. In January, 1887, Dr. Nugent, inspector of asylums, in a report urged the board to provide additional accommodation, as the overcrowding was dangerous to the health of the inmates. Plans were prepared last May to build for 120 patients, and were forwarded to the Board of Control, but the latter were of opinion that 152 should be allowed for, and that more cubic space should be given for each inmate. Nothing has been done since, although the attention of the Board has been directed to the matter, and the amended plans have been before them for some months.

THE DENTAL HOSPITAL OF LONDON.

At the annual general meeting of the Dental Hospital of London recently held, some interesting results of the working of this institution were given. Some fourteen years ago the hospital was moved from its old site in Soho Square to its present one in Leicester Square, and during these fourteen years the work of the hospital and the medical school thereto attached has enormously increased. The report shows that the actual number of patients treated in 1887-8 was over 47,000, or 15,500 more than in 1874. This large increase in numbers has sorely taxed the resources of the present hospital and staff, and it has been necessary to increase the size of their building. This has been effected by purchasing adjoining property, and converting it into a new (west) wing, which was opened after the meeting. The cost of the improvements amounts to a considerable sum, and was met partly by a munificent gift of £1,000 from the medical staff and lecturers, and £500 from Miss Claudius Ash, and partly by smaller sums from other friends. The deficit still amounts to £5,700. The present hospital and school will well repay a visit when the recent additions of a handsome lecture theatre, patients' waiting-rooms, extraction and operating (filling) rooms should be seen.

UNIVERSITY INTELLIGENCE.

OXFORD.

NOTICE is given to candidates for the second examination for the degree of Bachelor of Medicine, who offer all the subjects of that examination together, and who passed the first examination for the said degree under the statutes in force before 1886, that the examination in materia medica and pharmacy will in their case be conducted as it was under the provisions of the old statute.

An election to the Sherardian Professorship of Botany will be held in the course of next term. A fellowship in Magdalen College is now attached to the professorship. The stipend of the professor, inclusive of this, will be £700 per annum. Application to be made to the registrar on or before May 1st.

CAMBRIDGE.

On March 5th, Robert Michael Simon, M.B., of Genville and Caius College, duly performed the exercises for the degree of M.D. Thesis "Brass-workers' Diseases."

OBITUARY.

ROBERT GORDON LATHAM, M.D.(CANTAB.), F.R.C.P., F.R.S. We briefly announced last week the death, on March 9th, of Dr. R. G. Latham, who was for many years a leading authority in this country on comparative philology and ethnology.

Robert Gordon Latham was born at Bellingborough Vicarage, Lincolnshire, on March 24th, 1812, the eldest son of the Rev. Thomas Latham. He was admitted on the foundation of Eton College in 1821, and entered at King's College, Cambridge, in 1829. He graduated B.A. in 1833, and immediately went abroad, first to Hamburg, and afterwards to Copenhagen and Christiania. A product of this time is seen in his translation of Bishop Tegner's *Frithiof Saga*, and in a work on *Norway and the Norwegians*, published in 1840. He became Professor of English Language and Literature in University College, London, in 1839. He had been elected a Fellow of King's College, Cambridge, and had studied medicine in St. Bartholemew's Hospital, when in 1842 he obtained the licence of the College of Physicians, and commenced to practise medicine in London. In the same year he became Physician to St. George's and St. James's Dispensary, and in 1845 he was appointed Lecturer on *Materia Medica* and on Forensic Medicine at the Middlesex Hospital Medical School. In the following year he became Assistant Physician to that hospital. He was, however, already deeply engaged in the study of the subjects in which he subsequently became famous, and in 1841 the first edition of his great work on *The English Language* appeared; a second and enlarged edition was published in 1848, a third in 1850, a fourth in 1855. Long before this, however, he had retired from the medical profession. He resigned the post of Lecturer on *Materia Medica* in 1849, and that of Assistant Physician in 1850, being in both cases succeeded by Dr. A. P. Stewart. In the former year his place as Lecturer on Forensic Medicine was taken by Dr. Goodfellow. Dr. Latham's chief, if not his only, contribution to medical literature, was an edition of the works of Sydenham, with a translation prepared for the Sydenham Society; to this volume Dr. Latham prefixed a life of the great English physician.

Several textbooks on English grammar were written by Dr. Latham, and have been known to many generations of students. One of his most successful was a *Handbook of the English Language*, published in 1851; it attained the honour of a ninth edition in 1875. His *magnum opus* was an edition of Johnson's Dictionary which came out in parts, and was subsequently re-issued in an abridged form. He wrote also much on comparative philology, one of his most recent works being an *Outline of General or Developmental Philology*; and many years before he had prepared the vocabularies for Mr. A. R. Wallace's book of travels in the Amazon and Rio Negro.

As with philology, his most important contributions to ethnology were systematic treatises, and he did much good work in laying the foundation upon which the modern science has been built. In quick succession he published works on the ethnology of the British Colonies and dependencies, of the British Islands, of Europe, and of India, the first appearing in 1851 and the last in 1859; but he had previously published an essay on "Man and his Migrations," and later a large work on *Nationalities of Europe* (1863). He was, according to his friend, Theodore Watts, the originator, in 1862, of the theory that the Aryan race had its cradle in Europe and not in Asia, a theory which has come into much prominence lately.

For many years before his death Dr. Latham had lived a very retired life, and for the last ten years nothing of any importance had come from his pen. He belonged to a generation which has passed, a generation of encyclopædists who have been replaced by a race of specialists. His death was due to brain disease, which had produced aphasia.

POST-GRADUATE COURSE IN DENTISTRY.—The Dental Hospital of London, Leicester Square, has announced a post-graduate course of demonstrations for registered medical practitioners and dentists. It is intended to make the course one of a very practical character. Two demonstrations are to be given each day, and include such subjects as treatment of fractured maxillæ, of pyorrhœa alveolaris, alveolar abscess, fittings and stoppings of various kinds, etc.

MEDICAL NEWS.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—At a Special Examination for the licence to practise Midwifery held on Monday, February 27th, 1888, the following candidate was successful:

John James Orr, M.D. R.U.I.

CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.—Ten of the medical and surgical associations of America have united themselves together under the name of "The Congress of American Physicians and Surgeons." This Congress will hold its first session at Washington, on September 17th, 18th, and 19th, 1888, at which time and place the Association will hold their annual meetings separately as well as conjointly in the Congress. The preliminary programme issued, of which a copy has been forwarded to us, gives the following list of officers. *President*: John S. Billings, M.D., U.S. Army. *Vice-Presidents, ex-officio*: D. Hayes Agnew, M.D., Philadelphia, Pa.; President of the American Surgical Association; Edward L. Keyes, M.D., New York City, President of the American Association of Genito-Urinary Surgeons; Rufus P. Lincoln, M.D., New York City, President of the American Laryngological Association; Alfred L. Loomis, M.D., New York City, President of the American Climatological Association; William H. Draper, M.D., New York City, President of the Association of American Physicians; Jonathan S. Prout, M.D., Brooklyn, N. Y., President of the American Otological Society; William F. Norris, M.D., Philadelphia, Pa., President of the American Ophthalmological Society; James J. Putnam, M.D., Boston, Mass., President of the American Neurological Association; I. E. Atkinson, M.D., Baltimore, Md., President of the American Dermatological Association; Henry P. Bowditch, M.D., Boston, Mass., President of the American Physiological Society; Newton M. Shaffer, M.D., New York City, President of the American Orthopedic Association. *Chairman of the Executive Committee*: William Pepper, M.D., Philadelphia, Pa. *Treasurer*: D. B. St. John Reosa, M.D., New York City. *Secretary*: William H. Carmalt, M.D., New Haven, Conn. Among the subjects announced for report and discussion are the following: September 18th.—Intestinal Obstruction in its Medical and Surgical Relations. Papers will be read by Dr. Reginald H. Titz and Dr. Nicholas Senn, and will be followed by a discussion. September 19th.—Cerebral Localisation in its Practical Relations. Papers will be read by Dr. Charles K. Mills and Dr. Roswell Park, and will be followed by a discussion. September 20th.—Address by the President, John S. Billings, M.D., U. S. Army; to be followed by a general reception in the United States Army Museum Building. The Associations have decided to extend invitations to distinguished gentlemen from abroad, to visit America at that time as their guests, to be considered members of the Congress, and entitled to participate in all the discussions.

LECTURES TO SANITARY INSPECTORS.—The Parkes Museum, Margaret Street, have announced a fifth course of lectures and demonstrations for the instruction of sanitary inspectors, of which the following are the particulars: April 10th. (1) Introductory Lecture—General History, Principles, and Methods of Hygiene, Mr. A. Wynter Blyth, M.R.C.S. April 13th. (2) Ventilation, Measurement of Cubic Space, etc., Sir Douglas Galton, K.C.B., F.R.S. April 17th. (3) Water Supply, Drinking Water, Pollution of Water, Dr. Louis Parkes (Pub. Health Cert. Lond.). April 20th. (4) Drainage and Construction, Mr. E. C. Robins, F.S.A., F.R.I.B.A. April 24th. (5) Sanitary Appliances, Professor W. H. Corfield, M.A., M.D. April 27th. (6) Scavenging, Disposal of Refuse and Sewage, Mr. H. Percy Boulnois, M.Inst.C.E. May 1st. (7) Food (including Milk), Sale of Food and Drugs Act, Mr. Charles E. Cassal, F.C.S., F.I.C. May 4th. (8) Infectious Diseases and Methods of Disinfection, Mr. Shirley F. Murphy, M.R.C.S. May 8th. (9) General Powers and Duties of Inspectors of Nuisances; Method of Inspection, Mr. J. F. J. Sykes, B.Sc. (Pub. Health), M.B. May 11th. (10) Nature of Nuisances, including Nuisances the Abatement of which is Difficult, Mr. J. F. J. Sykes, B.Sc. (Pub. Health), M.B. May 15th. (11) Sanitary Law—General Enactments, Public Health Act, 1875, Model By-laws, Dr. Charles Kelly, F.R.C.P. May 18th. (12) Metropolitan Acts, By-laws of Metropolitan Board of Works, Mr. A. Wynter Blyth, M.R.C.S. A nominal fee only of five shillings for the course will be charged to cover expenses, and students attending the course will be granted free admission to the Museum and Library from April 1st to June 1st.

ROYAL HOSPITAL FOR SICK CHILDREN.—The Directors of the Royal Hospital for Sick Children, Edinburgh, have appointed Mr. George P. Boddie, M.B. and C.M., and George Wilson, M.B. and M. (at present resident physicians, Edinburgh Infirmary), to be resident physicians in the Sick Children's Hospital, for six months, commencing May 1st.

A SUNDAY COT.—There seems to be no end to the ingenious devices adopted by well-meaning individuals in appealing to the philanthropic for funds for benevolent institutions. The latest is that adopted by a lady who, being born on a Sunday, has adopted the expedient of appealing to other persons born on the same day for funds with which to endow a "Sunday cot" in the hospital for Incurables at Kilburn.

MEDICAL VACANCIES.

The following Vacancies are announced:

ETHNALL HOUSE ASYLUM, Cambridge Road, E.—Junior Medical Officer. Salary, £100 per annum, with board and washing. Application to the Medical Superintendent.

ROUGH ASYLUM, Birmingham.—Clinical Assistant. Board and residence. Applications to E. B. Whitcombe, Esq., Medical Superintendent.

STOL CITY LUNATIC ASYLUM.—Second Assistant Medical Officer. Salary, £150 per annum, with furnished apartments, board, and washing. Applications by March 28th, to the Chairman of the Committee of Visitors, the Council House, Bristol.

RUSSIAN SEAMAN'S HOSPITAL, Cronstadt, St. Petersburg.—Resident Medical Officer. Salary, £180 per annum, with furnished apartments, etc. Applications to H. M. Consul, St. Petersburg.

PARING CROSS HOSPITAL.—Assistant Surgeon. Applications by March 27th to A. E. Reade, Esq., Secretary.

PARING CROSS HOSPITAL.—Surgical Registrar. Applications by March 27th to A. E. Reade, Esq., Secretary.

DERBY BOROUGH ASYLUM.—Medical Superintendent. Salary, £350, with furnished house, etc. Applications by April 13th, to be addressed to the Derby Borough Asylum Committee, under cover to the Town Clerk, and endorsed "Medical Superintendent."

SEX LUNATIC ASYLUM, Brentwood.—Temporary Assistant Medical Officer for three months. Salary, £30 for the term, with board, lodging, and washing. Applications to the Medical Superintendent.

GENERAL INFIRMARY, Northampton.—House-Surgeon. Salary, £125 per annum, with board, etc. Applications by March 27th to the Secretary, S. P. Bennett, Esq.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton. Resident Clinical Assistants. Applications by April 7th, to the Secretary.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Mount Pleasant, Liverpool.—Medical Officer. Salary, £70. Applications by March 29th, to W. J. Johnson, Esq., Secretary.

DERBY BOROUGH ASYLUM, Willerby.—Assistant Medical Officer. Salary, £100 per annum, with board, lodging, and washing. Applications by April 2nd, to the Medical Superintendent.

INFIRMARY FOR CHILDREN, Myrtle Street, Liverpool.—House-Surgeon. Salary, £85, with board and lodging. Applications by April 9th, to C. W. Carver, Esq., Honorary Secretary.

LIVERPOOL DISPENSARIES.—Two Assistant-Surgeons. Salary, £80 per annum, with board, lodging, etc. Applications by March 24th, to E. R. Greene, Esq., Secretary, Leth Office, Moorfields, Liverpool.

TROPICAL ASYLUMS BOARD—SMALL-POX HOSPITAL SHIPS, Long Reach, Dartford.—Clinical Assistant. Board, lodging, etc. Applications by March 27th, to the Clerk to the Metropolitan Asylums Board, Norfolk House, Norfolk Street, W.C.

GENERAL LONDON OPHTHALMIC HOSPITAL, Moorfields, E.C.—Junior House-Surgeon. Salary, £50 per annum. Applications by March 24th to the Secretary.

PETER'S HOSPITAL FOR STONE, ETC., Henrietta Street, W.C.—Anaesthetist. Salary, £50 per annum. Applications by March 24th to the Secretary.

ST. LONDON HOSPITAL, Hammersmith Road.—Clinical Assistants. Applications to Secretary.

ST. MINSTER HOSPITAL.—Medical Registrar. Salary, £10 per annum. Applications by March 26th to S. M. Quennell, Secretary.

MEDICAL APPOINTMENTS.

FER, W. J. B., Esq., appointed Registrar to the Cancer Hospital, Brompton, vice W. H. Elam, F.R.C.S., resigned.

ALD, Archibald, M.A., O.M. Edin., appointed Surgeon to St. Mary's Hospital for Women and Children, Manchester, vice William Walter, M.A., M.D., resigned.

AL, A. O., M.B. Durh., M.H.C.S. Eng., appointed Pathologist to the Cancer Hospital, Brompton, vice Charles Stouham, F.R.C.S., resigned.

AL, A. F., M.R.C.S., appointed Assistant House-Surgeon to the York County Hospital, vice L. H. Williams, M.R.C.S., resigned.

OS, T. B., M.A., M.B., C.M., appointed Medical Officer to the Aberdeen Dispensary, vice James Brander, M.B., C.M., resigned.

ON, G. A. S., M.A., L.R.C.P. Edin., etc., appointed Resident Medical Officer to the Gainborough Amalgamated Friendly Society Medical Association.

ON, Matthew, M.D., appointed Medical Officer of Health to the city of Aberdeen, vice Theodore Thomson, M.A., M.B., resigned.

OOD, S. P., M.R.C.S., L.R.C.P. Lond., appointed Resident Clinical Assistant to the St. Marylebone Infirmary, vice W. P. Peake, M.R.C.S., L.R.C.P. Lond., resigned.

JACKSON, R. W. H., M.B., B.C.L., appointed House-Surgeon to the City of Dublin Hospital.

JONES, H., M.D., B.S., appointed Medical Superintendent to the Earlswood Asylum for Idiots, Redhill, vice C. S. W. Cobbold, M.D., resigned.

MACKEITH, Alexander Arthur, M.B. Glasg., and C.M., appointed Medical Officer and Public Vaccinator for the Bramford Speke and Upton Pyne districts of the St. Thomas Union, Devon, vice M. L. Brown, M.D., C.M., resigned.

MILLIGAN, William, M.B., C.M. Aberd., appointed Junior House-Surgeon to the Northern Hospital, Liverpool.

OPENSHAW, T. Horrocks, M.B., M.S., F.R.C.S., etc., appointed Curator of the Pathological Museum of the London Hospital Medical College, vice F. Charlwood Turner, M.D., F.R.C.P., resigned.

PEAKE, W. P., M.R.C.S., L.R.C.P. Lond., appointed Assistant Medical Officer to the St. Marylebone Infirmary.

ROLL, G. W., B.A., M.B., M.R.C.S., L.R.C.P., appointed Assistant House-Surgeon to the Leicester Infirmary and Fever House, vice E. Scott Sugden, M.B., resigned.

TYNAN, J. H., L. and L.M., R.C.S. and C.P. Edin., appointed Medical Officer to the Oldcastle Union (Crossroads) vice R. Ridgeway, M.D., F.R.C.S.I.

WALTER, William, M.A., M.D., appointed Physician to St. Mary's Hospital for Women and Children; Manchester, vice C. J. Cullingworth, M.D., F.R.C.P., resigned.

WARD, H. M., appointed Additional Examiner in Botany to the University of Edinburgh, vice Professor Bayley Balfour, resigned.

WATERS, W. E., L.K.Q.C.P.I., L.R.C.S.I., appointed Medical Officer to the Carbury Dispensary District, co. Kildare, vice W. Waters, L.K.Q.C.P.I., M.R.C.S., resigned.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.

MEDICAL SOCIETY OF LONDON (Clinical Evening), 8.30 P.M.—Dr. Orwin: A case of Lupus of Mouth, Pharynx, and Larynx. Mr. Edmund Owen: A case of Injury to Lower Epiphysis of Ulna. Mr. William Rose: A case of Gunshot Injury of Knee-Joint. Mr. Davies Colley: A case of Trephining for Middle Meningeal Haemorrhage. Dr. Beevor: A case of Charcot's Disease of Shoulder-Joint. Mr. Walter Pye: A case of Obliterated Arteritis from Crutch Pressure. Dr. Purcell: Two cases of Thiersch-Gould's operation for Removal of Penis. Also cases by Mr. John Morgan and others.

TUESDAY.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8.30 P.M.—Mr. G. H. Makins: A case of Extroversion of the Bladder treated by Preliminary Division of the Sacro-Iliac Synchondroses. W. J. Walsham, F.R.C.S.: A case of Wound of the Femoral Artery and Vein; Traumatic Varicose Aneurysm; Ligature of both Artery and Vein; Recovery. With remarks on the Treatment of Wounds of the Femoral Artery and Vein.

WEST LONDON HOSPITAL (Clinical Afternoon), 5 P.M.—Mr. Keasley: 1. Case of Transplanting Skin from Arm to Face. 2. Cases illustrating Deformities of the Toes and their Treatment. Mr. Edwards: Cases of Disease of Testis. Mr. Bruce Clarke: 1. Cases of Wired Patella. 2. Severe Flat Foot treated by Excision of part of Tarsus. Dr. Herringham: Hemiplegia with Heart Disease. Dr. Ball: Cases of Atrophic Rhinitis.

WEDNESDAY.

BRITISH GYNECOLOGICAL SOCIETY, 8.30 P.M.—The adjourned discussion on the Electrolysis of Uterine Myoma will be opened by Dr. G. Granville Bantock. Specimens will be exhibited by Mr. Lawson Tait, Dr. Mauseil-Moullin, the President, and others. Council, 8 P.M.

HOSPITAL FOR CONSUMPTION, Brompton, 4 P.M.—Dr. J. Kingston Fowler: On cases illustrating some points in the Prognosis of Valvular Disease.

PARKES MUSEUM OF HYGIENE, 3 P.M.—Dr. T. A. Schofield: On Home Nursing.

HUNTERIAN SOCIETY, 8 P.M.—Dr. Ryle: A case of Tympanites treated by Puncture of Intestine. Mr. Corner: A fatal case of Acute Intestinal Obstruction complicating Utero-Gestation, with Specimen. Dr. J. Dundas Grant: On Tinnitus Aurium.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 8s. 6d., which should be forwarded in stamps with the announcement.

BIRTHS.

LLOYD.—On the 14th inst., at 22, Broad Street, Birmingham, the wife of Jordan Lloyd, F.R.C.S., M.B., M.S., of a daughter.

MORRIS.—On March 10th, at Fernhurst, Haslemere, the wife of Edward Morris, M.R.C.S., L.S.A., of a son.

MARRIAGES.

JONES—EVANS.—On March 21st, at Emmanuel Church, Everton, Liverpool, by the Rev. C. Courtenay, vicar, Surgeon J. M. Jones, Army Medical Staff, eldest son of D. Jones, Esq., M.R.C.P., M.R.C.S., of Everton Road, Liverpool, to Kate, younger daughter of the late Captain G. O. Evans, United States Army, of Beaver Dam, Wisconsin, U.S.A.

SOMERVILLE—MAY.—March 14th, at St. James's Church, Higher Sutton, by the Venerable Archdeacon Gore, M.A., assisted by the Rev. F. Smith, M.A., vicar, John Somerville, F.R.C.S.E., to Geraldine, youngest daughter of John May, J.P., Ridge Hill.

DEATH.

KENYON.—On the 14th March, 1888, at 21, Park Lane, Bradford, Georgiana Elizabeth, the beloved wife of John E. Kenyon, L.R.C.P. Lond., M.R.C.S. Eng. Friends will please accept this intimation.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY.....	10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's (Ophthalmic Department); and Royal Westminster Ophthalmic.—2 P.M.: Metropolitan Free; St. Mark's; Central London Ophthalmic; Royal Orthopaedic; and Hospital for Women.—2.30 P.M.: Chelsea Hospital for Women.
TUESDAY.....	9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's; St. Bartholomew's (Ophthalmic Department); St. Mary's; Royal Westminster Ophthalmic.—2 P.M.: Westminster; St. Mark's; Central London Ophthalmic.—2.30 P.M.: West London; Cancer Hospital, Brompton.—4 P.M.: St. Thomas's (Ophthalmic Department).
WEDNESDAY.....	10 A.M.: National Orthopaedic.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: Middlesex.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: St. Thomas's; University College; Westminster; Great Northern Central; Central London Ophthalmic.—2.30 P.M.: Samaritan Free Hospital for Women and Children; St. Peter's.—3 to 4 P.M.: King's College.
THURSDAY.....	10.30 A.M.: Royal London Ophthalmic.—1 P.M.: St. George's.—1.30 P.M.: St. Bartholomew's (Ophthalmic Department); Guy's (Ophthalmic Department); Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Central London Ophthalmic; Hospital for Diseases of the Throat; Hospital for Women.—2.30 P.M.: North-West London; Chelsea Hospital for Women.
FRIDAY.....	9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.15 P.M.: St. George's (Ophthalmic Department).—1.30 P.M.: Guy's; Royal Westminster Ophthalmic.—2 P.M.: King's College; St. Thomas's (Ophthalmic Department); Central London Ophthalmic; Royal South London Ophthalmic; East London Hospital for Children.—2.30 P.M.: West London.
SATURDAY.....	9 A.M.: Royal Free.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: King's College.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Middlesex; Royal Free; Central London Ophthalmic.—2.30 P.M.: Cancer Hospital, Brompton.

HOURS OF ATTENDANCE AT THE LONDON HOSPITALS.

CHARING CROSS.—Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; Skin, M. Th., 1.30; Dental, M. W. F., 9.
GUY'S.—Medical and Surgical, daily, 1.30; Obstetric, M. Tu. F., 1.30; Eye, M. Tu. Th. F., 1.30; Ear, Tu. F., 12.30; Skin, Tu., 12.30; Dental, Tu. Th. F., 12.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS respecting editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

In order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the office of the JOURNAL, and not to his private house.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL, are requested to communicate beforehand with the Manager, 429, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication. CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

QUERIES.

CLIMATE OF BURMAH AND SIAM.

M.B. wishes for information regarding the climate of Burmah and Siam in general, and the neighbourhood of Bangkok in particular.

VITAL STATISTICS OF CONVICT PRISONS.

Dr. J. BARON (16, Whiteladies Road, Clifton, Bristol) writes: Will some member kindly tell me where I can get statistics as to the longevity of convicts; also the death-rate in our prisons?

TREATMENT OF HEARTBURN.

A MEMBER asks for suggestions for the treatment of obstinate heartburn in a man, aged about 40, who has suffered severely for years. Dieting, mineral acids, nuxvomica, and the usual remedies have been tried in vain. The one thing which affords complete temporary relief is carbonate of soda. The pain is always most severe in bed, or whilst in the recumbent position.

ANSWERS.

T.S.E. (Gloucester).—Yes.

MEDICUS.—Communicate with the Honorary Secretary of the Brussels Medical Graduates Association, Dr. T. Ernest Pocock, The Limes, St. Mark's Road, North Kensington, W.

FAS EST, ETC.—We have not the required information; it should obviously be obtained from another source.

R.W. asks where the *Deutsche Medicinische Zeitung*, No. 22, 1886, can be seen, or in what other journal an account of salicylate of bismuth, by Dr. Solger, can be found.

* * * Our correspondent will probably find the information which he desires at the library of the College of Surgeons. Search should be made in the last three or four volumes of the *Index Medicus*, and Virchow and Kirsch's *Jahresbericht*.

M.B.—Dr. Boxall's paper on Puerperal Fever, read before the Obstetrical Society, in January, is not yet published in full, but will in all probability appear in the first fasciculus of the *Transactions of the Obstetrical Society of London for 1888*, which will be issued in April or May.

CHRONIC SWEATING IN AXILLA.

M.B. writes: Bathe the axilla at night with equal parts of vinegar and lukewarm water; or apply lin. belladon. externally, combined with tr. belladon. internally.

Mr. C. HAYDEN COX (Cottingham, Cambs) would suggest to "M.B." the use of salicylic acid rubbed into the axilla every morning and night for a week. He has found the above invaluable applied between the toes, and dusted into the socks in fetid perspiration of the feet. He has also used boric acid for similar cases, with nearly equal results.

TREATMENT OF EPILEPSY.

M.B. writes: Oxide of zinc with valerian root and cannabis ind. ext. might be tried. Begin with half-grain doses of the oxide thrice daily, and gradually increase if required.

Dr. J. F. OLIVER, (2, Hertford Gardens, Albert Bridge Road, S.W.), writes to suggest to B. the following prescription, which he has found to answer admirably in a similar case (male), after fifteen years persistent treatment by the bromides: R Sodii nit. gr. v; liq. Fowleri m x; tinct. bellad. n v-x; syr zingiberi ʒj; aqua purj ʒj. Ft mist. Sig. One dose to be taken three times a day. Pills consisting of the leaves of bellad. and the ext., at night time may also add to the mitigation of the disease.

A GYNÆCOLOGICAL COUCH.

"H" (34, Princes Avenue, Liverpool), offers to describe to "A Country Member" a gynæcological couch, which may be of use.

DURATION OF INFECTION OF WHOOPING-COUGH.

Dr. J. T. RICHARDS (Wirral Children's Hospital, Birkenhead) writes: In answer to the inquiry of "Portusis," it is believed that the infection of whooping cough lasts for six or eight weeks after the manifestation of the disease, and that recurrence of the cough after this period is unattended by risk of infection. This view is acted upon in children's hospitals.

TREATMENT OF TRACHEAL COUGH.

Mr. SLADE INNES BAKER (Abingdon) advises "Cantah" to try inhalations of G and G. Stern's pumiline two or three times a day.

ONLY DIARRHŒA AND PODOPHYLLIN.

Dr. D. H. CULLMORE writes: In answer to "Surgeon-General," whose patient has chronic nightly involuntary diarrhœa, I would suggest change of residence; a large bandel bandage covering the whole abdomen; suppositories, cocaine, or of cocaine and belladonna zymine—the extract or the tabloids. Burroughs and Wellecome are admirable—chloride of ammonium, five grains twice a day in half a tumbler of water. In one case that I saw, four years ago, also in a boy, of all the astringents, acetate of lead was by far the best. In another fatal case (not oily) of chronic dysentery, brought on by fasting, the cure of krameria answered best. The withdrawal of fats and milk, unless of ture of krameria answered best. The withdrawal of the boy just mentioned tried this, but without any great advantage. Turkish bath, with shampooing now de-nationalised into massage, would probably do good.

As regards podophyllin, I believe it equally effectual in the liquid and solid forms. In some persons it has, however, but little purgative effect, and the form are even some forms of diarrhœa where it is very useful. Other drugs have, owing to some altered physiological condition, an effect the opposite of that which usually attends them. Thus, tincture of iron sometimes acts as

purgative; and tea, so generally productive of excitement and sleeplessness, has in certain states of nervous exhaustion, particularly in elderly people, a calmative effect. I have seen one case of herpes zoster where the only drug that produced sleep was a cup of tea, taken about 10.30 p.m.

NOTES, LETTERS, ETC.

A CASE OF DISTRESS.

A MEDICAL MAN, aged 58, with a wife and seven children under 13 years of age, has been struck down with paralysis, and is unable to practise, or do anything for the support of his family. Two of the children (girls, aged 8) have been approved by the committee of the St. Anne's Schools as candidates for election, and a gentleman has most generously offered to give £40, half the amount necessary, to purchase an immediate presentation for one of these girls, provided that the remaining sum (£90) be obtained within the next two months, that is, before May 31st.

The little money the father was able to save has long since been spent, and the family are in the greatest distress, and are now solely dependent on a small sum—ten shillings a week—granted temporarily from the Medical Benevolent Fund. The case is urgent, and the need for help immediate, to prevent the home being broken up.

The facts of the case are vouched for by Dr. Broadbent, treasurer, and by Dr. Jonson, Chairman of the Committee of the British Medical Benevolent Fund, who join in this appeal. It is hoped that the amount required to secure the presentation may be subscribed within the time stipulated. Should there be any surplus it will be applied to the relief of the family.

Donations towards the special objects in view, or offers to help in providing for the education and support of any of the other children, will be gratefully received and acknowledged by Dr. G. C. Jonson, 16, South Eaton Place, S.W., or by Dr. John M. Bright, Park Hill, Forest Hill, S.E., who will gladly answer any inquiries.

CHANGE OF ADDRESS.

MESSES. POPE AND PLANTE, manufacturers of elastic stockings, etc., have removed from 4, Waterloo Place, Pall Mall, to 139, Regent Street.

ORAL INSTRUCTION OF THE DEAF.

DR. W. MACFIE CAMPBELL (1, Prince's Gate East, Liverpool) writes: I have seen some correspondence on this subject, and a query from this neighbourhood, in a recent number of the JOURNAL. A lady, fully trained under Mr. Van Praagh and others, has commenced classes in Croxteth Road in this city. I can highly commend her as a competent teacher, and have one of my children under her care.

A CORRECTION.

SIR W. B. DALBY (18, Savile Row, W.) writes: At page 531 of the JOURNAL of March 10th, I am reported as having said: "An experience of ten years had given a mortality in cases of antral disease of 5 per cent." What I did say was "8 per annum."]

METROPOLITAN PROVIDENT DISPENSARIES.

DR. ROBERT R. KENTON (Liverpool) writes: It would appear that Dr. Paramore neither believes in sick clubs nor in provident dispensaries. Many, however, are strongly in favour of a well-conducted club system, its managers working the "wage-limit" clause closely. He also adds: "I challenge anyone to show any difference between the club system and the provident dispensaries." Well, the latter do not grant sick pay, funeral allowance, widow's fund, or give any division of funds at Christmas. Few members, indeed, go into the sick club for the doctor's sake. The fact to prove before a committee that they will want neither doctor nor drugs is one of their chief planks. They also—1. Avoid the two extremes of life, limiting membership to those of 18 to 45 years of age. 2. Exclude those of certain callings. 3. Make candidates pass a medical examination. 4. And have stringent rules against members who contract illness through venereal disease, or drink. Further, they give the member the use of the doctor from the day the former enters, the provident dispensary system deferring benefits from one to two months after entry. Are these sufficient differences? If not, there are more. Is it not well known that few club patients trouble the club doctor, generally going to the hospital, or "prescribing" chemist?

Will Dr. Paramore, or anyone conversant with the needs of our wage earning classes, hold that they are able to pay even the low medical fees mentioned in *Whitaker's Almanack*? Surely not. Well, then, how are these people to provide themselves with respectable medical treatment and drugs? The average wage of the working classes, in and out of work, may be put down at 15s. weekly. No doubt if a single man or woman had continuous pay of 40s. weekly he or she might be able to pay a doctor; but when sickness comes, or he is out of work, wages stop, and he is often so hard up as to be unable to pay his usual fee to his sick club; consequently, his 12s. of "sick pay" often also goes. Practically, then, the man has little money left, and the relations of the working man do not seem to help him much. This want of funds is the key of the provident scheme. One would have thought that the question of the necessity of having some system for supplying medical aid to those of slender means had long ago been settled. If medical men would look at the social side of this question it might help in its solution.

Dr. Paramore also says: "Contract work is notoriously bad." What will our lecturers say to this—our paid hospital doctors; our army, navy, colonial, and mercantile marine surgeons; our poor-law doctors, vaccinators, and health officers—all contract-paid? Do not our Court physicians and surgeons, with their eyes very wide open, contract to act for £200 a year, while the surgeon-apothecary secures £1,000? Enough, then, that contract work is "notoriously bad." One admits the fact that our fees are too small, and that "the good ones help to make up for the small," but the consequences are of our own making, and none other. Do not the Leicester Provident Dispensary is abused, but what earthly scheme is not? Even one notorious respectability found fault with the way in which things were managed in Heaven. But be-

cause a good many tout for hospital appointments, and treat patients for 2d. each, as at Guy's, or take commissions from druggists, these facts do not give one the right to let loose unmeasured and unrestrained condemnation on hospitals and medical men.

Let the provident dispensary system be as free from abuse as possible, so that it may command the respect of the profession. At present we doctors are cutting and hacking at each other in a most wicked and godless manner. While we are trying to acquire each other's income, we are sinking the social status of the entire profession. Therefore, let us all try and act in a more business-like way in our professional transactions. At present we are the laughing-stock of the community. Only a few weeks ago, in Liverpool, one doctor touted round the various offices for a hospital vacancy, while another sent in a large bundle of testimonials to a sweeps' sick benefit society, offering to do the work of the surgeon for "sixpence less" than their own "medical attendant."

Dr. Paramore seems ominously silent regarding the great abuse of our medical charities.

OROTAVA.

DR. POULAIN forwards us a communication from a patient, who writes to him from this new health-resort, concerning which we published last year a series of letters from Mr. Ernest Hart, showing that Port Orotava is this year very full, even to overflowing, and that the limits of the existing accommodation are overtaxed by the afflux of visitors. The accommodation of the African steamboats is spoken of with much approbation; and the new hotel opened at Laguna, the stopping place on the drive across the island from Santa Cruz to Orotava is said to be very clean and satisfactory. A new hotel has been opened called Casa Carpenter, where accommodation is to be had on very moderate terms. "There can be no doubt," this lady writes, "about the climate; it is perfect, of such lovely golden sunshine over sea and mountains; but at present there is not the accommodation necessary to satisfy all the requirements of English travellers. I am afraid they are somewhat exacting; the people who live in villas are contented because they can have their food cooked and served as they like, but in hotels folks are very much given to grumbling and fault-finding. We should frequently have the food differently prepared. I can recommend the Casa Carpenter with every confidence to reasonable people who will not expect to find the luxuries of a West End hotel and club combined. The water is good, and Dr. Perez assured me quite safe to drink." She adds that there are this year plenty of mosquitoes, and the place is not free from fleas (as are indeed few Spanish hotels), so that Keating's powder is a useful adjunct to travelling appliances. The postal arrangements are irregular, but she writes: "We have the priceless sunshine and pure sea breezes." There are already 150 English persons in Orotava, and it is stated that sixty more are expected by the next boat. It will be remembered that in Mr. Hart's letters intending visitors were informed that the accommodation was at present limited, the Grand Hotel only making up forty beds, and that the visitors would do well to ascertain beforehand what vacant accommodation might be available. There is no doubt that the singular equability of the climate, and its delightful winter sunshine, together with an absence of cold winds, or from any sudden changes of temperature after sunset such as constitute the besetting dangers of the Riviera and of Egypt, will make Port Orotava more and more frequented as a watering-place, if any place in the world can offer equal advantages of climate or a more interesting scenery; but the hotel accommodation is far from being fully developed, considering the numbers who are flocking to the island. We hear, however, that not only is the Grand Hotel likely to be considerably enlarged next year, but that a new hotel is projected on a neighbouring site, which will offer equal advantages. Meantime, visitors should be cautioned to ascertain beforehand that they will be able to obtain adequate and comfortable accommodation.

The effect of Mr. Ernest Hart's "Winter Trip to the Fortunate Islands" has been to give to Orotava a reputation which may easily overtax its existing resources, but this is a sort of difficulty which, in these days of energetic enterprise, is likely soon to remedy itself. Those who go to Orotava, however, without due notice, and without ascertaining that they can be received, will have only themselves to thank if they find a difficulty in housing themselves satisfactorily. We would recommend medical men who are proposing to send patients there at present, to communicate with Dr. Perez, to ascertain whether the patients can be satisfactorily provided for.

BRITISH QUALIFICATIONS.

A.B.C. writes: The letter of Mr. G. Pinder, in the JOURNAL of March 3rd, seems to me to invite criticism, although Scotch degrees do not need defence in your columns. Your correspondent's language is so involved, and his attitude so peculiar, that one can hardly guess the object of his letter. He confuses degrees with qualifications, talks of things English, and in the same sentence dubs them British, and speaks of "numerous" Scotch universities, so that one must conclude that his inability to sign the certificate he mentions has had a very disquieting and confusing effect on his mind. This state of mind is further indicated by his wish to throw "open" Scotch degrees to Englishmen, as English qualifications are to Scotchmen. I do not know if your correspondent appreciates in this sentence the difference between degrees and qualifications; probably he does, as the arrangement is so one-sided. I can only point out to him that the Scotch universities from which degrees emanate are at present open to "we Englishmen," who largely avail ourselves of their thorough and liberal system of education; they are open in the same sense and degree that English corporations are open to Scotchmen, "open" as long as their laws and regulations are complied with. This is the real kernel of the question. The regulations and curriculum of a university are very different to those of a mere examining and trading body like the Apothecaries' Company, which no doubt answered a useful purpose in its time, but is now out of date, as, in my view, there should be no body examining for medical qualification which does not teach or further medical science in some other way.

It is an incongruity that certain bodies of examiners practically irresponsible should be drawing large salaries from the pockets of needy students, the amount of such salaries being practically dependent on a rough and ready "result system," the more passed the merrier for all concerned. There are other abuses inseparable from a system of examination in which the examiner and candidate have never previously met, and these have been pointed out in the JOURNAL.

The last sentence of Mr. Pinder's letter seems to me the most curious and obscure of all. He states that everything English is under a cloud, in assertion which requires elucidation or confirmation, and reminds one of the

THE LUMLEIAN LECTURES

ON

THE TONGUE AS AN INDICATION OF DISEASE.

Delivered at the Royal College of Physicians, March, 1888.

By W. HOWSHIP DICKINSON, M.D., F.R.C.P.,

Honorary Fellow of Caius College, Cambridge; Senior Physician to St. George's Hospital; Consulting Physician to the Hospital for Sick Children.

LECTURE II.

CLASS 8.—*Encrusted Dry and Brown Tongue.*

THE variety about to be described is distinct enough, though it has points of contact with the two preceding classes, as a later stage of which it presents itself. The essential characteristic is the covering of the tongue with a brown dry crust, which surmounts and conceals the papillæ. It occurs as a later stage of the furred tongue, the spaces between the elongated papillæ getting filled up, as it would seem almost necessarily, and the accumulation carried up so as to level or overtop their summits. It occurs also as a later stage of the coated tongue, more particularly of that kind which has been described as plastered, the growth of the papillæ and of the epithelium in the intervals and the accumulation of parasites on the dry surface producing the result.

To the naked eye the characters of the encrusted brown and dry tongue are almost sufficiently described by these three words. It is irregularly covered with brown dry incrustation, variously broken and fissured. Sometimes the cracks are quite irregular; often the deeper are transverse, with longitudinal longer and shallower fissures, which together divide the crust into more or less rectangular scales. The surface, particularly in front, often displays, instead of incrustation, coarse elongated papillæ which are antecedent to it, while towards the back and central parts the coat covers and conceals these prominences. The colour is generally brownish, and the upper surface rough and dry, while the under part is smooth, uncoated, and only clammy. The teeth are often encrusted with brown matter.

It may be asked, Why is the encrusted tongue brown? First, because it is dry. Many animal substances dry brown, among them the white coat of the tongue. I have dried a thickly-coated white tongue at the temperature of 100°, and also at that of an ordinary room. When dry it became brown. A brown, dry, encrusted tongue, when soaked in water, became nearly white, but not quite, and brown as before when re-dried. Thus dryness appears to be the chief producer of brownness, but staining by food and medicine no doubt helps. Many coloured matters—beef-tea, wine, etc.—go into the mouth of a sick man, and cannot but discolour the tongue if the natural wash by saliva is wanting. The crusts on the teeth are probably similarly produced. They are not due to the drying of saliva on the teeth, for saliva at the heat of the body dries white.

With the microscope the chief points are the elongations of the papillæ, and their being embedded and overlaid by a heterogeneous brown mass, which will be further noticed. The incrustation differs from what has been shown to form the coat or fur, though attached to it so as to be inseparable without fracture. Sliced in section from within outwards, it presents first much epithelium, more or less horizontally arranged, flattened, but usually not old enough to have lost the power of taking carmine. Through this project long papillæ, chiefly consisting of horny, unstratified epithelium, upon the exalted summits of which rests a confused mass which constitutes the crust. While the tops of the papillæ support this material, their intervals are filled up by it. Thus there are two constituents of the covering of the encrusted tongue; first, a large growth or accumulation of epithelium, much of which is in the shape of elongated papillæ; and, secondly, a definite structure, which lies upon this and in its interspaces. The superimposed substance is mixed and irregular; much of it can be described only as amorphous; in it can be distinguished epithelial cells disposed without regularity, fat-globules, occasionally other adventitious and accidental matters, and last, not least, a multifarious collection of organisms, chiefly vegetable. In

two cases, in one during life, in the other after death, I found lying on the tongue large detached masses of dry brown crust, one of which was not less than a quarter of an inch thick. Sections of these prepared in different ways were examined; I show a diagram representing one of these sections made from a drawing which I owe to the skilful hand of Dr. Délépine. Both masses showed a profusion of vegetable organisms, chiefly micrococci and the *oidium albicans*. I am indebted to Dr. Délépine for a minute description of these organisms, which, however, I will not read. Besides these were many strands of horny or superficial epithelium, many epithelial cells of the deeper kinds, many fat-globules, and much indeterminate matter. The dry incrustation differs from the moist coat chiefly in this; whereas the major bulk of the white coat is epithelial, a very large proportion of the dark dry crust is parasitic. In the deeper parts of the epithelial structure, more especially in the Malpighian layer, there is often much profusion of nucleation or cell growth, the corium is in many cases distinctly hypernucleated and often over-injected. More rarely leucocytes are extruded within the papillæ and elsewhere.

To sum up the evidence afforded by the morbid anatomy of the encrusted dry tongue, we see first the results of the absence of friction and irrigation, most conspicuously in the accumulation which forms the crust. It is probable, also, that the elongation of the papillæ may be partly attributed to this cause. But there are also signs of increased cell formation and nutrient activity, so that we witness here a double process, over-production conjoined in larger measure with deficient removal. It is obvious that the dryness which helps to define this tongue has played an important part in it, both by want of scour and also by induration.

Coming to clinical considerations, much that has been said about the furred tongue, applies also here. It will be convenient to take together two classes which, though I have separated them for some of the purposes of the inquiry, are not to be distinguished save as the earlier and later stages of the same state. I shall for clinical purposes fuse together the tongue which is completely encrusted and that which is in the process of shedding its crust in the way to become denuded. So various are the conditions under which the encrusted tongue is seen that it is not easy to discern what the link of association may be, except the somewhat loose one of severe illness, and that of some standing. The instinctive sense of the physician carries him thus far. His looks are ominous, he talks of the "typhoid state," and he orders stimulants.

Analysing the details in the two tables before us (Nos. 8 and 9), comprising together thirty-four cases, pneumonia takes the first place in frequency with six cases; then come pyæmia with four and continued fever with three. Acute rheumatism with hyperpyrexia occurred in one instance, and erysipelas in one. In short, there is scarcely any protracted and depressing febrile disorder in which, if I may supplement the scanty records before us with unrecorded experience, this tongue is not apt to be developed. It is often characteristic of typhus by means of the black colour it then presents—possibly due to hæmorrhage into the coat (but of this I cannot speak from observation). The encrusted tongue is so commonly looked for in advanced typhoid that it is often spoken of as the "typhoid tongue," though by no means the only variety displayed in this disease. But the association with fever does not contain the whole story, nor is the febrile condition essential. This tongue may occur with its complete absence. The abstract shows that of the thirty-four cases in question, fifteen displayed a temperature above 102°, eight a temperature under 99°, in three of which it was subnormal. The low temperature was manifested with abdominal cancer, advanced phthisis, albuminuria, syphilitic mania, diarrhoea, alcoholism, and prostration from an unknown cause. Thus, pyrexia, though often present with the encrusted tongue, and no doubt, by the evaporation which it entails, helpful to its production, is by no means necessary to it. The average temperature is lower than with the plastered tongue. It is scarcely needful to inquire, after what has been said, whether this tongue is to be generally attributed to openness of the mouth during sleep or coma. The dry encrusted or furred tongue—for the two have similar clinical relations—is an especial property of coma or insensibility. I have not recorded any case in which well-marked coma persisted for more than twenty-four hours without one or the other being developed. The records are scanty, but a larger experience supports the general rule that with coma or long unconsciousness the tongue becomes as described. Many reasons are

obvious—dryness and disuse the chief. But why the dryness? It is manifest that coma, if it involve habitual openness of the mouth, must tend to dry the tongue; but if health is good in general respects, it does not appear that the mere passage of air over the tongue in respiration can produce anything like the degree of desiccation in question. I have noticed how little dryness has resulted in a person otherwise well whose nostrils have been surgically plugged, and we must take another point of view. Coma, however it acts, is connected with only a minority of cases in which the tongue becomes dry and encrusted. Putting aside all states of coma and unconsciousness, all in which the mouth has been habitually open from other causes, and all states of pyrexia, there remain many conditions, and these most various, in which the tongue has presented itself. Advanced phthisis, intra-thoracic or abdominal cancer, idiopathic anaemia, and diarrhoea have been mentioned; all were attended with much depression or prostration, and, indeed, it appears that, whatever else be present, a condition of much illness or lowered vitality runs through all and supplies the common factor. It has been shown that a similar condition of prostration often attends the furred tongue. I should have preferred to have been more explicit, but it is not easy to narrow the statement within a more strict definition. To most of the conditions the term "sinking" would be applied as indicating what is present or threatened. There is not necessarily any loss of consciousness nor any obvious failure of the nervous system. Sense and senses may be alike unimpaired. There is, as a rule, failure of circulation, of muscular strength, and of nutrition. Perhaps the term "asthenia" best implies this state. Any disturbance may be superadded, but none other is generally essential. I say generally, for direct dehydration will cause the state of tongue in question. This is seen in the effects of dry diet, and perhaps less simply in the effects of diarrhoea. It is to be observed that exhaustion by suppuration, as will be seen, causes other changes in the tongue than this.

It has been shown that the essential local change is dryness, and that this, as a rule, is not due to direct dehydration or to increased evaporation from pyrexia or patency of the mouth. That it is due to deficient secretion of saliva is a necessary conclusion, warranted by the obvious deficiency of liquid in the mouth, by the difficulty or impossibility of spitting, and by the usually fruitless result of catheterisation of the parotid, notwithstanding that acetic acid may be applied to the tongue as a stimulant to this gland. I shall revert to this point, but am not wrong so far in assuming the dryness to be, as a rule, due to suppression of this secretion. Associating this with the asthenia which accompanies it, we cannot but regard the local as the result of the constitutional state, and probably may accept it as a sign that the prostration is telling upon the functions of at least some of the organs. The bowels, kidneys, and skin do not obviously participate in the failure; but how about the gastric and other digestive juices? Observations here are difficult or impossible, but it may be conjectured that the salivary failure does not stand alone, and we may accept the state of tongue before us as an index not only of asthenia, but of a failure of certain vital functions connected with nutrition.

CLASS 9.—The Process by which the Coated, Furred, or Encrusted Tongue becomes Red, Smooth, and Dry.

The cleaning of convalescence requires no further notice; the shelving off of the coat at the tip and edges has been described. In less favourable circumstances the process of making bare occurs in this wise. The incrustation is very dry and correspondingly brittle, and the epithelium beneath it, in connection probably with the same want of moisture, does not grow properly. The coat or crust now wears off more or less at the tip and edges, in a gradual manner, and displays not the normal surface, but a red and dry one, usually covered with a delicate membrane, so thin as possibly to escape notice, but discernible to a careful eye. Under the microscope it is evident enough. After, or more or less together with, the exposure of the fore part of the tongue, the central part loses its covering along a broad stripe which reaches from this point not quite to the back. This may be an inch or rather more in width, and is the part of the tongue most exposed to the breath, and consequently the driest. The clearing is often effected by a very obvious cracking and breaking away of the crust, which may be so rapid that I have seen a much encrusted tongue become nearly naked in a day. The exposed surface may look raw, but is seldom absolutely so, for it is skinned over with the dry translucent membrane which has been described. This stretches straight along the surface, like the arachnoid of the brain, not dipping between the papillæ, the outlines of which it obscures. The bare and polished stripe is often fringed with white fur or coating as a line down each side, outside which is the nearly normal lateral margin. After a time the whole upper surface becomes nearly equally red, dry, and bare, the surface being intersected with fine or deeper lines or cracks, some longitudinal, the deeper transverse. The coating is retained longest at the root. A resumption of moisture is a sign of constitutional improvement, and precedes a gradual reclothing—too seldom observed—which restores the tongue to its normal state.

I will now bring the microscope to bear upon the process which has been described. I pass over the gradual change of convalescence to consider the modes by which the morbidly dirty tongue becomes morbidly clean. Starting with the elongated papillæ of the furred tongue, these, together with all the superficial epithelium, are often swept off accurately down to the Malpighian layer, which retains its place, and still uniformly clothes the corium. In time, or almost simultaneously, this may become covered afresh with epithelium of the horny sort, not at first as in health, but in the shape of the thin membrane of which I have spoken. Supposing the denuding process to continue, the Malpighian layer itself is removed and the corium exposed, making a surface which is uneven microscopically, though to the naked eye smooth, and necessarily red and raw. This process is attended with vascular injection, hypernucleation, and often the extrusion of leucocytes. Much of the injection and hypernucleation may be the consequence of the loss of the protective epithelium, with exposure and irritation of parts which should be covered. But in some cases it is apparent that a general inflammatory infiltration of the superficial parts precedes the denudation, and helps to produce it by a destructive process. This is most marked with scarlatina, where the infiltration is often most abundant. This may be due to the especial effect of the disease, which the tongue appears to share with the skin and throat. I have now traced the flaying operation down to the true skin. All that is special to the tongue has gone, at least in places; but more often, as I have said, the process stops on reaching the Malpighian layer, and here begins a process of repair to which I have alluded, but to which I must revert. The tongue is now red, level, and polished. To the hasty eye it looks

1 The extreme illness of many of these patients made it difficult to estimate the absence of saliva by attempts to spit or by catheterisation of the duct. The number therefore appears small. It is probable that saliva was wanting in nearly all, so far as the state of the mouth could be taken as an index.

like raw beef, a similitude often used; but the beef is wrapped in a silver paper. A continuous layer of horny epithelium, of extreme tenuity, presents itself, and resting on the more elevated eminences of what were papillæ, stretches from one to another without dipping into the hollows, like the roadway of a bridge. The hollows, however, are not empty, but contain epithelium of the deeper sort. The somewhat gradual process which I have described is sometimes replaced by one into which violence more obviously enters. This relates especially to the encrusted tongue. The felted mass of crust breaks through its deeper part, the fracture passing through the bases of the papillæ, leaving their broken rumps standing. These quickly become levelled down, and the Malpighian layer soon presents itself with a delicate membrane, as described. In this breaking away of the crust accident cannot be excluded, but more is probably due to the rising up of new epithelium from beneath, by which the brittle and mostly effete mass above is pushed from its stool. Probably something of this sort happens when scarlet fever patients and snakes shed their skin.

CLASSES 10 and 11.—*Bare, Red, and Dry Tongue.*
 In the description of the process of denudation I have anticipated much that applies to the bare tongue. The completely bare tongue, red, raw, and dry—for this state, does not seem to be attained except with dryness—is comparatively rare. The term *completely* bare or denuded relates to the completeness of the loss of the epithelium in certain places, not to its spread over the whole tongue. This change is more limited in extent than the more allowed divestures which have been described. I have already traced the process down to the Malpighian layer, which has become covered anew with a straight membrane instead of the normal serrated one. Should the repair be exceptionally wanting, this membrane is not formed, but the Malpighian layer is left to break away and lay bare the corium beneath. Occasionally it would seem that the destruction occurs after the formation of this membrane, which it involves, for the broken bits are often seen overhanging a tract of excretion. The exposure is effected not quite abruptly; the neighbouring epithelial structures shelve off until the patch of complete exposure is reached. Here no epithelium of any kind remains; the corium is left bare to the cavity of the mouth, and is even sometimes itself approached upon. I have not seen this process descend quite to the surface, though sometimes it has approached, the muscular fibres. The exposed corium sometimes shows little change of structure, more often it is infiltrated with leucocytes, sometimes to such an extent that the surface appears to be entirely composed of them. There is also injection of the blood-vessels. The infiltration is probably generally due to irritation by the unaccustomed contact of the contents of the mouth, and is subsequent, not antecedent, to the covering. Even in scarlatina, where the inflammatory denudation may possibly be a part of the eruption, the enucleation is greater in the exposed parts than elsewhere.
 For clinical purposes I shall place together two classes that cannot be always distinguished except with the microscope, and give a common consideration to the red denuded tongue, whether

absolutely bare, or protected only by the thin membrane which has been described.

The qualities of redness, smoothness, and dryness are nearly related. If the tongue be uncovered with the opaque superficial epithelium it will necessarily display the vascularity of the deeper parts; and this is usually increased because the tongue is irritated by exposure. The denuded tongue is dry partly because the loss of epithelial protection allows of increased evaporation from its surface, but chiefly from want of saliva. Want of saliva may encrust the tongue; it may also make it bare: of this more anon. This variety of tongue is that on which aphthous growths are most apt to occur. It presents itself in diverse circumstances, generally of exhaustion. The most prominent fact is its occurrence as the result of exhaustive discharges, especially of pus, and it is linked with the constitutional state described as hectic. The table shows that of thirty cases seven were connected with an ostensible escape of pus, including one case of lumbar abscess, one of empyema, two of discharge of pus with the urine, one dysentery with open hepatic abscess, and two of advanced phthisis with much expectoration and diarrhœa. Besides these, in which loss of pus was obvious, there was one instance of profuse dysenteric flux in which an abscess had formed in the liver but not found exit; two cases of lardaceous disease with the customary discharges, and five of advanced diabetes, brought to fifteen, of thirty, the number of instances in which this state of tongue was associated with exhausting discharges. The frequency of diarrhœa deserves remark. It has not been shown so far that simple diarrhœa causes it, but diarrhœa was prominent with other morbid conditions, notably dysentery and phthisis. The most striking tongue of this kind which I ever saw (it was as red and almost as smooth as sealing-wax) was in the case already referred to of acute dysentery, with unopened hepatic abscess. I have to thank Sir Joseph Fayrer for giving me some of his Indian experience, with regard more especially to tropical diarrhœa. In advanced cases of this, the tongue, he says, is shrunken, red, polished, and smooth; the papillæ have disappeared, and the epithelium is stripped off in patches. The gums, lips, and buccal mucous membrane are often aphthous. The tongue is very tender; alcohol or salt causes great pain in passing over it. As significant signs of convalescence, Sir Joseph notices a softening of the tongue, a change of the red to pink, less of tenderness, and the reappearance of the papillæ.

There remain cases in which the red, dry, smooth tongue has presented itself without any obvious association with discharge. Among them were five of pneumonia, all with much depression; one was double, and attended with maniacal delirium; one was complicated with delirium tremens; another was in a drunkard; two were attended with great prostration (not explained). There were two cases of typhoid, of which one was characterised by sleeplessness and nervous agitation; one of tubercular peritonitis, one of biliary colic, and one of a dangerous gorge of grapes,—all these conditions being attended with much depression. Advanced tubercular disease presents itself as a not infrequent associate of this tongue; there were five cases of this sort in the thirty. Pyrexia is not needful to the production of this tongue, though often present. A temperature not above normal was found with it in cases of lumbar abscess, pyelitis, lardaceous disease, several of diabetes, and some under dry diet. As compared with the encrusted tongue, there is no great difference in the frequency of pyrexia; both may occur without it; the average temperature of the bare tongue is somewhat lower than that of the encrusted.

To sum up the circumstances of the red, smooth, dry tongue, they are usually more chronic than those of the encrusted. This must be so, since the one is often a later stage of the other. Exhaustion by discharge is frequent with the smooth tongue; or, if this be absent, there are generally especial circumstances of prostration or depression, which are often connected with the abdominal organs. This tongue implies failing nutrition. The clinical evidence accords with the indications of pathology in this respect. The saliva is, I believe, always deficient, though I think it is not usually so completely absent as with the encrusted tongue. It will presently appear that in certain circumstances want of saliva prevents the growth of epithelium; though this failure of growth may also have its connection with a more general impairment of the nutritive process. Increased moisture of the tongue is a sign of the best omen; this is usually followed by re-covering, and possibly by recovery.
 The prognosis with this tongue is bad: of the thirty cases in

¹ Mouth invariably dry, but special observations on saliva not generally made, not reliable.

which it was recorded, sixteen ended fatally. The mind commonly remains clear, though the patient may be weak unto death.

CLASS 12.—Cyanosis or Venous Congestion of the Tongue.

This tongue is characterised mainly by a superabundance of recent or deep epithelium, which occurs in circumstances indicative of excessive production, not deficient removal. It especially belongs to heart disease or cyanosis from some other cause. To the naked eye there is a bluish or purple colour, and a smooth, wet, slippery surface like that of an eel, upon which the papillæ are almost indistinguishable, as if fused together, or in some other way deprived of their separating intervals. Upon this substratum may be overlaid more or less of one of the grades of coat which has been ascribed to the partial obscuring of the deeper characters. Microscopically, the most noticeable peculiarities are superabundance of the recent epithelium, vascular injection, and hypernucleation. The deep epithelium is amassed thickly over the surface, sometimes rising to the tops of the papillæ, but leaving these exposed, sometimes overlaying them completely, so that the whole papillary structure is embedded. The Malpighian layer shares in the overgrowth. The horny epithelium is usually deficient, as also are superficial vegetations, so that the surface is often abnormally clean and smooth. The corium and deeper parts are enormously over-injected and over-nucleated, and the fibrous tissue of the corium is often coarse and hypertrophied. The appearances presented suggest the means by which they are produced. In the excess of deep epithelium and of nucleation we see evidence of increased growth, while the generally clean surface shows that wear is not wanting. The essential factor is a hypertrophic process connected with mechanical congestion. The thick covering of the tongue with epithelium of the deep character, is not confined to heart disease or cyanosis. My classification was based on what can be surely recognised with the naked eye. Had microscopic examination been the criterion, a separate class must have been made characterised by excess of epithelium of this sort. But this peculiarity is not obvious. The horny or superficial epithelium when wet is white and conspicuous; the deep epithelium is neither: its presence in excess may be inferred from the appearance of cyanosis, and guessed at from some degree of paleness and fulness. Such a tongue may be thickly covered with superficial epithelium, by which the deeper characters may be hidden. Taking as the standard great excess of deep epithelium as displayed after death by the microscope, I find that of nineteen cases four were connected with cyanosis (cardiac or pulmonary), six with chronic albuminuria, two with acute tuberculosis, two with pyæmia, and one each of the following—pneumonia, diphtheria, prityphlitis, lumbar abscess, and leucocythæmia. Thus we see this form of epithelial hypertrophy in circumstances of three kinds—venous congestion, albuminuria, and diseases attended with pyrexia. To take the last first, no details of temperature are needed when once the disorders have been named. The overgrowth was no doubt a direct result of the increase of body heat on principles which have been stated. No further reference need be made to the congestion of cyanosis; but

I must halt for a moment upon the question of albuminuria. I have sections of eight tongues from cases of chronic renal disease, mostly the granular kidney; in six there was such accumulation as has been described; in two there was less, but enough to show the tendency. Why in these cases should the epithelium grow in such profusion? Not from pyrexia, for there usually was none; not from venous congestion, of which there was generally no sign. Was the hypertrophic process due to the increased arterial tension so constant in the circumstances? If this be so, we should find hypertrophy of epithelium elsewhere. The reason may admit of doubt; but I think none need apply to the observation that in chronic albuminuria certain parts of the lingual epithelium are remarkably increased.

I have now concluded the separate consideration of each variety of tongue. I shall proceed to make a few observations relating to some general conditions which belong to it or affect it, and while I do so I must ask the College to tolerate a certain amount of repetition which it will not be possible to avoid.

Having regard to the importance of dryness as necessary to some of the most significant alterations of the tongue and its value *per se* as a clinical indication, I shall take this quality into consideration, abstracted, as far as may be, from others. Before doing so I shall venture to delay the College with a few observations upon the saliva.

On the Saliva.

I am satisfied that of all the immediate causes which make the tongue dry, or tend to do so, arrest in the secretion of saliva is the most important. In advanced conditions of dryness, not only is saliva obviously absent from the tongue and mouth, but the patient cannot spit. When the dryness is less complete, he will sometimes produce with difficulty a little spittle, which is often tenacious or bloodstained. Frequently, in the absence of saliva, such patients will, on the request to produce it, hawk up a little mucus from the throat, which is clearly a different thing. I have made many experiments upon the salivary ducts—or rather, I should say, upon those of the parotid, which lend themselves most readily to the purpose. A tube passed into one of these channels in health could generally be made to drip saliva somewhat abundantly by the application of acetic acid to the tongue, or the secretion could be seen working its way out by the side of the tube. When the tongue was dry it was usually impossible to obtain any by such means. With advanced and complete dryness I have never been able to get a drop; with lesser degrees often a little. These observations show the dryness to be, as a rule, due to deficient secretion of saliva, not to its drying on the tongue, as has been supposed by some. This failure of secretion appears to be of much significance. It is not possible thus to gauge any other of the secretions which are concerned in the digestive process; but it is, at least, probable that the gastric and others may be similarly affected. It is a matter of immemorial experience that the dry tongue, more particularly that which is also encrusted, is incompatible with the digestion of solid food; the physician orders liquids and stimulants. This ancient practice has been arrived at not by reasoning, but by a less unsafe though a longer road—experience. We may be sure that there is natural truth at its foundation, though we may not know what that truth is. Provisionally we may assume that a deficiency of saliva, if it depend on other than local causes, goes with a deficiency of other juices concerned in digestion. At the same time it would seem that other secretions—those, for example, of the bowel, the intestines, and the skin—do not take part in any failure of secretion which may be supposed to exist. Putting aside cases where an excess of some secretion, as with diarrhoea or diabetes, has been contributory to the dryness, there are many of daily experience where, together with a dry tongue, the urine is fairly abundant, the bowels free, and the secretion of the skin not wanting or even excessive. If, therefore, it be presumed that the failure of the salivary secretion is associated with a similar failure elsewhere, it is clear that the arrest is limited, not common to all the glands of the body.

I may add a few words upon the action of saliva upon the coat of the tongue; we have seen that, as a general rule, as the tongue becomes more and more coated, especially with acute disease, it gets drier and drier. This association of want of saliva with increasing coat suggests the question whether the secretion has any solvent action on the coat, so that this thickens from the absence of normal solution. This must be answered in the negative. I have taken coated tongues and kept similar pieces of them, one in saliva and one in water, for periods ranging up to sixty-eight

ours. Then, making sections of each in the usual way, I have satisfied myself that there was no greater loss of epithelium in saliva than in water, and the same result has been given when the experiment was conducted at a temperature of 100° F. as at the ordinary temperature of a room. Whatever effect, therefore, is to be attributed to want of saliva, it is not by less of any solvent action.

Other causes have been shown to conspire to make the tongue coated, but it would seem that want of saliva by itself will do this. A boy was brought under the care of my colleague, Mr. House, with, as was believed, a fracture of the base of the skull. He had left facial paralysis, and an injury apparently of the chorda tympani on this side. The tongue was normally protruded, but the left half, sharply defined by the median line, was dry and presented a milky appearance. The suppression of saliva was probably the cause of the coat, though other effects of nerve injury could not in this case be absolutely excluded.³ I will take a simpler case reported by Mr. St. Clair Buxton. A lady had rumps, after which her mouth became quite dry. The tongue, gums, cheeks, palate, and pharynx presented a "fearfully dried up state." The tongue was thickly coated with a tough, brown fur, which was horn-like and so hard that it sounded under a nail like the cover of a book. After ineffectual treatment by other means, the salivary ducts were probed, the glands galvanised, and the secretion restored. In the course of the following day, Mr. Buxton tells me, in a letter for which I have to thank him, the fur became soft and spongy, though it had previously been as hard and dry as wood; in a week all had cleared off, and in a fortnight or three weeks the tongue was perfectly normal. The fur stripped off in patches, leaving a rather raw surface underneath, which gradually assumed a natural appearance. It has been shown how closely the conditions of furring and encrustation are associated with deficiency of saliva, and inferred that these are largely the physical results of the ensuing dryness; the normally wet surface is soft and liable to wear; deprive it of moisture, and it becomes horny and resistant to it; besides which, with no saliva solid food is unacceptable. So that while induration is created attrition is reduced; and in general terms, and up to a certain point, it holds good that the less saliva the more coat.

But there is another relation between the secretion and the covering, and that of an opposite kind. An interesting case of atrophic suppression of saliva was published by Mr. Rowlands, of Great Crosby,⁴ and I have to thank him for further particulars by letter. Ten years before the date of the report, a lady, aged 60, underwent sudden and complete suppression of the saliva, after a nervous shock. Since this the mouth and tongue have been perfectly dry. The tongue now presents the appearance of a piece of raw beef; it is perfectly clean, and intercepted with superficial fissures; no papillæ are to be seen with the naked eye, though to be made out with a lens. Here is a typical red, dry, leathery tongue, sequent, and probably consequent, upon simple deficiency of saliva. It is scarcely necessary to revert to the red leathery tongue of disease, of which deficiency of saliva has been shown to be a constant, if not a necessary, attendant. These experiences, showing coating and denudation from the same cause, are not so contrary as at first sight appears, for many smooth tongues were formerly rough. The difference is largely one of degree: furring and encrustation are early results of want of saliva, and denudation a late result. It has been shown that with the bare tongue of constitutional disease two agents are commonly present; want of saliva, and failure of general nutrition; but that want of saliva by itself is able to cause bareness is shown by such cases as that reported by Mr. Rowlands. Of the *modus operandi* I am long in doubt. The epithelium is fed by the blood, not by the saliva. Why does it waste in the absence of the non-nutritive fluid? Conversation with my colleague Mr. Bennett has, I think, given the clue. The epithelium, though not nourished by the saliva, needs to be kept moist by it, otherwise it cannot assimilate what is provided by the blood. Be this as it may, a general law may be formulated; the tongue tends to become smooth whenever a long time it is kept dry from deficiency of saliva, or possibly from other causes.

For this observation I have to thank Mr. Peel Davies, then house-surgeon. *The Lancet*, vol. 1, 1888.

Mrs. FLORA SCHLAMM, of New York, aged 102, is said to have had 180 descendants. Her great-grandfather lived to be 120.

THE PATHOLOGY OF ABORTION IN RELATION TO TREATMENT.

By MURDOCH CAMERON, M.D.,

Physician Accoucheur to the Glasgow Western Infirmary; Assistant to the Professor of Midwifery, Glasgow University.

It is not my intention to enter fully into the wide and complicated field of study as found in pathology relative to abortion, but simply to bring before your notice three specimens, which may interest as well as show the importance of a careful examination of the discharged clots in every case of abortion. I am afraid it is too much the custom to take the patient's description of the nature of the discharge, which is generally summed up as "a bleeding," or a "something that has come away."

Now, looking at the first two specimens, we see at a glance that there is a great difference in their appearance, and it is in being able to appreciate the reason for this that the accoucheur can carry out the proper treatment, and be alive to the dangers which may attend the one case rather than the other. Of course, in the early stage of abortion, say at the first month, there is the absence of the usual signs of pregnancy to guide us, and women them-

Fig. 2.—Embryo, sixth week. A. villi of chorion; B. umbilical vesicle with portion of amnion to the left.

selves frequently look upon the discharge simply as a period. If the ovum be discovered, it is found to be very small. In the second month, however, the absence of the last period, as well as the character of the pains, generally makes the patient suspect pregnancy.

If the discharged clots are carefully examined, the embryo will usually be found surrounded by its membranes, the amnion and chorion with its villi, some of which are found penetrating the decidua reflexa. This is well seen in Specimen I, in which a separation has been effected at the circular zone, marking the junction of the membranes of the ovum with those of the uterus, which, instead of following the ovum in its passage, remain attached to the uterus. You see the appearance of the discharged ovum is that of an ovoid mass, the surface smooth and rose-coloured, unless where the villi are exposed. These in the specimen are seen floating in the fluid. An incision in the wall has

³ Read in the Section of Obstetrics at the Annual Meeting of the British Medical Association held at Dublin in August, 1887.

cut successively the decidua, the chorion with its villi, and the amnion, thus allowing a full view of the cavity with the suspended embryo. At times the decidua gets divided, and so allows the enucleated ovum to escape, when it is seen entirely surrounded by the villi, which give it a shaggy appearance. This is very well seen in Specimen II. In such cases patients require more attention than in the preceding one, as the danger from hæmorrhage or septicæmia has to be guarded against if the membranes do not come away.

In this specimen the chorion was carefully divided, and the umbilical vesicle discovered. It is marked B on the card. A portion of the chorion and amnion was removed to obtain a clear view of the embryo, which is about the sixth week.

There is a popular idea that prostitutes are less subject to pregnancy than other women, but M. Serres has remarked that when they were cared for in a division of La Pitié, the excessive losses were as rare as in others, but the periods were sometimes delayed, and ended by the expulsion of what they called "*un bouchon*." He gave no heed at first to the expression, but having directed his attention to embryology, it was easy for him to detect in this discharge a portion having all the characters of the human embryo, and he was able to collect a large number in a short time, which had been expelled at the fourth or fifth week from girls 18 to 20 years of age.

In the third specimen which I show you, the ovum was expelled covered by the decidua vera and reflexa, which are still separate from each other. Several changes may be produced by any effusion of blood, and the appearance of the ovum is often very much modified, but this depends on the stage of development. Almost till the end of the second month the blood which escapes tends to surround the chorion. If a vessel in these circumstances ruptures, the blood will insinuate itself between the villi, and gradually invade the whole surface of the chorion. The ovum takes then a fleshy appearance. If the outside membrane is removed the chorion is found covered with coagulated blood, which is firmly retained by the ramifications of the villi which are imprisoned in its thickness. In this third specimen bleeding has occurred; but, as you will notice, it has been limited to one particular spot in the decidua reflexa, and forms a solid swelling, about the size of a nut, which has been incised at the point A to reveal the clot. It is difficult to explain in these cases the reason why the decidua vera is at times thrown off, as in this case, whilst in normal pregnancy it remains adherent to the uterine wall nearly till term.

Concerning the complications which might arise in such cases, those from hæmorrhage and septicæmia, or both combined, are the most common. The bleeding may be moderate in a large number of cases, yet at times it may be very alarming. This bleeding may be met with either at the outset, when the embryo is separating, or after it has been expelled, and the membranes yet remain within the cavity of the uterus, or even after complete delivery. The bleeding may be continuous or intermittent, even with days between the attacks. Sometimes the discharge arrested in the passage becomes clotted, and is expelled in a mass, which the physician is apt to mistake for the contents of the womb, unless he takes care to examine for the embryo and membranes.

Usually the bleeding ceases with the discharge of the embryo and membranes or placenta.

Should it continue it is likely that there is a portion retained within the cavity. If a small portion of the placenta remains adherent, the bleeding may continue for weeks.

If the odour of the lochia becomes foetid, we should be on our guard against septicæmia. The odour is very persistent, and the finger with which the patient has been examined retains the taint, in spite of repeated washings and scrubbing with a nailbrush.

The treatment adopted will determine the result for better or worse.

I do not wish to speak of the preventive treatment of abortion, but would like to say a few words on the treatment of these complications. To avoid the manufacture of complications, if I may so speak, I would recommend that the membranes should be left intact, and encouragement given to complete expulsion. If the membranes are ruptured, one should not be in a hurry during the earlier periods of pregnancy, but should pay special attention to the cleanliness and antiseptic condition of the passages, by making use of repeated injections.

Should the placenta be retained, I have seldom had much difficulty in extracting it with the fingers, and must say I have very little faith in the use of instruments for its extraction, unless when it is found protruding through the os. Some have recommended the use of a blunt curette, whilst others prefer a sharp one, with which they profess to remove the *débris* of the membranes. In addition to this, they either dilate the os to allow of such an operation, or they drag the uterus down by means of forceps. Now is such treatment reasonable in all cases? Is retention of the placenta so common and so frequently dangerous as to justify a procedure which is itself not without danger to the patient? I emphatically say No, and, after a very large experience, have no hesitation in condemning such practice. Why, in one case, after the uterus had been scraped, cauterised, and injected, to the surprise and chagrin of the operator there was expelled the next day an embryo minus the legs. Besides, with the curette you are working in the dark, and cannot fail to wound the healthy membrane and so assist septicæmia instead of preventing it.

If membranes alone have been retained, with proper antiseptic precautions there is little chance of evil resulting. Besides, when one considers the amount of injury that an inexperienced person can inflict with a uterine sound, we should surely pause before placing in the hands of every practitioner a curette, be it sharp or blunt, with the assurance "This is the real cure, use it."

In treating the hæmorrhage I generally make use of an antiseptic tampon, with the application of a well-fitting firm bandage, and usually find such means sufficient. I cannot say that I have got good results from ergot. Where spasm or rigidity of the uterus is the opposing cause of the escape of the placenta, I have frequently had good results from the administration of opium in the form of a two-grain pill.

Whenever a finger can be passed within the uterus, by fixing the fundus with the free hand little difficulty is experienced in extracting the portions retained. If there should exist any symptom of septic poisoning when the patient is seen for the first

Fig. 1.—Embryo, eight weeks. Portion of membranes removed. A. Amniotic cavity; B. decidua; C. villi of chorion; D. embryo.

time, I always make use of frequent antiseptic injections, say, every two hours.

Concerning medicinal treatment, I may say that quinine is freely given, and sometimes along with it salicylate of soda. Where everything has been discharged, and bleeding continues, very satisfactory results have been obtained by the administration of tincture of steel and ergot.

In conclusion, patience, I consider in such cases, will do less harm than meddling interference.

Dr. LOMBE ATTHILL confined his remarks to the treatment of cases in which abortion could not be averted. In such, if the hæmorrhage were alarming, plugging was the most certain mode of controlling it, but if used it was essential that the plugs should be removed after the lapse of, at most, six hours, when the uterus should be washed out with an antiseptic solution. But it was very seldom necessary to plug.

by washing out the uterus with a stream of hot water, a method which, if carefully carried out, was perfectly safe and nearly always efficient, the contents of the uterus being in the majority of cases soon expelled. He also expressed his disapprobation of the forcible removal of placenta in the earlier months of pregnancy till time was given to show whether it would not be cast off and expelled.—Dr. J. A. BYRNE said he was of opinion that, as a rule, the hæmorrhage accompanying, or preceding, or following abortion was not dangerous and did not terminate fatally; but still cases had been mentioned where death from that cause had occurred, so that we should be always ready to stop it if events called for interference. He agreed with Dr. Atthill that the washing out of the uterus with hot water was a most useful adjunct in this form of hæmorrhage. We must also attach great importance to the use of the *laminaria digitata*, and Dr. Robert Barnes's dilators and rapid dilatation if necessary, and if possible the removal of the ovum. He might mention that he was one of the first to draw attention to the difficulty in some cases of removing the placenta at an early period of gestation. Before the transformation of the chorionic structures and the formation of the placenta

there was not much difficulty in removal or expulsion, but about the fourth month the placenta was intimately soldered to the uterus. What first attracted his attention to this was a case in which a lady being almost moribund from hæmorrhage he proceeded to remove the placenta with his fingers; he did succeed after some time, but he was so much struck by the dense attachment of the placenta that he determined never again to attempt the removal, but to try to stop the hæmorrhage and allow separation and expulsion. He had lately seen a case in which fatal tetanus supervened upon an abortion.—Dr. AUST LAWRENCE stated that when the hæmorrhage was excessive he always plugged the cervix uteri with carbolised lint, and then, when the os was dilated, he cleared out the contents of the uterus with his fingers. If the contents could not be cleared out he passed into the uterus an iodoform bougie and plugged with iodoform wool, and then in twenty-four hours he could clear the uterus, and if he could not do so he repeated the

process.—Mr. LAWSON TAIT was of opinion that anyone who knowingly left a piece of placenta after a miscarriage might well lay himself open to a charge of gross carelessness. There was no need of any dilatation or of the use of any sharp curette. His (the speaker's) "alligator" ovum forceps would remove anything which had been left without any risk.—Dr. MURPHY (Sunderland) said that had he not heard the two distinguished members of the Dublin Obstetrical School who had preceded him advocate its use, he would have believed that speaking of the vaginal tampon as in use in the year 1887 was an anachronism; surely the place to plug was not the vagina, but the cervix, and the material not cotton wool—antiseptic or otherwise—but the caoutchouc hydrostatic bags of Robert Barnes if the cervix was large enough; if not, the instrument used by Professor Tarnier. On the question of treatment of the retained placenta was not Dr. Lombe Atthill, in advocating expectancy solely, relying on his experience as Master of the Rotunda Hospital, where he or an assistant Master was always

on the premises ready for any emergency that might arise? But how about his private patients, or those he saw in consultation at a considerable distance? Was it safe, however, in the one case or the other to leave a placenta *in situ*, and expose the patient to the risk of hæmorrhage and septicæmia? For his own part, he would not feel justified in doing so, and he invariably removed the placenta, the patient being chloroformed, and a hand introduced into the vagina and one or two fingers—the best instrument we possessed—into the uterus. There was no doubt, however, that for the operator it was a difficult, tedious, and even painful operation, and one to which no one could look forward with pleasure.

ASTON MANOR (Population, 63,637).—This district is fortunate in having a very low death-rate, considering the density and the social position of the bulk of its inhabitants. The average for the last seven years is 15.8 per 1,000. There were in 1887, 955 deaths registered, or a rate of 15 per 1,000, which was 2.8 lower than in 1886, but 1.4 per 1,000 above the rate for 1885. Mr. Henry May states that the deaths were increased to a large extent by the injurious effects upon health of the very long and severe winter, the cold weather being prolonged until the end of May, and the temperature in every one of the first five months of the year being considerably below the average. The mortality was also increased by the long, hot summer, which caused a large amount of fatal illness amongst infants. There had been an increase in the deaths from whooping-cough, but no exceptional mortality from any epidemic outbreak. Typhoid fever was less common than usual, only 17 cases coming under notice. Measles and scarlatina, though somewhat prevalent, assumed so mild a form that the mortality was slight. The deaths from diarrhoea were chiefly among infants. Mr. May confesses that the sanitary improvements of late years have failed to diminish the severity of this disease, and offers the explanation "that the infants are born with more inherited debility of constitution than formerly, and fall sooner victims to exhausting disease." He accounts in a similar manner for the increased infant mortality from bronchitis.

A CRITICISM OF THE MIDWIFERY FORCEPS IN GENERAL USE.¹

By WILLIAM STEPHENSON, M.D.,
Professor of Midwifery in the University of Aberdeen.

As a Scotchman, it is with some degree of diffidence that I venture to introduce this subject, seeing that a well-known authority has stated that "it is not to the land of the mountain and flood that we are to look for opportunities of acquiring experience in midwifery of this difficult kind; it must be in great centres of population—London, Manchester, Liverpool, Birmingham, Dublin." However, since both his geographical and historical knowledge are at fault in making such a statement, I may take courage, and introduce a subject which is of interest not only to the obstetricians of the large centres of population, but likewise to every country practitioner.

A medical man cannot, like a dentist, provide and carry about with him a number of forceps ingeniously modified to meet varying conditions. The necessities of practice demand that he should have but *one* pair, suitable for the ordinary and easy cases, but at the same time capable of meeting any contingency; not cumbersome to carry about, and simple in construction, with no weak point, liable to snap when severely tried. It is evident that such an instrument must belong to what we may speak of as the ordinary type of midwifery forceps, and not to the complicated and formidable looking traction forceps of recent years. Most of the forceps in general use are serviceable, but each and all have their weak points or defects; none can be said to combine in themselves the best features which experience has evolved. What is required at the present time is not the invention of novelties, but the judicious combination of such characters in the various instruments that have commended themselves to the profession at large.

It would be a matter of great importance if an Association such as this (by committee or otherwise) would thus arrange an instrument which would be known as the British forceps. They could be altered, as in the course of years new modifications commended themselves to the profession; and the young practitioner, when providing himself with instruments, would be guided by the general opinion of the profession instead of that of a single person. As a contribution to this end, I would submit the following criticism of the forceps in general use.

Amongst the many contributions to obstetrics which the authority above referred to has made, not the least is the introduction of an instrument which has been largely adopted. Barnes's forceps are well-known, but those who are unfamiliar with obstetric history can but faintly realise the good service he has done in England, in combating the dread of a powerful instrument, and exposing the fallacy of there being safety in weakness.

A formidable rival to his instrument is that of the late Sir James Simpson. No single form of forceps has, perhaps, been more generally adopted. Unfortunately, however, they have become stereotyped, and have undergone no modification for more than a quarter of a century. Had he lived it would in all probability have been otherwise. The process of evolution is to be seen in his entirely discarding the short forceps; and, had it not been interrupted, his long forceps would probably have been made slightly longer, and, perhaps, otherwise modified.

These two forceps, Simpson's and Barnes's, may be taken as the types of those in general use; and a comparison of one with the other will be found to cover most of the important points to be considered. The day of short forceps has gone by, and there is a very general consensus of opinion in favour of the pelvic curve, so that the question of "straight *versus* curved" need not be discussed.

1. *The Length.*—As to the length of the instrument, those who have been accustomed to use Simpson's forceps will agree that they meet the requirements of the vast majority of cases, even where the head is at the brim. Dr. Barnes totally misrepresents the capabilities of the instrument when he states in his latest work, "if one be accustomed to use a comparatively short double curved forceps, like Simpson's, which will mostly fail to seize the head at the pelvic brim." In his writings he has several times repeated

this opinion, which is at variance with that of most men who have been in the habit of using Simpson's forceps. I have never failed with them to grasp the head, even when above the brim; still I am at one with him in regarding it as an improvement were Simpson's forceps made of equal length with those of Barnes; it would render more easy their application in the high operation and give increase in power.

2. *The Handles.*—Less attention has been paid to this point than its importance deserves. The value of a pair of forceps lies quite as much in the form of the handles as in that of the blades. To be readily serviceable they should properly balance the blades in the hand; and this principle at once discards both the very short, as seen in Matthews Duncan's forceps, and the unduly long and heavy, as in the French type. The form of the handles determines not so much the amount of force that can be exerted as the conservation of the force. What is of importance is to avoid fatigue to the operator's muscles and the preservation of "the delicacy of diagnostic touch and the exactly balanced control over the movements" which is lost when fatigue is produced. For this end I have no hesitation in discarding all others and giving the preference to the well-marked type of handle found in Simpson's, that properly should be called the German handle. More than any other form it lends itself to comfort in grasping and readiness and variety in the mode of traction. One important characteristic is the hollowed shoulder at the head of each handle. For facilitating traction it far surpasses the device of the ring in the shanks, as in Barnes's and other forceps. Dr. Barnes has admitted that the shoulders answer the purpose better than the ring, yet strangely enough he has not adopted them.

The advisability of curving the handles so as partly to meet the difficulty of exerting traction in the proper direction will be referred to further on.

3. *The Lock.*—The general consensus of opinion is so strong in favour of the Smellie or English lock, that it need not be discussed in comparison with the button and mortice, or the screw. The fancied gain in the Ziegler lock is delusive; if there be a difficulty in locking, the blades are not in a position for traction; if the latter are so placed that traction can be made, there will be no difficulty in locking.

4. *The Parallel Shanks* have now been adopted in all the best forceps. It is here that a slight addition to the length is required in Simpson's forceps, so as to bring the lock more external in the higher operations. If the German handle be adopted, there is no need for the semicircular bow which forms a ring with its fellow when locked.

5. *The Pelvic Curve* has also now been decided, and does not differ in the two types of forceps under discussion.

6. *The Form of the Blades.*—The objection to thin springy blades is now well understood; several specimens of the Barnes's forceps I have seen err in this respect, a fault probably of the instrument maker more than the author. The actual form of the blades is to a large extent dependent upon the fenestræ. One extreme is found in Taylor's narrow forceps, so made for a special purpose; the other extreme is met with in several of the American forceps, as in those of Hodge, Smith, and Wallace. In them the fenestra is wider than in the English types. An intermediate form is preferable. In both Simpson's and Barnes's the fenestræ are too narrow. An increase was first suggested to me by a pair of forceps by the late Dr. Angus Macdonald, and since I have adopted this modification I have been fully conscious of the improved grasp, and greater retentive power of the blades so obtained. Slight as the modification is, I am certain no greater improvement could be made on the present type of forceps.

7. *Axis-traction Rods.*—It is extremely doubtful that the profession will ever lay aside the ordinary forceps, and take to one or other modification of Tarnier's instrument. The latter are essentially so much more complex and cumbersome that it would require a much greater deficiency on the part of ordinary forceps than actually exists to produce the revolution in general practice. Still it must be admitted that a defect in the ordinary curved instrument has been pointed out. This question I have discussed at length in this JOURNAL (August 28th, 1886), and have shown that the defect may be overcome by a much simpler method. Increasing experience in the use of the simple tractor, in the form of a hook, assures me that all the advantages claimed for the complicated apparatus can be obtained by the simple contrivance readily applicable to any forceps. It enables the operator to change the direction of the force in any way required; and gives much greater facility in employing both hands at once; it likewise diminishes the risk of

¹ Read in the Section of Obstetrics at the Annual Meeting of the British Medical Association held in Dublin, August, 1887.

fatigue by diminishing the strain upon the hands, and is simplicity itself in construction. The same end cannot be gained by curving the handles, as proposed by Aveling and others. The object is thereby attained in part only, for whilst traction can certainly be made with curved handles more directly in the required axis, yet a change in the direction of the force can only be made by changing the hold upon the head. With the tractor, on the other hand, the direction of traction can be changed at will without changing the grasp of the blades on the head.

The forceps which I now recommend are Simpson's, modified according to the opinions stated above, and embody such changes as we can suppose Sir James Simpson would himself have adopted had he lived. The instrument is lengthened by an inch added to the shanks, and the fenestræ are increased in width on the convex side by a quarter of an inch. The changes appear trifling; but experience has convinced me that they materially enhance the usefulness of the instrument. With them I would couple the simple forceps tractor, and, so armed, I am certain the practitioner will be able to cope with any difficult case where forceps are applicable, whilst at the same time the simplicity of the instrument is retained.

ON THREE CASES ILLUSTRATIVE OF RENAL SURGERY.¹

By KENDAL FRANKS, F.R.C.S.I.,
Surgeon to the Adelaide Hospital, Dublin.

THE surgical treatment of stone in the kidney is of such recent date that I need offer no apology for bringing forward at this meeting of the British Medical Association three cases, the first in Ireland, in which operative measures have been resorted to. Taken together, these cases are very instructive, each of them presenting features, both in regard to their history and the results of operation, which I think are well worthy of consideration. The first case has already been published in the *Annals of Surgery* for January, 1887. It represents a case in which a stone, which when dried weighed 171.3 grains, was readily detected both by the finger and by an exploring needle through an incision in the left loin. The second case was one in which the symptoms were almost conclusive of renal calculus, and yet through a lumbar incision careful manipulation with the fingers and free use of exploratory punctures failed to reveal the presence of a stone. In this case the kidney was not incised. The third case was one in which exploration with the finger and exploring needle also failed to detect a stone, and yet, after a free incision was made into the substance of the organ, a small calculus lying in an abscess cavity was found to exist. These cases, then, are typical cases of the varying conditions which may confront the surgeon in his search after a stone in the kidney; and as they open up several practical fields of thought, I will shortly sketch the history of each.

The first case was that of a man, aged 28, a silk weaver by trade, on whom I operated on May 6th, 1886, for stone in the left kidney. The history of this condition dated back for about six years. He had previously enjoyed good health, but had been a heavy drinker. In the winter of 1879-80, during one of his drinking bouts, he had rigors, followed by a feverish attack, and a fortnight later suppression of urine, which lasted three days. When the urine was again secreted it was passed mixed with blood. Concurrently with the hæmaturia severe and paroxysmal pain came on. It began in the left groin and hip, and sometimes shot down into the left testicle. Though varying in intensity, it was continuous during the six years previous to operation. The hæmaturia did not entirely cease for three months. When admitted to hospital the urine contained pus. I had him under observation for over six months. During this period he never passed blood, but the amount of pus was variable, sometimes amounting to a third. The urine was always acid, though sometimes extremely fetid. The specific gravity was about 1017. The microscope revealed pus cells and crystals of uric acid, but there were no pyriform cells and no tube casts. On examination of the site of pain nothing abnormal could be detected but well-marked tenderness over the left rib and below it, immediately external to the erector spinae, that is, over the region of the left kidney. He could not lie on the left side without increased pain. My colleague, Dr. Wallace Eantty, who examined the case with great care, concurred entirely

in the view I took of it, and accordingly I operated in the usual way, choosing the lumbar incision. When the kidney was reached a hard mass could be felt in the pelvis, and an exploratory puncture with a long needle showed that this was a calculus. It was about two inches in length, and completely filled the pelvis. An incision two inches long was made through the substance of the kidney down to the stone. The hæmorrhage at first was very brisk, but a finger passed through the wound served as a plug, and it quickly became checked. The stone was friable and chalky, but was so firmly embedded in the pelvis that it had to be crushed with a forceps and removed piecemeal. Part was hooked out with the finger and part with the assistance of a lithotomy scoop. The *débris* were washed out by means of irrigation. A drainage-tube was placed external to the kidney and brought out at the lower angle of the wound. The incised parts healed by first intention, excepting along the track of the drainage-tube, which was not finally closed till between the fourth and fifth week. After operation he was able to lie on the right side, and since he left hospital has been able to resume his work, which he had been obliged to give up entirely. He is now in good health, although the urine still contains a small amount of pus.

The second case was that of a farmer, aged 40, on whom I operated on February 24th, 1887. His renal history dated back to an accident he met with in August, 1885. A horse kicked him in the right groin; he fell backwards, striking his left side and back against a heap of stones on the road. He was stunned for a few minutes, but, on recovering, he experienced a sharp pain over the two last ribs on the left side. About a week later he noticed that the act of micturition caused him pain, which was most acute at the glans penis. It was increased in frequency, and was often followed immediately by the passage of a few drops of blood. These symptoms lasted for a fortnight, and then he was more or less free from them till September, 1885, when the hard work of the harvest brought them all back again. They continued without improvement till he came under my care. He then complained of pain over the left kidney, of a dull aching character, and continuous. It was increased by lying on his back or on his left side, or by exertion. It shot down into the left groin and into the penis, especially if he experienced a jolt. There was tenderness on pressure over the region of the left kidney. The urine was pale in colour and cloudy; it contained a small quantity of pus, and occasionally a little blood; it was acid, with a specific gravity of 1020; the microscope showed some renal cells, but no tube casts.

As some of the symptoms pointed to the possibility of a vesical calculus, he was sounded twice for stone, the second time under chloroform, but nothing abnormal could be felt except an increased rugosity of the lining membrane of the bladder. I therefore made an exploratory lumbar incision, and exposed the left kidney. I pressed it carefully all over between my fingers, but beyond an apparently thickened condition of the pelvis, I was unable to detect the presence of any stone. The kidney was then punctured systematically with a long needle, but nothing was found. I accordingly closed the wound, which healed rapidly, union being complete in a week, and he was then allowed to return home. Six weeks later I heard that he had returned to the country in "fairly good spirits and health, and that he had not much urinary trouble." But at the end of this period he got a chill from exposure, with high fever, rapid pulse, and he soon became delirious; but during the attack the urinary symptoms were not aggravated. He died on April 15th, the gentleman who attended him not having been able to arrive at a diagnosis as to the cause of death. It does not however appear to have been in any way connected with the renal trouble or with the exploratory operation. I should add that the pain in the side was materially improved by the operation, no doubt the result of the division of some of the nerves.

Though operation in this case failed to detect the stone, as has happened in many other cases, I have not hesitated to communicate it, as it forms a strong contrast with the third case, in which similar difficulties were encountered. This was the case of a married woman, aged 34, who was admitted to the Adelaide Hospital on February 16th, 1887. In 1869 she suffered for about a year from anæmia, but subsequently she enjoyed good health up to January, 1885. In the meantime she had married and had become the mother of four children. She became pregnant for the fifth and last time in May of that year. In the preceding January (that is, 1885), she began to suffer from a burning pain, not very severe in the region of the right kidney. It was accompanied by

¹ Read in the Section of Surgery at the Annual Meeting of the British Medical Association, held in Dublin, August, 1887.

profuse diarrhoea. At the end of three days she was seized with severe stabbing pain in the same situation, almost causing her to faint. Similar paroxysms occurred subsequently, while in the intervals between these paroxysms the burning pain continued. All these symptoms were aggravated during the months of pregnancy, which terminated prematurely at the eighth month in the birth of a stillborn child. This was in December, 1885. Immediately after this occurrence she experienced a new pain in the right side of the abdomen of a gnawing character. She referred this to a point about midway between the anterior superior iliac spine and the umbilicus of the right side. These symptoms were present when she was admitted to hospital. During her stay in hospital previous to operation she had frequent attacks of the paroxysmal pain, beginning at the back over the right renal region, and shooting through to the front under the right costal arch, as though a needle were being driven through from behind. This pain radiated across the abdomen, and more lately passed down to the hip; sometimes posteriorly, sometimes in front and down to the inside of the thigh. When an attack came on she used to coil herself up in bed and writhe with the pain. It was always accompanied by nausea and by vomiting if she had taken food shortly before. Since her last confinement menstruation had taken place fortnightly, lasting for eight days, and during these periods the pain in the abdomen was aggravated. On examination it was found that tenderness on pressure was marked in the back over the two last ribs and below them, but nowhere else in the neighbourhood. Anteriorly, where she complained of the abdominal pain, a swelling with its long axis vertical could be felt, tender to the touch and scarcely movable. It was difficult to determine what this tumour was; it felt in shape like a kidney, but it felt longer and occupied a distinctly lower position than that of the normal organ. The increased pain during the menstrual periods gave rise to the idea that it might be a diseased ovary.

The urine, which was frequently examined during her stay in hospital, nearly always presented the same characters. It was acid, of normal specific gravity, and contained no albumen, pus, or blood; but after standing a short time a well-marked deposit of oxalate of lime was invariably seen. Under the microscope numberless crystals were found, mostly octahedra, but sometimes ovoids and dumb-bells. Occasionally a deposit of amorphous lithates was thrown down. In addition to these might be seen vaginal epithelium and a few cells resembling pus corpuscles.

Dr. Wallace Beatty, who took a very great interest in the case, and who rendered me much valuable assistance, considered that it was a case in which operative measures should be adopted; and this view was also held by my other colleagues. Accordingly I performed the operation of nephrolithotomy on April 5th, 1887. I used the lumbar incision, about five inches in length. When the muscular layers had been divided, I found the lumbar aponeurosis was adherent to the peri-renal fat, and that it required some trouble and patience to clear the anterior surface of the kidney. The posterior surface was readily freed. The first thing which attracted special notice was a depression about the centre of the convex border of the kidney, which presented the appearance of a stellate cicatrix, but beyond a slight thickening of the renal substance beneath it, nothing could be felt to account for this. The kidney occupied a distinctly lower position than usual, and was decidedly longer than the normal, and I have no doubt but that this was the swelling which was felt through the abdominal wall previous to operation. There was absolutely nothing to be felt of an abnormal kind in the renal pelvis. As I could easily draw each part of the kidney in turns up to the lumbar incision, I carefully passed each portion through my fingers, but I could detect no hardness or inequality to guide me as to the position of a calculus. Exploratory punctures made seriatim in every direction likewise failed to give any clue. Under these circumstances I determined to make the exploration complete by incising into the kidney substance, as otherwise the only alternatives left to us would have been either to leave her unrelieved, or to excise, as Mr. Morris has done, an otherwise healthy organ. I began by making an incision about an inch and a half long, with the cicatricial depression as the central point, along the convex margin. The hemorrhage at first was very brisk, and took some time and pressure to arrest. This incision reached down to the pelvis. With my finger passed into it, I felt about in all directions, but without success. I then got a probe-pointed and grooved director, and passing it into the wound in the kidney, explored in several directions

into what was evidently a small abscess cavity, and some pus came along the groove of the director. A small calculus, about the size of a pea, was distinctly felt lying in the cavity. I now passed a knife along the groove, and by means of an extension of the wound upwards for about an inch, I laid the abscess cavity freely open. The amount of pus contained in it was about half a drachm. The wound now bled freely, and as pressure seemed to have little effect, I irrigated it with weak corrosive sublimate solution, which in a few minutes controlled it to a great extent. Unfortunately, the fluid washed out the stone, and before I could examine the returned fluid it had been thrown out. However, we succeeded in finding two or three very fine spiculae. As the oozing from the kidney substance was still free, I thought it best to plug the renal wound lightly with a piece of antiseptic gauze wrung out in weak carbolic solution, the end of the gauze being brought out at the angle of the skin wound beside the drainage tube. The parts were sutured in successive layers, and the wound dressed with gauze and a turf mould pad. For two days after the operation the patient suffered from incessant vomiting, which nothing seemed to check. She was nourished entirely by nutrient enemata. She had had no return of the spasmodic pain—that is, the renal colic, but the prostration from the vomiting caused me some uneasiness. On the morning of the third day, having tried every medicinal expedient I could devise, it occurred to me that the vomiting might be reflex from the kidney, and might be due to the plug which I had put in to stop the bleeding, much in the same way as nausea is so generally an accompaniment of renal colic. I accordingly at once removed the plug by gentle traction, with the happy result that vomiting only occurred once subsequently. From this time she made rapid progress. The wound remained aseptic throughout, and healed by first intention. The urine continued to flow along the track of the drainage-tube for four weeks, and a fortnight later the patient returned to her home in Holyhead. She completely got rid of the pain in the back and abdomen, and had no return of it when last I heard of her. I believe she is now in perfect health. When she left hospital she had regained flesh and colour, and looked a different woman.

This case is interesting in many ways, and I think it is one also of considerable importance. When Mr. Henry Morris excised an otherwise healthy kidney, and found in it a small calculus hidden away in one of the calices—which on a previous occasion he had been unable to detect, either by digital exploration or by needle puncture through a lumbar incision—he suggested that it might be better practice to open up the kidney and explore the calices rather than to sacrifice a healthy organ. This advice has been unfavourably criticised in some quarters, but I venture to say that this case goes to prove the wisdom of the suggestion. Had not cut into the kidney, I must have resorted to the more dangerous expedient of nephrectomy, or have been satisfied to leave my patient *in statu quo*; and I believe that the exploratory incision is by far the safest alternative. The result in this case makes me regret that I did not resort to it in the second case.

Another point which this case emphasises is that, to arrest the hæmorrhage from the kidney, should it prove difficult of control it would be better to compress the edges of the wound together by plugs applied external to the kidney, rather than by leaving any foreign body in the substance of the kidney itself. Taking these cases together, it will be seen that the only symptoms common to all three are the pain and the localised tenderness. In forming a diagnosis, the condition of the urine may act as a guide, but the absence of blood or pus from it is not to be depended on as indicative of the absence of a stone.

ILLUSTRATIONS OF THE ORTHOPÆDIC APPARATUS; REFERRED TO AT A DEMONSTRATION OF MODERN ORTHOPÆDIC METHODS.¹

By NOBLE SMITH, F.R.C.S. ED.,
Surgeon to All Saints' Children's Hospital, London.

THE points chiefly urged in regard to the use of instruments were as follows:

1. Determination by the surgeon himself as to the kind of instrument to be used, if any.

¹ Read in the Section of Surgery at the Annual Meeting of the British Medical Association held in Dublin, August, 1887.

2. Simplification of the mechanisms (combining lightness with efficiency) and.

3. Construction admitting of easy alteration by the surgeon.

Success in treatment often depends upon the skilful application of these principles.

Knock-knees in children may generally be cured by instruments. In slight or moderately severe cases the following splint, or a modification of it, may be efficient. In this case the leg could be at once drawn into a straight, or nearly straight, position.

Plate at top of straight metal splint coming well up }
thigh, for firm bearing.

Stiff band behind thigh to counteract the tendency of }
the splint to come forward; soft strap in front.

Knee-cap and straps to pull knee outwards

Lower end of splint forming a peg, at right angles, work- }
ing in a round socket in the boot.

Fig. 1.

The splint can be bent by the surgeon with wrenches.

In many cases where both legs are affected it is necessary to connect the tops of the splints by a band across the buttocks, to keep the thighs sufficiently forwards, and the feet from turning in too much.

In more severe cases a rack joint must be placed opposite the knees.

Fig. 2.

It is also necessary to keep the legs always extended.

Many modifications have to be made as a severe case progresses towards recovery.

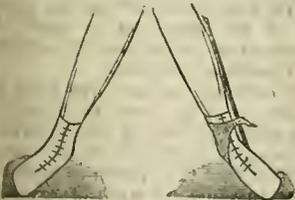

Fig. 3.

Where there is flat foot or a giving way of the ankle inwardly, a T strap can be used.

Bowed legs can generally be straightened by splints in children. The patient can walk about, but it is essential that the splints take a bearing from the ankle, coming down to the ground and from the inner condyle of the femur.

Band of attachment at knee

Band to act upon the curve

Round peg working freely in a socket

Fig. 4.

When the curve is forwards, splints are not of much use, as we lose the points of firm resistance at each end.

If any splint is used it may be made as shown here.

Gutta percha shield to protect anterior sharp edge of tibia.....

Forked end taking a bearing upon each side of the heel.....

Fig. 5.

Here osteotomy is often the only means of correcting the deformity.

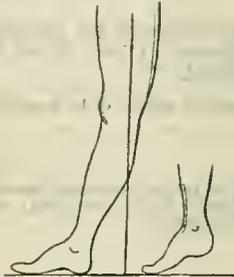

Fig. 6.

Fig. 7.

Fig. 7 is a case of talipes equinus. The patient, in continually attempting to place the sole of the foot flat on the ground, has caused the knee to give way, producing hyper-extension, shown in Fig. 6.

Treatment consisted in division of the tendo Achillis, and rectification of the position of the foot. Then the wearing of the apparatus shown in Fig. 8.

Thigh band at upper end of single lateral bar

Front stop joint at knee preventing hyper-extension, but }
permitting free flexion.

Joint at ankle at first fixed, then either front stop joint to }
protect tendo Achillis from too much strain, or back }
stop joint to prevent recontraction, or limited movement }
both ways according to disposition of case.

Fig. 8.

Fig. 9.—A case of rupture of the internal lateral ligament of the knee-joint. Instrument applied to outer side of peg, with free movement of knee-joint and limited flexion of foot.

Fig. 9.

Without this support the patient could only walk with the aid of crutches, and then with difficulty. With it she could walk well with the aid of one stick, and even the stick was not absolutely necessary. She wore this for a few months; six months after, the knee was quite well and strong.

Fig. 10.—G. C., aged 8. Scrofulous disease of knee-joint; very bad family history. Duration of disease, three years, commencing after an injury. Knee said to be out by celebrated bonesetter; he used forced movements, and abscess came; knee made much worse. There was constant pain and swelling of joint. Applied instrument.

Trough to support thigh attached to each }
lateral metal rod (one on each side) with- }
out movement of knee.

Knee-cap to keep knee towards support.....

Joint at ankle with front stop, so that weight }
of body in walking was transmitted up- }
wards without use of muscles of leg.

Raised sole to compensate for flexion of knee

Fig. 10.

Result.—Rapid improvement and cessation of pain and heat in joint. A year after was walking about comfortably, but owing to very bad family history was directed to continue to wear instrument, which is no trouble.

Fig. 11.—Modified Thomas's splint for acute hip-joint disease. Attached above by shoulder straps, leaving chest perfectly free.

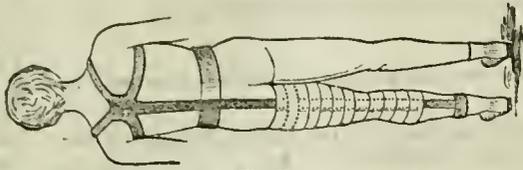

Fig. 11.

Fig. 12.—Dr. Judson's (New York) ischiatic crutch for hip disease, used by him in all stages of the disease. I have found it very useful after the acute stage has subsided.

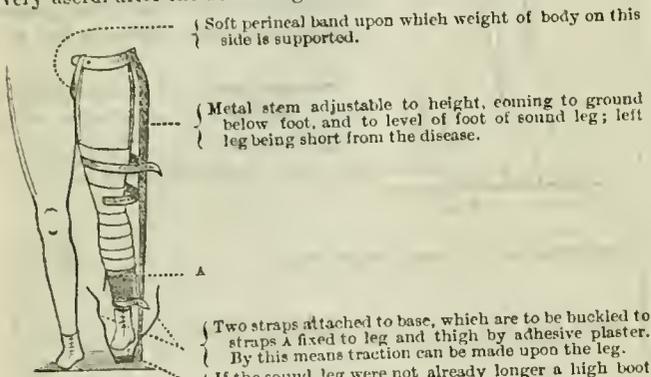

Fig. 12.

This apparatus my friend Dr. Virgil P. Gibney (New York) intended to show at the meeting, but, unfortunately, it did not arrive in time.

Fig. 13.—For curies of the spine. Plaster-of-Paris, leather, or gutta percha back splint moulded to the back while the patient is recumbent in a prone position, with the legs at an angle of 45° with the straight line of the body (so that the lumbar part of the spine does not bend in too much).

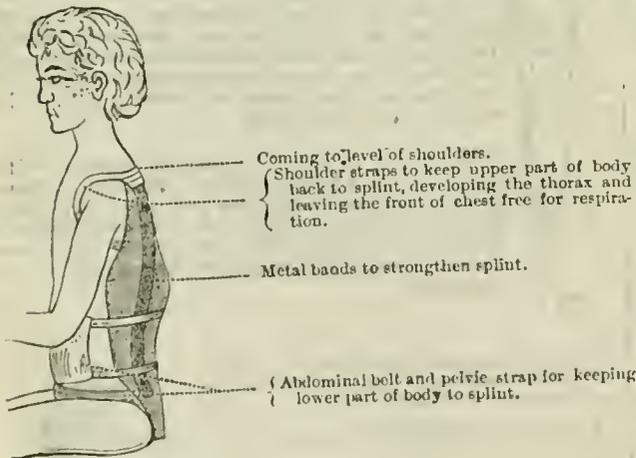

Fig. 13.

This splint is applied upon the principles of Mr. E. J. Chance's instrument. The latter is the more perfect appliance, because it enables the surgeon to regulate more exactly the bearing of its different parts in accordance with the progress of the case; but for general purposes the splint here depicted is applicable, and by it the spine is held firmer than by any jacket.

Fig. 14 represents a plaster-of-Paris spine support for caries leaving the chest perfectly free, strengthened in back by metal bands.

Fig. 14.

THE ETIOLOGY AND CLASSIFICATION OF THE ANÆMIA OF PUBERTY.¹

By E. MACDOWEL COSGRAVE, M.D., F.K.Q.C.P.,

Physician to Simpson's Hospital and Whitworth Hospital, Drumcondra; Lecturer on Biology at the Carmichael College of Medicine, Dublin.

A LARGE number of girls suffer during puberty from a condition of ill-health characterised by a very constant train of symptoms, and to which the names anæmia and chlorosis are applied. Although the disease is so common, its symptoms so plain, and the treatment, as a rule, so successful, the etiology is by no means well established, various theories being put forth by different writers.

Trousseau² considered it a neurosis, the blood changes being secondary. Niemeyer³ appears to consider it as a result of premature sexual activity. He writes: "According to my observation, obstinate chlorosis attacks all young girls without exception in whom the menses have appeared in the twelfth or thirteenth year, before the development of the breasts and pubes." Mitchell Bruce⁴ says the origin of the disease lies in a peculiar condition of the blood and blood-vessels, which is believed to be congenital and perhaps hereditary. Aitken⁵ considers chlorosis as one of the "functional diseases of the female organs of generation in the unimpregnated state." Sir Andrew Clark⁶ considers "fæculent retention and its consequences" as the cause. Sée⁷ looks upon the inability of the organism to meet the demands made upon it by the simultaneous advent of menstruation and of rapid growth of the tissues as the cause.

A great many predisposing and exciting causes have been described by various authors; most of these seem to be not so much causes as merely coincident with the time of life at which the disease begins, but, generally speaking, all things are causes which lessen metabolism and the power of the system to meet the demands made upon it, such, for instance, as want of exercise, improper food, and vitiated air, and the variety of the disease caused will depend greatly upon the force and direction of these causes.

The distribution of the disease bears this out. It is not confined to any class, but is more often met with in large towns than in the country, and is much more common amongst girls who sit at their work than amongst others. When it does occur amongst servants, defective drainage is often an exciting cause. In Dublin the disease is very common; yet in Huddersfield, where the great

⁷ Quoted by Sir Andrew Clark.

majority of the girls work from an early age in mills, it does not seem to be common, as, on looking over the notes of more than 600 cases treated there consecutively, I find only three examples of the disease, and one of these girls is specially noted as having a "sitting job" in a mill. The chief differences between the girls in Yorkshire towns and those in Dublin are that the former are better fed and have more exercise, both at their work and after it.

But, although these causes are generally met with, sometimes they are absent, and the disease occurs in girls of good physique, living in country air, warmly clad, and well fed.

In Sir Andrew Clark's paper⁸ the graphic description of the patients only dealt with one variety of the disease—that generally termed chlorosis; but other well-marked varieties of the anæmia of puberty are met with. I would venture to propose the following classification:—

1. Fat anæmia, where there is a well-marked deposit of adipose tissue.
2. Anæmia of overgrowth, where there has been well-marked general increase of growth without much deposit of fat.
3. Anæmia of general malnutrition.

The first and second and the second and third may overlap, but never the first and third. In the first variety the symptoms of anæmia generally follow the deposit of fat in the tissues; in the second they follow the rapid growth; in the third they generally follow the appearance of the menses. The second and third (those in which there is no deposit of fat) are liable to be complicated by tubercular disease.

In spite of the great weight of Sir Andrew Clark's experience I cannot look upon constipation as even an important cause of this anæmia. Constipation and anæmia are often associated, but very often the constipation is not greater than would be expected from the general sluggishness of the functions, and is similar in significance to the copious pale urine, of low specific gravity and deficient in urates, so generally associated with this anæmia. That the constipation is accompanied not only by torpidity, but also by loss of power, is shown by the failure of belladonna and *aux vomica* to relieve it.

Another argument against constipation being the cause of the disease is that cure often follows the use of iron in the form of Griffith's mixture or Bland's pills, without any purgatives being administered.

Habitual constipation is a common complaint, and as long as the bowels are evacuated regularly, uncomfortable symptoms seldom arise, no matter what the interval between the motions. There seems no reason why constipation should at one age and in one sex cause this characteristic train of symptoms, and produce none of these symptoms at other times.

In some curious cases the constipation is persistent through life, but is not accompanied by any definite symptoms except at puberty and the menopause, at both which periods there is palpitation with shortness of breath on exertion. In one case, at present under observation, there has been obstinate constipation, as a rule not more than one motion in nine days; the patient is now 40, and it is only quite lately that the palpitation and shortness of breath have appeared.

With regard to the occurrence of the menses, my experience is very different from that of Niemeyer.⁹ Early development and premature menstruation seems the rule. Often the anæmia sets in without any appearance of the menses, but in many of the cases there has been a slight appearance for from one to three or four months, and then either a total cessation or an occasional light appearance for a month or two, and then several months without any.

Generally speaking, I have found that in the anæmia of general malnutrition the menses may be absent, scanty, or, in rare cases, normal. In the anæmia of overgrowth there is an attempt at establishment of menses without development of the breasts, etc. The beginning of fatty anæmia is coincident with the development of the breasts, etc.

In the fatty anæmia there is certainly an hereditary acquired disposition. It is very common to find several sisters affected. In one family I have noted four, in another three, and in several two or three affected. In these cases I have often found that the mother has been married early in life, and I have learned to look upon this as an important factor. In one family of good means, and living in the country, the mother was eighteen years of age at the birth of

her first child. She has had five sons and three daughters; all the sons have been very strong, but the daughters, although when young, strong, and of healthy colour, have all passed through well-marked fatty anæmia. In another case the mother never suffered from anæmia; her first child, a daughter, was born when she was only seventeen; the child is now rapidly getting stout, has no appearance of the menses, and is, in fact, passing into fatty anæmia.

Another very interesting point in this variety of anæmia is, that if any strong call in a particular direction is made upon the system, it will be able to meet it; thus, there is generally marked shortness of breath and palpitation on going upstairs, and but little whilst walking not too rapidly on level ground, yet domestic servants so anæmic as hardly to be able to walk on level ground, will sometimes be able to carry heavy weights upstairs. This I have never observed in the other forms of anæmia.

A most important contribution to the etiology of the disease has been made by Beneké,¹⁰ who has shown that the annual increase in the heart and blood-vessels in girls up to puberty is 8 per cent., per annum, whilst during the establishment of menstruation it is 80 to 100 per cent., so that if puberty is established in a single year, an extra growth of from 70 to 90 per cent. weight, in addition to ordinary growth, is entailed, and that at the end of puberty the lungs have arrived at the fullest development, and the excretion of carbonic acid gas has reached its highest. There is no such rapid change in the male.

Professor Bowditch¹¹ says that, up to 11 or 12, boys are, on the average, taller and heavier than girls; for the next two or three years girls have the advantage, whilst after 14 or 15 boys again excel in strength and height.

It is probable that the rapid development of the female is to be found in sexual selection. Men generally choose wives younger than themselves, and so women who are early sexually mature are most likely to be married and have offspring. In time this ought to cause a rapid maturity, and the general tendency would be emphasised in the offspring of mothers who were married young.

The parts affected in this rapid development are the various tissues derived from the mesoderm. The white cells and blood corpuscles, the heart and blood-vessels, the reproductive organs, and the supporting and connecting tissues are chiefly affected. During puberty the mesoderm is largely called upon by the rapid growth of the organs concerned in generation. If the system is unable to meet the demands made upon it, anæmia results. If badly under-nourished, the system is almost certain to fail to meet the extra demands, and the anæmia of general malnutrition is established. If, at the time the rapid growth of the organs of circulation and reproduction is set up, there is active growth of the bones, muscles, and other tissues, the system may be overtaxed by the further demand, and the anæmia of overgrowth gradually appear. In a third class of cases the mesodermal energy is misdirected, and instead of the demand being supplied, an excessive amount of reserve tissue (possibly resulting in part from deficient oxidation) is formed, and fat anæmia develops.

That there is not only an accumulation of fat, but deficient growth and a fat substitution, is shown by the aorta of small calibre and the unequal thickness and fatty metamorphosis of the intima, which are so well-marked as to have led to the idea that the cause of the disease is a congenital condition of the blood and blood-vessels.¹¹

With regard to prognosis and treatment, I would add only a few words. In the variety of anæmia associated with deposit of fat there is sufficient, but misapplied, vitality, and cure may be looked for. The treatment is twofold, specific and symptomatic. Iron may fairly be called a specific; introduced in quantities far exceeding the ordinary needs of the system, it does good, and often, without any assistance, cures. Dr. Oswald Schmiedeberg¹² says: "The possibility cannot be denied that under conditions otherwise favourable and necessary to the cure, the formation of red blood corpuscles may be forced, even by an increase of the iron absorbed, which, though in itself minute, is kept up a considerable time, because of a long-continued extra supply of the metal."

It seems probable that the iron acts by modifying the mesodermal growth and checking the excessive formation of a reserve

⁸ *Loc. cit.*

⁹ *Loc. cit.*

material. Arsenic and the mineral acids also do good, but I believe not so rapidly.

As bearing on the specific action, I may mention that the syrup of the iodide of iron has seemed to me to act much more rapidly and effectively than the syrups of the phosphates and of the hypophosphites.

The form in which the iron is given must vary with the necessities of the case. As a rule I prefer four or five grains of the iron and aloes pill of the *B.P.* each night and morning. In this combination I have never found iron disagree. If there is a catarrhal condition of the mucous membrane of the stomach, I use a mixture containing sulphate of magnesia and sulphuric acid, either adding sulphate of iron to it or ordering the myrrh and iron pill of the *B.P.* In some forms of dyspepsia the sulphate and carbonate of magnesia with aromatic spirits of ammonia in a bitter infusion act well in conjunction with the iron and myrrh pills. Very rapid improvement follows the use of the solution of the perchloride of iron. *B.P.*, but some people cannot take it; I find however that it disagrees with comparatively few since I have prescribed it (on the suggestion of my friend Dr. Cameron, of Huddersfield) with an equal quantity of spirits of nitrous ether.

Hygienic treatment is also important. Fresh air, good food (especially meat), and moderate exercise are useful, but over-exertion is hurtful, and tends to prolong the anæmia, or even to render it permanent.

In the anæmia from overgrowth the prognosis is generally good, but the possibility of tubercular disease must not be overlooked. Fresh air, nourishment (especially milk), and comparative rest are all important. Iron has not seemed to me to be so necessary; when given it is generally best in the form of the syrups of the iodide of iron and of the phosphates. If purgatives are required, I prefer the saline ones and avoid aloes.

In the anæmia of general malnutrition the prognosis is bad; the excessive demand comes upon a system but badly able to fulfil its ordinary duties, and permanent debility generally results. In such cases, country air, perfect rest, and plenty of milk and other easily assimilated food, with cod-liver oil, is what is required, and medicine is of secondary importance. I have found most benefit from the sulphates of iron, quinine, and magnesia, in combination with hydrobromic acid.

ON THE EXCISION AND SCRAPING OF CARBUNCLE.

By RUSHTON PARKER, M.B., B.S., F.R.C.S.,
Professor of Surgery in University College, Liverpool.

THERE are few procedures in practical surgery that better deserve recommendation than the local extirpation of carbuncle, of which the pain and tenderness are thereby ended, and the state of gangrene, always virulent and sometimes inveterately spreading, replaced by simple inflammation in a healing sore.

If the carbuncle be small enough, or seen early enough, an abortive treatment may sometimes be practicable by syringing through it an effective antiseptic liquid; but we seldom get such a good chance of doing this in carbuncle as in boil. In my own case I have several times arrested a boil in its early commencement, when little more than a pustule in a hair follicle, by injecting strong carbolic or sublimate solution a few times, at short intervals, with a hypodermic syringe. But the manipulation necessary for this in even a small carbuncle is at least as painful and prolonged as the excision of the virulent centre (or centres), and not appreciably more saving of tissue. When an anæsthetic is given, the question of pain, as of time, is unimportant; but there are cases of small carbuncle, especially facial, in which excision there and then, without assistance, is very convenient to the surgeon and readily borne by the patient. The disease is almost always acutely tender, if not constantly painful, while constitutional disturbance is sometimes great and increasing. The effect of extirpation is immediate relief to the former ill, and a gradual but sure end to the latter when not too late. I concur with the support given to this important practice by Mr. Herbert Page and Mr. Edmund Owen in the *JOURNAL* of March 24th, and with the tribute there paid to Mr. Teale's excellent paper on "Scraping," adding, in this brief reference to my cases, some details that usefully supplement those accounts. I prefer, however, to consider together erosion and excision, as both may be required in different parts of the

same carbuncle, while other carbuncles require the one or the other according to the softness or hardness of their affected tissues.

CASE I.—A servant girl, aged 19, was sent by Dr. Grimes to the Liverpool Royal Infirmary on the evening of September 4th, 1885, suffering from an acute brawny inflammation on the left side of her chin, of four days' duration. As there was a question of malignant pustule, I was summoned, and went to her at once. Under chloroform an incision was made, and the nodule inspected within. The tissues in the centre were grey and purple, and the thing was decided to be carbuncle. A conical piece was excised, pure carbolic acid put into the wound, with a sublimate dressing laid on. The inflammation melted rapidly away day by day, and the girl was well in a fortnight. There was, I believe, no anxiety about her constitutional state from the first, but I have no note of the details.

Here the best practicable form of immediate local extirpation seemed to be excision with a sharp knife, on account of the density of the tissues. The virulent centre was about the size of a pea, and yet the collateral swelling was as big as half a walnut.

CASE II.—A night-soil carter, aged 23, had a pimple on his neck on May 24th, 1886. This he picked, but was none the worse next day, when, however, he took too much drink, and, the day following, his neck began to swell, and his head to ache intensely. On the 28th he was sent by his medical man to the Liverpool Royal Infirmary, with the left side of his neck in a swollen, red, angry state, very like in appearance to the illustration of malignant pustule given in the *JOURNAL* by Mr. Marrant Baker on June 14th, 1884. His temperature was 104°, and the disease was at first supposed to be a mild form of malignant pustule. Excision of the centre, dirty-grey and purplish, with some surrounding skin, was performed by me without anæsthetic shortly after his admission. Pure carbolic acid was put in, and sublimate dressings applied. His temperature rose to 105° that evening, but fell to 100° during the night. It was taken every two hours for four days, and found to rise after mid-day and fall after midnight. The second day after admission it did not reach higher than 102°, but the day following it again became 104°, after which it kept below 100°, before eventually subsiding to normal. This case was on clinical grounds regarded as a mild form of malignant pustule; the local appearances, absence of pus, and constitutional state favouring the idea. But neither the juice of the excised fragment nor the patient's blood or urine showed bacilli under the microscope, though there were abundant micrococci found in the urine and juice of the wound. The case is therefore considered to be a small carbuncle, or aggravated boil, with unusually severe symptoms, presumed to be due to ptomaine poisoning.

CASE III.—Another carbuncle of the chin, right side, in a woman aged 22, who came to me on January 15th, 1887, eight days after its appearance. In local characters it was like Case I, and getting worse every day. But the temperature was only 99.8°, and the pulse 72, which I thought augured well for the patient. I excised the centre, without anæsthetic or assistance, in my consulting room, applied carbolic acid inside and a sublimate dressing outside, with the same good effect.

A few years ago I read an account by, I think, a Parisian surgeon, of the excision and antiseptic after-treatment of ordinary carbuncle, and determined to adopt it at the first opportunity. This did not occur until April 29th, 1886, when (CASE IV) a man aged 43, came under my care in hospital. He was not ill, and the carbuncle was not severe, though moderately large. But it was, as usual, tender and painful, situated at the back of the neck, and he was likely to be benefited by its removal. I therefore commenced to excise it at once, under chloroform, through a crucial incision, dissecting back such part of the remaining skin as seemed not too far injured. But I soon found that the sharp spoon more easily served the purpose, most of the carbuncular tissue being soft and pulpy. The bleeding was certainly abundant, but was controlled with hot water and the pressure of sponges. The next day he expressed himself very pleased, feeling that "a load had been removed from him," in the loss of all discomfort. Sublimate dressings and eucalyptus ointment were used, and he was well in a fortnight.

CASE V was that of a man, aged 50, who came under my care on January 19th, 1888, with a large carbuncle on the nape of the neck of some ten or twelve days' standing. He was not ill nor in distress, but he readily agreed to its removal. Here I began to erase, but soon found that excision had to be done with knife or scissors in some portions that were hard and brawny, and entirely

influenced by the spoons. The fascia was in places undermined, and these I opened up and scraped well out. The bleeding here, too, was profuse, but kept down with hot water and the pressure of sponges. Dressings as in the previous case were applied, and the patient was well pleased with the effect, and the speedy restoration of suppleness to his neck. He was up and about in a day or two, and well in a fortnight.

I have gone thus far, but I hope not tediously, into these five cases to show that while neither erosion nor excision is by itself panacea for all carbuncles, the two processes combined or selected are applicable to every case, not as a matter of mere novelty or variety, but as the most effectual treatment that we can adopt, if not put off too late. Not that I doubt that any of these carbuncles, all of them, perhaps, were capable of recovery under expectant treatment, which differs little from no treatment. I am perfectly sure that all were exceedingly benefited by local extirpation; and if it be that any of them were likely, if too prolonged, to end in fatal septicæmia or pyæmia, that disaster was undoubtedly averted by the operation performed.

There is no means known to me at present of deciding in the early stages of a carbuncle whether it be likely to end in recovery or death if allowed to run a natural course; but it does seem to me that timely extirpation in some form or another, indiscriminately used, is the most certain means whereby diminished fatality is to be hoped for in the most serious cases, while minimising the discomforts of the slightest. I can look back upon several fatal cases in which I should gladly have known that excision was likely to be curative.

Just a word about potassa fusa, which I personally seldom use, but on which Mr. Page seems rather hard. If for some reason it should not be possible for me to scrape or cut out a carbuncle, I should consider it a very fair substitute to mash up the interior with sticks of potassa fusa. To be sure this would in effect be a more or less thorough erosion; but any of the gangrenous virus removed would have the chance of being permeated by a pretty efficient antidote, that might easily arrest further spread of the disease.

Some persons rub in caustic potash or other powerful chemicals in addition to excision, but their additional necessity is at least doubtful. Of these I consider solid nitrate of silver the best for æmestatic purposes, but it causes great pain. Pure carbolic acid as the advantage of producing local anaesthesia in addition to its antiseptic qualities.

THE GOULSTONIAN LECTURES ON INSANITY IN RELATION TO CARDIAC AND AORTIC DISEASE AND PHTHISIS.

Delivered before the Royal College of Physicians of London.

By WM. JULIUS MICKLE, M.D., F.R.C.P.LOND.,
Medical Superintendent, Grove Hall Asylum.

LECTURE III.—INSANITY IN RELATION TO PHTHISIS. (Concluded from page 689.)

Some, hearing hallucinatory abuse and reviling, fancy that very old scores is raked up against them, and that their delusively imagined misdeeds, known to and unadverted upon by all, occasion the finger of derision or of scorn. A few take delusions about being baffled, annoyed, or us, to malevolent and injurious interference with their mind and its operations. Having links with these, but in themselves mostly of neutral emotional character, are delusions such as that new patients electrify the old, that bells are kept ringing and electrify the air.

Third Sub-group: Morose, Angry Mania, or Cases with Delusions of Injury, Persecution, not or not yet Systematised.—Phases of times of emotional depression, though present in some examples, are far less frequent in this than in the previous sub-group, as also are suicidal tendency, apathy, and indolence. On the other hand, many are irritable, sullen, morose, moody; some obstinate, or are given to refuse food; on the other hand also excitement predominates—excitement, usually angry, but in some temperately angry and gay; indeed at first there may be acute mania. Such patients, too, are usually restless and violent, whether merely destructive, or dangerous, or threatening, or homicidal; usually also are they fidgety, gesticulating, muttering, swearing, denouncing; some are noisy, some mentally confused.

Of many are the utterances at times voluble but incoherent, rambling, confused, irrelevant, peculiar; and their conversation may be with imaginary people. The memory is often impaired, occupation or amusement unsought, the glance furtive, the visage grimacing.

A majority are hallucinated, hallucinations of hearing being the most frequent, and those of sight coming next. A majority, again, are extremely suspicious; a majority are at times either obstinately silent or very taciturn; a few lose sleep.

Delusions.—Injuries to, or maleficent influences affecting, the patient's body are frequent subjects of the delusion; delusions of persecution, of the hostility of others, or of poisoning, are somewhat frequent; those of conspiracy are occasional.

The delusions as to bodily damage or injurious influence are, such as that "the contents of the head are drawn out by the nose," that the sufferer is "interfered with," that "electricity plays on him," and by it he gets hallucinatory messages or "is electrified," is "worked on by spiritualism," is "placed in strange malpositions by the country he is in." Or, that he is "full of another's spittle," "a weight is imposed on the nape, chalk is thrown into his mouth and urine into his body," sees a "blue, gaseous substance inside him." His "frame vibrates" with the persecutors' movements; "the attendants threw wrong things, thus stopping his breath and nearly killing him;" "has been torn from head to foot all his life."

Similarly depressing and expressive of a sense of hostility in the environment are the ideas that voices gibe at and vex him; that the newspapers write against him; that detectives follow him; that he is surrounded by blaspheming infidels, or affected by the operation of "secret telegraphy," that he is "robbed," is about to incur evil and injury from those around; that his wife is unfaithful to him, and he therefore kept in an asylum in furtherance of an immoral object; that whilst in the army he "suffered more than any man in the world."

Nevertheless, expansive ideas may crop up in the more active and gayer mania; rarely, if ever, does this state assume a chronic character. The patient says he is a better doctor than his physician; or that "a saint put a ring on his finger;" or that, having been electrified, he can by a touch tell what others have done all day; or he says he is Christ, or has a saintship from him, or is the Trinity; "has thousands of millions of money, brought the sun back, will live 100 years."

Fourth Sub-group.—These cases are of the monomaniacal type, in some instances abortive or imperfect, in some a rapidly deteriorating psychosis. For the most part of the persecutory querulous types, occasionally they are of the hypochondriacal or of the exalted; the characters, however, are often mingled.

An example mainly taking the persecutory querulous form may be as follows: at first eccentric, silent, restless, he becomes disrespectful, morose, sullen, noisy, angry, threatening, sleepless, mutters curses, and entertains delusions of persecution and of poisoning; later he takes delusions such as that, for love of him, a rich woman had him sent from India under fictitious names, and, he being under a course of opium, she also took the opportunity "to work off his mind and brain, because work is taken off by people who are outside." He sees them, they draw themselves before his eyes, he hears them, and they annoy his mind and brain, and say that they "persecute one man;" he is that man. Day and night, but especially the latter, he hears the men who follow and annoy him, paid to do so by a woman, who also mesmerises him constantly, and keeps him in the asylum. "Opium is put into his food and brain; the time-giving and seeing of opium through the brain is destroying him." Under the delusions of injury he becomes excited.

In some cases many of the delusions are more of a neutral tint. One "has cannon balls in his head; his name is written on his forehead. The chaplain is not ordained, is a debauchee; a nurse causes death of the inmates, so does the baker;" the officials about him are "in false names," and his language is foul and threatening towards them under the delusion that they are receiving bribes from a woman to cut off his head. "Against him bad characters have a spite; day and night people talk about him, and what he has been through."

Occasionally the expansive element is relatively more marked than in the preceding examples. Thus, one "is an heir: his relations were about to shoot or poison him, and day and night they talked of doing this," their object being to give his property to

another heir; therefore he fears being killed. "Has an estate; the asylum premises belong to him," and so do the clothes worn by those in charge of him, and because of this, and of his detention in what he delusively calls his own mansion, he threatens and tries to attack. He asserts that he is "wanted in the city," is to marry a rich lady; has enormous wealth. Later on, he shouts his orders to imaginary persons in an unintelligible jargon. Or, another "sees Christ, or the devil frequently, or whenever he likes; hears God; sees Him in Heaven; needs not to work, inasmuch as God will always provide him with food."

Fifth Sub-group.—In a few cases phthisis appears to widen, deepen, modify the mental defect of a weak-minded person; as it were, to add dementia to a degree of imbecility, and bring the individual affected under notice, and into an asylum, owing to the grave loss of mind, the failing mental capacity, now obvious. Such persons are usually young (18 to 25). Hopeless as this condition may appear to one unacquainted with its true nature, or lacking experience of the kind, it is sometimes the theatre of therapeutic triumph, and under outdoor exercise, a regular life, large diet, cod-liver oil and tonics, the patient may be found to lose the marked signs of phthisis, gain greatly in body weight; and, throwing off all the supervenient dementia, return to the degree of mental capacity normal to him, such as it is. Similarly I have seen, at least temporary, mental recovery in one example presenting relations similar to the weak-minded cases just mentioned, and occurring in a youth, aged 19, the subject of moral disorder, of inveterate kleptomania, impulses to theft, also to strange acts; vertigo; and, somewhat doubtfully, of hallucinations of hearing, at times.

Second Group.—Cases in which the order of incidence of phthisis and insanity was doubtful, that is to say, in which the two apparently came on simultaneously, or so nearly simultaneously that it could not be definitely stated which of them preceded the other.

Of the 106 cases already analysed with regard to the question of insanity supervening on phthisis, the order of incidence, on closer scrutiny, was found to be doubtful in a goodly number, owing to apparent approximate simultaneity. Taking the twenty-four examples most adapted for our present purpose, I have examined my notes and records of them with some interest to ascertain, more precisely than from a general impression, how far these cases, on the whole, resembled those of insanity supervenient on phthisis, and forming our first great group already discussed. In cases of insanity and phthisis coming on about simultaneously, and of doubtful order of incidence, obviously we cannot expect to find, as the initial disorder, those actively quasi-delirious symptoms and hallucinations sometimes coming on in established or advanced phthisis, and forming the clinical aspect of the first sub-group of cases of insanity supervenient on phthisis. But if we find a general likeness to the other sub-groups of cases of insanity supervenient on phthisis, in those where the order of incidence is doubtful, it affords the necessary confirmation to my view that phthisis gives origin to, or assists in the causation of, many examples of insanity like those most apt to begin nearly simultaneously with the invasion of lung tubercle; or, in other words, that actual phthisis produces or precipitates a state of the constitution or of the organism similar to that which, in this second group, leads to the practically simultaneous breakdown manifest in both phthisis and insanity. We find that those under the present head show a general grouping somewhat similar to those under the preceding head; particularly do they repeat the symptoms of the second, third, and fourth sub-groups above, as may be seen in the following general summary.

Summary.—In many there is emotional depression. This may assume the more common aspects of melancholia; fear, weeping, grief for alleged, but imaginary, guiltiness of crimes; or vexation about the "abuse" he receives, and the "evidence" raked up against him; or a suicidal tendency, or attempt, may be observed. But in some the state is apathetic or stuporose; a condition more of less of *melancholia attonita*.

Even still more frequent and striking than phases of emotional depression are the cases with delusions as to bodily injury, damage, torture or detriment of various kinds; those as to persecution of manifold variety, or of plot or conspiracy against the lunatic; those as to being poisoned by food, or deprived of food; those as to hostility, annoyance, as by hallucinatory voices, whether these be reviling or not; those as to interference, threats or designs against him, adverse influences, mysterious agencies.

Usually either not, or imperfectly, systematised, the above de-

lusions of injury or persecution often tend to become fixed and systematised. Yet may expansive delusions occur in some, and when they exist are usually found alternating with depressed or persecutory delusions; as in some forms of monomania.

Sleeplessness is frequent; violent, restless, noisy, destructive states, or foul habits, may be found. Some are scowling, angry, threatening and abusive in language. Some are suspicious, some are apathetic, or confused, incoherent, or unsociable or irritable, or shy in appearance and demeanour, or act with an air of mystery or secrecy, or are discontented, malicious.

The great majority are hallucinated, hallucinations of hearing being the most frequent, those of sight next, those of other special senses sometimes observed. Usually disagreeable, the hallucinations are so, or the reverse, according to the predominant co-existent mental colouring. Visceral illusions are frequent.

Thus we see how closely the above cases, set down as examples of those in which the incidence of phthisis and insanity is nearly simultaneous, and its precise order doubtful, resemble the second, third and fourth sub-groups of those cases of insanity supervenient on phthisis, of which we have already spoken, thus justifying the remarks preceding the particular description of this second great group of cases.

It will scarcely have escaped notice how large a number of the cases collected for our first two groups we eventually excluded from immediate consideration, and in how considerable a share the precise order in which phthisis and insanity came on was obscure and difficult to determine.

Not only are there, in phthisical cases of insanity, the usual difficulties often attending the attempt to attain correct information on the causation and inception of disease, as experienced by all practitioners of our art, but there is the further and unusual difficulty engendered by two factors; the one being that the mental condition of many a one precludes us from obtaining accurate information from the sufferer himself; the other, that in many of the insane the phthisical process is extraordinarily latent, fails to reveal itself in its full symptomatic aspects, and does not occasion some of the usual reactions of the organism, or at least in the customary degree. But the latency of phthisis in some of the phthisical insane forms a separate subdivision of the subject, and one which I had hoped time would permit me to take up in this lecture.

Third Group: Phthisis Supervenient in Insanity.—1. Relations of forms and clinical aspects of insanity to the subsequent occurrence of phthisis. 2. Relations of phthisis to the modification of pre-existent mental symptoms.

1. *Clinical Forms of Insanity in Relation to Supervenient Phthisis.*—Almost any form of mental affection may become complicated by the supervention of phthisis, but some forms are particularly liable thereto. In these latter forms of insanity there are operative, and for a somewhat protracted space of time, not merely such of the general asylum influences as may foster phthisis, but also the chief causes of the mental disease which predispose to phthisis—the special habits, carelessness, neglectfulness, tendency to self-exposure, and disinclination for or refusal of food, which characterise these cases. Nor is this all; there is a still further puissant influence in the diathetic state, in that hereditary degeneration which displays itself in psychical degradation, and in a tendency to pulmonary or other tuberculosis; the diathetic influence promoting the break-down simultaneously, or successively, in different parts and organs.

Depressed or suspicious lunatics often neglect or refuse food, exercise, warmth of body, or the conditions of its maintenance; or are of depraved habits, not merely filthy, self-neglectful ones, but also sexually self-abusive; if present, the habits of night-restlessness and self-denuding, or of food-vomiting, also degrade nutrition; and this degradation of the nutrition is enhanced if refusal of food necessitates artificial feeding for a protracted space of time, especially if with co-existent disorder of the digestive organs, or if the patient is a garbage-eater, and thus dissipates his digestive powers and irritates his digestive organs by that which yields little or no sustenance. The mere disregard of, or disinclination for, food is apt, in spite of care, to lead to defective nutrition. Some of these, or other, patients persistently keep immovable in one position, vegetating there, neglectful of warmth, of comfort, of cleanliness, regardless of draughts of air or other injurious impressions. Many insane persons, also, are in the habit of covering up the head in bed at night, repeatedly rebreathing air impure and carbonised from their own lungs. The crowding or defective ventilation (if any) of asylums, the sense of confine-

ment and of surveillance, add a depressing element. Also the conditions of life in psychically degenerate families, the irregularities, imprudences, hygienic blunders, and social solecisms found in the members of such, under the home-roof, build up an inclination to phthisis, and long before the subjects thereof reach an asylum.

In relation to the present subject, I have taken about twenty cases, as sufficiently illustrative of the forms of insanity in which phthisis is most apt to occur; and of the modification undergone by the preceding mental symptoms under the effects of pulmonary phthisis. Unfortunately, I might illustrate this group by a large number of cases, but as this third and last is the least important of the three great groups—least important, that is, in relation to our present inquiry—I have thought it quite sufficient to analyse a modest number only, although under the present head would come all the cases of phthisis in the insane in more recent years under my care, save and except the 106 already referred to under the first two great groups, and except some occurring in recent months and not enumerated here, and except those with forms of mental disease already specified as being omitted. The age at death, varying from 24 to 52, was, on the average, between 36 and 37. The cases are examples of the sub-groups in which phthisis most frequently occurs; and, as under the other groups, so here, I have purposely excluded phthisical cases of general paralysis, epilepsy, or any gross organic brain disease.

1. *One Sub-group*, with supervenient phthisis, is that consisting of examples of monomania of the mingled persecutory and expansive form, the persecutory element usually predominating. In these cases, hallucinations and illusions are frequent, especially those of hearing and sight, while those of taste and smell may be present. Some of the patients have led a very irregular life, have deserted their duties, wandered hither and thither through their country or the world, come into frequent conflict with social usages, the rights of others, and with the law. The delusions have been those as to persons working adversely to the sufferer, of annoyance, and often by individuals of the other sex; of various kinds of injury; of being poisoned; of being haunted by shadows and voices, or by the devil and his wife; of carrying Mr. Punch on his back; of being transported as a convict, or affected by witchcraft, or of having all his thoughts repeated by others. Hypochondriacal monomania may exist.

2. *Another Sub-group*, with supervenient phthisis, consists of cases with chiefly unsystematised delusions of persecution, ill-treatment, annoyance, injury, medical malpraxis on the sufferers; of damage, hurt, and annoy from electricity brought to bear on them; of conspiracy to annoy or injure them; or delusions leading them to claim what others wear. In some, these delusions, however, tend to become systematised and fixed.

With these are often querulousness and hypochondriacal symptoms. Hallucinations may be frequent and vivid. Occasionally patients of this sub-group may also overflow with the foulest sexual delusions and illusions.

3. *Third Sub-group*.—In some such cases chronic moral and intellectual perversions have followed acute mania, or have supervened in melancholia, now become chronic. The melancholic ideas may be on religious subjects, and such a patient may also delusionally believe himself or herself to be the subject of criminal charges. Hypochondriacal melancholia may be found.

4. *Another Sub-group* consists of stuporose cases, which, whether of the more simple or of the melancholic form, find many phthisical victims; but the stereotyped clinical features of which it is quite unnecessary for me to limn.

Dr. Clouston⁴⁵ long ago described what he termed "phthisical" mania or insanity, and which he regarded as being "a direct result of a strong tubercular diathesis, or tendency which was then being developed, or about to be developed, into direct tuberculosis." At one moment including "only cases which died within five or six years after becoming insane, and in which the development of the two diseases was somewhat contemporaneous," at another this "typical phthisical mania" consists of cases in which symptoms of phthisis came within five years of the commencement of the insanity, and in the majority of them within two years. Thus, in many, the order of incidence of the two was problematical; in many the phthisis came some considerable time after the insanity, which latter, therefore, could not positively be termed "phthisical." If present at all the acute stage was very short, and passed either into a chronic stage nor into deep dementia, but into an excitable, sullen, and suspicious state; a mixture of sub-

acute mania and dementia; with want of periodicity, and of fixity of mental condition, disinclination to exertion of mind or body, and unprovoked short attacks of mild excitement;—suspiciousness the chief and most nearly characteristic symptom.

Whilst many of these cases form an important contingent of those springing, or partly so, from a phthisical or tubercular basis, nevertheless a further sub-division is requisite; and the several distinct clinical sub-groups I have described (under Groups 1 and 2) fell within my experience.

I do not take up the relation of phthisis or tuberculosis to idiocy. From his large experience, Dr. Langdon Down⁴⁶ concluded that tuberculosis is frequently a cause of idiocy, impressing special characters thereon.

2. *The Modifying Effects of Phthisis on the Clinical Aspects of Pre-existent Insanity*.—In the foregoing and similar cases of the third great group, what are the modifications of the mental state wrought by the supervention of phthisis? In about two-thirds we find some change; on the other hand, in about one-third very much the same state before and after the supervention of phthisis.

The cases where change was wrought being of the types already described, I need not state the mental symptoms preceding phthisis and compare them at length with those existent subsequently to the incidence of the phthisis; it will suffice to mention, in several cases, the new symptoms or modifications coming subsequently to phthisis, itself a complication of insanity.

New symptoms after supervention of phthisis, or modifications of previous mental state:—

Many become more quiet during the phthisis, more manageable, less dominated by delusions than previously. One gets more depression, less delusion. One becomes less hypochondriacal and less suicidal, but, on the other hand, apathetic, and makes ridiculous, childish, trivial, inept statements.

As more marked new symptoms following phthisis occurring in chronic insanity, one gets the delusion that his food is bad, that he is ill-treated or improperly dealt with; and has perversions of smell, and taste.

Another takes the new delusion as to poison being in his medicine, and, more frequently than before, has emotional depression and delusion as to hostile and injurious intentions and acts of those about him.

Another, after phthisis, takes delusions that he is annoyed by bad women; that women worry him, take his blood, force him to dirty himself, give him pain in the heart and chest disease, afflict him by the Divine power; also that he will die a martyr to the creed, and is "Israel of God."

In one, whose monomania had been of a mingled expansive and persecutory type, after phthisis the expansive symptoms fell completely into the background. The persecutory delusions and their associated illusions, hallucinations, and other sensory perversions, concerned chiefly the imaginary lizards which were put on him and ate him, and the animals which touched him. Visual, tactile, and visceral hallucinations and illusions existed, and so did the delusions of being "haunted and enchanted."

In a case with the same symptoms as the last before phthisis was marked, the expansive delusions receded entirely from the foreground after the inroads of pulmonary disease, and there were increase and augmented influence on the acts and demeanour of the patient of delusions as to malpraxis and evil workings exerted against him, and increase of the delusions of injurious influences, annoyance, and hostility, which largely replaced the exalted ones.

In another case the new symptoms were that "the angels tried to strangle him at night," thereby causing his cervical strumous adenitis and its swelling, pain, and discomfort; and that prostitutes impertuned him nightly.

Another, for a time sad and free from delusions than before phthisis, then intensely irritable; the old delusions of persecution, the hallucinations related thereto, more active than ever. And now came refusal of food and medicine.

Differently from what had previously been, the delusions of injury, after phthisis had supervened in one case, referred chiefly to ill effects of imaginary applications of electricity to him.

That the other patients are in the asylum because he is here, and that everything he swallows brings fresh patients in, was the chief new feature in one case.

⁴⁵ *London Hospital Reports*, vol. iii; *Lancet*, September 21st, 1887; *Lettsomian Lectures British Medical Journal*, January 23rd, 1887, page 150; *Lancet*, January 23rd, 1887; *Mental Affections of Childhood and Youth*, 1887.

⁴⁶ *Journal of Mental Science*, Nos. 45 and 50.

In two cases I noticed the idea on the part of the patient that he had been an enormous length of time under care and was hundreds of years old.

Of the modification occurring in stuporoso cases this is an example:—The subject of mental stupor, and dying phthisical, begins to speak again. What he says refers to adverse influences operating against him, and he speaks of "twenty evil spirits coming to him in the night," and of the other patients being devils who torture him. He speaks of injury, asks to be put out of his misery, writes that his brother came drunk (not so) to see him, and advises the latter "not to come in a coffin, as these are dangerous places." Finally, he takes the delusions that the attendants punish, persecute, and deprive him of strength; and, though prostrate, wishes to get up and be about.

Time fails me to speak, as I had hoped to do, of acute tuberculosis and of tubercular meningitis occurring in the insane; of the latency of phthisis in many of them; and of the alternations of phthisis and insanity. Nor can I bring before you, as I intended to do, the salient therapeutic points relating to numerous cases of cure and of prolonged arrest and vast improvement of phthisis in the insane; nor the temperature charts in my possession illustrating the effect of antifebrin therein. Nor is there space for a summary of scattered contributions in medical literature bearing on the subjects of these lectures. It remains only that I thank you for your presence here, and the courtesy shown to me.

SURGICAL MEMORANDA.

ON COMFORTABLE ARTIFICIAL LEGS.

I HAVE often during years past intended to send a note to the JOURNAL upon an important detail in the construction and comfort of artificial legs, and my intention was strengthened by the illustration and advocacy by Mr. Barwell of what is called his modified Beaufort leg in the Journal of January 10th, 1885. This leg, and others that I have seen, are secured by straps that tightly encircle the thigh, and quickly cause wasting of the soft parts around the femur, to the great discomfort of the patient.

Some twelve years or more I made use of Thomas's knee-splint, with or without a boot attached to the lower end, as a comfortable, durable, and light form of stiff artificial leg, that can be procured for from ten to twenty shillings. The patient sits upon the perineal edge of the padded ring, and the unconstricted thigh fattens on the amputated side equally with that on the other.

Mr. Joseph Critchley, 83, Upper Pitt Street, Liverpool, has since adapted to his artificial legs, for use after amputation above, through, or below the knee, the padded ring of rod-iron exactly as used for the upper end of Thomas's knee-splints. The advantage of this is incalculable, and many working men have thrown away the artificial leg of ordinary pattern, presented to them by railway companies or by private subscription, in favour of a leg made by Critchley, purchased at the patient's own cost, simply because the constricting thigh attachment of the former caused intolerable discomfort in wasting, that entirely disappeared on wearing the latter.

A glance at the illustration will explain the appearance of this important improvement in the attachment and upper end of the legs, the practical value of which cannot be understood by those familiar with the use of Thomas's splints. Particulars I must refer the reader to Mr. Critchley's lunatic asylums and prospectuses. His cheapest artificial legs are quite so low in price as the one described by Mr. Barwell, and are beyond all comparison superior in practical value. Usually ci

utility, and are more comfortable and durable than many others. They are well known and highly approved by the hospital surgeons of Liverpool, for whose poorer deserving patients the cost is without difficulty raised by private subscription.

Critchley's best artificial legs, with springs and joints for knee and ankle, are superior in my opinion to the most exquisite articles of other make, by reason of their physiological and rational fitness, while far below them in cost.
RUSHTON PARKER,
Professor of Surgery in University College, Liverpool.

TOXICOLOGICAL MEMORANDA.

POISONING BY BELLADONNA AND ACONITE.

At 6.5 P.M. on February 10th, 1888, I was called to a girl, aged 17, who had swallowed liniment instead of her medicine. The liniment was composed of equal parts of aconite and belladonna liniment, of B. P. strength, prepared with methylated spirit. The patient was convalescing from a third attack of rheumatic fever. She had a mitral systolic murmur, with slight accentuation of second sound over the area of the pulmonary valves.

She took two tablespoonfuls of the mixed liniment at 5.45 P.M. on the day in question. On my arrival at 6.15 the patient was delirious, the face and neck were flushed, and there were violent convulsive movements, principally of the muscles of the neck and upper limbs, though the lower limbs did not escape. I was informed that "she had been sensible till within a few minutes of my arrival, and had been putting her fingers down her throat to make herself sick," and that "this had had the desired effect." The vomit smelt strongly of spirit and camphor.

The pupils were widely dilated, and not influenced by light. The pulse was barely perceptible at the wrist. The heart's action was very turbulent and irregular, the beats being, as nearly as could be estimated, 300 per minute. The patient was throwing herself about so much that two people were required to hold her on the bed. The teeth were firmly clenched, and a gag had to be introduced before 30 grains of sulphate of zinc in warm water (a good deal of which was lost) could be poured down her throat. Any stimulus, whether of touch, light, or sound, seemed to aggravate the convulsive movements. The breathing was deep, hurried, and becoming stertorous.

6.45 P.M. The pulse was imperceptible at the wrist. There were short periods of complete intermission of the convulsive movements, and these were accompanied by apnoea. The heart's action was not so turbulent, but still irregular, and the beats 240 per minute; the face and body getting more and more anæmic; the tongue and throat were quite dry and gritty to the feel.

7.25 P.M. Heart suddenly stopped, and respiration continued only a few seconds. Hot fannels to the heart and brandy and ether subcutaneously had been employed. In one attack of apnoea the breathing was set going by artificial respiration, but in the others it began again of its own accord. Artificial respiration and stimulation of the heart after its beats failed to be felt had no effect. The temperature was taken five minutes after death; but the thermometer registered 97° F., the point at which it stood when introduced. Rigor mortis quickly supervened and as rapidly passed off.

St. Albans.

EUSTACE H. LIPSCOMB, L.R.C.P. Lond.

THERAPEUTIC MEMORANDA.

LOCAL APPLICATION OF CALOMEL IN PHAGEDÆNA.

I HAD a case of phagedænic ulceration of the under surface of the glans penis under my charge at the Station Hospital, Brighton, in August last, which defied the recognised treatments of this disease. I applied nitric acid in the most thorough manner on six different occasions during a period of eighteen days without success. I then applied pure carbolic acid, but the disease again returned. Constitutional treatment with opium was adopted throughout. For six days the patient sat in a hot water hip-bath on an average about four hours daily, without any appreciable effect on the course of the disease. The condition of the penis on the twenty-first day was as follows:—

A large ulcer existed, covering the entire under surface of the glans, moulding it like the mouthpiece of a flute, and extending to the reflected foreskin in the vicinity of the ulcer. A third of the glans had been destroyed. The surface of the ulcer was covered with a reddish grey secretion, irregularly disposed, and

ierced here and there by large red granulations. The edges were angry and undermined.

I applied calomel powder on the twenty-first day of the disease, spreading it thickly, and pressing it well into the interstices of the ulcer. The calomel acted like magic; the ulcer began to heal rapidly. Now and then a suspicious spot appeared, but it was at once dissipated by a thorough application of the calomel. The patient made an excellent recovery, and was very pleased at the result, for he believed he was going to lose the whole affair. I could give him very little hope. I had used all the recognised methods of treatment, and the literature of the subject pointed to those slow, creeping ulcerations as almost incurable, except by amputation, and then very often the disease returned in the lump. I was tempted to use calomel, as I have found it very useful in all forms of syphilitic ulceration.

T. J. GALLWEY, M.D., Surgeon-Major M.S.
Newcastle, Jamaica.

IDIOSYNCRASY TO ANTIPYRIN.

SOMEWHAT similar case to that lately recorded by Dr. Sturge recently came under my notice. I administered to a lady on two different occasions 8 grains of antipyrin for attacks of migraine, and on each occasion, very shortly after taking it, a tight feeling and constriction was felt across the chest, with a burning sensation in the pharynx. These symptoms were immediately followed by sneezing, by intense suffusion of the eyes, and by quantities of mucus flowing from the nose, giving her all the appearances of having a severe attack of coryza; there was also great irritation of the larynx, causing severe fits of coughing, but unattended with expectoration. After a quarter of an hour these uncomfortable symptoms gradually subsided. There was no urticaria. I followed it up on each occasion with an equivalent dose of antifebrin (3 grains) which (with one repetition in the course of an hour on the first occasion, but which was not required on the second) completely relieved the severe hemicrania, as it has done in subsequent trials without using antipyrin at all. It appears, therefore, that antifebrin may be used equally with antipyrin in migraine as in febrile conditions, and may replace it with advantage where the latter disagrees.

REPORTS

OF

**HOSPITAL AND SURGICAL PRACTICE IN THE
HOSPITALS AND ASYLUMS OF
GREAT BRITAIN, IRELAND, AND THE COLONIES.**

WELLINGTON HOSPITAL, NEW ZEALAND.

CASE OF SUPRAPUBIC CYSTOTOMY.

Under the care of G. GORE GILLON, M.B., C.M., Hon. Visiting Surgeon.)

M., male, aged 35, labourer, formerly a seaman in the British navy, was admitted July 26th, 1887, suffering from pain in the penis and frequent micturition. He stated that he had voided a very much the last two years, and had had trouble with his urine for the last seven years.

On examination Dr. Gillon felt a stone at the neck of the bladder, its size being estimated at over an inch and a half in length. Deep suprapubic palpation, under chloroform, discovered a hard substance behind the pubes—this was evidently one end of the stone, and it appeared to be fixed firmly in that position.

On July 30th, 1887, Dr. Hassell, giving chloroform, suprapubic cystotomy (as described by Petersen, of Kiel, and Sir H. Thompson) was performed by Dr. Gillon, in the presence of Drs. Grace, Hance, Hassell, and Robertson; a large oblong stone was extracted by means of the fingers and secoop. The peritoneum was not seen. Ten ounces of Thompson's fluid (hot) were used for the bladder, and ten ounces of hot water for the rectal bag. A medium-sized Barnes's bag was used in the rectum. The stone was partly encysted in a pouch just behind the pubes, with its long axis vertical, and there was a little difficulty in extracting it. It was composed mainly of triple phosphates, and felt very hard; its length being 2½ inches, and breadth 1½ inch. No stitches were placed in the bladder.

Next morning, owing to the tube having become blocked during

the night, it was found that the urine had forced its way round the tube and into the surrounding tissues. All the stitches in the abdominal muscles and skin were immediately removed, and a large drainage-tube inserted. Iodoform was used freely, and charcoal poultices applied. The bladder was washed out with Thompson's fluid, and one grain of opium given every four hours. The temperature was 99.4°. Two incisions were made in the abdominal wall, drainage-tubes were inserted, and brought out at the original wound.

August 12th. The wound looked unhealthy; the patient was turned on his face with pillows to support the chest, pelvis, and thighs, leaving a space underneath the wound for a vessel to catch the discharges in. The wound was syringed out every three hours with carbolic lotion (1 to 30) from below. He felt much easier in the prone position.

August 15th. The prone position was maintained; he slept and ate with comfort. The urine came freely, and also much pus through the tubes.

On August 18th he was turned on to his back again. There was still a copious discharge of pus and urine. The bladder was washed out through the penis with Thompson's fluid, and much flaky pus thus expelled from the bladder wound.

August 25th. The patient had a rigor. Two more incisions were made in the abdominal wall, and the patient again turned on his face.

	Morning.	Evening.
August 2nd	99.2°	99.6°
" 5th	100.4°	101.6°
" 7th	99.4°	100°
" 9th	98.6°	104°
" 12th	—	99.2°
" 15th	99°	99.4°
" 18th	99.8°	100.4°
" 25th	103.8°	101°

On September 2nd urine came through the penis for the first time without the catheter, some still coming through the wound. The patient was turned on his back again.

September 10th. The bladder was still washed out daily. Pus still in the urine. Urine came occasionally through the wound, but generally through the penis. The temperature remained about 100.6°.

On September 19th another rigor occurred, the temperature rising to 103.8°. The patient was again turned with his face downwards; there was increased discharge of pus from the tubes in the left iliac region.

On September 23rd the temperature was normal night and morning, and there was very little discharge from the tubes. On October 4th the bladder-wound was quite healed. He got up on November 9th, and walked about in the ward. The urine was quite clear, and contained no pus and no albumen. He could hold his urine for six hours. A slight discharge from one of the old deep sinuses in the abdomen on the left side continued, but this had healed by November 29th, and he was perfectly well, and gaining flesh rapidly.

REMARKS BY DR. GILLON.—1. There was considerable cystitis present, due, I think, to the raw surface in the front of the bladder where the stone was lodged.

2. The drainage-tube should be constantly seen to be clear the first twenty-four hours, and if blocked, removed, and a larger rigid tube inserted. The stitches should also be all taken out, and, if necessary, the patient kept in the prone position, as recommended by Trendelenburg and Schmitz.

3. The pus seemed to burrow its way beneath the muscular layers—in fact, at one time I could get my finger between the skin and muscular layers, and underneath that I could pass a soft probe, lying deeply on what seemed to be the transversalis fascia, up as far as the spine of the left ilium, and under the conjoined tendon.

DUNDALK DISPENSARY.—A retiring allowance of £100 per annum has been granted to Dr. Brown, who filled the office of medical officer to the Dundalk dispensary district for the long period of forty years.

A LIBRARY FOR THE BLIND.—Sir Charles Lowther, Bart., desirous that the blind population of the East of London should have a library for themselves, has presented the trustees of the People's Palace with a large number of embossed English works (in all 345 volumes) in Dr. Moon's type for the blind, comprising, besides the Holy Scriptures, a large number of religious and secular works.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MARCH 27TH, 1888.

Sir E. H. SIEVEKING, M.D., President, in the Chair.

A Case of Extroversion of the Bladder Treated by Preliminary Division of the Sacro-Iliac Synchondroses.—Mr. G. H. MAKINS read a paper on this subject. The patient was a male child, aged 5. An attempt to raise a flap after Thiersch's method had failed three years previously. On the second admission a cicatrix on the left side of the extroverted bladder marked the position of the unsuccessful flap, and prevented any considerable shifting of the skin on that side. On November 29th, 1886, the sacro-iliac synchondroses were divided on each side, with the result of allowing approximation of the anterior superior iliac spines to the extent of one inch, with corresponding diminution of the gap existing in the situation of the symphysis pubis. This gain was maintained by means of continuous extension. On January 22nd, 1887, an attempt was made to unite the opposite boundaries of the bladder, which failed, presumably in great part, in consequence of the tension due to the old cicatrix. The bladder was then covered by means of a single lateral Thiersch's flap at a later date, the exposed surface having been reduced in area from $3\frac{1}{2}$ in. \times $3\frac{1}{2}$ in. to $1\frac{1}{2}$ in. \times $1\frac{1}{2}$ in. by the closure of the symphyseal gap. The special features of the case were discussed, and some of the possible objections to the method were considered, the following advantages being claimed for it:—1. Saving of time. In one of Trendelenberg's cases the whole procedure, excepting the closure of a small fistula, occupied eight weeks only. 2. A perfect mucous lining to the new bladder, interrupted only by a median cicatrix, was attained. 3. Failure of the primary operation in no way prejudiced subsequent measures. 4. Should primary union fail, much smaller flaps were needed than in the usual operations. 5. The superficial area was not merely lessened, but a gradual backward sinking of the bladder-wall accompanied the decrease in diameter. 6. The last two points were of special importance in cases like the one related, where cicatrix interfered with the ready fashioning of flaps. 7. The closure of the symphyseal gap offered a better support for the abdominal viscera.—Mr. THOMAS SMITH had not operated on many cases of this kind, and, though he was glad that the new operation had been tried, was afraid that much good would not come of it.

A Case of Wound of the Femoral Artery and Vein; Traumatic Varicose Aneurysm; Ligature of both Artery and Vein; Recovery; with Remarks on the Treatment of Wounds of the Femoral Artery and Vein.—Mr. W. J. WALSHAM read a paper on this subject. R. H. W., aged 19, a medical student, received a punctured wound in the upper third of the left thigh. The profuse hæmorrhage that resulted was controlled by digital pressure and a firm bandage. On the following afternoon an arterio-venous aneurysm was detected. Three days after, as the tumour was increasing, it was explored. The femoral artery and vein in Hunter's canal were found wounded, and were tied above and below at the injured spot. The patient made an uninterrupted recovery. The question of the treatment of a wounded femoral artery and vein was discussed under the following heads: 1. Immediate simultaneous ligature of the artery and vein. The author gave twelve cases in which immediate ligature was applied. In four, and probably in five, gangrene occurred. It was submitted, however, that, especially as concerned the superficial femoral vessels, the danger of gangrene had been overrated. 2. Continuous pressure without operation. Out of thirty-six cases so treated, thirty-five resulted in arterio-venous aneurysm. The dangers of treating this affection were commented on. The author concluded that pressure alone could not be recommended, and showed that pressure itself involved the danger of sloughing and secondary hæmorrhage. 3. Temporary pressure in order to allow the collateral circulation to become established before resorting to ligature. The danger of gangrene after ligature was reduced to a minimum when the collateral circulation had become established. Grillo, of Naples, tied both vessels in fifteen cases for aneurysm without a single bad result. In twenty cases collected by the author, gangrene occurred in five only, and in four of these five cases the gangrene was due to other causes. 4. Ligature of the artery and application of pressure to the vein. Cases at St. Bartholomew's Hospital were mentioned in which the vein was pricked in tying the artery. No harm followed where the ligature was withdrawn and the artery

tied higher up. But where the artery was tied at the same spot thrombosis and blood-poisoning ensued. In all the hæmorrhage from the vein ceased on tying the artery or on applying pressure to the vein. The author considered that in a wound of the artery and vein there was some risk in tying the artery above and below and leaving the vein untouched, or in trusting to pressure upon it, and that such treatment should only be undertaken when the wound in the vein was very small, and there was a reasonable prospect of the external wound healing by the first intention. 5. The question of the lateral *versus* the circular ligature of veins. In four cases of wounds of large veins observed by the author, its use was successful, as it was also in thirteen cases out of sixteen collected from other sources. The fatal cases occurred before the days of antiseptic surgery. The following conclusions were drawn: 1. That when the femoral artery and vein were involved in a punctured wound of the thigh, the safest course was to apply pressure for a few days in the way described in the above case, in order to allow the collateral circulation to become established, and then to cut down and tie the proximal and distal ends of both the artery and vein. 2. That immediate ligature (that is, before the collateral channels have had time to enlarge) of both the femoral artery and vein, and especially of the common femoral vessels, was liable to be attended with gangrene, although this risk was probably less than had generally been assumed. 3. That ligature of both vessels when, in consequence of pressure, as of a tumour, the collateral circulation had become established, was attended with much less risk of gangrene. 4. That when the femoral artery and vein were wounded, ligature of the artery and pressure on this vein, if the wound of the latter vessel was a mere puncture, was a safe treatment, provided that the nature of the injury allowed of reasonable prospects of the external wound being kept aseptic and uniting by the first intention. 5. That when the wound in the vein was too large to permit of treatment by pressure, the walls might be safely nipped up and a ligature thrown around them without obliterating the calibre of the vessel; but that this procedure should only be resorted to, as in the former case, when there was a reasonable prospect of the wound healing by the first intention. 6. That considering the grave risks of gangrene that attend the sudden obliteration of the common femoral vein, the lateral ligature should in this situation, for all small and moderate-sized wounds that require immediate ligature, be the treatment adopted.—Mr. HULKE congratulated the author on the success of his case, and said that in regard to treatment it was very often difficult when hæmorrhage was great to diagnose whether the vein was injured as well as the artery. He had twice (in cases of cancer) been obliged to ligature both the iliac vessels at the same time, and in both cases the patients had survived a week or ten days, and the ligature had not been followed by gangrene or other bad result. He thought perhaps when both vessels were ligatured the risk of gangrene was less. Every case of arterio-venous aneurysm could not be treated in the same way; much must depend on the nature of the case. A man came to him to be treated for slight eczema of the foot, who for years had been treated with elastic bandage for an aneurysmal varix, and had been able to follow his occupation as a carpenter. The patient complained only of the eczema, and did not mention the varix, which Mr. Hulke discovered accidentally. He thought varix sometimes followed bruises of vessels, as in cases of bullets passing between artery and vein, when there could be no hæmorrhage at the time of accident.—Mr. HARRISON CRIPPS referred also to difficulty of diagnosing when the vein was injured as well as the artery. He thought that pressure ought always to be tried first, and recommended the following method: Limb to be firmly bandaged from bottom to top; wound to be left exposed; then fire-stick to be applied above, and above and below wound, and retained by narrow webbing at each end of stick. Compresses over the stick, and a Liston's splint to leg. Many cases had probably been cured by pressure treatment that had not been recorded.—Mr. THOMAS SMITH related a case of a boy treated by pressure, who had recovered.—Mr. PEARCE GOULD mentioned a case of Mr. Lawson's which had not been improved under pressure treatment. He was operated on, and communication found between artery and vein. The artery was tied, but the vein left alone, and complete recovery followed. He thought that all surgeons who had tried pressure in wounds of the palmar arch were dissatisfied with the treatment, and would always cut down and tie the bleeding points, and that arteries in all parts ought to be treated in the same way. Pressure on vessels was probably as dangerous as ligature. He preferred immediate operation as

gure of bleeding points.—Mr. WALSHAM replied that the pressure in his case was done while Mr. Cripps was looking on. His treatment gave the patient the chance of recovering with pressure only. In one case, supposed to have been cured by pressure, an aneurysm appeared after a sudden strain ten years later.

CLINICAL SOCIETY OF LONDON.

FRIDAY, MARCH 23RD, 1888.

W. H. BROADBENT, M.D., F.R.C.P., President, in the Chair.
Hyperpyrexia in Acute Rheumatism treated by Ice-Pack.—Dr. WILLIAM M. ORD related this case. The patient was a man, aged 2, a heavy beer drinker, who had contracted, three weeks before admission to St. Thomas's Hospital, a sharp attack of acute rheumatism, referred to exposure to cold. On admission he was found to have acute inflammation of many joints, marked signs of pericarditis, and slighter signs of endocarditis, with some leucis. His temperature was 102.4°, the respirations were quickened, the urine contained one-sixth of albumen and very little chloride. He was slightly delirious. Two days later the delirium had increased to such a degree that it was necessary to remove him from the large ward to a single-headed ward. He was very violent, had hallucinations and delusions, and was with difficulty kept in bed. The delirium strongly suggested the existence of hyperpyrexia, but the temperature was only 101.4°. After this the temperature rose steadily, till at 4 A.M. on the morning of the fourth day from admission it reached 108.4°, while the patient had fallen into a state of restless unconsciousness, with tremors. The ice-pack was now applied, and was maintained for four hours, at the end of which the temperature was 100°, the patient had recovered consciousness and spoke sensibly, and the pulse had fallen from 160 to 100. During the next few days the temperature, after first rise to 103.4°, kept between 100° and 101°. The signs of pericarditis disappeared, but those of endocarditis remained. The joint affection had greatly decreased, and the albumen had disappeared from the urine. On the seventh day after admission temperature again began to rise, and at 2 A.M. on the morning of the eighth day was 105.4°, the patient having passed through delirium into restless unconsciousness. The ice-pack was again applied. By 5 A.M. the temperature was 100°, and the patient had recovered consciousness. After this the patient made a steady recovery, and was discharged six weeks after admission in good general health, and without sign of lung or heart disease. The treatment was effectively carried out by Dr. Ord's house-physicians, Dr. Wheaton and Mr. Macevoy. Dr. Ord brought the case before the Clinical Society, not because it presented anything new or original, but with the intention of emphasising the value of cold applications to the surface of the body in hyperpyrexia. He urged that, notwithstanding the acknowledged value of the various antipyretic drugs in pyrexia, their use in hyperpyrexia was comparatively unsafe, large and frequent doses being required, whereby toxic symptoms were often produced. He admitted that the bath treatment was not of universal applicability, but pointed out that it involved no poisoning, and had a remarkable effect, not only in reducing temperature, but in restoring the nervous system to a natural condition. The rapid disappearance of inflammation in the thoracic viscera and joints was also noteworthy.

Two Cases of Hyperpyrexia Successfully Treated by Cold.—Dr. J. ARKLE read notes of these cases. Case I.: A.W.G., aged 27, married, railway clerk, was admitted into University College Hospital, September 21st, 1887, with an ordinary attack of rheumatism. His previous health and habits were good. He had syphilis nine years ago. His mother died after an attack of acute rheumatism. His sister was rheumatic. On admission he was treated with large doses of salicylate of soda. The night after admission he became very delirious, the joint pain disappeared, the skin became hot and burning, and the temperature was up to 110.4°. He was treated with ice-cold bath for forty minutes. The temperature fell to 97°, but ran up four hours later to 107.2°, while he was taking antifebrin. The bath was repeated for twenty-five minutes. The temperature fell again, and showed no further tendency to run up successively. No visceral lesion followed. The patient was ultimately discharged cured.—Case II.: E.C., aged 30, a married woman, had rheumatic fever eighteen years ago, but no complications. There was no family history of rheumatism. Present illness: She had been ailing with joint pain for a week before she had been seen by a medical man. The temperature at midday on October 9th, 1887, was 102.5°; at 10.30 the same night it was 110.4°. The patient was violent and delirious. No bath being available,

she was treated with ice-cold packs. The temperature fell one hour later to 101°, and for the next twenty-four hours averaged 103°. It then fell to normal under salol and salicylate of soda. The patient was discharged well on October 27th, 1887. She had been readmitted with another attack of acute rheumatism and pericarditis, but was now convalescing. Remarks: These cases showed the value of the cold bath or pack as antipyretics. Both belonged to the type in which the temperature, after maintaining for one or two days a moderate level, suddenly rises to an excessive height. In both cases the temperature was very tractable, having a little tendency to run up repeatedly. The cases threw no light on the etiology: one was a male and the other a female; one a first attack and the other a second; both seemed mild uncomplicated attacks. In both there was cessation of sweating, and in one disappearance of articular pain. In both the delirium accompanied the hyperpyrexia, and was of the same violent character. Both patients had marked retraction of the head, and one severe or persistent opisthotonos.—Dr. MACLAGAN thought all the cases formed a valuable addition to the literature of an important and somewhat obscure subject. In the way of criticism he had nothing to say; he would only homologate in its entirety what had been stated by both gentlemen, that the salicyl compounds, all potent in rheumatic pyrexia, were of no use in rheumatic hyperpyrexia. In the treatment of that condition the external application of cold was the only remedy on which one could rely, and it was waste of valuable time to have recourse to any other. He would try to give some indication as to why it was that a remedy which rapidly cured rheumatic pyrexia was of no service in rheumatic hyperpyrexia, and that the one agency on which one depended in rheumatic hyperpyrexia one never thought of applying in rheumatic pyrexia. Rheumatic pyrexia and rheumatic hyperpyrexia were two totally different morbid conditions, essentially distinct in their pathogenesis. It was because of this that their treatment was so essentially different, and that what cured the one was of no avail in the other. Rheumatic pyrexia was of metabolic origin; rheumatic hyperpyrexia of neurotic origin. In the one the fever was due to increased metabolism and consequent increased production of heat; in the other the rise of temperature resulted from paralysis of heat inhibition. As the subject was not before the Society, he did not stay to consider how rheumatic pyrexia was produced, or how the salicyl compounds cured it. Hyperpyrexia was not a disease *per se*, but an incident occurring in the course of various and different ailments. It might occur in any of the specific fevers. How was it induced. The fever in these ailments was of metabolic origin, due to increased production of heat; normally heat production was prevented from passing due bounds by the heat-inhibiting function. Increased production of heat necessarily gave rise to stimulation of this function. Prolonged stimulation (as in the tetanising of a muscle) might lead to exhaustion of function. Stimulation of the inhibitory function might in any fever lead to fatigue, and even paralysis of that function, and consequent rapid rise of temperature. Rheumatic fever was the one in which this was most likely to occur, because in that fever much metabolism, the chief source of heat production, was more increased than in any other; as a result, heat production was greater, heat inhibition more strained, and therefore more likely to be paralysed. But hyperpyrexia did not consist solely in excessive rise of temperature any more than pyrexia consisted in increased body heat. That a very high temperature did not necessarily cause nervous symptoms was evidenced by what one saw in relapsing fever, in which it was not uncommon to have a temperature of 106°, 107°, or even 108° without the patient presenting any other symptom by which his case could be distinguished from that of the man in the next bed, whose temperature might be only 102° or 103°. The condition to which was applied the term hyperpyrexia essentially consisted in paralysis of inhibition of the functions of organic life, heat inhibition being only one of them. How did cold produce its curative action in this condition? Not by lowering the temperature, for to say that would be equivalent to saying that the high temperature was the cause of the disturbance. Moreover, cold actually removed the whole morbid condition and cured the patient. It could not do this simply by a refrigerating action. The physiological effect of long exposure to cold was to produce a sense of drowsiness and a tendency to sleep, which, if not resisted, gradually deepened into fatal coma. Cold was evidently a powerful agency, experiencing a sedative action so great that it might prove fatal by coma; but, like other sedatives, it might

be used in moderation, and have its quieting action turned to good account. He would illustrate what he believed to be its mode of action in hyperpyrexia by a reference to the action of digitalis in heart disease. Stimulation by the cardiac inhibitory nerve, the vagus, slowed the heart's action. When, as often happened in mitral disease, the heart's action was excited and disturbed, one did not try to allay the disturbance by soothing the excitomotor nerve of the heart, but by giving digitalis, and stimulating the inhibitory nerve. To stimulate inhibition was the physiological and scientific way of allaying excessive functional activity. It was thus that cold acted in hyperpyrexia. That condition essentially consisted in paralysis of inhibition. Cold stimulated inhibition and cured the patient. Its mode of application was a matter of detail and convenience. Ice or cold water were the two means of applying it. Care must only be taken that inhibition was not over stimulated, for complete inhibition of organic life meant death. Cold acted in hyperpyrexia not by lowering the temperature, but by causing such peripheral excitation of the cutaneous nerves as resulted in stimulation of the inhibiting centres. It was only by recognising that rheumatic pyrexia and rheumatic hyperpyrexia were different morbid conditions, totally distinct in their pathogenesis, that one could explain why it was that the treatment suitable in the one was inapplicable in the other.—Dr. COUPLAND thought that although Dr. MacLagan had clearly differentiated between pyrexia and hyperpyrexia, they were both equally due to disturbance of the nervous system, and that cold was equally a means of reducing pyrexia as of lowering hyperpyrexia. Dr. MacAlister's argument in his lectures on fever was based on the neurotic origin of fever, of pyrexia as of hyperpyrexia. The cases related were all good examples of the benefit produced by the treatment by cold in hyperpyrexia. Dr. Ord's patient had well-marked nervous disturbance before the hyperpyrexia set in, and this, fortunately, was often the case; so that, by watching the patient in whom these symptoms arose, and taking his temperature, one might anticipate and prevent the hyperpyrexia. A committee appointed by the Society some years since had found that the cases had marked prodromata, the chief of which were in the nervous system. If, when the temperature rose to 105°, the bath was always used, the patient would probably be cured. In Dr. Arkle's patients there were no prodromata mentioned. Dr. H. Thompson had years ago advised to look ahead in these cases, and treat them carefully, so as to avoid the sad fatality which awaited the patients unless treatment was prompt.—The PRESIDENT thought the cases were all of extreme interest, but the fact that in Dr. Ord's case there was cerebral disturbance before the hyperpyrexia was noted was of far-reaching importance. Whatever the explanation, it was clear that the delirium and subsequent coma were not altogether due to the rise of temperature. The nervous element in the case came first; the disturbance was probably of the whole nervous system, not of the inhibitory heat centre. In failure on the part of the nervous system the trouble seemed to commence. In relapsing fever, with a temperature of 107°, the patient was sometimes furiously delirious. In two cases he had seen the peculiar delirium mentioned by Dr. Ord; no high temperature followed in either case; both patients were under the influence of salicylate of soda, and both proved fatal. Possibly the cold treatment might have averted the fatal result. Two factors were at work in the cold treatment; one was the abstraction of heat; the other was that that treatment enabled the nervous system to reassert its control over the body, and thus led to the cure of the patient.—Dr. BASIL MORISON cited the case of an infant, 14 days old, whose pulse, consequent on over-feeding, fell to 30 per minute, the skin becoming cold. A drachm of tincture of belladonna was injected into the rectum, whereupon the pulse rose to 180 and the temperature to 130°. In fact, the child's life appeared to be in danger. Ice was applied, and the temperature cooled down—to such an extent, indeed, that the heart stopped for a few beats. The child, however, recovered with artificial respiration. He thought the case might serve to illustrate the action of cold.—Dr. ANGEL MONEY remarked that in Dr. Arkle's first case, when the man recovered from the coma, his first remark was "Isn't this marvellous?" He thought the use of this expression well illustrated Dr. Hughlings Jackson's theory that the centre in the brain, which was well used (for this was an ordinary expression with that patient) was the first to act.—Dr. BARLOW had treated a case of acute rheumatism in a delicate woman who could not be removed from her bed to a bath when it was neces-

sary to apply the cold. The patient was stripped, except at the waist, and the bed tipped at the head so that cold water which was poured over her ran away at the foot. The water was used several times, and she was rubbed dry after each application. This simple procedure reduced the temperature from 107° to 100°. This was a good substitute for a cold bath where the latter could not be applied. The constant application of cold in slight pyrexia produced depression and rigor, and made a patient look quite blue. It was really a powerful remedy. He cited also the case of a barman, with furious delirium at the beginning of pneumonia, whose temperature was lowered by similar treatment.—Dr. ORD remarked that Dr. MacLagan's theory of hyperpyrexia being due to paralysis of the centres of organic life, of which heat was one, was partly corroborated by Dr. Buzzard's views that rheumatic fever might be due to an affection of the cerebellum, in which the heat-inhibition centre seemed to be situated. He (the speaker) also thought that the effect of cold was not simply mechanical, as was evidenced by some experiments performed upon cadavers. Having heated them to a height in warm baths, he treated them by a cold bath without reducing the temperature in anything like the proportion to which a cold bath reduced the temperature of a hyperpyrexial patient. His patient, who was before delirious became quite clear, and slept; his pleurisy disappeared, and the peri- and endocarditis both thenceforward diminished. Hyperpyrexia was a fever out of proportion to the local symptoms. For its treatment one must look to prevention in cases of rheumatic fever; and if the temperature rose over 105° he had recourse to the cold treatment. It was said that pericarditis was usually accompanied by delirium. This he had not found in his cases; but it was a sign of rising temperature. He thought a graduated bath was preferable to the ice-pack.—Dr. ARKLE said that possibly in his second case prodromal symptoms were present before the hyperpyrexia. In the first case the patient was a little deaf and light-headed—symptoms that frequently occurred when the salicylate treatment was pushed. That man had taken 240 grains in the day preceding his hyperpyrexial symptoms.

Gall-stones exciting Suppuration: Operation: Recovery.—Mr. PEARCE GOULD described this case. The patient was a gentleman, aged 38, who had symptoms of gall-stones two years before he consulted Mr. Gould for an abscess in the abdominal wall at the junction of the epigastrium and right hypochondrium. The abscess was opened, and 140 small biliary calculi were removed, together with pus. The sinus that was left was long in healing. No bile was discharged through it at any time. Many of the calculi showed evidence of spontaneous fracture of a larger calculus. Mr. Gould mentioned that he had found reference to thirty-five other cases of gall-stones making their way through the abdominal wall, but this was the only one in which the diagnosis appeared to have been made prior to the abscess bursting. The abscesses had pointed at various places in the abdominal wall, most often above and to the right of the umbilicus. As a rule no bile had escaped with the stones, and these latter had generally been numerous. There appeared to be lacking any satisfactory explanation of the very different results of biliary calculi in different cases.—Dr. ORD said that the disintegration of urinary calculi had much interested him, but as to that of biliary calculi he knew nothing. The disintegration of urinary calculi might be the result of either of many different causes; the shrinkage of the outer layer, or of the inner portion, in consequence of the different composition of the layers. Biliary calculi were composed of a mixture of cholesterine and biliary pigment, and the bile might act on one or other of these constituents alone.—Dr. MACLAGAN mentioned the case of a woman who died from peritonitis, and in whom *post mortem* 180 small calculi were found in the peritoneum, and of which twenty or thirty were disintegrated. He thought that possibly the squeezing of small calculi against one another by the contraction of the walls of the gall-bladder, when it became distended, might produce disintegration.—The PRESIDENT thought the explanation offered by Dr. Ord seemed very reasonable. Calculi being formed of heterogeneous materials, and then exposed in a medium of a different character from that in which they were originally formed, would be liable to suffer disintegration. He remarked that unless the cystic duct were closed no abscess would form externally.—Mr. GOULD thought it remarkable that, considering the variations to which calculi were exposed in the intestine, more of them were not found broken up. As to Dr. MacLagan's explanation, he thought that, if it were correct, one would expect to find after biliary spasm that the stones voided were broken up by the contracting gall-bladder and ducts, but

uch stones were not found disintegrated. He thought that the sharp angles of these disintegrated calculi might, perhaps, have determined the abscess in his case. The specimens in the various London museums were of faceted stones, quite unlike the fragments he had handed round.

MEDICAL SOCIETY OF LONDON.

MONDAY, MARCH 26TH, 1888.

KNOWSLEY THORNTON, M.B., C.M., Vice-President, in the Chair.
CLINICAL EVENING.

Lupus of the Mouth, Pharynx, and Larynx.—Dr. ORWIN showed a girl, aged 21, who came to him in 1886 with lupus of the nose. There was then no disease of pharynx or larynx, but she returned in March, 1888, with lupus of the gums and soft palate, pharynx, and larynx. In this case the lupus had spread through the nose to the palate by lymphatic channels.—Mr. LENNOX BROWNE said he had recorded eleven cases of lupus of the larynx. He had never seen lupus of the posterior wall of the pharynx, and he did not agree with Dr. Orwin's view as to the path followed by the lupus. A distinguishing point between lupus and tertiary syphilis was that the latter often attacked the palate, both soft and hard, by extension from the nasal mucous membrane, whereas lupus always extended by the buccal mucous membrane.—Dr. ORWIN, in reply, said that there was no history of syphilis.

Injury to Lower Epiphysis of Ulna.—Mr. EDMUND OWEN showed a girl, aged 18, who, sixteen years previously, had been under his care at St. Mary's Hospital for an incised wound of the left wrist. The blade had passed through the ulna, just above its articulation with the lesser sigmoid cavity; that joint was not opened, but the lesser sigmoid cavity was sliced from the radius, and the wrist-joint was laid widely open. The tendon of the flexor carpi ulnaris, the ulnar nerve and artery, and some of the adjacent flexor tendons were cleanly severed; circulation and utaneous sensibility were ultimately restored along the inner side of the hand, and though inflammation attacked the surrounding tissues and an abscess formed on the back of the hand, the power of movement became in due course as free as ever. Indeed, the hand was left-handed; as she grew up she easily used her knife in that hand; ultimately she became a useful domestic servant. But the ulna had ceased to be developed, and bent the growing radius over to its side. In September, 1887, the girl fell upon the inner side of the damaged wrist, and immediately afterwards (according to her account) sensation became diminished along the inner side of the hand, and the member became useless. How far the case might be influenced by hysteria Mr. Owen could not say, but it was evident that the ball of the little finger and the web of the thumb were wasted; probably the nerve was injured. The chief interest consisted in the apparent overgrowth of the radius; actually, however, that bone was half an inch shorter than the opposite one, whilst it was bowed in its lower two-thirds towards the ulna, which latter bone was three inches and a half shorter than its fellow on the right side. The case showed how largely the ulna depended on the integrity of its lower extremity for growth in length. The upper epiphysis was of comparatively little importance in that respect. Reference was briefly made to cases reported by Mr. Augustus Clay and Mr. Walter Brown, of Leeds. In these cases the radius had been injured, but the deformity had not been so great because the radius was less dependent for its growth on the lower epiphysis than was the ulna. He then made some remarks as to the best method of treatment.—Dr. Wm. Rose alluded to the case of a boy with fracture of the tibia above the internal malleolus. The boy subsequently returned to the hospital with marked deformity in consequence of the growth of the fibula and the arrest of growth of the tibia. He removed an inch and a half of the fibula, and thus restored the symmetry of the limb.—Dr. DAVIES-COLLEY spoke of a case of a fractured tibia involving the epiphysis, which gave rise to serious deformity, which he treated in much the same way as Mr. Rose had done.—Mr. WALTER PYE said that he did not think the symptoms were due to damage of the ulnar nerve at the date of accident, as the wasting had been far too rapid.—Mr. KNOWSLEY THORNTON asked whether it was not advisable in such cases to wait the full development of the bones.

Paralysis of the Ocular Muscles.—Dr. S. WEST showed a woman, aged 62, addicted at one time to drinking, who had suffered from headache. This returned about two months before admission, chiefly at night. It rapidly got worse, and was most marked in the left temporal region. On getting up one morning five weeks

ago she saw double, and the eyelid dropped a few days later. No other symptoms were noticed, no vomiting nor giddiness. Eyesight began to fail on March 19th, and she could then hardly see at all. No changes were visible on examination of the disc. She had lost flesh, but had picked up more recently. There was no history of gout, rheumatism, or syphilis. There was complete paralysis of all the recti and the inferior oblique, and ptosis. No other nerves were affected.

Gunshot Injury of Right Knee-Joint.—Mr. Wm. ROSE related a case of gunshot injury of the right knee treated by opening up the joint, and cleansing with solutions of carbolic acid and sublimate. A full report of this case will shortly be published.

Trephining for Middle Meningeal Hæmorrhage.—Mr. DAVIES-COLLEY showed a man who had sustained an injury to the head from a fall. He lost consciousness, and on recovery there was slight paralysis of the left arm, and great bruising over the temporal region on the right side. The paralysis afterwards became complete, and extended to the left side of the face. He passed his urine and motions involuntarily, and his temperature went down to 97°. On the eleventh day Mr. Davies-Colley trephined, and found a clot three inches long by seven-eighths of an inch thick, which he scooped away, washing out the cavity. The patient rapidly and completely recovered. Mr. Davies-Colley observed that very few such cases were on record.

Charcot's Disease of the Shoulder-Joint.—Dr. BREVOR showed a man with symptoms of ataxia who had suddenly developed symptoms of Charcot's disease of the left shoulder-joint. No history of previous injury; no pain.

Obliterative Arteritis from Crutch Pressure.—Mr. WALTER PYE showed a man who had been obliged to use a crutch since the age of 8. A year ago he had noticed some loss of sensation in his fingers, and ultimately the artery from the axilla downwards had solidified. The circulation had since returned to some slight extent.—Mr. HADDEN said that he had seen three cases resembling the above, and thought that there was a class of cases in which plastic effusion into the arteries gave rise to thrombosis.

Thiersch-Gould's Operation for Removal of Penis.—Dr. PURCELL showed a man, aged 45, who had been operated on several times for cancer of penis, the first time in March, 1886, and the last in January last. He had operated according to the method described by Mr. Gould. The testicles were not removed, and the patient had complete control over his bladder. He was now comparatively well. The second case was not well enough to leave the hospital. He was operated upon on February 21st last. He was 68 years of age. Epithelioma of penis began last year, but no glands were enlarged.

Carcinoma en Cuirasse.—Mr. MORGAN showed a woman, aged 52, who presented a typical example of the disease named and described by Velpeau as carcinoma en cuirasse. Last summer induration and swelling of the right mamma began, and was followed very shortly by a similar condition in the opposite breast, and this by hardness of the skin of the chest over the whole surface above and between the mammae. When sent to the hospital in October, there was a hard œdematous condition of the whole of the skin of the chest, which was red and even on the surface, presenting almost perfect symmetry, and so hard as to obscure the exact condition of the mammae. The skin of the axillæ were little if at all enlarged. Since October, little change in this condition had taken place, except some ulceration of the skin around the margin of the right breast. Both nipples were surrounded by thick crusts of pigmented epithelium.

ROYAL ACADEMY OF MEDICINE IN IRELAND

SECTION OF MEDICINE.

FRIDAY, MARCH 9TH, 1888.

JAMES LITTLE, M.D., President, in the Chair.

Case of Pneumothorax.—Dr. WALTER G. SMITH exhibited a patient suffering from pneumothorax.

Etymology and Classification of the Anæmia of Puberty.—Dr. E. MACDOWELL COSGRAVE read a paper, which is published in this day's JOURNAL, p. 688.—Mr. COX said his treatment was, first of all, absolute rest in bed for a fortnight, then purgation by sulphate of magnesium, then iron. He combined the iron with tincture of digitalis or of nux vomica, and sometimes used a combination containing ferrum redactum in 2-grain doses, with $\frac{1}{2}$ -grain of the arseniate of iron.—Dr. C. J. NIXON said he could not understand any distinction between the anæmia of puberty and chlorosis. Why not as well speak of the anæmia of dentition or of diarrhœa?

The object was to determine the origin of anæmia—whether it was essential or symptomatic. The essential forms were of three classes: First, the constitutional, which had its origin from birth; that was a form of which they knew nothing, whether as regards its being due to a deficiency in the manufacture of the elements of blood, or to an increased amount of the destruction of those elements. The second class was the anæmia of puberty, ordinarily spoken of as chlorosis. The third class was the form known under the name of pernicious anæmia, the certainty of the existence of which they only arrived at because the patient died. When the pathological principles as to the basis came to be investigated, they recognised all forms of anæmia as standing on the same level with regard to the condition of the blood-cells, in simple anæmia as in cases of chlorosis, or in the most profound forms of pernicious anæmia. Chlorosis applied not only to the female, when special calls were made on the vascular system in puberty, but to the male also. The reason the female was more subject to the disease was because the red blood-cells were normally fewer in number; and certainly, from the condition of the generative system—ovulation and menstruation—there was more disturbance in the blood-forming process in the female than in the male.—Dr. WRIGHT said the only way to cure the patient was to recommend her, the moment she felt her health fail, to put herself under treatment and commence taking iron. Although Sir Andrew Clark had recently claimed the credit of being the first to indicate fecal accumulations as a cause of the disease, he well remembered that the late Mr. Richardson taught his class years ago that he could cure as many cases by using aloes as by using iron.—Mr. Foy mentioned a case of five daughters and two sons, the offspring of an early marriage, of whom the girls became anæmic; the boys escaped.—Dr. J. W. MOORE said that season exercised an influence on the occurrence of anæmia or chlorosis in young adult life; for instance, there was a greater prevalence of the disease in winter than in summer.—The PRESIDENT thought it would be a very dangerous thing to make a diagnosis of anæmia in any case where there was loss of weight accompanying it. Where he saw a girl who became breathless and had palpitation on exertion and had got white, if she did not increase in weight, he would fear he had to deal with tuberculosis and not with anæmia. There were cases where anæmia had been set going by shock; for instance, that of a young lady who accidentally killed her father by giving him a poisonous liniment. Then there were affairs of the heart and other exciting causes, suggesting that anæmia was due to some influence on the nervous system.—Dr. COSGRAVE replied.

Gastric Epilepsy.—Dr. A. W. FOOT made a communication on gastric epilepsy. A lad aged 17 had a series of epileptic attacks for two years, induced by eating rich and indigestible things, or ordinary food in a rapid manner. His attacks occurred at meals and in the dining-room almost exclusively. He was seen by Dr. Brown-Séguar, and, after persevering in his treatment for five years, the seizures ceased to occur.—Dr. FINNY mentioned the case of a young student who, crossing the Channel, had a supper of beefsteak about 3 o'clock in the morning on board the steamer. After breakfast he became the victim of a very severe attack of epilepsy. The cause proved to be the undigested beefsteak, and there was no return of the disease. He had experience of another case of a young man who had, when a child, suffered from scarlet fever. That youth, whenever the large bowel became loaded with animal food, became liable to epileptic seizures.—Dr. C. J. NIXON said Dr. Foot's case was one of extreme interest, in view of the important fact that an epileptic of five years had got completely well. It was not sufficient to direct attention to the peripheral irritation alone. A healthy person would not get an attack from a mass of undigested food in the bowels. There must be a peculiar condition of the cortex of the brain which, from irritation, set up the epileptic condition; and the special danger was that, once it was developed, it was apt to continue.—Mr. COX made some remarks, and the PRESIDENT said there were two factors at work. Besides the irritation, there was the mobile excitable condition of some portion of the brain, which made it liable to discharge itself on slight provocation. Some twenty years ago he saw a boy, aged 8 or 9, whose case left a great impression on his mind. The boy had had a succession of epileptic seizures. His father and mother were first cousins, and he had five uncles and aunts confirmed epileptics. Still it occurred to him that the boy might have worms. Means were taken that dislodged a vast quantity of round worms. From that time to the present the patient, who was now thirty years of age, had never had

a recurrence of the epileptic seizure. If the worms had been allowed to remain some time longer, until the epileptic habit had been established, he would have been, like his uncles and aunts, a confirmed epileptic.—Dr. FOOT replied.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, MARCH 16TH, 1888.

J. SPOTTISWOODE CAMERON, M.D., Vice-President, in the Chair.

Cystic Kidney.—Dr. CUFF showed a kidney in an advanced state of cystic degeneration; weight, 10 ozs. The other kidney weighed 7½ ozs., being healthy.

Abscess of Brain.—This was shown for Dr. EDDISON. There was a large collection of very foetid pus in the substance of the right hemisphere. There was no bone or tubercular disease discovered.

Specimens.—Mr. JESSOR showed the following. 1. Lipoma nasi. 2. Adenoid tumour of kidney (successful nephrectomy). 3. Sarcoma of femur (amputation). 4. Large, round-celled, alveolar sarcoma, from popliteal space. 5. Hæmatoma of arm.—Dr. ALLAN showed: 1. Primary cancer of bladder. The symptoms had existed for six months. 2. Spleen, greatly enlarged, from case of leucocythæmia. The intestine, also, was shown. The latter showed pearly nodules, and the mesenteric glands were enlarged, but there were no nodules in the spleen. 3. Cancer of stomach and liver. 4. Viscera from a syphilitic infant. 5. A collection of gall-stones. 6. Twin chickens, united by the thorax.

Knee-joint.—Mr. TEALE showed a knee-joint from a man, who on two occasions had received injury by strain or wrench followed by pain and swelling. A loose body could be felt, and the joint was opened for its removal. It was then found that besides partial detachment and great thickening of the synovial fringes, there was destruction of the cartilage on the inner side, and the surface of the bone had been worn into a deep groove, with a sharp edge, as if a piece had been removed by two saw cuts at right angles to each other. Several loose pieces of bone and cartilage were also removed. In a second operation the knee-joint was excised, but the patient died from acute septicæmia. Mr. Teale thought a piece of bone and articular cartilage had been broken off by the injury, which had worn the groove in the opposing surfaces of femur and tibia.—Dr. JACOB, Dr. BARRS, and Mr. LITTLEWOOD made some remarks.

Pelvic Cysts.—Mr. MAYO ROUSON showed a series of preparations illustrating the origin of pelvic cysts. He showed specimens of hydrosalpinx, pyosalpinx, parovarian and broad ligament cysts, dermoid, unilocular, multilocular, and papillomatous ovarian cysts, and fibro-cystic tumour of the uterus, demonstrating by means of diagrams the seat of origin of the various tumours. He remarked on the frequent gonorrhœal origin of tubal disease; and, aftershowing specimens of follicular degeneration of the ovary, said that such disease, though forming no tumour, was frequently a cause of intense pelvic distress, incapable of relief except by removal of the appendages. In all the cases shown the patient had recovered from the operation.

Ankylosis of Atlas and Occiput.—Dr. WARDROP GRIFFITH showed a specimen of ankylosis of atlas and occiput. There was a history of suppuration about the neck in childhood. There was a thickening of the bone at the origin of the trapezius.

Cirrhosis of Liver.—Dr. GRIFFITH also showed a specimen of this condition. There was a very large vein, in the position of the fetal umbilical vein, passing from the portal vein to the umbilicus, providing collateral circulation. This perhaps was the reason that ascites had not recurred after the patient had been tapped.

Liver Disease in Cat.—Dr. GRIFFITH also showed the liver of a cat studded with large nodules, presenting somewhat the appearance of a human syphilitic liver.—Dr. BARRS and Dr. JACOB thought the condition a congenital abnormality, and not pathological.

Papillary Growths.—Dr. JACOB showed on a screen, by means of a Lewis Wright's lantern microscope, a number of preparations illustrating papillary forms of growing epithelium from various inflammatory and neoplastic growths, including papillomata of the tongue, coccidium nodules from rabbit's liver, and adenoid growths from the kidney and prostate.

Miscellaneous Specimens.—Mr. MAYO showed a specimen of Tubercular Arthritis of Knee. Specimens of Abnormalities of Arteries, from the Anatomical Department of the Yorkshire College, mounted by Dr. OLIVER, were shown, as well as a number

of ophthalmic and other preparations recently added to the Yorkshire College Museum.—Mr. LITTLEWOOD showed sections of hard chancre (excised on the sixth day) and pigmented moles. In the former a characteristic induration had appeared at the edges of the wound.—Mr. LITTLEWOOD, for Mr. BROWN, showed Median and Ulnar Nerves, becoming bulbous and adherent to the stump of the forearm.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

FRIDAY, MARCH 16TH, 1888.

ALFRED HILL, M.D., President, in the Chair.

Death-Rates as Tests of Healthiness.—Dr. LOUIS PARKES read a paper in which the fallacies arising from a faulty enumeration of the population on which death-rates were founded were pointed out, and it was shown that in the ten years intervening between two censuses, it was in many cases impossible to arrive at even an approximate enumeration by any method at present known. The only effectual remedy would be a quinquennial instead of a decennial census. The author next pointed out the fallacies which might arise from disregard of the different age and sex distributions of different populations, when their death-rates were used for the purposes of comparison and as tests of health and sanitary condition. It was urged that no public statement of death-rates should be made, which had not been corrected for age and sex distribution on the basis of the proportions found to exist in the country generally at the date of the last census. The method employed by the Registrar-General in the case of the twenty-eight large towns of England and Wales was simple and efficient, and with no great labour might be applied to every community of persons throughout the country. The influence of birth-rate upon death-rate was considered, and the late Dr. Letheby's views upon the relations which should subsist between a high birth-rate and a high death-rate were alluded to. The fundamental distinctions between mean age at death and mean duration of life were insisted upon, and it was shown that the mean duration of life was one of the best tests of the healthiness of a population. In conclusion, the author brought under notice the high death-rates which had distinguished for so many years some of the northern manufacturing towns, and urged that this excessive mortality, which was largely confined to the earliest periods of life, was due to causes which could be brought under control, and that an authoritative inquiry into all its aspects was demanded. Such an inquiry would bring public opinion to bear upon a condition of things which should not be allowed to exist any longer.—In the discussion which followed, the PRESIDENT, Drs. BATE, SYKES, SAUNDERS, and SEATON, and Messrs. BUTTERFIELD, BLYTH, NOEL HUMPHREYS, LOVETT and SHIRLEY MURPHY took part, and Dr. PARKES replied.

REVIEWS AND NOTICES.

A TREATISE ON CHEMISTRY. By Sir H. ROSCOE, F.R.S., and C. SCHORLEMMER, F.R.S. Vol. III, Organic Chemistry. Part IV. Messrs. Macmillan and Co.

THE present volume, consisting of 544 pages medium octavo, forms a further instalment of the well-known textbook on chemistry, both inorganic and organic, with which the names of these authors are associated. This part is devoted to a description of the aromatic compounds containing seven atoms of carbon, including the toluene, benzyl, benzoyl, and hydrobenzyl groups, as well as the xylene group of the compounds containing eight atoms of carbon. The volume is a worthy successor to those which have preceded it, and is characterised by the lucid and comprehensive manner in which the extremely unwieldy mass of acts composing modern organic chemistry is presented to the reader. Of particular value are the historical retrospects given in introducing the more important compounds, and which serve to indicate the progress and development of the various branches of organic chemistry. It is these passages which make this something more than a mere work of reference, and render a large part of the volume suitable for continuous reading. As a work of reference, the treatise of the authors cannot, of course, compete with the exhaustive compilation of Beilstein, *Landbuch der Organischen Chemie*, in which the avowed aim of the author has been to refer to every organic substance the composition of which has been determined by analysis. But there can

be no doubt that the work, as far as it has progressed, is not only without a rival as a treatise on organic chemistry, but is also unequalled as a book of reference in the English language. The present part is not one which contains much that is of special interest to medical men generally, although there is a very clear account of the relationship between benzoic and hippuric acids and of the causes to which the appearance of these substances in the urine of man and of the lower animals is due. The description of the preparation and properties of salicylic acid, as well as of some of the products of oxidation of the opium alkaloids belonging to the 8-carbon-atom group will also be read with interest.

THE CURABILITY OF INSANITY. By JOHN S. BUTLER, M.D., Hartford, Connecticut. Messrs. Putnam. 1887.

AT first sight one is prejudiced against this very small work on such a very large subject, and but for personal knowledge we should have supposed that it was the first effort of a young man who was starting on the path of authorship. As it happens it is the summing up of the experience of an old man who has seen much, and probably discovered into how small a space all our real knowledge can be put.

Dr. BUTLER begins by discussing the proportion of patients to medical men in asylums, in the past and in the present. He is a strong advocate for the separation of the curable from the incurably insane, and for the individualised treatment of the former. Why should it be necessary to state this proposition that the insane must be treated as individuals? But so it is and so it will remain as long as medical superintendents are expected to be medical stewards, or are men appointed for social rather than medical fitness. We do not know of a single English asylum or hospital for the insane which is sufficiently officered if there is to be thorough medical supervision of the cases. No general physician, even with a staff of clinical clerks, would pretend to be responsible for the diagnosis and treatment of two or three hundred cases; and yet in the best hospitals for the acutely insane this is what is expected. Skilled and experienced general physicians, with special training, should be at the head of asylums, and they should be free from mere administrative work, and have every assistance in providing suitable companions and attendants.

Dr. Butler points out how many cases of functional mental disorder require special treatment, and nowadays one must admit that in asylums lady nurses and lady companions have replaced the "Mrs. Gamps" of former days, yet here in England there is still much to be desired. The general hospital nursing is in advance of that of our asylums, and even this is much better than the nursing provided for those cases which are treated at home. Individual treatment, such as that recommended in this little book, implies thorough knowledge of the conditions under which the disorder has arisen, and a proper exertion of force to counteract the evils. It is surprising that so little has been written on the functional cure of functional disorders, for there is plenty of room for the exercise of this kind of treatment among the insane.

The majority of medical men seem to have three courses open to them in treating the insane. Either they narcotise them, send them to an asylum, or send them abroad. Any one of these forms of treatment may be abused, but we think that the sending of a person of unsound mind abroad without having fully considered what he is going away for is unreasonable and may be dangerous. The mind is at least as much influenced by rest as the organs of sense, and rushing over the Continent is not rest. Rest in bed and careful watching may be much better than railway or even ocean travel. The advice given by our author is sound, his examples are interesting, and his authorities are the best in lunacy. He exhibits the old man's love of quotation, and his quotations will be found to be correct and apposite.

A TREATISE ON ASTIGMATISM. By SWAN BURNETT, M.D., St. Louis, Missouri: J. H. Chambers and Co.

NOTWITHSTANDING the author's preface, we much doubt the wisdom of writing a book on astigmatism alone. It appears to us to be both theoretically unsound and practically inconvenient to divorce the consideration of one form of ametropia from that of others, and the book before us could have been only complete had it formed part of a larger work.

The theoretical parts are, we think, the best. The nature of a bi-axial and a tri-axial ellipsoid is well explained, and the effect of spherical and ellipsoid surfaces in causing spherical aberration

tion is fully dealt with, and illustrated by an excellent diagram (fig. 7). In astigmatism, as it occurs in the eye, we miss any clear explanation of the fact that an eye with simple astigmatism sees lines best which are at right angles to its emmetropic meridian. It is true that all the data for the explanation are given, but hardly, we think, arranged so that they would be put together by a beginner without assistance. Yet this is the *pons asinorum* of astigmatism.

In speaking of mydriatics, we are surprised to see that the author recommends the use of atropine of the strength of 2-4 per cent. Solutions of this strength are never used in this country, and are quite unnecessary. He also supports the practice—which used to be widely adopted, but which we thought had been abandoned by most—of postponing the ordering of the correcting glasses till the effect of the mydriatic has passed off. We must confess that we could never see the necessity of this; the condition of the accommodation can and ought to be ascertained before a mydriatic is used, and the objection that the dilatation of the pupils affects the result is trivial, since any difference arising from this source can easily be eliminated by means of a diaphragm.

Most of the illustrations are excellent. It is, however, unfortunate that the ellipsoid in fig. 6 does not fulfil the conditions of the definition. We think that the nature of an ellipse would have been rendered much more obvious to the notice if the old school-boy trick of drawing it had been given, namely, by fixing a slack string between the two foci, and running a pencil-point round within the string. We must object more forcibly to fig. 30, which is a blemish to the book. It is supposed to represent the mode in which the inverted image is formed in the indirect method. It is inaccurately drawn, and has not even the merit of being clear as a diagram. Rays from two widely separated points on the fundus are depicted as emerging in a single pencil, which could not possibly come from either.

The apparent increase in the size of the image in emmetropia is mentioned and explained, an obvious omission from most of our textbooks. The explanation of the changes in the shape and size of the image of the disc on withdrawing the lens in the various forms of astigmatism might be given more fully in a special treatise. The author does not appear to have seen M. Patent's excellent paper on this subject (*Rec. d'Ophthalm.* 1881).

The description of the ophthalmometer of Javal and Schiötz is the best we have seen in English, and the author pays a high tribute to its scientific value; its practical use is much limited by its cost. It is not the author's fault that he has nothing new to say as to the practical testing of astigmatism.

On the whole, we doubt whether the book will be of much use to the ordinary student, since it contains hardly enough elementary matter. For the specialist it contains much that is of interest.

NOTES ON BOOKS.

Notes on Dental Surgery, Intended for Students of Medicine and Medical Practitioners. By J. SMITH, M.D., LL.D., F.R.C.S.E. (Edinburgh: Maclachlan and Stewart).—This is a small foolscap 8vo. pamphlet of 70 pages, of which about thirty are occupied with such subjects as dental anatomy, dentition, and anaesthesia. This leaves altogether inadequate space for a sufficiently clear description of dental diseases and their treatment, and it is not, therefore, wonderful the author has failed to produce a really useful work. It, however, contains plain directions for extracting teeth. It is a pity the author has not instead brought out a new addition of his *Handbook*, now out of print. That *Handbook*, revised and amplified, might perhaps have successfully competed with well known manuals of a similar kind; but this meagre pamphlet is not likely to do so.

The Etiology and Pathology of Hydræmia, with its Relation to certain Fœtal Deformities. By JOHN PHILLIPS, B.A., M.B. Cantab., M.R.C.P., Physician to the British Lying-in Hospital. Pp. 17. (Edinburgh: Oliver and Boyd. 1887).—This is a reprint from the *Edinburgh Medical Journal*. The subject is discussed under two heads (a) the etiology and pathology of the disorder, (b) the relation of the excessive secretion to certain fœtal deformities. The article appears to be a summary of the works of such men as Gussow, Bar, Ahlfield and others who have laboured in this field,

while the conclusions arrived at are similar to those now generally accepted.

The Refraction of the Eye. By G. HARTRIDGE, F.R.C.S. Third Edition. (Messrs. J. and A. Churchill. 1888).—When a book has shown itself to be sufficiently popular to require a third edition, there can be no occasion to cavil much at its contents. We are glad to see that several slips that occurred in the earlier editions have been corrected, notably Figs. 63 and 43, though it is not clear why Fig. 54 remains unaltered. It is most difficult in a small work on a large subject to know what matters to treat of and what to omit, but we think those which are mentioned should be treated with some approach to completeness, and that when an explanation of facts cannot be given, the reader should, at any rate, be put on the right track for finding an explanation for himself. The statement on page 29 as to the mode in which distance is estimated is so incomplete that it would be better omitted, while the statement attributed to Landolt, but without a reference, that when the correcting lens is placed 13 millimètres in front of an ametropic eye, the retinal image is of the same size as in emmetropia, would have been of value had it been pointed out that this is because that point is the anterior focus of the eye. The statement in this latter form occurs indeed in Landolt's work on *Refraction*, but it is no more his than is the multiplication table. Mr. Hartridge is, we think, rather hard on Donders. It is true that he stated that hypermetropia did not pass into myopia, but that was twenty years ago, when anyone else would have said the same. We thought that he had confessed and received absolution long ago. There are several alterations in the chapter on the shadow test, and it has on the whole been improved. We dissent, however, entirely from the statement that the obliquity of the edge of the shadow in astigmatism with oblique meridians is due to the shape of the image. It is due solely to the fact that only that part of the edge which coincides in direction with one of the principal meridians is seen sharply defined by the observer. Fig. 88, illustrating the measurement of a squint with the prismeter, is inaccurate, since the patient is fixing a near instead of a distant object, so that about ten degrees of the squint is really normal convergence. Notwithstanding these slight defects, we believe that the book is nearly as complete as it could be made within its present limits.

Pathology and Treatment of Abortion. By LESLIE PHILLIPS, M.D. Pp. 110. (Birmingham; Cornish Brothers. 1887).—This small pamphlet of 110 pages, dealing with the pathology and treatment of abortion, contains nothing original or new. The subject is dealt with in the usual manner, the terminology being that used in most of our textbooks. The part played by the mother, father, or fœtus with its membranes in the production of abortion is shortly described, the references to the Lumenian Lectures being numerous. Part II includes the treatment of abortion, which is thoroughly practical and sound, though we can hardly agree with the author in recommending Tai's uterine dilators in incomplete or concealed abortion. Dr. Phillips has, however, found these instruments "reliable and certain in action," and his preference for them is perhaps natural. The essay does not pretend to originality, but is intended to supply a want frequently felt by the busy practitioner, whose time is too much occupied to read the literature on the subject published in journals, pamphlets, and other periodicals.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS, IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

LIQ. PODOPHYLLIN ET BELLADONNÆ C. STRYCHNIA (HOCKIN).

THIS is another of Messrs. Hockin, Wilson and Co.'s convenient fluid preparations. It is perfectly miscible with water, and each fluid drachm contains $\frac{1}{4}$ grain of resin of podophyllum, $\frac{1}{8}$ grain of alcoholic extract of belladonna root, and $\frac{1}{16}$ grain of strychnine. This combination is recommended in cases of habitual constipation in which peristaltic action of the intestines is deficient, and the liver is "torpid." It has been highly praised by Professor Quinlan, who advises in suitable cases one fluid drachm to be taken three times a day in combination with a tonic.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1888.

SUBSCRIPTIONS to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the West Central District Office, High Holborn.

The British Medical Journal.

SATURDAY, MARCH 31st, 1888.

THE BUDGET.

MR. GOSCHEN'S annual financial statement was this year complicated by the necessity for providing an income for the new county authorities proposed to be established under Mr. Ritchie's Local Government Bill. The very satisfactory surplus of Imperial income over expenditure in the year 1887-8 will be practically swallowed up by the claims of the county authorities, and Mr. Goschen, casting about for some means of popularising his Budget, has imposed a number of petty taxes in order to satisfy the income-tax payers. We have little concern with bonds to bearer, and contract notes, and bottles of champagnes, and need not therefore discuss whether increased duties upon them are or are not statesmanlike and wise.

Besides the local budget, to which we shall presently refer, the only point in the Budget which particularly affects the medical profession is the continuance of the tax on carriages, and the new tax of £1 on pleasure horses. Apparently a country doctor will in the future have to pay for the privilege of getting about the country £1 for his horse, 5s. for a two-wheeled trap, or £1 1s. for a four-wheeled vehicle drawn by one horse. The happy possessor of a one-horse rougham—provided it has not pair-horse fittings—has to thank the Chancellor, therefore, for a net saving per annum of 1s., as under existing arrangements he has had to pay £2 2s. for his carriage.

The tax on horses will bear with especial severity upon practitioners in country districts, who, by the very nature of their practice, are compelled to traverse great distances; and it is only by a very severe straining of the definition that such a man may be held to keep a horse for "pleasure." The pecuniary demands of country doctors are already so inadequate that an impost upon what is in effect a part of the apparatus of his profession cannot be permitted to pass without protest.

As letters published elsewhere show the profession is becoming alive to the injustice which is threatened, and we trust, therefore, that Mr. Goschen will see the desirability of inserting in a special Bill which he proposes to introduce a clause giving the same exemption to the nag of the hard-worked country doctor as to the farmer's cob.

We have now to consider broadly the local budget introduced by Mr. Goschen. The Government propose to cancel all the grants in aid that have been thrown as sops to local authorities by weak governments in the past, as some particular want made itself articulate. These amounted for 1886-7 to £2,582,000, the chief items being for roads £237,000, poor-law medical officers £147,000, sanitary officers £72,000, pauper lunatics £480,000, police £1,412,000, and grants to public vaccinators £19,000. To make good these grants the Imperial Government will hand over to the County Councils various licence duties, amounting in all, with the new proposals for taxation, to £3,800,000, the largest proportion of which is from liquor licences. In addition, the Government will give to the counties half the receipts from the probate duties, estimated to amount to £1,800,000. This will give the County Councils an income of £5,600,000, against which they will have to make good the grants now received from the Treasury to defray the cost of maintenance of distumpiked and main roads, estimated at £1,040,000, and to pay 4d. per head per day for indoor paupers, estimated at about £1,200,000. This will make the total expenditure £4,600,000, thus leaving an annual income of about £1,000,000 for defraying the cost of the new duties imposed upon the county authorities by the Local Government Bill. To give time for the new authorities to get fairly started, it is proposed this year to make certain temporary arrangements, which need not, however, concern us here.

The transference of the licence receipts from the Treasury to the county exchequers will no doubt meet with universal approval. Licences are in reality local imposts, and belong strictly to the district. In the same manner the horse tax is *par excellence* a local affair, and we regret that the Chancellor did not recommend that the receipts from this source should be handed over to the counties instead of meddling with the probate duty, which stands on a different footing altogether.

Until the terms of Mr. Ritchie's Bill are generally available (for, although the measure is technically "published," copies are not, at the time of writing, procurable), it is impossible to say how far Mr. Goschen's gifts to local finances will suffice for the purpose. But anything which will help ratepayers to see exactly the financial position of the district in which their lot is cast deserves encouragement and support, and Mr. Goschen's proposals, if they do nothing else, will certainly help to a clearer understanding, both of our national and local balance-sheets.

THE POSITION OF MEDICAL OFFICERS OF HEALTH.

WHILST the general public are wading through the intricacies of the Local Government Bill, and are discussing the constitution of County and District Councils from the political and financial standpoints, and whilst fierce fights are brewing over this and that particular proposal of the Ministry, we fear that one of the most important matters in local administration, from a public health point of view, runs great risk of being overlooked, or, at all events, of not being treated with the serious consideration it

deserves. It is notorious among all who are conversant with the management of local affairs that the position of medical officers of health has long been one of a very unsatisfactory character, and has been gradually going from bad to worse. And yet we cannot discern any proposal in the Bill designed to secure an improvement of the present system, or which in practice under the new state of things would effect the much-needed reform.

In a few of the larger boroughs, where a health officer with special qualifications in preventive medicine has been appointed and has been assigned a proper position as medical adviser to the sanitary authority, where the officer's whole time has been secured by a reasonably sufficient salary and where his tenure of office has been fixed on a tolerably secure footing, the duties of the office have been efficiently performed. Benefit has accrued to the public health and to sanitary knowledge, and credit to the medical profession. In some of the smaller towns also many an energetic health officer has faithfully discharged his duties for a mere nominal salary, and, in spite of many discouragements, carried them on concurrently with his private practice. But, in a much larger number of insignificant urban districts and in the majority of the existing rural districts the omission of the sanitary authorities to make proper arrangements, and the obstacles thrown in the way of energetic officers anxious to fulfil their duties have been fatal to adequate sanitary progress.

To many boards of guardians the transaction of their sanitary functions as rural sanitary authorities has been distasteful. They have habitually treated those functions as subsidiary to the poor-law administration, and at their meetings they have frequently deferred the sanitary business to the end, with the consequent result of shelving it altogether or postponing action indefinitely. In many districts nothing short of an outbreak of actual disease has been sufficient to goad the authority into action and to secure the remedy of glaring sanitary defects. When the medical officer of health is appointed at a merely nominal salary of a few pounds a year, when he is not debarred from private practice, and, having regard to the salary, is unable to give enough of his time to his sanitary duties or to the examination of the unwholesome conditions prevailing in his district, or when he hesitates to report to his authority some unpleasant truths, lest he thereby endanger his chances of re-appointment at the end of his year of office, or estrange some of his best private clients—when conditions of this kind surround the health officer's appointment, as they do too frequently at the present time, it is not surprising to find sanitary work neglected and sanitary officers dissatisfied and discouraged.

Apart from the representations that have from time to time been made to ourselves, a cursory glance at the reports of the recent sanitary survey made by the Medical Department of the Local Government Board discloses numberless examples of such cases. In one instance "the office of medical officer of health has been allowed practically to be a sinecure, the medical officer being also district medical officer;" in another the "medical officer of health does his best in advising under much discouragement;" "medical officer of health zealous, but working under

great difficulties;" "medical officer of health fair, but advice not attended to by sanitary authority;" "originally an energetic officer, who has come to acquiesce in an incompetent administration of affairs;" "work efficient, but salary only £3 per annum;" "unsatisfactory, poorly paid for work requisite;" "medical officers of health (who are also district medical officers) admit wretched condition of their districts, but do little or no work because of their dissatisfaction with scale of payment"—and so on. These examples afford ample indication of a faulty system.

Under the new arrangements it is proposed to constitute a popularly-elected "County Council" for each shire, to take over the general administration of the county and many other powers, and also to substitute popularly-elected "District Councils" for the existing urban and rural sanitary authorities, to take over the existing powers of those authorities and certain additional powers. Existing officers are to be transferred to the new authorities or compensated. Certain of the powers of the Local Government Board under Sections 189 and 191 of the Public Health Act, 1875, as to the appointment of medical officers of health, the prescribing of duties, the amalgamation of districts for the appointment of medical officer of health, etc., are transferred to the County Councils. But the Local Government Board still retain some control in the matter, Section 23 (b) of the new Bill proposing that the county authorities shall pay out of the County Fund and charge to the new Exchequer Contribution Account

"To every local authority by whom a medical officer of health or inspector of nuisances is paid, one-half of the salary of such officer, where his qualification, appointment, salary, and tenure of office are in accordance with the regulations made by order under Section 191 of the Public Health Act, 1875, as amended by this Act; but if the Local Government Board certify to the Council that such medical officer has failed to send to the Local Government Board such report and returns as are for the time being required by the regulations respecting the duties of such officer, made by order of the Board under the said section, a sum equal to such half of the salary shall be forfeited to the Crown, and the Council shall pay the same into Her Majesty's Exchequer."

This is practically a proposal to continue the present system and all its anomalies.

It appears to us that each county authority should have a superintending medical officer of health, who should be specially qualified in hygiene and its many branches, should be debarred from private practice, should assume many duties—such as those of county analyst, the making of *post-mortem* examinations for coroners' inquests, etc., which at present are not performed according to any recognised plan—should hold his office during "good behaviour," and should be assigned such a salary as would secure the services of the ablest men. The division of the county into districts for the appointment of the subordinate health officers should also be adjusted according to the same considerations. The necessity for some such plan is seen when it is remembered that the powers at present vested in the Local Government Board under Section 299 of the Public Health Act 1875, for compelling negligent authorities to perform their duties are transferred to the new County Councils. Who is to advise the

County Council in such cases if they have not a recognised medical adviser independent both of private practice and of local authorities?

The burden of responsibility in advising on sanitary operations should rest with the medical officer of health, and it is of the first importance that he should have a special training for his duties. In order to secure this, the sanitary service of the country should be so reorganised as to afford inducements to the best and ablest men in the medical profession to join its ranks. Now is the opportunity to effect such a thorough reorganisation, and it is to be hoped that it will not be lost.

THE ELECTION OF PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS.

THE movement which is now on foot to remove the disabilities under which students educated at the medical schools of London at present labour, and the part which the College of Physicians of London has taken in that movement, invested the election of a President this year with an interest which could not have belonged to it in the days, not so very long distant, when the College was little more than a learned and highly exclusive club. By undertaking to grant licences to practise medicine to the rank and file of the profession, the College stepped out of the narrow groove along which it had travelled for centuries; and by doing it not only increased its influence within the profession, but largely added to its responsibilities. So complete has been the success of this experiment, which met at the time with much opposition from the more conservative elements within the College, that it must have been a surprise to many of the younger generation of Fellows, who had grown up to a belief that the existence of the great order of Licentiates was a part of the established order of Nature, to find that one of those whose names were most upon the lips of the quidnuncs who during the last month have been speculating on the probable result of last Monday's election, had taken a large share in carrying the reform.

The interest taken in the election by the Fellows was shown by the unprecedentedly large attendance. The retiring President, Sir William Jenner, delivered a long and interesting address, and immediately afterwards the business of the election was proceeded with. The method of procedure is peculiar and susceptible of improvement. The voting is by secret ballot, and each Fellow when he enters the College buildings is supposed to be completely unacquainted with the names of the Fellows who are likely to command the largest number of suffrages.

As will be seen by a letter published in another column, the etiquette which forbids canvassing has been on the present occasion broken through, in the presumed interests of a party within the College. No fewer than ten names issued from the urn at the first ballot, the list being headed by Dr. Richard Main, who had obtained a clear majority. It is, however, necessary, in order that the election shall be completed at one

ballot, that one Fellow should receive the suffrages of two-thirds of the Fellows voting.

A second ballot became necessary. The contest was now seen to lie between Dr. Quain and Sir Andrew Clark, and, amid a scene of unwonted excitement, the voting papers of the second ballot were drawn from the urn, and it then appeared that there was a slight preponderance in favour of the younger Fellow, who was therefore declared elected.

While Dr. Quain would have brought to the duties of President remarkable business capacity and an unrivalled acquaintance with the affairs of the College and with the history of medical policy in this country, Sir Andrew Clark has already given evidence of sterling qualities, which the responsibilities of office may be expected to develop. He has assumed these responsibilities at a moment in the history of the College when it is within its power to render great services to the cause of medical education. Sir William Jenner threw himself into the movement for the extension of university facilities with an admirable energy, and thanks to his vigorous leading and strength of character, he leaves the College pledged to do its utmost to remedy the injustice now suffered by metropolitan medical students.

The scheme propounded by the delegates of the Conjoint Board was drafted upon too narrow a basis; conscious of the integrity of their own motives, its framers proposed to perpetuate the worst traditions of the College of Surgeons, and failed to perceive that no scheme could be really acceptable to the great body of the diplomates of the two Colleges which did not recognise their right to have a voice in their own affairs. So little was this understood by some that there were petulant whispers of an intention to abandon the whole if every detail was not accepted with unquestioning gratitude. The Royal Commission will afford time and opportunity for wiser counsels to prevail, and we may venture to express the confident hope that the new President will use the influence which his official position will give him not in the interest of any party or clique, but with a broad-minded appreciation of the many sides of a complicated question which cries aloud for solution.

MR. JUSTICE GRANTHAM ON THE SANITATION OF PRISONS.

THE great work of prison reform, begun by Howard and continued by Neild, has apparently in the eyes of some of our judges gone too far. Our gaols are in too sanitary a condition; our prisoners are too comfortable. A residence in prison is, according to Mr. Justice Grantham, rather a pleasure than a punishment, and, although he does not actually say so in as many words, this judge seems to intimate that he would regard a higher prison death-rate with a certain degree of complacency. In his charge to the Grand Jury at Lancaster during the recent assizes, he said: "There was another aspect of the case that he thought it desirable to call their attention [to, as a way of accounting for the circumstance of these habitual criminals coming back time after time as they did, and that was the ab-

solate comfort and perfect sanitation in our prisons at the present time, as compared with the homes of many of these people, and especially compared with the workhouses. He found that, taking last year as an example, the death-rate of the prison population was only 8 per 1,000, and when they remembered the class of persons they had before them in the dock—the worst class very often, the most ill-fed, and the most acquainted with insanitary conditions—it was startling to find that prison life was a curative for these people. Taking the population of the towns round about, they found that the Liverpool death-rate was 24 per 1,000, Manchester 28, Preston 27. He commented on the contrast Prisoners were placed in much more favourable relations than most of the working population. They were well housed, in a sanitary sense, and were supplied, night and day, with pure air. They were not exposed to one of the chief causes of the high rate of mortality. Could the same thing be said of all their workhouses, or some of their barracks? They did not make such reports as that of the medical inspectors of gaols. It was for that reason he thought it very desirable that the people who were so fond of going back to prison time after time should be taught that the prison was not merely a comfortable home." By these arguments he excuses himself apparently for inflicting the brutalising punishment of the "cat" so often as he has lately done.

Of course Mr. Justice Grantham's figures are entirely fallacious. It is impossible to compare the death-rate of adults, taken under most peculiar conditions, with that of the whole population. We believe that, excluding reformatories, the general age of prisoners would not range either much under or much over that of soldiers, namely, 20 to 45, and we find that the death-rate for adults of the general population in England between these ages is about 10 per 1,000 per annum, making a difference of only 2 per 1,000 in favour of the prison-rate, instead of from 16 to 20, as Mr. Justice Grantham seemed to intimate. The other conditions of prison life, the numerous persons suffering only short terms of imprisonment, mixed up for statistical purposes with those undergoing long terms of penal servitude, lower the prison death-rate again, and make the comparison still more untrustworthy.

But although judges may be pardoned if they are neither sanitarians nor statisticians, they cannot be excused for returning on the strength of false deductions to brutalising and degrading punishments. A distinct blow has been struck at prison reform, when a judge authoritatively declares from the bench that imprisonment as at present conducted is no punishment at all, and that the only way to improve criminals is to give them as short a stay in our prisons as possible, and rather to send them back to the world in a few weeks, with their backs marked and scarred with the lashes of the cat.

The only logical deduction from such remarks is that we must either recur to the methods of the preceding centuries—the cart tail, the pillory, the gallows—or must make residence in our gaols less sanitary, our prison death-rate somewhat higher. There could be no doubt of the punitive effects of a

committal to Newgate, for instance, during the period 1755-65, when no less a number of prisoners than 132 died of gaol fever. A residence in the Leopoldstadt Prison of Vienna from 1834 to 1847 also had some claim to the term "physical punishment," since out of 4,280 prisoners there, 378 died, a death-rate of 86 per 1,000 of whom 51.4 per 1,000 died of phthisis produced by insufficient ventilation.

Perhaps, however, our judges themselves are not altogether the losers by the better sanitation of prisons, since we find that the fevers endemic in these foul dens previous to the present century did not confine their attention to insanitary gaols or overcrowded prisoners. According to Wood, in 1521 a contagious fever broke out at the Cambridge Assizes, and the "justices, gentlemen, bailiffs, and others resorting thither took such an infection that many of them died, and almost all that were present fell desperately sick and narrowly escaped with their lives." At the "Black Assizes" at Oxford in 1577, the Lord Chief Baron (Bell), the Sheriff, and 300 other persons present died. In 1730, at the Taunton Assizes, the Lord Chief Baron (Pengelly), Sir James Shepherd, Sergeant; John Pigott, Esq., Sheriff, and some hundreds besides died of the gaol distemper. In 1750, at the May Sessions at the Old Bailey, Sir Samuel Pennant; the Lord Mayor (Sir Thomas Abney); and Baron Clark, the judges present, together with Sir Daniel Lambert, Alderman, were seized with the distemper and speedily succumbed, while, according to Lord Campbell, the Lord Chief Justice (Lee) was attacked the same year by gaol fever, but recovered. In 1752 another Lord Mayor (Winterbottom) fell a victim to the disease. Well might Lord Bacon, in writing on the subject say: "The smell of the gaol is the most pernicious infection, next to the plague. When prisoners have been long and close and nastily kept, whereof we have had in our time experience twice or thrice, both judges that sat upon the trial, and numbers of those that attended the business or were present sickened upon it or died."

If it be a fact that our gaols are better sanitized than either workhouses or the dwellings of the poor, all honour to those to whose wise labours the better condition of the former is due—all shame to our local authorities who permit crime to be better housed and treated than poverty and misfortune. But it is the workhouses and the homes which must advance to perfection, not our prisons which must recede from it. Whatever be the disciplinary or reformatory measures introduced into these latter, one thing must be secured—that the punishment ceases when the prisoner is liberated; that he does not pass back to the world with health injured or wrecked by the treatment he has received in prison. Above all that the punishment inflicted should mean no more than the sentence conveys, and that that which was on the face of it only a temporary deprivation of liberty, should not be converted by insanitary surroundings into a capital punishment of the most lingering and cruel description, or convey a permanent injury which shall remain throughout the rest of life.

That public opinion, supported by wise experience, will not permit a return to the degrading physical punishments of past

yes is certain. It is owing to the replacement of these by more humane methods that criminals are decreasing in numbers daily; hence the classes from which criminals are recruited—themselves better educated and more enlightened—see that they are no longer treated as wild beasts, against whom every man can raise his hand, and, therefore, are not driven by desperation to war against society. But still less will England allow any tampering with the health or life of prisoners. A wise philanthropy sees in these unfortunates, not lazy and irreclaimable villains returning to prison as to a comfortable home, but brothers, driven by hereditary instinct and injurious environments to crime, and reclaimable, not through greater physical sufferings, but by wise and judicious influences, acting not only on the mind, but on the body, through improved sanitation, using the word in its widest and noblest sense. That profession which numbered John Ruskin, the friend of Neill, among its members, will not permit the degradation of those of its body who practise in Her Majesty's gaols into the registrars of the capacity of weak humanity to bear torture. Our duty is to alleviate sufferings and relieve pain. Our highest privilege is to extend our ministrations to the mind as well as to the body, to offer to erring brothers the hand of help, to bring back to honesty and wisdom those who through misfortune and weakness have fallen far away from both.

HABITUAL DRUNKARDS ACT.

CAMERON, owing to unforeseen parliamentary complications, has postponed the second reading of the Habitual Drunkards Act Amendment Bill till April 9th. The Chairman of the Committee for Legislative Restraint for Habitual Drunkards, Dr. Norman Kerr, has received a communication from the Home Secretary promising assent to the second reading, with a reservation as to certain clauses. The main object of the Bill is the enactment of a permanent measure which, it is hoped, will be secured during the current session of Parliament; but the business of the House of Commons is so uncertain, that no effort should be spared to bring strong pressure to bear upon as many members as possible, each of our readers will write to his parliamentary representative, that permanent legislation may be accomplished this year, leaving the future free for further and much needed amendment.

IMPURE ANTIPYRIN.

An extraordinary demand for antipyrin is very much in excess of the supply, and great pressure is put upon the manufacturers to increase the amount of the manufactured article in the market. In consequence has been that due care has not been shown in the purification of the drug, a certain proportion of benzene being detected in samples submitted to analysis, according to Dr. Dujardin-Beaumont. This impurity may account for some of the toxic symptoms which have been reported, such as cutaneous eruptions, gastric troubles, and even grave cerebral symptoms, more particularly in the aged.

THE PROGRESS OF CREMATION IN ITALY.

CREMATION in Italy, says a correspondent of the *Times*, has not in the last two years or so made so much headway as at first, for example of Milan in 1876 soon found many imitators, especially in the northern and central provinces of Italy, and there are now something like thirty-two societies and committees for promoting cremation, though they have not all got crematoriums of their own yet. The number of persons burnt last year was only

165, as against 181 in 1886. The Pisa Society, however, has not yet opened in its statistics for last year, and crematoriums will be opened in the course of the present year at Turin, San Remo, Verona, Bologna, Pavia, and one or two other towns. Of the total number of 952 cremations that have occurred in 17 cities in Italy, since 1876, as many as 518 have taken place in Milan, and 155 in Rome. The new crematorium at Milan is situated at the extreme end of the Campo Santo, just outside the walls of the city. The temple, as it is called, is a building in the Doric style, constructed of stone, and having an open façade supported by columns, from behind which rises a tower which, as seen from the outside, looks as if it formed part of the temple, although in reality it stands quite by itself, and is the chimney. The inside of the building is divided into several rooms, in the first of which the religious rites are performed; its walls are lined with funeral urns containing the ashes of many of those who have been cremated at Milan. There is a separate room in which the bodies are placed pending cremation, and a third in which the relatives and friends spend the two hours occupied by the cremation itself. There are two furnaces—one being for general use, and the other for the bodies of persons who have died of contagious diseases and are not natives of Milan. The body is not visible to the on-lookers when being put into the furnaces, nor are the ashes afterwards.

BEATING AN EPILEPTIC GIRL.

A HOSPITAL physician has drawn our attention to the case of a child under his care. The mother brought the girl, aged 11, to the hospital on account of her becoming liable to "attacks" in which she either "turns foolish" or drops down. The case proved to be one of minor epilepsy (*petit mal*). On a recent occasion, while getting coals for her mother from the cellar, she was seen to fill her shovel, then walk to the end of the street, holding the coals before her till she came to herself. Last week, when her father was having his dinner, she combed her hair and put the combings on his plate. The mother says that she often "loses herself," and stands looking vacantly before her; in such conditions she does not answer a question, or move when touched. The child looked fairly nourished, but was rather anæmic; she answered questions well, and complained of headache. This girl attends school and is in the third standard; it appears that, on more than one occasion, when in the foolish, vacant state, the teacher has struck the child, doubtless in ignorance of the cause of her apparent stupidity; happily, however, the child has not yet been removed from school. It is not upon the individual teacher that we would cast a word of blame, still we cannot but think that a system in training and supervising teachers which allows of such mistakes ought to be reformed. The introduction of two or three medical advisers amongst Her Majesty's school inspectors would form an authority capable of following up and explaining such cases to teachers, preventing repetition of direct, though unintentional, cruelty. Occasional visits to certain schools by a medical inspector, with power to report, would do much to increase the care taken of feeble-brained children; it would lessen the responsibility of teachers in making exemptions, and they would be grateful for the assistance. As to this individual child, it is well that it should be educated and cared for; if left uneducated mental degeneration will follow. Should the child be so fortunate as to be removed to an asylum, she would probably be placed in a well ordered class in the asylum school. Why should not suitable classes for such feeble children be provided for day scholars?

ENLARGEMENT OF THE WORCESTER INFIRMARY.

DR. STRANGE writes: The Worcester County Infirmary has just been enlarged by the addition of thirty beds. This building

which has an unrivalled position overlooking the valley of the Severn, and open on all sides, has been for a long time much overcrowded, more than 1,200 patients passing through its wards annually, giving the large number of twelve patients per bed, the average of other county infirmaries being about eight or nine. The medical staff have found it impossible in this state of things adequately to treat many prolonged cases of disease, such as empyema with drainage, diseases of the spine, bones, and joints. At the annual meeting held on March 19th, the enlarged wards were thrown open to the inspection of the governors. The enlargement has been effected by bringing forward the south wing 30 feet, giving ten additional beds to each of the three wards in this wing. These wards have now twenty-six beds in each, with superficial area and air space about equal to those of the new central portion of the Great Northern Hospital mentioned in the JOURNAL a few weeks ago. The cost was under £3,000; £500 of which was contributed by one donor. The appearance of the building, formerly so symmetrical, is now somewhat lopsided, and presents a standing invitation to the next generation to restore its symmetry by a similar addition to the north wing. When this is done the Worcester Infirmary will be second to no county hospital in healthiness and situation, in the arrangement of the wards, and in its complete administrative department.

AN ENGLISH SANATORIUM IN THE HIGHLANDS OF BRAZIL.

AMONG the health-resorts beyond Europe where invalids and tourists may find sunshine and warmth, and a dry bracing climate, along with home comforts, San Paulo, in Brazil, has already attracted attention. From Rio de Janeiro to San Paulo is a railway journey of thirteen hours, but from the port of Santos it is only a three hours' run. The voyage from Southampton to Santos, in the steamers of the Royal Mail Steam Packet Company, occupies only twenty-three days, and from New York (by the Brazilian Mail Steamship Company) twenty-eight days. Owing to its natural and commercial advantages, San Paulo is destined to become the third great city in South America. As yet it has only between forty and fifty thousand inhabitants, among whom are Brazilians, Portuguese, Germans, Italians, French, English, and Americans. In its immediate vicinity are charming country walks and scrambles amongst a rich and almost tropical vegetation, with fishing, boating, and shooting for those who love sport. The climate during both winter and summer is delightful, and has been recommended by Dr. Walshe (*Diseases of Lungs*, 4th Edition, p. 649) for pulmonary invalids. The atmosphere is dry and exhilarating, and the barometric range so remarkably limited that it does not exceed three-quarters of an inch throughout the year. The average maximum temperature in the hottest month, January, is 80° in the shade; in the coldest month, July, 72°. The average minimum night temperature in January is 64°; in July, 49°. The number of days on which there is brilliant sunshine for the whole or the greater part of the day averages 235 per annum, and such days are pretty equally distributed throughout the year. Unlike the Mediterranean winter resorts, San Paulo has no unhealthy season of the year. Invalids are recommended to spend both seasons there, and it is a disputed point which is the more beneficial; but those who like sea-bathing, and want a change, can go to Santos for sea-bathing in June or July. Two miles from the city, a sanatorium has recently been built by an English gentleman, on a hill commanding a splendid view. It is well-drained and supplied with excellent water. It has reception rooms, billiard and bath rooms, and every modern convenience. Dr. William Ellis, an English physician resident in San Paulo, is an able guide-adviser to those who go there in search of health. The enterprise of visitors and residents has supplied a Roman Catholic chapel, and Church of England, Presbyterian, and

Wesleyan services; concerts, operas, musical societies, public gardens and bands, and riding clubs are to be found, as in other pleasure loving and prosperous cities. Where a sea-voyage is ordered for invalids, a sojourn in San Paulo may prove in some cases an additional recommendation.

PHYSICAL TRAINING OF THE GREEKS AND ROMANS.

MR. A. S. MURRAY, Keeper of Greek and Roman Antiquities British Museum, delivered an interesting lecture at the Parkes Museum on Thursday, March 22nd, on the "Physical Training of the Greeks and Romans." He observed that it had been said in ancient times that the two things which the Greeks desired most were to be healthy and to be beautiful. Beauty in their eyes was attainable largely by a careful system of physical training. We see, he observes, their idea of physical beauty nowhere better than on the sculptured frieze of the Parthenon at Athens, now in the British Museum, for the greater part of it is a simple glorification of the beauty of youth as developed by physical training on horseback and in chariot racing. There was no more marked difference between the Greeks and the semi-barbarous races that surrounded them than in this matter of physical training. In one of his dialogues Lucian introduces the Scythian Prince, Anacharsis, who visited Athens in the sixth century B.C., and in the course of his visit went to the Palaistra. He was much surprised at the various exercises of the youth, thinking them ridiculous. He asked Solon, the legislator, how he could defend such folly. Solon explained that the exercises of the youth might seem absurd to an onlooker, but that they were meant to train up a race of men who, largely by this training, should become valuable citizens, capable of taking their part in war through the skill of body they had thus acquired, and capable of taking a share in the administration of public affairs through the clearness of head and ready judgment which the habitual training of the Palaistra fostered in them. The lecturer then proceeded to describe the ordinary exercises of boys previous to their reaching the age of joining the Palaistra; and, secondly, the series of athletic contests which they practised in the Palaistra, giving instances of the skill attained in the various contests of leaping, running, wrestling, boxing, throwing the disc and the spear. Lastly, he noticed the physical training of girls, to whom running was the only form of public contest allowed, and that only in a very restricted degree. He concluded with a brief sketch of a limited range of physical exercises, as practised by the Romans.

COMPULSORY NOTIFICATION OF INFECTIOUS DISEASE.

THE Local Government Board at the end of last year addressed a series of questions to sanitary authorities of districts in which there is a system of compulsory notification of infectious disease, with a view to obtaining information which may be useful to the Board in considering the extension of this method. The Salford Town Council have since published a report by their medical officer of health, Dr. John Tatham, which gives a useful account of the results obtained in that borough. Dr. Tatham says that, on receipt of notification, the house is at once visited by himself or the sanitary inspector, and particulars obtained as to the cause of illness, the opportunity for isolation, and other points of importance. More than half the cases visited are removed to hospital, disinfection carefully performed, and, in case of small-pox the inmates revaccinated. Where patients remain in their own homes, care is taken to limit the extension of the disease, and school authorities are informed when school children are found resident in a house with a case of infectious disease. In Salford there is very little concealment of such disease, and medical men loyally support the health department in their duties under the Notification Act. The result has been exceedingly satisfactory.

as regards small-pox and typhus, importations of disease never giving rise to extension of a serious kind. In the case of scarlet fever, a sufficient time has not yet elapsed for the formulation of trustworthy evidence based on reported cases of sickness, but the death-rate from this disease since the Notification Act came into force has been lower than during the immediately preceding quinquennium by not less than 33 per cent. Dr. Tatham points out the effect of a district where there is no notification upon those where it exists, and shows the necessity for the extension of the system throughout the whole country, and he urges the need for the central registration of all cases of this class of malady, in order that a district may learn what is taking place in others from which it may receive infection. The report is an excellent piece of work, and shows how valuable are the services an able health officer can render to a community.

COCAINE AND ITS SALTS.

SINCE cocaine gained for itself a reputation as a local anæsthetic, attention has been directed to the fact that the cocaine salts supplied for medical use are far from being constant or uniform in their purity and general characters. The subject was thoroughly discussed at a recent meeting (March 14th) of the Pharmaceutical Society, in a paper by Dr. B. H. Paul, from which some very useful conclusions may be drawn. Samples of the hydrochlorate of cocaine may be classed as crystalline and amorphous, and it is well to note that the author of the paper doubted whether the salt in a pure state ever assumed the amorphous condition. In fact, salts which are crystallisable with difficulty are in all cases mixtures, in various proportions, of cocaine salts with other salts of a different nature. The test of purity, based on the more ready solubility of the non-crystallisable portion of the salt in chloroform, is not altogether reliable, and the weight of the crystals obtainable on the neutralisation of an aqueous solution by ammonia is stated to be preferable. Some investigators professed to have identified an impurity, which they called "hygrin," the presence of which accounted for the difficulty with which certain specimens are crystallised. This substance, however, Dr. Paul considers to be apocryphal, although it is evident that a product known as "amorphous cocaine" is not infrequently present, and admits of identification. Its hydrochloride is the usual impurity. It is of a pale yellow colour, a bitter taste, and of feeble anæsthetic properties. It has an alkaline reaction, and is sparingly soluble in water, though freely in alcohol and ether, differing in this respect from the pure salt. A dilute solution becomes milky on the addition of ammonia, and remains so. The aqueous solution of this neutral hydrochloride becomes acid on boiling, and this accounts for the tendency of solutions of cocaine to become acid. Cocaine itself readily undergoes decomposition with benzoyl ecgonine, on being heated with alcohol or water, and this constitutes another source of impurity in the course of preparation. To obtain a pure product, the alkaloid itself should be dealt with and not the hydrochloride, which is wasteful because of its extreme solubility. It would appear from these results that the quality of cocaine hydrochloride varies very much. In fact, as Dr. Paul observed, the salt is sold at a price far too low to ensure its purity. The makers who produce a good salt are heavily handicapped in the competition with others who supply an inferior article at a low price.

ENGLISH AND FOREIGN HEALTH RESORTS.

"HARROGATE as a Winter Health Resort" was the subject of an interesting paper read by Dr. T. Britton, the president of the Yorkshire Association of Medical Officers of Health, at a recent meeting of that society. In favour of Harrogate as a winter health resort, Dr. Britton pointed to its elevated position—400 feet

above the sea—the sheltered position of Low Harrogate, its dry and bracing air, its low death-rate—13.7 per mille. The mean average temperature during the winter months was 39.3, and the rainfall compared favourably with other British watering places. The drainage and water supply were all that could be desired, and the sanitary condition of the place excellent. There are, he says, a large number of first class hotels and lodging houses where the comfort of visitors is carefully studied. In the winter months the charges for rooms are extremely small. For those who like them there are high-class hydropathic establishments, under experienced medical supervision, and there are also several good boarding houses. The country around is singularly beautiful, and abounds in places of historical interest. The roads are good, and of easy gradient. The town is partly surrounded by a belt of grass—"The Stray"—of 200 acres in extent, the remaining part being open fields and country. "But," he adds, "it is somewhat wanting in light amusements. Concerts and lectures are good and plentiful, but there is nothing during the day." This he hopes the energy of its inhabitants will soon supply, as nothing tends more to aid the system in throwing off illness than rational amusements. The *Harrogate Advertiser* in giving a report of Dr. Britton's paper, quotes *in extenso* from the *JOURNAL*, the advice and information as to the means of extending the resources and pleasures and usefulness of health resorts given by Mr. Ernest Hart in his recently published letters from Carlsbad. These letters and the information therein given have, we notice, been largely quoted by the provincial press; and it is to be hoped that now that the attention of the local authorities of our British health resorts has been called to this need, the matter will not be allowed to end merely in words, but that steps will be taken by some of our leading health resorts to bring into play the same intelligence and public spirit which have enabled small German watering places by imposing a reasonable "cure tax" on the guests, to derive resources which have been wholly devoted to public purposes. The lessons derivable from the study of the administration of Carlsbad by Mr. Ernest Hart have evidently been taken to heart in many places; but practical steps might well be taken in this direction in such places as Buxton, Bath, Harrogate, Droitwich, and Cheltenham, all of which, by somewhat similar means to those employed by German health resorts might be made centres of continuous attraction and delightful resorts for English visitors. In the end such a policy would quickly repay any outlay involved, while it would quickly become, as at Carlsbad, more than self-supporting, and a source of great profit to landowners and residents.

FOREIGN MEAT.

It would be very desirable that Ministers of Her Majesty's Government, before replying to questions put to them in Parliament, should consult with practical men as well as with their legal advisers. On Tuesday, March 20th, Sir M. Hicks-Beach, in reply to a question put by Captain Cotton on the sale of foreign meat as English produce, said that he believed, although he could not give an authoritative opinion, that the sale of foreign imported meat as English meat when English meat is demanded was an offence under Section 6 of the Sale of Food and Drugs Act, 1875, and that, therefore, he did not see that any further legislation was required. Section 6 provides that "no person shall sell, to the prejudice of the purchaser any article of food or any drug which is not of the nature, substance, and quality of the article demanded;" and undoubtedly, if English meat is demanded, the seller offends against the Act if he supplies foreign meat. Action cannot, however, be taken except upon the certificate of the public analyst duly appointed. Considering that analysis is incapable of distinguishing between beef, mutton, or veal,

it is rather too much to expect of the public analyst to discriminate analytically between English and foreign meat of similar descriptions. There is not, at present, the faintest probability that such differences as would enable the most skilful analyst to give a certificate upon which a prosecution might be based will be discovered, and the Sale of Food and Drugs Act is, therefore, likely to remain a dead letter on the subject of meat, eggs, and kindred articles of food. Sir Michael Hicks-Beach's answer to Captain Cotton is, therefore, although theoretically correct, no answer at all. It should be known, however, that there are other means of punishing vendors who sell articles not of the nature, substance, and quality demanded besides the Sale of Food and Drugs Act. Only quite recently a vendor of butter, which proved to be margarine, was sentenced to six months' imprisonment at the Essex Assizes, the prosecutor having elected to proceed against him for having obtained money under false pretences. In such a case the certificate of a public analyst would not be absolutely requisite, other evidence, such as might be furnished by the police or the shippers of the meat, being available. It is not a little remarkable that whilst it was felt desirable to pass an entirely new Act against the sale of foreign fat under the name of butter, although the matter has always, and could well have been further dealt with, under the Sale of Food and Drugs Act, the Government now refuse to consider the far more important subject of meat, which is not amenable to the Food Act, and attempt to make believe that that Act is all that is needed. We can only strongly advise Sir Michael Hicks-Beach to place himself in communication with the Society of Public Analysts.

HOW TO CURE GOITRE.

FRENCH army surgeons have been profitably employed in drawing up medico-geographical reports of the French Departments. Surgeon-Major Aubert has already reported to the Académie de Médecine on Calvados, Loire-Inférieure, and La Vendée. On February 14th, his report on the Medical Geography of the Ain was read. In reference to ninety-three men with goitre from the mountainous districts of that department, who were exempted from military service from 1872 to 1886, Dr. Aubert makes a most reasonable suggestion. As most cases of goitre between the ages of 18 and 20 are curable, a great service would be done to them by enrolling, instead of rejecting them, and placing them in the territorial army in healthier parts of France, particularly in coast stations. By sending these men far from their mountains to naval arsenals they might be permanently cured, and at least could not fail to derive great benefit from the change.

THE EMPEROR OF GERMANY.

It is stated on what appears to be good authority that formal application has been made by the Empress Victoria of Germany to the Queen, her mother, requesting her to permit Sir Morell Mackenzie and Mr. Howell to wear the orders which the Emperor intends to bestow upon them. The former will probably receive the Grand Cross and Star of the Order of the House of Hohenzollern, and the latter the same order of a lower class. With regard to the health of His Imperial Majesty, we think it well to point out that, as the medical attendants are still forbidden to furnish any information beyond that contained in the official bulletins, little or no reliance is to be placed on the statements which appear from day to day in the political papers, though professedly made "on the highest authority." These are nothing more than rumours, which are in every case unwarranted, and in many glaringly absurd. As medical men know, it is absolutely immaterial to the real issue that the Emperor is still able to go about indoors, to transact business, give audiences, and even to speak. A man may do all this, and may have the outward appearance of health, and yet be suffering from advanced cancer of the

larynx. When it begins in this region, the disease, as a rule, does not spread beyond it, and is slower in its course than in many other parts of the body. Under favourable circumstances life may be prolonged for three or four years, or even more, and during the greater part of that time the general health may scarcely be affected to any degree appreciable by an ordinary observer. With regard to the nature of the disease, although the result of Professor Waldeyer's examination has not been made public, the general drift of his report has been communicated to us by a well-known pathologist, whose authority as to the facts may be implicitly relied on. Professor Waldeyer found the microscopic appearances of the fragments of expectorated tissue which were submitted to him precisely as Professor Virchow had described them. He did not discover any trace of alveolar structure, although there were a good many particles of relatively considerable size in the sloughy material which he examined. Professor Waldeyer, however, came to the conclusion that the disease was epithelioma, his decision being based on the great number, and variety in form, of the cell-nests. In spite of this, however, the present aspect of the case, together with its clinical history from the beginning up to the present time, still give grounds, in the opinion of those who have most closely watched its progress, for a less unfavourable interpretation. We understand that, a few days ago, Sir Morell Mackenzie removed through the opening in the windpipe a large flat piece of cartilage which had apparently been thrown off from the cricoid or thyroid. We are not disposed to attach so much importance to this occurrence as has been done in some quarters, for unfortunately there is ample evidence to show that perichondritis and malignant disease are not mutually exclusive. Exfoliation of cartilage is certainly not a common feature in laryngeal cancer; but it is by no means an unknown, although a rare, phenomenon of that disease. Though it may sound like a paradox, we are convinced that much of the obscurity of the present case is due to the extraordinarily close and unremitting attention that has been bestowed upon it. Probably no case in the history of medicine has ever been watched through all its varying phases with such anxious vigilance, and it is possible that what seem to us, with such knowledge as has hitherto been available, puzzling and anomalous elements in the case, may be nothing more than the ordinary course of things when the natural evolution of the disease is fully seen.

EARLY RISING AND LONGEVITY.

PROFESSOR HUMPHRY'S recent Collective Investigation Report on Aged Persons, published in the JOURNAL, contains some very positive evidence on a matter which has already engaged the attention of moralists as well as physicians. "The opportunity for nutrition to do its restorative work was in nearly all provided by the faculty of 'good sleeping,' to which was commonly added its appropriate attendant, the habit of 'early rising.'" Thus there is a relation between early rising and longevity. No doubt many people will hastily seize upon the sentence just quoted, and employ it in edifying lectures or essays for the perusal of youth, or embody it in popular medical works. Important qualifications follow in Dr. Humphry's Report, but they are likely to be overlooked. Doubtless the habit of early rising is, in itself, healthy; most of all, it is a good sign of health when it evidently signifies rapid recovery from fatigue. Again, it usually denotes a strong will, the gift as a rule of a good physical constitution, or at least the safeguard of average bodily strength. Late risers are generally either invalids or persons of bad habits, idlers who are never free from other vices besides idleness. The nervous exhaustion which keeps a man wakeful throughout the small hours produces sleep late in the morning. This exhaustion is invariably due to one of several life-shortening influences, especially anxiety or indiscretion in diet or drink. Early rising

is thus rather one effect of certain favourable influences, another result of which is longevity, than a cause of longevity. To turn a weakly man out of bed every morning at 7 o'clock will not prolong his life. It will be noted that by "good sleeping" Professor Humphry signifies quick sleeping, "that is, the reparative work which has to be done in sleep is done briskly and well." Here, again, we have an effect of a cause; but preventing a weakly subject from sleeping more than four or five hours nightly would not cause him to live long, but would rather tend to shorten his life. Equally important are Professor Humphry's observations which show that by "early" he does not entirely mean the time by the clock. The word "has a relative significance with reference to the time of going to bed. A person who retires to rest four hours after midnight and gets up at 10 A.M. may be strictly regarded as an 'early riser.'" Thus early rising is synonymous, in long life histories, with short sleeping, which means rapid recovery from fatigue, a sign of bodily strength. These scientific facts in no wise contradict the alleged value of early rising as a practice to be cultivated by all persons in good health. It is excellent as moral discipline, and eminently healthy as a matter of fact. Most persons will eat three meals daily. When a man gets up late those meals will probably follow each other at too short intervals to be wholesome. When he is an early riser it will probably be otherwise. He can enjoy a good breakfast, and by the time for his lunch or mid-day dinner he will have an honest appetite again.

SLUMS IN LAMBETH.

An inquest was held before Mr. William Carter on Monday, March 26th, on the body of a child aged 10 weeks, who was found dead in a dwelling, 19, Opal Street, Upper Kennington Lane, where the sanitary conditions were incredibly bad. The father of the child, a labourer, possessed only one bedstead, at the top of which slept the mother, father, and two children, while at the bottom slept two other children. Dr. Farr said that on entering the passage he found the boards in a rotten condition, and the plaster falling off the walls. In the front room a shocking scene presented itself. The parents, with four children, were in bed. In a cupboard where the food was kept he found the dead body of the deceased. He had no doubt that death was due to suffocation. He found the ceiling of the particular room all down, and the rain was rushing in. The jury returned a verdict of accidental death from suffocation, at the same time stating that they were of opinion that the sanitary authorities should be at once communicated with. Dr. Farr informed the Court that the houses were totally unfit for habitation. The coroner promised to report the matter to the proper authorities.

CÆSAREAN SECTION—UNUSUAL COMPLICATIONS.

On December 16th, 1887, Dr. Norment, of Hampden, Maryland, was called in to a single woman, aged 26, who was eight months pregnant. She was forty-nine inches high, and very thin. There was marked kyphosis, involving the entire dorsal region. The lower ribs were in the upper pelvis. The uterus hung pendulous over the pubes, the symphysis lay a little posterior to the umbilicus when the patient stood on her feet. The vulvar orifice was directed slightly backwards. There was marked contraction at the perineum, the distance between the coccyx and pubes being about 10 inches, but Dr. Norment failed to discover any contraction in the vaginal inlet. The ensiform cartilage was approximated to the pubes. The lower extremities were œdematous, the urine was highly albuminous, and contained abundance of hyaline and fatty casts. There were two old suppurating sinusses tracking from the iliac region downwards, one opening below the anterior superior spine of the left ilium, the other opening on the right thigh. The patient had a hacking cough and

bad headache. Dr. Norment did not consider craniotomy or cephalotripsy to be safe in this case. He notes that Charpentier speaks of 37 maternal deaths in 119 cephalotripsies (minimum conjugate 2.7 inches) as "fairly satisfactory," and most probably his case was in an unfavourable condition as the worst of Charpentier's 37 who died. He also dreaded the prospect of being compelled to perform Cæsarean section after the failure of one of the destructive operations. There was little prospect of saving the mother by Cæsarean section, but a good chance of rescuing the child. In order to give the best chance to the mother, Dr. Norment operated on January 13th, almost directly labour pains began. He described the operation in the *Philadelphia Medical News*, February 11th. The lumbar sinusses were washed out with a 1 in 2,000 sublimate solution, the vagina with a 2 per cent. solution of carbolic acid. The operation was performed on Sanger's principles. The uterus, by its own weight, protruded through the abdominal incision, and lay on a disinfected towel between the patient's thighs. The membranes could not be conveniently ruptured from the vagina, so they were left intact to the last moment. The situation of the placenta could not be determined. Dr. Norment took care to incise the anterior wall of the uterus, but in so doing cut through the placenta. The membranes were ruptured after the placenta had been separated from the left side of the incision, and the child seized by the feet. It was asphyxiated, but recovered, and was well and alive early in February. A row of fourteen carbolised silk sutures were passed through the muscular wall of the uterus; on each side of the incision a continuous suture of the same material was made to unite the cut edges of the serous coat. The wound was closed after the uterus had been cleared of its contents, and made to contract firmly by "massage." The patient, however, suffered much from shock, and uræmic symptoms set in. She died sixty-two hours after the operation.

MENSTRUAL BLEEDING FROM A LAPAROTOMY SCAR.

At a recent meeting of the Kiev-Obstetrical and Gynæcological Society, Professor Georg E. Rein showed (*Writch*, No. 7, 1888, p. 136) a menstruating woman from whom he had about three years before removed a cyst of the right ovary weighing 37 pounds, fixing the pedicle in the abdominal wound. The patient soon recovered, and the wound healed, but at one part of the scar there remained a diminutive slough, which fell off just before the beginning of menstruation, its separation being followed by a constant flow of blood from the denuded surface during the whole catamenial period. The phenomenon had regularly recurred monthly ever since. As a rule, the scar begins to bleed somewhat earlier than the uterine flow makes its appearance. The menstrual blood from the cicatrix has a characteristic odour. It is difficult to explain such an occurrence. Possibly, a Fallopian tube or one of the uterine cornua had been stitched together with the pedicle into the abdominal wound. However, Professor Rein hopes soon to ascertain the nature of this interesting and rare case, since the patient must undergo a second laparotomy for disease of the left ovary.

THE NEW EDITIONS OF THE "MEDICAL," "DENTISTS'," AND "MEDICAL STUDENTS' REGISTERS."

The *Medical Register*, the *Medical Students' Register*, and the *Dentists' Register* were published on March 21st, and copies may now be had from Messrs. Spottiswoode and Co., the publishers to the Medical Council. The publication of these volumes is always awaited with much interest, and this year it will be found that under the able superintendence of the Council's indefatigable Registrar, Mr. W. J. C. Miller, B.A., statistics and tables of great value have been prefixed to the *Medical Register*, from which it appears that whereas the number added to the *Register* in 1877

was only 940, the number registered last year was 1,531, an increase of 591. In 1876, the first year in which such data as are now presented were ascertained, the total number on the *Register* was 22,200, while this year it amounts to 27,246, an increase of 5,046. About 66 per cent. of this number registered in London, 19 per cent. in Scotland, and 16 per cent. in Dublin. The increase in the number of registered medical practitioners may also be gauged by comparing the number of pages in the successive volumes; the number of printed pages in the *Register* for 1859 was 335, in 1870 it was 548, in 1876 it was 598, and this year it is 1172, an increase quite out of proportion to the contemporaneous increment of population. The population of the United Kingdom at the present time, including persons serving in the army and at sea, cannot exceed forty millions, so that it would appear that on an average there is one registered medical practitioner to every 1,480 persons. Among the statistics prefixed to the *Medical Students' Register* will be found tables showing the numbers registered in 1887 in each division of the United Kingdom as having passed the several recognised examinations, and the numbers registered at each place of medical study. The *Dentists' Register* has been very thoroughly and carefully revised, a process involving much unnecessary labour, owing to the extraordinary carelessness of many registered dentists. This peculiar weakness appears to have been anticipated by the framers of the Dentists' Act, which (Section 12, § 3) provides that the Registrar may send a notice to any registered dentist inquiring whether or not he has ceased to practise, that if no reply is received within three months, a registered letter is to be sent making the same inquiry, and that if the Registrar gets the letter back through the dead letter office, or after another interval of three months, receives no reply, the dentist is to be deemed to have ceased to practise, and his name shall be erased from the *Register*. Soon after last Midsummer letters of inquiry were sent to all persons on the *Dentists' Register*; three months later a thousand registered letters had to be sent out to those who had not answered the first inquiry. By this means it has been possible to correct an unprecedented number of errors. From the tables and statistics prefixed to the *Register* it appears that the unqualified dentists were, in 1879, 4,806, or 91 per cent. of the whole, while the dental licentiates were 483; but in the present *Register* the licentiates have increased to 977, and the unqualified persons have diminished to 3,889, or 79 per cent. of the total, thus showing clearly a decrease of 12 per cent.

SCOTLAND.

EXAMINER IN MEDICINE AND CLINICAL MEDICINE, GLASGOW UNIVERSITY.

THE University Court at their last meeting elected Mr. Gulland, M.B.Édin., to be Examiner in Medicine and Clinical Medicine for the ensuing year. Mr. Gulland only graduated in medicine in August, 1886.

PHILOSOPHICAL SOCIETY, GLASGOW.

At a large meeting of this society, Mr. Maylard gave a most interesting demonstration on bacteriology. He showed the processes and media adopted for the cultivation of bacteria, and amply illustrated the value of the study in its connection with the etiology of diseases.

MEDICO-CHIRURGICAL SOCIETY, GLASGOW.

DR. JAS. FINLAYSON reported a most interesting and rare case of recovery after embolism of the superior mesenteric artery in a woman, aged 45. The patient had heart disease, and more

than a year before had had an apoplectic seizure. Dr. R. S. Thomson reported some observations on the treatment of whooping-cough in Belvedere Fever Hospital, with special reference to the influence on the disease of nitric acid, ergot, and chloral. After a long series of careful observations he concluded that none of these drugs exerted the slightest specific influence on the disease, but that chloral diminished the frequency and severity of paroxysms.

SOUTHERN MEDICAL SOCIETY, GLASGOW.

DR. FLEMING read a paper on some notable surgical cases recently under his care. He reported five cases of intestinal obstruction, in one of which the patient recovered after inflation. He also reported a complete cure of traumatic epilepsy of eighteen months' duration by trephining, and successful cases of suprapubic lithotomy and nephro-lithotomy.

DISTAL LIGATURE FOR INNOMINATE ANEURYSM.

SOME weeks ago, at the Glasgow Royal Infirmary, Professor Dunlop ligatured the common carotid and subclavian arteries for innominate aneurysm. We are glad to learn that the patient is doing well.

MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE quarterly meeting of the Scottish Branch of this Association was held in the Hall of the Faculty of Physicians and Surgeons in Glasgow on March 8th. Dr. Watson was called to the chair. Dr. Yellowlees narrated his experiences in visiting a number of American asylums. Various other members who had been in America joined in the subsequent discussion. Dr. Turnbull then read notes of a case of exophthalmic goitre with insanity. Dr. Ireland read a paper giving an account of a recent visit to the Institution for Idiots at Bergen. Drs. Clouston, Howden, Urquhart, and Yellowlees were appointed a committee to make arrangements for the annual meeting of the Association in August next, which this year is to be held in Edinburgh.

THE UNIVERSITIES (SCOTLAND) BILL.

THE Government have at last taken the reform of the Scottish universities seriously in hand, and by the introduction of this Bill so early in the session show a disposition to settle this long-vexed question. This Bill, as introduced, is drafted on broad and liberal lines, and promises to effect what may be described as a revolution both in the administration and teaching of the universities. The greatest changes are made in the constitution and powers of the Court. The present Court, with its limited powers, is to be swept away, and to be replaced by a large representative body with complete and sole control over the entire administration of the university, both financial and otherwise. This Court is to consist of the Rector, Principal, head of any affiliated college, Lord Provost of the city, Chancellor's Assessor, Rector's Assessor, four Assessors elected by the General Council, four Assessors elected by the Senate, two Assessors nominated by the Crown, and such number of the governing body of any affiliated college as the Commissioners may determine. The Senate is to be restricted to the work of teaching and the maintenance of discipline. The Council is to have power of more frequent meeting and of adjourning discussions. The special commissioners appointed under the Bill are to possess executive powers, to make new ordinances for the better regulation of the universities, to modify the composition and increase the number of the various faculties and to create new faculties, to appoint new professors and intra- or extra-mural lecturers, to affiliate colleges, and to make a complete medical school at Dundee. They are also to regulate the admission of students to the universities by examination or otherwise, to

arrange their courses of study, the manner in which they shall be taught and examined, and by whom. The appropriation of the students' fees and the other emoluments of the universities, and the whole question of the salaries of the professors, are also left to their decision. Other sections of the Bill deal with questions of property and the amount of money to be advanced by the Treasury. The Bill will no doubt evoke abundant criticism, but it will be readily acknowledged that it is by far the most comprehensive scheme of reform yet brought forward; in many respects it is the most rational attempt yet made to bring the work of the Scottish universities into harmony with present requirements.

THE TECHNICAL COLLEGE, GLASGOW.

At a recent meeting of the Governors of the Technical College, the chairman stated that the Senate of the University had made a favourable reply to the application for recognition of attendance at the Technical College as qualifying in part for the degree of B.Sc., and were prepared to bring the application under the notice of the expected Universities Commission. He also stated that the Senate, as custodians of the Hunterian Museum, had agreed to accept the gift of the zoological and ethnological collections, at present in Anderson's College Museum. In regard to this gift, the Governors of Anderson's College and the medical professors sent a strong remonstrance against alienating such valuable specimens from the College, depriving their professors of much useful teaching material, and the people of the east end of the city of a museum that was once a popular holiday resort. It came out in the discussion that followed that the museum had been practically closed to the public for some years, that it had never been properly looked after, and that only one professor had used the specimens to illustrate a popular course of lectures now given up. And, further, that the governors of the Technical College, to whom the museum now belongs, having no interest in any form of instruction except what is mechanical and technical, found an anatomical collection useless and an encumbrance, and were glad to get rid of it. It may seem hard that the professors of Anderson's College should be deprived of these valuable collections, but it was much too late for them to remonstrate after the gift to the University had been made and accepted. There is, moreover, much to be said in favour of Professor Young's contention that a large well-equipped museum like the Hunterian is the most fitting resting-place for such specimens, as they can there be properly displayed and in such order as to make them more generally instructive.

TUBERCULOSIS IN CATTLE.

The local authorities of Paisley and Glasgow have had an interview with Lords Cranbrook and Lothian to call attention to the prevalence of tuberculosis in dairy stock and the danger thereby caused to the community through milk supply and otherwise. Principal McCall, of the Glasgow Veterinary College, has also addressed a long and alarming letter on the same subject to the local authority of Glasgow, in which he states that there are few towns in the three kingdoms, if any, where there are so many tuberculous and emaciated animals sold in the open market as in Glasgow. He thinks the reasons for this are that the persons who traffic in them are not sufficiently punished by confiscation of carcasses, and that it pays them to feed the inhabitants of Glasgow and the West of Scotland on the abominable carrion. He is so fully of opinion that the only remedy for this state of matters is that tuberculosis should be included among the scheduled diseases and so stamped out, compensation being given to owners as in pleuro-pneumonia, and he seeks to impress on all local authorities that it is their duty to do all in their power to induce the Government to act promptly in the matter.

IRELAND.

DR. EAGLETON, of Carrahoe, Galway, died last week from fever contracted in the discharge of his professional duties. The deceased gentleman was only twenty-six years of age, and his untimely death is much regretted.

DR. ROBERT TRAVERS, Professor of Medical Jurisprudence in the University of Dublin, died on Tuesday, March 27th. He graduated in medicine in 1835, and was appointed to his professorship in 1864.

THE LATE DR. JOHN MEENAN.

An oil-painting of this lamented physician has been presented to the Mater Infirmorum Hospital, Belfast, with which he was for some time connected. Dr. Meenan had attained much popularity alike with the public and his professional brethren, and his untimely decease is deeply regretted.

THE INSPECTORSHIP, LOCAL GOVERNMENT BOARD.

THE report that Dr. Edward Thompson, of Omagh, has been appointed to the office of Medical Inspector under the Local Government Board, vacant by the promotion of Dr. O'Farrell as yet lacks confirmation. Dr. Thompson is surgeon to the County Tyrone Infirmary, and visiting physician to the district lunatic asylum. If the rumour should turn out to be true, this appointment also will have been given outside the service, and many very well-known and competent candidates trained as dispensary officers been disappointed.

SIR PATRICK DUN'S HOSPITAL.

THE Governors of Sir Patrick Dun's Hospital have unfortunately incurred the displeasure of the Dublin Corporation in regard to the building of a new fever wing. A newspaper writer directed notice to the fact that fever wards were being built close to several dwellings, and urged that a distinct element of danger would be introduced in that special locality. It was asked why the Corporation had permitted the building, but it has turned out that the contractor sent the plans to the wrong place, and that the wards were erected without the knowledge of the borough engineer, and, therefore, contrary to the law on such matters. It is not unlikely that the Corporation will require such modifications in the building as will meet the popular objections.

BELFAST ROYAL HOSPITAL.

AN election was held on March 26th, to fill the post of house-physician, vacant by the resignation of Dr. S. H. Dunlop, who retires after two years' service. There were three candidates, Dr. H. L. Mackisack, Dr. W. B. McQuitty, and Dr. John Campbell, and much interest was taken in the election, the attendance of voters being one of the largest on record. The result of the polling showed a decisive majority for Dr. Mackisack.

BELFAST DISPENSARY DISTRICT.

WITH reference to a paragraph published on March 17th, we regret to find that we were misinformed in stating that Dr. Spedding had been dismissed by the Belfast Dispensary Committee. Dr. Spedding tendered his resignation to the committee at its meeting on March 5th, and it was accepted by the Local Government Board in a letter dated March 22nd. Dr. Biggar has been transferred to the district formerly held by Dr. Spedding, and to fill the vacancy thus created an election was held upon March 26th. There were six applications, but the contest lay virtually between Dr. Osborne, who has been acting as *locum tenens* for some time, and Dr. J. C. Ferguson, of the Belfast Union Hospital. The former was successful at the final ballot, and was declared duly elected.

MEMORANDUM FOR THE INFORMATION OF MEDICAL PRACTITIONERS IN REGARD TO THE EMPLOYMENT OF UN- QUALIFIED ASSISTANTS.

A.—On April 21st, 1883, the General Medical Council passed the following resolution:

"That the Council records on its minutes, for the information of those whom it may concern, that charges of gross misconduct in the employment of unqualified assistants, and charges of dishonest collusion with unqualified practitioners in respect of the signing of medical certificates required for the purposes of any law or lawful contract, are, if brought before the Council, regarded by the Council as charges of infamous conduct under the Medical Act."

B.—On November 20th, 1886, the attention of the Council having been directed to this resolution, it was determined that steps be taken with a view of making it public; accordingly, on July 25th, 1887, the Executive Council resolved that it should be inserted twice, at an interval of a month apart, as an advertisement in the following medical journals: *Lancet*, *BRITISH MEDICAL JOURNAL*, *Medical Press and Circular*, *Provincial Medical Journal*, *Edinburgh Medical Journal*, *Glasgow Medical Journal*, *Dublin Medical Journal*.

C.—On November 22nd, 1887, a report was adopted by the General Council stating that, as a consequence of the publication of the foregoing advertisements, a number of letters chiefly marked "Private" on the subject of the employment of unqualified assistants had been received by the Registrar. The report proceeds as follows:

"From these communications, from notices in the newspapers, and also from common report, it is evident that magistrates, coroners, county court judges, and other representatives of the public sense of justice, as well as medical men themselves, are becoming alive to the professional misconduct of registered practitioners who place patients under the sole charge of unqualified assistants.

"The administrators of the law regard as implicit fraud any claim of payment for the service of such substitute assistants, when it is represented as 'medical attendance.'

"This fact is encouraging, for when it is found that the owner of a 'branch practice' cannot get a claim allowed for the services of his unregistered substitute, and, moreover, that the protection of a 'cover' does not enable the unregistered practitioner to recover charges, these two kinds of irregular practice will probably not long continue to exist in this country."

D.—Since the date of the foregoing report, a case of the mis-employment of an unqualified assistant has been brought before the notice of the Council and adjudicated upon; and the registered practitioner concerned, having been informed of the grave disapprobation with which the Council regarded his conduct, promised at once to discontinue the practice condemned. Other cases have also been brought under the notice of the Executive Committee.

E.—In the prosecution of their desire to put a stop to this wrongful practice, the following resolution was passed by the General Council on November 26th, 1887:

"That it be referred to the Executive Committee to consider under what circumstances a registered medical practitioner would render himself liable to the censure of the Council in reference to the employment of unqualified assistants."

F.—On February 27th, 1888, the Executive Committee, without attempting to make a formal definition of the misconduct in question, reported to the General Council that, in its opinion,

"A registered medical practitioner would render himself liable to the censure of the Medical Council in case of the employment of an unqualified assistant in the practice of medicine, surgery, or midwifery on behalf and for the benefit of such registered practitioner, either in complete substitution for his own services, or under circumstances in which due personal supervision and control are not, or cannot be, exercised by the said registered practitioner."

The Executive Committee also stated, in reference to the procedure known as "covering," that in its view a registered practitioner covers an unregistered person, when he does, or assists in doing, or is party to, any act which enables such unqualified person to practise as if he were fully qualified.

The Executive Committee furthermore called attention to a re-

solution passed by the General Council on April 21st, 1883 (vol. xx, p. 91), which implies that, in the Council's opinion, "any registered practitioner practising for gain, who knowingly and wilfully deposes a person not registered or qualified to be registered under the Medical Act to professionally treat on his behalf, in any matter requiring professional discretion or skill, any sick or injured person 'should' be subject to the same legal liabilities as a person who falsely represents himself to be a legally qualified medical practitioner; but with special proviso that such enactment 'should' not hinder any duly regulated training of pupils in medical schools or otherwise by legally qualified practitioners, nor the use of trained pupils in partially treating the sick or injured under the direction, supervision, and responsibility of such practitioners, nor any legitimate employment of nurses, midwives, or dispensers."

JOHN MARSHALL, President.

March 1st, 1888.

ROYAL COLLEGE OF PHYSICIANS.

ON Monday, March 26th, the day after Palm Sunday, as required by statute, an extraordinary comitia was held for the election of a President. There was a very large attendance of Fellows, and the chair was taken by Sir William Jenner, Bart., M.D., K.C.B., who has been President of the College for seven years. Before resigning the chair, Sir William Jenner delivered his annual address, narrating the history of the College during the past twelve months, and concluding with an account of the lives and labours of the Fellows deceased in the same period, of whom the most distinguished were Dr. Wilson Fox and Sir George Burrows, Bart.

The by-law regulating the proceedings for the election of a President having been read by Sir Henry Pitman, a ballot was taken, with the following result: Dr. Quain, 46 votes; Sir Andrew Clark, Bart., 42 votes; Dr. Wilks, 25 votes; Dr. George Johnson, 17 votes; Sir E. Sieveking, 12 votes; Dr. Andrew, 4 votes; and 1 vote each for Sir H. Pitman, Sir W. Gull, Bart., Dr. Bristowe, and Dr. Charles West.

No Fellow having obtained two-thirds of the votes, a second ballot was taken for the two highest, Dr. Quain and Sir Andrew Clark. The result was: For Sir Andrew Clark, Bart., 79 votes; for Dr. Quain, 71 votes.

Sir Andrew Clark, Bart., was thus elected President, and was duly admitted to that office by the Senior Censor. In a few fitting words he acknowledged the honour conferred upon him, and promised to maintain the honour and dignity of the College.

ASSOCIATION INTELLIGENCE.

COUNCIL.

NOTICE OF MEETING.

A MEETING of the Council will be held at the Offices of the Association, No. 429, Strand (corner of Agar Street), London, on Wednesday, the 18th day of April next, at 2 o'clock in the afternoon.

FRANCIS FOWKE, *General Secretary*.

March 15th, 1888.

NOTICE OF QUARTERLY MEETINGS, FOR 1888. ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Meetings of the Council will be held on April 18th, July 18th, and October 17th, 1888. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before each meeting, namely, March 28th, June 27th, September 26th, and December 28th, 1888.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No member can be elected by a Branch Council unless his name has been inserted in the circular summoning the meeting at which he seeks election.

FRANCIS FOWKE, *General Secretary*.

COLLECTIVE INVESTIGATION OF DISEASE.

THE Report upon the CONNECTION OF DISEASE WITH HABITS OF INTemperance, which was presented to the Section of Medicine

in the Annual Meeting of 1887 will shortly be published in the JOURNAL.

Reports upon the two remaining inquiries, namely, that into DIPHtheria, and that into the GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES, are in preparation, and will be published as soon as ready.

The following inquiry only of the first series remains open, namely, that on THE ETIOLOGY OF PHTHISIS.

A fresh inquiry into the ORIGIN and MODE of PROPAGATION OF EPIDEMICS of DIPHtheria has been issued.

Memoranda upon these subjects, and forms for recording observations, may be had on application to the Secretary of the Collective Investigation Committee, 429, Strand, W.C.

BRANCH MEETINGS TO BE HELD.

SOUTH WALES AND MONMOUTHSHIRE BRANCH.—The spring meeting of this Branch will be held at Pontypridd about the second or third week in April. Members wishing to read papers, etc., are requested to send titles to either of the Honorary Secretaries by the end of March, in order that they may be inserted in the circulars.—ALFRED SHEEN, M.D., Cardiff; D. ARTHUR DAVIES, M.B., Swansea, Honorary Secretaries.

METROPOLITAN COUNTIES BRANCH: EAST LONDON AND SOUTH ESSEX DISTRICT.—The next meeting will be held on Thursday, April 19th, at the Hackney Town Hall, at 8.30 P.M. The chair will be taken by F. M. CORNER, Esq. A paper on the Surgery of Abscess will be read by HOWARD MARSH, Esq. Visitors will be welcome.—J. W. HUNT, 101, Queen's Road, Dalston, Honorary Secretary.

WEST SOMERSET BRANCH.—The spring meeting will be held at the Railway Hotel, Taunton, on Thursday, April 12th, at 5 P.M. Dinner at 5.30 P.M. The subject settled by the Council to be discussed after dinner is Bone Setting. Mr. W. J. PENNY, Assistant-Surgeon to the Bristol General Hospital, and Demonstrator of Anatomy to the Bristol Medical School, has kindly promised to come and open the discussion. The election of representative of the Branch on the Council of the Association for the ensuing year will take place at this meeting.—W. M. KELLY, M.D., Taunton, Honorary Secretary.

SOUTH-EASTERN BRANCH: WEST KENT DISTRICT.—The next meeting of this District will take place on Friday, April 27th, at the Hospital, Gravesend, R. J. BRYDEN, Esq., in the chair. Gentlemen desirous of reading papers or exhibiting specimens are requested to inform the Honorary Secretary of the District not later than April 8th. Further particulars will be duly announced.—A. W. NANKIVELL, F.R.C.S., St. Bartholomew's Hospital, Chatham, Honorary Secretary.

NORTH OF ENGLAND BRANCH.—The spring meeting will be held at the Infirmary, Sunderland, on Wednesday, April 25th, at 3 P.M. Members intending to read papers or show specimens are requested to communicate at once with the secretary. The dinner after the meeting will take place at the Queen's Hotel, at 5 o'clock. The following papers are already promised.—Dr. HUME: A Case of Congenital Fistula of the Stomach, Cured by Operation. Dr. COLEY: On the Treatment of Effusion into the Pleura in Children. Dr. MURPHY: A Man 229 Days after Gastrostomy. Dr. OLIVER: Notes on an Unusual Case of Hæmaturia.—G. E. WILLIAMSON, F.R.C.S., 22, Eldon Square, Newcastle-on-Tyne, Honorary Secretary.

NORTH OF IRELAND BRANCH.—A general meeting of this Branch will be held in the Royal Hospital, Belfast, on Thursday, April 19th, at 11 A.M. Gentlemen who wish to bring any business before the meeting will kindly communicate as early as convenient with JOHN W. BYERS, M.D., Lower Crescent, Belfast, Honorary Secretary.

OXFORD AND DISTRICT BRANCH.—The next meeting will be held at the Radcliffe Infirmary, Oxford, on Friday, April 27th, at 3 P.M. Notice of papers to be read must be sent to W. LEWIS MORGAN, 42, Broad Street, Oxford, on or before April 18th. A dinner will be provided for those members who signify their intention to dine to the Secretary two days before the meeting.—S. D. DARBISHIRE and W. LEWIS MORGAN, Honorary Secretaries.

SOUTHERN BRANCH: SOUTHAMPTON DISTRICT.—The next meeting of this District will be held on Tuesday, April 10th, 1888, at the residence of Dr. Maclean, C.B., 24, Carlton Crescent, at 8 P.M. Business: Election of officers. Passing of accounts. At the same time, a joint meeting with the Southampton Medical Society will take place, when a paper will be read by Brigade-Surgeon Godwin, M.S., on the Treatment of Wounds of the Abdominal Viscera. Dr. L. M. BUCKELL will bring under notice a case, with specimen, of Monster Birth. Association and Branch subscriptions for current year, amounting to £1 3s. 4d., became due on January 1st, and may be paid in the Honorary Secretary as soon as convenient.—THEOPH. W. TREND, M.D., Honorary Secretary, 6, Anglesea Place, Southampton.

SOUTHERN BRANCH: SOUTH-EAST HANTS DISTRICT.—Ordinary meeting at the Grosvenor Hotel, Queen's Gate, Southsea, on Thursday, April 11th, 1888. The chair will be taken by the President, Dr. James Watson, at 4.15 P.M. Gentlemen who are desirous of introducing patients, exhibiting pathological specimens, or making communications are requested to signify their intention at once to the Honorary Secretary. Dinner will be provided at 6.30 P.M.; charge, 5s., exclusive of wine, etc.—J. WARD COUSINS, Honorary Secretary.

NORTH WALES BRANCH.

The intermediate meeting was held on Tuesday, March 20th, at the Pwllcrochan Hotel, Colwyn Bay, under the presidency of CHARLES WILLIAMS, Esq.

New Members.—Mr. J. Owen Jones, Flint Dispensary, Holywell, was elected a member of the Association and Branch; and Messrs. E. Parry Edwards and Alfred W. Hughes, Flint, of the Branch.

Treasurer's Report.—The accounts of the Branch for the year 1887, showing a balance of nearly £4 in hand, were read and confirmed.

Architects, Surveyors, and Engineers' Compulsory Registration Bill.—It was resolved that the members should petition in its favour.

Payment of Fees to Medical Witnesses in Civil and Criminal Cases.—After a discussion initiated by Mr. RICHARD WILLIAMS, and taken part in by Drs. IMLACH and GRIFFITH, and Messrs. BICKERTON, JONES-MORRIS, and the PRESIDENT, it was unanimously resolved: "That the members of the North Wales Branch, having had under consideration the question of fees for attendance in courts of law, beg to declare their opinion (1) that in civil cases the law should be so altered as to place services rendered in the witness box on the same footing as any other professional services; (2) that the present scale of remuneration for attendance in criminal cases is wholly inadequate."

Vote of Thanks to President.—On the motion of Dr. ROBERTS, Menai Bridge, seconded by Dr. GRIFFITH, Portmadoc, a vote of thanks was passed to the President for his address at the annual meeting.

Papers.—Mr. BICKERTON related the history of two cases in which he had removed a piece of glass which had lain in the eye for seven and ten years respectively with complete success, showing the foreign bodies, and illustrating by diagrams the line of incision in each case and the condition of the eye at the time of operation;—Mr. L. F. COX related the history of two cases of Climacteric Insanity.—Dr. IMLACH read the report of a case of Hystero-epilepsy of twenty years' duration cured by removal of the Uterine Appendages.—Mr. ROBERT JONES read a paper on the Causes of Non-union in Cases of Fracture, and remarks were made by Dr. GRIFFITH and Mr. T. L. JONES.—Dr. JOHN ROBERTS showed some Pneumococci from a Case of so-called "Creeping Pneumonia," and gave the history of the case, and made some remarks on its pathology.

Consultation with Homœopaths.—Dr. E. J. LLOYD introduced a discussion on this subject, which was taken part in by the majority of the members present. No resolution was passed, the evident sense of the meeting being that it was not well to alter the present rule of the profession.

SOUTH-EASTERN BRANCH: EAST AND WEST SUSSEX DISTRICTS.

A CONJOINT meeting of the above Districts was held at Brighton, on March 22nd. Dr. MOORE (in the unavoidable absence of Mr. Salzmann) took the chair.

Next Meeting.—Resolved: "That the next meeting be held at Hastings in May."

Representative of Branch on Council.—Mr. G. F. HODGSON, of Brighton, was nominated as a representative for Sussex on the Council of the Association.

Communications.—The following papers were read: Dr. STARLING: A Case of Fibroid Induration of the Stomach.—Mr. HOWARD MARSH: Recovery after Laparotomy for Intestinal Obstruction.—Dr. MACKAY showed cases of Lupus Erythematosus, Lupus Non Exedens, and Seborrhœa.—Mr. VERRALL: A case of Lupus Exedens.—Dr. MACKAY read Notes of Treatment; all the lupus cases, including Mr. Verrall's, being treated locally with resorcin ointment.—Mr. VERRALL: A Case of Nephrotomy for Renal Calculus.

SMALL-POX IN NOTTINGHAM.—A report on the recent outbreak of small-pox in Nottingham issued by the medical officer of the borough states that thirty-six patients from Nottingham have been admitted to the Bagthorpe Hospital from December 27th to the present time, and seven of these cases have ended fatally. So far no revaccinated person has taken small-pox. Twenty-three out of the thirty-six had been vaccinated in infancy, but not since, and of these three died. The remaining thirteen were unvaccinated at the time of infection, but six were vaccinated subsequently, and five out of these six escaped with a mild attack. Of the seven persons who were never vaccinated, four died and a fifth had a very dangerous (confluent) attack.

MEDICAL MAGISTRATE.—Mr. William Neale, L.R.C.S.L., of Drogheda, has been appointed a justice of the peace for Queen's County.

SPECIAL CORRESPONDENCE.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

Hæmoglobinuria in Rheumatism.—Arsenical Rhinitis.—Paris Water-Supply.

At a recent meeting of the Société Médicale des Hôpitaux, M. Hayem made a communication on hæmoglobinuria in rheumatism. The patient, a woman, aged 37, was attacked with rheumatism in 1886, and again in 1887. She was then suckling her sixth child. Six days after the second attack came on she entered the hospital. The urine was completely red; there was pain, adynamia, rheumatic œdema in the arms and hands, copious perspiration, rheumatic pneumonia of the right lung, followed by symptoms of pericarditis. The urine, which was scanty at first, became abundant, and the patient recovered. She did not lose her milk, and began to suckle her child again. The urine presented the characteristics of hæmoglobinuria; it contained no red corpuscles, but a large proportion of albumen and white corpuscles. The blood was normal. This case shows that hæmoglobinuria may appear during an attack of acute rheumatism. It differs from hæmaturia in that the urine contains neither red corpuscles nor stroma. Rheumatic nephritis evidently existed in the case described by M. Hayem. The serum of the blood was not modified during the attack of hæmoglobinuria, and the red corpuscles were not dissolved by the urine. M. Hayem ascribes the hæmoglobinuria to the existence of renal mischief. M. Bucquoy cited a case which he had observed twenty years before of paroxysmal hæmoglobinuria *a frigore*. The patient passed black urine when he was out of doors. The urine became normal when he was indoors. The patient was rheumatic but not albuminuric. At the time paroxysmal hæmoglobinuria *a frigore* was not properly known. M. Hayem observed that such patients must be regarded as suffering from the effects of cold. The renal lesion, which undoubtedly exists, is not persistent; it is only during the attacks of hæmoglobinuria that albumen is observed in the urine. M. Albert Robin cited two cases of hæmoglobinuria. In the first the patient had a genuine attack of acute rheumatism. The urine became red; there were no traces of red corpuscles; there was considerable albuminuria. Symptoms of inflammatory nephritis soon showed themselves. In the second case hæmoglobinuria appeared before rheumatism. In both cases there were unmistakable signs of severe inflammatory nephritis.

Dr. A. Cartaz made, some little time ago, an interesting communication to the Société Clinique of Paris on a case of arsenical rhinitis. Workmen handling arsenical products are often subject to accidents of this nature which, commencing with coryza, lead to deep ulcerations, and ultimately to destruction of the mucous membrane and perforation of the septum. The affection is identical with that observed in workmen employed in manipulating chromic salts, only in the latter case the course of the disease is generally more rapid. Notwithstanding the extensive ulceration and profuse sanious discharge, there is scarcely any œzema. It would seem as though the deleterious substances acted as parasitocides, and prevented the putrefaction of the eliminated products. This opinion has been already expressed by J. N. Mackenzie with regard to the accidents caused by chromic salts. The sense of smell is not generally much affected. The case under consideration was that of a man, aged 48, employed in a manufactory of arsenical colours, Mittis green, and Schweinfurt green. He first came to the hospital in 1835. His general health had always been good. He commenced handling arsenical products at the age of 17, and continued that trade without interruption until he was 30 years old. He had only now and then slight ulcerations on the arms, thighs, penis, and scrotum; these ulcerations had disappeared under treatment by baths and sulphate of iron lotions. He had had on two or three occasions deep ulcerations of the fingers. At the age of 25 he contracted simultaneously gonorrhœa and chancre, as to the nature of which he could give no information. Up to this time he had never been occupied in pounding or sifting arsenical products. From 30 to 38 he was employed on other work. At 38 he resumed his first trade, but this time was much employed in sifting. At the age of 43 he had facial paralysis *a frigore*. He remained a fortnight in hospital, but was subjected to no internal treatment, the only trace left of the paralysis being a slight deviation of the right commissure of

the lips. He then returned to his work, and from that moment crusts began to form in his nose. Soon afterwards he noticed a swelling of the right side of the root of the nose, and considerable suppuration ensued. On examination perforation of the septum was discovered. Syphilis being suspected he underwent a severe specific treatment, followed by a month of mixed iodide-mercurial treatment, without any effect. At this period Dr. Cartaz took charge of the case. The patient had then discontinued his work for a month, and there were no ulcerations on the fingers or other parts of the body; the nose, however, appeared much damaged. It was flattened, deviated to the right, and very red; the point was swollen, the skin tense, and erysipelatous-looking. On the left side there was some bony overgrowth affecting the bones of the nose and the nasal process of the superior maxillary. This tumefaction filled up, as it were, the internal angle of the eye. Rhinoscopic examination showed that the cartilaginous septum had completely disappeared, while the turbinate bones on the left side presented extensive though superficial ulcerations covered with brown crusts. The mucous membrane was everywhere else greyish red, and slightly swollen. The edges of the vomer were eroded in places by superficial necrosis, and at several points higher up the probe touched bare bone. A small sequestrum was detached. The left middle and lower turbinate bones were destroyed. There was not much discharge, and but little smell. The pharynx was of a deep red colour but without ulceration. Washing out with disinfectants was employed, and the patient was discharged a month after entering hospital, but was instructed to continue treatment, consisting of sulphur baths, nasal irrigations of chloride solution of tar water, insufflations of subnitrate of bismuth and iodoform, with iron and quinine internally. Some time afterwards he returned to his previous work, but after two months the symptoms came on again as severely as before. He then definitively gave up his old occupation, and his condition gradually improved.

At a meeting of the Société de Médecine Publique et d'Hygiène Professionnelle, M. Bechmann, chief manager of the water supply of Paris, announced that in 1884 some beautiful springs of pure fresh water had been purchased by the city of Paris. Until now these springs have not been utilised, and at certain times water which is known to contain typhoid germs is distributed to the inhabitants of the city. M. Bechmann has tried to prove that the assertion made by Dr. Bronardel and other medical men that the Seine water contains poisonous principles is unfounded. He admits that this water is not altogether harmless, but gives statistics to show that during the distribution of Seine water last summer the rate of mortality from typhoid fever was lower in the arrondissements to which it was distributed than in those which were supplied with water from the Vanne and Dhuys springs. M. Bechmann quite passed over the fact that in a convent inhabited by 300 persons in the nineteenth arrondissement an epidemic of typhoid fever was produced by the use of Seine water. Within ten days 132 of the inmates were attacked with toxic, septic, and typhoid symptoms. M. Mosny's report on the use of pure drinking water at Vienna and the consequent diminution of typhoid fever in that city, furnishes the strongest evidence of the influence of water in propagating this and other affections. Since the town was supplied with new water-pipes no case of cholera has been recorded in Vienna. Dysentery, which killed about seventy persons every year, has disappeared since Vienna was furnished with a supply of pure spring water in 1874. In 1877 this water was temporarily replaced by Danube water in certain quarters of the town. A terrible epidemic of typhoid fever was the consequence. Since Vienna has been exclusively supplied with spring water, typhoid fever has almost disappeared, and a case of typhoid fever in the hospitals is a rare occurrence. M. Mosny is perfectly convinced that water is the principal agent in transmitting typhoid fever, and that the only means of suppressing this affection in a town is by supplying the inhabitants with large quantities of absolutely pure water. In replying to M. Bechmann's statements as to the rate of mortality from typhoid fever in Paris during the time that Seine water was distributed, M. Bronardel and M. Chantemesse observed that it was only twelve or fourteen days after this water was supplied that its effects could be demonstrated, and that death from typhoid fever usually occurs four or five weeks after the appearance of the affection. M. Bechmann's table of statistics records six deaths from typhoid fever during the fourth week after the Seine water was supplied, fourteen deaths during the fifth and sixth week, twenty-nine during the seventh week,

thirty-six during the eighth, and forty-four during the thirteenth. The mortality did not diminish so rapidly as might have been expected when spring water was substituted for Seine water; but this M. Brouardel attributes to the microbes deposited in the water-pipes by the Seine water. He considers it most essential that the Government authorities should immediately take the necessary measures to utilise the springs that were purchased four years ago, and considers that the immunity of the inhabitants of Paris from typhoid fever is more necessary than the establishment of a metropolitan railway, which the Government is bent upon carrying out before adopting any other measure.

BERLIN.

[FROM OUR OWN CORRESPONDENT.]

WE are living under the sign of Cancer. Cancer is the subject of discussion in all medical assemblies, from the cancer-bacillus of Dr. Scheuerlen to the operative removal of carcinomata in the different organs. Cancer forms the subject of private conversation among medical men, and also among the laity. "What do you think of the illness of the Crown Prince?" the principal question till lately, has now been altered to: "What do you think about the illness of the Emperor?" Our Emperor Frederick enjoys an extraordinary popularity, and the whole interest of Germany is concentrated on the great question: "How long?" In these questions the position of Sir Morell Mackenzie is very much discussed. There is a large party of laymen and, unfortunately, also of medical men who hate him. The former do so from Chauvinism because they are foolish enough to believe that the honour of German science is wounded by an Englishman being the first physician of the German Emperor. His professional detractors accuse him of having, by his optimism, prevented a radical operation being undertaken whilst there was yet time. However, happily, there is a much larger number who are thankful to him for having prolonged for some time so precious a life; and he enjoys in full measure the confidence of His Majesty the Emperor himself, and of his illustrious consort. It is just announced that Dr. Herman Krause has been named Professor.

SWITZERLAND.

[FROM OUR OWN CORRESPONDENT.]

The "Bund" on English Practitioners in Switzerland; Memorandum of the Schweizerische Aerzte-Commission; Memorandum of the Société Vaudoise de Médecine.

AN excellent paragraph on the recent decision of the Bundesrath see the JOURNAL, March 3rd, 1888, p. 422) has just appeared in the *Bund* (March 19th, 1888). According to the correspondent (a Mr. "S." of Geneva—probably a Swiss medical man), the decision of the Federal Council "affords a striking proof that the questions relative to medical practice are still settled on the ground of a narrow-hearted protective-duties theory (*Schutzalltheorie*), which might be logical enough with regard to commercial articles, but most assuredly appear quite absurd when applied to medical aid to sick and suffering fellow men..... The very fact that a medical man holding a British diploma can be prohibited from practising amidst his countrymen abroad is nothing but an obvious and untenable anachronism, though it might answer to the spirit of our (Swiss) medical laws. Or possibly the Swiss practitioner stands in sad need of legal protection in his business from foreign competition? Now, if there is anything on which competition and even over-supply might be useful to the community, it is just in medical help to the sick. As a matter of fact, however, there is no fear of competition or of over-supply of the sick market with skilled medical help from granting facilities to English practitioners to settle in the Swiss health-resorts, for the wish expressed by the Engadine colonies (*vide* the JOURNAL, February 8th, p. 334) is an outcome of a real necessity, and is most intimately connected with the foreign industry (*Fremdenindustrie*), that is, with a prosperous development of our foreigners' stations (*Fremdenstationen*). Foreign practitioners generally attract to us their countrymen, and give the widest possible publicity to the climatic advantages of our country, as well as to our health-resorts and hotels. Because a Swiss physician practises in London without an English qualification, scores of our health-resorts, hotels, summer stations, etc., are to suffer heavily by losing the largest element of their prosperity! It is simply absurd. Have Germany and Italy prohibited Sir Morell Mackenzie, and Italy Professor Bergmann from practising in Berlin and San Remo, though

without local diplomas? Supposing that Her Majesty the Queen had come to Switzerland; would her medical attendant be prohibited from practising medicine? Or, given a British subject who did not happen to speak German or French; is he bound in duty to consult a Swiss practitioner, notwithstanding the fact that the patient cannot possibly understand the doctor, nor the doctor the patient? After alluding to other absurdities of the same kind, the correspondent of the *Bund* lays down a principle which will certainly find acceptance among enlightened members of the medical profession all over the world. "Science," he says, "is cosmopolitan, and the practice of any scientific calling must be founded on the most liberal basis, absolutely free from any degrading spirit of a caste or a trade corporation." A different spirit is shown in the two official documents which have been published here, one from the Swiss Medical Committee (*Schweizerische Aerzte-Commission*), the other from a Special Committee of the *Société Vaudoise de Médecine*. Both of them are addressed to the Swiss Ministry of Interior, which is urged absolutely to refuse the "reciprocity" between Great Britain and Switzerland as regards medical practice, which was a couple of months ago proposed to the Federal Council by the British ambassador at Berne. Both documents lay stress on the general inferiority of English medical men as regards scientific training and professional ability to Swiss practitioners, and argue that the proposed bargain would be altogether in favour of the former, whilst the latter would receive nothing like an equivalent in exchange. This attitude is, no doubt, admirably logical, but it is, perhaps, another mark of our inferior intellectual training that it strikes us as extremely unwise, from a practical point of view. Granting that English doctors are, on the whole, poor creatures, it is nevertheless true that their sick countrymen prefer them to the superior beings radiant with the culture of Berne, Zurich, and Geneva, who wish to supplant them. This is national prejudice, perhaps, but it is none the less a hard fact against which the most faultless logic is of no avail. Whatever may be thought of British qualifications, there can be but one opinion as to the effect of English visitors on the prosperity of Switzerland, and the Federal Government may be trusted not to drive away such useful guests, merely to gratify the jealousy of a few native doctors.

CORRESPONDENCE.

THE ELECTION OF PRESIDENT OF THE COLLEGE OF PHYSICIANS.

SIR,—The result of the election of President of the Royal College of Physicians has given satisfaction to many; but a protest must be made against the means by which this result has been attained; to some extent they involve a departure from precedent. Canvassing was had recourse to, if not in favour of one candidate, yet against another. It is now known that a portion of what is called "the Collega party," supported by the popularity of the Registrar of the College, used its influence in a certain direction. It would, in my opinion, be more becoming if the officials of the College in future were to abstain from such interference, and to leave the Fellows entirely free in choosing their President.—I am, etc.,
ONE OF THE FELLOWS.

THE BUDGET.

SIR.—I think a strong, unanimous, and active opposition should be started at once against the proposal of the Chancellor of the Exchequer to tax doctors' horses. If great efforts are not made during the Easter recess, the intolerable injustice will be completed. I at present pay £1 10s. tax for a groom and trap. Under this iniquitous scheme, my taxes will be raised to £3 10s. for the one item of conveyance alone. Beside the monstrous income-tax, with trade as depressed as it has been, such a burden will be of serious import to many country doctors.—I am, etc.,
MEXBOROUGH, near Rotherham. W. SYKES.

SIR.—The new budget of Mr. Goschen seems about to place another burden on our already overweighted profession. I see that it is proposed to exact a fresh tax of £1 for every pleasure horse, and doubtless, unless some steps are promptly taken, the absolutely necessary horses of struggling medical practitioners will be reckoned under this category. Surely something might be done, through our representatives in Parliament, to have it

definitely settled that our horses shall be regarded as being kept for purely business purposes, as much so as in the case of any tradesman, for it could never be asserted in the case of the latter that his horses are not at times used for other purposes.—I am, etc.,
 MAJOR GREENWOOD, JUN., M.D.
 18, Queen's Road, Dalston, E., March 27th.

CONSULTATION WITH HOMŒOPATHS.

SIR,—As a member of the British Medical Association and one of the oldest practitioners in Cheltenham, I protest, in common with Dr. Needham, against the recent vote of the Gloucestershire Branch of the Association being regarded as any fair criterion of the feelings of the profession generally in Gloucestershire as regards meeting homœopaths in consultation.

Let the homœopaths drop their distinctive appellation and cease to delude the public with the idea that they possess a new and improved *methodus medendi*, and professional fellowship will be conceded as a matter of course. Until they do this no *rapprochement* is possible or desirable. I am, etc.,
 W. PHILSON, M.D.
 Cheltenham.

LIGHTING BY GAS.

SIR,—The examination of the various methods of lighting by gas has been an interest to me for some time. I hope the following notes may be of use to those who, like your correspondent "F.R.C.S. Eng.," wish to know how to obtain light in the least objectionable manner.

So long as gas, as supplied by the companies, contains the usual excessive sulphur impurity, and the gas is burnt in the usual wasteful fashion, and ordinary sitting-rooms remain unventilated, so long will gas prove more or less objectionable. As a rule, with the usual fittings which the plumber supplies, about twice as much gas is burnt and paid for as is really required.

Gasburners of the better class may be divided into:

1. Regulated flat flames, such as the automatic governor burners of Sugg, Peebles, and others, varying in price from one to six shillings. These obtain the full parliamentary standard of sixteen candles, and sometimes slightly more.

2. Regenerative burners. These are mostly of the Argand type, large, costly, and, in the cheaper forms, somewhat unsightly. They require, moreover, rather careful looking after, and are apt to get choked with soot. They are, on the other hand, very economical in working, giving about 50 per cent. more light than the simple burners; and the light is extremely pure, white, and steady. Of this type are the Weymouth and Cromarty lamps. Quite recently some new forms have been brought out by F. Siemens, of which one, a simple Argand selling for a few shillings, gives a most brilliant light, and, if fitted with a regulator, ought to be very useful when a strong light is required for professional purposes, such as the examination of the larynx, etc. It is far superior to all other non-regenerative Argands in the market.

There remains another class—namely, the incandescent lights—of which the "Auer-Welsbach" is best known. This gives an extremely brilliant light at a most economical rate if the pressure be high—say two inches of water. At a pressure below an inch and a half it is not worth having. It is simple in construction, but the "mantle" which is rendered incandescent by a Bunsen flame, is very fragile, and, if not accidentally broken, requires occasional renewal. In some parts of America, where "water gas" of low illuminating quality is supplied at high pressure, this method of lighting is found to answer very well. The price, however, of the burner is very high, and at the present rates some ten or twelve shillings a year would probably be expended in mantles.

Of the large number of carburetters which have been introduced, the "albo-carbon," in which ordinary gas is enriched with the vapour of naphthaline, is the only one which survives. The light is brilliant, steady, and very economical of gas. It has, however, the disadvantages of requiring attention to the supply of "albo-carbon," of not giving its full light till some time after it is lighted, while at times, if not properly attended to, it gives off a disagreeable odour. It will be seen that a light varying from about two candles and a half to about eight candles per foot of gas consumed can be obtained, according as a common burner, or a more artificially-constructed one is used.

Every room which is lighted by gas should have an outlet, near the ceiling, either a chimney-breast ventilator or a tube opening from the centre of the ceiling into the chimney. If a reg-

tive lamp be placed under this opening, no inconvenience will be felt from the gas.—I am, etc.,
 ERNEST H. JACOB, M.D.
 Leeds, March, 1888.

THE CAUSATION OF HAMMER TOES.

SIR,—I was much struck by the remarkable unanimity of opinion that existed as to the causation of hammer toes between the reader of a paper upon the treatment of that deformity at a recent meeting of the Medical Society and the majority of those who took part in the discussion upon it. I have dissected a very large number of feet affected with hammer toes, abducted toes, and those of two female subjects affected with marked flexion of the metatarsophalangeal joint of the great toe, and in not one of them was it necessary to explain the change in the normal position as being dependent upon what appears to me to be so obviously the effect of the displacement, namely, the altered condition of the ligaments. Why should we not explain simple abduction of the great toe as being produced by primary shortening of a ligament? The reason is that the cause is so obvious, but if the condition is a more complex one, and when the pressure very frequently acts indirectly and not distally, the deformity called hammer toes, like many other acquired deformities of the human body, is attributed to a change which is an effect and not a cause.

I have discussed the question very fully in a paper on the Causation of Deformities in the last number of the *Guy's Hospital Reports*, so I will not do more than refer to it here.—I am, etc.,
 W. ARBUTHNOT LANE.
 14, St. Thomas's Street, S.E.

LOOSE BODIES IN THE KNEE-JOINT.

SIR,—In replying to the remarks of Professor Humphry at the Medical Society of London on February 27th, I endeavoured to make it clear that I did not attribute the presence of the "loose cartilages" in the knee-joint of the patient exhibited to fracture of portions of normal cartilage, but rather alluded to the possibility of the breaking off of portions of cartilage altered in marginal contour, especially having in mind those outgrowths from the edges of articular cartilages which are found in chronically diseased articulations, and notably in joints the subject of chronic rheumatic change. The man had long suffered from chronic joint affection, and in violently using his knee, which he was accustomed to do at his trade despite the pain, such outgrowths might have been broken off. The idea of these bodies originating from violence has survived in the writings and teachings of a succession of surgical authorities.

Brodie upheld this doctrine, and the most recent work on diseases of the joints in this country seems to take the same view. Brodurst, writing in vol. ii of the *St. George's Hospital Reports*, alludes to the case of a clergyman who sustained a violent wrench to his knee at football. This was followed by pain and swelling, which lasted for six weeks. Then a loose cartilage was found on the inner side of the joint, and extracted by incision. "It proved to be the anterior portion of the internal semilunar fibro-cartilage." An inspection of this specimen will inevitably suggest to an unprejudicial observer that the above description is true, and that the cartilage has been separated by fracture. Simm, writing in vol. xv of the *Pathological Society's Transactions*, relates a case of loose cartilage occurring soon after injury, and describes it as "a broken off bit of the articular end of the femur covered on one side with its natural cartilage." It is important to observe that these were the cases of healthy and vigorous young men, not likely to have had calcareous arthritic formations of antecedent date. It is surely possible for a portion of bone and cartilage to be fractured and still retain its place by untern fragments, so that union may again take place. Hence, in "extraordinary and violent" accidents which do occur to the larger joints, such lesion may be overlooked in the subsequent ankylosis, or spoiling of function of the injured articulation. Should the patient die, the joint is not often so closely examined as to detect, for instance, a detached portion of cartilage.

The report of Goodhart in Bryant's *Surgery* refers to the possibility of fracture of articular cartilage and bone, so that we may fairly doubt whether the explanation offered by Professor Humphry will apply to all cases.

There seems no more reason that a portion of the articular end of a bone, with its encrusting cartilage, should not quietly exfoliate after severe bruising, than that it should be impossible for a similar process to occur on the superficial aspect of any bone. Paget, writing in *St. Bartholomew's Hospital Reports* for 1870,

most strongly upholds this view. Furthermore, he examined the specimen microscopically. Teale's well known case seems equally conclusive. There are obvious reasons why I should be anything but desirous of entering into controversy with so accurate an observer and reasoner as Professor Humphry. From old associations it may be considered an act of heresy on my part to attempt to differ from him. I confess, on looking into the matter, that the cases seem rarer than I previously imagined, or than is usually taught and believed. Doubtless many specimens of this kind have really the origin that the Professor so ingeniously suggests.—I am, etc.,

A. MARMADUKE SHEILD.

20, Stratford Place, W.

SIR.—In reference to Professor Humphry's remarks on the above subject, I venture to draw his attention to a specimen which was exhibited by me at the Pathological Society some twelve or more years ago, and was reported on by a committee of the Society. It was removed by me from the knee-joint of a young man, who had received a severe injury to the joint some time previously. It had all the appearance of structure of a piece of articular cartilage which had been detached by violence, and was thought to be so at the time.

I regret that the specimen was accidentally thrown away, and I have not by me the report of the Committee, which is printed in the *Transactions of the Society*.

There was no suspicion of the man having suffered from rheumatoid arthritis, and as he is still alive I have not been able to verify its origin.—I am, etc.,

J. WALTERS, M.B.

Reigate, March 26th, 1888.

SIR.—In the *JOURNAL* of March 17th, Professor Humphry asserts "his scepticism with regard to the possibility of the formation of these bodies by the detachment of portions of articular cartilage."

I hope shortly to bring before your notice two, if not three, cases which will, I think, induce Professor Humphry to reconsider his opinion.—I am, etc.,

T. PRIDGIN TEALE.

Leeds.

RESECTION OF THE PYLORUS FOR CANCER.

SIR.—In the very instructive account of "A Case of Cancer of the Pylorus in which Pylorotomy was performed," in the *JOURNAL* of March 24th (page 633), Professor George Buchanan has paid me the compliment of quoting my opinion on the subject (*Operative Surgery of Malignant Disease*, 1887). And immediately beneath the quotation, he has published a short note from Professor Billroth's assistant, Dr. Salzer, in which an opinion almost diametrically opposite to my own is expressed. Professor Buchanan says that the important question "Is pylorotomy justifiable or not?" may be disposed of by quoting these two opinions.

Even had the two opinions been precisely similar, or to the same effect, I doubt whether the question would have been so readily disposed of. But I am afraid they are likely to raise fresh controversy rather than to prevent it.

Before entering on the question of the prospects of operative surgery for the radical cure of cancer of the pylorus, I must first point out that the opinions expressed by Professor Billroth and myself are not answers to the same question. His opinion is, on the face of it, a reply to the question of the justifiability of pylorotomy for all and every cause; my opinion refers solely to pylorotomy for the removal of cancer.

In my book I do not say that the operation is unjustifiable, but that I am led to doubt (from the evidence which has been laid before the profession) "whether the operation of resection of the pylorus for cancer is ever a justifiable operation." And the evidence was to this effect: Of 55 patients on whom the resection was performed for cancer, 41 died of the results of the operation, 13 recovered, and the result was not mentioned in the remaining case. Ten of the patients who survived the operation were followed up. In every one recurrence took place, and I think I am within the truth when I say that there was not one of them who was quite well a year after the operation, while several died of recurrence in the course of a few months. With a mortality of over 70 per cent. on the one hand, and such a failure as the results show on the other hand, I think my doubt of the justifiability of the operation for cancer will scarcely be deemed unreasonable.

Professor Buchanan pleads, in favour of continued experiment,

the marvellous improvement which has taken place in the statistics of ovariectomy, and seems to think it possible that practice in the operation of pylorotomy may secure for it some such improved measure of success. Pylorotomy is never likely, for obvious reasons, to be as safely performed as ovariectomy. And, in any case, when the operation is performed for the relief of cancer, if a comparison is made, it must be between pylorotomy for cancer and ovariectomy for cancer. My book shows (page 347) that, of 99 patients who were operated on for either sarcoma or carcinoma of the ovary by several operators, 33 died of causes directly connected with the operation. Nor is the mortality likely to be diminished by practice, for the operators were all men singularly skilled and successful in the ordinary operation of ovariectomy. The mortality is so much larger than that due to ovariectomy for non-malignant diseases, and the recurrence and dissemination was so rapid in some of the patients, that one of the operators, Mr. Knowsley Thornton, has openly expressed a doubt "whether it is not a positive injustice and cruelty to the patient to operate at all." Yet the results in some of the cases in which the patient survived the operation were brilliant compared with those in which the patients recovered from the operation of pylorotomy.

In the introduction to my book I have dealt much more fully than I can do here with the comparison between operations on the same part of the body for innocent and malignant disease, and have pointed out that when great benefit may be derived from an operation, a greater risk to life may reasonably be incurred; but when the benefit is small and of short duration, the risk of the operation ought also to be small in proportion. Operations for malignant disease ought, therefore, not to rank among the most fatal. I go even further than this, and maintain that, as a general rule, the least severe and fatal operations for malignant disease are the most successful in their final results.

It is difficult to judge of the relative malignancy of cancer of the pylorus as compared with cancer of other parts of the body; but I cannot but believe that its malignancy is above rather than below the average, and that it tends to involve the surrounding structures and to affect the lymphatic glands at an early period of its existence. Professor Buchanan's case is in point, for, although the symptoms had only been noticed between four and five months, there was already a cancerous gland in the lesser omentum.

One of the objects which I had in writing *The Operative Surgery of Malignant Disease* was "to discourage the repetition of useless and dangerous operations" by showing the large mortality by which they have been attended and the low measure of success which has resulted from them. In attaining this object, I have been very careful to err rather on the side of leniency than harshness in judgment, and have been at great pains not to wound the feelings of individual operators. I would not on any account venture to criticise my friend Professor Buchanan, for whose surgical ability I have a great respect. I can only say that the case appears to have been as well suited as any for resection of the pylorus, and that the operation appears to have been as well designed and executed as one could reasonably wish.

But the whole question is one of grave importance (which must be my excuse for the great length of my letter), and the position of operative surgery may be seriously affected by it. The brilliancy of the Vienna school of surgery, from which most of these questionable operations for malignant disease have emanated, has naturally produced an influence on operative surgery in all countries, and has led surgeons to push surgery to its limits. It would not be reasonable to expect that British surgeons should have wholly escaped this influence. But an examination of the reports of some of these operations shows how small is the influence which has been exercised on British surgery by the Vienna school, and during the last two or three years it has been a source of great pleasure to me to see that very few of these modern operations for cancer have been practised in this country.—I am, etc.,

HENRY T. BUTLIN.

82, Harley Street, W., March 26th.

THE CLIFTON LUNACY CASE.

SIR.—In your editorial remarks on "The Clifton Lunacy Case," you refer to the "annoyance and loss of time," as also to the "heavy costs irrecoverable from an impecunious plaintiff," incurred by medical men who sign lunacy certificates, no matter how carefully and properly they may act in the matter. This is

exceptionally true in this case. Dr. Shaw and I gave our professional services gratuitously. The patient was suffering from an attack of acute mania, with suicidal symptoms. She required detention in different asylums for about two years and a half, and a year later we were served with a writ, and called upon to answer charges of having falsely, maliciously, negligently, without reasonable or probable cause, well knowing the same to be untrue, in collusion with each other, given insufficient certificates. The charges of conspiracy, malice, and wilful and criminal falsehood were not withdrawn till after the case had opened, after an appeal from the judge (Mr. Justice Field), but without any apology that such grave accusations should have been made regardless of truth and unsupported by a particle of evidence. The learned counsel for the plaintiff (Sir Walter Phillimore), contrary to the better traditions of the bar, conducted the cross-examinations in a spirit that called forth frequent censures from the Bench, and was in marked contrast with the conduct of the defence, as we, on our part, avoided bringing forward much evidence of a painful nature, and imputed no intentional untruthfulness to the plaintiff.

The expense of a trial occupying the court for four entire days must necessarily be very great, and the burden is not lightened by "costs" being granted against an impecunious plaintiff, but I ask your permission to state that these expenses are, at all events, considerably lessened by the generous support we have received from those of our professional brethren who aided us both before and during the trial by advice and by their evidence in the witness box, and who have in no case accepted any professional fees. I do not know if the medical witnesses for the plaintiff were equally disinterested, but I feel that my thanks are due to them also for the aid they rendered us. The one, Dr. Tibbits, by showing the kind of expert (?) evidence the prosecution had to rely upon, and which, I may add, was accepted precisely at its just value. The other, Dr. Lyttleton Forbes Winslow, who, on account of the notoriety he has obtained in connection with breaches of the lunacy laws, might possibly have been regarded as an authority on the subject, expressed (so far as it was possible to gather) an opinion favourable to the certificates.

Allow me, in conclusion, to express my sincere and appreciative thanks to the large number of my professional brethren who have offered me their sympathy, together with their congratulations, on the verdict of the jury.—I am, etc.,

HENRY MARSHALL.

28, Caledonian Place, Clifton, Bristol, March 24th.

SIR,—Will you allow me to correct an error which appears in your issue of March 24th, in your comments on the late lunacy action at Bristol?

You say: "The other medical man declined to go so far as to say that rambling, incoherent conversations, refusal to answer questions, and vague statements of ill-usage were sufficient to justify the certificates." The actual words were as follows:—Sir W. Phillimore: "Are there any facts in the certificates indicative of insanity?" to which I answered that "I did not understand the question as put." Sir W. Phillimore, continuing: "Do you consider rambling, incoherent conversation, refusal to answer questions, and vague statements of ill-usage are sufficient to justify the certificates?" my reply to this question being, "Rambling, incoherent conversation are certainly signs of insanity." In response to the learned judge, to give an answer to the whole question, I said: "Then I cannot answer the question;" to which his lordship replied, "I did not think the doctor could when he understood it." That there was a distinct action to be tried against the convent for false imprisonment previous to obtaining the lunacy certificates was the opinion I entertained previous to the action coming into court, and was substantiated by Mr. Justice Field during the hearing of the case, who said, referring to the locking up of the plaintiff in her room: "This was undoubtedly interference with the plaintiff's liberty, and he would tell the jury that this entitled her to a verdict *unless circumstances justified it.*"

A medical expert is called in to advise on *ex-parte* statements, not on evidence which he is unaware of at the time and only comes to light subsequently during a trial. It is sufficient, however, for my purpose to show that the learned judge entertained and expressed the same as that originally done by me.—I am, etc.,

L. FORBES WINSLOW, M.B., LL.M. Camb., D.C.L. Oxon.

70, Wimpole Street, W., March 26th, 1888.

MEDICO-LEGAL AND MEDICO-ETHICAL.

FEES FOR ATTENDING INQUESTS.

By Section 25 of the Coroners Act 1887, 50 and 51 Vic. c. 71, the local authority for a county or borough is empowered "from time to time to make a schedule of fees, allowances, and disbursements which, on holding an inquest, may lawfully be paid by the coroner holding such inquest. We do not know whether this power has as yet been generally acted on; but we see from a report that in Norfolk the local authority have adopted a scale which is far from liberal, allowing nothing to jurymen, very little to witnesses, and only 5s. for a medical witness. As regards jurymen and witnesses in general, the local authority were apparently acting within their powers in framing the schedule as they did; and if the scale of fees is inadequate, the only thing to do is to bring pressure on the framers to revise their work, and allow proper remuneration to those who attend.

As regards medical witnesses, however, their general power of disallowing fees is fortunately limited by the Act. By Section 22 "a legally qualified medical practitioner who has attended at a coroner's inquest in obedience to a summons of the coroner" is entitled to receive, by way of remuneration for attending to give evidence, the sum of one guinea, and more if he makes a *post-mortem* examination. The schedule which only allows 5s. is, therefore, in that respect wrongly framed by the local authority, and *ultra vires*. No doubt the error will be corrected as soon as pointed out, and any medical practitioners who have been refused their guinea will get the difference paid over on pointing out their rights under the Act. In case similar deprivations have been attempted elsewhere, we think it well to point out what has been done in Norfolk, and what the rights of members of the profession are under the new Act.

ELECTION OF CORONERS.

WHILE Lord Halsbury proposes to vest the appointment of coroners in the Lord Chancellor, the object of Mr. Wootton Isaacs's Bill is to leave the election in the hands of the freeholders who are voters for the county or the part of a county, the election being by ballot, and in all other respects like parliamentary elections. The maximum amount permitted to be spent by a candidate, other than personal expenses and returning officer's charges, would be limited to £400 where the freeholders on the register do not exceed 2,000, and £430 where they do exceed that number; and an additional £50 would be allowed for every complete 1,000 electors above 2,000. A petition against the return of a candidate would be tried by a commissioner appointed by the election judges.

CERTIFICATES OF DEATH.

RESTICUS asks: Is it legal for a registrar of births and deaths to register the deaths of patients who have only been seen by an unqualified man, and on his certificate, he openly stating to the registrar that he is unqualified, and that he is not a medical man?

"* A registrar of deaths must register the deaths of all persons, whether attended by qualified or unqualified practitioners. Whenever a certificate, or any written statement of the cause of death, signed by an unregistered practitioner is produced, such certificate or statement is regarded by the registrar merely as part of the information tendered by the legal informant of the death. In such cases, only the cause of death is inserted in the register, and the name of the person signing such document is not recorded therein.

A DISPUTED FEE.

PRACTITIONER.—Under the Coroners Act, 1887, 50 and 51 Vic. c. 71, s. 22, a legally qualified medical practitioner, who has attended at a coroner's inquest in obedience to a summons, is entitled to a fee of one guinea. The Act says nothing as to the allowances to be made to medical witnesses who attend voluntarily, but we think that a witness who attended in obedience to a message specially sent by the coroner ought to be held to have attended in obedience to a summons, and, consequently, to be entitled to his fee. The matter is not free from doubt, but a claim brought in the county court, if properly conducted, ought to succeed. The action should be for a mandamus directing the coroner to pay.

UNREASONABLE REFUSAL TO CONSULT.

THAT "A. B.," an M.D., C.M. Abern., M.R.C.S. Eng., and L.S.A., should have declined to meet in consultation "F. H. V.," an L.R.C.P., L.R.C.S., and L.M. Edin., L.F.P.S. and L.M. Glas., and L.S.A. Lond. (such being the several degrees and diplomas of the respective practitioners recorded in the *Medical Directory*) on the absurd plea that "he considered his degrees superior" to those of the latter, would be incredible were it not that Dr. "A. B." himself so averred in his discourteous written response to "F. H. V.," polite request for an explanation. It may therefore be well to intimate to such general practitioners who, on the strength of being graduates, may perchance feel disposed to decline to meet a physician practising generally in like circumstances, that the possession of a degree, in contradistinction to a diploma

in medicine is not to be regarded as conferring or implying superior practical professional knowledge or position, but rather, though not necessarily so, as a mark of simple academical culture. Under all the circumstances, although ever desirous to promote professional concord and unity, we could not blame "F. H. V." if, from a feeling of self-respect, he abstained from intimate association with "A. B." his colleague, at the local dispensary.

FEE FOR POST-MORTEM EXAMINATIONS IN HOSPITALS.

Dr. PETER YATES (Infirmary and Dispensary, Bolton) asks whether he is entitled legally to claim a fee for performing a *post-mortem* examination on, and attending the inquest of, one of the in-patients of the hospital. The *post-mortem* examination was ordered to be made by the coroner of the borough, and Dr. Yates was also ordered to attend the inquest.

* * No claim can be legally made.

NAVAL AND MILITARY MEDICAL SERVICES.

CANCELLING CLAUSES OF THE ROYAL WARRANT OF 1879.

WE have received several letters protesting against foreshadowed tampering with the best clauses of the above Warrant, especially with the valuable right of retirement on pension after twenty years' full pay service. We do not question the right of the authorities to cancel or amend Royal Warrants, but such documents should be considered very sacred. In common fairness however, alterations cannot justly be made to the detriment of officers who have entered, or are serving under clear conditions of contract; in other words, changes should not have retrospective effect. We will not assume the Secretary of State will so act, and await the statement of his specific intentions.

ARE BATTALION SURGEONS NON-COMMISSIONED OFFICERS?

A VOLUNTEER SURGEON writes: After a company drill, at which I was present in plain clothes, the adjutant said he wished to address a few words to the non-commissioned officers in an adjoining room, and, turning to me, said, "You're one of them; you'd better come in." Now, sir, is this one of the effects of the relative rank question? If so, the sooner surgeons and acting-surgeons make an effort to resist similar snubbing the better. Surgeons and acting-surgeons are not commissioned, therefore I suppose we are non-commissioned officers. But it sounds very odd, and I feel I should like some opinion or explanation of it.

* * Such conduct ought to have been at once brought to the notice of his superior officer by our correspondent.

ARMY SURGEONS AND FOREIGN SERVICE.

A CORRESPONDENT asks the Parliamentary Bills Committee of the British Medical Association to obtain returns from the Secretary of State for War as follows: Average proportion of home and foreign service of each of the following classes of officers: 1, Cavalry of the Line (on the relief roster); 2, Royal Artillery; 3, Royal Engineers; 4, Infantry of the Line; 5, Chaplain's Department; 6, Commissariat Staff; 7, Medical Staff; 8, Ordnance Store Staff; 9, Pay Department; 10, Veterinary Staff. If it should appear that the Medical Staff have more than the average share of service in tropical and unhealthy climates, then in justice they are entitled to higher rates of pay and better conditions of retirement.

* * Such a return would probably work out to show that the medical have a larger proportion of foreign service than other officers; but the comparison, we fear, would not be satisfactory or conclusive, because it could be urged the conditions are dissimilar. Regimental conditions of service could hardly be well contrasted with departmental, and even the latter materially differ from each other. The Chaplain's, Commissariat, and Ordnance Departments of the home army do not, for instance, serve in India; service in the cavalry abroad is, on the other hand, almost confined to India. The wear and tear of hard foreign service is unquestionably one of the causes of the greater sickness and mortality among medical officers than others; it is one reason why they should receive good pay and pensions, but we would remind our correspondent that medical officers command higher salaries because they are professional men, taking with them into the public service special knowledge, privately-acquired. Every turn of the screw brought to bear on medical officers will inevitably bring on the authorities the old Nemesis of failure in the supply when medical candidates are wanted for the Army.

VOLUNTEER MEDICAL ASSOCIATION.

THE following resolutions were passed at a meeting of the Council of this Association held on Friday, March 16th, at 24, King William Street, Strand.

On the motion of the Treasurer, seconded by Surgeon-Major Baines, it was unanimously resolved: "That having considered the terms of the Royal Warrant for creating an Army Medical Reserve, this Council recommends that no action be taken by the Association in reference thereto; thus leaving the question of joining the Medical Reserve entirely open for the individual members to act as they think fit."

It was further proposed by the Treasurer, seconded by Surgeon-Major W. G. Shephard, and unanimously carried: "That this Council, recognising the fact that in the recent Royal Warrant not any of the suggestions emanating from this Association for the better organisation of the Volunteer Medical Service being conceded, and further noting that the promises of the Secretary of State for War relative thereto, which were made in the House of Commons on August 16th last, have not received effect, a deputation be appointed to wait upon the War Secretary with the view of urging the adoption of the same."

ARMY MEDICAL RESERVE WARRANT.

BRIGADE-SURGEON (Retired List) writes: It is matter for satisfaction to see you appear to quite grasp the scope and drift of the Army Medical Reserve Warrant. As one who, having retired from active service, can afford to discuss the scheme "without fear, favour, or affection," there appears only too much reason to suspect that its "plan of campaign" may be intended to give "a lever" to the War Office luminaries to stir up the full pay Medical Staff with a long pole when it suits them to do so. Should the plan succeed we may expect soon to hear that "full pay" medical officers have to spend nearly all their services abroad, that an endeavour will be made to prevent them going on to the pension list till "quite worn out," and unfit to enjoy the hard earned pension, which, to a great extent, induced many good men to enter the service. You also justly say it is strange that the "retired regular medical officers" are not mentioned, and it is often a wonder to me that those willing to accept temporary employment are not called upon now and then to keep their hand in. It would also be interesting to know if those joining will have to provide themselves with uniform, or if they will be expected to do so, "without compensation," although liable to be relegated again at short notice to the "unemployed lists" when it suits the convenience of the War Office to do so. I am quite at one with your remarks also that whilst the profession wish to do all in their power to "support the regular medical service in case of national emergency," yet all concerned ought to "look well before they leap" in aiding the military authorities, who have so often shown such regrettable "animus" against the profession, to put themselves in a better position to be able to "sit on" the much abused army surgeon more than ever. In any case, it seems certain that unless the profession unite as a corporate body, putting personal wishes on one side, we must fully expect to find the "military caste" continue their scarcely veiled endeavours to "play off the doctors one against the other."

MEDICAL OFFICERS IN THE GERMAN ARMY.

A CORRESPONDENT, who signs himself "Observer," writes: The treatment of medical officers in the mighty German army, and of the medical profession at large in that great and enlightened empire, is in marked contrast to that afforded to medicine in this country. Witness the account of the *Daily News*, how, at the funeral of the late emperor, his personal physicians, as well as the chief physicians of the army, were accorded most honourable positions in the procession; they immediately preceded the Emperor's personal chamberlains, walking close to the coffin; also that they wore "brilliant uniforms," which, at all events, the "model army" of the world consider suitable for them. What, he asks, would be the positions accorded to our chief army surgeons or court physicians in such a State pageant? They would in all probability, be conspicuous by their absence. Medicine and science are held in small honour in this country compared with Continental nations. Especially do poor social jealousies and narrow caste prejudices, retreating before the advancing wave of democracy, seek a refuge in our army. This is as apparent in every-day military life as in State ceremonial.

RED CROSS ASSOCIATION.

WE are asked by a correspondent writing from Karachi, India, to state when and where the competition is to take place for the prize offered by the Empress Augusta of Germany, of which a notice appeared under the heading of "Red Cross Association," at p. 271 of the JOURNAL of February 4th last. Our correspondent will obtain full information on the matter he inquires about, as well as all essential particulars regarding the terms of the competition, in the JOURNAL of February 25th, pp. 442-3.

MEDICO-PARLIAMENTARY.

HOUSE OF LORDS.—Thursday, March 22nd.

Poor-law Guardians.—On the motion of the Earl of KIMBERLEY the following peers were appointed as a Committee to inquire as to the various powers now in possession of the poor-law guardians, and their adequacy to cope with distress that may from time to time exist in the metropolis and other populous places; and also as to the expediency of concerted action between the poor-law authorities and voluntary agencies for the relief of distress: the Lord Archbishop of Canterbury, Earl Spencer, Earl of Milford, Earl of Onslow, Earl of Strafford, Earl of Kimberley, Earl of Aberdeen, Lord Balfour, Earl of Hopetoun, and Lord Thring.

Friday, March 23rd.

Lunacy Acts Amendment Bill.—On the motion for the third reading of this Bill, Earl SPENCER said he believed it was now perceived that the Bill did not meet a case which he adduced when the Bill was in Committee. He was not now prepared with a clause, but he trusted that, if it were found practicable to frame a clause, the object he had in view would be attained when the Bill was in Committee in the other House.—The LORD CHANCELLOR was inclined to think the noble earl was right, and, if it turned out to be so, he should have no objection to the necessary amendment of the Bill.—Lord BALFOUR said the communications that had taken place had reduced the matter at issue to a small point, which should be fully considered before the Bill reached the stage of Committee in the other House.—The Bill was then read a third time, and, after an amendment had been made, was passed.

The Sale of Foreign Meat.—Lord LAMINGTON asked Her Majesty's Government whether they could not introduce some measure to prevent the fraudulent practice of selling foreign imported meat as home produce. The remedy he suggested for this state of things was the insertion of two clauses into the Adulteration Act of 1875, one clause providing that every person selling foreign meat should take out a licence, and the second clause

should impose severe penalties on any person who sold foreign meat without having over his shop a board stating that the shopkeeper was licensed to sell foreign meat. This would have the effect of putting purchasers on their guard against having foreign meat palmed off upon them as home meat and at the high price of home meat.—Lord TRURO thought some sort of personal disgrace ought to be inflicted on those who habitually indulged in fraudulent practices. In France they entailed sentences of imprisonment varying from fifteen days to three months.—Lord WANTAGE said the foreign meat was sometimes better than English.—The Earl of ONSLOW remarked that, if the practice of selling foreign meat was fraudulent, there must be some law which made it so. There was the Sale of Food and Drugs Act, 1875, and other Acts for the protection of the public. Until it had been proved that the law was not sufficient to meet the case, the Government could not bring in a Bill on the subject. There were also Acts of Parliament to provide punishment for obtaining money under false pretences. He could not undertake to substitute imprisonment for fines in cases of adulteration, for some of the practices were laudable, as, for instance, when publicans sold water for gin.

HOUSE OF COMMONS.—Thursday, March 22nd.

The Children's Dangerous Performances Act, 1879.—Mr. H. VINCENT asked the Home Secretary, having regard to the public exhibitions of young children in acrobatic and other performances apparently dangerous to the life and limbs of children now taking place in the metropolis, whether it was the duty of the Metropolitan Police, or of the Metropolitan Board of Works, or of what other public authority, to take action where necessary under the provisions of the Children's Dangerous Performances Act, 1879.—Mr. MATTHEWS replied that the statute referred to did not give the power or impose the duty of taking action upon the police, or the Metropolitan Board of Works, or any public authority. The Act left it open to any person or society to initiate a prosecution in a proper case. He understood that there was a society which had occasionally taken proceedings under this Act.

Friday, March 23rd.

Length of Foreign Service for Army Medical Officers.—Dr. TANNER asked the Secretary of State for War whether it was the intention of the War Office to prolong the period of foreign service for officers of the Army Medical Staff; and whether, in the event of such an event taking place, any compensation would be given for the increased risk.—Mr. E. STANHOPE said the length of foreign service would be extended by one year in all departments in the interests of economy, and for the purpose of lengthening the period of service at home. As the service of an officer was available wherever Her Majesty might require it, no case for compensation arose.

Adulteration of Lard.—Sir M. HICKS-BEACH, in reply to Dr. CLARK, stated that the Board of Trade were aware that cottonseed oil was extensively used in the United States in the manufacture of lard. He thought that the selling of the adulterated lard in this country would bring the seller within the Adulteration Act.

Small-pox.—Mr. PICTON gave notice that on that day four weeks he would move the appointment of a Select Committee to inquire into the circumstances attending the epidemic of small-pox in Sheffield and the surrounding district, and especially to ascertain whether its origin could be traced to defective vaccination, to insufficient sanitary precautions, or to any other causes.

Monday, March 26th.

Re-employment of Retired Army Medical Officers.—Dr. TANNER asked the Secretary of State for War whether army medical officers of the retired list re-employed would receive the same pay, allowances, and military status as other officers of their rank; and whether their additional service would count for increased pension when compulsorily retired by age; and, if not, what advantages they would derive.—Mr. BROADBRICK said, as regards pay and allowances, the regulations limited the payment to a retired medical officer to £150 in addition to his retired pay. As regards military status, such officers were entitled, under certain restrictions, to the rank and position which they held in the Army Medical Department before their retirement. They did not count service subsequent to retirement towards increase of pension.

St. John's Hospital for Diseases of the Skin.—Mr. LAWSON asked the Secretary for the Home Department whether his attention had been called to the constant charges in the public press,

of the wilful misappropriation of the funds of St. John's Hospital for Diseases of the Skin; whether he was aware that no legal action had been taken against any of the members and late members of the Board of Management making such charges; and whether at the present time an appeal for funds was being made and their receipt publicly acknowledged on behalf of the hospital; if so, whether he would instruct the Public Prosecutor to take action in the matter, with a view to protect the public from possible fraud.—Mr. MATTHEWS said he had received a letter from the authorities of the hospital, who informed him that an action for libel was now pending, at their instance, against a weekly journal with reference to the charges in question. It was true that subscriptions were now being received and publicly acknowledged. On January 18th the subscribers, at a special general meeting, passed by an overwhelming majority a vote of confidence in the Board of Management. He could discover no reason which would justify interference on his part.

Fires in Theatres.—Mr. DIXON-HARTLAND asked the Home Secretary whether, having regard to the destruction of another theatre by fire at Oporto, where a great number of lives had been lost, he could state when it was the intention of Her Majesty's Government to introduce their Theatres Bill to diminish as much as possible the risk of such accidents in England.—Mr. MATTHEWS said the Government had decided not to introduce a Bill on the subject.—Mr. DIXON-HARTLAND inquired whether, that being so, the Government would no longer continue to block his Bill.—Mr. MATTHEWS would give no undertaking of the kind.

Sanitary Condition of Bethnal Green.—Mr. RITCHIE, in answer to Mr. HOWELL, said that the report of the Commission which held an inquiry into the sanitary condition of Bethnal Green had been received, and would be laid before Parliament at once.

HOSPITAL AND DISPENSARY MANAGEMENT.

CORK FEVER HOSPITAL.

DURING the past year 199 cases were under treatment in this hospital, of which 58 were typhus patients and 71 typhoid. On examining the number of admissions for the past eight years, it is at once evident that a steady decrease has taken place in infectious diseases; and when, in the course of time, the clearances of the overcrowded areas condemned by the corporation are effected, and proper sanitary dwellings substituted, it is hoped that the public health of the city of Cork will materially improve. Typhoid fever prevailed during the entire year, principally in highly-situated localities, probably owing to the want of proper ventilation of the sewers of the city. As regards typhus fever, it has been gradually decreasing for some years, in numbers as well as in the severity of its type. The Cork Fever Hospital affords accommodation for many of the poor who are of a better class than the very poor, who are obliged to go into the workhouse hospital, and prevents to a great extent the spread of infectious disease.

PROPOSED REBUILDING OF THE ROYAL LONDON OPHTHALMIC HOSPITAL.

THE Committee of Management of the Royal London Ophthalmic Hospital have recommended the erection of a larger building, either on the present or an adjacent site. The Corporation of London have been communicated with, and negotiations are proceeding. The cost of the new building is estimated at £30,000.

OBITUARY.

FELIX KERANS, M.R.C.S. ENG.

WE have to announce the death, after a lengthened illness, of Mr. Felix Kerans, at the early age of 29, from phthisis. The deceased was educated at the University College, Liverpool, where he succeeded in carrying off silver medals for materia medica and medical jurisprudence, together with four honorary certificates. After qualifying, he held appointments as house-surgeon to the South Dispensary, and at Toxteth Workhouse Hospital.

MEDICAL MAGISTRATE.—The Chancellor of the Duchy of Lancaster has appointed Mr. Thomas Munns Wills, F.R.C.S.I., etc., a Justice of the Peace for the Borough of Bootle-cum-Linacre.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

THE PROCEDURE IN PLACING PAUPER LUNATICS UNDER CARE AND CONTROL.

An inquest was recently held on a pauper patient who died of pneumonia a few hours after being admitted into the Lancashire County Lunatic Asylum. The deceased appears to have been a cab-driver of intemperate habits, and to have been under the influence of drink at about the time he fell ill with pneumonia. Delirium appears to have supervened, and the union medical officer recommended the removal of the deceased to the workhouse. Whilst being taken there the deceased rambled a good deal in mind, but a conflict of evidence sprang up as to what happened on his arrival at the workhouse in charge of his wife and of others, the porter there alleging that his wife reported the deceased as being out of his mind; whilst she, on the contrary, declared that she had not done so, and that she was unaware of what passed on the arrival of the deceased at the workhouse gates. But be this as it may, the next step was that the deceased was driven to the house of the relieving officer, to whom the workhouse porter, who accompanied the party, is said to have reported that they had brought the relieving officer a lunatic. The relieving officer decided that the deceased must be sent to the county asylum; or, at all events, that he must be examined with a view to that being done if he was found to be of unsound mind. The deceased, therefore, was next driven to the medical officer of the union workhouse, who, as reported, stated in his evidence that the wife of the deceased told him the latter was insane, and that the deceased, after answering several questions lucidly, suddenly drew attention to a horse and a drove of pigs, which he imagined were flying down the street. Witness diagnosed the case as one of mania from drinking, complicated with a low type of pneumonia, and signed the necessary certificate for admission of the deceased into the asylum. A magistrate's order had still to be obtained, and after considerable delay this was accomplished, and the deceased was eventually taken in the evening to the asylum, having been left at the workhouse by his wife, who understood he was to be sent to the asylum, and who in fact is reported to have stated in evidence that although told by the union medical officer to take her husband to the workhouse, "she thought he might mean the asylum, as her husband was rambling."

A case of this kind, it is clear, would have been better met by prompt admission to the workhouse; and the facts relating to it afford confirmation to the view taken by our Parliamentary Bills Committee, that in any coming lunacy legislation the already too secure provisions concerning the reception of pauper lunatics into asylums should not be further relaxed; the relaxation of one of these provisions in the Lunacy Bill now before the Legislature being incongruous with the increased stringency in relation to lunatics of the private class.

IMPORTANT DECISION UNDER THE PUBLIC HEALTH ACT.
The Doncaster county magistrates had before them a case on Saturday last where a Mrs. Staniforth, of Sheffield, was charged under the 126th section of the Public Health Act of 1875 with being in charge of a person suffering from a dangerous infectious disorder, and exposing such sufferer in a public conveyance.

It appeared that the servant of Mrs. Staniforth became ill, and then developed a general rash, which turned out to be small-pox. Mrs. Staniforth at once said that the girl must leave and go to her home at Mexborough immediately. Mrs. Staniforth ordered her to get a cab, herself helped to lift the luggage on the vehicle, and directed her to return to Mexborough by a certain train. The fence set up was threefold. First, as a matter of fact, that Mrs. Staniforth did not know that the disease was small-pox. The magistrates held, however, that since small-pox was at the time prevalent in Sheffield, that since the girl twice suggested to the mistress that her disease was small-pox, that since (on the girl saying, "What shall I do if they stop me in the street and say I've small-pox?") Mrs. Staniforth lent her two veils and a pair of gloves with which to cover her hands and face, there could be reasonable doubt that the mistress was cognisant of the nature of the complaint.

The other two points raised were questions of law. First, that if Mrs. Staniforth did expose the girl in a public convey-

ance within the meaning of the Act, the offence began and ended in the borough of Sheffield, and that, therefore, the West Riding magistrates at Doncaster had no jurisdiction, for that the only exposure of the girl which took place in their jurisdiction was the act of travelling in a third class carriage at Mexborough, which was the girl's own offence and not Mrs. Staniforth's.

Here the magistrates held that the whole journey was undertaken consequent on the acts and orders of Mrs. Staniforth; that while the exposure began in the Sheffield cab, it continued in the train and in the Mexborough streets, and that, therefore, they had jurisdiction.

The last point was that a mistress was not "in charge" of her servant within the meaning of the section. This objection the magistrates also overruled, and fined Mrs. Staniforth £2, the presiding magistrate, Lord Auckland, stating that he considered the case a very bad one, and but for the very heavy costs (£5 6s.), the magistrates would have inflicted the full penalty allowed, namely, £5. Mr. Binney, of Sheffield, the solicitor for the defence, at once gave notice of an appeal on the two points of law raised, which the magistrates granted. The Mexborough Local Board was the prosecuting authority.

HEALTH OF ENGLISH TOWNS.—In the twenty-eight largest English towns, including London, which have an estimated population of 9,398,273 persons, 5,903 births and 3,792 deaths were registered during the week ending Saturday, March 24th. The annual rate of mortality per 1,000 persons living in these towns, which had been 23.3 and 20.3 in the two preceding weeks, rose again last week to 21.1. The rates in the several towns ranged from 14.8 in Huddersfield, 15.4 in Cardiff, and 16.3 in Halifax to 26.3 in Preston, 28.1 in Blackburn, 30.4 in Manchester, and 37.6 in Plymouth. In the twenty-seven provincial towns the mean death-rate was 21.8 per 1,000, and exceeded by 1.6 the rate recorded in London, which was only 20.2 per 1,000. The 3,792 deaths registered during the week under notice included 118 which were referred to whooping-cough, 50 to measles, 43 to scarlet fever, 30 to diphtheria, 27 to "fever" (principally enteric), 26 to diarrhoea, and 25 to small-pox; in all, 319 deaths resulted from these principal zymotic diseases, against 442 and 363 in the two preceding weeks. These 319 deaths were equal to an annual rate of 1.8 per 1,000; in London, the zymotic death-rate was 1.9, while it averaged 1.7 in the twenty-seven provincial towns, and ranged from 0.0 in Portsmouth, Preston, Halifax, and Newcastle-upon-Tyne to 2.6 in Wolverhampton and in Blackburn, 3.9 in Sheffield, and 6.7 in Plymouth. Measles caused the highest proportional fatality in Bradford and Plymouth; scarlet fever in Oldham and Huddersfield; whooping-cough in London and Wolverhampton; and "fever" in Nottingham and Leicester. Of the 30 deaths from diphtheria recorded last week in the twenty-eight towns, 17 occurred in London, 2 in Norwich, 2 in Birmingham, and 2 in Oldham. The 25 fatal cases of small-pox included 17 in Sheffield, 2 in Blackburn, 2 in Hull, and 1 each in Bristol, Nottingham, Manchester, and Sunderland. The number of small-pox patients in the Metropolitan Asylums Hospitals on Saturday, March 24th, was 15, of whom 1 had been admitted during the week. These hospitals also contained 1,107 scarlet fever patients on the same date, which showed a further decline from the numbers in recent weeks; 77 cases were admitted during the week, against 100 and 94 in the two preceding weeks. The death-rate from diseases of the respiratory organs in London was equal to 5.6 per 1,000, and was considerably below the average.

HEALTH OF SCOTCH TOWNS.—During the week ending Saturday, March 24th, 870 births and 562 deaths were registered in the eight principal Scotch towns. The annual rate of mortality, which had been 24.2 and 21.0 per 1,000 in the two preceding weeks, rose again to 22.2 during the week under notice, and exceeded by 1.1 per 1,000 the mean rate during the same period in the twenty-eight large English towns. Among these Scotch towns, the lowest rates were recorded in Perth and Leith, and the highest in Paisley and Glasgow. The 562 deaths in these towns during the week under notice included 56 which were referred to the principal zymotic diseases, equal to an annual rate of 2.2 per 1,000, which slightly exceeded the mean zymotic death-rate during the same period in the large English towns. The highest zymotic rates were recorded in Edinburgh and Glasgow. The largest proportional fatality of whooping-cough occurred in Glasgow and Edinburgh, and of measles and scarlet fever in

Glasgow. Two deaths from diphtheria were recorded in Dundee. The mortality from diseases of the respiratory organs in these Scotch towns during the week was equal to 5.6 per 1,000, and corresponded with the rate from the same diseases in London.

HEALTH OF DUBLIN.—The 201 deaths registered in Dublin during the week ending Saturday, March 24th, were equal to an annual rate of 29.7 per 1,000 (against rates declining from 34.0 to 29.0 in the three preceding weeks), the rate for the same period being only 20.2 in London and 20.4 in Edinburgh. The 201 deaths included 20 which resulted from the principal zymotic diseases (equal to an annual rate of 3.0 per 1,000), of which 5 were referred to measles, 4 to scarlet fever, 4 to whooping-cough, 4 to "fever," and 3 to diarrhoea, and not one either to small-pox or diphtheria.

TEXTBOOKS ON HYGIENE.

M. E. T. asks what are the best books to read for the examinations for the diploma in Public Health.

* * Parkes's *Practical Hygiene* and Wilson's *Handbook of Hygiene*. A useful elementary book is *Principles of Hygiene*, by Dr. E. F. Willoughby.

R. asks to be recommended a work to read in preparing a course of lectures on hygiene to be given in a normal school to young adults.

* * R. cannot do better than read *Principles of Hygiene*, by Dr. E. F. Willoughby.

HOSPITALS FOR INFECTIOUS DISEASE.

DR. C. G. HAVELL (Felixstowe) writes: Your note on "Infectious Hospital Provision at the Seaside" in the JOURNAL of March 10th induces me to ask you for reference to any practical, working articles treating on hospitals suitable to small communities, say 2,000 or 3,000 inhabitants. I am very anxious to provide such accommodation here, but there are so many pressing claims that expense is a great object. There is obvious difficulty in finding an existing building suitable; to erect a special one would be costly. Have you any opinion of the extent to which a portable building, such as the "Dacker," would meet the requirements?

* * The supplement to the Tenth Annual Report of the Local Government Board contains the report and papers on the use and influences of hospitals for infectious diseases. Temporary hospitals are not to be encouraged.

WHO IS TO PAY?

IN DOUBT writes: As a poor-law medical officer I have had the following exceptional case to deal with.

A small farmer's family of eight individuals were afflicted with disease, one after the other being struck down until six were prostrated. They were under the care of a medical practitioner from a neighbouring town as his private patients. The medical attendant failed to give any notification to the medical officer of health, and evaded the inquiries of the neighbours as to what was the matter. The two yet remaining well, a boy and a girl, were totally incompetent to nurse the six patients, and they could get no outside assistance, as people were afraid to go near the family through fear of infection. As a consequence, the house, its inhabitants, and the premises around, got into a state of filth and uncleanness better imagined than described, and the neighbours thought it time to complain to the parish authorities. They did so, and I received an order from the assistant overseer to visit the family, and find out the state of affairs. On calling I found the cases to be enteric fever. The girl before-mentioned was also feverish, and should have been in bed; so that at this time there was only the boy to do everything for the seven sick ones. There were no disinfectants to be seen, and the father and mother both told me that they were still under the care of Dr. —, and that he was coming to see them again. I reported these facts to the assistant overseer, and said in my note that I did not think it my duty to call at the house again, as there was a medical man already in attendance. However, the sanitary authorities took the matter up, and caused a communication to be sent to the family medical attendant, asking him not to visit these patients again. The assistant overseer was then instructed to request me to take charge of the cases, which I did. The sanitary authorities supplied me with a trained nurse and a woman scrubber, workmen were sent to clean up the drains and put the premises generally in better order. All necessaries ordered by me for the patients, and all wants for domestic purposes, even to coals and a fine toothcomb, were generously supplied out of the sanitary funds. For full three months I had the care and treatment of the eight patients (for the boy took the fever also), and they have all recovered, thanks to the excellent nursing and the generous assistance rendered just at the right moment. Every expense seems to have been met out of the sanitary funds except that for medical attendance and medicine, and as the farmer and family were not paupers, it appears hard on me as the parish doctor to be called upon to attend them as such, and, at the same time, to see everybody else paid fairly well.

I put the particulars thus fully before you, and shall be glad if you will kindly inform me if I have any prospect of extra remuneration from the guardians, or ought I to make a claim on the funds of the sanitary board.

* * "In Doubt" must certainly make his claim on the funds of the sanitary board.

FACTORY INSPECTORS.

W. J. S.—Factory inspectors are appointed by the Secretary of State for the Home Department to whom applications for this office should be addressed. The report of the Chief Inspector of Factories gives the best idea of the duties.

THE whole of the Shildon Lodge Colliery ambulance class (instructed by Dr. Fielden) have received certificates of proficiency.

MEDICAL NEWS.

MEDICAL VACANCIES.

The following Vacancies are announced:

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's Inn Road.—House-Surgeon. Applications by April 10th to the Secretary.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park.—Resident Clinical Assistant. Applications by April 12th to the Secretary, 24, Finsbury Circus, E.C.

DERBY BOROUGH ASYLUM.—Medical Superintendent. Salary, £350, with furnished house, etc. Applications by April 13th, to be addressed to the Derby Borough Asylum Committee, under cover to the Town Clerk, and endorsed "Medical Superintendent."

ESSEX LUNATIC ASYLUM, Brentwood.—Temporary Assistant Medical Officer for three months. Salary, £30 for the term, with board, lodging, and washing. Applications to the Medical Superintendent.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton. Resident Clinical Assistants. Applications by April 7th, to the Secretary.

HULL BOROUGH ASYLUM, Willerby.—Assistant Medical Officer. Salary, £100 per annum, with board, lodging, and washing. Applications by April 2nd, to the Medical Superintendent.

INFIRMARY FOR CHILDREN, Myrtle Street, Liverpool.—House-Surgeon. Salary, £85, with board and lodging. Applications by April 9th, to C. W. Carver, Esq., Honorary Secretary.

LIDDELL PROVIDENT DISPENSARY, Jarrow-on-Tyne.—Medical Officer. Salary, £200. Applications to John Christie, Esq., 28, Cobden Street, Jarrow.

ROYAL ALBERT HOSPITAL, Devonport.—Honorary Ophthalmic Surgeon. Applications by April 9th to the Chairman of the Selection Committee at the Hospital.

WESTPORT UNION, Achill and Ballycroy Dispensary.—Medical Officer. Salary, £117 per annum and fees. Applications to Mr. John Corrigan, Honorary Secretary. Election on April 9th.

MEDICAL APPOINTMENTS.

FRASER, David, M.B., C.M. Edin., appointed Medical Officer for the Collieries of Cardenden, Deuch, and Dundonald, Fife.

LAWSON, Mr., appointed Resident Medical Officer to the parish of Resolis, Rosshire, vice J. Gunn, L.F.P.S. Glas., resigned.

MOULD, W. T., L.R.C.P., M.R.C.S., appointed House-Physician to the London Hospital, vice C. G. May, B.A., M.B.

PHILLIPS, J. R., L.K.Q.C.P.I., appointed Medical Officer to the Aghnacloy Dispensary, Clogher-Union, Co. Tyrone, vice L. M. Corder, L.K.Q.C.P.I., resigned.

POPE, P., M.R.C.S.E., L.R.C.P. Edin., appointed Clinical Assistant to the Borough Asylum, Birningham.

POTT, F. H., L.R.C.P., M.R.C.S., appointed Assistant Medical Officer to the Cotton Hill Lunatic Hospital, vice S. E. Holder, M.B. Lond., resigned.

SPICER, Scares, M.D., appointed Physician to the Department for Diseases of the Throat, St. Mary's Hospital, London.

MEDICO-LEGAL SOCIETY OF NEW YORK.—The following are the officers of this Society elected for the present year:—*President*: Clark Bell, Esq. *First Vice-President*: W. G. Stevenson, M.D. *Second Vice-President*: Ira Russell, M.D. *Secretary*: Albert Bach, Esq. *Assistant Secretary*: Clark B. Augustine, Esq. *Corresponding Secretary*: Morris Ellinger, Esq. *Treasurer*: E. W. Chamberlain, Esq. *Assistant Librarian*: Benno Loewy, Esq. *Curator and Pathologist*: T. H. Kellogg, M.D. *Chemist*: C. A. Doremus, M.D. *Trustees*: Charles Milne, M.D.; Richard B. Kimball, Esq.; M. J. B. Messemmer, M.D.; Fred C. Valentine, M.D.; Simon Sterne, Esq.; William G. Davies. *Permanent Commission*: Clark Bell, Esq.; R. O. Doremus, M.D.; Judge John R. Dillon; Stephen Smith, M.D.; Hon. David Dudley Field; R. S. Parsons, M.D.

THE MEDICAL JURISPRUDENCE OF INEBRIETY.—The November meeting of the Medico-Legal Society of New York will be devoted to the discussion of this subject. Short papers have been promised by Dr. Joseph Parrish, of New Jersey; Dr. T. D. Crothers, of Connecticut; Dr. Norman Kerr, of London; Dr. E. C. Mann, of Brooklyn; Dr. Wright, of Bellefontaine, Ohio; and others have been invited and are expected to read short papers on the medical side, while prominent members of the legal side will also take part in the discussion.

MORPHINE AND CHLORAL POISONING.—An inquest was held recently by Dr. Danford Thomas on the body of a man aged 65, who had long suffered from neuralgia, to relieve the pain of which he had been in the habit for a long time past of taking chloral and morphine by injection and otherwise. He was found nearly unconscious, and breathed with difficulty. In a moment of consciousness he said, "I have taken too much, I am suffocating." He had two convulsions of epileptic form, and died shortly afterwards. A verdict of death from misadventure was returned.

THE Manchester magistrates were engaged during two days recently in investigating charges against five men named Buchanan, Wilson, Nelson, Shires, and Thomas, who had, it was alleged, under various aliases, practised as "medical specialists," and defrauded a great number of people of large sums of money. Some remarkable evidence was given as to the profits of the imposture. The prisoners have been committed for trial at the sessions.

AMBULANCE CLASSES FOR RAILWAY MEN.—Thirty-two of the London and North Western Railway employes belonging to the Birmingham Branch of the St. John Ambulance Association, were examined by Surgeon-Major Hutton, of Leamington, on March 26th, and so satisfied the examiner as to receive high commendation.

DR. FERREIRA DOS SANTOS, who was sent to Paris by the Brazilian Government to study the experiments of M. Pasteur's laboratory has, we learn, been instrumental, in conjunction with Baron de Cotegipe, in promoting the establishment of a Pasteur Institute at Rio de Janeiro.

SIR LYON PLAYFAIR has been elected Chairman of the Committee on the City of London Fire Inquest Bill, which would enact that inquests shall be held in all cases where fires of suspicious origin have led to fatal results.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

TUESDAY.

PATHOLOGICAL SOCIETY OF LONDON, 8.30 P.M.—Mr. Colman: Intestines in Diphtheria; Dr. N. Moore: Some Anatomical Relations of Chronic Joint Disease. Dr. Hadden: Cyst in the Heart. Dr. Semon and Mr. Shattock: (1) Subglottic Alveolar Sarcoma in a Patient Aged 81; (2) Epithelioma of Right Half of Larynx, with Epitheliomatous Insula on Left Vocal Cord. (3) Intra-tracheal Carcinoma, continuous with Carcinoma of the Thyroid. Dr. Handford: New Growth of Lung Perforating Oesophagus, and Invading Pericardium. Dr. H. G. Mackenzie: Cystic Kidney with Calculi in Cysts. Mr. Silcock: Cystic Disease of Testis. Card Specimens—Mr. Ewe: Cyst of Spermatic Cord. Mr. F. J. Smith: Aortic Stenosis. Dr. Handford: (1) Single Hypertrophied Kidney; (2) Multiple Tubercular Strictures of Intestine. Mr. Fenwick: (1) Vesical Carcinoma. (2) Prostatic Carcinoma. Dr. Drewitt (for Dr. H. P. Cholmely): Lung from Case of Hamoptysis in an Infant. Mr. Shattock: Recurrent Sarcoma of Thyroid, associated with Hypertrophy of Accessory Thyroid.

WEDNESDAY.

OBSTETRICAL SOCIETY OF LONDON, 8 P.M.—Specimens will be shown. Adjourned discussion on Dr. Boxall's papers on Scarlatina During Pregnancy and the Puerperal State. Dr. Champneys: Description of the New Operation for Vesico-Uterine Fistula. Dr. Cullingworth: Cyst connected with the Uterus, and Simulating Enlargement of that Organ. Mr. Bland Sutton: The Glands of the Fallopian Tubes and their Function.

THURSDAY.

HARVEIAN SOCIETY OF LONDON, 8.30 P.M.—Dr. John Phillips: On the Management of Pregnancy Complicated with Fibroids. Dr. Robbison: Alopecia Areata.

FRIDAY.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, 8 P.M.—Second clinical evening. Mr. Rothe Lynch: Case of Cancer of the Vertebrae; adjourned discussion. The President (Mr. Keetley): (1) Case of Exophthalmic Goitre; (2) Case of Large Wen in Neck Treated by a New Method. Mr. Swinford Edwards: Case of Inguinal Colotomy. Dr. Percy Potter: Case of Rare Congenital Deformity of the Hands. Mr. Prior Mallam: Case of Dermoid Cyst of the Ovary Expelled During Labour. Mr. Percy Dunn: Case of Perforation of an Eyeball by the Knot of a Whip. Dr. Alderson: Case of Calculus in a Tonsil.

BIRTHS, MARRIAGES, AND DEATHS.

The charges for inserting announcements of Births, Marriages, and Deaths is 5s. Gd., which should be forwarded in stamps with the announcement.

BIRTH.

STEWART.—At Glenaber, Mapperley Road, Nottingham, on March 24th, the wife of Donald Stewart, M.D., of a daughter.

MARRIAGES.

KEMBLE—BALDOCK.—On March 20th, at St. Nicholas's, Lincoln, by the Rev. F. H. Blenkin, Vicar of the parish, Arthur Charles Kemble, L.R.C.P., L.R.C.S.Ed., Worthen, Salop, youngest son of the late Rev. W. Kemble, Rector of West Hammingfield, Essex, to Mary Elizabeth, second daughter of the late Rev. R. Baldock, Vicar of Carlton-le-Moorland, Lincolnshire.

ROBERTS—MARSDEN.—On March 8th, at St. Mary's, Scarborough, by the Rev. Arthur Bolland, George A. E. Roberts, M.R.C.S., L.S.A., Twyford, to Laura E., elder daughter of George Marsden, Esq., solicitor, Hensworth, Yorks.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS respecting editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

IN order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the office of the JOURNAL, and not to his private house.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL, are requested to communicate beforehand with the Manager, 429, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication. CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED to the OFFICE of THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

QUERIES.

L.R.C.S., L.R.C.P.Ed. asks for details respecting the examination for the Fellowship of the Royal College of Surgeons of Edinburgh, and also of that for the M.D. of Brussels, whether they are of a very searching nature, and what books are recommended for study by a busy country practitioner desirous of obtaining both qualifications.

PRACTICE IN AMERICA.

STARS AND STRIPES asks in which of the American and Canadian States it is not necessary to pass a qualifying examination? Can a surgeon and physician (British) practise in America without registering his degrees there? In those States where a qualifying examination is necessary, is the ordeal a trying one? What is the cost of registering in America when the individual is already fully qualified and registered in England?

SURGEONCY TO COOLIE SHIPS.

W. L. C. asks to whom he should apply for appointment as surgeon on certain coolie emigrant ships (government) running between Calcutta and the West Indies? He also asks for particulars of the service as regards pay, etc.

ANSWERS.

SNOW AND RAIN.

OLOGY asks what quantity of snow is the equivalent of an inch of rain. Opinions appear to differ. Symons (*Modern Meteorology*, p. 139) says one foot; a local genius says ten inches. Which is correct?

* The depth of snow corresponding to an inch of water must vary with the density of the snow. According to Mr. Symons (our best authority on the subject) as a rough average 12 inches of snow in England will correspond to an inch of water. A table of figures given in Symons's monthly *Meteorological Magazine* for 1886 (p. 174) showed the proportion to vary in different instances from 5.7 inches to 11 inches of snow for 1 inch water.

QUININE IN PREGNANCY.

DR. T. O. PARTRIDGE (Cachar, India) writes: I have prescribed quinine for malarial affections in more than one case of pregnancy, and should not hesitate to do so again, and, with care, I cannot see the harm of it.

THE ENTOMOSTRACA.

D. H. G. writes: Can you kindly tell me the best recent work on the British entomostroaca since the one published by the Ray Society in 1850?

* There is no book since Baird's *British Entomostroaca*, published by the Ray Society (an octavo). It is very serviceable, but a good deal out of date. The best way for anyone working at this most interesting subject is to take either Claus's *Zoologie* (the French or German large edition), or the "Crustaceae" of Brown's *Thierreich*, and look up all the different references there given to recent original papers, many by Claus, others by Weissman on the Daphniidae, others by Lilljeborg. Miss Beck's, we believe, completing a work on the British Freshwater Daphniidae. There are many interesting forms in the English lakes which were not known to Baird.

TREATMENT OF HEARTBURN.

DR. JAMES McNAUGHT (Newchurch) writes: In reply to a member, in the JOURNAL of March 24th re persistent heartburn, it would seem almost certain, from the fact that it persists during the night, that he has to deal with a case of continuous secretion of a hyperacid gastric juice. For temporary relief alkalies in large doses must be given: a combination of half a drachm of magnes. carb. pond. and sodii bicarb. acts very well. The condition of excessive irritability of the gastric mucous membrane, which leads to the pouring out of large quantities of acid, may be more permanently dealt with by small doses of morphine, by the prescription of light, easily digestible food, and especially the avoidance of fats. Washing out the stomach with the tube at bedtime, so as to remove all remains of food, and the administration then of an alkali combined with a little opium will, in the course of a short time, remedy both the symptoms and the condition which underlies it.

NOTES, LETTERS, ETC.

METROPOLITAN PROVIDENT DISPENSARIES.

MR. M. G. BRIGGS (101, Northcote Road) writes: Will you kindly allow me to say a few words in favour of the provident dispensary scheme which Dr.

THE LUMLEIAN LECTURES

ON THE TONGUE AS AN INDICATION OF DISEASE.

Delivered at the Royal College of Physicians, March, 1888.

By W. HOWSHIP DICKINSON, M.D., F.R.C.P.,

Honorary Fellow of Caius College, Cambridge; Senior Physician to St. George's Hospital; Consulting Physician to the Hospital for Sick Children.

LECTURE III.

Dryness.

I now come to the consideration of dryness of the tongue and its causes. A glance at the annexed table will suffice to show how largely this depends on constitutional and how little on local circumstances.

Concomitants of Dryness of the Tongue.

	Cases.
Tongue dry, irrespective of other qualities...	113
Pyrexia (temperature 102° or over) ...	37
Temperature not above normal ...	39
Discharge by simple diarrhoea or dysentery ...	6
Discharge, diarrhoeal or other, connected with lardaceous disease ...	2
Diarrhoea in connection with other forms of organic disease—phthisis, cirrhosis, etc....	9
Chyluria ...	1
Discharge by suppuration ...	8
Serous discharge by frequent tapping of pleura ...	1
Diabetes (including 3 of diabetic coma) ...	8
Dry diet... ..	6
Coma or unconsciousness, with general openness of mouth ...	14
Openness of mouth from obstruction of nose, tonsillitis, or other causes unconnected with coma ...	6 (?)
Great prostration or exhaustion ...	51
Cases ending fatally ...	56

The old physicians recognised dryness of the tongue as of evil omen. Hippocrates, who very seldom takes notice of the tongue, refers more than once to dryness of it as a bad sign. The great Willis speaks of the dry tongue in certain cases of fever, and refers it to constitutional causes as expressed in the fanciful language of his time. "The nervous juice," he says, "is thoroughly roasted by a long concoction, and so becomes almost like glue, thick; wherefore, not being able to be dispersed neither by spittle nor by insensible transpiration, nor to be separated by the urinary passages, at length leisurely runs out by the passages of the spittle, and forthwith by reason of its thickness grows into that glueiness." I think most physicians at the present time regard the dry tongue as a constitutional symptom, and as a bad one, notwithstanding that there are some who have sought to refer it rather to local conditions than to the system at large. My cases, collected without special selection, show with the dry tongue, be its origin what it may, a startling mortality—one of almost exactly 50 per cent.; of 113 patients with dry tongues, 56 died.

I will now come to the causes in detail. The immediate causes are two: increased evaporation from the mouth; diminished secretion into it.

1. Increased evaporation may be due to exposure of the mouth by persistent openness: as when the nose is obstructed, and when coma exists; or to increased heat of body, and as a consequence of expired air. Further, there is a double relation between dryness and bareness; dryness has been seen to cause bareness; but must not bareness at least help to cause dryness? Epithelium is conservative of moisture, as may be witnessed in any dissecting-room; wherever the surface of the skin has been rubbed off the deeper part dries and cornifies. Thus, if by chance the upper epithelium of the tongue should be lost, the deeper investments must be more amenable to evaporation and desiccation.

2. Diminished secretion may be either of the salivary or the

mucous glands; but the moisture of the tongue depends more upon the salivary secretion, which is abundant and watery, than upon the mucus, which is scanty and thick.

From the immediate conditions which determine dryness of the tongue I now approach the more complicated morbid circumstances which lie behind them. First, I will take conditions which entail persistent openness of the mouth, and so increased evaporation. Secondly, states of pyrexia, of which the bearing is more complex, but which involve increased evaporation from the tongue by reason of the heat of the expired air, and also general dehydration and consequent diminution of saliva from the generally increased evaporation which the heat of the whole body entails. Thirdly, profuse discharges which consist largely of water, by which the body is dehydrated and the salivary glands in particular stunted of their proper material. Fourthly, conditions of prostration or exhaustion, which states are adequate in themselves to suppress the saliva and dry the tongue, though often they are assisted by other causes, more especially discharges and pyrexia.

Habitual Openness of the Mouth.—Much importance—I think I can show too much—has been attached to this either as occurring during sleep, or from obstruction of the nasal passages, or from coma. If the tongue be persistently and generally dry, I believe that other causes are always at work. I have known the tongue to remain perfectly moist while the nostrils were, and had been for some days, plugged for epistaxis. On the other hand, it is common to find a path of dryness down the centre of the tongue, corresponding to the exposure to breath in tonsillitis and other throat affections. With regard to the chronic enlarged tonsils of childhood, when the child sleeps with the mouth open, I am assured by my colleague Mr. Bennett, who has removed many of these, and always does it early in the morning, that on waking the tongue is usually dry, but afterwards soon becomes moist; certainly such tongues are usually moist when they come under my notice. If the tongue is persistently dry from enlarged tonsils, I think the affection is usually inflammatory, so that causes other than exposure assist. In the earlier part of this inquiry it was my rule to examine into the course of the breath whenever I found the tongue to be dry; but the conviction was forced upon me that the state was generally due to other than mechanical causes, and I ceased to look for this with the attention I had before given to it. My figures are therefore less reliable than the general impression which I record. In the great proportion of cases where the mouth is habitually open, it is either from coma or some illness which interferes with full and alert consciousness; the relaxed jaw and gaping mouth are but signs of ebbing vitality, of which the failure of secretion is also a part. I have sometimes ascertained by catheterisation, what was obvious without, that the tongue in such cases is dry, not because normally abundant saliva has dried upon it, but because the secretion has been wanting. In cases where the tongue is dry and the mouth open; other circumstances generally concur in causing the condition: as in a case of tonsillitis with a temperature of 103°; one of acute rheumatism with a temperature of 101.5°; one of suppression of urine with profuse diarrhoea; and I might add others. But I need not dwell further upon a cause of dryness which, though it has a place, has not an important one; nor does it obscure to any considerable extent the great constitutional significance of the sign in question.

Pyrexia.—To take this next, dryness of the tongue is so frequent with it that the two must be connected; at the same time, the occurrence of the dryness with little or no pyrexia shows that other causes may produce it. As the temperature of the body rises the moisture of the tongue diminishes; on the other hand, it by no means follows that if the tongue be dry the temperature is, or has recently been, raised. Many causes intervene which complicate the relation between heat of body and dryness of tongue. With typhoid or acute rheumatism the tongue is apt to be dry at a temperature under which, with pneumonia, it would probably not be so. Something is due to time; the more chronic disease is the more drying. A temperature of 102° has little effect in drying the tongue. Even much higher temperatures are reached without the tongue becoming dry, though its moisture is lessened. I have noted many instances of acute disease where the plastered tongue has retained enough moisture to forbid its being called dry under temperatures of from 103° to 104°. It would appear that over 104° dryness is general; over 105° nearly constant. The extent to which other causes intervene is shown

by the annexed statement, showing the maximum temperatures in 103 cases of dry tongue.

Temperatures subnormal in ...	16
" ranging up to normal in...	19
" " " 100° " ...	16
" " " 102° " ...	28
" " " 103° " ...	15
" " " 104° " ...	5
" " " 105° " ...	3
" " " over 105° " ...	1

Total ... 103

In a third of the number the temperature was not over normal; in half it was not over 100°. There is no variety of dry tongue which gives so high a mean temperature as the moist plastered tongue of acute disease. It is clear, then, that though pyrexia is a drying agent, yet there are others which are important.

General Dehydration.—Next, as a cause of dryness of the tongue, I come to general dehydration of the body, whether by deprivation of drink or excessive aqueous discharges. Apart from complications, we presumably have to do not with increased evaporation from the mouth, but with diminution of the saliva, often as a simple and direct result.

First, as to deprivation of water. I have never seen this carried to extremity, nor can I adopt as my own the experience of "The Ancient Mariner":

And every tongue through utter drought
Was withered at the root;
We could not speak no more than if
We had been choked with soot.

But of lesser degrees of deprivation, mostly in the treatment of aneurysm and some forms of dropsy, I have recorded eleven instances, in six of which the tongue became dry; I need say no more of these cases now than that they show the results of dehydration in its simplest form; diminution of saliva and dryness of the tongue, with sometimes furring, sometimes more or less denudation.

As a mode of dehydration less simple but more definitely morbid, I may next refer to diarrhoea. Of the 113 cases of dryness this flux, simple or complicated, was present in seventeen. Here exclude typhoid. Six were cases of simple or dysenteric diarrhoea; the rest were associated with phthisis, cirrhosis of the liver, lardaceous or other organic diseases, which it would serve no purpose to recapitulate. In six the temperature was 102° or over, in five not above normal. In the larger number the complications were such that it was impossible to assign the state of tongue to the diarrhoea only; but there were three which served to exemplify the dryness as a direct result of diarrhoea, without either organic disease or marked pyrexia; in one of these the temperature was subnormal. More often when this appearance presents itself under the flux some other condition is present, often organic disease, the fatal end of which is not far off.

The maintenance of the moisture of the tongue under diarrhoea, profuse even to death, is a matter of common experience in Asiatic cholera. The tongue here remains moist, creamy, and noticeably cold during the whole of the purging or algid stage. When the discharges have ceased and reaction and fever set in, then as the pulse rises the tongue begins to dry and becomes quite dry and brown, as often in typhoid, the edges and the tip being red. Probably the persistent moisture of the algid tongue is in some measure due to the watery vomit which so abundantly flows over it, but something must also be attributed to its low temperature. It is a matter of experience that a tongue which is in itself dry is not easily kept otherwise by external wetting. The patient may drink often to this end, but only with a superficial and evanescent effect.

Excessive discharges of urine may be next considered. Diabetes mellitus is a cause of extreme dryness of the tongue; of the 113 cases where this state of tongue was recorded, 8 were of this disease. When the tongue has been dry under a mixed diet it will often become moist under a restricted one. By restriction both the sugar and the water of the urine are lessened; the formation of sugar is checked, and with this the discharge of water. Whether the presence of sugar in the blood or the discharge of water takes the chief part in drying the tongue may be ascertained by a comparison with diabetes insipidus, where the loss of

water occurs without the production of sugar. I have notes of eight cases of this kind, in most of which the discharge of water was greater than with diabetes mellitus. The tongue was recorded as moist, generally slightly coated, in six; in one as "cleaning;" in another as "dryish, pale, and flabby." The desiccation was therefore decidedly less with diabetes insipidus than with diabetes mellitus, and in the latter disorder must therefore be attributed to some other cause than the simple loss of water by the kidneys. I may mention a case which bears on this point. A woman had profuse diabetes insipidus, passing on an average a pint of urine an hour for the twenty-four hours, and drinking to almost exactly the same amount. The tongue remained moist, slightly coated, scarcely unnatural, except that it displayed a syphilitic scar. Three years afterwards I saw the patient again, having lost sight of her in the interval. A very unusual change had taken place; the diabetes had altered from *insipidus* to *mellitus*; the urine was now loaded with sugar, and in exactly half the quantity, the amount of drink having fallen in the same proportion. The tongue was now dryish, reddish, and a little brown. The temperature of the body was subnormal. The patient was on the verge of diabetic coma, in which she shortly died. The access of dryness of the tongue with glycosuria, though the diuresis was diminished and the temperature not increased, was instructive. The osmotic action of the sugar in the blood is probably the chief cause of the dryness of the tongue in the circumstances, as it has been shown to be of the dehydration of the lens and consequent cataract. The proximate cause of the dryness of the tongue is absence of saliva; as is evident by the state of the mouth and of the parotid.

Prostration.—In speaking of the several varieties of dry tongue, I have shown how much fatal disease they present—altogether about 50 per cent. A dry tongue, more than any other, foretells the ending of mortality. The kinds of disease which it accompanies are chronic more than acute; if febrile, usually continued. Putting aside designed restriction in drink, and also diabetes, where the dryness is due to special circumstances, one is at once struck with the gravity of the cases and the large proportion of those which end fatally. The conditions are most various; it is not easy to see what they have in common, except it be something which may be indicated by such terms as "prostration" and "exhaustion." Exhaustion by suppuration of many sources, advanced phthisis and tuberculosis of other kinds are frequent when the tongue is dry and smooth. When it is dry and rough, the tables show concluding brain disease, concluding cirrhosis, advanced cancer, advanced pyæmia, and severe pneumonia. Of twelve cases of pneumonia in which the tongue was dry, seven ended fatally; of twenty-seven in which the tongue was moist, only five ended fatally. A dry tongue in rheumatic fever is commonly recognised as an unfavourable omen, though not necessarily a fatal one. In typhoid the converse may be stated—a persistently moist tongue is indicative of a mild attack.

I have used the term "prostration" as a somewhat inclusive one—one which can be better understood than defined—representing great failure of strength and nutrition, however brought about. With the 113 cases of dry tongue, this condition was noted in fifty-one; in 222 cases where the tongue was moist, it was noted in but twenty-four. We cannot but conclude that prostration or failure of vital force is the most important factor of the dry tongue; pyrexia takes the second place. Clinical experience warrants the assertion that, though dryness of the tongue may occur without great prostration, great prostration is never long continued without dryness of the tongue. Great prostration occurs with little alteration of the tongue in connection with abdominal collapse, as in acute obstruction and perforation, but the condition has not been of long continuance.

Besides prostration—or, be it rather said, together with it—coma presents itself in connection with lingual dryness; this is not wholly due in the circumstances to the open mouth, as I have already shown, but to deficient secretion of saliva. It is to this that the dryness of the tongue is usually due, and it is because the dryness is an index of this deficiency that it has the clinical importance which, I think I have shown, must be attributed to it.

On the Influence of Food upon the Tongue.

In considering the causes of the several states of tongue, more particularly of dryness, I have said much which I need not repeat as to various influences which bear upon it; but there are still one or two which demand separate consideration, however brief.

¹ In this description of the tongue in cholera I have been enabled to supplement my own recollections by the more extensive experience of Surgeon-General Cornish.

First comes the question of food. The act of eating undoubtedly has an effect in cleaning the tongue, which is mechanical; and coating has been thought to depend, more largely than upon any other circumstance, upon the absence of the attrition which this process entails. It has been shown that the tongue is commonly more coated before food than after, that it is apt to be coated on the side of a tender tooth where mastication is limited, while it remains clean on the sound side, where it is not; and much of the effect of acute disease in coating the tongue has been ascribed to the attendant loss of appetite and limitation of diet. But I have already shown that coating is a matter not only of want of wear, but in part of overgrowth; and that other causes (notably pyrexia), are directly concerned. As regards the influence of food, I have sought instruction in cases where there was absence or limitation of it, apart from pyrexia or other causes which act upon the tongue. I have watched the state of this organ in many cases of stricture of the œsophagus where solid food has been entirely disused, and have before me the notes of five such, and I might add as a sixth a case in which the patient refused food in consequence of cancer of the larynx. The back of the tongue here was covered with long shaggy fur, like coarse hair. There was another instance in which the tongue was furred, but it did not become so, notwithstanding long total absence of solids, until it became dry under extreme prostration and absolute pulselessness. Among the other cases there was no instance (though, in some, solids by the mouth were impracticable, and feeding conducted chiefly by the bowel) in which the higher degrees of coat existed. In two the tongue was coated but not plastered; in one it was partly stippled or dotted, being coated only in the back and central parts; in one it was dotted only. In the last case, slight as the covering was, the difficulty of taking food was such as to call for gastrostomy. This case declared in a manner to which accident gave effect how slight is the coating produced by absence of food as compared with that due to acute febrile disease, for it chanced that I had at the same time in near proximity some typical cases of the plastered tongue of pneumonia and pyæmia. The difference was graphically displayed; among other points the general spread of the acute coat over the dorsum was contrasted with the tendency of the other to collect at the back and in the median line, leaving much of the tongue nearly free.

Cases of restriction to liquid diet, not as a mechanical but a physiological necessity, are seen daily. The physician knows that no other will "agree with" the patient; he is guided chiefly by the presence of pyrexia and the state of the tongue; the more coated the tongue the more liquid the diet; if the tongue be dry, the diet is wholly liquid, and alcohol part of it. Here the tongue determines the diet, not the diet the tongue; but not without instruction is the issue. As the acute disease abates the tongue cleans, notwithstanding the limitation; as it cleans, and because it cleans, solids are added and may help the process, but the cleaning comes first. In my table of normal tongues are seven which were so under a strictly liquid diet; on every ground, therefore, it appears clear that, though some influence must be ascribed to food and mastication in cleaning the tongue, yet these are of secondary importance.

I need not revert to the effects of dry diet which have been discussed in relation to dryness of the tongue; these are briefly want of saliva, and in some cases furring, in others denudation.

On Conditions of the Alimentary Canal in Relation to the Tongue.

It is a common belief that the tongue is directly indicative of many disturbances of the stomach, bowels, and organs directly connected with digestion; some appear even to be possessed with the fancy that the tongue is but an exposed sample of the alimentary canal, and declares by its changes the existence of similar changes in the hidden parts. With those who do not go thus far the white tongue is taken as a sign of constipation, or that the stomach or the liver is out of order, and that alteratives, especially of the mercurial kind, are needed. It is not easy to disentangle the complications which involve this subject; in the endeavour to do so I must appeal to a wider experience than I have been able to tabulate.

First as to the stomach. I have examined this organ after death with the naked eye and with the microscope where the tongue has been thickly coated or furred. Examination of the stomach is unsatisfactory, partly from the *post-mortem* influence of its contents; but it may be safely said that this organ presents no changes which are obviously analogous to those of the tongue, and the

same statement may be extended to the rest of the alimentary canal.

I have not been able to discern any state of tongue especially connected with dyspepsia or ulcer of the stomach. When dyspepsia is associated with stomatitis the tongue is sometimes thickly coated, probably as a local result. In simple dyspepsia and ulcer the lower degrees of coating are usually present, possibly in connection with the loss of appetite and the limitation of food. In one case of ulcer I noted the tongue as clean but flabby.

Next as to the bowels. Some forms of constipation or diseases associated with it are undoubtedly connected with changes in the tongue; but that the arrest is not necessarily connected with any such change is evident. I have seen the tongue perfectly clean and normal after three weeks of nearly total constipation in a hysterical woman, and equally so after twenty-eight days of nearly total constipation in a woman who was next day made the subject of colotomy for stricture of the sigmoid flexure; and it would not be difficult to cite other cases where the tongue has remained natural under long constipation, either functional or connected with chronic obstruction. On the other hand, where the obstruction is acute, the tongue, early becomes stippled, or coated and dry. I think the difference between the tongue of acute and of chronic obstruction, and between one case of chronic obstruction and another, is in the presence or absence of constitutional disturbance. The early dryness of acute obstruction is not, as a rule, associated with pyrexia, but depends on salivary deficiency associated with the constitutional state. The dryness determines the state of tongue. Unless there be constitutional disturbance, which with simple constipation or chronic obstruction there often is not, the tongue may remain natural. I have more than once noticed an old block in the rectum to be attended with thick coating, which has disappeared or lessened on the removal of the accumulation. It may be inferred that in such cases there is general disturbance and probably pyrexia connected with morbid absorption, as the factor of the accumulation cannot fail to suggest.

Passing from constipation to the opposite condition, diarrhoea is early and powerfully productive of lingual changes. The tabulated cases speak for themselves, and I might largely add to the evidence they present. Looking through my notes not included in the tables, I find the tongue of diarrhoea described as "thickly coated and dry," "thickly coated, mouth dry, saliva scanty," "foul and coated," "brown, dry, and furred," "coated with brownish fur," "very dry, brown in centre, coated," "dry, brown, and cracked." There is scarcely any condition in which the tongue becomes more rapidly dry, coated, furred, and encrusted than severe diarrhoea. The absence of saliva is self-evident: direct dehydration helps to cause this; and pyrexia, which is often present, helps the desiccation.

I have already referred to the red and bare tongue which is sometimes associated with dysentery, together with abscess of the liver. Here we have fever of the hectic type together with the purging.

Opium.

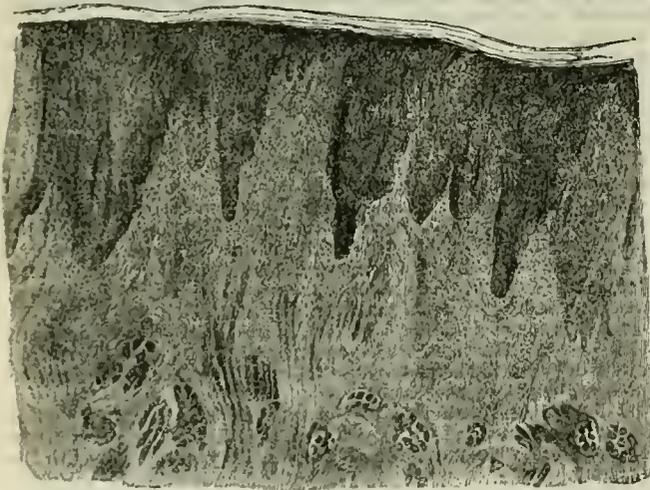

It is no part of my design to describe the action of drugs upon the tongue, but I will nevertheless insert a word as to opium. It is well known that opium makes the mouth dry. I have frequently given it experimentally to persons whose tongues have been clean, or nearly so, and moist. The effect has always been to coat the tongue, impair the appetite, and diminish the saliva. In one case the temperature rose from normal to 100°. Some of the coating may be due to the loss of appetite and of friction, but the diminution of saliva must also have importance attached to it, and falls in with what has been already said with regard to the relation of this secretion to the coat.

On the Influence of the Nervous System upon the Tongue.

This is not to be ignored, though I think more has been attributed to it than can be demonstrated. The late Mr. Hilton showed that coating of the tongue was often confined to the side of painful teeth, and referred this to reflex nervous irritation. I have already adverted to such cases in the view that the effect was due to want of wear on the tender side. It is a matter of common observation that in hemiplegia the tongue is not unilaterally affected as if from the local change, but bilaterally as if from the constitutional results of it. On the other hand, I have already cited an instance in which there was reason to believe that unilateral dryness and coating of the tongue depended on an injury

to the chorda tympani on the affected side. Here we have the intervention of saliva, and may with probability ascribe the coating to the want of this secretion rather than to the direct effect of the nervous lesion. It has already been shown how largely deficiency of saliva affects the tongue, and it is a matter of ancient as well as modern experience that this secretion is much under the influence of the nervous system. I do not now refer to physiological experiments, but to conditions of wider range. The mind affects the saliva, and may, or even must, by its means, or by means of its absence, affect the tongue. The dryness of agitation is well known; the tongue "cleaves to the roof of the mouth." The Eastern ordeal by rice, which can be swallowed by the innocent, not by the guilty, will occur to everyone. I have often noticed the tongue to be white and sodden-looking after an exacerbation of nervousness, associated in particular with phosphatic urine, and thought the first change to be a want of saliva, the coating secondary. I was told by Mr. Charles Hawkins that a certain practitioner, who saw many men of business after their business hours, could always tell how things were in the City by the tongues of his patients.

I need not here discuss in relation to the tongue the general conditions of dehydration, pyrexia, and prostration, since to do so would be but to repeat what I have said in connection with coating and dryness. Neither need I delay, or only for a moment, to point out that if one were to seek to connect the states of the tongue, as a general rule, with individual diseases, so various and apparently so contradictory would be the results that nothing but confusion could result. What can be said towards this end may be briefly put. There is a tongue of heart disease of which the

Denuded tongue covered with straight membrane like the roadway of a bridge.

cyanotic character is evident to the naked eye, and a somewhat similar condition which is apt to accompany chronic albuminuria, which needs the microscope for its detection. The tongue of diabetes mellitus has a special tendency to dryness, as has been sufficiently explained; but this does not prevent its being sometimes normally moist or even normal in all respects. Among the febrile diseases it would commonly be said that the tongue of scarlatina and that of typhoid are characteristic. The well-known strawberry tongue of scarlatina approaches nearly to the pathognomonic, for the eruption helps to make it so; but even here other febrile disorders, like pneumonia, in which the face and mouth are apt to be injected, produce an excellent counterfeit, besides which the strawberry character in scarlatina is soon replaced by other phases of coating and by denudation. The tongue of typhoid presents many varieties, according to the stage of the disease and other circumstances. In eighteen cases it was stippled and coated, coated, plastered, strawberry, furred, encrusted, and denuded. Only two presented the dry, furred or encrusted state, which is commonly regarded as typical. The dry, bare condition was not absent. The tongue of pyæmia more often shows the ideal typhoid state than does that of typhoid itself. I say nothing of the tongue of typhus, of which of late years I have seen but little. In the only case I have recently

seen it was dry and black, as it is known often to be. Lobar pneumonia presents a range of tongue which runs through the whole gamut, the plastered type preponderating, as it does with typhoid and most other acute febrile states. In bronchitis the lower degrees of coating are generally presented, but if the disease be considerably febrile the tongue is apt to be plastered, which may be accepted as a sign of severity. With regard to acute rheumatism the variety is considerable, the lower degrees of coating being more often seen than with diseases which present a higher temperature and more depression. Nevertheless, the dry, furred, and encrusted tongues, with their significations, are not absent from the series. It would serve no purpose, and would involve repetition, were I to dwell further upon the relations of the tongue to individual disease; the tables speak in this sense, though the experience therein recorded is but a fragment small indeed compared to what must be in the minds of many who honour me with their presence to-day.

I have not dealt with local affections of the tongue, nor have I had much experience of them. That local irritation increases the coat may readily be believed. The coated or thickly stippled tongue of the smoker is well known; this may even assume (though, I trust, but rarely) the startling form of leucoplakia, an exaggeration, I presume, of the epithelial growth, though here I speak without *post-mortem* observation. I present a drawing from a patient with regard to whom I had the advantage of the opinion of Mr. Jonathan Hutehinson. I will dwell no further on this part of the subject, save to repeat what I hope has been made evident, that general influences tell more widely upon the tongue than local ones.

It only remains that I should sum up briefly the conclusions which have been arrived at.

The tongue is an index of constitutional states, seldom of individual diseases. An ancient theologian described the face of a wicked man as a map of the empire of sin. It has been fancied that the tongue presents a map of the empire of disease; and a writer, though one of no great note, has gone so far as to divide the lingual surface into a number of rectangular regions as numerous as the United States of America, which he places under the rule of separate organs; the larynx, the bronchi, the lungs, the pleura, the large intestine, the small intestine, the kidneys, and the brain each possessing a distinct territory. The heart, says this writer very wisely, has a common control over all. But in truth the tongue has no such local signification; it seldom points to solitary organs or isolated disorders, but is rather a gauge of the effects of disease upon the system than an indication as to the locality of it. It is often a guide in treatment, so far as treatment is general, not local; and it is an important help in prognosis. It may, indeed, be doubted whether any means of observation open to the physician, including the pulse and the thermometer, give him more insight into constitutional states than he can derive from the tongue. Clinically it always speaks the truth, and in a language which is not foreign to the experienced physician. And how much truth, or rather how many truths, are to be read on how small a page! Conditions of fever and of feeding; states of the nervous system; the maintenance or abeyance of vital secretions; failure of vitality, though we may not be able to find out why; in one case that the disease is getting the better of the patient, in another that the patient is getting the better of the disease—all these are discernible to the educated eye. The clinical value of the tongue largely depends on the number of interests it represents; these are more or less mingled in its indications, and the impression they convey is a combined one, but it is none the less valuable because comprehensive; it gives to a glance what otherwise could only be learned by detailed inquiry.

It has been shown that the white coat of the tongue essentially consists of horny epithelium, and that the various grades of coating are mainly due to its increase. I have not dwelt upon the parasites which are apt to gather upon the coat; these are only of secondary interest; they do not determine the character of the coat or of the tongue, and they have been subjected to an exhaustive examination by Mr. Batlin, with results in negation of their practical importance. It has been shown that the several degrees of coat are mainly due to overgrowth of epithelium, though in a smaller measure to its want of removal, and that there is a remarkable correspondence between the heat of the body and the coating of the tongue. If the tongue be coated, the indication is usually of febrile disturbance without especial reference to the stomach or liver, and points more to the general system than the alimentary. Though something is to be ascribed

to disuse, yet I think I have shown that too much has been; and that more than one modern observer, like an uncharitable pedagogue, has attributed to idleness what is directly due to illness.

Superadded to the *forcing process*, if I may so speak, of fever, we have step by step other changes, dryness, furring, and incrustation, which are essentially connected with want of saliva. I have endeavoured to show that this diminution or arrest is declared by the state of the tongue almost as certainly by observations on the ducts, and is the chief cause of the furring and incrustation which accompanies it. It is true that in the crust are parasites, but these are secondary; the primary fact is the want of saliva, a clinical indication always of importance, though the process by which it is brought about is not always the same. I have shown the effect of dehydration in diabetes and by diarrhoea; but it has, I think, been made clear that the most frequent and important concomitant of the dryness is a certain failure of bodily force and function which I have not assumed to describe with physiological exactness, but have expressed by such terms as weakness, prostration, and exhaustion. I do not ignore the effects of deprivation of water, of alcohol, and of opium; but, nevertheless, the relation to which I have drawn attention, so far as it concerns such dryness as to cause incrustation, has a general hold. It is difficult not to infer that with the salivary are other glandular failures, more especially such as concern the digestive system. Good digestion waits on appetite. Putting aside diabetes, where there are special circumstances, it may be said with general truth that with the dry encrusted tongue appetite is *nil*, and solid food impossible, not merely from the local difficulty caused by the dryness of the mouth, but from inability more profoundly seated. It may be inferred without rashness that the loss of power to take food is connected with a loss of power to assimilate it; and if the digestive function is in abeyance it is not likely that the digestive fluids are abundant. Hence it presents itself as what may be called a working probability that a want of the more vital juices concerned in nutrition may be indicated by the want of saliva which is sometimes so conspicuously displayed. Physicians acknowledge in their practice some such guidance; the dry and encrusted tongue is seldom disregarded as a call for animal liquids, which require little digestion, and alcohol, which requires none. To translate theory into practice is not only dangerous because the theory may be wrong, but the means may be ill-adapted, though the theory be sound. I have often taken the dry tongue as an indication for peptonised food, and thought it beneficial, but have not as yet had enough experience to speak confidently.

Proceeding from the varieties of clothing which dryness produces, we come to the opposite, but sometimes succeeding, condition—that of nakedness. This is often connected, like the previous, as has been shown, with want of saliva, of which it is usually a latter concomitant. It may be simply due to this cause, but other circumstances are so often present that it is difficult not to assign to them some share in the loss of integument, and attribute this, in part at least, to the failure of nutrition which belongs to hectic fever and suppurative waste. When the tongue becomes dry and bare it is ill with the patient. He is not sure to die, but likely to. If, as has been said, the tongues of dying men enforce attention, it must be often directed to this. The indication of the red, smooth tongue, is for what failing nutrition calls for—tonics, stimulants, and food, probably liquid, but nourishing. The failing pulse does not more surely tell of asthenic tendencies than, as a rule, does the red, dry, and polished tongue.

The tongue, indeed, has a whole book of prognostics written upon its surface. When the tongue is approaching the condition of health, so, as a rule, is the patient, as is seen whenever the red, dry, and bare tongue acquires moisture and clothing. There is no better sign in diabetes than the resumption of the natural moisture by the tongue which has been dry. Something may be judged by the way an encrusted tongue cleans; if gradually and from the edges, well; less so when in scales, especially when the surface exposed is red and dry. One glance at the coated or plastered tongue may give an assurance, which perhaps could not be otherwise obtained, that the disease is on the wane. If the thick coat in the centre steeply shelves towards the sides and front, revealing a normal, moist, not over-injected surface, the tongue is in process of cleaning; the natural friction is overcoming the coating process, and tongue and patient are on the mend. A tongue acquires coat more evenly and generally than it parts with it; we can thus tell whether the coating is on the advance or decline, and apply this rule to the disease.

There remains to me only the pleasant duty of mentioning those to whom I have not yet referred to whom I have been indebted. No one who has worked at the tongue can fail to have profited by the labours of Mr. Jonathan Hutchinson, to whom, indeed, I have been under special obligation, though as surgeon and physician our points of view have not been the same. I must next record my debt to Mr. Sweeting and Mr. Armstrong, of the Western Fever Hospital, and Dr. Collie, of the Eastern Fever Hospital, for kindly providing me with scarlatinal tongues. Clinically, I have to acknowledge the services of a series of excellent clerks—Mr. Brushfield, Mr. Le Cronier, Mr. Sortain, Mr. Ogle, Mr. Drabble, and Mr. Barlow. And I have, finally, to thank the Fellows of the College and all who have formed my audience for the attention they have bestowed upon what I fear must too often have been tedious.

ABSTRACT OF LECTURES

ON THE

DEVELOPMENT OF THE ORGANS OF CIRCULATION AND RESPIRATION,

INCLUDING THE

PERICARDIUM, DIAPHRAGM, AND GREAT VEINS.

Delivered at the Royal College of Surgeons, March, 1888.

By CHARLES B. LOCKWOOD, F.R.C.S.,

Hunterian Professor of Anatomy in the Royal College of Surgeons of England
Surgeon to the Great Northern Central Hospital; and Demonstrator of
Anatomy and Operative Surgery in St. Bartholomew's Hospital.

LECTURE I.

THE lecturer began by saying that he did not think he could show his appreciation of the honour conferred upon him by his re-election to the post of Hunterian Professor better than by lecturing upon a subject which was especially in need of elucidation. Others might be mentioned of more immediate professional interest, but none of greater scientific importance. The development of the pericardium and diaphragm was involved in much obscurity and surrounded by many difficulties, more especially as English authors had not, so far, treated it systematically. In endeavouring to repair this the synthetic method had been adopted, and the various phases of development followed step by step, beginning with the simplest and gradually proceeding to the complicated. It had, however, been found impracticable to obtain human embryos to show the earliest stages, and these, therefore, had been studied in rabbits' embryos ranging from the eighth to the seventeenth day of intra-uterine life. The results of these investigations had already been communicated to the Royal Society, and in these lectures they would be described chiefly with a view of explaining and illustrating their applicability to human embryology. Ultimately it would be seen that, whilst bearing more directly upon the development of the vascular and respiratory systems, they threw light upon the origin of the fetal membranes, the placenta, and other problems.

Beginning, therefore, at the eighth day of intra-uterine life, it will be found that the uterus of a rabbit which has reached that stage has along each of its tubes three or four vesicular dilatations which almost double its calibre. If one of these vesicles be opened in warm saline solution at the side furthest from the mesometrium and uterine vessels, after a little clear albuminous fluid has escaped, a delicate film (the blastodermic membrane) is to be seen spread out upon the surface of the interior of the uterus which faces the opening. The shadowy outline of the embryo occupies the central part of the film, and is of an oblong form, and slightly constricted at its middle. At the head end of the oblong the fore-brain projects very slightly, and behind it, on either side, and a little way apart, are two small fusiform swellings, which indicate the commencement of the heart in two separate halves. Section through the embryo, and through the part of the uterus with which it is in contact, shows that it lies with its dorsal surface, covered with epiblast, next to the uterus, and with its ventral aspect, lined with hypoblast, towards the interior of the blastodermic vesicle. In some types this arrangement is reversed in an extraordinary manner, and the lecturer argued that that

circumstance suggested that applications of developmental data from types which were known to those which were not, ought to be received with great caution. Proceeding, it was said that between the epiblast and hypoblast lay the mesoblast, which at the eighth day had divided into somatopleure and splanchnopleure. The cleft between these two layers is usually called the cœlom, and it extends from behind the fore-brain far towards, and beyond, the tail end of the embryo. The somatopleure, covered with epiblast, lies upon the wall of the uterus, and has no feature of particular import, but the splanchnopleure on either side has about its midst a slight thickening, which is bent with its concavity ventralwards, that is to say towards the hypoblast, and its convexity towards the cœlom. These bilateral symmetrical thickenings are the beginning of the heart, and it is to be noted that (A), they are of purely splanchnic origin, and (B), that they project into the fore part of the cœlom. As the embryo grows, these cardiac splanchnic loops become more complete, and horseshoe-shaped (Fig. 1), and, simultaneously, owing to the bending inwards of

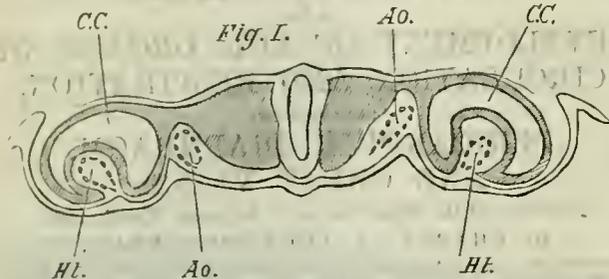

Fig. 1.—Rabbit's embryo of eight days and four hours, showing the splanchnic cardiac loops. C.C., cardiac portion of the cœlom; Ht., heart; Ao., aorta.

the splanchnopleure to form the pharynx, they gradually approximate and finally coalesce. Whilst these events are in progress, there is no change in the relation of the heart to the cœlom, and it continues to project into the foremost part of that cavity. By the beginning of the ninth day, the rabbit's heart is a slightly bent tube attached to the pharynx by the supracardiac splanchnopleure, which has become the mesocardium posterius, and to the ventral wall of the cœlom by the infracardiac splanchnopleure, which has become the mesocardium anterius. Moreover, the hinder end of the heart now receives two large veins which, originating in the blastoderm, run inwards at right angles to the axis of the embryo along the splanchnopleure and, consequently, along the ventral wall of the cœlom.

These vessels, therefore, may be said to divide the cœlom into two portions, namely, a cardiac and a pleuro-peritoneal, and are the first factors concerned in separating the one part from the other. This is effected as follows: the venous end of the heart and the cardiac ends of the omphalo-mesenteric veins are fixed to the ventral wall of the pharynx by the mesocardium posterius, and in addition, after the early part of the ninth day, the veins become fastened by an adhesion, the mesocardium laterale, to the somatopleure, at a point which is almost at the same level as their entry into the heart, but some distance nearer the lateral limits of the embryo. Thus a portion of the cœlom is converted into a passage which has the following boundaries: in front, the cardiac end of the omphalo-mesenteric vein; behind, the body wall; externally, the mesocardium laterale; and internally, the mesocardium posterius and pharynx. As this passage owns its formation to one vein and its subsequent closure to another, it may be called the "iter venosum;" and it is unnecessary to repeat that it leads from the cardiac into the pleuro-peritoneal portion of the cœlom (Fig. 2). The mesocardium laterale is a union of splanchnic with somatic structures, and is the route by which the somatic veins (that is, those developed in the body wall) find ingress into the splanchnic (that is, those developed in the splanchnopleure). So far the portions of the vascular system which have been mentioned, namely, the heart and omphalo-mesenteric veins, are purely splanchnic in their origin, but coincident with the establishment of the mesocardium laterale, a large vein makes its appearance on either side in the substance of the body wall, and after coursing in the body wall the whole length of the pleuro-peritoneal portion of the cœlom, passes through the mesocardium laterale into the omphalo-mesenteric veins. These newly-formed vessels are the umbilical veins, and

the manner of their commencement is particularly interesting, because it has to do with the formation of the placenta. The hinder part of the somatopleure, in the region where the umbilical veins begin, maintains its original proximity to the uterine wall. As development proceeds this relation to the uterine wall persists, and the somatopleure, in the region of the commencement of the umbilical veins, becomes much thicker than elsewhere, and broken by venous spaces, and to all appearances forms the main part of the placenta.

The lecturer then discussed the development of the allantois, and was of opinion that observers had been misled in assuming that in the rabbit, and probably in the human embryo, there was a balloon-shaped allantois, similar in development to that of the chick. On the contrary, he believed that in the rabbit and in man somatic structures took a much greater share in the development of the placenta than had yet been assigned to them; and, moreover, he endeavoured to show that the allantoic vesicle of the rabbit originated in a different manner to that of the chick.

LECTURE II.

Returning to the great organ of circulation, it will be found that, after the beginning of the ninth day, the heart grows rapidly, and bulges the wall of the cardiac portion of the cœlom

Fig. 2

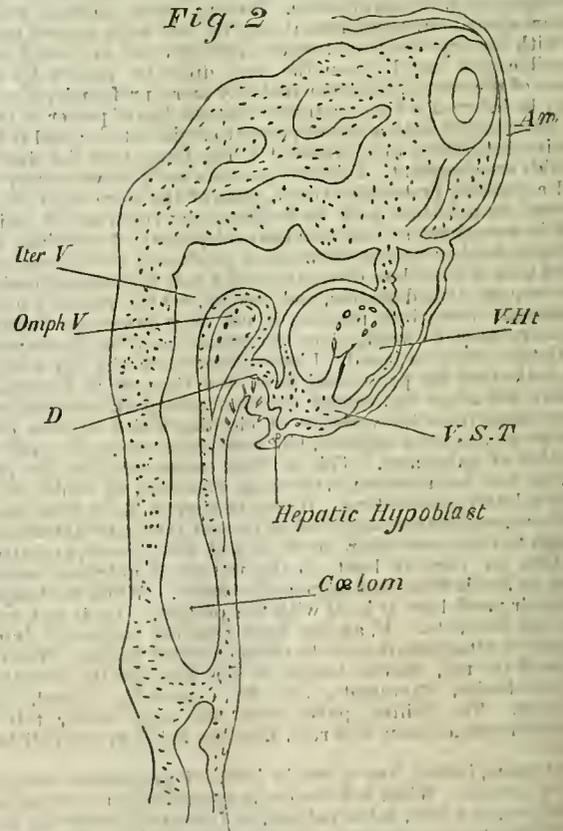

Fig. 2.—Rabbit's embryo of nine days and four hours, to show the cardiac portion of the cœlom continuous behind the omphalo-mesenteric vein with the hinder or pleuro-peritoneal portion. ventralwards (Fig. 2). But, near the hinder end of the heart, this displacement is prevented by the omphalo-mesenteric veins, which, as was said before, are themselves fixed dorsalwards by the mesocardium posterius and the mesocardium laterale. In consequence of this fixation, when the heart expands and the cranial flexure is formed, the ventral wall of the cœlom is retro-flected opposite to the omphalo-mesenteric veins, and becomes a transverse fold, the septum transversum, which stretches behind the heart from one mesocardium laterale to the other. The origin of the liver was then discussed, and that organ was

considered to originate in the hyboplast which clothed the hinder surface of the septum transversum, so that that structure formed a partition between the heart and the liver, and was, in fact, the commencement of the diaphragm.

Towards the end of the ninth day the rabbit's embryo has assumed many of its later and more familiar characters (Fig. 3).

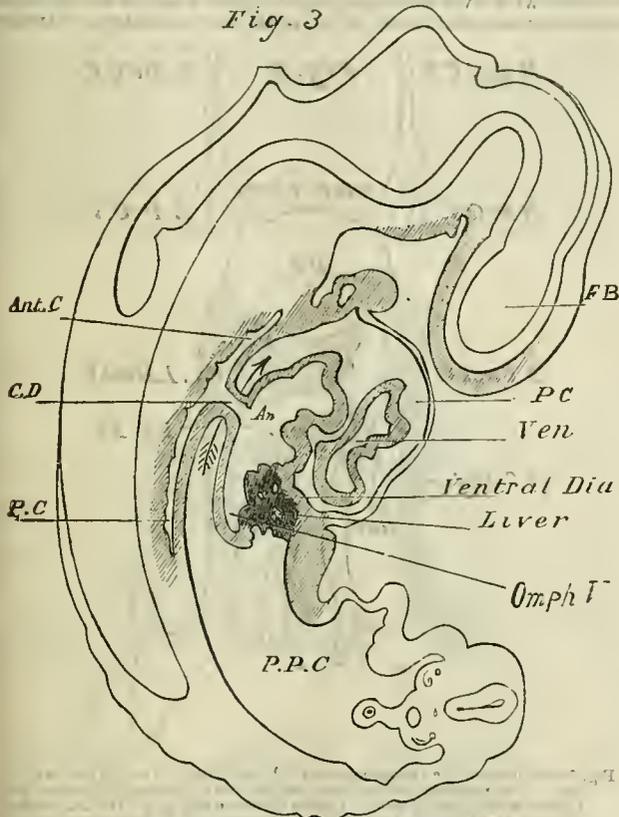

Fig. 3.—Semidiagrammatic figure of rabbit's embryo of latter part of ninth day. An arrow has been drawn in the iter venosum. Ant. C., anterior cardinal vein; P.C., posterior cardinal vein; C.D., Cuvierian duct; An., auricle; Ven., ventricle; Ventral Dia., ventral diaphragm; Liver; Omph. V., omphalo-mesenteric vein; P.P.C., pleuro-peritoneal cavity; F.B., fore-brain.

There is still a wide communication between the cardiac and pleuro-peritoneal portions of the cœlom, but the former has a much greater resemblance to the pericardium. Moreover, an important addition has been made to the venous system. The anterior cardinal, or jugular, veins appear during the earlier part of the ninth day, and, being somatic in their development, run tailwards in the body wall, and empty into the umbilical veins, just before the latter open into the omphalo-mesenteric.

About the middle of the ninth day, the posterior cardinals originate also in the body wall, and empty into the anterior cardinals, a little distance from their termination. The portion of the vein which conveys the blood of the anterior and posterior cardinal veins towards the heart is the Cuvierian duct, and it has considerable influence upon the development of the pericardium. It owes this importance, as we shall presently see, to its relation to the iter venosum, for, as both transverse and longitudinal sections show, it runs towards the heart in the part of the body wall which forms the outer boundary of that passage (Fig. 3).

By this time, the latter part of the ninth day, the iter venosum has for its inner boundary the wall of the pharynx, which, in common with the rest of the embryo, has grown considerably. Moreover, the lungs have begun to project on each side from the sides of the alimentary canal, in the shape of small buds, situated a little farther back than the Cuvierian ducts, and close to the dorsum of the septum transversum and liver.

In the next stage of development the heart and venous system undergo a modification which greatly alters their anatomy. So far the heart has been said to receive two venous tributaries,

namely, the right and left omphalo-mesenteric veins. But towards the end of the tenth or the beginning of the eleventh day the venous heart expands, and engulfs the whole of the cardiac ends of the omphalo-mesenteric veins and the terminations of the umbilical veins. In consequence, the omphalo-mesenteric veins are no longer the ventral boundary of the venosum, for they have been converted into the venous end of the heart, which takes their place. Owing to this expansion the other veins acquire separate and independent openings into the heart, which now receives on either side the Cuvierian duct, the umbilical vein, and the omphalo-mesenteric vein (see Fig. 4). The liver has also grown, an

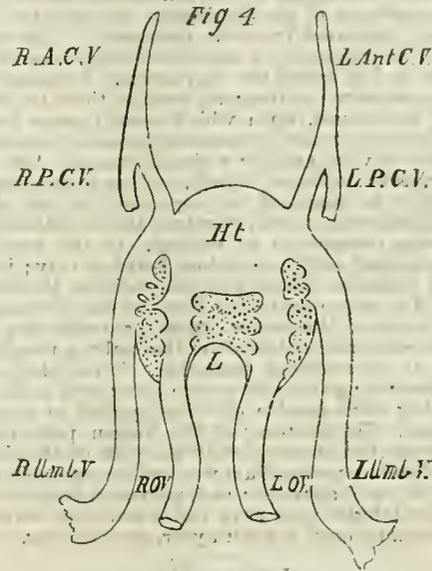

Fig. 4.—Scheme of the venous system of the rabbit's embryo at the end of the ninth day (nine days and sixteen hours). R. and L. Ant. C. V., right and left anterior cardinal veins; R. and L. P. C. V., right and left posterior cardinal veins; R. and L. Umb. V., right and left umbilical veins; Ht., heart; L., liver; R. O. V. and L. O. V., right and left omphalo-mesenteric veins.

surrounds the part of the omphalo-mesenteric vein which is nearest the heart, and the substance of the organ is penetrated by venous channels, which open into the omphalo-mesenteric veins, and through them find a passage to the heart. The venous system remains but a little while in this condition, and about the beginning of the eleventh day the umbilical veins upon each side acquire communications with the venous spaces of the liver, and can, therefore, send their blood to the heart by two routes; the first being, of course, by their original cardiac openings; the second by the omphalo-mesenteric veins, through their communications with the hepatic venous spaces. The eleventh day also witnesses the commencement of a dorsal pericardium, which is a mesoblastic septum uniting the venous end of the heart and the omphalo-mesenteric veins to the body wall, and continuous with the dorsal part of the septum transversum. This structure seems to be formed partially, perhaps, from the mesocardium laterale, but mainly by elongation of the septum transversum. From its earliest formation it constitutes a partition betwixt the cardiac portion of the cœlom and the foremost part of the pleuro-peritoneal cavity, that is, the part in which the lungs lie. Moreover, the characters of the dorsal pericardium are such that a part of each omphalo-mesenteric vein, immediately before entering the heart, is between its layers and, as will be seen presently, the right omphalo-mesenteric vein becomes the mouth of the inferior vena cava, and permanently retains this relation. It is convenient, therefore, to divide the course of the omphalo-mesenteric veins into three parts—a septal, a hepatic, and a mesenteric; the latter being the part before their entrance into the liver; further, it is to be noted that the foremost part of the dorsal pericardium is continuous with the Cuvierian ducts. Whilst the cardiac and pleuro-peritoneal portions of the cœlom have been expanding, the iter venosum has remained stationary, and, in comparison with its surroundings, looks like a narrow passage leading behind the venous end of the heart, from the

pleuro-peritoneal into the cardiac cœlom, and is the same as a passage found in that position in the skate and dog-fish. But before the iter actually closes, changes are effected in the venous system which determine the permanent characters of these channels. First, the hepatic portion of the left omphalo-mesenteric vein becomes occluded with liver substance (Fig. 4). This early closure of the left omphalo-mesenteric vein is associated with an inequality of the right and left halves of the liver, the left side being, after the occlusion of the vein, rather smaller than the right.

The lecturer argued that this left a larger area of pleuro-peritoneal cavity to be bridged over upon the left side of the body when the completion of the diaphragm was effected, and the pleural cavity separated from the peritoneal. This would explain the greater frequency of congenital deficiencies of the posterior part of the left half of the diaphragm. Variations of such important organs were not frequent, because their incidence was governed by two causes, upon which enough stress had hardly been laid. In the first place, structures essential to existence had little tendency to vary, and for a simple reason. Any variation of a great organ or important muscle, such as a crico-arytenoidens posticus, might be supposed to jeopardise the life of the individual afflicted with it, and, therefore, the variation had little chance of being transmitted by descent. In the second place, structures developed early are seldom found to vary; indeed, the frequency of variation seems in inverse ratio to the time of development. The reason for this is likewise simple—namely, that a variation in one of the earlier organs produces such an effect upon its after-comers that the life of the embryo is again jeopardised, and it is rendered incapable of reaching maturity. Examples illustrating these laws were given, and it seemed probable that they were capable of being applied to neoplasms as well as organs. The anatomy of the human pericardium and diaphragm were then discussed with the view of showing that in early life the fibrous pericardium was easily separable from, and independent of, the diaphragm: and, moreover, that the thoracic portion of the inferior vena cava had a complete investment of fibrous pericardium until the third year, or even later.

LECTURE III.

The next step in the development of the great veins is the obliteration of the cardiac openings of both umbilical veins. This is followed, subsequently, by the entire disappearance of the right, and by the diversion of the left into right omphalo-mesenteric vein (see Fig. 5). The manner in which the umbilical veins lose their cardiac openings is far from clear, but the event seems to be associated with an elongation of the cardio-thoracic portion of the embryo. The left umbilical vein acquires its channel into the right omphalo-mesenteric by taking advantage of its alternative route through the liver substance, the venous spaces of which seem merely to dilate. The passage caused by this alteration is called the ductus venosus Arantii. Moreover, the septal portion of the left omphalo-mesenteric vein disappears, so that, upon the left side, the dorsal pericardium, between whose layers it lay, becomes a simple membranous septum between the auricle and pulmonary portion of the pleuro-peritoneal sac. The septal portion of the right omphalo-mesenteric vein, on the other hand, now carries to the heart its own blood, and that of the liver and of the ductus venosus. In addition, the right omphalo-mesenteric vein, before its entrance into the liver, receives a number of veins from the alimentary canal, and is in process of conversion into the portal vein. Most of these events take place during the twelfth day, and by the time they are completed the iter venosum has almost closed. The Cuvierian ducts are the chief cause of that event.

At the end of the twelfth day the fore limbs have developed, and empty their blood into the Cuvierian ducts, which become larger and are in process of conversion into the superior vena cava; just as in the earlier stages of development (Fig. 3) the Cuvierian ducts run round the outer wall of the iter to gain the heart, but, owing in a measure to their expansion, they are approximated to the wall of the trachea and œsophagus, whilst simultaneously the tissues which surround these canals become more bulky and assist the process. By the thirteenth day there is no trace of any communication between the pericardium and the pleuro-peritoneal sac. The thirteenth day also witnesses the formation of the inferior vena cava. This vessel originates either a little sooner than or simultaneously with the permanent kidneys, from which at first it derives most of its blood.

As a preliminary to the appearance of the vein in the urogenital

ridge, the dorsal lobe of the liver forms a junction—caval junction—with the tissues near the base of the mesentery. The cava enters the liver by this union, and runs through the tissues of the organ into the right omphalo-mesenteric vein, close to its junction with the ductus venosus (Fig. 5). When, at a later period, the hinder hepatic portion of the right omphalo-mesenteric vein becomes occluded with liver substance, the familiar features of the fetal circulation are established. Thus, in the rabbit's embryo of twelve

Fig. 5.—Scheme of the venous system of the rabbit at the end of the twelfth day. The portions of the veins which have become obliterated are shaded with diagonal lines. Letters the same as Fig. 4. D.V.A., ductus venosus Arantii; V.C. Inf., vena cava inferior; M.V., mesenteric veins.

and a half days of intra-uterine life, the heart is contained in a closed sac, and the lungs lie in the pleuro-peritoneal cavity, just behind the superior vena cava (that is, nearer the tail end of the embryo), and in contact with the dorsal pericardium and dorsal surface of the liver.

The next stage is the formation of a partition or dorsal diaphragm between the pulmonary portion of the pleuro-peritoneal sac and the hinder or peritoneal part. This is accomplished by a crescentic fold, which, during the latter part of the twelfth day, grows inwards from the side body wall towards the mesentery (Fig. 6). At first this growth is incomplete, and consists of indifferently mesoblastic tissue; but by the fourteenth day it has grown inwards as far as the mesentery, and, near the body wall, contains muscular fibres. Moreover, as the dorsal diaphragm grows inwards from the body wall, it becomes joined to the foremost end of the urogenital ridge. There is reason to believe that the foremost end of the urogenital ridge develops into the suprarenal body, whose connections with the diaphragm are more intimate in early embryos than at later periods.

The lecturer showed two human embryos, one of the seventh week, in which the suprarenal body contained glomeruli, and was continuous with the Wolffian body, and another of the tenth week, in which the connection had almost disappeared. He was inclined to think that the suprarenal bodies assumed their diaphragmatic relations very early in intra-uterine life.

The development of the sides and crura of the diaphragm, and the manner in which the pericardium and diaphragm assume their permanent characters, was then traced both in rabbits and in human embryos.

Before concluding an attempt was made to ascertain how far the data derived from the rabbit were applicable to the human embryo. Evidence was adduced to show that the human embryo

was developed with its dorsum to the uterine wall, and that it afterwards, like the rabbit, underwent rotation; so that, in the placental region, its venter was turned towards the uterine wall. It seemed uncertain in which direction this rotation occurred, whether to the right or left.

With regard to the question whether the cavity in which the heart lies ever, in human embryos, communicates with the pleuro-peritoneal cavity, the lecturer showed sections of a human embryo in which the passage could still be seen, lying between the Cuvierian duct and the wall of the trachea and oesophagus. The same specimen also indicated that the closure of the passage was the same in man as in the rabbit, namely, by the approximation of the Cuvierian ducts to the wall of the alimentary and respiratory canals. Traces of the passage (the iter venosum) had been looked for at later periods, but without success until lately, when traces of its persistence seemed to be seen in an exceedingly abnormal fœtus dissected by Mr. D'Arcy Power, who very kindly allowed it to be shown. On theoretical grounds it might be expected that before long the persistence of the iter venosum would be definitely

Fig. 6.

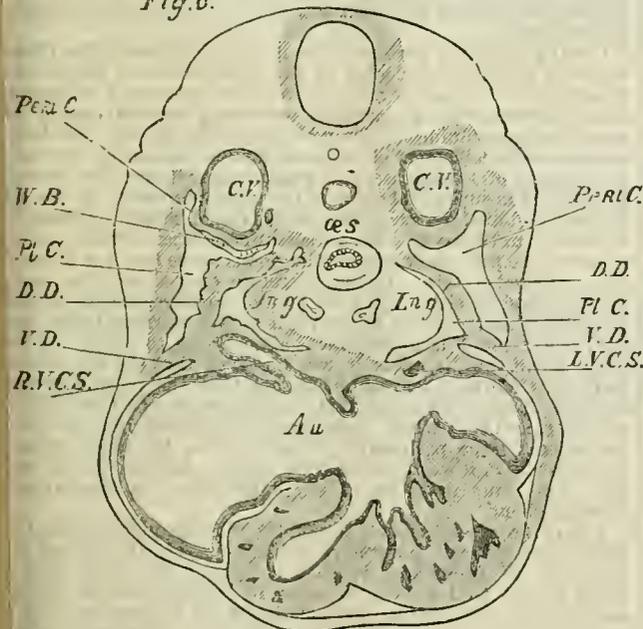

Fig. 6.—Transverse section through the thoracic portion of a human embryo to show the dorsal diaphragm. C., pleural cavity; Ings., lung; Œs., oesophagus.

established. Human embryos young enough to display the commencements of the umbilical veins and their relation to an allantoic outgrowth had not been obtained, but specimens were at hand which showed that those vessels were closely related to the body wall and most probably began in a modified portion of that structure. There was no evidence to show that the umbilical veins of the human embryo opened directly into the heart, although the researches of His made them empty into the sinus reuniens—a chamber singularly like the cardiac ends of the omphalo-mesenteric veins of the rabbit; the difference seemed rather one of detail than of principle. Specimens of human embryos were shown which seemed to indicate that in other respects the evolution of the great veins was the same in man as in the rabbit. The dorsal diaphragm of the human embryo was developed in exactly the same way as in the rabbit, and consisted of a crescentic process, which grew inwards from the foremost part of the side body wall towards the mesentery (see Fig. 6). Owing to the expansion of the lungs, the pericardium and dorsal and ventral diaphragm underwent considerable modification.

The lecturer concluded by describing the development of the pulmonary veins and the formation of the hepatic ligaments.

ABSTRACT OF A CLINICAL LECTURE ON PERICARDIAL EFFUSION WITH PULSUS PARADOXICUS.

By P. BLAIKIE SMITH, M.D.,

Physician and Lecturer on Clinical Medicine, Aberdeen Royal Infirmary.

GENTLEMEN,—Many of you have recently seen in my wards a case of pericarditis with large effusion, accompanied by symptoms of such a nature as to baffle for a time the efforts that were made to interpret their significance and arrive at a satisfactory diagnosis. The patient was a man aged 45, a stone-cutter by trade, and his history briefly is as follows. He had enjoyed uninterrupted good health up to eighteen months ago, when, after exposure, he began to suffer from cough and expectoration. His illness persisted for nearly a year; it then subsided, and he described his recovery as complete. About five months ago, however, his cough returned. Hæmoptysis occurred on one occasion, and a gradually increasing breathlessness, with debility, induced him to seek advice at the Aberdeen Royal Infirmary, where he was admitted on August 10th. As regards his family history, there was no mention of rheumatism or phthisis, but he told us that his father died from bronchitis. When he came under observation his appearance was indicative of dyspnoea; he spoke in short sentences, frequently stopping from want of breath, and using energetically the forced muscles of respiration to enable him to get air into his lungs. There was slight cough, with scanty muco-purulent expectoration. The temperature was 102°. Examination of the lungs anteriorly revealed signs of consolidation at both apices, most marked on the left side, where they were accompanied by small moist râles. The apex beat of the heart could neither be seen nor felt; the sounds were feeble and rapid, and accompanied by a peculiar murmur, systolic in rhythm, best heard during inspiration, fainter during expiration, and almost inaudible during the respiratory pause. The bruit was loudest about the lower end of the sternum, but was quite distinct in the left infra-axillary region. The cardiac dullness was manifestly increased in area and in intensity; it extended from the second space to the sixth rib in the mammillary line, and from the left edge of the sternum to a little beyond the nipple. Over the whole of this area the respiratory murmur was feeble or absent, and vocal resonance and fremitus were reduced to a minimum. The lungs posteriorly gave a dull percussion note in the suprascapular regions, while over the lower half of the left side there were present bronchial breathing and signs of some consolidation. Nowhere was there any evidence of venous engorgement, arterial pulsation, or glandular enlargement; and there was neither aphonia nor dysphagia. The liver and spleen were of normal size; the urine acid and free from albumen and sugar.

Three days after admission it was noted that the patient presented a well-marked pulsus paradoxicus—that is, a pulse whose beat became enfeebled or absent on every inspiration, returning at the commencement of expiration; and that the right radial artery pulsated with greater force than the left. About the same time, also, it was observed that the left pupil was distinctly larger than the right. From this date until the termination of the case the difference between the two pulses and the inequality of the pupils were frequently observed, but on some days careful examination failed to discover any abnormality in these respects. The pulsus paradoxicus, however, persisted up to about ten days before death, when it became gradually less marked, and finally subsided into a feeble and rapid but otherwise normal pulse.

Without following minutely the gradual changes that took place in the physical signs, I may mention that the peculiar cardiac sound heard on admission slowly disappeared, apparently resolving itself into a pericardial friction murmur heard upon one or two occasions at the site of the normal apex beat; and that the cardiac dullness slowly extended downwards and laterally until, becoming triangular in shape, it crossed the lower end of the sternum and caused a dull percussion note between the cartilages of the fifth and sixth right ribs. Symptoms of pleurisy with effusion soon appeared on the left side, and a few days before death the right side became similarly affected. The superficial thoracic veins, especially in the left infra-axillary region, showed signs of engorgement; dyspnoea increased, compelling left decubitus; inspiration became more laboured, and was accom-

panied by distinct epigastric recession; and œdema of the feet was not long in making its significant appearance. Gastric troubles added to the patient's miserable condition; the intellect became impaired; and finally an attack of dyspnoea occurred on September 24th, which was of such severity as to cause death next day.

Throughout the progress of the case the pulse beat on an average 120, and the respirations numbered 36, per minute; and the temperature, which was at first decidedly febrile, became normal after a short time, remaining so during the last fortnight of the patient's existence. The state of the urine is worthy of notice. Acid at first, it soon became alkaline, and so alkaline that the addition of nitric acid caused effervescence to such a degree as instantly to overflow the test tube. It was highly pigmented, giving a well-marked reaction from the presence of indican, and deposited a very large amount, sometimes as much as a fifth of its bulk, of sediment, consisting of crystals of ammonium urate, of triple phosphate, and amorphous phosphate of lime.

The treatment of the case consisted in the employment of cardiac tonics, and remedies to relieve the distressing breathlessness and gastric troubles. The operation of paracentesis pericardii was at one time contemplated, but its performance was rejected mainly owing to the pulmonary complications.

At the *post-mortem* examination, the right pleural cavity was found to contain 70 ounces and the left 10 ounces of greenish-coloured serum. Both lungs were marked by several depressed cicatrices, which at the apices had resulted in considerable deformity, and in those situations the lungs and costal pleuræ were firmly adherent by fibrous bands, a state of matters which was especially noticeable at the extreme left apex. Scattered over the pulmonary surface and throughout its substance were numbers of hard nodules, all about the size of a mustard seed. At first sight they resembled tubercles; but, taking into account the other features of the case, they were probably due to the inhalation of stone dust. The bronchial glands were all considerably enlarged, and of a universal deep slate colour. The pericardial sac contained 43 ounces of deeply-stained serum. The surfaces were free from adhesions, and were covered with a thick, firmly-adherent coating of lymph, which throughout had a characteristic honeycomb appearance. The mucous membrane of the stomach seemed in a state of catarrhal inflammation, and its condition afforded a ready explanation of the gastric troubles complained of by the patient. Nothing unusual was observed about the other organs.

The case which I have above briefly narrated affords a good example of the difficulty which sometimes attends the early diagnosis of pericardial effusion, and illustrates the importance of carefully observing the symptoms as they arise, and of weighing the evidence that they supply.

When I first examined the patient, I thought his case might be one of thoracic aneurysm, a suspicion which was strengthened by the unequal pupils and the disparity in the radial pulses; but the unsteadiness of these conditions, the absence of other signs of aneurysm, and the occurrence, *inter alia*, of the pulsus paradoxicus, soon caused the rejection of that theory. Led away by the presence of this peculiar form of pulse, I next entertained the theory of its commonest cause, namely, indurative mediastino-pericarditis, a disease in which inflammation of the pericardium and anterior mediastinum results in the formation of fibrous bands connecting the posterior surface of the sternum with the prolongations of the pericardium along the great vessels. Such a state of matters would readily explain the paradoxical condition of the pulse; for you can easily understand that the act of inspiration, by elevating the chest, would tighten the bands of induration, compress the aorta and other great vessels, and bring about not only weakening or obliteration of the pulse on inspiration, with its revival on expiration (when the bands would become relaxed), but also inspiratory venous engorgement in the veins tributary to the superior vena cava. Such a condition of the upper venous system, however, did not exist, nor would an increasing area of cardiac dullness result from the form of pericardial and mediastinal inflammation to which I have just alluded. This theory, then, also fell to the ground.

Was a tumour occupying the anterior mediastinum the cause of the symptoms? Such a tumour might undoubtedly produce dullness on percussion; but there were none of those signs of pressure which an unyielding body growing within the thorax is bound to exercise on contiguous structures. He had no tracheal stridor nor dysphagia, and no localised dropsy, and in addition the normal

state of the supra-clavicular and axillary glands gave no support to this diagnosis.

So far having failed to find a satisfactory explanation of the chief symptoms in this case, there remained but two other diseases which might reasonably be suspected of being the main cause of the dyspnoea and the physical signs referable to the heart. I allude to extensive cardiac dilatation and to pericarditis with large effusion. And first as to the dilatation: In this complaint we get the physical signs of enlargement of the heart; but the dullness does not extend beyond the apex beat, and its outline is pretty much that of the heart itself. Generally some impulse is to be felt, and the cardiac sounds, though weak, are never inaudible. Pericardial friction is, of course, absent. Dropsy is very frequently present; and if the dilatation affect mainly the right side of the heart, we have in addition urgent dyspnoea, venous engorgement, and epigastric pulsation.

Well, then, cardiac dilatation, though it explains the breathlessness, yet leaves untouched the main symptoms of the case. It does not account for the triangular-shaped area of cardiac dullness nor the absent heart sounds; it is quite unfit to produce friction, and it has not been observed to accompany the pulsus paradoxicus.

Coming lastly to pericarditis with large effusion, the disease which I ultimately selected as the chief source of the patient's troubles, let us see what symptoms it presents: distressing breathlessness, with a gradually increasing area of cardiac dullness, finally assuming a triangular shape having the base below the apex beat, and absence or enfeeblement of the heart sounds, pericardial friction, some period of the disease, and pressure symptoms—for example, fullness of the superficial veins of the thorax or neck. In the case before us all of these symptoms were present sooner or later, but it was not until the area of cardiac dullness became triangular and involved the fifth right intercartilaginous space that the diagnosis was rendered certain. Do not, therefore, omit to note the importance of this physical sign—when the area of cardiac dullness becomes triangular, and extends to the right of the sternum below, pericardial effusion of large amount is almost sure to exist. As confirmatory of the diagnosis, it was observed that the epigastric pulsation sank a little inward on inspiration, and that the pulse was paradoxical. You are all aware that the diaphragm is a muscle of inspiration, and that when it contracts the epigastrum protrudes; but when a large pericardial effusion exists, the long-continued pressure which it exercises on that muscle induces partial paralysis, and thus recession of the epigastrum on inspiration is brought about.

I have already mentioned to you the most frequent cause of the pulsus paradoxicus, indurative mediastino-pericarditis, and have explained its production in that complaint, but this form of pulse is also well known to occur in large pericardial effusion and in a few other diseases interfering with respiration, such as stenosis of the trachea. When it results from effusion, it is supposed to be due to pressure on the vena cava, especially during expiration (when the intra-thoracic pressure is augmented), that the heart contains less blood at the beginning of inspiration than at the commencement of expiration. This condition is well illustrated by the accompanying sphygmogram.

taken soon after the patient's admission into hospital, but when the pulse ceased to be paradoxical, while its reputed cause, pericardial effusion, was about its maximum, I am unable to explain. It may have been that the physical changes in the right pleural cavity (you will remember that it contained much fluid towards the end of the patient's illness) so altered the conditions essential for the production of this form of pulse as to cause its peculiarity to disappear. At all events, the two occurrences coincided in point of time. The extremely alkaline condition of the urine latterly, with its large deposit and peculiar reaction, can be for comment, but I regret to say that I am unable to account satisfactorily for either the one or the other, nor am I aware of a similar state having been observed in any analogous case.

Lastly, although the presence of pericardial and pleural effusions proved to be the correct diagnosis, how is it possible, you may ask, that they should have brought about the dilated left pupil, and the small left radial pulse? I believe that the real cause of these symptoms lay in the extreme fibrosis of the apex of the left lung, which excited pressure on the sympathetic nerve and on the subclavian artery, and that the intermittence of these symptoms is to be explained by the alterations in the intra-thoracic pressure, due to a varying amount of pericardial and pleural effusion.

I have said little with regard to the pulmonary signs noted during life, and their explanation as witnessed in the *post-mortem* room. I expected to find signs of consolidation at both apices, with evidence of double pleurisy, and I was not disappointed; the large effusion on the right side was clearly of recent occurrence, and its rapid accumulation proved fatal to the patient. Although the pulmonary signs there were comparatively easy to understand, yet I believe that read in the light of the *post-mortem* examination, they had an important bearing on the patient's illness. Apparently the inhalation of granite dust induced fibrosis of the lungs, which, slumbering for awhile, broke out anew, and resulted in the pericardial and pleuritic effusions which gave rise to the peculiar symptoms that I have endeavoured to interpret to-day.

METHOD OF PREPARATION OF LARGE SECTIONS OF THE LUNG.¹

By G. SIMS WOODHEAD, M.D., F.R.C.P.ED., F.R.S.ED.,

Research Scholar, Grocers' Company, London; Superintendent of the College of Physicians' Research Laboratory, Edinburgh; Pathologist to the Royal Infirmary, Edinburgh, etc.

ONCE Professor Hamilton had introduced his most valuable process of making large sections of the whole brain, the application of his method to other organs became merely a matter of time, necessity, and opportunity. Whilst working at the subject of phthisis I saw how invaluable such a method would be for demonstrating the localisation of tubercular and other lesions in such an organ as the lung, and during the period that I was working with Professor Greenfield a number of the lung sections to be demonstrated were so prepared. Since that time I have, in connection with my work as Research Scholar of the Grocers' Company, prepared a very large number of sections of various forms of diseased lungs.

The *modus operandi* is as follows: After the first incision through the lung—which should be made in the direction in which you wish to have your sections, usually from apex to base and from the antero-external angle of the lung down to the root, so as to obtain as large a section as possible—a second incision is made parallel to the first, so that a thin slice, not more than half an inch in thickness, is obtained. This slice is carefully hardened in Müller's fluid for five or six weeks. The hardening must be as perfect as possible, if even moderate success is to be attained. I find that the best way to accomplish this is to lay the section out flat in a dish on a layer of lint, then to cover with several layers of lint, and immerse the whole in Müller's fluid, a plate of glass or weighted wood being used to keep it down. Spirit also hardens the sections well, and in some cases this reagent may be used, but it must be remembered that it is somewhat difficult to get rid of the whole of the spirit without softening the textures too much; especially is this the case in warm weather; but it may be done by running a continuous stream of water over the section for about thirty-six hours before further preparation. The specimens hardened in Müller's fluid need not be washed with water for more than twenty-four hours. The slice of tissue is then placed in a mixture of five parts of mucilage (*B.P.*) and four parts of a syrup made by boiling 20 ounces of sugar in a pint of water. The proportion may be varied a little in winter by using only three parts of the syrup. Two to the ounce drops of carbolic acid may be added to prevent the formation of fungi; the tissue should be soaked in this for forty-eight hours at least, but it may be left for a fortnight or even a month without injury.

The microtome used is one modified by Dr. Alexander Bruce, in which are combined the best features of both the Hamilton and Williams microtomes. It consists of a large square tub in which are fixed nine brass pillars; to the top of these is screwed a large

zinc plate. To the tub are fixed a couple of rails similar to those on the bed of a metal planing machine, and on these rails runs a heavy plane, to which is attached a knife blade fixed at an angle of 45°. This knife is moved upwards and downwards by means of a fine screw, which is so adjusted that sections of very great delicacy may be cut (if the knife is sufficiently well sharpened). The best and cheapest knives are those made for paper cutters' guillotine machines. To this microtome I have added for the sake of convenience and rapidity of working, first, a second metal plate which may be screwed to the fixed plate, so that after a few sections have been obtained, the plate with the piece of tissue may be removed and put aside until again required; and, second, a tin box about 4 inches deep with a bottom an inch from the lower part of the sides, which fits over the second plate. It is provided with a lid, has the bottom sloping to one end, and has an outlet pipe to which a piece of india-rubber tubing may be attached.² Tub and tin box are both filled with ice and salt. The section is taken from the gum and syrup, carefully dried with a soft clean cloth, and then placed in *B.P.* mucilage until the surface is thoroughly saturated (ten minutes is quite sufficient for this), after which it is transferred to the freezing plate, on which a very thin layer of gum has been laid. The section becomes fixed immediately. It must then from time to time be carefully banked up with gum, the tin freezing box being placed over it during the intervals. When nearly frozen, take a long thin knife and pare the tissue down to the level of the rails. Now prepare a large clean white flat dish, fill with slightly warm distilled water, to which a little syrup may be added (especially if the tissue is at all brittle), and place it in front of the tub, about an inch below the level of the sections, so as just to clear the plane. In this lay the sheet of glass which is to serve as the cover glass. This should be considerably larger than the section. The glass I find best suited for the purpose is thin rolled plate, which is to be obtained only from Messrs. Chance, of Birmingham. Bring the knife down to the level of the tissue by means of the screw, and cut away all fragments till a complete section is obtained. The first complete section, if thin enough, is spread out with the aid of a camel hair pencil on the glass, on which it is carefully removed from the water and transferred to a second vessel containing distilled water, where it is allowed to stand for a few hours in order that all the mucilage and sugar may be thoroughly washed out.

The sections may be mounted either as they are, unstained, or they may be stained with alum-carmin, picro-carmin, or ordinary ammonia-carmin; but I find that the two former are the most satisfactory reagents. In staining with picro-carmin, a rapid staining on the slide, with no after-washing except around the section, is best. For the alum-carmin staining the best method is to transfer the cover glass with its section to the staining fluid, where it may be left for a night. It is then put back into distilled water, and is there thoroughly washed in order that all alum crystals may be removed. In order to clear up some of the unstained sections, Hamilton's liquor potassæ method may be used. After the sections have been thoroughly washed, he pours over the surface with a pipette a strong solution of liquor potassæ and water. Strength of 1 to 4 gives the best results. When thoroughly cleared up the section may be mounted.

To imbed and mount these sections, take a quantity of gelatine (Nelson's, or Cox's and Coignet's), wash well and cover with a saturated and filtered solution of salicylic acid; allow to soak all night, so that a considerable quantity of water may be absorbed. Pour off superfluous water and heat over a water bath until the whole is thoroughly melted; add one part by measure of this to two parts of glycerine, heat over a water bath, stirring regularly until the whole is thoroughly mixed; strain through a piece of close clean flannel into a flask, in which it may be reheated over the water bath as required. When not in use the flask should be kept corked.

Having allowed most of the water to drain away from the section by tilting it against some object, with the glass protecting the section from dust (it must not be allowed to dry, or air-bubbles will be enclosed in the section and it will be spoiled) it is placed, section upwards, on a level stand (a screw tripod serves the purpose admirably), and a thin layer of the warm glycerine jelly is run gently over the surface of the section by means of a pipette. Great care must be taken not to allow the jelly to run too rapidly, or the margins or even the whole section may be displaced. It is then set aside to cool, after which, if kept away from dust

¹ A description of a demonstration in the Section of Pathology at the Annual Meeting of the British Medical Association in Dublin.

² This microtome is made by Mr. Alexander Fraser, Lothian Street, Edinburgh.

and heat, it may be left for a week or two until time and opportunity be found to finish it off.

This finishing-off process requires a little practice, but is not difficult. The slide on which the section is to be mounted is placed on three or four pieces of cork over a water bath until it is warmed through. This is to prevent the too rapid setting of the jelly. It is then transferred to the tripod, and a quantity of jelly is poured on to the centre and gradually on to the end nearer the manipulator; the cover glass is then taken and gently lowered, the near end first and so gradually down on to the slide. The jelly on the cover keeps the section in position sufficiently long to allow of the cover glass coming into its place. The slide usually retains sufficient heat to melt away all superfluous jelly. Should this not be the case, the whole slide may be again heated over the water bath, and by the application of gentle pressure the extra mounting medium is squeezed out. If this extra medium be left at the margin of the cover, the slide may be left for some time without further treatment. To preserve the section remove the extra jelly with a spatula, wipe carefully with a moist cloth and then with a dry one. After this the margin of the cover glass and the slide should be carefully painted over with benzole balsam, layer after layer being applied at intervals of two or three days, until there is a good firm coating. Unless this be done at once after clearing off the extra jelly, the jelly at the margin under the cover dries rapidly, air bubbles make their way in, and once there, will eventually spoil the section. At one time I afterwards pasted first a layer of calico and then a strip of black glazed paper over the edges of the slide. I have found, however, that it is better to mount them in common wooden frames like slate frames, so that the cement may be examined from time to time, and if necessary repaired. The sections are now ready for examination.

List of specimens exhibited by means of limelight lantern with 9-inch condenser, kindly lent by Dr. Alexander Bruce, of Edinburgh: Specimens of normal lung (1) uninjected, and (2) injected with carmine gelatine; (3) sections of emphysematous lung uninjected; and (4) injected with Prussian blue to show the normal structure and arrangement of the blood vessels, alveoli, and air passages, and the altered conditions in emphysema.

5. Lung of child in which lower part of upper lobe had been invaded by tubercle. The gland at the root apparently corresponding to this area is much enlarged, and evidently caseous; radiating from this to the surface are masses of tubercle, some small and not caseous, others larger, apparently formed of several smaller nodules fused and now become caseous. Here septa are slightly thickened, and the tubercle nodules are apparently commencing in the small lymphatic nodes.

6. Tubercular catarrhal pneumonia in the lung of a child. The lobular distribution is very distinctly marked, small areas of healthy tissue appearing here and there. Away from the large consolidated patches are small tubercle nodules, evidently growing in the inter-alveolar or small interlobular septa. Here also the glands are enlarged, caseous, and tubercular.

7 and 8. Other sections in which the patches of catarrhal pneumonic consolidation are not quite so typical, and in which there is more marked interstitial tubercle.

9. Miliary tuberculosis in child. Section injected with Prussian blue and stained with picro-carmin. In this the tuberculosis appears to have spread by the lymphatics, but catarrhal changes have quickly supervened. An examination points, however, to the fact that the tubercle is primarily strictly confined to the interlobular septa. The glands at the root are enlarged and caseous. The non-vascular condition of the tubercle nodules is well seen in this specimen.

10. Section of acute miliary tuberculosis. Here the nodules are very small, and are quite distinct in appearance from anything we have yet seen. They are found commencing in the interlobular septa, and have evidently arisen in connection with infection by the lymph channels or blood vessels. Around some of these points catarrhal changes may be observed, but they are comparatively little marked. The patches are very different from those that are due to infection by the air passages.

11. Lung with well marked catarrhal pneumonia in lower lobe. In the upper lobe is a large gangrenous cavity, opening directly into the large bronchus. In the walls of this cavity we have a slight development of granulation tissue in which is a considerable quantity of altered blood pigment.

12. Section of lung from a case of chronic fibroid phthisis with emphysema. At the apex are small cavities filled with partly caseous, partly calcareous, material. The walls are composed of

deeply pigmented fibrous tissue, which, by its contraction, has caused a puckering of the thickened pleura at the surface. The pleura is thickened over the whole lung, and the two lobes are firmly bound together. A few firm fibroid nodules are to be seen scattered throughout both lobes.

13. Typical case of phthisis. Chronic fibroid phthisis at the apex; thickened pleura and septa. Small cavities with fibroid, deeply pigmented walls, little normal tissue left; base consolidated, catarrhal and caseating pneumonia well marked; a few masses of racemose tubercle throughout the lobe. There is evidently considerable congestion in the lower portion of the lung.

14, 15, and 16. Similar specimens from other cases.

17. Stonemasons' phthisis. Lung much consolidated; pleura enormously thickened; lobes adherent; several cavities with thickened fibrous and pigmented walls; nodules of chronic fibroid thickening, firm at the margin, frequently deeply pigmented, and in some cases caseating in the centre; septa thickened. The glands at the root are enlarged, dense, and fibrous; medullary portion deeply pigmented; cortex free from pigment.

18. Section of coal miner's lung with thickened pleura. Small, deeply pigmented, fibrous nodules, paler in the centre, darker at the periphery; no cavities. The distribution of the pigment in the deep layer of the pleura, the interlobular septa, and the lymphatics around the vessels and bronchi is here well seen.

Other specimens of pulmonary infarction, tubercle of the liver (acute miliary in the tissue of the portal spaces, and caseating tubercle affecting the bile ducts), waxy sago spleen, showing localisation of the disease in the Malpighian bodies, old infarction of the spleen, in which a fibrous and contracting capsule around the caseating or softening central mass is well seen; waxy kidney (large and small forms), granular contracted kidney, waxy liver, cancer of the lung, etc., were exhibited.

A METHOD OF EXAMINING AND REMOVING THE SPINAL CORD FROM THE FRONT.

By THOMAS HARRIS, M.D.LOND., M.R.C.P.,

Pathological Registrar to the Manchester Royal Infirmary; Assistant Lecturer and Demonstrator of Pathology in the Owens College; and Assistant Physician to the Manchester Hospital for Consumption and Diseases of the Throat.

THE method of examining and removing the spinal cord which is adopted in the majority of the pathological departments of the hospitals of the United Kingdom is by means of a median incision along the posterior aspect of the body, the laminae of the vertebrae from the cervical to the lumbar region being subsequently removed with the aid of a saw, or of a saw assisted afterwards by a strong pair of bone forceps. In the majority also of the German universities a similar method is employed. However, as far back as 1863, Professor Brunetti, of Padua, published an account of a method which he had introduced for removing the cord from the anterior aspect of the body by means of specially constructed chisels, with the aid of which he removed the bodies of the vertebrae, and so exposed the interior of the vertebral canal. This method has been employed in the Pathological Institute at Vienna for the past fifteen or twenty years, and having heard very favourable accounts as to the advantages of the method, I took an opportunity last autumn of visiting Vienna, chiefly with the object of becoming practically acquainted with the details of the process. Since that time, I have adopted it in the *post-mortem* department of the Manchester Infirmary, and finding it most expeditious and in many ways convenient, a short account of the method may not be unacceptable to those who have many *post-mortem* examinations to make, and who have not yet tried it. A brief notice, by Dr. Cayley, of the method will also be found in Quain's *Dictionary of Medicine*.²

The organs in the neck, thorax, and abdomen are first examined, by means of the usual median, incision from the chin to the symphysis pubis, and are all removed from the body, so that the anterior and lateral aspects of the bodies of the vertebrae are exposed along the whole length of the spine. After the exposed parts of the vertebrae have been examined, a wedge-shaped wooden block³ is placed under the body

¹ *Gazzetta Medica Italiana Provincie Venete*, Anno vi, Nos. 17, 18, 19, 20.

² *A Dictionary of Medicine*, edited by Richard Quain, M.D., F.R.S., 1st Edition, page 1020.

³ A convenient block for this purpose is one 12 inches long, 6 inches high, and 6 inches broad at the base.

in the lumbar region, so as to make that portion of the spine arch well forwards. By means of a strong knife the intervertebral cartilage between the fourth and fifth lumbar vertebrae and that between the fifth lumbar vertebra and the sacrum, are divided. For the subsequent procedure we require a moderately heavy wooden mallet, a strong pair of forceps (Fig. 3), and two chisels. The chisels are of peculiar shape, as will be understood from studying the accompanying illustrations (Figs. 1 and 2), it will, however, be unnecessary to enter into a detailed description of them. Each chisel is 14 inches long, and has a cutting edge $1\frac{1}{2}$ inch broad; adjoining the cutting edge is a small blunt projection $\frac{1}{2}$ inch long, which being introduced into the vertebral canal, acts as a guide. One chisel is used for dividing the pedicles of the vertebrae on one side of the body, the other for the pedicles on the opposite side. The only difference in the chisels is that

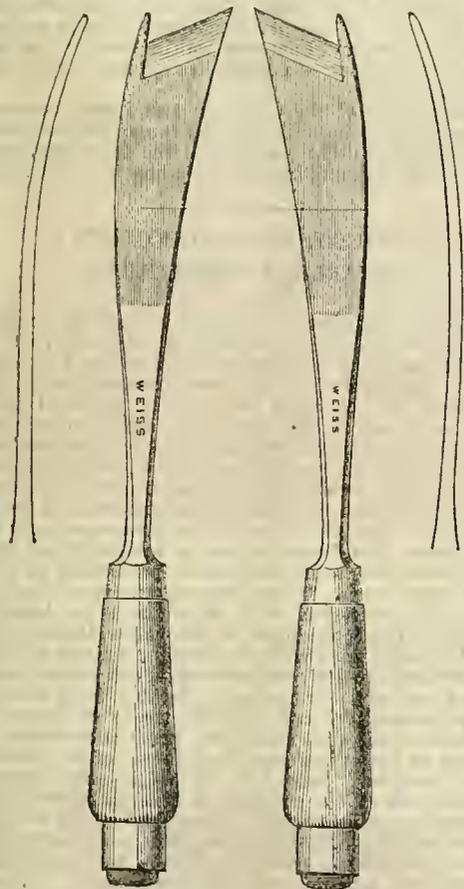

Fig. 1.—Chisel for dividing the pedicles on the left side of the spine. (Surface and side view.)

Fig. 2.—Chisel for dividing the pedicles on the right side of the spine. (Surface and side view.)

which is necessary for their employment on one or other side of the spine.

After the intervertebral cartilage above and that below the fifth lumbar vertebra have been divided, the intervening vertebral body removed by chiselling through, with the aid of the chisels and mallet, the pedicles of that vertebra, one chisel (Fig. 2) being used for the right pedicle, the other (Fig. 1) for the left pedicle. After the pedicles have been divided, the body of the fifth lumbar vertebra is very easily removed by seizing it with the forceps (Fig. 3), and using a knife to free it from any surrounding soft structures.

The dura mater covering the corda equina is thus exposed for a short distance, and the whole of the vertebral canal may now be opened by chiselling through the pedicles of the vertebrae, or, where that is not readily accomplished, as in the dorsal region,

through the posterior part of the bodies of the vertebrae. It is, however, impossible to divide these parts from the lumbar to the upper cervical region, firstly all along one side and then all along the other: it is necessary to divide the pedicles of only four or five vertebrae on the right side with one chisel, and then the pedicles of the left side of the same vertebrae with the other chisel, after which the intervertebral cartilage above the body of the vertebrae (the pedicles of which were last cut through) is divided, and the bodies of the separated vertebrae being seized with the forceps are removed. The wedge-shaped block of wood is now moved a few inches higher, until it is placed beneath the vertebrae of the lower part of the dorsal region, so as to make those project well forwards. The pedicles of four or five more vertebrae are then divided by means of the chisels and mallet, and after the intervertebral cartilage above them has been divided, the bodies of those vertebrae are removed. Then the block is again moved upwards a few inches, and four or five more vertebral bodies removed in a similar manner, and so on until the base of the skull is reached. By this means the dura mater is exposed from the occipital foramen to the lowermost part of the lumbar region, and if the operation has been done carefully, both it and the enclosed cord are uninjured. In using the chisels it will be found necessary to keep the cutting edge nearly horizontal when working with them in the lumbar and dorsal regions, but in the cervical part it should be held obliquely or nearly vertically. Although not absolutely necessary, an assistant will be found very useful in seizing the vertebrae with the forceps and pulling them forwards away from the vertebral canal, when the operator is using either of the chisels.

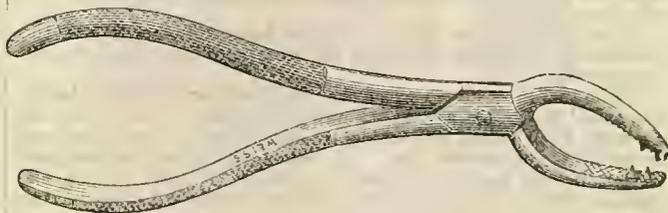

Fig. 3.—Forceps for removing the bodies of the vertebrae after the pedicles have been divided.

After the vertebral canal has been exposed, the external aspect of the dura mater and its surrounding structures are examined. That membrane and the nerves of the corda equina are next divided at the lowermost part exposed, and, together with the spinal cord, removed by dissecting from below upwards from the vertebral canal. The dura mater is then laid open by means of scissors, and the spinal cord examined in the usual way.

There are several advantages in this method of removing the spinal cord. We avoid all necessity for an incision along the back; the only incision into the skin of the trunk is the usual median one along the anterior aspect of the body. The corpse is consequently not so much disfigured, and we avoid the labour of extra stitching. The method is more expeditious, and involves less labour when the operator has had a little experience of its details. This, however, is not the case at first. The majority of beginners will probably find it hard work, and I must confess that my first two or three attempts caused me some little disappointment, as I found the chiselling really hard labour. When, however, one has done the operation a few times, it is easily and quickly accomplished. That it is much more rapidly carried out than the method of opening the canal from the dorsal aspect is sufficiently testified to by the fact that it is the only method employed in the Pathological Institute of Vienna, where they have so many *post-mortem* examinations to make that an expeditious method is indispensable. In Vienna it is carried out by the *post-mortem* room porters, who accomplish the task in a wonderfully short time. By this method also we obtain a much better view of the spinal cord and spinal nerves, and can more readily localise any lesion in the cord, so as to state exactly the relation of the lesion to any particular part of the vertebral column.

As will be surmised, the removal of the bodies of the vertebrae renders the corpse very limp, much more so than when the spinal cord has been removed from the dorsal aspect. This, however, is but a very slight drawback to the method, since it requires but the exertion of a small amount of ingenuity to render the body

rigid by means of a broom-handle or piece of iron tubing. Even that, however, is unnecessary, as with care the body can be placed at once without difficulty into the coffin.

The method is one which I believe will be much more frequently employed in the United Kingdom when it becomes more fully known than is the case at present.

The chisels and forceps are now made by Messrs. Weiss and Sons, Oxford Street, London, to whom I am indebted for the accompanying illustrations.

A CASE OF HYSTERO-EPILEPSY OF TWENTY YEARS' DURATION, TREATED BY REMOVAL OF THE UTERINE APPENDAGES.¹

By FRANCIS IMLACH, M.D.

OF the treatment of various neurotic pathological conditions by removal of the uterine appendages I have little knowledge and less belief. By a curious coincidence, two entirely different motives appear to have suggested this much discussed surgical procedure almost simultaneously to men of different bent of mind. One motive may be termed transcendental, hypothetical, doubtful; it is determined by the belief that certain untoward neurotic manifestations depend upon morbid ovarian activity, and may be cured, and can only be cured, by removal of the ovaries. The other motive is commonplace, obvious, sure; namely, that disturbing, disabling and often more dangerous and even fatal conditions, due to acute or chronic inflammatory diseases of the uterine appendages can only be relieved, and ought to be relieved, by removal of the diseased parts.

It is by the latter motive I have been influenced, and the greater my experience becomes, the more convinced I grow of its soundness.

While in Tenby, however, at the new year, Mr. Beamish Hamilton asked me to see a hystero-epileptic patient, who might, he thought, be benefited by surgical treatment, and whose record may be useful at the present time. She was aged 40, and had been bed-ridden for the past nine years. At 20 or 21 years of age she became subject, she said, to epileptic fits, which had continued to the time I saw her. Indeed she appeared to have become bed-ridden almost as much from the increasing severity and frequency of the fits as from pain; her fits generally recurred three or four times in the day, and it was rare to pass a week with so few as four or five fits. She was always unconscious for ten or twenty minutes during a fit, but did not sleep heavily after it. Having been in five different hospitals, special and general, for periods varying from six weeks to four months, without relief, she had given up expectation of cure, and Mr. Hamilton informed me that bromides and other nervines appeared entirely useless.

It was plain, upon examination, that the Fallopian tubes were greatly distended, and I therefore advised their removal. Menstruation was very profuse, and there was great pain; my opinion was formed regardless of the neurotic condition which now, however, induces me to record the case in detail. At 28 years of age she married, and had a child, which died two years later. I have no record of the condition of the uterine appendages previous to this.

As I was unable to remain at Tenby, she was brought to Liverpool, entered my private hospital on January 10th, and four days later I removed her uterine appendages. It was a case of double hydrosalpinx, with extremely cirrhotic and shrunken ovaries. The right tube contained half a pint of serous, shreddy fluid, and the left about half an ounce. The left ovary was no larger than a dried split pea, and the right ovary about double that size (specimens shown). While being anaesthetised she had a prolonged and rather alarming fit; she became suddenly unconscious, her lips turned blue, respiration was arrested, and her back became strongly arched. An hour after the operation, which lasted only a few minutes, she had a similar attack, and, to our disappointment, a week later she had another, but no more.

On February 15th, being able to walk alone, she returned to Tenby, and the following letter was received on March 18th from her medical attendant, Mr. Hamilton:

"Tenby, March 17th, 1888. Dear Dr. Imlach.—In reply to your letter of queries about Mrs. B., she has been practically bed-

ridden for the past twelve years, since her 29th year, and has passed through the hands and treatment of many medical men, without getting the smallest benefit. Eight years ago she was kept upon her back for three months in the — Infirmiry, and treated with pessaries, etc.; twelve months ago she was treated in the — Hospital with stem pessaries, etc., but without relief. For the past twenty-one years she has suffered from epileptoid seizures, accompanied with marked arching of the spine at the commencement of the attack, insensible for periods varying from ten to twenty-five minutes, for which she came under my treatment about eight months back; but nothing I could do seemed to mitigate them, and they were increasing in frequency and duration, when she had the good fortune to fall into your hands. Since her return home there have been only two fits of any severity, and they seem now to be amenable to bromides. Seven weeks from the day of operation she had a spurious menstrual flow, which lasted for five days. This made her nervous, and I think was the cause of the fits mentioned. She is eating well, her back-pain is gone, and I am only waiting for the fine weather to send her out of doors.—In great haste, yours very faithfully, BEAMISH HAMILTON."

As a primary result of the operation this is very encouraging. Had this treatment been carried out years ago, the patient would probably have been a useful housewife, free from pain, and a fit companion to her husband, in place of a hopeless and expensive invalid.

PRACTICAL ANTHROPOMETRY.

By CHARLES ROBERTS, F.R.C.S.

I HOPE that the suggestion thrown out by Dr. Stone in his Harvardian Oration that "medical physics" shall form part of the science to be taught in the proposed laboratory for "scientific purposes" to be attached to the new Examination Hall of the Royal Colleges, will be acted on, and that practical anthropometry will form part of that important branch of the medical man's education. Anthropometry, or "man-measurement," strictly speaking, is a branch of human anatomy, and deals with the body as a living organism, while the anatomy taught in our medical schools deals only with the structural arrangement of its several parts; and it is obvious that if our students were properly taught, their first lesson should be to acquire a knowledge of the physical characters of the whole body before proceeding to study its elementary constituents. It is necessary, moreover, that, in order to practise his profession with satisfaction to himself, his patients, and, in public medicine, to the public, that the medical man should be acquainted with the normal condition of the body, and the variations in its conformation which result from race, sex, age, and sanitary surroundings. Besides being a branch of anatomy, anthropometry is a valuable means of diagnosis, not only for defining diseased conditions, but the influence of external agents on the growth and development of the whole body, or some of its organs. Indeed, in its widest sense diagnosis is anthropometry, for all our attempts at differentiation of diseases are measurements of either time or space, and all our instruments, whether for pathological or physiological investigation, are anthropometric instruments when applied to the investigation of the anatomy and functions of the human body. "The indispensable part of the experimental observation of physical facts is the measurement of quantities," says M. Henri Martin in his *Physiques*. "All physical objects are extended, and consequently measurable, though they may not always be measurable by the methods and instruments we possess; and all physical phenomena take place in periods of time susceptible of measurement, although some of the measurements are imperceptible by our senses. The right method as regards all these phenomena," he goes on to say, "is that taught by Galileo, to measure all that is measurable, and to endeavour to render measurable all that is not directly so." But while claiming for anthropometry this relation to medical physics, and thereby securing its recognition as an essential element of that much neglected branch of medical study it is desirable in these days of the division of labour to confine the sphere of anthropometry to the study of the physical characters or qualities of the body, and to leave the subjects which have hitherto been included in the provinces of physiology and pathology, such as the functions of the senses and other obscure physico-psychological phenomena, which, though measurable by suitable instruments, can only be properly studied by persons

DR. W. HOWSHIP DICKINSON'S LUMLEIAN LECTURES ON THE TONGUE AS AN INDICATION OF DISEASE.

who are acquainted with the minute anatomy of the body and of the various imperfectly, as yet, understood functions of the nervous system.

I mention this here because I fear that practical anthropometry, generally understood on the Continent and America, as well as in this country, is likely to suffer from a series of ingenious inventions manufactured and sold by the Cambridge Scientific Instrument Company, and advertised in the columns of the JOURNAL as anthropometric apparatus. Now the instruments required for recording the purely physical qualities of the body, that is to say, the stature, the length, breadth, circumference, and thickness of different parts of the trunk and limbs; the weight, strength, and breathing capacity; and of the complexion, as distinguished by the colour of the hair, eyes, and skin, are few in number and inexpensive, and consist of a pair of ordinary callipers, two or three light modifications of the shoemaker's rule, a measuring rod and scale, a weighing machine, one or two dynamometers, and a spirometer. Not only does the catalogue of the Cambridge Company contain instruments of this description, but many others for testing the keenness of eyesight and appreciation of colour (not the means as have been perfected by ophthalmic practitioners); keenness of hearing, and appreciation of musical pitch; and the numerous qualities of the senses and the mind which are largely, not entirely, the result of education and individual experience. Such as "judgment of the eye [mind?] as regards squareness and angular division; judgment of the eye [mind?] in estimating the vision of a line; reaction time to sound and sight; appreciation of slight differences of weight." These are doubtless interesting objects of inquiry, but they are not anthropometric inquiries in the sense in which the word is generally understood, and to which I think it is desirable to restrict it.

I am inclined to think, moreover, that Mr. F. Galton, who has designed these instruments, does not see what complicated problems he is asking us to investigate under such an apparently simple question, as, for instance, "the judgment of the eye as regards squareness." An instrument for this purpose might serve a rough way to distinguish between an artist and a barrister, an artisan and an agricultural labourer; but between two persons of equal training and experience the test would be one of the different amount of astigmatism in the two persons under examination. Similar objections occur to me with regard to some of the other instruments in the catalogue; but my object is not to criticise them, but rather to point out to the members of my profession the proper sphere and the practical utility of anthropometry as generally understood and as was understood by Quételet, who invented the word to cover the series of inquiries which he carried out on the human body, and which are recorded in his work entitled *Anthropométrie ou Mesure des Différentes Cultés de l'Homme* (1870).

When I published my *Manual of Anthropometry*, in 1879, I was soundly rated by the *Lancet* for making such free use of Quételet's observations, but it would be just as reasonable to rate Bain and Gray for appropriating the labours of previous anatomists. Although anthropometry has existed in a slipshod manner for many centuries among artists and sculptors, it was Quételet who first reduced it to a scientific form and applied it to scientific uses; and it is desirable, if any progress is to be made in the same as in other sciences—and especially in those which, like anthropometry, so largely depend on collective investigation—that changes in its methods of procedure should not be made without very grave reasons.

Unfortunately for the stability of the science of anthropometry, Quételet was a mathematician and an artist, and not an anatomist, and he gives us in his book only the results of his anthropometric observations, and not the method by which he obtained them. He dealt with the subject as if he had exhausted it, as indeed, for scientific purposes, he very nearly has done so. It is when we come to try to apply his method to the distinctions of the races of man, to medical, sanitary, and other scientific uses, that it fails us, simply because he has not defined the conditions under which his observations (mostly made by his medical friends) were made, and was for the purpose of defining these conditions that my essay was published, and this only after a translation of Quételet's work, with the necessary notes, was refused by the Sydenham Society. I mention all this because I wish to impress on everyone who takes the subject of anthropometry that it is better to get some results by methods which have been found to work fairly well, than to be constantly tinkering the methods and obtaining no results but disheartening others of a less critical turn of mind. *Ars longa,*

vita brevis is a motto especially applicable to this subject. While we are inventing instruments and illustrating mathematical problems by our miserably small collection of anthropometric observations, the French are applying the science in its simplicity to the identification of criminals, the Germans to the differentiation of races, and the Americans to the results of gymnastic and athletic exercises, and to all of them anthropometry has become serious everyday duty and study—as serious, to compare large things with small ones, as the study of micro-organisms is with ourselves. Sufficient work has, however, been done in this country to form a basis for more and better work in future, and sufficient has been done, especially in differentiating sanitary conditions such as the influence of occupations, food, social status, etc., and of the racial elements of the population, to promise great results if the methods of anthropometry we already possess were recognised, and their practice properly encouraged by the Colleges of Physicians and Surgeons and the medical schools.

Simple and easy as anthropometry is in practice, its application to the solution of racial, physiological, and sanitary questions is so wide and comprehensive, that it is hardly within the power of individuals to carry it out. Quételet first described the method but he shrank from the labour it involved, and instead of measuring men, women, and children by thousands he measured them by tens, and so missed seeing some important facts in relation to sexual and racial differences which have since been discovered. Dr. Beddoe has spent a lifetime in collecting anthropometric data for differentiating the racial elements of our British population. Professor Bowditch has with much labour discovered by anthropometric observation the difference in the rate of growth of the two sexes.

Mr. F. Galton has illustrated in a similar way some important facts relating to the hereditary transmission of physical characters, and I have endeavoured to establish standards for comparison, and to define some of the results of the "conditions of life" on the development of the body, while in another field Hutchinson's investigations have become classical.

But not only does all this work want revising and extending, we want also a profession which can understand and appreciate its value, which we have not got at present, and which, I fear, we never shall have till the heads of the profession, as represented by the colleges and schools, recognises its importance as equal at least to those of comparative anatomy, chemistry, and botany, and, indeed, as superior to them in its educational value, the mathematical and statistical accuracy which anthropometry demands being of supreme importance as a check on the imagination of the student, and a suitable training for other investigations necessary to the progress of medicine and surgery in our day.

HOW TO REFORM THE DENTAL DEPARTMENTS OF OUR HOSPITALS.

By F. NEWLAND PEDLEY, F.R.C.S. AND L.D.S.,

Dental Surgeon and Lecturer on Dental Surgery to Guy's Hospital.

THIS is a problem I took in hand at Guy's Hospital, and now that the experiment has resulted well and nearly two years have been allowed to lapse as a time-test, I bring the matter forward in the hope of inducing other hospitals and other dentists to adopt necessary changes.

I do not advocate that each medical school should be a school for dental students; at present this is impossible. Let dental students seek special training at special hospitals, but those who hold the dental surgeoncies to hospitals should show their operations and the scope of their subject as the other specialists do. The status of dental surgery, though improved, is far from what we would see it, and from what we think it deserves. What can be more damaging to our profession, which, above all, rightly claims to be a branch of surgery, than the lamentable fact that medical men so frequently feel obliged to admit utter ignorance of the subject? Hence it becomes a frequent source of complaint amongst dentists that the importance and value of their work is inadequately appreciated, and the medical fraternity is blamed for possessing little or no knowledge about teeth. The work done at the dental hospitals is admirable, but busy medical students cannot give the time to attend there, and they go into practice with the idea that the extraction of teeth and their replacement artificially form the limit of our practice and science.

The fault lies with those dentists connected with hospitals who

do not take practical means to dissipate this illusion. The position of ophthalmic surgery would not be what it is if the eye-surgeons treated every hospital case by excision of the eyelid. The schools would condemn such teaching and practice as a barbarous exhibition of bad science.

If each hospital dentist devoted one sitting a week to extractions, and one sitting to the other operations of dental surgery, the difficulty would be overcome. No one is called upon to treat all the diseased teeth of his district, but it does not follow that nothing whatever should be done or taught. I do not consider two sittings a week too large a demand upon the time of those who occupy the responsible position of connecting link between dentistry and surgery.

I will now briefly run over the arrangements made at Guy's Hospital. There are two dental surgeons' dressers; they hold office for two months. A fresh dresser is appointed each month, who becomes "senior" during his second month of office. The dressers attend daily at 12.30 to see out-patients. In very urgent cases they are at liberty to give "gas," but of course the administrator must be a qualified man. General practitioners are very frequently asked to give "gas" for dentists, and it is to be regretted that they so often find themselves lacking in practical knowledge upon this subject.

At first I had to do nearly all the extra work of the new department myself, owing to the absence of my then senior colleague, Mr. Moon, but of late I have had the assistance of a present student, Mr. Wynne Rouw, an ex-house-surgeon at the Dental Hospital of London. He attends on Tuesdays at 1.30, and I on Thursdays at the same hour for out-patients, and these are our afternoons for gas extractions and surgical cases. Nitrous oxide gas should be given as a matter of routine in our severer operations, and in the numerous cases where the health of patients renders them physically incapable of enduring pain without severe suffering. An anæsthetic so safe should always be at hand, and I am more suitable for many patients in the wards of the hospital than ether or chloroform when a tooth has to be removed. On Friday afternoons at 1.30 we both work, doing anything except extractions. It is on this afternoon that we see patients under treatment for fracture of jaw and children wearing regulating plates, and we frequently have cases where plates are required to restore parts removed by operation for surgical diseases. All such patients are supplied with mechanical appliances and plates, for which the hospital pays the senior dental surgeon £40 a year. I am informed that this sum represents an equivalent fixed by Mr. Salter. The rest of our time on Friday is devoted to "stopping," including gold.

It is a mistake to suppose that medical students are not interested in even tedious operations. I have had abundant proof of how keen an interest they take in our work, and have been astonished at what good men apply for dental surgeon's dresserships. At one time I had an ex-house-surgeon as senior and a F.R.C.S. as junior dresser. Advanced students do not require much teaching, and I am not sure to what extent their services might not be available in filling simple cavities with "plastic" stoppings. That aspect of the subject I will pass over as "not proven." Suffice it to show what work can be done by two dental surgeons, and how. The time may come when we may be able to cope with all the decayed teeth that require attention, and I will admit that the question is one of national importance, which may some day affect the supremacy of the Anglo-Saxon race, and I quite sympathise with those who would demand State aid for dental hospitals, and that in the army and navy, and wherever medical supervision is provided, salaried dental appointments should be invariably added. But at the present time these considerations must be deferred, and what dentists have first to do is to educate the medical profession, and through them the laity, in the merits and bearing of their science.

Those who are opposed to those suggested changes in our hospital practice plead that they could not devote the time to the increased work. In the first place, I only suggest two attendances a week for each dental surgeon, and one cannot say that is an excessive claim on their time, or that it reaches the average period spent in the hospital by the dentist's colleagues. Granted, metropolitan schools are undermanned as regards dentists. Such important hospitals as London, St. George's, University, King's, and Charing Cross, have only one dental surgeon each. If these need aid they can ask that assistant dental surgeons be appointed. There are young men available for future appointments ready to devote part of their time to a hospital, and to rise thereby in a

way usual amongst members of a staff. If possible, the "assistants" should hold independent appointments, as at Guy's. The *Medical Directory* shows that there are in London 86 "hospitals" and 67 "dispensaries." Some of the latter are very large, and one shows an annual attendance of 24,000 patients. We know it is the exception for a London hospital or large dispensary to be without an appointed dentist. This gives an idea of what could be done if each dentist attended twice a week, and reserved part of his allotted time to operations other than the extraction of teeth. It is a noteworthy fact that some dentists hold two appointments, and I may be permitted to add that I resigned my post on two hospitals in order to devote adequate attention to one.

The matter of necessary funds should be considered, although, to avoid probable delay and obstacles in what had something of the nature of an experiment, I made the additional expenses at Guy's a personal affair. Accepting £40 a year as the equivalent of the "artificial work" done, I should estimate the cost of "gas" for the past year at £50, and the instruments, stoppings, etc., about £30. Thus I judge the expenses of the department are at present about £120 per annum. With the result of my experiment I am satisfied, and do not desire any alteration of existing conditions as affects myself; but I am of opinion that, when new dental appointments are made by hospitals requiring efficient dental departments, the cost of the instruments, materials, etc., should be defrayed by the institutions benefited. If the dental surgeons were to express willingness to do the better work, and the hospitals were to decline to provide the expenses, the onus of bad dental departments would be entirely thrown upon the authorities. But there is now a great competition amongst the hospitals, each vying with the other as to which shall have the most complete administration and the best teaching, and as they undoubtedly wish to improve their dental departments, I have yet to learn that they will demur to furnishing the means. At St. Bartholomew's all the working expenses are supplied at the cost of the hospital, and an annual sum of £250 is divided amongst the four dental surgeons appointed, made up thus: the Treasurer pays £50 a year to each senior, and £25 to each junior; and the school pays an additional £25 a year to each of the four. On the one weekly occasion when each senior attends he is assisted by his corresponding junior, and between them they see twenty or thirty patients, and they do what they can to preserve some of the teeth at this sitting by stopping. Having so many patients to see, many of whom require gas, it is obvious that little can be done in the way of stopping. I recently made a formal visit to St. Bartholomew's the day when my friends Mr. Paterson and his junior, Mr. Ackery, were sitting. They did not profess that their stoppings done under such conditions were up to the standard of their work in private practice, and no gold fillings were attempted. Each assistant also attends three times a week for extractions. The assistant dental surgeoncies are dependent appointments.

There is, of course, an advantage in numerical strength, though it leaves them still hopelessly unable to cope with even a small percentage of their cases. And there is this drawback: such a corps could not expect to be placed on the staff of the hospital, and, in fact, no dentist at St. Bartholomew's has a seat on the staff committee. The number seems to me more than sufficient for the requirements of a general hospital and school for medical students, yet insufficient for a dental hospital and school for dental students. Such a staff of dentists could well afford to keep their extraction cases separate from their other operations and could then do their best work. They are, however, utterly unable to give dental students the practice and teaching offered by the dental hospitals, as a cursory visit to one of those institutions will show. Yet, London, St. Bartholomew's, and some other hospitals have the right to sign-up dental students for the dental practice required by the College of Surgeons. This privilege, never exercised, imposes a grave responsibility on the dental department of such a hospital. London Hospital, in its Calendar, says: "The attention of dental students is particularly directed to the fact that the Council of the College of Surgeons recognises the dental department of the London Hospital as a school at which may be obtained the dental practice necessary to qualify a student for the examination for the dental diploma."

In the foregoing sketch I have tried to show how a creditable dental department can be carried on by two dental surgeons, and at very moderate cost. Doubtless other hospitals will take the matter up, and will see that dental surgery is duly represented amongst the special branches of surgery.

SURGICAL MEMORANDA.

COCAINE IN TRACHEOTOMY.

SINCE the introduction of cocaine, neither I nor my colleagues at the Central London Throat and Ear Hospital have employed chloroform when performing tracheotomy, but have in substitution injected five minims of a ten per cent. solution of cocaine on each side of the immediate region at which the trachea is to be opened. Ten to twelve minutes have been allowed to elapse before commencing an operation, and in the majority of instances pain has not been felt even from the first incision through the skin. Local anæsthesia has been maintained sufficiently long to allow of a careful and leisurely performance of the operation, without, however, encouraging that undue tediousness against which Mr. Christopher Heath has recently spoken so opportunely, as a besetting fault of modern surgeons who operate under chloroform.

My experience with cocaine in tracheotomy would be represented by about forty cases; we have had twenty in the hospital and in my private practice during the last year. I have witnessed its good effect especially in the last fortnight, during which time I have had occasion to perform the operation four times, all the cases being on account of cancer, and occurring in patients aged 75, 58, 77, and 54 respectively.

Beyond the advantages of cocaine as a local anæsthetic, this remedy so applied has the effect of depriving the part of blood, and thereby diminishing hæmorrhage during the operation, whereas with chloroform and ether the contrary effect is often produced. It also quiets the breathing and steadies the larynx in cases in which respiration is seriously hurried. In only one case have I seen any toxic action, and that was at once remedied, when the trachea was opened and a full flow of air admitted into the lungs.

LENNOX BROWN, F.R.C.S.Ed.

Weymouth Street, Portland Place.

TREATMENT OF CARBUNCLE.

THE treatment of carbuncle by erosion, as now advocated, is no doubt speedy and effective, but seems severe for ordinary cases. I have been for some years in the habit of treating carbuncle by injecting three or four times a day a solution of a drachm and a half of carbolic acid in eight ounces of water, by means of a small glass syringe. This can be done as soon as an opening, however small, appears. If there is more than one opening, the fluid injected will pass out through all the other apertures. After syringing I apply a small fold of rag soaked in the carbolic lotion, and over this a warm linseed poultice.

I advise a good diet, stimulants in strict moderation, and sometimes a course of the sulphide of calcium. Under this treatment the slough at once ceases to extend, and is soon washed away in shreds by the injections, and the swelling and hardness rapidly disappear.

I have hitherto had no case that has not yielded rapidly to this simple and rational mode of treatment, which I have no doubt has often, with whatever modifications, been adopted by many others.

HENRY LOWNDES, M.K.Q.C.P.I.,

Consulting Surgeon Northern Hospital.

Liverpool.

THERAPEUTIC MEMORANDA.

ACETIC ACID AND ERGOT.

SINCE Dr. Grigg called attention to the value of vinegar as an æbolic, I have frequently used it for that purpose. And I have also found that four drops of the strong acetic acid (representing nearly half a drachm of vinegar) combined with strychnine has been successful in bringing about contractions of the uterus after ergot had failed. In one noteworthy case where in a very weak and anæmic woman the pains, after continuing feebly for a day or two, seemed to be leaving her, and ergot had been exhibited (the waters having broken), I found acetic acid and strychnine produce sharp and effectual pains.

The same thought, therefore, occurred to me as to Dr. Francis, of the possibly good results of combining it with ergot, and, in addition, observing that acetic acid could extract the active principle from colchicum and ipecacuanha, I asked Messrs. Corbyn to make a preparation of ergot, using acetic acid as a menstruum, with a standard surplus of free acid. In a short time I received

from them two samples, one of ergot extracted by acetic acid, of which a fluid drachm represented sixty grains of ergot with ten minims of free acid; the other an alcoholic extract of ergot, which also represented sixty grains of ergot and ten minims of free acid in each drachm.

Both preparations had the colour of the ordinary extracts, but the acetic acid frothed when shaken, which, of course, the alcoholic extract did not do. The acetic acid process should be more economical than the spirit method.

In a case where there was retained discharge after labour I gave some of this extract, and when the medicine was exhausted wrote a prescription for a similar dose of *B.P.* extract, to which I also added some bromide of potash, which is stated to aid the involution of the womb. The case was still unrelieved on my next visit, the uterus being obviously distended, so, after syringing out the cavity, I told them to have the medicine made up again, when the patient said, "Oh, sir, the medicine you gave me at first brought away something every time, but this medicine has done no good." This seems like a comparative test in favour of the acetic extract.

In a case of flooding, due to a large fibroid, I found that twenty minims injected deeply into the buttock gave rise to no local irritation, and there was no bleeding the night following, but there needs further experience before attributing this result to the drug. Ergotine discs did not always control it.

CARBOLIC ACID IN PERTUSSIS.

THE results of the following four cases of whooping-cough treated by glycerine of carbolic acid of the *B.P.* may be of interest. I give them in the order in which I find them in my casebook, without comment.

1. G. W., male, aged 7 years, suffering from whooping-cough, with roughened breathing over right apex, but otherwise healthy, had a week before I saw him; given 2-minim doses of glycerine of carbolic acid in simple syrup every third hour: distinct improvement on third day; cured in two weeks from beginning of treatment. Carbolic acid given only every fourth or fifth hour on second week; no other treatment; no complications.

2. F. W., female, aged 2 years, similarly affected, had six days before treatment was adopted; given 1 minim of glycerine of carbolic acid in tr. gent. co. No improvement till fourth day, when patient retained nourishment on the stomach, which she had not been able to do for some days previously owing to the severity of paroxysms. The cough gradually disappeared, and the little sufferer was all right in seventeen days.

3. C. W., female, aged 4 years, got $1\frac{1}{2}$ minim of glycerine of carbolic acid every third hour; progressed favourably till twelfth day, when she had a rigor. On examination of chest next day, there were well-marked evidences of croupous pneumonia over right lung. Continued glycerine of carbolic acid every second hour. Worse next day. Vin. ipecac. and spt. am. arom. added. Complained of pain in stomach and soreness of throat on following day; carbolic acid stopped. On seventeenth day seemed better, but left lung affected similarly to right. Died on sixth week from onset of double pneumonia.

4. J. B., female, aged 14 months, also suffering from capillary bronchitis; fifteen days bad before seen; $\frac{1}{2}$ minim of glycerine of carbolic acid administered every third hour, in combination with tr. senegæ. All right in three weeks; no other treatment adopted.

Medical Officer, Forns District.

SALIX NIGRA.

DR. J. HUTCHISON, Glasgow, in the *JOURNAL* of February 13th, draws attention to the adulteration of salix nigra by elm bark, but a more probable and less easily recognised form of adulteration is that by salix phylicifolia L. (the ten-leaved willow). To discriminate between the two in the dried state is simply impossible; only a very experienced botanist can say which is *S. nigra*, and that only by examining the fruit or drying the leaves, those of nigra always turning dark. For this reason, I doubt if ever there has been a pound of genuine *S. nigra* bark in the market, the common *S. phylicifolia* being usually so named.

The trees under consideration differ so slightly from one another that most botanists consider "nigra" but a form of the other. There is, on that account, probably but little difference in their medicinal virtues if they possess any special virtues at all. In the

fresh state "nigra" possesses more tannin, and the leaves and shoots possess some form of albuminous matter, only present in the very young leaves.

I trust some of your readers will be able to throw more light on the doubt here raised.
ANSTRUTHER DAVIDSON, M.D.
Sanquhar, N.B.

CARBOLIC ACID IN NASAL CATARRH.

LAST summer I prescribed, for a gentleman, the mouth lotion as follows: B Acidi carbolici. ℥iv; spt. chloroform. ℥iij; tr. myrrh. ℥ij; eau de Cologne ad. ℥vj. This of course to be used with water.

Suffering severely from nasal catarrh, he consulted an eminent throat specialist, who ordered some powder to be sniffed through the nostrils. This treatment he continued for the prescribed time without benefit; so he tried my mouth lotion, and putting a few drops of that into about an ounce of water, sniffed it up instead of the powder; this immediately and completely relieved every symptom of the troublesome complaint. The watery discharge and the constant sneezing ceased, so also did the distressing pain in the frontal sinuses and nasal passages.

I suppose that in this case the disease is due to the development of germs, which are completely destroyed by the carbolic acid. It would be interesting to find out whether some severe cases of hay fever would be cured by similar treatment; but, instead of using the somewhat clumsy contrivance of a tube, I would suggest a spray apparatus.

Wimpole Street. NATHANIEL STEVENSON, M.R.C.S., L.D.S.

PHENACETINE.

WILL you permit me to call the attention of the profession to a new antipyretic and antineuralgic agent, called "phenacetine," though, correctly speaking, it bears the chemical name of paracetphenetidin, the formula of which is $C_9H_9 \begin{cases} O.C_6H_5 \\ NH(CO-CH_3) \end{cases}$.

It can be given with perfect safety in doses of from eight to twelve grains every four hours. Phenacetine is a febrifuge which compares favourably with any of the modern antipyretics in the certainty of its effects and freedom from evil consequences. In fevers its administration is followed by relief of the symptoms; and in sciatica, in which I have employed it very frequently, its utility cannot be overrated.

Phenacetine is a white, crystalline powder, soluble with difficulty in water, but easily so in hot alcohol.
ROBERT BELL, M.D.
Glasgow.

PATHOLOGICAL MEMORANDA.

CONGENITAL UMBILICAL HERNIA.

MRS. S., aged 32, primipara, was delivered at term, after normal labour, of a male child, which presented the following condition of parts:—On a level with and a little to the right of the umbilicus was an opening about two inches in diameter, through which protruded the caecum, ascending and greater part of transverse colon, much distended with flatus and meconium, and which had evidently severely suffered from uterine pressure, as it was bruised and extravasation had taken place from a few small ruptures. The whole of this hernia lay loose on the child's body, reaching down to the upper part of the thigh. It could not be replaced, nor more bowel withdrawn. The child lived for twenty-four hours. No history of "maternal impression" was forthcoming.

Darlington.

A CASE OF CEREBRAL ABSCESS.

Mr. HORSLEY concludes the narrative of a successful case of trephining for cerebral abscess with a brief reference to fœter of the pus as indicating its connection with otitis media. In this regard it may be interesting to record the fact that only a few days ago I had occasion to make a *post-mortem* examination of a case of cerebral abscess, in which there was most marked fœter of the pus therein contained, although a minute examination of both petrous bones and the cranial wall generally failed to reveal any evidence pointing to the secondary origin of the cerebral

A short note on this drug will be found in the Retrospect for 1887, Art Pharmacology and Therapeutics, p. 1429.

lesion. The abscess was situated in the white substance of the right hemisphere, immediately beneath the "motor area," and extending down to, but not through, the roof of the lateral ventricle.

I may mention that the only other lesions found in the body at all explanatory of the condition were caseation and suppuration of the left bronchial glands, and an acute miliary tuberculosis of the kidneys. By these evidences I was led, though with much hesitation, to conclude that the cerebral abscess had originated in some acute suppurative change in a solitary caseous mass in the right hemisphere.

HOSPITAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN, IRELAND, AND THE COLONIES

ST. BARTHOLOMEW'S HOSPITAL.

EXCISION OF THE KNEE-JOINT FOR OLD DISEASE: ENDS OF THE BONES FIXED TOGETHER BY STEEL PINS.

[Under the care of Mr. MORRANT BAKER.]

(For the notes of the case we are indebted to Mr. RICHARD J. REECE, late Senior House Surgeon.)

THE following case is a good sample of the benefit derived from fixing the bones after the operation of excision of the knee-joint. The method adopted was that to which Mr. Morrants Baker drew attention in a paper published in the JOURNAL of February 12th, 1887.

J. H., aged 32, housewife, was admitted into "Sitwell" ward on March 12th, 1887, suffering from old disease of the right knee-joint. She states that eighteen years ago she knelt on a rusty pin, which penetrated the joint just below, and to the inner side of, the right patella. She pulled out the pin and continued her usual work, although in severe pain. At the end of a week the leg and thigh became swollen and inflamed; there was pain on pressure and insomnia, and on applying to the hospital she was admitted to "Stanley" ward. Shortly after admission the knee-joint was opened on the inner side by an incision an inch and a half long, and some incisions made in the neighbourhood to relieve pain. About a month later the joint was again opened, under chloroform, on the outer side, and still later reopened from the inner side. Patient remained in the hospital six months, and when discharged had no pain, and the limb was nearly straight and she could walk on it.

Until three months ago she had no trouble with the knee, but from that time until the present it has been gradually getting worse, more painful and more flexed, and walking has been only accomplished with great difficulty. The patient was quite willing to undergo amputation if no other means of relief could be afforded.

Family History.—Father and mother died of phthisis. Two brothers healthy.

Present Condition.—The knee-joint is enlarged, misshapen; the leg flexed to an angle of 65° with the long axis of the femur, and rotated outwards. The tibia is displaced backwards on the condyles of the femur. There are three scars, one on the inner side of the leg, 3 inches long by 1½ inch wide; another opposite the centre and lower part of the joint, 2½ inches by 1½ inch, and the third on the outer side of the lower part of the thigh, 3 inches by 1 inch. There are also other small scars scattered about the neighbourhood of the joint. On examining the knee-joint, very slight movement can be detected. The patella situated on the outer side of the external condyle of the femur, and firmly ankylosed—the place where it ought to be feels soft and grooved. Down the inner margin of the tibia for about an inch or two, a nodular condition of the bone is felt, and on examining the site of the large scar on the inner side of the knee, a small nodule can be detected which is very painful on pressure. The knee-joint measures 14 inches in its largest circumference.

Operation.—March 23rd. Ether was administered to the patient and Mr. Morrants Baker performed excision of the knee-joint. An incision was made across the front of the joint commencing on the inner side, and the skin reflected upwards over the patella.

The position of the joint could not be distinguished; what was taken to be the inner tuberosity of the tibia was then sawn off and an attempt made to bring the limb into a straight position; this failing, a portion of the bone from the proximal side was removed with a saw, the section passing through the centre of the patella. A further piece of bone was sawn off the distal end, and removed with the lower part of the patella. The first piece of bone removed was then found to be the inner condyle of the femur. The remaining half of the patella was then separated from the outer condyle of the femur and removed. The limb was brought straight and put up on a back-splint with a foot-piece. There was some bleeding stopped by ligature. The contiguous surfaces of the bones were kept in apposition by two steel pins, inserted into the bones from below, passing through the skin, one on the outer, and the other on the inner side. The skin flaps were sutured by horsehair, and a piece of gutta-percha tissue inserted on each side for drainage. The wound was dressed with "Sanitas" oiled lint, covered by a thick layer of absorbent cotton wool.

March 24th. During the night some pain in knee and heel.

March 25th. Pain relieved by altering position of foot.

March 30th. Urine, drawn off by catheter, contained a trace of albumen.

April 3rd. Can move leg in splint without pain.

April 5th. Wound dressed. The wound has healed by first intention, except for an inch and a half at inner side, and for about half an inch at outer extremity, where tissue has been introduced. All the sutures except three at the inner extremity of the wound, and both pieces of tissue, removed. No swelling, pain, or tenderness around the wound. Wound dressed as before. General condition good; takes food well; sleeps well.

April 6th. Has had difficulty in retaining her urine during sleep, and pain before the act of micturition. Thick sediment of pus in urine.

April 13th. Patient has recovered power over her bladder since the 10th.

April 15th. Wound dressed again to-day. No pain or tenderness in limb, which is in good position.

April 21st. Wound dressed again; looks healthy. Patient can now raise the limb several inches off the bed unaided, and can also rotate the limb without any pain.

April 27th. Mr. Baker removed the back splint and the steel pins. Limb put up on a straight back-splint. Patient feels comfortable. Urine, acid, 1020; no albumen or sugar.

April 29th. Experiences no pain when the sole of the foot is struck with the palm of the hand.

May 3rd. Can raise the limb considerably on the back-splint without any pain.

March 10th. Patient gets about the ward on crutches, not venturing to bear weight on the limb.

March 16th. Leather splint for thigh and leg.

June 1st. Patient went to the Hospital Convalescent Home at Swanley.

On the evening of March 30th the temperature rose above normal for the first time, reaching 99.6°, falling to subnormal next morning, and continuing subnormal until patient left the hospital.

August. Patient has been seen lately, and can walk well with a thick sole to her boot. She is to wear a leather splint round the thigh and leg for some time.

BRISTOL ROYAL INFIRMARY.

A CASE OF INTUBATION OF THE LARYNX IN THE ADULT.

(Under the care of Dr. WALDO.)

[For the report of the case we are indebted to Mr. P. WATSON WILLIAMS, M.B.Lond., House Physician.]

H. S., a married woman, aged 42, was admitted on October 5th, 1887, for syphilitic ulceration of the larynx and bronchitis. She had been ill, losing flesh and getting thinner for the previous twelve months, and had the characteristic raucous voice of tertiary syphilis; the expectoration was mucous; the pulse was 96, and the respirations 22 per minute; the temperature was 101.6° F. Examination of the throat showed scars of old ulcers on the fauces and soft palate, and an old perforation of the velum, all these parts being red and injected. The epiglottis had almost entirely ulcerated away. The ary-epiglottidean folds were red and somewhat thickened, preventing the anterior commissure of

the glottis being seen. Both vocal cords had ulcers on their free margins about a line from the posterior commissure.

The patient did well till October 7th, when she complained of difficulty in breathing and a feeling of obstruction in the chest, not in the throat. Respiration was a little croupy. In the evening Mr. Watson Williams was called in great haste, and found the patient propped up in bed, livid, struggling for breath, covered with clammy perspiration, with a rapid, feeble pulse, and only half conscious. A few whiffs of chloroform were administered, but so little air entered the chest that no more time was wasted in giving an anæsthetic, and the largest-sized O'Dwyer's tube was placed in the larynx forthwith, the silk thread being left attached to the tube. The intense dyspnoea was immediately relieved, and the patient recovered consciousness completely after a short interval of delirium. She was put into a steam bed. The tube was coughed out four hours later, but she asked that it might be replaced; and, as respiration soon became embarrassed, it was reinserted with ease, but was again coughed out in the night. No operative interference was called for after this till October 11th, when dyspnoea once more became marked, and, at the patient's request, she was intubated, but after the tube came out in the course of the day it was not required again. The patient left the infirmary on November 11th, having been perfectly free from respiratory embarrassment for three weeks.

REMARKS BY MR. WATSON WILLIAMS.—One cannot of course argue at length on the merits of intubation in the adult on the strength of a single case, but it is certainly of great moment to adopt such simple measures for the relief of dyspnoea due to temporary obstruction of the glottis, instead of resorting to tracheotomy with its additional dangers and obvious disadvantages, being in itself a painful operation requiring an anæsthetic, and often involving difficulties in leaving off the tube after the obstruction in the glottis has disappeared. So simple is the process of intubation that this patient could bear it apparently without discomfort after the cocaine spray, and declared that she "did not mind it much." The largest-sized O'Dwyer's tube being intended for a child 12 years of age was, of course, too small for the patient, and was too readily coughed out, for which reason the silk thread attached to the tube on insertion was not removed, as it is always well to do when intubating children. Had it been of a suitable size for an adult larynx, it would have remained *in situ* and been readily borne, if necessary, for several days consecutively. The patient in this case had some slight difficulty in swallowing fluids, which always set up coughing, but, considering how little epiglottis she had left to cover the tube, she managed very much better than one would have expected. I would therefore strongly recommend intubation in œdema of the glottis as being more effectual and easier of accomplishment than scarification of the larynx, and just as effectual but less dangerous and objectionable than tracheotomy. At any rate, I venture to think that it should always, if possible, be given a trial before proceeding to tracheotomy, which, I am well aware, has been very successful in these cases.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, APRIL 3RD, 1888.

Sir JAMES PAGET, Bart., F.R.C.S., F.R.S., President, in the Chair.

Intestines in Diphtheria.—Specimens of intestines from three cases of diphtheria were exhibited by Mr. COLMAN. Diphtheritic lesions were present in the pharynx and larynx. The spleen was not enlarged in any of the cases, and the œsophagus and stomach were healthy. Peyer's patches and the solitary glands in all three cases were enlarged, and all the lymphoid structures were injected, and the mesenteric glands were enlarged. A similar acute swelling of Peyer's patches had been observed by Dr. John Harley in scarlet fever.—Dr. WILKS thought that the cases illustrated how much there was in common in the various specific fevers. In cholera the great enlargement of the solitary and agminated glands was remarkable. Dr. Vandyke Carter had described changes of the same nature in malarial fevers. The condition of the intestinal glands in diphtheria closely resembled that seen in typhoid fever. If these glands were so commonly affected in other specific diseases, it would tend to negative the theory that in typhoid fever the virus first established itself in them, and from thence infected the whole organism.—Dr. COUPLAND, though he

had seen the enlargement of the glands, had never observed the ulceration which was so characteristic of typhoid. Dr. Vandyke Carter had observed such ulceration, and that observation tended to break down the sharp distinction which had been drawn between the morbid process seen in the intestines in typhoid and in other specific fevers.—Dr. NORMAN MOORE referred to the existence of so-called typho-malarial fever. If it could be shown that ulceration of the intestines was an occasional incident in such cases, but characteristic of typhoid, it would explain the occurrence of such cases.—Mr. COLMAN, in reply, said that there was no ulceration in the cases he had observed, but quoted Dr. Barlow, who had stated that he had in one case of uncomplicated diphtheria seen ulceration of the intestine.

Articular Lesions in Gout and Cirrhosis.—Dr. NORMAN MOORE: 1. Knee-joint from a case of gout, a man aged 40, showing a deposit of urate of soda in part of the synovial fringe. Deposit in this situation was rare, the commonest regions for a deposit being the articular surface of the patella, and the intercondyloid groove of the femur next the condyles, then the semilunar cartilages, and last the surface of the tibia. The patient had granular kidneys and a hypertrophied left ventricle and well-marked emphysema of the lungs. In the synovial fluid of both knees and both ankles there was a floating deposit of urate of soda, and the fluid itself was thicker than natural. Besides the knees and ankles, several joints of the foot showed deposits of urate of soda, but there were none in the hands or shoulders, and none in the hip. 2. Knee-joints from two cases of cirrhosis of the liver, showing degeneration of cartilage, erosion, eburnation and lipping, from a male patient aged 67, and a female aged 61. This condition in a greater or less degree was the common one in the joints of patients with cirrhosis of the liver. Out of twenty-four cases of cirrhosis of the liver, urate of soda was found in only three, while twelve showed these degenerative changes.—Dr. W. B. HADDEN said that it was rare to find uric acid deposits in the joints in cases of cirrhosis of the liver. As cirrhosis was undoubtedly due to alcohol, the fact threw some doubt on the supposed relation between alcohol and gout.—Dr. WILKS said that the kidneys and liver were not commonly affected together by alcohol; in the majority of the cases of cirrhosis of the liver the kidneys were not affected, whereas they were commonly diseased in gout.—Dr. COUPLAND questioned whether it was safe to associate the erosion of cartilage with the visceral lesion, and referred to Mr. Arbuthnot Lane's views as to the influence of long continued pressure due to special occupations.—Dr. NORMAN MOORE said that in large pale kidneys, commonly attributed to beer drinking, it was very rare to find urate of soda deposited. He thought it desirable that careful observations should be made on the influence of various alcoholic beverages on the anatomy.—The PRESIDENT referred to the report on alcohols recently presented to the Académie des Sciences, which showed that alcoholic beverages contained many and various secondary products due to the mode of manufacture which might have very varying effects on the economy.

Cardiac Cyst.—Dr. HADDEN brought forward a specimen of cyst in the heart. The patient was a woman, aged 66, who died from cirrhosis of the liver. There were no symptoms pointing definitely to the condition of the heart, and nothing in the history to explain the origin of the cyst. It was $1\frac{1}{2}$ inch in diameter, globular, thin walled, and situated in the inter-auricular septum. The contents were pink and microscopically were found to consist of finely granular fatty material. The walls of the cyst were of loose fibrous tissue. There was no evidence that the cyst was hydatid, dermoid, or serous. Its nature and origin were obscure.—Dr. G. N. PITT showed a small closed cyst projecting on the ventricular surface of the mitral valve; it had contained a puriform fluid which, however, was found to consist entirely of cholesterine and debris without any pus. As the arteries were atheromatous, he thought that the cyst was also of that nature.

Malignant Disease of the Air-Passages.—Three cases of malignant disease of the air-passages were brought forward by Dr. FELIX SEMON and Mr. SAMUEL G. SHATTOCK. The first was one of alveolar sarcoma of the larynx in a patient, aged 81. Hoarseness, gradual loss of voice without pain, and dysphagia, were the chief symptoms, together with abundant expectoration of frothy, sometimes sanguinolent, sputum. Dr. Semon was consulted on account of considerable aggravation of the dyspnoea. A fortnight previously the diagnosis of bilateral paralysis of the glottis-openers had been made. The patient would not permit a laryngoscopic examination. The larynx was slightly tender on pressure, and on the right half of the cricoid there was a hard swelling,

apparently intimately connected with the cartilage, and of the size of a hazel nut. There was complete aphonia, and respiration was stridulous, but not sonorous in character, expiration, as well as inspiration, being affected. Dr. Semon arrived, by exclusion of other possibilities, at the probable diagnosis of malignant disease of the larynx, the nature of the dyspnoea and the aphonia rendering bilateral abductor paralysis highly improbable. The patient would not submit to tracheotomy, which was advised. Two days afterwards death took place from asphyxia. Examination of the parts showed an extensive, though nowhere very prominent, swelling, extending over the greater part of the laryngeal cavity, below the cords, which were involved in the disease, and lay almost in apposition. The growth extended through the cricothyroid space, and appeared externally in front of the larynx. The mucous membrane over a large area of the growth was villous. This condition was quite independent of any ulceration, and was one that might in certain cases be of much clinical importance. Microscopic examination showed the growth to be an alveolar sarcoma. The total number of cases of sarcoma of the larynx hitherto recorded did not exceed 50, and in none had the age of the patient been so advanced as in the present case. In the second case there was epithelioma of the right half of the larynx, with an epitheliomatous insula on the left vocal cord. The patient, a gentleman, aged 57, was seen by Dr. Semon on October 12th, 1887, on account of hoarseness without pain or dysphagia. Laryngoscopic examination showed a widespread, red infiltrating mass, involving the whole of the right half of the larynx, except the epiglottis. There was no history of syphilis, and the other organs were healthy. On October 21st Mr. Butlin saw the patient, and shared Dr. Semon's views as to the malignant nature of the disease. Extirpation of the right half of the larynx was performed by Sir William MacCormac on November 1st, 1887. The patient died from pneumonia on the third day after the operation. The presence of a small isolated growth on the lower surface of the left vocal cord was only ascertained at the time of operation by means of an electric lamp introduced into the larynx. It was excised by a circular incision in the healthy parts around it. Microscopic examination showed the growths on both sides of the larynx to be similar and epitheliomatous in kind. The case illustrated the necessity of arriving at a diagnosis of malignant disease of the larynx in certain cases by clinical symptoms only, without the aid of the microscope; since the infiltrating nature of the growth would have rendered the intralaryngeal removal of fragments for microscopic examination impossible. The presence of the isolated growth on the left cord was one of the class of facts that might be interpreted as evidence of a direct cancerous inoculation, although, in the absence of direct experiment, it might always be held in argument that the spot opposed to the primary tumour was, by the advent of an inflammatory process, only prepared to become cancerous for the same general reason which lay at the bottom of the original disease. At any rate, facts of this character were exceedingly rare, and no case of laryngeal carcinoma similar to the one now recorded had, so far as Dr. Semon and Mr. Shattock knew, been reported. Professor von Bergmann had recently shown to the Berlin Medical Society a case of carcinoma of exactly opposite spots of the upper and lower lips. The third case was an example of intratracheal carcinoma continuous with carcinoma of the thyroid. The patient was a man, aged 39, under the care of Dr. Ord and afterwards of Dr. Sharkey in St. Thomas's Hospital. The chief symptoms were hæmoptysis of some standing, emaciation, cough, and night sweats. There was paralysis of the right vocal cord and rather indistinct pulmonary symptoms. As regards local signs, there was some thickening external to the trachea low down, and laryngoscopic examination revealed what appeared to be tracheal ulceration just at the lower border of the field of vision. All symptoms present in the case appeared compatible with the diagnosis of tubercular disease of the lung and trachea, but no bacilli were found in the sputum, and towards the end of the patient's life Dr. Sharkey, who watched the last stages, entertained a strong suspicion of malignant disease of the trachea. Death ensued from increasing hæmoptysis. At the *post-mortem* examination double pneumonia affecting the lower lobes was found, and a smooth ovoid growth projected into the trachea from the anterior aspect about 1.5 centimetre below the lower border of the cricoid. Sections showed an extensive submucous infiltration, the tumour substance spreading between the tracheal cartilages to the thyroid gland and to the exterior of the trachea below the latter. The right recurrent laryngeal nerve was found to enter

the mass of malignant disease which lay around the trachea. The histology of the growth was that of cylinder-celled carcinoma; the investing epithelium of the trachea was not involved. As the tumour was traced outwards its thyroidal nature became plain. The cell columns had everywhere a lumen, and were formed by a single cell layer. This form of thyroidal carcinoma was very rare. Wölfler had recited seven cases collected from different authors, and figured a specimen very like the present. It was also remarkable that the extension into the trachea took place in the form of a well-defined, comparatively large tumour, and not, as usual, by mere infiltration of the tracheal walls.—Mr. GODLEE referred to two cases of thyroid tumour, in which the secondary tumours were situated in bone.—Dr. PITT, in connection with the theory of the transmission of malignant diseases by contact, referred to the frequency with which growths secondary to malignant disease of abdominal viscera occurred in Douglas's pouch.

Mediastinal Tumour involving the Heart.—Dr. HANDFORD showed a specimen of mediastinal tumour taken from a man aged 45, who had complained of cough for six months and a half. His chief trouble was dysphagia, which eventuated in complete inability to take food by the mouth. He died from slow hæmoptysis. A mediastinal carcinoma was found after death, which involved the lower lobe of the left lung. The left auricle was also implicated, and communicated by a small opening, which was probably the source of the hæmorrhage, with the pericardial sac, which contained blood-clot, and also an irregular sloughy cavity between the roots of the lungs. With this cavity the trachea and bronchi, the walls of which were extensively destroyed, freely communicated. The œsophagus was not involved in the growth, and was not strictured, but communicated with the same cavity by three openings, one of which was more than an inch long. There were numerous secondary growths in the liver, which, on microscopic examination, presented typical alveolar stroma of scirrhus. In a very similar case mentioned by Dr. Spacciati (*Lo Sperimentale*, January, 1888) the left auricle was involved, but not perforated. The œsophagus presented two small perforations, and death occurred from inanition from difficulty of swallowing. A third case was described, where death had been due to pulmonary hæmorrhage. There was a carcinoma of the root of the lung, spreading along the bronchi and blood-vessels into the lung, and secondary growths in the humerus, muscles, and kidneys.

Cystic Kidney.—Dr. H. W. G. MACKENZIE showed a kidney with cysts containing calculi. The patient, a woman aged 69, died of cerebral hæmorrhage; and the arteries were atheromatous and the left ventricle hypertrophied. Both kidneys were cystic, but in the right only calculi existed. The largest of the calculi was about the size of a small bean, the others, about thirty in number, were about the size of coriander seeds. They were highly polished, very hard, consisted of oxalate of lime, and weighed together 13½ grains. The kidney was not enlarged, and contained, besides numerous small cysts, two large ones an inch in diameter in the cortex. The largest calculus was contained in the largest cyst, a number of others were contained in the second cyst, and the remainder were in the small cysts. There was no calculus in the bladder, ureter, or pelvis. No communication existed between the cysts and the pelvis. No such case had previously been brought before the Society, but Dr. Dickison referred in his work on *Diseases of the Kidneys* to a somewhat similar specimen in the Guy's Hospital Museum. Assuming that the cysts were the result of obstruction of tubules, either the obstruction must have been incomplete or the cysts must have communicated with non-obstructed tubules so as to permit some flow of urine through the cysts. The cysts were not due to the calculi, as the presence of cysts in the other kidney without calculi showed. He thought that it was not improbable that the cysts were due to obstruction by small concretions.

Card Specimens.—Mr. EVE: Cyst of Spermatic Cord, originating in the Organ of Giraldo's.—Dr. F. J. SMITH: Aortic Stenosis.—Dr. HANDFORD: 1. Simple Hypertrophy of Kidney. 2. Multiple Tubercular Strictures of Intestine.—Mr. FENWICK: 1. Vesical Carcinoma. 2. Prostatic Carcinoma.—Dr. DREWITT (for Dr. CHOLMELEY): Lung from Case of Hæmoptysis in an Infant.—Mr. SEATTOCK: Recurrent Sarcoma of Thyroid associated with Hypertrophy of Accessory Thyroid.—Dr. HADDEN: Intestinal Concretions.—Dr. MORISON: Valvular Disease of Heart in an Infant.—Dr. PITT: 1. Caseous Gland Ulcerating into œsophagus and Stomach by Numerous Openings. 2. Hypertrophy of œsophagus associated with Hypertrophied Heart.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

WEDNESDAY, MARCH 21st, 1888.

JOHN SMITH, M.D., LL.D., President, in the Chair.

Nephrotomy.—Mr. A. G. MILLER presented a report of three cases of nephrotomy. The general conclusion suggested by the results obtained was that nephrotomy for pyo-nephrosis and similar conditions was not a favourable method of treatment. The immediate result was often good, but, more especially in the young subject, the ultimate issue was bad. The tendency to sinus formation was very great. Such sinus was exceedingly intractable, particularly in the young, and in a large proportion of cases led to the supervation of amyloid disease. When surgical interference was necessary, Mr. Miller believed that nephrectomy was a better operation.

Respiratory Neuroses.—Dr. ANDREW SMART described some forms of respiratory neuroses which had come under his attention in the out-patient department and in the special ward for alcoholic patients. Charts were exhibited illustrative of various rhythmic alterations in the respiratory tracing, to which Dr. Smart believed attention had not yet been drawn. Ingenious theories were elaborated in explanation of the phenomena.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SURGICAL SECTION.

FRIDAY, MARCH 9th, 1888.

A. H. CORLEY, M.D., Pres. R.C.S.I., in the Chair.

Subcranial Hæmorrhage treated by Secondary Trephining.—Mr. THOENLEY STOKER said this case was that of a man, aged 50, who was received into the Richmond Hospital four days after he had fallen from a cart and sustained such injury that he became insensible. At the time he came under observation he was in a state of stupor, with left brachial motor-monoplegia and a very partial paralysis of the facial nerve on the same side. The left leg showed a barely detectible motor insufficiency. There was no sensory paralysis, and the pupils were responsive and symmetrical. A bruise simulating depressed fracture existed in the scalp over the upper part of the right fissure of Rolando. No accurate history could be obtained, and it was not possible to say whether his symptoms were of apoplectic origin or due to pressure on the surface of the brain, the result of laceration of a meningeal artery. This uncertainty as to the nature of the case caused delay in operating. On the ninth day of the case the man had become worse, and was evidently dying. He was completely hemiplegic on the left side, profoundly comatose, could swallow in the most imperfect manner, and breathed with stertor only twelve or fourteen times in the minute. The conclusion came to was that the symptoms were probably due to hæmorrhage between the bone and dura mater, dependent on a laceration, with or without fracture, of the middle meningeal artery. Although there had been, so far as could be ascertained, no complete recovery between the injury and the advent of the later symptoms of pressure, and therefore an absence of that interval so characteristic of subcranial pressure, yet, on the other hand, there had not been that even level of ills, or that uniformly downward path of symptoms, indicative of laceration or apoplectic pressure. The reading of the case, as expressed at the time, and fully borne out by its subsequent history, was this: 1. Hæmorrhage over the right motor area, between the bone and dura mater, probably due to laceration of the middle meningeal artery or one of its branches, most likely associated with fracture, and producing the partial left paralysis which at first existed. 2. Subsequent increase of the hemiplegia, either due to renewed hæmorrhage or to that sudden yielding of brain function which was repeatedly seen both in hæmorrhages or serous effusions which had existed for some time, even though no additional mechanical pressure was called into play. The existence of the scalp injury over the upper and back part of the motor area was of less value in indicating the seat of pressure than the opposite paralyses, which pointed clearly to the engagement of the greater portion of the right motor area, including the extensive surface occupied by the cortical centres for the various parts of the upper extremity, the face and tongue, and lower extremity, the interference with them being in the sequence in which they are written. As to the assumption that the pressure was cortical, and not apoplectic, it was founded on his belief in the absence of any sensory paralysis, and the teaching on that point, so well expressed by Ferrier,

who says that "strictly cortical lesions of the motor area do not cause anaesthesia in any form, and it may be laid down as a rule, to which there are no exceptions, that if anaesthesia is found along with motor paralysis, the lesion is not limited to the motor zone, but implicates also, organically or functionally, the sensory tracts of the internal capsule or the centres to which they are distributed." The cortical nature of the pressure was further supported by the existence in the early stage of the case of a pronounced brachial monoplegia, as it is well established that monoplegia is a condition due to interference with the cortex, and not usually found in more deeply situated lesions. Considering the whole story of the case, and in view of the inevitable death of the patient if not relieved by treatment, it was determined to trephine him. This was done on June 21st, the day on which he exhibited the pronounced conditions just described, and the ninth after his accident. The patient was completely comatose, and no anaesthetic was used. The injury over the fissure of Rolando was taken as the point indicated for operation, because, although not in the centre of the engaged portion of the motor area, a possible fracture existed there. A trephine with a diameter of 26 millimètres was applied, and, on the disc of bone being removed, the antero-inferior edge of the opening disclosed the edge of a well-formed blood clot. A second trephine opening was made immediately below and in front of the first, and an oval opening, measuring 52 millimètres, rendered available for removing the clot. At its centre the clot was so thick that the dura mater was distant from the cranium about 40 millimètres. Before the patient was taken off the operating table he moved his left arm and leg with tolerable freedom, asked for a drink of water, which he readily swallowed. An uninterrupted good recovery was made. The evening of the day of operation the paralysis and brain symptoms had all but disappeared, and he could pass water voluntarily. A day later he was in a perfectly normal condition as regards any brain symptoms. He was kept under observation until September 29th, when he left hospital. If another case resembling this offers itself for treatment, he would consider the propriety of making drainage as efficient as possible by forming a small trephine opening at the nearest accessible point to the lower edge of the line of separation between the cranium and dura mater. He was able to arrive at a conclusion justifying a useful operation by two circumstances—first, that he could, independent of any knowledge of a fracture enabling him to localise the hæmorrhage, put his finger over the motor area and say with sufficient accuracy, "There is pressure here over the cortical centres for the upper extremity; it extended downwards and forwards to those for the face; it afterwards reached upwards to those for the lower extremity." The sequence is anatomically perfect. First, a brachial monoplegia; then, as the blood or pressure effect extends, a facio-lingual; and, finally, a crural paralysis. Independently of these points, the case—as one in which no defined bone lesion served to localise the hæmorrhage—belonged to a class sufficiently rare to deserve notice. If he required any other apology for presenting it at such length, he would have it in the words of so eminent a surgeon as Mr. Hutchinson, who says, speaking of instances of effusion of blood between the bone and dura mater, "These are especially important, because generally supposed to be capable of relief by treatment. Yet it is a remarkable fact that the modern annals of surgery do not, so far as I am aware, contain any cases in which life has been saved by trephining for this state of things." On a careful study of the light which modern investigation had thrown on the localisation of intracranial pressure, and the security which modern surgical methods had given to the operation of opening the cranium, and bearing his clinical observation of deaths from doubtful intracranial accidents in mind, he had come to this conclusion for future guidance, that if he were in doubt he would operate.

Traumatic Subdural Abscess of the Brain and its Treatment by Trephining and Aspiration.—Sir WILLIAM STOKES referred to the statistical records of Abercrombie, Gull, and Sutton, which show that of cerebral abscesses the traumatic subdural forms are those which occur with least frequency. He also pointed out how, until comparatively recently, cerebral abscesses were considered as a rule a necessarily fatal condition, and that the reason they are no longer considered as such is due to the knowledge we have acquired of the localisation of cerebral function, injury, and disease, and also to our improved knowledge of the principles and practice of antisepticism. The author was of opinion that the advantages to be derived from trephining in such cases are more likely to be observed in these cases than in other conditions causing pressure, and alluded to eleven recorded cases operated on,

in five of which the recovery was complete. He then gave the details of two cases in which he had performed trephining in the Richmond Hospital, both of which were illustrative of the pathological fact noted by Dease, as to the late appearance of cerebral trouble after cranial traumatism. In the first of these cases he did not succeed in reaching the abscess, and the patient died; in the second, however, he did, and the recovery was complete. In this the matter was not reached until the needle of a hypodermic syringe was introduced to its full length. The relief was immediate. About an ounce and a half of pus was removed, and the abscess cavity then washed out with a 1 per cent. solution of carbolic acid. The author then mentioned the principal details of the cases that were operated on by Dupuytren, Roux, Fenger, and Lee, Rentz, Macewen, Hulke, Sir J. Paget, and Marshall, and from these as well as his own cases he considered the following propositions might be stated: 1. That after the primary symptoms of cerebral traumatism had subsided, there was frequently a latent period of varying length, during which there were no distinct brain symptoms connected with abscess formation whatever. 2. That their appearance was, as a rule, sudden, and, if uninterfered with, ran a rapidly fatal course. 3. That the occurrence of pus production resulting from cerebral traumatism was not incompatible with a perfectly afebrile condition. 4. That this latter fact would probably aid in differentiating traumatic cerebral abscess from meningeal or encephalic inflammation. 5. That both as regard colour and consistence there was great variety in the contents of cerebral abscess cavities, and that, as shown in Wilm's case, published by Rose, of Berlin, they might be transparent. 6. That antisepticism had largely diminished the risks of the operation of trephining. 7. That having regard to the great mortality of cases of cerebral abscess when uninterfered with, namely, from 90 to 100 per cent., the operation was indicated even when the patient was *in extremis*. 8. That in the case where the trephine opening did not correspond to the situation of the abscess, exploratory puncture and aspirations might be employed. 9. That by the adoption of this measure the necessity for multiple trephine openings could be largely obviated. 10. That the employment of a blunt-pointed aspirating needle, as suggested by Rentz, was probably the safest mode of exploration and excavation. 11. That drainage was desirable in the after-treatment of such cases. 12. That both during and subsequent to operation interference in these cases a rigid antisepticism was imperatively required.

Case of Traumatic Aphasia Successfully Treated by Trephining, and Removal of a Blood Clot from the Interior of the Cerebrum.—Mr. C. B. BALL read notes of the following case. F. B., aged 26, admitted September 1st, 1887. He stated that he had been struck on the head with a penknife ten days before coming under observation. He presented himself at another hospital immediately after the accident, but his case was not considered sufficiently urgent for him to be detained as an in-patient. Since the accident he had found difficulty in using the right word, as, for instance, he said he had a "man" in the side of his head when he meant "pain." He stated that the difficulty of speaking and pain in his head had increased considerably during the last few days. Upon examination a small scab was found adherent to the scalp, over the squamous portion of the left temporal bone; this, when detached, showed a cicatrix apparently extending deeply through the temporal muscle, but the wound was quite healed. Classifying the symptoms presented by this patient during his stay in hospital, it was found that his motor aphasia was to the extent of being unable to name articles which were shown to him, correctly, while in speaking he constantly used wrong words or parts of words. Although he was able to write his name correctly, and with rapidity, and copy writing, he was unable to write from dictation, or to write sentences which he originated himself; his attempts to do so did not show a single properly formed character. (Word blindness).—When given a book to read he said the words ran into one another, and then he could not make them out. (Word deafness).—When asked questions his answers were sometimes so irrelevant as to suggest that he had not appreciated the meaning of the query correctly; and when told to put out his tongue he opened his mouth only, but when he was set an example he at once protruded the tongue. This was frequently tried with the same result. There was no paralysis whatsoever to be detected of any of the voluntary muscles when he came under his observation; and, judging from the fact that immediately after the accident his case was not considered sufficiently grave for admission into another hospital, there could not have been at that time any overt paralysis. Five days after

his admission his symptoms had so much increased that it was determined to operate. A flap was turned down, including portion of the temporal muscle, and containing in its centre the cicatrix; this disclosed a wound of the squamous portion of the temporal bone, of a size and shape likely to be produced by the small blade of an ordinary penknife, held horizontally, with the back of the knife towards the patient's back, and the edge looking directly forwards. A medium-sized trephine was now applied, and a circle cut out, containing in its centre the cut in the bone; this was attended with some difficulty, as the lower part of the circumference was exceedingly thin, while the upper portion was tolerably thick; the piece was removed without injury to the dura mater by the trephine. It was found that the knife had perforated the dura mater and brain. The wound in the dura mater was enlarged, in doing which the large posterior branch of the middle meningeal artery was divided, and gave some little difficulty to control; this vessel had very narrowly escaped injury by the penetrating knife. A sinus forceps was gently passed along the brain wound, and the blades separated, when a dark-coloured blood presented, and was gradually extended by the internal brain pressure. Some more fragments of clot were removed by the sinus forceps, and by a stream of weak perchloride of mercury solution from a syringe. A drainage-tube having been introduced, the flap was replaced and held in position by deep sutures, including the temporal muscle. On the evening of the same day the patient was much more rational, and carried on a long conversation, with very few mistakes in his selection of words. Next morning he was again more aphasic, and it was found that the drain had become blocked. Upon freeing it a considerable quantity of fluid, containing broken-down blood clot, was removed, and his power of speech improved. He made an uninterrupted recovery, and regained completely his power of writing, reading, and speaking. In this case he believed the knife penetrated the superior temporo-sphenoidal convolution, traversed the fissure of Sylvius, and probably injured Broca's convolution, and that his symptoms were due to a blood clot in the fissure of Sylvius, which was breaking down, and which was evacuated by timely surgical operation.—The discussion was postponed to the next meeting.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

THURSDAY, MARCH 15TH, 1888.

M. M. DE BARTOLOME, M.D., President, in the Chair.

Specimens.—Dr. HUNT exhibited (1) Large Indurated Glands removed from a Child's Neck; (2) Appliances for receiving the discharges during operations, and securing cleanliness and comfort; they were in use in the Boston (U.S.A.) General Hospital.

Plumbism.—Mr. PRIESTLEY introduced a case of plumbism, a patient of Dr. Dyson's, the only assignable cause being the impregnation of the drinking water by lead.

Exophthalmic Goitre.—Mr. BALDWIN related particulars of the termination of a case of exophthalmic goitre shown to the Society some time since.

Hæmophilia.—Mr. PYE-SMITH related brief notes of a case which ended fatally in a man aged 47. He was admitted into the Public Hospital for a wound in the left hand. The hæmorrhage was with difficulty stopped by styptics and pressure, but a fortnight later blood began to be passed by the rectum, and, after losing a good deal for two days, the patient suddenly became faint and died with symptoms of internal hæmorrhage. At the *post-mortem* examination the stomach was found to be full of soft-clotted blood. The small intestines and the rectum were empty, but covered with blood-stained mucus and small ecchymoses. The male children of the patient's mother's sister were also bleeders.

Etiology of Chorea.—Dr. PORTER gave a series of cases which had come under his personal notice. In 49 there were 37 females and 12 males, the usual proportion of 3 to 1, which was a singularly constant one. He found that in 44 cases some member of the family had suffered from acute or subacute rheumatism alone in 13, and in 2 more there was a history of both rheumatism and chorea; of chorea alone there were 3 cases, and of other nervous affections (epilepsy, insanity, etc.) there were 3 more. There was a rheumatic history, either family or personal or both, in 22 out of 46 cases, and nervous predisposition or antecedent chorea alone in 18. He held that chorea alone could produce endocarditis and organic valvular diseases. In 8 out of 39 there was in his cases an organic murmur, and in 3 only was there a rheumatic history. He alluded, among exciting causes of chorea, to educational pres-

sure. The pathology of rheumatism was doubtful; some had claimed for it a nervous basis, and it was possible that there might yet be found some antecedent condition common to it and chorea; whether the two affections occurred vicariously was the question.—Remarks were made by Dr. DYSON, the PRESIDENT, Mr. PRIESTLEY, and Dr. S. ROBERTS.

SUNDERLAND AND NORTH DURHAM MEDICAL SOCIETY.

THURSDAY, MARCH 15TH, 1888.

G. B. MORGAN, L.R.C.S.I., President, in the Chair.

Tracheotomy.—Mr. MACKAY sent a woman on whom this operation had been performed eleven years before. Since the operation she had borne five children, but she had never been able to do without a tube.

Excision of Shoulder-joint.—Mr. HOPGOOD showed a boy in whom acute periostitis of the upper end of the right humerus had followed a blow on the shoulder.

Specimens.—Mr. E. A. MALING: Large Vesical Calculus.—Mr. HOPGOOD: (1) Ovarian Cyst. (2) Caries of Femur.—Dr. GRAY: Excessive Hypertrophy of Toe-nail.—Mr. WHITEHOUSE: Reduction *en Bloc*.

Post-aural Branchial Fistula.—Mr. WHITEHOUSE read notes of a case which had been under his care. The patient, a strong man, aged 30, complained of repeated formation of abscesses in front of his right ear. For the last two years one had formed about every two months. A small depression was found leading to a passage large enough to admit a bristle. Before the abscesses had fully formed he always noticed a slight discharge of creamy fluid from the sinus. The seat of the abscesses was about three-quarters of an inch in front of the depression, which was on the upper part of the helix. His hearing was perfect, and no branchial fistulae existed in the neck. The tract was laid open and scraped, and the temporal artery tied, and so far there had been no return of the abscesses.—Mr. SEVILLE made some remarks.

The Treatment of Stricture of the Urethra.—Mr. WHITEHOUSE read a paper on this subject advocating the operation of internal urethrotomy whenever the circumstances of the case demanded it.—The PRESIDENT, Mr. HOPGOOD, and Dr. GRAY made remarks.

REVIEWS AND NOTICES.

THE CHILDREN OF SILENCE: OR THE STORY OF THE DEAF.

By JOSEPH A. SEISS, D.D., LL.D. Philadelphia. Porter and Coates. 1887.

THE author of this commendable little work tells us modestly in his preface that it "has grown out of some special studies, intended for his own information, the more intelligently to discharge his duties as a director of an institution for the deaf and dumb." It would be well if other directors of such institutions considered and acted upon their obligations in the same spirit and with the same ability.

The volume before us is for the most part accurate, as far as it goes, and impartial; the compiler has evidently had access to the valuable library on matters connected with deaf-mute education, which was in the possession of the late Charles Baker, head of the Yorkshire Institution for Deaf-Mutes, and, unfortunately for us, curiously transferred to the United States of America some years ago. The *American Annals of the Deaf and Dumb* during its "thirty or more years" of existence is an evidence of this. The author concludes his preface by hoping that the present volume will be influential in demonstrating the sources of the sad misfortune of deafness. We are very sorry that he did not add "and more especially dumbness."

To diminish the sources of deafness is a labour truly Herculean. As regards dumbness arising from the source of deafness, there seems to be little, if any, difficulty in dealing with this condition in most countries, the exception being the United States of America, Canada, and Great Britain.

Dr. SEISS treats of the classification of deaf-mutes, that is, those who are, and who are not, to be considered as such. This is most important when the question of their education comes under review. Many a child with only a moderate degree of deafness has been sent to these special schools and has become dumb in consequence of the peculiar form of teaching employed. It is needless to say that in such institutions the total deaf always remain dumb; further, which seems saddest of all, children becoming deaf

after having acquired spoken language in the usual way, have lost it under the sign system of instruction.

The question of the number of deaf and "dumb" is, of course, also interesting, but most difficult to arrive at for many obvious reasons. The author of the *Children of Silence* has revived an amusing incident which occurred in the Irish census years ago, when a quite unusual number of children were returned as "dumb, but not deaf or otherwise defective." Upon inquiry these were found to be infants under 12 months; that collector was evidently not a father.

Dr. Seiss (pp. 17 and 18) curiously observes in a like manner: "All children are born mute," although in another paragraph he is quite careful to show how rare muteness is. So long as any misunderstanding continues as regards the term "articulate language and voice," so long will the deaf child be considered to be dumb or mute in the popular mind. When the two words "deaf and dumb" are divorced, a distinct advance will have been made towards a proper appreciation of the true condition of these afflicted children.

The writer says that the "deaf are not always nor necessarily dumb," and that 20 per cent. are capable of being taught to speak, whilst other authorities assert that 80 per cent. or more can be successfully taught. It is a pity that he does not mention those largely diverging authorities. The smaller percentage will be found in the American and English estimates, and the larger in those of the Continental.

The causes of deafness are naturally most interesting just as they are perplexing in so many cases. Dividing the causes as usual into ante- and post-natal, Dr. Seiss writes soundly on Intermarriage of Blood Relations, Hereditary Transmission, and Constitutional Taint, quoting well-known authorities on these points, and proceeds to consider under the heading of "Impressions on Mothers," the vexed question of maternal emotions affecting intra-uterine life to subsequent permanent injury to the offspring. A considerable number of cases are quoted to support the opinion that this is so. It is impossible to prove a negative, and it would, therefore, be useless to quote the innumerable cases where frights and impressions during the period of gestation did not have a baneful effect upon the offspring. We are assured by one who has had considerable experience amongst the deaf, and has made particular inquiries upon this point, that he has never heard of any case of a hearing female connected with an institution for deaf-mutes having borne a deaf child owing to her association with the deaf and dumb.

Physiologically considered, suppose a nervous woman in a state of pregnancy to receive a shock, which affects her offspring in a characteristic way—namely, deafness, some part of the organ of hearing is presumed to be undeveloped, owing to the supposed shock and subsequent maternal impressions. But what caused the shock? Not the condition of deafness in another individual. One may pass a hundred deaf persons in the course of a short period without being at all aware of their condition, how then can a shock be received even to the most delicate organisation? The usual account is not that the mother was frightened by a "silence," but by an unnatural and unpleasant noise; if then her offspring were found reproducing this noise, we might admit the theory of "maternal impressions," but why a child should be born deaf because the mother was disturbed by a disagreeable sound is, to say the least, somewhat perplexing.

A typical instance of the sound, not the silence, being supposed to cause deafness will be found on page 74 of Dr. Seiss's book. It is possible to entertain the theory of a morbid hypersensitive imagination incessantly dwelling upon the condition of deafness and its terrible consequences influencing injuriously in some way the offspring of a mother of weak constitution, but authenticated evidence on this point is very difficult to obtain. In fact, few parents will even admit deafness in their own child to be congenital.

In comparing the terrible misfortunes of congenital blindness and deafness, Dr. Seiss is probably right in his view that the latter is by far the more deplorable.

The historical portion of the book is useful and fairly full and accurate; the usual drawback to this part being that the writer confines himself far too much to the consideration of one county and one system. But we cannot dismiss this matter without defending one of the early English teachers, who has been assailed more than once by American writers, respecting the Rev. J. Gallaudet's visit to London in 1815 to gather information and experiences in deaf-mute education. Dr. Seiss says: "That the

extravagant demands of time and money made on him in England to secure the object of his mission became the occasion of his going to Paris, when he brought back with him the sign system and an educated deaf-mute to assist him in teaching it." As a matter of fact, he accepted from the Paris Institution almost identical terms which he refused from the London Asylum. A Birmingham daily paper recently, in describing a visit of Mr. Chamberlain to the National Deaf-Mute College at Washington, U.S.A., writes as follows: "The President of the College, Dr. E. Gallaudet, came over to England in 1886 to give evidence before the Royal Commission, etc., in spite of the fact that England refused information to his father seventy years ago." This same Dr. E. M. Gallaudet was sent to Europe some twenty years ago to study the system of education for the deaf pursued in Europe, and after an inspection of schools reported most unfavourably on the speech system; and at the Milan Congress, referred to by Dr. Seiss in 1880, again opposed most vigorously, as the writer says, the same method, he forming one of the minority of 4 in a majority of 160. We cannot for a moment accept Dr. E. M. Gallaudet either as friendly to or an authority on the pure oral system. He has certainly advocated what he calls the "aural system;" this seems to be a method of teaching children who can hear in schools for the deaf—a somewhat unusual proceeding one would think.

The least satisfactory part of Dr. Seiss's compilation is, in our opinion, that devoted to statistics, which will be found at the end of the volume. These figures are by no means brought down to date, in fact, we may roughly say are quite antiquated, because they do not deal with the extraordinary revolution in teaching which has been effected since the year 1880 in Europe and elsewhere.

In looking through these statistics, we find, for instance, the London Asylum in the Old Kent Road (we believe the oldest and most richly endowed institution for the deaf and dumb in the United Kingdom) is credited with teaching 158 pupils on the oral system; this in the year 1879! The year following the responsible head teacher of that institution, in company with Dr. E. M. Gallaudet already referred to, "most vigorously" opposed the speech system. Then, again, mention is made of a school at Castle Bar Hill, Ealing, W., founded in 1878, returned as having six pupils and one teacher, the system employed being described as the "oral." The methods of education employed in these two schools, we venture to say, have nothing in common one with the other; in fact, the term "oral," as applied to deaf-mute education, is most misleading. The Ealing School, whatever its merits or demerits may be, has a peculiar history and interest. It was founded by a society formed in 1877 due to the personal exertions of a gentleman, the father of a deaf daughter, who wished to save her from dumbness. The reasons given for the formation of the society were:—1. That a great number of children were allowed to grow up without any education whatever. 2. That nearly all the schools in the kingdom used the French, or silent, method, namely, teaching by signs and the manual alphabet.

No teachers of the pure oral system were at this time obtainable in England outside their engagements, and the few who were employed (at most 5) were imported foreigners, notwithstanding that at that time a society for the training of teachers, started under most influential patronage, had been at work some years. The chief object of the Ealing Society was announced to be to train teachers of the deaf on the German system, and so to diffuse this mode of instruction. The figures, so far as England is concerned, connected with deaf-mute education may be approximately quoted as follows:

Year.	No. of Teachers.	No. of Pupils.
1866	4	34
1876	15	117
1886	136	1,120

The marked increase both in teachers and pupils after the establishment of the school at Ealing (which figures so insignificantly in Dr. Seiss's statistics) will be noted; further, that directly and indirectly due to its training and teaching we find Ealing (eight years established) has trained, down to the end of the year 1886, 62 students, and been the means of teaching 437 pupils. The most marked change of all, however, has occurred in France, the birthplace of the sign system, and where, up to the year 1880, when the International Congress of Teachers of Deaf-Mutes was held at Milan, the method generally employed, was the sign or silent one. Now, out of over 60 institutions, we under-

stand that not more than 2 refuse the use of speech to their pupils.

There are many other points in Dr. Seiss's volume we should wish to dilate upon had we space. One thing may be said in conclusion with respect to the merits of the speech and the silent systems (the combined, being illusory, we may disregard), namely, that if a deaf child can be taught to use spoken language and saved from dumbness, it ought, without any question, to be taught, and that it can we have the fullest evidence throughout the length and breadth of Europe. Let America and England follow this good work as speedily as possible.

THE TRANSACTIONS OF THE EDINBURGH OBSTETRICAL SOCIETY.

Vol. xii. Session 1886-87. Edinburgh: Oliver and Boyd.

The work contains a record of the proceedings of the Edinburgh Obstetrical Society for the year 1886-87. Though it may seem invidious to mention one article rather than another where all are so good, we cannot omit to praise especially the papers brought before the Society by Dr. Berry Hart, Dr. Freeland Barbour, and Dr. Halliday Croom.

Dr. Berry Hart contributes extremely important papers on "The Anatomy of the Post-partum Uterus, with Special Reference to Placenta Previa;" and a "Note on the Mechanism of the Separation of the Placenta during the Third Stage of Labour." Taken in conjunction with Dr. Champneys's series of papers on "The Mechanism of the Third Stage of Labour," they form an important contribution to this subject. Another article by the same author, entitled "A Contribution to the Sectional Anatomy of Advanced Extra-uterine Gestation," is also of the utmost importance, and the subject could not have been undertaken by a more competent or painstaking observer. It is here conclusively shown, what has long been disputed by many, though contended for by Tait, that an ectopic gestation may be entirely extra-peritoneal. For this condition he author suggests the term "subperitoneo-abdominal."

Dr. Freeland Barbour contributes an article on "The Sectional Anatomy of Labour," a contribution showing much study and original work. The diagrams illustrating the subject are remarkably good and clear.

The President, Dr. Halliday Croom, in a paper of great practical value, treats exhaustively of "The Indications for, and the Methods of, Washing Out the Puerperal Uterus." The value of corrosive sublimate as an intra-uterine injection in puerperal cases and the dangers attending its indiscriminate use are laid before the society, while the indications and contra-indications for the intra-uterine douche are clearly pointed out.

Another paper of interest on "A Case of Myxomatous Degeneration of the Chorion; Profuse Hemorrhage; Transfusion; Recovery," by the President, is also worthy of note.

The volume, which is elegantly bound and clearly printed, contains numerous beautiful lithographs. A complete index and a list of the Fellows, with the office-bearers for the year 1886-87 are included. The Transactions are valuable and important, and we wish the Society as great an amount of success in the future as it has obtained in the past.

DESCRIPTIONS OF NEW INVENTIONS,

IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

THE TELEPHONIC BULLET-PROBE.

At a recent meeting of the New York Academy of Medicine, Dr. John Harvey Girdner exhibited a telephonic bullet-probe, which is illustrated by the accompanying engravings. Fig. 1 represents a telephonic receiver (R), to which two terminal wires (A and B) are attached; the framework of the receiver is of hard rubber; G is a central bar of soft iron, round which is coiled an insulated wire (I); the two ends of the wire are connected with the terminals; a metal diaphragm (1) is suspended close in front of the central bar (G). If a current of electricity passes through the coiled wire, the central bar (G) is rendered a magnet, and will attract the diaphragm (1), causing it to vibrate, so that each time the current is made and broken a clicking or rasping sound is heard when the receiver is held to the ear. In practice it is found convenient to connect the two receivers, one for each ear; a steel band (depicted in

Fig. 2) connects the two receivers and keeps them closely applied to the ear; in this way extraneous sounds are excluded, and both hands of the operator are left free; when the double instrument is used the two receivers are connected by the short wire to be seen in Fig. 2.

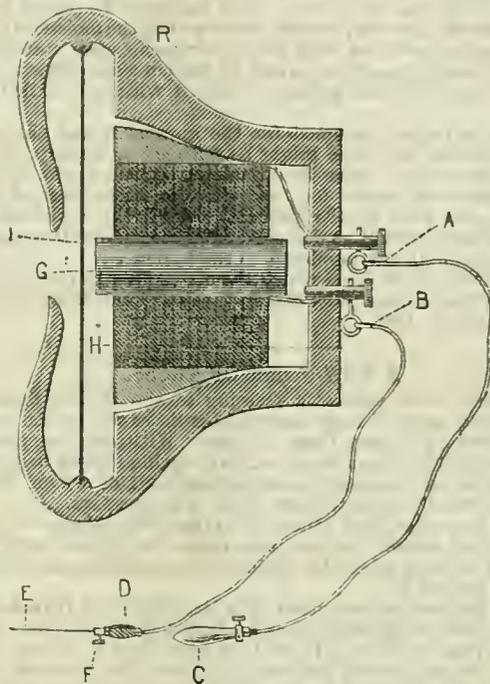

Fig. 1;

The instrument is thus used: the operator having adjusted the telephones, the patient takes the steel bulb (Fig. 1 C, and Fig. 2)

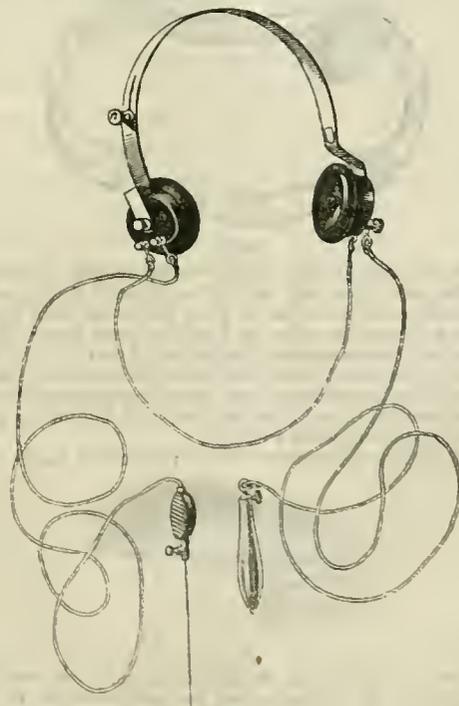

Fig. 2.

in his mouth, and the surgeon introduces the thin probe (Fig. 1, E, and Fig. 2), which is fixed in the holder (D) by the screw (F) into the

sinus which is to be searched for a bullet; bone and other tissues can be felt by the hand using the probe, but no sound is heard in the telephone until metal is touched, when immediately a rasping sound is perceived in the telephones. The patient's body, under the circumstances stated, furnishes a sufficient current of electricity to work the telephones. The bulb may be placed in any other cavity of the body, or may be grasped by the moistened hand. The indications obtained with this instrument were stated to be far more reliable than those given by the porcelain-tipped probe, which, if the bullet was greasy or coated with salts, failed to be marked.

Another advantage claimed for the apparatus was that when no sinus existed the probe might be replaced by a sharp, slender, steel needle, which, having been rendered aseptic, might be thrust into the tissues to search for the bullet or other piece of metal without much pain to the patient. When the metal has been struck the needle could be detached from the handle (D) and would serve as a guide in cutting down on the bullet.

Dr. Girdner's paper, from which the above description and drawings are extracted, was published in the *New York Medical Record* on February 4th, 1888.

A NEW FORM OF TRUSS.

In December of last year, at a meeting of the Medical Society, I showed some cases of large inguinal hernia in which the rupture was retained by a new form of truss. With one exception, in which no truss had been worn, ordinary spring trusses had proved inefficient or inconvenient to the patients, all of whom were at that time satisfied with the new pattern in question.

I have since that time followed up these and other cases, and I have satisfied myself that the truss is an efficient and useful one, especially in cases where the abdomen is pendulous, and the buttocks are rolls of fat.

It is, I believe, the invention of a Mr. Fry, of 18, Ivydale Road, Nunhead, and its appearance and construction are shown in the accompanying woodcut. It will be seen that it differs widely from the better known patterns; it resembles, however, rather closely in principle a truss described by Mr. Rushton Parker in the *JOURNAL* of February 25th of this year.

The truss (Fig. 1) consists of a bar of gun metal sufficiently

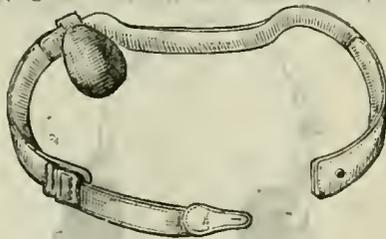

Fig. 1.

flexible to be bent by the hands to the general contour of the front of the pelvis, but stiff enough to retain that shape. It is of such a length and shape that it runs across in from just below one anterior iliac spine to below the other, and has a dip in the middle, where it rests against the pubes. From the ilia the curve of the bar is continued round the buttocks on either side by two strips of stiff leather (which were in the earlier patterns made of stout malleable metal), and these are fastened behind by a piece of soft elastic webbing with a buckle.

The pad (Fig. 2) by means of which pressure is made upon the

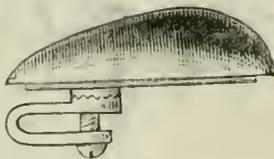

Fig. 2.

hernia aperture, is of wood or vulcanite, and is so arranged that it can be slid along the gun metal bar and clamped in its right position; it can also be adjusted to the right angle by means of a binding screw. It is obvious that in this truss, as in Mr. Parker's, there can be no constant pressure inwards against the

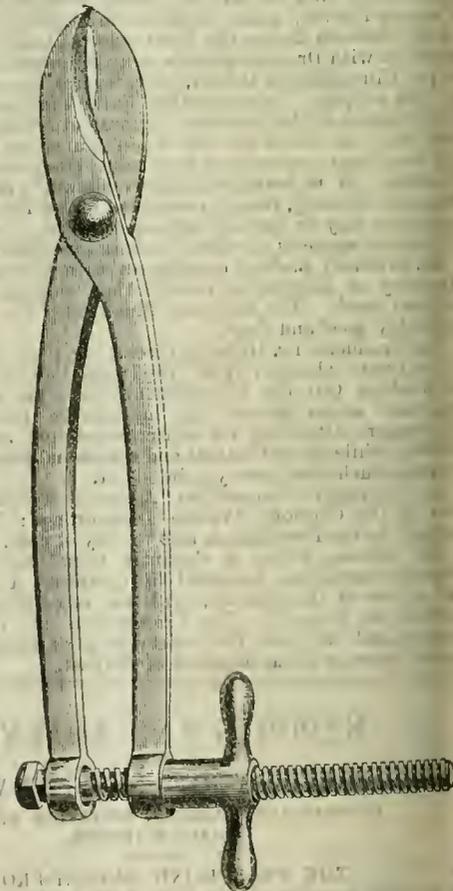

presumably constant outward pressure of the rupture, save only the very slight action which the elastic spring behind may exercise. The door is closed by something heavy placed against it rather than by a continuous push, and I can see no reason to suppose that it can be in any way curative, or applicable to ruptures in which a cure may be looked for. But it is strong, light, and inexpensive; it can hardly ever wear out, and does in practice afford very efficient relief in cases in which that relief can only be given by a spring truss at the expense of a great deal of especially troublesome fitting.

WALTER PYE, F.R.C.S., Surgeon to St. Mary's Hospital.

A NEW FORM OF SEQUESTROTOME.

THE accompanying engraving represents a form of sequestrotome shown to the Nottingham Medico-Chirurgical Society in connection with two successful operations for total diaphyseal necrosis.

The entire length of the instrument is thirteen inches. The engraving shows the shape and proportion of its various parts. The mechanical points on which it varies from the bone-forceps in use are these:—

(a) It is forged from the finest steel at cherry heat, and tempered between a pale straw and bat's wing.

(b) The cutting edges are of a less acute single bevel than is usual.

(c) The edges are not opposed, but move on contiguous parallel planes. This greatly increases the breaking power, but offers the mechanical disadvantage that it tends to separate the blade laterally with divergence of planes.

(d) The latter is remedied by the forceps having a very large accurately fitting pivot, of the same steel as the instrument, with large steel counters, so that it is impossible for movement to take place unless the material or workmanship is inferior.

RUPERT C. CHICKEN, F.R.C.S.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1888.

Subscriptions to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the West Central District Office, High Holborn.

The British Medical Journal.

SATURDAY, APRIL 7TH, 1888.

LOCAL GOVERNMENT BILL: SANITARY ADMINISTRATION.

MR. RITCHIE'S Local Government Bill bears examination satisfactorily, and although since the publication of the full text it has been subjected to searching criticism and is likely to undergo some important modifications, nevertheless, the general feeling of the country is, we believe, in favour of its main provisions. We have already pointed out what we consider to be some of its defects, which are chiefly faults of omission. We notice that the most competent authorities, such as Mr. Stansfeld, regret in the expression of regret to which we gave utterance, that the Government have not seen their way to go further than the Bill provides, and to unify all the local authorities which now exist, so that there might be one local authority, and one exercising jurisdiction over a particular area. Mr. Ritchie's proposal to leave the poor-law unions and the poor-law guardians absolutely untouched is, in Mr. Stansfeld's view, as in our opinion, an obvious defect, which, if it cannot be supplied now, will have to be remedied at no distant date. The continuance of the divorce of the administration of relief of the poor from other branches of local administration is a great blot, and we are still of opinion that by grasping the question in a more comprehensive spirit, it would have been possible to have avoided a repetition of the constant tinkering at reform which have been the bane of the local administration of the country for the last generation, and which must still continue unless the Bill be amended in the direction we suggest. It will, however, at the present time be useful to many of our readers briefly to analyse the features of the Bill as it is at present drafted.

The Bill is mainly one of decentralisation and readjustment, by which powers and duties already exercised by a variety of authorities, and even by Parliament itself, will be transferred to particular representative local bodies. New powers and duties are proposed to any very great extent proposed to be created. At the outset a broad line is drawn between the judicial and administrative functions of the existing county authorities, i.e., the Courts of Quarter Sessions. The former are to remain vested in the magistrates, as at present, whilst the latter, including the administration of county rates and financial business,

county buildings, county bridges, the provision and management of the county lunatic asylums, the establishment and maintenance of reformatories, etc., the granting of licences for music, dancing, and the sale of intoxicating liquors, the execution of the Acts relating to the contagious diseases of animals, the adulteration of food and drugs, weights and measures, and certain duties as to main roads, are to be transferred to the new "County Councils" which it is proposed to constitute. These County Councils are also to undertake all the powers at present exercised by the Board of Trade with respect to the making of provisional orders under the Pier and Harbour Acts, the Tramways Act, the Electric Lighting Act, and the Gas and Waterworks Facilities Acts as regards companies, and the powers of the Local Government Board as regards the making of provisional orders as to schemes of local authorities under the Gas and Waterworks Facilities Acts, the sanctioning market tolls, fixing the scale of charges in respect of water supply, the investment of a rural authority with the powers of an urban sanitary authority, the settlement of disputes as to boundaries and other matters under the Public Health Act, the Public Health (Water) Act, the Artizans' Dwellings Acts, the Valuation (Metropolis) Act, the Sale of Food and Drugs Acts, etc. Certain borrowing powers are also to be given to them, and they are to be empowered to aid emigration amongst non-paupers. They are further to have certain powers for securing the efficient administration of the Rivers Pollution Prevention Act, 1876, and they are to share with the justices the control of the police force.

In deference mainly to the sentimental objection which is widely raised to any material alteration of the ancient landmarks of the country, the jurisdiction of the new County Council is at first to coincide with the geographical area of the county, but it will be competent to the new authorities, when constituted, to obtain a revision of boundaries. London (as defined by the Metropolis Local Management Act), and ten of the largest boroughs—Liverpool, Birmingham, Manchester, Leeds, Sheffield, Bristol, Bradford, Nottingham, Hull, Newcastle—are to be constituted separate counties in themselves, whilst in the remaining sanitary districts—Urban and Rural, Local Board and Improvement Act—"District Councils" are to be elected to supersede the existing authorities, and to exercise powers as to the Petroleum Acts, Dogs Acts, Infant Life Protection Act, the licensing of slaughterhouses, game dealers, pawnbrokers, fairs, etc. As regards the mode of election of those Councils, the Municipal Corporations Act is to be extended to the whole country, thus giving a qualification to all ratepayers. Three-fourths of the new County Council are to be directly elected by the ratepayers, and the remaining fourth are to be "selected" by the councillors, either from within or from without their own body. The District Councils are to be elected on the same franchise. Thus the complete organisation of the county will be—for the judicial work, the magistrates; for the administrative work, the County Council; all internal areas to conduct the municipal government of their areas; and all elected upon the same franchise. The poor-law guardians will continue to exercise their functions with

reference to the administration of the poor-law within the areas which exist at present. No alteration whatever in regard to the election of guardians or their poor-law powers is proposed.

As regards finance, the relations between Imperial and local taxation will be materially affected. Certain Parliamentary grants in aid, amounting to £2,600,000, are to be withdrawn, and instead a sum of £5,600,000 is to be allocated to the new authorities, in relief of local burdens.

The existing chaos of areas and overlapping jurisdictions has been so detrimental to sanitary progress that, from a public health point of view, any reasonable scheme for the simplification of local administration is welcome. It is also well that at last the poor-law and the sanitary administrations should be separated. One of the greatest obstacles to the proper execution of the Public Health Act in rural districts has resulted from the assignment of sanitary functions to boards of guardians. Apart from the fact that the poor-law unions were not designed to meet the requirements of sanitary operations, and are not, except by accident in some cases, suitable units for sanitary administration, such administration has often, if not as a rule, been distasteful to boards of guardians, and has invariably been subordinated to the poor-law business. Nor is the supersession of the small local boards a matter for regret. In the large compact boroughs health matters have in most cases been honestly and energetically dealt with during recent years, and reduced sickness and increased prosperity have resulted amongst the inhabitants. But there are, scattered over the country, scores of small urban districts where sanitary affairs have been grossly neglected. It is to be hoped that in the new subdivision of the counties due regard will be had to the configuration of the localities for sanitary administration, and to the exigencies of water supply, drainage, and such like.

The assignment to the new county authorities of certain powers under the Sale of Food and Drugs Acts and the Rivers Pollution Prevention Act, 1876, inspires a hope that these important enactments may be more thoroughly enforced in future than they have been in the past. The Adulteration Acts are practically a dead letter in many counties and boroughs, whilst many rivers continue to be polluted because the sanitary authorities who are responsible for enforcing the Act are themselves the chief offenders. The Aire and Calder, which are as filthy rivers to-day as they were when the Commission of 1868 reported on their condition, are glaring examples of this unsatisfactory state of things.

Vaccination was only incidentally referred to by Mr. Ritchie when he announced that the Parliamentary grant in aid of public vaccination would be withdrawn, but that part of the larger grant to be made to the county authorities would be devoted to the same object. Whether this means that vaccination, which is a distinctly sanitary operation, is to be detached from the control of the poor-law authorities remains to be seen.

As regards the position of medical officers of health under the new scheme, Mr. Ritchie's statement contains no information.

The question must not, however, be regarded as one of mere detail; it is of vital importance if the full benefits derivable from the reform of sanitary government are to be obtained. At present the system of appointment of health officers is, as has been so often pointed out in these columns, very unsatisfactory, not only from the point of view of the interests of the medical profession, but from that of individual efficiency and local usefulness. There should be sufficient inducements for able men with special scientific qualifications to enter the ranks of the sanitary service of the country, and the constitution of county authorities affords an admirable opportunity for securing this result. The larger area would enable a salary to be paid which would secure the whole of the officer's time. But the appointment should be during "good behaviour," and not from year to year, as is the general rule at present. There would also be public advantage in assigning to the medical officer of health the duties—such as those of county analyst, the making of *post-mortem* examinations for coroners' inquests, etc.—which at present are not performed on any recognised plan.

It was wisely said by John Stuart Mill that "power may be localised, but knowledge to be most useful must be centralised." We hope that the new system will result in a closer local enforcement of proper hygienic principles, and the extension of the local study of preventive medicine in the manner that it is already practised with good results in many of the larger municipalities. Concurrently with this local impetus to sanitary science we should be glad to see an extension of the valuable scientific work of the Medical Department of the Local Government Board, whereby the observations of local observers would be checked by the light of wider experiences, and problems locally propounded might be satisfactorily pursued to a useful conclusion.

THE UNIVERSITIES (SCOTLAND) BILL.

THE introduction into the House of Lords of a fresh Universities (Scotland) Bill has excited great interest in the university centres of Scotland. The publication of the text at the end of last week has called forth an endless variety of criticism. The Bill proposes to hand over the administration and management of all the revenues and properties of the university to the University Court, to which it would give the powers of enacting regulations for graduation and conditions for the tenure of Fellowships, etc., and of affiliating to the university, with the consent of the Chancellor and the approval of Her Majesty in Council, new colleges, duly incorporated and endowed, under conditions to be laid down by the Commissioners to be appointed under the Act. For these purposes the Court will be enlarged and made more representative. It will include the Principal, Rector, and head of any affiliated college, an assessor nominated by the Chancellor, and one nominated by the Rector. The Senate and General Council will each be represented by four assessors. The university town is to be represented by its Lord Provost for the time being, in the case of Glasgow, Edinburgh, and Aberdeen, while the Edinburgh Town Council re-

ceives the privilege of nominating an assessor. In the case of each university the Bill provides that the assessors are nominated by the Crown, while in the event of colleges being affiliated provision is made for a representation of their governing body in the Court. The Rector may take the assistance of the students, as represented by their Representative Council, in the choice of his assessor. The powers of the Senate are, under the Bill, reduced to educational matters and the discipline of the university. Provision is made for a Committee of the Privy Council, to be called the Scottish Universities Committee. The Commissioners, under the Bill, are given powers to transfer the patronage of professorships vested in individuals to the Court, to regulate foundations, etc., to regulate the powers and privileges of chancellors, professors, and other university officers, to alter the constitution of faculties and create new ones, to regulate fees, courses of study, degrees, and examinations, to enable the universities to be opened to women, to regulate salaries of professors, to found new chairs or lectureships, and to affiliate colleges. The application of the College of Dundee to the University of St. Andrews is specially mentioned in the Bill. The noticeable point in the financial proposals of the Bill are that the finality clause is omitted, and Glasgow University receives, in addition to its proper average, an annual sum of £500 for maintenance of buildings.

The essential features of the proposed measure are, it will be seen, the transference of the financial administration of the universities to the University Courts, the increase of function delegated to the Courts, and the reconstitution of the Courts in such manner as will allow of a fuller representation of university graduates and of the public generally. The Bill ought to give satisfaction to the reform party. The enlarged and representative character of the new Court, the transference of the management of the university to it from the Senate, and the powers of affiliation are among the chief demands of that party, and are very fairly met in the Bill.

Since the suggested alterations are of so sweeping a character, the Bill, as might be expected, cannot be said to meet the wishes of those members of the professoriate who find it possible to combine the immediate duties of their chairs with close attention to the large and varying problems which the administration of so important an institution implies. On the other hand, a growing section looks with favour on a measure which appears to promise them relief from burdens, which are, in no sense, essential appanages of their office. To the wide circle of university graduates the Bill has evidently commended itself. At a meeting of the Committee of the Association of the General Council of the University of Edinburgh, resolutions were passed expressing full satisfaction with the proposed measure, and praying that it might speedily become law.

SIR JAMES PAORT will preside at the dinner of the Royal Literary Fund on May 2nd. Many of the leading members of the medical profession have signified their intention of being present.

SIR JOHN SIMON, K.C.B., F.R.S., and Dr. C. J. B. Williams, F.R.S., have been proposed by the Council of the Pathological Society for election as Honorary Members of that body. Dr. Williams was the first President, and Sir John Simon is a past President.

By the resignation of Mr. Watson Cheyne, a Research Scholarship of the British Medical Association becomes vacant. The scholarship is of the annual value of £150. Applications should be forwarded at once to the Secretary at the offices of the British Medical Association, 429, Strand.

SIR PRESCOTT HEWETT, Bart., Consulting Surgeon to St. George's Hospital, and Sir Thomas Longmore, Professor of Military Surgery at the Army Medical School, were elected *Associés Etrangers* at the meeting of the Academy of Medicine, Paris, on March 27th. Both gentlemen have been corresponding members of the Academy for several years past.

MR. R. BANNISTER, F.I.C., F.C.S., is announced to give the Cantor Lectures at the Society of Arts; he will take as his subject Milk Supply and Butter and Cheese Making. The first lecture will take place on Monday, April 9th, and will be continued on the two subsequent Mondays.

MR. BENJAMIN WAINEWRIGHT was elected, on Wednesday last, April 4th, Assistant-Surgeon to Charing Cross Hospital. Mr. Wainewright received his professional education at the University of Edinburgh, and is Assistant-Surgeon to the West London Hospital.

THE new laboratory at the College of Surgeons is now in working order. It can be reached by a lift, a great advantage, as it is built very high above the level of the roof of the Museum. The rooms set apart for the preparation of specimens appear to be well adapted to the purpose for which they were constructed. The windows admit plenty of light, and there is no want of the necessary appliances for dissection.

THE INDEX MEDICUS.

WE regret to learn from the publisher, Mr. George S. Davis, Detroit, Michigan, U.S.A., that the *Index Medicus*, a publication which we have more than once noticed with approval, is still languishing for want of support. As a key to the books and articles on medical subjects published in the year, this publication seems to us to fill a useful purpose, and as such we should be sorry to hear that it had come to an untimely end.

SMALL-POX IN ABYSSINIA.

THE following information as to the prevalence of small-pox in Abyssinia has been received by the Exchange Telegraph Company. At Shea the annual epidemic of small-pox is said to be raging with great severity. The heir to the throne, Ras Mulcheha, aged 25 years, is dead, also three other members of the Royal family. At Massowah the heat is said to be intense—47° C. in the shade. The sanitary condition is deplorable. Typhus is prevalent among the men and the cattle. Water is scarce, and it will be necessary for the greater portion of the Italian expedition to re-embark for Europe.

A MEDICAL HERO.

AT the annual meeting of the Bristol Royal Infirmary, the President stated that a memorial window had just been completed for the chapel in commemoration of the heroic deed of a young surgeon, Mr. W. Courser Lysaght, who lost his life in endeavouring to save a poor patient who had undergone the operation of trache-

otomy while suffering from diphtheria. The window is in three panels, representing incidents from the parable of the Good Samaritan, and it will be inscribed "To the glory of God, and in affectionate remembrance of William Conner Lysaght, who was born May 7th, 1851, and died July 24th, 1887." Acts of medical heroism are not rare, and unhappily, a fatal issue in such cases as these has been repeatedly recorded.

LESSONS FROM CARLSBAD FOR ENGLISH HEALTH RESORTS.

DR. YATES BAINBRIDGE in the *Droitwich Guardian* reprints the third of the series of letters called "Spray from the Carlsbad Sprudel," by Mr. Ernest Hart, which was published in the *JOURNAL* of January 17th. He takes as his heading "How Carlsbad ensures Success: a Lesson for Droitwich;" and, in reprinting the whole letter, he adds a series of observations in support of it, and asks the Droitwich citizens whether they should, from sheer apathy and neglect, encourage sufferers from gout, rheumatism and kindred complaints to seek relief abroad while they have at their own door, at less expense, trouble, and worry, waters superior in every respect to foreign waters, and which (as was the case with Droitwich) performed cures which foreign waters had failed to do, at great expense and loss of time to the patients themselves. In calling the attention of the people of Droitwich to the suggestions in Mr. Ernest Hart's letter "for dispelling the cloud of dulness which darkens the future of this as of so many other of our health resorts," he expresses the conviction that the suggestions of Mr. Hart, if acted upon even in a modified sense, would greatly increase the number of visitors and ameliorate the lot of those who now from necessity visit Droitwich, besides bringing in a rich harvest to the town directly or indirectly, in place of the poverty now existing there.

TANNIN IN THE TREATMENT OF TUBERCULAR DISEASE.

At the fifth meeting of the Società Italiana di Chirurgia, recently held at Naples, Professor Andrea Ceccherelli, of Parma, drew attention to the value of tannin in the treatment of local affections of tubercular origin. From experiments which he had made on animals, and from clinical experience, he believed it to be a powerful antiseptic, with a specific power of destroying the tubercular virus. He found that the addition of tannin prevented the putrefaction of animal tissues and fluids, and that decomposition was very considerably delayed in the bodies of animals which, while alive, had undergone a course of treatment with tannin. He had also found that whilst he could produce tubercles in certain animals by the injection of phthisical sputa, or of tubercle bacilli, the injections produced no bad effect when tannin was injected simultaneously, or was given internally every day for some time. He had treated twenty patients suffering from tubercular diseases with tannin, both externally and internally, with very satisfactory results. He therefore looks upon tannin as an excellent remedy in tubercular affections of the bones and joints; under its influence ulcers heal kindly, any tubercular formations that may already exist are destroyed, and generalisation of the disease is prevented. Dr. Ceccherelli considers that tannin is much superior to iodoform in the treatment of tubercular disease, besides having the further advantage of being perfectly harmless.

THE HEALTH OF THE GERMAN EMPEROR.

It is with the greatest pleasure that we learn by special telegram from Charlottenburg that the Emperor of Germany is going on most satisfactorily. The disease appears for the moment almost quiescent; there is no sign of its spreading, and the glands are not in the least involved. His Majesty's general health is excellent, and his appearance shows no trace of illness or suffering, except

that his hair has become very grey. The position which Sir More Mackenzie took up from the first, and which he has steadfastly maintained ever since, that no radical surgical measures were advisable in the case, appears now to find more favour among the medical profession in Germany than has been the case till quite lately. The disastrous results of several cases in which similar operations have recently been performed seem to have opened men's eyes to the magnitude of the risk to which the Imperial patient would have been exposed but for the intervention of the English physician, in whom he not unnaturally places such confidence. Our Berlin correspondent, who is in a position to know the facts, informs us that Herr Kayser, a prominent member of the Social Democratic party in the German Reichstag, died a few days ago, immediately after half of his larynx had been cut out by Professor von Bergmann for cancer. We are also informed that of the eleven other patients on whom that distinguished surgeon has performed this severe operation have since died. Dr. Eugen Hahn, who has hitherto been the most successful operator in that line, has been equally unfortunate in his last two cases. Only the other day an operation of the same kind, performed by a leading London surgeon, resulted in the death of the patient on the third day. In private one hears mention of similar cases which have not yet come publicly before the profession. These facts, in our opinion, quite independently of any other reasons peculiar to the case, go far to justify the course which has been adopted with regard to His Imperial Majesty. Sir More Mackenzie was to have returned to London on Tuesday next April 10th, but we understand that in compliance with the urgent request of the Emperor he has agreed to postpone his departure from Berlin for a short time. Dr. Norris Wolfenden, who attends the Emperor professionally for some weeks during his stay in England last summer, has gone to Berlin at the invitation of His Imperial Majesty.

ABDOMINO-VAGINAL COMPLETE HYSTERECTOMY FOR UTERINE FIBROIDS.

PRIOR to operation on a case of fibroids of the uterus recently at the Hospital for Women, Mr. Reeves, in his remarks, stated to the students and visitors present that he intended to adopt a new plan which had occurred to him, provided that the relations of the growth permitted it. If, on opening the abdomen, the tumour proved to be an ordinary form of fibroid involving the fundus of the body, and did not extend too far laterally into the broad ligaments, he intended to tie these on either side in two interlocking ligatures, including the upper two-thirds of these structures, and after applying pressure-forceps to their uterine side, to divide between. Then the peritoneal folds attaching the growth to the bladder and rectum would be divided well up on the tumour, as to form flaps in the pelvic floor when the growth was removed. The ureters, bladder, and rectum would then be cleared from the cervix until the vaginal mucous membrane was nearly reached when the vaginal part of the operation would begin. This consists in separating the mucous membrane, as in vaginal hysterectomy. The uterine arteries would be compressed with forceps to be left on or tied according to circumstances, and the uterus removed entire. The pelvis would be cleansed, the serous flap placed in apposition, or stitched together if thought desirable, and a drainage-tube inserted *per vaginam*. The subsequent treatment would be as for vaginal hysterectomy. Mr. Reeves explains that his object in combining these plans was to do away with the uterine stump and its disadvantages, such as secondary hæmorrhage, septicæmia, dragging on the bladder and rectum, and occasionally the risk of its slipping into the abdomen and causing peritonitis. The combined operation should occupy less time than supravaginal hysterectomy with external treatment of the stump, as much time is taken up with trimming this at

suturing the peritoneum over it. Seeing that the best results in the supra-vaginal operation have been obtained by extra-peritoneal treatment of the stump, and that the mortality is still a high one, any practical plan which will reduce the causes of death should be acceptable. The chief of these are now-a-days hæmorrhage, septicæmia, and peritonitis, and it is believed that the proposed plan will banish all but a possible traumatic peritonitis; and as in vaginal hysterectomy for cancer this has been practically abolished, there is no reason—except, perhaps, the greater size of the growth removed—why the same favourable result should not follow the proposed operation. Complete removal of the fibroid uterus by Freund's method has been done, but the results of his mode of operating have been far from encouraging. The combined plan suggested allows of free drainage and syringing of the pelvic cavity, and offers every element of operative success, while doing away with many drawbacks. The case mentioned proved to be one of pedunculated fibroids, the larger of which was impacted in the pelvis, and the specimens will be shown at an ensuing meeting of the British Gynæcological Society.

THE ROYAL SOCIETY.

THE list of candidates for election into the Royal Society this year has just been issued to the Fellows. It contains sixty-one names. The candidates belonging to the medical profession are: Dr. Thomas Buzzard; Sir Charles Cameron, of Dublin; Professor W. H. Corfield; Dr. D. J. Cunningham, Professor of Anatomy, Dublin; Dr. Douglas Cunningham, Professor of Physiology, Calcutta; Dr. W. H. Dickinson; Dr. W. D. Halliburton, Assistant Professor of Physiology in University College; Dr. C. McMunn, of Wolverhampton; Dr. W. M. Ord; Dr. W. O. Priestley; Mr. Alfred Sanders, F.L.S.; Dr. David Sharp, President of the Entomological Society; Dr. Thomas Stevenson; Sir William Stokes; Mr. T. Pridgin Teale; Dr. R. Thorne Thorne; Professor C. M. Tidy; and Dr. Henry Trimen, Director of the Royal Botanic Gardens, Ceylon.

STROPHANTHUS AS AN ANTIPYRETIC.

DR. A. ROVIGHI, of Bologna, in experimenting on the effect of tincture of strophanthus (prepared according to Professor Fraser's directions) in cases of cardiac disease, came to the conclusion that it was much inferior to digitalis and caffeine in its power of regulating disordered action of the heart, relieving dyspnoea, and increasing the excretion of urine. He was, however, struck by the way in which it seemed to lower the temperature, and he therefore tried it in various febrile affections with very satisfactory results. Thus in four cases of pulmonary phthisis in which for months there had been considerable pyrexia, and in which other antipyretic remedies were useless or were badly borne by the patient, tincture of strophanthus in doses of from four to six minims every six hours reduced the temperature by two or three degrees. In a lad suffering from tubercular disease of the intestine with peritonitis, with a temperature of from 40° to 40.5° C., three minims of the strophanthus tincture every six hours brought the temperature down to 37.5° in the course of twelve hours, and as long as the remedy was continued, the temperature never rose beyond 37.8° C. In a patient with tubercular disease of the left hip, a pyrexial temperature of 39.7° C. fell to 37.2° after the administration of fifteen minims (five every six hours) of tincture of strophanthus. In a case of typhoid fever in the second week four to six drops every six hours lowered the temperature by two degrees. In all these cases the drug eased headache, lessened the quickness of the pulse, and produced a feeling of comfort in the patient, and did not in any instance give rise to symptoms of collapse, nor to disturbance of the gastro-intestinal canal, nor profuse sweating. Dr. Rovighi states that these clinical observations were confirmed by experiments on rabbits, in which

tincture of strophanthus in doses of ten or twelve minims lowered both the general and the local temperature to a very marked degree. On the other hand, Dr. V. Martini, of the University of Siena, has (*Sul Valore Antipiretico dello Strofantho*, Siena, 1888), tested the alleged antipyretic properties of strophanthus with absolutely negative results. He used a tincture prepared by Merck, of Darmstadt, of the same degree of concentration as Fraser's, and also one made by Messrs. Burroughs, Wellcome, and Co. according to Professor Fraser's latest formula. He tried it in cases of phthisis, tubercular peritonitis, broncho-pneumonia, acute rheumatism, erysipelas of the face, acute purulent cystitis, and hysterical pyrexia. From ten to fifty drops were given daily in three, four, or more doses at regular intervals. The thermometric readings were carefully noted every three hours for three or four days before and after each experiment, as well as during the course of it; in some cases the temperature was taken every hour whilst the drug was being administered. In the majority of cases no effect whatever on the temperature was observed; in a very few instances there was a slight fall, extending only to some fractions of a degree, which was followed almost immediately by a return to the former level. Dr. Martini concludes that strophanthus has not the slightest value as an antipyretic.

FEVER AND SANITARY DEFECTS AT BUCKINGHAM.

THE sanitary authority of the little town of Buckingham has just been awakened by an outbreak of typhoid fever to the conclusion that the general sanitary condition of the locality is not so satisfactory as it should be. For some years past Mr. De'Ath, the medical officer of health, has drawn the attention of the authority time after time to the need for improvement in the sanitary arrangements, but, as a member remarked at a recent meeting, his reports have been ignored. He has pointed out that the drainage is in many respects defective; that, although the water supply is good at its source, he could not feel certain that in the course of its distribution it might not become fouled by the leakage of some faulty drains; that in many cases the closet accommodation is not what it ought to be, that the scavenging needs to be better done so that the accumulations of filth at present to be found round about dwellings might disappear. In fact, the town needs a general cleaning up and putting in order, and afterwards a careful supervision, in order to secure a wholesome state of things. The Local Government Board have been appealed to for an immediate inspection, but surely in these days of local self-government that is a sign of weakness and unnecessary panic. The facts are admitted by the Mayor and other members of the Town Council, who have verified them by personal inspection. They have been reported many times by the responsible health officer. What advice can the central authority give in such a case except to clean up the district, put the drainage in proper order, protect the water supply, and establish a system of frequent and periodical removal of filth and refuse? It is strange that the outbreak of disease, with its attendant misery and expense, should so frequently be required to secure improvement of defective local hygienic arrangements.

COCAINE POISONING.

IN the *Vratch*, No. 4, 1888, p. 64, Dr. Nikolai M. Unkovsky, of Moscow, relates the case of a strong man, aged 56, suffering from hydrocele, in whom the hypodermic injection of two Pravaz syringe-fuls of a 4 per cent. solution of hydrochlorate of cocaine was followed in a few minutes by intense excitement, agonising pain along the spine (especially in the lumbar region), giddiness, blanching of the skin and mucous membranes, dryness of the mouth and throat, weakness of the pulse and voice, paroxysmal dyspnoea, failure of sight, prostration, and complete inability to move the limbs. The patient's state rapidly growing worse, Dr. Unkovsky resorted to free inhalations of amyl nitrite (recom-

mended as the best antidote to cocaine by Professor W. F. Grube, of Kharkov, and Dr. Schilling—see JOURNAL, vol. i, 1887, (pp. 695 and 1401) and subcutaneous injections of ether. The symptoms gradually disappeared in about an hour and a half. The total quantity of amyl nitrite inhaled (from a piece of cotton wool) in the course of an hour amounted to nearly one gramme while three syringefuls of ether were injected. The operation for hydrocele (injections of a 4 per cent. carbolic solution, etc.) was absolutely painless. Dr. Unkovsky also saw a case in which mental disturbance occurred an hour after the injection of half a syringeful of a 20 per cent. solution of the alkaloid into the gum. In another patient, an injection of a syringeful of a 4 per cent. cocaine solution under the skin of the leg gave rise in about six hours to giddiness, suffocation, slowness of the pulse, pallor, and faintness.

INHALATIONS OF HYDROFLUORIC ACID IN PHTHISIS.

SEVERAL French physicians have been trying the effects of inhalations of hydrofluoric acid gas in the treatment of pulmonary tuberculosis. Several methods of administering the gas have been suggested: probably the simplest form is that brought before the Therapeutical Society of Paris by M. Constantin Paul. M. Paul uses an ordinary wine bottle, containing a solution of fluoride of ammonium of the strength of two parts to a thousand. The bottle is closed by an india-rubber stopper with two holes, through which pass two glass tubes, one of them passing nearly to the bottom. The patient is directed to take from fifteen to twenty deep inspirations, and the acid smell of the acid is distinctly perceptible in the expired air. In this way the patient not only derives benefit from the powerful antiseptic qualities of the vapours, but he exercises the lungs. M. Paul is unable to explain how the gas comes into contact with surfaces which are protected by mucus, but he claims to have met with considerable success in several severe cases of pulmonary excavation and bronchiectasis. Under this treatment patients regain flesh and strength, and the malady appears to be arrested for a time in its course.

MULTIPLE ABSCESSSES IN SUCKLINGS.

SEVERAL authorities have noted the frequency of abscess in infant life. Hensch has shown that suppuration of the connective tissue is especially marked during the first years of infancy. He refers to the multiple abscesses which appear simultaneously and successively in many parts of the body without appreciable cause. The younger the child the more frequent are the abscesses. He believes that there must be a distinct suppurative diathesis. Dr. Bouchut attributes this frequent suppuration of the subcutaneous tissue to three diatheses: first, the puerperal diathesis; secondly, struma; and thirdly, syphilis. The latter two conditions are well known; the former is seen when a mother has continued to suckle her child after the appearance of symptoms of puerperal fever. In a case of this kind the child was seized with erysipelas a week after weaning, it having been weaned when eight days old. After the subsidence of the erysipelas, abscesses developed in the arm, abdomen, elbow, knee, breast, foot, etc.; they were opened, but more appeared, and the child was not well till the third month. Dr. Roulland, of Niort, has recently written on this subject in the *Annales de Gynécologie*. He observes that Hensch and Bouchut alone have considered the question in a scientific manner. He concludes that subcutaneous multiple abscesses are seen in sucklings, and appear to be traceable to several causes. Hereditary taints, syphilis, and acrofula especially, are decided sources of the affection. There remains a more important and essential form, Bouchut's puerperal diathesis. Dr. Roulland believes that he has proved auto-infection in a case of green diarrhoea at least. The child, aged six weeks, was closely

watched and kept scrupulously clean; the mother was in robust health, and continued to suckle her child, but, the milk diminishing, the child was allowed too frequent use of the bottle; this had set up diarrhoea. Dr. Roulland succeeded in curing that dangerous complication, and persisted in seeing that the child was kept clean. However, abscesses freely formed. Three months after recovery the child was again seized with diarrhoea, though it had been carefully brought up. During convalescence, fresh abscesses formed. The infant ultimately recovered. Dr. Roulland believes that this patient must have been infected by the absorption of noxious alkaloids formed in the intestines. True infection from without may follow the ingestion of milk from a mother stricken with puerperal fever, or may result from erysipelas, or suppuration of the stump of the cord. Dr. Roulland also quotes the important researches of Dr. Escherich (*Centralblatt für Kinderheilkunde*, No. 2, 1887), who declares that in all children at the breast, whether they be well or ill, the staphylococcus albus and the staphylococcus aureus are constantly to be found in the liver and in the more superficial layers of the epidermis. These pyogenic germs can enter the sebaceous and sudoriparous glands, and set up inflammation. Of course they more usually enter through a breach of surface, which is so common in the tender integuments of an infant. Throughout his memoir Dr. Roulland uses the term "*nourisson*" indiscriminately for all infants at the breast, whether suckled by their own mothers or by wet nurses. Some of the worst cases which he describes were nursed by their mothers, who were in many cases quite healthy. From the case above quoted every practitioner will draw the natural conclusion that in many other instances the bottle, and not the breast nor the binder, is to blame.

SCOTLAND.

PRESENTATION TO PROFESSOR CLELAND OF GLASGOW.

IMMEDIATELY after the close of the winter session of the medical classes at the University, the students assembled in the Anatomical Theatre and presented Professor Cleland with several very handsome pieces of silver plate on the occasion of his approaching marriage.

PRELIMINARY EXAMINATIONS.

THE half-yearly preliminary examinations in general education for degrees in medicine and science in the University of Glasgow were held last week, simultaneously in the examination hall of the University and in the University College of North Wales Bangor. There were in all 482 candidates, being the largest number ever entered for these examinations. At the medical preliminary examination held by the Faculty of Physicians and Surgeons there were seventy-five candidates.

ANDERSON'S COLLEGE DISPENSARY, GLASGOW.

At the annual meeting the directors reported that during the past year 3,149 visits, comprising 1,291 new cases, had been made to the sick poor, and that 12,106 new cases had attended the dispensary. In addition, the dispensary has undertaken the visitation of the pensioners on the outdoor fund of the Association for the Relief of Incurables. These, during the past year, numbered about 150, and were attended by the students of the College under proper supervision.

DR. THOMAS KEITH'S REMOVAL TO LONDON.

It is announced that Dr. Thomas Keith has made arrangements for removing to London shortly. Though it has often been rumoured that the distinguished surgeon meditated such a change, little attention has hitherto been paid to the statement. But now the announcement comes with startling unexpectedness.

It seems but yesterday since the fact was formally published that Dr. Keith had obtained funds which enabled him to institute an Edinburgh Hospital for Women, to be practically under his own management. Apparently this project has been abandoned. By the removal of Dr. Thomas Keith, the Edinburgh school loses one of its most striking figures, and the Royal Infirmary one of the most distinguished members of its staff. The position Dr. Keith has for many years occupied in the public mind, as well as among his professional brethren, is so completely unique that the blank will not easily be filled. No one is more generally respected, and no one is more devotedly revered by the few who have been permitted to know him well. It is with much reluctance that Edinburgh releases another of her favourite sons for further triumphs in the wider field of the metropolis.

MEDICO-CHIRURGICAL SOCIETY, GLASGOW.

At a meeting of the surgical section, Dr. Knox showed a patient on whom he had successfully performed the old operation for ruptured femoral aneurysm. Drs. Knox and Beatson showed a patient who had suffered from double popliteal aneurysm, the larger having been cured by compression of the common femoral by Dr. Knox, the other at a later date by ligature of the superficial femoral by Dr. Beatson. Dr. Beatson also showed a patient suffering from femoral arterio-venous aneurysm and two card specimens, a large parovarian cyst, and an old intracapsular fracture of the neck of the femur.

TUBERCULOSIS IN RELATION TO FOOD SUPPLIES.

THE Medico-Chirurgical Society of Edinburgh, at its last meeting, agreed to memorialise the Privy Council on the subject of tuberculosis in relation to the supply of meat and milk, with the prayer that the matter may receive early and full consideration, and such measures be adopted as the grave issues demand. The Society has also under consideration the advisability of addressing the local authorities on the subject of the better inspection and ventilation of cow-houses and dairies. An evident difficulty in connection with this latter move is the necessity that such a system, to be effective, must be more general than can be ensured by the city authorities.

CLINICAL EXAMINATIONS AT EDINBURGH UNIVERSITY.

THE Board of Examiners of Edinburgh University has adopted certain suggestions for the conduct of the final examination for the M.B. degree which will be received with much satisfaction by candidates. The new arrangements are of the most common-sense description. In place of the clinical examination in medicine dragging its weary length through six weeks it will be completed in a fortnight. The system of examination will be no less thorough than formerly, but students will not have their mental powers kept in the state of very uncertain equilibrium through six long weary weeks. The regular summer clinical instruction also will be less disturbed. It is to be hoped that similar arrangements will be made for the surgical side of the examination, which, it is announced, will be made more stringent.

ST. MUNGO'S COLLEGE BILL.

THE managers of the Glasgow Royal Infirmary have issued a statement in favour of this Bill. They dwell on the size and importance of the infirmary, and briefly but pointedly state its history. Contrasting the large numbers of students that used to be trained within its walls and the small numbers that now attend, they attribute the decline to the removal of the university westwards, the opening of the Western Infirmary close to the new university, the impossibility of a student now obtaining a degree at St. Andrews as could be done before 1862, and the facilities

for obtaining degrees in England by the affiliation of the Newcastle School to Durham University, and by the colleges of the Victoria University. The statement emphasises the value to a hospital of the attendance of students in numbers, and points to the overcrowding at the Western Infirmary. It expresses the willingness of the managers to grant to the proposed college the use of the buildings at present occupied by their medical school, and of the furniture contained in them, so that, without further endowment, the new college might start fully equipped.

ABERCROMBY STREET INDUSTRIAL SCHOOL, GLASGOW.

A FURTHER report has been made by Dr. J. B. Russell on the extraordinary epidemic among the boys in this school, from which we learn that up to this date there have been 4 deaths in the institution, 27 boys and 2 girls have been removed to Belvedere, and 31 boys are more or less ill, being a total of 64 attacked. The occurrence of the two cases among the girls gave rise to great anxiety, because both were employed in the kitchen, and one had a brother who was one of the first attacked among the boys, and the mother had more than once gone from visiting her son to see her daughter. These circumstances were strongly suggestive of infection, but the girls were promptly removed, and there has been no more illness among them. As regards the nature of the disease, the opinions of those who have observed it are still at variance. Of hitherto defined diseases "influenza" of a malignant type, and "infectious pneumonia" are the only choice. Something may be said both for and against each, but whether this outbreak falls under either denomination, or arises from some new septic poison, or from some other known septic poison acting under circumstances of special local aggravation, cannot be discussed till all the lines of inquiry are completed. Whatever may be the ultimate diagnosis, we are driven back upon the local insanitary condition. There is a blood-poison of some sort which is either created or intensified by these conditions. Much public attention has been directed to the graveyard beside the institution, especially on account of the cholera pits of 1848 therein. But the graveyard is only one item—a serious item, no doubt—in the aggregate of insanitary circumstances. It has been found that tobacco chewing was much practised by the boys, and, while such a practice could not cause a febrile disease, it may be added to the other causes of depressed vitality which render these boys ready victims to disease. Dr. Russell further refers to similar outbreaks that have occurred from time to time in similar institutions. Ten years ago there was an outbreak in Werthorn Roman Catholic Reformatory for Boys, in which two boys died rapidly. In January, 1887, there was an outbreak at Birkdale Roman Catholic Reformatory for Boys, in which twenty-three were affected and three died. Dr. Seaton, of the Local Government Board, has also described a febrile epidemic disease that broke out in a Roman Catholic school for boys near London, and caused 157 illnesses and 7 deaths, some as rapidly as in the present instance, and with almost identical symptoms. In all these cases doubts as to the nature of the disease did not prevent the inference that obvious local insanitary circumstances were the cause.

PIT BURIAL AT DALBETH, NEAR GLASGOW.

THE Barony Parochial Board, as local authority, have been investigating the mode of interment, called "pit burial," at Dalbeth Cemetery, of which Dr. James A. Adams has complained as a nuisance and dangerous to the health of the inmates of the neighbouring Roman Catholic convent. Dr. Christie, the medical officer of the board, has visited the cemetery, and condemns the system most strongly. He says that the burial pits at present in use are 12 feet deep, 7½ feet long, and 6 feet wide. The pit is dug into from 4 to 6 feet of the original stiff clay soil, the upper portion being made-up soil. A layer of coffins is placed on the bottom, and sprinkled

over with a little earth, then another layer of coffins, and so on, until the pit is filled to about 3 feet from the surface, when it is covered over with stiff clay. Each pit, when full, will contain about 36 adult bodies, and about the same number of children, making about 70 in all. The pit inspected had been but recently opened, and in the space of half an hour Dr. Christie witnessed 5 interments therein. The pit system has been in vogue since 1863, when the cemetery was opened, but at first and for several years the pits were much smaller than those now in use. No offensive odour could be detected on going round the pits and over the ground, but the weather was cold and unfavourable to decomposition, and it is hardly possible to conceive that these pits during the hot dry weather of summer could be inodorous. Dr. Christie further investigated the causes of deaths that have taken place in the neighbourhood of the cemetery since 1881, but he has failed to connect any of them with the insanitary state of the cemetery. The question of deaths in the neighbourhood, however, is comparatively immaterial; for those who attend the funerals are most exposed to the danger, and there may be cases of severe illness without death. According to the Public Health (Scotland) Act, 1867, "any churchyard, cemetery, or place of sepulture, so situated or so crowded with bodies or otherwise so conducted as to be offensive or injurious to health, may be treated as a nuisance, and shut up or regulated on sufficient proof being laid before the sheriff by the local authority of the place in which the graveyard is situated." According to the Burials Act, it is in the power of the local authority to shut up or regulate all graveyards which are "conducted in such a manner as to be dangerous to health, or offensive, or contrary to decency." Seventy coffins disposed of within the space mentioned, and covered with three feet of clay, is a nuisance within the meaning of these Acts, and such a nuisance exists at Dalbeth.

IRELAND.

THE LABOURERS ACT: CELBRIDGE UNION.

LAST week Dr. Hayes made an application to the board of guardians for a remuneration of ten shillings a house for each house inspected by him under the Labourers Act. The guardians, however, considered this too much, and unanimously passed a resolution awarding him half-a-crown a house, which Dr. Hayes indignantly refused, and the matter has been referred to the arbitration of the Local Government Board.

TRINITY COLLEGE: LECTURESHIP ON MEDICAL JURISPRUDENCE.

ON Saturday (to-day) the Board of Trinity College will proceed to the election of a successor to the late Dr. Travers, Lecturer on Medical Jurisprudence. Among the candidates mentioned are Dr. Quinlan, Dr. E. MacDowel Cosgrave, Dr. Pratt, Dr. Bewley, and Dr. Auchinleck.

THE LOCAL GOVERNMENT BOARD INSPECTORSHIP.

AS yet there is no official confirmation of the statement that Dr. Edward Thompson, of Omagh, has been appointed inspector under the Local Government Board. It is, however, generally believed that he has been selected, and already numerous candidates are in the field for the various offices held by him.

BELFAST WATER SUPPLY.

THE controversy which has been waged during the past winter regarding the quality of the water supplied to the inhabitants of Belfast may be regarded as finally set at rest by the reports recently presented to the Belfast Water Board by Dr. Tidy and Dr. Davis, of Netley. When public attention was first drawn to the alleged impurities of the Belfast water, the Water Commissioners

obtained the services of Dr. Tidy, who came over and personally inspected the water sources, the reservoirs, the public fountains, and the supply to private houses. He brought away samples of water for examination, and the results of his analysis are now presented to the public. He states that, while the quantity of organic matters in the Belfast waters is rather high, "he has no hesitation in advising the Commissioners that this organic matter is of vegetable and not of animal origin, and that it is of a perfectly harmless and innocuous nature. The dissolved organic matter is less than is often to be found in the much-lauded Loch Katrine water, and, all told, amounts to less than one grain per gallon." He also reports favourably regarding the state of the water sources, and believes that the Commissioners have not been guilty of any negligence in the past in their choice of feeders for the reservoirs. He advises that the water should be filtered, rather to improve its colour and appearance than to avert any positive danger. The report of Dr. Davis is similar in tone. These reports from such competent authorities will finally reassure the public mind, which had naturally been disturbed by the very alarmist statements made both in the press and in the Belfast Town Council. These statements were believed more readily than would otherwise have happened, owing to the fact that the death-rate of Belfast has been abnormally high during the past winter, and the blame was not unnaturally cast upon the alleged defects in the water supply.

METHODS OF EXECUTING CRIMINALS.—The committee of the Medico-Legal Society of New York, to whom the subject of the best method of executing the death penalty was referred for consideration and report, has had under its consideration some important papers dealing with this subject, by medical men and others who have given special study to it. The suggestions made by the committee in their report, which have been approved and adopted by the Medico-Legal Society, include the following:—That hanging should be abolished as cruel, and contrary to the public sense of our civilisation. That as a substitute for the present death penalty they recommend—Death by the electric current; or, death by hypodermatic, or other injection of poison; or, death by carbonic oxide gas injected into a small room in each gaol, as recommended by Prof. John H. Packard (*Med.-Leg. Papers*, vol 3, p. 521), giving preference to the first, or death by electric current. In their judgment executions should be private, and not public, for if it was possible to prevent the publication of details of executions in the public press, it would be a public good. A further suggestion is that the bodies of criminals should be delivered to the medical schools after execution for dissection. No opinion is expressed by the committee as to the propriety of inflicting capital punishment by the State, as to which there is a strong opinion of the popular mind. This report bears the signatures of the following members of the committee: R. Ogden Doremus, Clark Bell, J. Mount Bleyer, M.D., Chas. F. Stillman, M.D., Frank H. Ingram, M.D.

DOMESTIC HYGIENE.—An interesting course of lectures has just been given at the Parkes Museum by Dr. Schofield on Domestic Hygiene. The lectures were addressed especially to ladies, and the good attendance and great attention showed that the lectures met a want that had been much felt. After the lecture on March 16th on "Boys and Girls," some specimens of reasonable or, as it is called, rational dress combined with beauty were shown, and a capital demonstration of the value of improved physical culture was given by Miss Chreiman, and, after the fifth lecture on "Home Nursing," an illustration of the mode of handling a patient in bed under various circumstances was given by two trained hospital nurses. The lectures will be followed by an examination in the subjects dealt with, and H. R. H. the Duchess of Albany, Patroness of the museum, has consented to distribute the certificates to the successful candidates on May 5th.

REGISTRATION AND EXAMINATION OF PLUMBERS.—The Registration Committee of the Worshipful Company of Plumbers received at the Guildhall on Wednesday the first nominations for the registration of Plumbers in Edinburgh and the East of Scotland. They were forwarded by the Council recently formed in Edinburgh, under the presidency of Sir Douglas Maclagan, M.D., to extend the registration system in that district of Scotland.

PETITION TO THE HOUSE OF COMMONS AGAINST THE TAXATION OF HORSES OF MEDICAL PRACTITIONERS.

It is suggested that the following, or some similar, petition be addressed by every medical practitioner who desires to oppose the imposition of the tax, to the member of Parliament for his district, with a request that he will present it and support its prayer. It should be written on one sheet of paper, and on one side of the paper only. If addressed to an M.P. at the House of Commons, and the wrapper marked Petition, it does not need to be stamped.

ERNEST HART,
Chairman of the Parliamentary Bills Committee,
British Medical Association.

TO THE HONOURABLE THE HOUSE OF COMMONS IN PARLIAMENT ASSEMBLED.

The petition of your petitioners humbly sheweth—

That in view of the proposal in the forthcoming Budget to impose a horse tax and increase in the carriage tax, a grievous burden will be inflicted upon members of the medical profession, who have often, in discharge of their duties both in the public service and in private practice, to travel long distances—such as, in many instances of very unremunerative work, necessitate the use of a horse and vehicle.

That as such horses and vehicles are used for the exclusive purpose of the performance of such duties, or other purposes in connection with the conduct of medical practice. We humbly pray your Honourable House to amend or rescind this clause, as introduced by the Chancellor of the Exchequer, which will have an oppressive effect on the performance of the duties of the medical practitioner, and tend to injure the interests of the health of the community.

And your petitioners will ever pray.

RECURRENCE OF MALIGNANT GROWTHS AFTER REMOVAL.

At the recent meeting of the French Surgical Congress perhaps the most important question discussed was the recurrence of malignant growths after extirpation. M. Cazin, of Bercy-sur-Mer, introduced the subject by giving a summary of the results of operations which he had performed from 1862 to 1886. During these twenty-four years he had removed no less than 564 tumours, including myxomata, chondromata, and sarcomata, besides true cancerous growths. In 102 cases of scirrhus of the breast there was secondary glandular affection in 60; of these 7 were permanently cured, in 48 recurrence took place, 3 died, and in 2 the result was unknown. Among the remaining 42 cases, in which the glands were unaffected, there were 8 cures, 28 recurrences, 2 deaths, and 5 were lost sight of. In 120 cases of encephaloid, the glands were involved in 80; of these 5 were cured, the disease returned in 67, 4 died, and 4 could not be traced. Thus in a total of 222 cases there were 28, or 12.6 per cent., permanent cures. Taking the scirrhus cases separately, we find that the total number of cures was 15, or 14.7 per cent.; but of those in which the glands were affected, only 7 out of 60, or 11.66 per cent., were cured, while of the others, in which the disease was limited to the breast, permanent cure was obtained in 8 out of 42, or a fraction over 19 per cent. Among the 120 cases of encephaloid, 13, or 10.8 per cent., were cured; but of the 80 in which the glands were involved, the proportion of cures was only 5, or 6.25 per cent., whilst of the 40 in which there was no glandular enlargement, no fewer than 8, or 20 per cent., were cured. In the cases in which recurrence took place, the disease returned from three months to seven years after the operation; this statement, it is to be presumed, applies to the whole mass of cases taken together, and not to the cancer group alone. M. Cazin is right, we think, in looking upon these results as fairly satisfactory in the present state of surgical science, and he attributes his success to the freedom with which he removes apparently healthy tissues surrounding the growth, and to the care with which he seeks for and removes, not only diseased glands, but the lymphatics between them and the tumour. He is not content with exploring the axilla, but makes minute search

in the subclavicular region, behind the clavicle, and in the supraclavicular fossa.

M. Verneuil, whilst laying stress on thorough-going methods of operating, drew attention to a point which he considered of the utmost importance in the prevention of recurrence after extirpation. He said that when a cancerous tumour was removed, some seeds of the disease were, in the vast majority of cases, left behind, which sooner or later developed into a fresh growth. This, however, did not as a rule take place for some time after the operation, and during that period the morbid process was in abeyance. That was the time, in his opinion, when the morbid elements being in an inactive state, there might be some chance of destroying them or eliminating them from the system by internal medication. Thus a prolonged course of alkaline treatment (Vichy water, magnesia, etc.), together with arsenic, should be tried after operation, with the view of neutralising the gouty diathesis, which M. Verneuil believed to be the predisposing cause of cancer. Again, as it had been shown by M. Reclus that cancer was all but unknown among persons whose food was exclusively vegetable, this fact might afford a useful hint as to diet in the prevention of recurrence. M. Verneuil, alluding to the increased prevalence of cancer at the present time, said that when he was Lisfranc's house-surgeon, in 1844, that enthusiastic operator had only two or three cases of cancer of the anus or rectum in the course of the year; to-day, M. Verneuil, at the same hospital and with the same number of patients, had on an average fifteen such cases come under his hand annually. The same might be said with regard to the breast, the lip, and the tongue; in fact, there were three or four times as many cases of cancer now as there were forty years ago. He believed that this was largely due to the carnivorous habits of diet of the present generation. Whilst speaking of the length of time that cancer might remain latent in the system, M. Verneuil mentioned the case of a lady from whom, thirty-four years previously, he had removed a tumour which was examined after the operation and pronounced to be cancerous. Thirty years afterwards the disease recurred in the scar, and was again extirpated; the microscopic examination completely confirmed the former diagnosis.

M. Labbé agreed with M. Verneuil as to the probable advantage of post-operative treatment with arsenic and alkalies; he was also disposed from his experience, extending over many years, to place some reliance on tincture of condurango as a preventive of recurrence.

M. Galezowski confirmed M. Verneuil's statement as to the increased frequency of the occurrence of cancer from the field of ophthalmic practice. He had, during the six years that he was assistant to Desmares, seen only one or two cases of melanocarcinoma of the eye; he now saw on an average six every year.

M. Mollière, of Lyons, said that the great point to attend to in estimating the probability of recurrence was the patient's age. If he were young, the disease was so certain to return, that he doubted whether it was worth while to operate; after 50 there was a fair chance that recurrence might not take place, after 70 it was almost certain that the patient would remain free from the disease.

ASSOCIATION INTELLIGENCE.

COUNCIL.

NOTICE OF MEETING.

A MEETING of the Council will be held at the Offices of the Association, No. 429, Strand (corner of Agar Street), London, on Wednesday, the 18th day of April next, at 2 o'clock in the afternoon.

FRANCIS FOWKE, *General Secretary.*

March 15th, 1888.

NOTICE OF QUARTERLY MEETINGS FOR 1888. ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member *by the Council* or by any recognised *Branch Council*.

Meetings of the Council will be held on April 18th, July 18th, and October 17th, 1888. Candidates for election by the Council of the Association must send in their forms of application to the

General Secretary not later than twenty-one days before each meeting, namely, June 27th, September 26th, and December 28th, 1888.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No member can be elected by a Branch Council unless his name has been inserted in the circular summoning the meeting at which he seeks election.

FRANCIS FOWKE, *General Secretary.*

COLLECTIVE INVESTIGATION OF DISEASE.

THE REPORT UPON THE CONNECTION OF DISEASE WITH HABITS OF INTEMPERANCE, which was presented to the Section of Medicine in the Annual Meeting of 1887 will shortly be published in the JOURNAL.

Reports upon the two remaining inquiries, namely, that into DIPHThERIA, and that into the GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES, are in preparation, and will be published as soon as ready.

The following inquiry only of the first series remains open, namely, that on THE ETIOLOGY OF PHTHISIS.

A fresh inquiry into the ORIGIN AND MODE OF PROPAGATION OF EPIDEMICS OF DIPHThERIA has been issued.

Memoranda upon these subjects, and forms for recording observations, may be had on application to the Secretary of the Collective Investigation Committee, 429, Strand, W.C.

BRANCH MEETINGS TO BE HELD.

METROPOLITAN COUNTIES BRANCH: EAST LONDON AND SOUTH ESSEX DISTRICT.—The next meeting will be held on Thursday, April 19th, at the Hackney Town Hall, at 8.30 P.M. The chair will be taken by F. M. CORNER, Esq. A paper on the Surgery of Abscess will be read by HOWARD MARSH, Esq. Visitors will be welcome.—J. W. HUNT, 101, Queen's Road, Dalston, Honorary Secretary.

WEST SOMERSET BRANCH.—The spring meeting will be held at the Railway Hotel, Taunton, on Thursday, April 12th, at 5 P.M. Dinner at 5.30 P.M. The subject settled by the Council to be discussed after dinner is Bone Setting. Mr. W. J. PENNY, Assistant-Surgeon to the Bristol General Hospital, and Demonstrator of Anatomy to the Bristol Medical School, has kindly promised to come and open the discussion. The election of representative of the Branch on the Council of the Association for the ensuing year will take place at this meeting.—W. M. KELLY, M.D., Taunton, Honorary Secretary.

SOUTH-EASTERN BRANCH: WEST KENT DISTRICT.—The next meeting of this District will take place on Friday, April 27th, at the Hospital, Gravesend, R. J. BRYDEN, Esq., in the chair. Gentlemen desirous of reading papers or exhibiting specimens are requested to inform the Honorary Secretary of the District not later than April 8th. Further particulars will be duly announced.—A. W. NANKIVELL, F.R.C.S., St. Bartholomew's Hospital, Chatham, Honorary Secretary.

NORTH OF ENGLAND BRANCH.—The spring meeting will be held at the Infirmary, Sunderland, on Wednesday, April 25th, at 3 P.M. Members intending to read papers or show specimens are requested to communicate at once with the secretary. The dinner after the meeting will take place at the Queen's Hotel, at 5 o'clock. The following papers are already promised:—Dr. HUME: A Case of Congenital Fistula of the Stomach, Cured by Operation. Dr. COLEY: On the Treatment of Effusion into the Pleura in Children. Dr. MURPHY: A Man 229 Days after Gastrostomy. Dr. OLIVER: Notes on an Unusual Case of Hematuria.—G. E. WILLIAMSON, F.R.C.S., 22, Eldon Square, Newcastle-on-Tyne, Honorary Secretary.

NORTH OF IRELAND BRANCH.—A general meeting of this Branch will be held in the Royal Hospital, Belfast, on Thursday, April 19th, at 11 A.M. Dr. JOHN STRAHAN will read a paper on Turpentine in Whooping-Cough and some other affections. Dr. O'NEILL will show two patients on whom he operated for Congenital Inguino-Scrotal Hernia (Radical cure), and read notes of the cases. Professor SINCLAIR will report upon a Successful Jejunal Enterectomy performed on the day of the last Branch meeting, and exhibit the segment of intestine excised. Dr. BURDEN will show a series of Microscopic Preparations of Tumours. Dr. BYERS will show an Ovarian Tumour which he successfully removed.—JOHN W. BYERS, M.D., Lower Crescent, Belfast, Honorary Secretary.

OXFORD AND DISTRICT BRANCH.—The next meeting will be held at the Radcliffe Infirmary, Oxford, on Friday, April 27th, at 3 P.M. Notice of papers to be read must be sent to W. LEWIS MORGAN, 42, Broad Street, Oxford, on or before April 18th. A dinner will be provided for those members who signify their intention to dine to the Secretary two days before the meeting.—S. D. DARRISLIRE and W. LEWIS MORGAN, Honorary Secretaries.

SOUTHERN BRANCH: SOUTHAMPTON DISTRICT.—The next meeting of this District will be held on Tuesday, April 10th, 1888, at the residence of Dr. Maclean, C.B., 23, Carlton Crescent, at 8 P.M. Business: Election of officers. Passing of accounts. At the same time, a joint meeting with the Southampton Medical Society will take place, when a paper will be read by Brigade-Surgeon Godwin, M.S., on the Treatment of Wounds of the Abdominal Viscera. Dr. L.

M. Buckell will bring under notice a case, with specimen, of Monstee Birth. Association and Branch subscriptions for current year, amounting to £1 3s. 6d., became due on January 1st, and may be paid to the Honorary Secretary as soon as convenient.—THEOPH. W. TREND, M.D., Honorary Secretary, 6, Anglesea Place, Southampton.

SOUTHERN BRANCH: SOUTH-EAST HANTS DISTRICT.—Ordinary meeting at the Grosvenor Hotel, Queen's Gate, Southsea, on Thursday, April 11th, 1888. The chair will be taken by the President, Dr. James Watson, at 4.15 P.M. Gentlemen who are desirous of introducing patients, exhibiting pathological specimens, or making communications are requested to signify their intention at once to the Honorary Secretary. Dinner will be provided at 6.30 P.M.; charge, 5s., exclusive of wine, etc.—J. WARD COUSINS, Honorary Secretary.

SOUTH WALES AND MONMOUTHSHIRE BRANCH.—The spring meeting of this Branch will be held at Pontypridd, on Friday, April 13th, at 12.30. Papers promised:—J. P. FRY: A Case of Excision of the Thyroid. J. ARNALL JONES: A Case of Oedema of Hand, with Specimen. J. TAHAM THOMPSON: On Detachment of the Retina.—ALFRED SHEEN, M.D., Cardiff; D. ARTHUR DAVIES, M.B., Swansea, Honorary Secretaries.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.

A MEETING of this Branch was held at 193, Union Street, Aberdeen, on Wednesday, March 21st, at 1 P.M. Dr. URQUHART, Vice-president, in the chair.

Minutes and Nomination of New Members.—The minutes of last meeting being read and approved, Dr. James Cravie, Newburgh, was nominated for ballot at next meeting.

Admission of New Members.—The following gentlemen were balloted for and admitted as members of the Branch, namely:—Dr. John Anderson, Elmhill House, Aberdeen; Professor Cash, Dee Street; Dr. John W. Hutcheon, Alford; Dr. George Mair, 21, Crown Street, Aberdeen; Dr. Robert Morrison, Rosieburn, Methlie; Dr. Stephen, Belhelvie; Dr. Whitton, Aberchirder, Banffshire.

METROPOLITAN COUNTIES BRANCH: NORTH LONDON DISTRICT.

A MEETING of this District was held on Wednesday evening, March 28th, 1888, at the North-West London Hospital, Kentish Town Road, N.W., A. E. DURHAM, Esq., President of the Branch in the chair.

Cases.—Several interesting cases from the wards of the hospital and out-patients' department were exhibited.—Dr. HOOD: Case of Marked Lineæ Albicantes after Dropsy.—Mr. F. DURHAM's cases: Fissured Fracture of Skull; Trephining; Recovery. Tumour of Neck, pushing Trachea and Larynx to opposite side. Osteotomy of Femur. Pathological Specimens: Cancer of Breast; Sarcoma of Sole of Foot; Melon Seed Bodies from Compound Palmar Ganglion; Two Breasts with Scirrhus.—Dr. COLLINS's cases were Paralysis of Fifth Nerve; Opacity in Vitreous.—Dr. CAMPBELL's cases: Early Puberty in Boy of 7 years. Coloboma.—Mr. BLACK: Ulceration of Tongue; Epithelioma.

Communications.—Dr. HOOD read a paper on Empyema following Pneumonia.

Vote of Thanks.—Votes of thanks to the President, Dr. Hood, and the gentlemen who had shown cases, as well as to the Committee of the hospital, were given.

SHROPSHIRE AND MID-WALES BRANCH.

A HALF-YEARLY meeting of the Branch was held at the Salop Infirmary on Tuesday, March 27th, at 3 P.M.; the President, W. EDDOWES, Esq., occupied the chair.

New Members.—The following gentlemen were elected members of the Branch: E. L. BIRD, Shrewsbury; R. T. CESAR, Wellington; C. I. GIBSON, Shifnal; F. K. PIGOT, Shrewsbury; S. H. PUEKLE, Bishop's Castle; A. F. WHITWELL, Shrewsbury; G. F. JOHNSTON, Wellington.

Communications.—Mr. J. T. MEEK read notes of a case of Intestinal Obstruction, and on a case of Cirrhosis of the Liver, with nervous symptoms.—Mr. J. F. HARRIES gave a demonstration of the latest Antiseptic Dressings.—Mr. J. L. WEBB read notes on three cases of Carcinoma of the Breast, and asked for answers from members of the Branch to the following questions: 1. The average duration of life, after operation for cancer of the breast, in old and young cases? 2. Is eczema of the nipple a common precursor of cancer? 3. Whether it is common to find tumours of the scalp in recurrent cases? Mr. Webb also showed microscopic sections of the growth.

Electric Cystoscopy.—Mr. ASHTON SALT, of Birmingham, attended the meeting, and exhibited and practically demonstrated some new and interesting inventions for examinations by Electric

Light of the Bladder and its entrances, also various appliances for cauterisation.

The PRESIDENT subsequently entertained the members in a most hospitable manner.

EAST ANGLIAN BRANCH: ESSEX DISTRICT.

AN ordinary meeting of this District was held at the Saracen's Head Hotel, Dunmow, on March 23rd, 1888, R. B. MARRIOTT, Esq., President, in the chair. There were also present ten members and visitors.

Election of Honorary Secretary.—Mr. C. E. ABBOTT, Braintree, was re-elected Honorary Secretary for the ensuing year.

Next Meeting.—It was decided that the next meeting be held at Clacton-on-Sea in September.

Communication from the Lancashire and Cheshire Branch.—Dr. W. A. ELLISTON, Ipswich, proposed the following resolution: "That this meeting expresses its approval of the memorial of the Lancashire and Cheshire Branch respecting the inadequate fees paid to medical witnesses at assizes and county sessions, and requests the Council of the Association to petition the Home Secretary to revise the fees which are at present paid to medical witnesses."—This was seconded by Dr. S. R. ALEXANDER, and carried unanimously.

New Members.—The following members were elected: H. Stear, Esq., Saffron Walden; E. W. Holland, Esq., Chelmsford.

The late Mr. W. T. Jackman.—Dr. HOLDEN, Sudbury, proposed in appropriate terms that a letter of condolence be sent to the relatives of the late Mr. W. T. Jackman, Brixton, S.W., who was mainly instrumental in the formation of the District in 1885, and filled the post of Honorary Secretary for two years, and whose untimely death, at the age of 34, occurred on November 2nd, 1887.—This was seconded by the PRESIDENT, and carried unanimously.

Communications.—R. B. MARRIOTT, Esq. (President): Short Notes on a few Cases of Stone in the Bladder.—Dr. F. DE HAVILLAND HALL, London: Remarks on certain Remedies employed for the Relief of Pain and Spasm.—Dr. DOWNES, Chelmsford: Remarks on Epidemic Diphtheria in Rural Districts.

Cases.—Mr. C. HARTLEY, Dunmow, exhibited several interesting surgical cases.

The members afterwards sat down to a "high tea" at the hotel.

GLOUCESTERSHIRE BRANCH.

AN ordinary meeting was held on Tuesday, March 20th, at 7.30 P.M., at the General Hospital, Cheltenham, under the presidency of Dr. CURRIE.

Minutes of Last Meeting.—The minutes of the last meeting were read. It was proposed by Dr. NEEDHAM and seconded by Dr. SOUTAR that the last paragraph be omitted. Carried.

Paper.—Mr. MASON (General Hospital, Cheltenham) read a paper on seventy cases of typhoid fever which had been admitted into the hospital during the last six months. A discussion followed.

SPECIAL CORRESPONDENCE.

VIENNA.

[FROM OUR OWN CORRESPONDENT.]

Nephrectomy.—Melanosarcosis.—Phlegmonous Pharyngitis.

At a recent meeting of the Imperial Royal Society of Physicians of Vienna, Professor Weinechner showed a woman, aged 51, on whom he had performed nephrectomy for pyonephrosis. The patient had suffered for ten years from pains in the right part of the abdomen, and a tumour, the size of which was constantly varying, developed beneath the right costal arch. At different periods the patient was attacked with fever, and suffered from pains in the swelling, the urine being clear, and the tumour increasing in size on each of these occasions; in the apyretic periods the urine was found to contain pus, the swelling diminished, and the patient felt well. These alternating periods were, during the first five years, observed only once every twelve months, but during the last few years they had become much more frequent, so that the patient was never quite free from pain. On admission a tumour, which extended almost to the symphysis, was detected; it was tender on pressure, and presented a distinct fluctuation; the urine was clear. Professor Weinechner performed nephrectomy by the extraperitoneal method. An incision

was made at the outer margin of the sacro-lumbalis muscle, the kidney was laid bare, and about half a litre of pus was discharged from it by puncture. After the upper and lower ends of the organ had been detached and the pedicle ligatured, the kidney was removed. Healing took place without any trouble; the quantity of the urine increased from 600 to 900 grammes, and on the twentieth day after operation it amounted to 1,300 grammes.

Docens Dr. Zemann, assistant to Professor Kundrat in the chair of pathological anatomy, brought before the same Society, specimens of two cases of melanosarcoma with secondary formations. The first case was that of a patient, aged 35, who had been treated in the clinic of Professor Billroth, and who was, at the beginning of his disease, affected with a small *nevus pigmentosus* on the back. Melanosarcomata of a colossal size developed later on in the axillary glands, a certain number of which were removed by operation. Innumerable small melanotic tumours also formed in the skin over the whole body. The *post-mortem* examination, which was made by Dr. Zemann, showed that there were a great number of secondary formations in most of the internal organs. What was of a special interest in this case, was the uniform dark brown colour of some organs, such as the liver and the spleen. The cancellous tissue of the bones, especially of the vertebrae, was also intensely dark in colour. Some nodules could also be detected in the pleura, the pericardium, the œsophagus, and the pharynx. In the second case, that of a man aged 70, a melanosarcoma of the left eyeball was the primary affection. Enucleation was performed, but the patient died some time afterwards. The number of secondary formations was still greater in this case, some melanosarcomatous patches having been found even in the large veins, and on the internal surface of the dura mater.

Dr. Zemann also showed a specimen of "pharyngitis submucosa phlegmonosa" from a man aged 60. This case was of special interest from the fact that Senator, who had recently described this affection in the *Berliner Klinische Wochenschrift*, stated that the disease was previously quite unknown. According to Dr. Zemann, however, pathologists, if not clinicians, had long been well acquainted with the affection, and the disease was not so very rare, as four or five examples of it were generally observed each year in the *post-mortem* rooms of the Vienna General Hospital. The disease was characterised by phlegmonous inflammation of the submucous cellular tissue of the pharynx and the larynx, running a very acute course; this was why the diagnosis could be made only with great difficulty in the living subject. The patient from whom Dr. Zemann's specimen was taken had been admitted into the General Hospital on March 8th, with symptoms of emphysema, severe bronchitis, and slight dyspnoea. His condition improved during the night, but on the morning of the 9th the dyspnoea increased, and death supervened before an exact examination of the case had been made. In the pharynx, extensive infiltration of the submucous layer with cloudy serous fluid was found. There was, moreover, enormous swelling of the right ary-epiglottic fold from infiltration with pus, and there were superficial ulcerations of the pharyngeal mucous membrane. The swelling and infiltration also affected the right wall of the larynx, and extended as far as the ventricular bands. Besides emphysema and bronchitis, parenchymatous degeneration of the cardiac muscle, the liver, and the kidneys, and acute swelling of the spleen were observed. Dr. Zemann remarked that the disease was to be looked upon as a most dangerous infectious malady, with an exceedingly rapid course; its origin was still unknown. Persons attacked died either from parenchymatous degeneration of the heart or from asphyxia caused by narrowing of the air-passages. Another case which had been recently observed was that of a young girl with cardiac failure. Owing to sudden dyspnoea, tracheotomy was resorted to, but without success, and death immediately supervened. The *post-mortem* examination showed that death was due to acute phlegmonous pharyngitis. In conclusion, Dr. Zemann urged clinicians to study more closely at the bedside this disease, which was well known in the deadhouse.

BERLIN.

[FROM OUR OWN CORRESPONDENT.]

The Health of the Emperor.—Fatality of Laryngectomy.

I AM in a position to give you authentic information as to the present condition of the Emperor. The growth is absolutely localised and limited, the neighbouring glands are not in any way affected, and even where the disease is worst it makes little or

no progress. His Imperial Majesty's general health is excellent; he has become very grey, but still retains his elastic step and soldierlike bearing. He takes daily walks in the sunny gardens of Charlottenburg Schloss. Yesterday, March 30th, he visited his capital for the first time since his accession, and was received with the utmost enthusiasm by the Berlin people.

Some days ago Herr Kayser, member of the Social Democratic section of the Reichstag, died, immediately after a partial extirpation of the larynx for cancer, which was performed by Professor von Bergmann, our leading surgeon. A like result followed the last two operations of the same kind done by Dr. E. Hahn, who is well known in England for having operated on Mr. Montagu Williams. It is also said, but I cannot vouch for the truth of the statement, that all the eleven other patients on whom Professor von Bergmann has performed laryngectomy, have died. The fatal results of these operations go far to justify those who refused to expose the precious life of the heir to the throne to so formidable a risk. Public opinion is beginning to veer round to that view of the case. A brighter view of the situation is now generally taken, and at any rate it appears certain that no immediate danger is to be apprehended.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

A Curious Case.—Iodism.—Vitality of Rabie Virus.

M. PETER has recently had under his care at the Hôpital Necker a curious case of hysteria, presenting the phenomena of sensibility of the integuments to gold, and susceptibility to the influence of medicinal substances at a distance. The patient was a man, who applied on account of contracture of the entire right side, principally in the leg. He is a well known hysterical subject, and it was on him that the theory of telepathic medicine, broached not long ago by two surgeons of Rochefort, was chiefly based. It was noticed that his skin was extremely sensitive to the contact of certain metals; but Dr. Peter, who is very cautious in accepting such facts, seeing that the patient was an inveterate liar, took every precaution to ensure absolute accuracy in the experiments he undertook. Dr. Peter, as if by accident, touched the back of the man's hand with a gold ring which he was wearing. The patient complained of a sensation of pain, and the next morning there was a small blister, as of a burn of the second degree, on the spot touched by the ring. The same day the head-nurse, while helping the patient, accidentally touched one of his fingers with her gold chain, and the same result was produced. To prove that there was no trickery, and that the man had not purposely burnt himself with a match, Dr. Peter's assistant, Dr. Caron, percussed the man's back, particularly where his hand could not reach, even with a lighted match, and wherever Dr. Caron's gold ring had touched the skin there was a blister as in the first case. Other metals similarly applied did not give the same result. Following up these experiments with regard to the influence of medicaments at a distance, the following curious effect was observed. Without the patient being aware of it, a small tube wrapped up in paper, the contents of which were unknown to Dr. Peter himself and to his assistants, was held within about four inches of the back of the patient's neck. In less than ten minutes his face became covered with profuse perspiration, he was seized with nausea, and soon vomited some liquid. On tearing off the paper cover from the tube, it was seen to contain ipecacuanha. Similar experiments with alcohol and opium gave no results whatever.

According to M. Duret, poisoning by iodine shows itself in three distinct forms—the eruptive, the cerebral or delirious, and the syncopal or hypothermic. The eruptive form is the most frequent. It is characterised by a rubeolar eruption appearing on the different parts of the body, and far removed from the point of application. The poisonous and iodised principles are absorbed by the body, and this eruption is probably caused by the eliminative process carried on through the glands of the skin. The second form is characterised by epileptic symptoms, or by fits of sleeplessness accompanied with delirium. The third form is more serious. The absorption of the iodine is followed by a great increase or decrease in the temperature, which sometimes falls as low as 34.6° C. These symptoms cease as soon as the iodine is no longer given. Thus, if iodine is valuable on account of its antiseptic properties, yet it must be employed with caution, as in some cases it gives rise to lymphangitis with diffuse suppurative

cellulitis. M. Duret has twice seen inflammation produced by its use in wounds on the hands and fingers. The inflammation ceased when the iodine was discontinued.

The virus of rabies is so active in buried corpses, that when subsequent doubts arise as to the nature of the disease which proved mortal, inoculation with the exhumed medulla oblongata will settle the question. M. Galtier has observed that the medulla of a dog dead from rabies, removed seventeen days after death, then buried in the earth for fifteen days longer, preserved all its virulence. Inoculations from it caused rabies in twelve days.

GLASGOW.

[FROM OUR OWN CORRESPONDENT.]

Glasgow Faculty of Physicians and Surgeons.—Glasgow University.—Glasgow Philosophical Society.—Small-pox on Board an Atlantic Liner.—Prosecution under the Margarine Act.—Measles Epidemic in Port Glasgow.

At the meeting on April 2nd, the election of a representative to the General Medical Council took place. Dr. D. C. McVail has represented the Faculty recently, having been elected to complete the term for which the late Dr. Scott Orr was appointed. It was decided that the new election should be for five years; and, thereafter, Dr. Alexander Robertson, seconded by Dr. James Dunlop, nominated Dr. McVail for re-election. Dr. James Finlayson nominated Dr. Hector Cameron, and was seconded by Dr. Donald Fraser, of Paisley. The vote was by ballot, and 54 voted for Dr. Cameron, 50 for Dr. McVail, 2 declining to vote. Dr. Cameron was, accordingly, declared elected. Unusual interest has been manifested in the election, the meeting being the largest ever held, and many Fellows coming considerable distances to take part in the business.

The number of candidates for the medical preliminary examination at this University has been steadily increasing at each half-yearly examination. At this term the very large number of 482 has been reached. The winter session of the medical classes closed last week. The examinations for degrees in medicine and science begin to-day (Friday). For the degrees in medicine, first, second, and third examinations, there are 86, 50, and 68 candidates respectively, a total of 204; while 60 candidates apply for the examinations for B.Sc. The Board, recently appointed in connection with Glasgow University, for the extension of university teaching by local lectures and classes, has issued an account of the scheme and the mode of working it, in which, after the results of the scheme, as carried on by the Universities of Oxford and Cambridge, have been described, the various tentative efforts made in the same direction in Scotland are alluded to. The pamphlet follows with a careful explanation of the purpose and method of the scheme, and the proper manner of working it, ending with detailed information for the benefit of local committees, of the means they should adopt for making the scheme effective, and of the cost of so doing. With the issue of this pamphlet there ends the preliminary stage of this movement. The fruits of the scheme cannot begin to appear till next autumn and winter, but the account has been published in good time to give those directly interested in the movement the opportunity of considering whether they will take advantage of it. The pamphlet can be obtained from the University publishers, Messrs. Maclehoose and Sons, Glasgow.

At the last two meetings of the Glasgow Philosophical Society very interesting communications have been made in reference to atmospheric particles and micro-organisms in air, water, etc. On March 8th, Mr. John Aitken, F.R.S.E., showed a most ingenious method of counting the number of dust particles in the atmosphere. The essence of the method consists in producing a fog, by supersaturating the air whose dust particles one wishes to count with water in a glass receiver. Each fog particle has a dust particle as a nucleus, and by a simple method of magnifying and illumination, the particles are seen falling on a small silver mirror with a ruled surface. The details of the method were published in *Nature* of March 1st. By his method Mr. Aitken calculated the number of particles in the outside atmosphere, when rain was falling, to be 521,000 per cubic inch, and 2,119,000 when it was fair. In the atmosphere of a room the number was 30,318,000, and in the air near the ceiling 88,346,000, all per cubic inch. In a Bunsen flame he calculated the number to be 489,000,000. Mr. Aitken adds: "It does seem strange that there may be as many dust particles in one cubic

inch of the air of a room at night when the gas is burning as there are inhabitants in Great Britain, and that in three cubic inches of the gases from a Bunsen flame there are as many particles as there are inhabitants in the world." At the meeting of March 21st, Mr. Ernest Maylard, M.B., gave a most interesting demonstration of bacteriological methods adopted for the detection and cultivation of micro-organisms in air, water, and soil. He also demonstrated some of the pathogenic organisms. Referring to the recent report regarding the pollution of Loch Long, Mr. Maylard gave results of some observations he had recently made by bacteriological methods, which showed that, from this point of view, while Loch Goil was nearly as pure as Loch Katrine, Loch Long was little better than the Clyde itself. Mr. Maylard's demonstration brought together a very large meeting.

The Anchor Line steamer *Circassia* arrived in the Clyde from New York on March 22nd, with five cases of small-pox on board. The first case was reported four days after the vessel left New York, and the other cases occurred at intervals of one and two days. Immediately on the arrival of the ship opposite Greenock, the men were removed to the Greenock small-pox hospital. Half of the crew had been revaccinated on the voyage, and Dr. Wallace, of Greenock, revaccinated the remainder, together with all the passengers. All of the men affected belonged to the crew. After thorough disinfection, the vessel was allowed to proceed to Glasgow. No other cases have yet been reported.

The first case of prosecution in Glasgow under the Margarine Act was brought up on March 23rd, when the accused was fined a modified penalty of £2, for failing to mark clearly the margarine he had exposed for sale in his shop.

The School Board of Port Glasgow have found it necessary to close one of their schools in the east end of the town, because of the prevalence of measles among the scholars. Towards the close of last week, 150 were reported absent from this cause, and by March 26th the absentees had increased to 227. Very few cases have been fatal, but the epidemic has spread with very great rapidity.

CORRESPONDENCE.

MR. STANHOPE AND THE RANK OF ARMY MEDICAL OFFICERS.

SIR,—I was much disappointed with the tone of Mr. Stanhope's reply to my question on March 13th. His courtesy in all matters connected with the department had been so great last year, and the reception given by him to the Parliamentary Bills Committee deputation was so cordial and friendly, that I was quite unprepared for the cavalier way in which he has now flung down the gauntlet of defiance to the civil profession.

No doubt, according to the strict letter of hard and fast military law, the collection of the opinions of medical officers by a "civilian association" may be in "contravention of discipline," for we know that combination is specially abhorrent to the official mind. But whether it is judicious, in the interest of a service which depends for its very existence on the estimation in which it is held by medical schools and by medical practitioners outside, to take this line is a question which I must leave every unprejudiced reader to settle for himself.

In my judgment, nothing can be gained but everything may be lost by an ostentatious indifference to the views of army doctors, however expressed, at a time when great changes are impending, and when it will become the duty of the advisers of our medical students seriously to consider whether they can continue to recommend military medical service under the altered conditions of the future.

Mr. Stanhope airily informs us that "the status of medical officers is just what it was before." This may be his opinion; but as he does not himself wear the shoe, he cannot tell where it pinches, and nearly 1,000 experienced surgeons on active service, whose views you have so ably analysed, in addition to many who have favoured me with private letters, have stated most emphatically that they have lost much, both in prestige and position, by the abolition of relative rank. We are further told by the Secretary of State for War that a "proper channel" is open to anyone for the discharge of his grievances; and by

this is no doubt meant a personal interview with the Director-General at Whitehall Yard. No one can hold Sir T. Crawford in higher respect than I do. He is courteous and able, and as little formidable as possible under the circumstances; but surely it would be an act of some personal heroism for any individual officer (junior, perhaps, in rank) to enter the dread sanctum for the purpose of arguing out the terms of a Royal Warrant; and, of course, anyone on foreign service can only make his views known through the medium of his principal medical officer, and the fatal defect of this mode of action is that it is scattered and intermittent, and devoid of that cohesive and collective force which a large body of united opinion must possess. You have given the department the opportunity of expressing this with no uncertain sound, and whatever the reception of your communication may be to-day, it must have its due weight in the future, and its influence may make itself felt in quarters the most inconvenient to those who have been induced by their military advisers to brush it contemptuously on one side.

Unfortunately, there does not seem to be any immediate prospect of discussing Vote 4 in the House. The preliminary stage of the army estimates on the motion that the Speaker do now leave the chair is usually devoted to the consideration of every variety of grievance, but this time it was entirely taken up by Sir W. Barttelot's motion for a Royal Commission, and when I rose to address the House on medical questions I was ruled out of order by the Chair. Mr. Stanhope has since declined to give me a pledge that the vote will be taken at a time and hour when full discussion is possible. Last year it came on in August, towards the small hours, and great uncertainty necessarily attends its appearance now; so we must only watch and wait, and make the best use of opportunities as they arise.—I am, etc.,

House of Commons, March 27th.

R. FARQUHARSON.

P.S.—Will you allow me to take this opportunity of gratefully acknowledging the communications I have received in answer to my appeal for definite details regarding the abolition of relative rank? Medical officers have written to me from all parts of the world, and have not only expressed their opinions with fulness and ability, but have told me how they have actually lost prestige and position by what outsiders consider a very trifling change. Armed with this brief, I hope to render some service to the cause when the discussion on the vote comes on.

THE ELECTION OF PRESIDENT OF THE COLLEGE OF PHYSICIANS.

SIR,—As one of your correspondents last week observed, the result of the election of President of the Royal College of Physicians will have given satisfaction to many, but the mode in which it was attained has given dissatisfaction to a large number of Fellows. It is quite true that a form of canvassing, *sub silentio*, was had recourse to, but this was not the only unusual phenomenon which marked the election. A report of a meeting of the Committee of the College of Physicians, published in the *JOURNAL* of February 4th, p. 253, contains a resolution to the effect that it was undesirable for Fellows, Members, or Licentiates to write on professional subjects in journals supplying medical knowledge to the general public. Though etiquette forbade you to reveal the tenour of the animated discussion which took place on this resolution, there was a very strong feeling against it, which found formal expression in an adverse amendment, lost only by a small majority. Many Fellows who were aggrieved at the action of the Censors' Board took advantage of the presidential election to make a protest by voting at the second ballot in favour of that Fellow owing to whose action more especially the resolution of February 2nd had originated.—I am, etc.,

ANOTHER FELLOW.

THE BUDGET.

SIR,—From Mr. Goschen's speech he appears inclined to include the medical man's horse amongst those kept for pleasure, and therefore to be taxed; whereas, as you well know, a horse is just as much a necessary adjunct to a country or town practice as a butcher's or a baker's cart is to his business—the baker's cart carrying bread, and the doctor's brains. Instead of our getting up any memorial on this question, I would ask every medical man in England to write to his member of Parliament, putting the facts before him.—I am, etc.,

JOHN WOODMAN, M.D., President-Elect, South-Western Branch, British Medical Association.

SIR,—Your leading article in the JOURNAL of March 31st appears to assume that doctors' horses will become liable to the new tax. I venture to think the presumption is the other way, and I wrote a letter to the *Times*, which appeared in that journal of April 2nd, pointing out that recent judicial rulings to the effect that the business of general practitioners is "a trade," would appear to strengthen this presumption.

I suppose that in filling up the form for the payment of stamp duty we should be at liberty to declare how many of our horses (if any) were kept for pleasure purposes, and to be liable for the tax only so far as they were concerned. Where a country practitioner carries on an extensive country practice, he not infrequently requires to keep from four to six horses, and it would be monstrously unjust if he were obliged to pay the new impost upon them all.

Perhaps the Parliamentary Bills Committee of our Association will make inquiry on the subject.—I am, etc., J. HOLMES JOY.
Manor House, Tamworth, April 2nd.

SIR,—I do not think we will be dealt so hardly with as you imagine. At present the income-tax people allow us to deduct £30 for each horse from total income, on the ground that the horses are used for professional purposes. I hope, under the new scheme, we will be allowed to pay the "wheel tax" instead of the carriage tax. I for one will make a try to do so. When we are allowed to deduct the keep of the horse as a necessity in the practice, surely we cannot be taxed as if he, she, or it was kept for pleasure. If the horse, then the carriage. If this contention is correct, we shall save by the new Budget.—I am, etc.,

Wilmot House, Erdington, WILLIAM DONOVAN, L.R.C.P.Ed.
Birmingham, March 31st.

SIR,—By the new Budget just before the public we shall have to pay £1 on each horse we use, which is very hard on us country practitioners. The Chancellor of the Exchequer admits in his speech that it will be a great hardship on "doctors and clergymen." If the medical profession, through your valuable Association, were to forcibly urge this injustice upon him, he might be induced to exempt us from this further tax; also the wheel tax as well, if we are to pay this. A petition should be signed and sent in at once, which would materially strengthen your arguments.—I am, etc.,
GENERAL PRACTITIONER.

SIR,—Can nothing be done to prevent so great an injustice to the medical profession as this new horse tax? Surely the Chancellor of the Exchequer, by however great a stretch of the imagination, cannot think a medical man drives about in all weathers and both day and night for pleasure. The medical profession is taxed up to its neck already, without this additional burden, and with the wheel tax in addition it will indeed be a severe burden on many a poor doctor. Perhaps if every member of the profession interested in the matter wrote to the Member of Parliament for the division in which he lives and put the subject clearly before him, it might have some good effect.—I am, etc.,
F. L. NICHOLLS.

April 1st.

** We recommend that course to be adopted without delay. Meantime, the Parliamentary Bills Committee will also no doubt take action; but each medical man should individually and promptly act for himself through his own member, so as to support the proceedings of the Committee.

THE POSITION OF MEDICAL OFFICERS OF HEALTH UNDER THE PROPOSED COUNTY COUNCILS.

SIR,—There is every prospect, as you have justly indicated in your leader on the above subject, that unless some effort be made to supplement an obvious deficiency in the County Government Bill, a great opportunity of improving sanitary administration, especially in rural districts, will be lost. It is remarkable that while the Bill provides the new authorities with advice in the legal and constructive aspects of sanitary matters, it leaves them entirely without any in regard to medical ones. This is the more astonishing considering that every District Council will have such an adviser in the person of its medical officer of health, for it is scarcely to be supposed that if these minor authorities require such advice, the central body, which is to be invested with their control, can do its work efficiently without such help.

No one who knows anything of the practical requirements of our sanitary organisation can have any doubt that the County

Councils have a most important work before them in the direction of organising, consolidating, and unifying sanitary administration, if they are only properly equipped for such functions, and if they understand, on their creation, that such work is expected of them. I have no hesitation in saying, with some experience in the matter, that the efficiency of sanitary work in rural and the smaller urban districts might be enormously increased by the influence which a competent central health officer, backed up by such a strong body as we may hope the County Councils will become, could exercise. In co-ordinating the statistics of infectious disease alone, he would have, under the uniform enforcement of notification, which cannot be far distant now, an opportunity, such as does not now exist, of preparing the authorities in his district to resist its attacks. And, indeed, it is so obvious as not to require arguing, that if such an officer is necessary in order to stimulate, advise, and generally direct the work of sanitary administration in a small area, he must *a fortiori* be the more so in an organisation which is formed by grouping such small areas together, and the professed object of which is to regulate their administration.

There is, perhaps, room for doubt whether the provisions of the Bill as at present drawn would place any insuperable obstacle in the way of a County Council availing itself of the advice of any medical officer of health in its district, if it desired to do so; but the possibility of such an arrangement is questionable, and it is much better, in view of the importance of the matter, that it should not be simply optional, but as imperative on a County Council to provide itself with such an official as it is at present for a local sanitary authority to do so. Such a requirement should be accompanied with the power of so ordering the relations of the poor-law medical officers to the central officer and to the local authorities as to allow of the whole machinery of public medical administration being used in the most advantageous and economic manner practicable for the public sanitary interests.

And here I venture to differ with you in regard to two of the duties which you suggest might be imposed on such an official, namely, the making of *post-mortem* examinations for coroners' inquests and the work of a county analyst. I feel sure that a central health officer would find quite enough to occupy him in most counties in the way of handling statistics of various kinds, correspondence, attendance at meetings of local authorities, as well as on those of the County Council, to make it very difficult for him to be available at short notice, as is often necessary, in any part of the county, to make a *post-mortem* examination, still less to give the continuous attention which is requisite for food analyses, which are now very well provided for in the hands of men with whose daily occupation such work is much more cognate. It should, however, certainly be the duty of the county medical officer to act as medical assessor to the coroner when the latter was not a medical man, and to make inquiries of first instance, for example, in cases of uncertified deaths, with the view of ascertaining whether there were any *prima facie* grounds for holding an inquest. And in this capacity there would be no difficulty in entrusting him with the general supervision of *post-mortem* examinations.

There is one most important department of sanitary work which should certainly come under the observation of such an officer, and that is vaccination. It is simply absurd that whilst the medical officer of health is required to deal with measures for arresting the spread of small-pox, he has no official cognisance of vaccination. In those counties in which the experiment of combining a number of sanitary districts under a single medical officer of health has been in operation for the last fifteen years, the transition to attaching this official to the County Council would probably in most cases be made without difficulty, but where no such combination has been hitherto effected, it might not be easy at once to create the office without either sacrificing vested interests or entailing a charge for a new salary which might create much opposition. Whilst imposing upon the County Council the absolute duty of appointing a sanitary adviser it is, I think, desirable to give them a certain amount of latitude in determining how they can best make such an appointment with a due regard to economy and to antecedent conditions. We may be quite sure that if the lines of duty are clearly laid down for such an official, the Council may be as safely trusted to do their best to meet this requirement, as the corporations of the large towns, which are now to be created counties of themselves, have shown themselves to be in making similar appointments. It is very inexpedient that the ratepayer should be led to look on the new machinery as likely to

be more expensive than is absolutely necessary. What is wanted is reorganisation as opportunity offers, rather than any sudden upsetting of existing organisation, however imperfect it may be.

I trust, therefore, an effort will be at once made to direct the attention both of the Government and of Parliament to the serious defect which the County Government Bill exhibits in this respect, and there is no body by which such effort could be so appropriately initiated as by the Parliamentary Bills Committee of the British Medical Association.—I am, etc.,
CUIVIS.

NOTIFICATION OF INFECTIOUS DISEASES.

SIR,—I send you herewith a report of proceedings taken against Dr. Dalton, of South Norwood, by the Corporation of Croydon. Dr. Dalton is an M.D. of the University of London, a practitioner of twenty years' standing, and holds a high place in the estimation of his neighbours.

The object of notification of infectious diseases is not for the purpose disclosed in these proceedings. The information being given to the authority, it is immaterial as regards repression by whom the information is given, provided they get it as soon as its nature is established. The Act says that it shall, in some parts of the kingdom, be given by the householder or person in charge of the patient, and also by the medical attendant. In this case, Dr. Dalton had instructed the householder to give notice to the authority; the authority had actually acted upon the notice, and had disinfected the house. The dignity of the authority is, however, damaged, for the notice is not given by the medical attendant. This result is brought to the knowledge of the town clerk, who revenges it by putting the doctor into the dock. This, Sir, may be law, but it is neither justice nor satisfactory to the true promoters of disease repression. It opens the road to private malice, and to conflicts between members of the medical profession, in which it is possible for a superior in social and professional life to be treated with indignity by one of a lower standing, for no true reason whatever, and for no good purpose, as in this case there is nothing to be gained but revenge.

As I have often said before, and the medical profession by the British Medical Association at its annual meeting has endorsed that view, the object of the Act is to procure the repression of disease, and I am doing as much as anybody to promote repression. That repression can only be obtained by information from the source, and the proper person to give that information is, in the opinion of the medical profession, the householder. The law should and, in some cases, does allow the householder to employ the medical attendant as his agent, and, when so acting, the medical attendant should be entitled to a fee, but it should be the householder who ought to be summoned, if the Act is not complied with. The medical attendant could then be called as a witness in the case. In Dr. Dalton's case there was no damage to anyone, except the dignity of somebody, for the spirit of the Act was complied with. I will not insult Dr. Philpot by suggesting for one moment that he has been the instigator of these proceedings, but I am really sorry that he has been compelled to be a party to them. It may be, and it doubtless is, convenient to the medical officer of health to get the information direct from the medical attendant; but how about cases where there is none? I am aware of the existence of such in this borough; in which there has been no medical attendant on cases of infectious disease for reasons best known to the householder, and the action taken by the corporation is more likely to increase the number of cases than to discover them, to the serious detriment of true sanitary work and the continued spread of infectious disease among us. There is a curious idea upon this point which is prevalent among the people, and among lawyers especially, that the doctor should be held liable to a criminal procedure if he does not disclose facts which only come to his notice by reason of his professional employment.

1. It makes the doctor a *particeps criminis* if the disease is not disclosed, and the evidence forthcoming against the householder cannot be satisfactory as to diagnosis, without his aid.

2. It tends to prevent the very people who are most likely to spread the disease, such as lodging-house keepers, hotel keepers, and shopkeepers, employing a medical man at all in such cases, and encourages them to send for an acknowledged quack, or so-called "botanist," two or three of whom are actually practising in Croydon and its neighbourhood.

3. It places two medical men in antagonism to each other, to the detriment of good feeling, and damage to the estimation in which our profession ought to be held by the public, and especially by lawyers, who like to pit one doctor against another.

I think, sir, that the whole medical profession will object to the extension of the law upon the basis on which it stands in this borough, and will call for a law applicable to the whole kingdom, that the householder shall alone be liable to prosecution unless the doctor is acting in an official capacity as the medical officer to a public authority, or a benefit society, etc., the law also enacting that the medical attendant shall act as the agent of the householder when required to do so by him, and that when so acting he shall be entitled to a proper fee to be paid by the local authority.

It could never be intended by the Legislature that a new series of crimes should be put upon the statute book; namely, that doctors must be common informers, and that the dignity of the local authority is lessened, unless the information comes by the medical instead of by another source. The knowledge was actually obtained, in this case, and the measures for the prevention of the spread of disease were actually taken primarily by the act of Dr. Dalton, yet he is prosecuted, and the justices were foolish enough to put a fine upon his conduct, instead of doing him the justice which was really due to him in the matter; namely, inflicting a nominal penalty only.—I am, etc.,

Croydon, April 2nd.

ALFRED CARPENTER.

THE CLIFTON LUNACY CASE.

SIR,—I am sorry that Dr. Marshall should have thought proper to have made what I must pronounce as being an offensive and unwarrantable attack upon me, and made personal because I have dared to differ from him in opinion. I have been strongly urged to take other measures than I now do, but I give him an opportunity of retracting his remarks after he has perused this. The facts are shortly as follows.

I was consulted about the case of Miss Mason in the month of January of this year. I examined her on two occasions, and heard her account of the incarceration in three lunatic asylums. I advised, both in writing and verbally, that Dr. Marshall's action should be dropped altogether; but that there was a strong case against the convent for locking Miss Mason up in her room and depriving her of liberty previous to obtaining the lunacy certificates I felt positive of, and I do so now.

I was examined, on entering the witness-box, on the very certificate of Dr. Marshall on which I had stated that the case ought to have been dropped. I, therefore, declined to answer the question relative to his certificate. One of the witnesses for the defence said to me on leaving the witness-box, "Dr. Winslow, by your answer you have upheld the honour of the profession."

In my last letter, which appears under that of Dr. Marshall, I showed clearly that the course advised by me and the answers given by me met with the approval of the learned judge who tried the case. I cannot but think that had Dr. Marshall considered well before writing as he has done, without the facts before him, it would have been a wiser step to have adopted. I never put up with an insult from anyone, and as I have been grossly insulted by Dr. Marshall, I demand through your columns an apology from him with regard to his statements. I challenge him to substantiate the truth of any one of them, and caution him as to his reply.—I am, etc.,

L. FORBES WINSLOW, M.B., LL.M.Camb., D.C.L.Oxon.

70, Wimpole Street, April 3rd.

THE EDUCATION OF FEEBLE-MINDED CHILDREN.

SIR,—In the JOURNAL of March 31st, I notice under the heading, "Beating an Epileptic Girl," you say, "Why should not suitable classes for such feeble children be provided for day scholars?" There is no reason why classes should not be provided, and some years ago I wrote to Sir E. Currie, who was then on the School Board, urging that classes for feeble-minded children should be formed. I went into details, and showed that the scheme could be easily carried out. Sir E. Currie said, at the time I wrote to him, that the School Board was busy on other matters, but the scheme should be attended to. Nothing however came of it. I am of opinion that feeble-minded children have as much right to be educated by the School Board as the blind and deaf and dumb, who for some time past have received instruction. Schools for the feeble-minded have been in operation in Germany and Norway for some years, and those who are interested in the subject will find an instructive article by Dr. Shuttleworth in the April number of the *Journal of Mental Science*.

There is also no doubt that schools should be visited occasionally by a medical man, who should have power to report to the

authorities. The teachers would be glad of the assistance, and feeble-minded children would benefit. I was sent, some years ago, by Sir E. Currie to report on the case of a child, whose father wished that she should attend the Board School, but the teacher refused to receive her, as she upset the school and could not be instructed. The child was an undoubted imbecile, and about a year ago was admitted into the Darent Asylum.—I am, etc.,
April 4th. FLETCHER BEACH.

"CONSULTATIONS WITH HOMEOPATHS."

SIR.—As three letters have appeared in the JOURNAL, referring to the last paragraphs of the report of the meeting of the Gloucestershire Branch, held on February 21st at Gloucester, I think it only right that I should draw your attention to the report of the meeting held on March 20th, at Cheltenham, when it was resolved that the paragraph in question be erased from the minutes.—I am, etc.,
Cheltenham. G. ARTHUR CARDEW, Honorary Secretary
Gloucestershire Branch.

THE ALLEGED ARREST OF SYPHILIS IN ITS PRIMARY STAGE.

SIR.—Whilst entirely concurring in the view of Mr. Jonathan Hutchinson that syphilis is caused by the presence of a microbe—as yet unknown to the microscope—I have not been able to corroborate his experience that this microbe may be destroyed in its early phase of existence, or when the initial lesion of syphilis alone is present, by means of small doses of mercury. For many years I tried, by giving small doses, first, of green iodide, and then small doses of mercury with chalk, to prevent the occurrence of roseola in my hospital patients, who were all very young women, at the Rescue Society's Lock Hospital; but in all cases I found that when there was a well-marked syphilitic sore, some symptom, such as roseola or mucous tubercles, followed, although often the symptoms were very slight indeed.—I am, etc.,
CHARLES R. DRYSDALE,
Late Physician to the Rescue Society of London.

A NEW INCANDESCENT LAMP CYSTOSCOPE.

SIR.—It may perhaps be of interest to those who contemplate providing themselves with a cystoscope similar to the one so cleverly described by Mr. E. Hurry Fenwick, in the JOURNAL of February 4th, to know that through the agency of Mr. K. Shall, of Wigmore Street, Leiter (of Vienna) has made for me a cystoscope, which, although identical in principle, is of much larger size, and, in my opinion, of much greater practical utility than the one originally introduced.

The diameter of Leiter's first instrument is No. 22, French gauge, that of mine No. 40. The advantages of the increased size are that the larger instrument obviously affords a wider field of vision and the employment of a larger incandescent lamp with corresponding increased brilliancy of light. The window of observation in the new instrument is at least twice the area of that in the old one, and the lamp is double the size.

As there are few urethras with a capacity of 40 French gauge, I propose using, as I have already done, the cystoscope through a median incision in the membranous urethra upon those patients whose urethras will not admit the instrument in the ordinary manner. The objections to the perineal incision have very little foundation in actual practice and are insignificant in comparison to the advantages to be gained by a correct diagnosis—a diagnosis which can frequently only be obtained by a visual and tactile examination of the interior of the bladder, a means for which the perineal incision provides the most direct, the safest, and the most convenient facilities. Recently I explored the bladder of a man with the new cystoscope, and I was able to demonstrate that the illumination and field of vision left nothing to be desired. The following day the patient passed the whole of his urine the natural way.

Lleiter has written to say that he was very much impressed with the suggestion, and that he had tried the cystoscope on a dilated female bladder with the greatest success.—I am, etc.,
Manchester, April 2nd. WALTER WHITEHEAD.

¹ See page 763.

The Local Government Board have sanctioned the appointment of Dr. T. McCorbett as medical officer of the Clonslee Dispensary District.

NAVAL AND MILITARY MEDICAL SERVICES.

ARMY MEDICAL SCHOOL.

The summer session of the Army Medical School at Netley commenced on Monday, the 2nd inst., the opening lecture being given by Professor Sir Wm. Aitken, M.D., F.R.S. Twenty-four surgeons of the Army Medical Staff, and fourteen candidates for commissions in H.M.'s Indian Medical Service, have joined to go through the courses of instruction at the school.

EXTENSION OF FOREIGN SERVICE.

In answer to a "Member B.M.A.," we gather from Mr. Stanhope's reply to Dr. Tanner's question in the House that the extension of foreign service will apply to officers of all the departments of the army; this, he said, would be done in the interests of economy, and with the effect of lengthening the period of home service. We have as yet no information as to the "reasonable period" which must be served before claiming pension in any rank; this must be made known very soon now.

MR. STANHOPE'S MEMORANDUM.

FOREIGN SERVICE writes that the reorganisation of the Medical Staff foreshadowed in Mr. Stanhope's memorandum will inflict injustice on officers serving abroad by exacting additional foreign service without any equivalent money compensation; he also complains that the question of rank and status seems ignored in the memorandum, and says it is quite impossible for a civilian to understand the military position of a medical officer from existing titles.

THE ARMY MEDICAL RESERVE.

A MILITIAMAN writes: As a militia medical officer entitled to selection for employment already, the only advantage offered by the new Warrant, why should I subject myself to the chance of being found unfit, and, as you suggest, removed from the department altogether? Besides, as medical officers of militia not belonging to the department get double pay when attending other men than their own, it is much more advantageous not to belong to a department (see Med. Reg., page 167, paragraph 968, Part 5, Section 1). For instance, I was placed in charge of 1,200 men in addition to my own at the training; as a departmental man I received nothing extra; if I had been strictly regimental, I should have got £40 in addition.

Members of the Reserve are to have precedence over civilian practitioners. Does that mean they will not be reckoned as civilians themselves?

THE NAVY.

STAFF-SURGEON WILLIAM EVANS, retired, died in London on March 20th, at the age of 83. His commission as Surgeon bore date September 1st, 1846, and as Staff-Surgeon February 17th, 1858.

Surgeon H. J. M'C. TOBN has been appointed to the *Alexandra*.
Staff-Surgeon A. R. R. PRESTON, M.D., retired, died at Port Alfred, South Africa on February 13th. He entered the service September 1st, 1846, and was made Staff-Surgeon May 1st, 1857.

THE MEDICAL STAFF.

SURGEON-MAJOR R. TURNER, of the 3rd Brigade Cinque Ports Division Royal Artillery (otherwise the Royal Sussex Artillery Militia), has resigned his commission, which was dated March 1st, 1873; he is permitted to retain his rank and uniform.

Brigade-Surgeon J. INKSON, M.D., on arrival from England, is posted to do general duty in the Bangalore District, Belgaum and Ceded Districts, Madras command.

Surgeon R. E. KELLY, M.D., on arrival from England, is posted to do general duty in the Burmah Division, Madras command.

Brigade-Surgeon R. J. W. ORTON died at Newcastle, Staffordshire, on March 20th, aged 56. He entered the service as Assistant-Surgeon May 25th, 1853; became Surgeon March 1st, 1873; and Surgeon-Major April 1st, 1873; he was placed on retired pay with the honorary rank of Brigade-Surgeon June 27th, 1881. Brigade-Surgeon Horton served on the Medical Staff in the Crimea from February 23rd to September 12th, 1855 (medal with clasp from Sebastopol, and Turkish medal), and with the 4th Regiment during the campaign in the North of China in 1868 (medal and clasp for Talien).

Surgeon-Major R. H. GARDNER, M.D., died at Cheltenham on March 19th, at the early age of 36. His Surgeon's commission was dated September 30th, 1873, and that of Surgeon-Major September 20th, 1886. He was engaged in the war in Zululand in 1879, and had received the South African medal and clasp.

Surgeon-Major L. CORBAN, M.D., is promoted to be Brigade-Surgeon (ranking as Lieutenant-Colonel), *vice* John MacKenzie, M.D., retired. Dr. Corban entered the service as Assistant-Surgeon September 30th, 1864; became Surgeon March 1st, 1873; and Surgeon-Major September 30th, 1876. He was (*says Hart's Army List*) specially thanked by Lord Napier of Magdala, Commander-in-Chief in India, in General Orders for services during an epidemic of cholera in Oude in 1872. He served in the Egyptian war of 1882 in medical charge of the 2nd Battalion Duke of Cornwall's Light Infantry, and was present in the engagements at El Maghar and Tel-el-Mahuta, in the two actions at Kassassin, and at the battle of Tel-el-Kebir (mentioned in despatches, promoted Surgeon-Major, with relative rank of Lieutenant-Colonel, medal with clasp, and Khe-rove's Star). He served also with the Nile Expedition in 1884-85 as Senior Medical Officer to the Camel Corps, Medical Field Inspector on the Lines of Communication, and Senior Medical Officer at Abn Fatmah (clasp).

Surgeon-Major R. F. BUCHANAN is granted retired pay. His commissions are dated:—Assistant-Surgeon, March 31st, 1866; Surgeon, March 1st, 1873; and Surgeon-Major, March 31st, 1878. He served during the Afghan war in 1878-79 with the Kuram Field Force, and received the medal for the campaign.

Surgeon W. R. SMITH, M.D., of the 3rd Volunteer Battalion West Kent Regiment (late the 4th Kent), is appointed Surgeon-Major (ranking as Major) in the new Army Medical Reserve.

THE INDIAN MEDICAL SERVICE.

The retirement of Surgeon-General W. J. MOORE, C.I.E., of the Bombay Establishment, and of Deputy Surgeon-General R. F. HUTCHINSON, M.D., of the Bengal Establishment, announced some time since in the JOURNAL, has received the approval of Her Majesty. Dr. Hutchinson is granted the honorary rank of Surgeon-General, his retirement dating from December 9th, 1887.

Surgeon-Major W. F. KNAPP, of the Bombay Establishment, has been transferred to the retired list from the half-pay list, on which he was placed March 18th, 1884.

The services of Surgeon-Major J. WILSON, M.D., Bengal Establishment, are temporarily placed at the disposal of the Government of Bengal.

The services of Surgeon A. O. EVANS, Madras Establishment, are temporarily placed at the disposal of the Government of India in the Home Department for employment in Lower Burma.

Surgeon H. P. DIMMOCK, Bombay Establishment, is appointed to act as Professor of Pathology, Grant Medical College, during the absence of Surgeon R. Manser.

The services of Surgeon J. MACGREGOR, M.D., Bombay Establishment, are temporarily placed at the disposal of the Government of India.

Surgeon W. H. QUICKE, Bombay Establishment, is posted to general duty in the Mhow Division.

Surgeon M. A. T. COLLIE, Bombay Establishment, is appointed Secretary to the Surgeon-General with the Government of Bombay, vice Surgeon-Major D. A. Patterson, transferred to other duty.

Brigade-Surgeon H. COOK, M.D., Bombay Establishment, Civil Surgeon at Poona, is allowed leave of absence to Europe for twelve months on private affairs, with the necessary subsidiary leave.

Surgeon-Major JAMES PETERLIN, late of the Madras Establishment, died at Kew on March 18th, aged 70.

Surgeon-Major E. SANDERS, Bengal Establishment, is appointed Honorary Surgeon to the Central Bengal Light Horse, vice Brigade-Surgeon S. M. Shircore, resigned.

Surgeon F. D. C. HAWKINS, Bengal Establishment, Civil Surgeon 2nd class, is transferred from Sultanpore to Mintoorie.

Surgeon-Major D. P. MACDONALD, M.D., Bengal Establishment, of the 1st Battalion 2nd Goorkhas, has leave of absence for one year on private affairs; and Surgeon D. ELCUM, of the Madras Establishment, Zillah Surgeon at Berhampore, has leave to Europe for eighteen months.

Surgeon-Major T. C. H. SPENCER, of the Madras Establishment, having returned from furlough, is posted to do general duty in the Eastern District.

Surgeon W. H. BURKE, M.B., Bombay Establishment, is directed to act as Civil Surgeon, Rutnagherry.

Surgeon-Major A. BARRY, M.D., Bombay Establishment, is promoted to be Brigade-Surgeon. He entered the service March 31st, 1865, and became Surgeon-Major twelve years thereafter. He was in the Abyssinian war in 1867-68, and in the Afghan war in 1880, and took part in the march to Candahar with the force under Major-General Phayre; he has the Abyssinian and Afghan medals.

THE VOLUNTEERS.

The undermentioned gentlemen have been appointed Acting-Surgeons to the corps specified:—A. W. KNOX, M.B., 1st Volunteer (Norfolk) Brigade Eastern Division Royal Artillery (late the 1st Norfolk Artillery); G. A. GLOAG, 2nd Gloucestershire (the Bristol), Fortress and Railway Forces, Royal Engineers (that is, Engineer Volunteers); F. J. KNOWLES, 2nd Volunteer Battalion South Lancashire Regiment (formerly the 21st Lancashire); SIMON LINTON, M.B., 1st Fifehire Artillery; J. F. TABB, 2nd Kent; G. D. TODD, 1st Volunteer Battalion, West Yorkshire Regiment (late the 1st West Riding).

Acting-Surgeon TALFOURD JONES, M.B., of the 1st (Brecknockshire) Volunteer Battalion South Wales Borderers (late the 1st Brecknockshire), has resigned his commission (dated February 26th, 1876), with permission to retain his rank and uniform.

Surgeon J. L. W. WARD, of the 3rd Volunteer Battalion Welsh Regiment (late the 2nd Glamorgan Volunteers), has been granted the honorary rank of Surgeon-Major.

Acting-Surgeon W. L. BRADDOX, M.B., of the 2nd Volunteer Battalion Worcester Regiment (late the 2nd Worcester), has resigned his appointment dating from September 10th last.

Mr. A. C. TAYLOR, M.D., is appointed Surgeon to the South Nottinghamshire Yeomanry.

Surgeon H. P. SYMONDS, from the 1st (Oxford University) Volunteer Battalion Oxford Light Infantry (otherwise the 1st Oxford), is appointed Surgeon to the Queen's Own Oxford Yeomanry Hussars.

Acting-Surgeon G. BOLTON is transferred from the 1st Northumberland and Sunderland Artillery, on its division into two corps, to the 5th Durham Artillery as Acting-Surgeon, the date of his commission remaining unaltered.

Acting-Surgeon F. E. STREETEN, of the 1st North Riding of Yorkshire, has resigned his appointment, which bore date February 19th, 1887.

Acting-Surgeons A. F. TURNER and B. F. ELLIOT are transferred from the 1st Volunteer (Hampshire) Brigade, Southern Division Royal Artillery, on its division into two corps, to the 3rd Volunteer Brigade of the same Division, the dates of their commissions remaining unchanged.

Surgeon and Honorary Surgeon-Major A. T. NORTON is appointed Surgeon Commandant to the London Division of the Volunteer Medical Staff Corps, vice J. Cantlie, M.B., resigned. Surgeon-Major Norton joined the corps on June 11th, 1885.

2. "I agree, if appointed by the Directors, to accept the office of medical referee for the National Medical Aid Company, Limited, at —, upon the following terms: A remuneration of 2s. 6d. per annum for each member placed on my books by the Company."

The above are extracts from two forms given to me by an individual who represented himself as agent for, and wanted me to become medical referee to, the two above societies.

I took No. 2 first, and asked, "Who is the club intended for?" His answer was: "The middle classes." I told him I should never dream of attending "middle-class" patients at 2s. 6d. per head per annum. "Then what would you take?" he asked. I mentioned a sum considerably larger. "Oh! I can write to the managers and get you that I think, or at any rate 80 per cent. on the gross collections," was his reply.

I said no more, but wondered where the extra money was to come from, and how an "agent" could promise me such exceptional consideration. I might add that the rate of payment of members is 1d. per week adults, 3d. per week under 14 years of age.

Now for No. 1. I thought what examination for life insurance means. Details of personal history, details of family history, examination (by percussion, auscultation, etc.) of thoracic viscera; examination of abdominal viscera, examination and testing of urine, and various other details required. Then I thought of the time it all took; then I thought of the fee, 1s.

I soon made up my mind, and told the agent, "I would rather not accept the office for either." In which conclusion I sincerely trust all other professional brethren will heartily concur.

Surely the profession has not become so regardless of our "status" as to allow such societies "to cram down our throats" any patients they may think fit for us to attend at fees according to their appointing. Let us stand together as a body, unanimous on every point, and refuse to have to do with such affairs, or make them come to consult us first as to our charges and class of patients whom we consider should be admitted into such societies for attendance.

Let us think of our "social" position as a body, and each and everyone of us, by refusing to have to do with such as the above, protect not only our own personal interests, but that of every professional brother; in doing which we should also increase that one end which should always be our aim: "Unanimity in our brotherhood."

IMPERFECT PROTECTION.

MR. BUCHANAN.—Unless the person complained of, by fraudulently adopting a registrable title, has exposed himself to a prosecution under the 40th Section of the Medical Act, we know of no steps that can be taken.

The surgical nature of the case would debar the Society of Apothecaries from taking proceedings; and, as we understand, an indictment for false pretences has already been brought against him, and thrown out.

NATIONAL MEDICAL AID COMPANY.

A COUNTRY MEMBER writes to us with reference to the action of the National Medical Aid Company, in his neighbourhood. We have several times lately expressed our opinion as to the conditions offered by this Company, and we cordially agree with our correspondent that "it is not creditable to our profession that men should be found willing to undertake work on such conditions."

HOSPITAL AND DISPENSARY MANAGEMENT.

MERCER'S HOSPITAL, DUBLIN.

The annual report for the year ending December 31st, 1887, shows that the expenditure was £2,360 12s. 4d.; the income, £1,741 13s. 3d., showing an excess of expenditure of £618 19s. 1d. A serious deficit would have occurred but for some large legacies. The decrease in income, however, occurs almost entirely under the heads of interest and dividends. The governors complain of the resolution of the Dublin Hospital Sunday Fund Committee striking them off the list of those entitled to a share of the annual collections. They state that they have begun the construction of new buildings.

CORK DISTRICT LUNATIC ASYLUM.

DURING the past year 278 patients were admitted into the asylum, while the discharges numbered 151. The deaths amounted to 94. The admissions show an increase of 38, the recoveries an increase of 40, and the deaths a decrease of 6, as compared with 1886. A gratifying feature in last year's report is that the recovery rate was higher than for any of the past five years. On the last day of the past year there were 958 patients in the asylum. The question of increasing the accommodation at the female side of the house, in order to relieve the congestion that has existed for some time, is one that the resident medical superintendent recommends to the consideration of the board of governors. The average allowance of cubic space in Irish asylums appears to be 600 cubic feet per patient. At this rate the accommodation in the asylum, including hospitals, is for 902; excluding hospital beds, which may at any time be necessary, there is only accommodation for 802. The Cork District Lunatic Asylum at present contains 151 pauper lunatics from the Cork Union, and from the entire county 226 workhouse patients. The Cork guardians formerly paid the governors for these patients, but latterly have dis-

MEDICO-LEGAL AND MEDICO-ETHICAL.

A LIBERAL FRIENDLY SOCIETY.

A HORRIFIED CORRESPONDENT writes:—1. "I agree if appointed by the Committee of Management, to accept the office of medical referee for the Liverpool Victoria Friendly Society, at —, upon the following terms: For examination of assurers for amounts above £12 and up to and including £25, not more than 1s. in each case; for assurers above £25 and under £50, not more than 4s. in each case; for assurers above £50 and under £100, not more than 5s. in each case, and for assurers for £100 and upwards, not more than 7s. 6d. in each case."

continued it. The governors, however, insist upon payment, and a meeting of a committee from the governors and guardians has been agreed to in order to consider the question of payment. Dr. Nugent, an Inspector of Lunatic Asylums in Ireland, has expressed his approval of enlarging the accommodation in the workhouse lunatic wards, which has been done very successfully in Belfast, but he does not approve of the lunatic asylum being made subsidiary to the workhouse with reference to the admission of dangerous lunatics.

BELFAST OPHTHALMIC HOSPITAL.

The annual meeting of the supporters of this institution was held on March 29th, under the presidency of Mr. F. D. Ward, J.P., and was largely attended. The medical report showed that 76 cases had been received into the hospital for treatment or operation. At the dispensary attached to the hospital 956 eye cases, 290 ear cases, and 160 throat affections had been treated, making a total of 1,482 cases. Dr. Walton Browne reported that among the operation cases were 25 cases of cataract, which had been operated on without the loss of a single eye. By a recent resolution the certificates of the hospital had been recognised by the Royal University.

The Bishop of Winchester (Dr. Harold Browne) will open the new wards of the Royal Portsmouth and Gosport Hospital on the afternoon of Wednesday, May 30th.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

HEALTH OF ENGLISH TOWNS.—During the week ending Saturday, March 31st, 5,564 births and 3,882 deaths were registered in the twenty-eight large English towns, including London, which have an estimated population of 9,398,273 persons. The annual rate of mortality per 1,000 living in these towns, which had been 20.3 and 21.1 in the two preceding weeks, further rose to 21.6 during the week under notice. The rates in the several towns ranged from 15.1 in Birkenhead, 17.8 in Hull, and 18.3 in Cardiff to 26.4 in Manchester, 31.3 in Bolton, 33.3 in Blackburn, and 33.4 in Preston. The mean death-rate in the twenty-seven provincial towns was 22.6 per 1,000, and exceeded by 2.3 the rate recorded in London, which was 20.3 per 1,000. The 3,882 deaths registered during the week under notice in the twenty-eight towns included 388 which were referred to the principal zymotic diseases, against 363 and 319 in the two preceding weeks. Of these, 166 resulted from whooping-cough, 63 from scarlet fever, 42 from measles, 35 from "fever" (principally enteric), 31 from diarrhoea, 27 from small-pox, and 24 from diphtheria. These 388 deaths were equal to an annual rate of 2.2 per 1,000; in London the zymotic death-rate was 2.4, while in the twenty-seven provincial towns it averaged 2.0 per 1,000, and ranged from 0.0 in Preston and 0.7 in Portsmouth and in Halifax to 3.4 in Nottingham, 4.5 in Sheffield, and 6.1 in Blackburn. Measles caused the highest proportional fatality in Plymouth, Bradford, and Nottingham; scarlet fever in Blackburn; whooping-cough in Leeds, Brighton, Bolton, Salford, Derby, and Blackburn; and "fever" in Derby. The 24 deaths from diphtheria in the twenty-eight towns included 15 in London, 3 in Norwich, and 2 in Sunderland. Of the 27 fatal cases of small-pox recorded during the week under notice, 19 occurred in Sheffield, 3 in Blackburn, 2 in Nottingham, 1 in Bristol, 1 in Manchester, and 1 in Hull. The Metropolitan Asylums Hospitals contained 9 small-pox patients on Saturday, March 31st, of whom 1 had been admitted during the week. These hospitals also contained 1,087 scarlet fever patients on the same date, which showed a further decline from the numbers in recent weeks; there were 70 admissions during the week. The death-rate from diseases of the respiratory organs in London was equal to 5.6 per 1,000, and was below the average.

HEALTH OF SCOTCH TOWNS.—In the eight principal Scotch towns, 816 births and 590 deaths were registered during the week ending Saturday, March 31st. The annual rate of mortality, which

had been 21.0 and 22.2 per 1,000 in the two preceding weeks, further rose to 23.7 during the week under notice, and exceeded by 2.1 per 1,000 the mean rate during the same period in the twenty-eight large English towns. Among these Scotch towns, the lowest rates were recorded in Perth and Aberdeen, and the highest in Paisley and Glasgow. The 590 deaths in these towns during the week under notice included 45 which were referred to the principal zymotic diseases, equal to an annual rate of 1.8 per 1,000, which was 0.4 below the mean zymotic death-rate during the same period in the large English towns. The highest zymotic rates were recorded in Edinburgh, Aberdeen, and Glasgow. The largest proportional fatality of whooping-cough occurred in Aberdeen and Glasgow, and of diphtheria in Edinburgh. The mortality from diseases of the respiratory organs in these Scotch towns was equal to 6.1 per 1,000, against 5.6 in London.

HEALTH OF DUBLIN.—The 211 deaths registered in Dublin during the week ending Saturday, March 31st, were equal to an annual rate of 31.2 per 1,000 (against 20.0 and 29.7 in the two preceding weeks), the rate for the same period being only 20.3 in London and 22.8 in Edinburgh. The 211 deaths included 15 from the principal zymotic diseases (equal to an annual rate of 2.2 per 1,000), of which 8 were referred to whooping-cough, 3 to measles, 2 to scarlet fever, 1 to diphtheria, and 1 to "fever."

GUARDIANS AND MEDICAL OFFICERS.

A MEETING of medical men of Croydon and the neighbourhood was held at the Croydon General Hospital on Wednesday, March 28th, to meet Mr. E. Marshall, of Mitcham, and hear his statement of the difficulty between the Holborn Board of Guardians and himself.

Although convened at short notice, the meeting was largely attended, and the subjoined resolutions unanimously agreed to.

Dr. ALFRED CARPENTER, Vice-President of the British Medical Association, was appointed Chairman. Dr. Duncan, the Honorary Secretary to the East Surrey District, South-Eastern Branch of the British Medical Association, through whom the arrangements for the meeting were made, acted as Honorary Secretary.

After Mr. MARSHALL had made a statement from which it appeared that he had been medical officer to the Mitcham schools belonging to the Holborn Guardians or their predecessors for thirty-two years, and after he had satisfactorily answered the numerous questions which were put to him by the assembled gentlemen, among whom were Dr. W. F. Coles, Croydon; Dr. Wilton, Sutton; Mr. Kelsey, Redhill; Dr. P. T. Duncan, Croydon; Dr. Alfred Carpenter, Croydon; Dr. McNeice, Carshalton; Dr. Hearnden, Sutton; Dr. Moger, Carshalton; Dr. W. Smith, Croydon; Dr. Parsons-Smith, Addiscombe; Dr. Barnes, Croydon; Dr. A. B. Carpenter, Croydon; Mr. T. A. Richardson, Croydon; Dr. Nicholls, Croydon; Dr. Philpot, Croydon; Dr. Adams, Croydon; Mr. George Wray, Mr. A. Matthey, and others:

It was moved by Dr. COLES, and seconded by Dr. HEARDEN: "That having heard the statement made by Mr. Edward Marshall, and the correspondence which has passed between him and the Holborn Board of Guardians having been read, this meeting is of opinion that the action of the Holborn Board is unjust to an old and well-tried officer; that the circumstances in no way warrant the action which that Board proposes to take; and that the President of the Local Government Board be requested to refuse his consent to the proposed removal of Mr. Marshall from his office."

Moved by Dr. PARSONS-SMITH, seconded by Dr. WILTON: "That it is only a matter of justice to the medical profession that medical and sanitary officers, who have fulfilled their duty to the satisfaction of a local authority, should be entitled to some superannuation, according to their length of service and the character of duties performed."

Moved by Mr. A. KELSEY, seconded by Dr. MOGER: "That this meeting is of opinion that no sanitary or medical officer holding office under any public authority should be removable except for grave neglect of duty or for some other cause which has rendered him incompetent to perform the duties of his office."

Moved by Dr. P. T. DUNCAN, seconded by Dr. McNEICE: "That the above resolutions be published in the BRITISH MEDICAL JOURNAL, and forwarded to Mr. Ritchie, the President of the Local Government Board, and to the Chairman of the Parliamentary Bills Committee of the British Medical Association."

OBITUARY.

PROFESSOR FEDELE FEDELI, M.D.

THIS eminent Italian physician died on March 6th, at the age of 76. He was born at Campiglia Marittima in 1812, and spent his life in the teaching and practice of his profession. He occupied the chair of Clinical Medicine in the University of Pisa with great credit to himself and benefit to several generations of students. He was also medical inspector of the hot springs of Montecatini, the virtues of which he set forth in a variety of publications, both in French and Italian. He wrote also on several other medical subjects, his last work being the *Clinica Medica della R. Università di Pisa*. In 1876 he was named a Senator of the kingdom of Italy,

but he took little share in the work of the Senate. He was buried at Pisa, the funeral being attended by the municipal authorities and a vast concourse of students and citizens.

MEDICO-PARLIAMENTARY.

HOUSE OF COMMONS.

NOTICES OF MOTION.

NOTICES have been given of the following questions:

DR. TANNER: To ask the Secretary of State for War whether the Royal Warrant of November, 1879, which gave officers of the Army Medical Staff the right to retire after twenty years' service, is about to be interfered with or set aside. Whether the condition of retirement was intended as an inducement to medical men to enter the service. And whether this provision under the said Warrant, if interfered with, will affect the retirement of those medical officers who entered the service since the Warrant was issued.

DR. TANNER: To ask the Secretary of State for War if it is a fact that a General Order has recently been issued to officers of the Army Medical Staff Corps restricting the height of recruits for the corps to the minimum of 5 feet 3 inches. Whether an important portion of the duty allocated to the men of the said corps is to act as litter bearers for the purpose of carrying the wounded men out of action. And what was the previous minimum standard of height for recruits.

MEDICAL NEWS.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the Second Examination in Anatomy and Physiology at a meeting of the Board of Examiners on April 2nd, namely:—

J. Stalker, T. G. Ouston, A. B. Sturges, and C. Benson, of Leeds School of Medicine; J. E. Gosdon, A. W. McMichael, S. H. Perry, L. P. Gamgee, C. A. Green, and A. J. Green, of Birmingham; H. S. Jackson, L. W. Dryland, S. H. Lucy, and F. R. Scrase, of Bristol School of Medicine; D. L. Davies, J. H. Dow, J. L. Fletcher, R. M. Littler, and J. S. Whitaker, of Owens College, Manchester; H. Hopkins and R. H. W. Dunderdale, of Liverpool Infirmary School of Medicine.

Passed in Anatomy only.

H. Cross, of Sheffield, and W. Pearson, of Owens College, Manchester.

Passed in Physiology only.

W. S. Finch, of Liverpool; A. W. Senior, of Manchester; and C. Wintle, of Bristol.

Passed in Anatomy only on April 3rd.

B. R. Sawhny, of Newcastle-on-Tyne; B. G. Neale and J. S. Griffith, of Bristol School of Medicine; F. C. Bottom and A. H. Beardmore, of Sheffield; J. T. Barrow, of Charing Cross Hospital; J. S. Sewall, of Liverpool; W. A. Stott and J. Fearnley, of Leeds School of Medicine; J. S. Pickford, D. Headridge, and G. W. Holton, of Owens College, Manchester; G.

Kendrick, of Birmingham; D. N. Morgan and R. R. H. Wonnacott, of London Hospital; C. W. Emyln, of St. Bartholomew's Hospital; and O. E. Keller, of Leipzig.

Passed in Physiology only.

C. F. Sutton, A. H. Aldridge, and R. Smith, of Owens College, Manchester; W. B. Pollitt, O. F. Rowley, H. Tempest, E. B. Collings, and A. H. Reinhardt, of Leeds; E. P. H. Lulham and A. H. Meadows, of Guy's Hospital; G. M. Arkle, E. C. Wimberly, and S. Greenwood, of Birmingham; W. Hutchinson, of Haward University; W. B. de Mille, of Halifax.

Passed in Anatomy and Physiology on April 4th.

B. G. M. Baskett, of Bristol School of Medicine; C. H. Preston, of Owens College, Manchester; R. H. Shaw, of Leeds; B. L. Robinson, of St. Mary's Hospital; T. L. Paget, M. L. Hepburn, R. G. Hogarth, E. Turner, and C. Addison, of St. Bartholomew's Hospital; F. R. Riley, E. Chichester, A. H. Smith, C. S. Walfridsson, and W. H. Sturge, of London Hospital; R. M. H. Walford, of St. George's Hospital; C. de Silva, of Ceylon Medical College; C. Ellerman, of Heidelberg and Mr. Cooke's School of Anatomy; H. C. Harper, of Westminster Hospital; T. G. Stevens and W. Winslow, of Guy's Hospital; D. F. Shearer and W. P. Umney, of St. Thomas's Hospital; T. H. Ionides, of University College; N. J. Vaishnav, of Grant Medical College.

Passed in Anatomy only.

A. W. German, of Liverpool; G. Martyn, of King's College; A. A. Fennings, of St. Mary's Hospital; and J. W. Graham, of St. Bartholomew's Hospital.

Passed in Physiology only.

S. F. Wright, of St. Thomas's Hospital.

SOCIETY OF APOTHECARIES OF LONDON.—The following gentlemen having passed the Qualifying Examination in Medicine, Surgery, and Midwifery have received certificates entitling them to practise in the same, and have been admitted as Licentiates of the Society.

Abbott, Frederic William, Redrath, Cornwall.
Barratt, John Ogleshorpe Wakelin, 46, Holloway Head, Birmingham.
Clarke, Thomas Henry, Montague Place, Poplar, E.
Cleveland, Henry Francis, 26, Kidbrooke Grove, Blackheath, S.E.
Coryn, Herbert Alfred William, 153, Aere Lane, Brixton, S.W.
Evans, Evan, King Street, Trinity Square, E.C.
Griffiths, John, The Grove, Ruyton XI Towns, Salop.
Metcalfe, William, Field House, Ingletton.
Read, Arnold Edward, St. Paul's Vicarage, Devonport.
Samman, Charles Thomas, Deddington, Oxfordshire.
Sbirthliff, Edward Dickinson, Elmside, Kingston-on-Thames.
Watkins, William James, 19, Rivers Street, Bath.
Williams, Frederic Newton, 131, High Street, Brentford.

The following gentleman passed the Medical portion of the examination.

H. T. S. Aveline, of the Bristol School of Medicine; E. Baly, of the London Hospital; A. E. Howse, of King's College Hospital; H. H. B. Macleod, of King's College Hospital.

The following gentlemen passed the Surgical portion of the examination.

B. H. Andrew, of King's College Hospital; W. J. Best, of the London Hospital; M. P. Cooke, of the Middlesex Hospital; C. H. Cosens, of St. Bartholomew's Hospital; E. V. Pegge, of King's College Hospital; C. J. Stanley, of King's College Hospital; H. B. Trist, of St. Bartholomew's Hospital.

MEDICAL VACANCIES.

The following Vacancies are announced:

BIRKENHEAD BOROUGH HOSPITAL.—Junior House-Surgeon. Salary, £50, board, etc., and extras. Applications by April 16th to the Chairman of the Weekly Board.

BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon. Salary, £150, and £30 extra for cab hire. Applications by May 10th to A. Forrest, Esq., Secretary.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's Inn Road.—House-Surgeon. Applications by April 10th to the Secretary.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park.—Resident Clinical Assistant. Applications by April 12th to the Secretary, 24, Finsbury Circus, E.C.

DERBY BOROUGH ASYLUM.—Medical Superintendent. Salary, £250, with furnished house, etc. Applications by April 13th, to be addressed to the Derby Borough Asylum Committee, under cover to the Town Clerk, and endorsed "Medical Superintendent."

DURHAM UNION WORKHOUSE.—Medical Officer. Salary, £50, and extras. Applications by April 20th to William Lisle, Esq., Clerk to the Guardians, 38, Sadler Street, Durham.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton. Resident Clinical Assistants. Applications by April 7th, to the Secretary.

INFIRMARY FOR CHILDREN, Myrtle Street, Liverpool.—House-Surgeon. Salary, £85, with board and lodging. Applications by April 9th, to C. W. Carver, Esq., Honorary Secretary.

LIDDELL PROVIDENT DISPENSARY, Jarrow-on-Tyne.—Medical Officer. Salary, £200. Applications to John Christie, Esq., 28, Cobden Street, Jarrow.

OUGHTERARD UNION, Cloonbar No. 2 Dispensary.—Medical Officer. Salary, £102 per annum and fees. Applications to Mr. James Higgins, Honorary Secretary. Election on April 17th.

OUGHTERARD UNION, Lettermore Dispensary.—Medical Officer. Salary, £132 per annum and fees. Applications to Mr. John Wallace, Honorary Secretary, Tully, Inveran. Election on April 17th.

PARISH OF TARBAT EUSTER, Ross-shire, N.B.—Medical Officer. Salary, £115. Applications to Finlay Munro, Rockfield-by-Fearn, Ross-shire, N.B.
 ROYAL ALBERT HOSPITAL, Devonport.—Honorary Ophthalmic Surgeon. Applications by April 9th to the Chairman of the Selection Committee at the Hospital.
 ST. LUKE'S HOSPITAL.—Resident Clinical Assistant. Board and lodging. Applications by April 26th to the Secretary.

MEDICAL APPOINTMENTS.

BLACKETT, W.C., M.R.C.S., L.S.A., reappointed Medical Officer of Health to the Durham Union.
 BOND, O. K., M.R.C.S., L.R.O.P., appointed Clinical Assistant to the Central London Throat, Ear, and Nose Hospital, Gray's Inn Road, W.C.
 BROOKS, J. Pratt, M.R.C.S., appointed Clinical Assistant to the Central London Throat, Ear, and Nose Hospital, Gray's Inn Road, W.C.
 BROOKS, R. P., M.R.C.S. Eng., L.R.C.P., appointed Second House-Surgeon to the Tottenham Training Hospital, Tottenham.
 BROWN, M. L., M.D. Ed., appointed Surgeon Administrator of Anesthetics to the Dental Hospital, Exeter, vice A. C. Roper, M.R.C.S., resigned.
 CLARKE, J. St. Leger, M.R.C.S., L.K.Q.C.P., has been appointed Senior House-Surgeon to Jervis Street Hospital, Dublin, vice G. Stoker, L.R.C.S.I., L.K.Q.C.P., resigned.
 DAVEY, W. H. C., appointed House-Surgeon to the Charing Cross Hospital.
 DUNLOP, T. Cameron, M.D., appointed Medical Officer to Glasgow Iron Works, St. Rollox, vice Dr. Walker, deceased.
 FIELD, A. Theodore, M.R.C.S. Eng., L.S.A., appointed Medical Officer and Public Vaccinator of the 4th District of the Hillingbourne Union.
 GODFREY, A. E., M.B. Lond., L.R.C.P., M.R.C.S., appointed House-Surgeon to the General Infirmary, Northampton, vice W. E. Audland, L.R.O.P., M.R.C.S., resigned.
 GRAYLING, Arthur, M.R.C.S., appointed Medical Officer to the Forest Hill Provident Dispensary, vice G. C. Parnell, M.R.C.S., resigned.
 GUNN, Christopher, M.D., M.Ch., appointed Surgeon to the Dublin United Tramways Company, vice E. A. White, deceased.
 JAMES, J. T., M.B., appointed Assistant-Surgeon to the Central London Ophthalmic Hospital, Gray's Inn Road.
 MITCHELL, W. G., M.B., M.A., appointed Medical Officer to the Glenmuick Parochial Board, vice H. Haldane, L.F.P.L.S., deceased.
 PECK, Herbert, L.R.C.P. Ed., appointed Resident Assistant Medical Officer to the Workhouse, Walton-on-Hill, vice Henry T. Groom, M.R.C.S. Eng., resigned.
 PROWSE, Arthur B., M.D. Lond., F.R.C.S. Eng., appointed Physician to the Bristol Royal Infirmary, and Dean of the Faculty, Bristol Royal Infirmary.
 SINCLAIR, W. J., M.D., M.A., appointed Professor of Obstetrics to the Owens College, Manchester, vice Professor C. J. Cullingworth, M.D., resigned.
 WEATHERBY, A. J., L.R.C.P., M.R.C.S., appointed Assistant House-Surgeon to the General Infirmary, Northampton.
 WELLS, A. P. L., M.B., C.M., appointed Assistant-Surgeon to the Central London Ophthalmic Hospital, Gray's Inn Road.
 WILLS, W. A., M.B. Lond., M.R.C.S., appointed Medical Registrar to the Westminster Hospital, vice H. W. Syers, M.D., resigned.
 WOOD, T. Outterson, M.D., F.R.C.P., F.R.C.S. Edin., M.R.C.S. Eng., appointed Physician to the St. George's and St. James's Dispensary, vice F. H. Hawkins, M.D., resigned.

THE REFORM OF LUNACY PROCEDURE.—The annual reports of Garlands Asylum, Carlisle, always contain some interesting information either on the treatment of insanity or the management of asylums. The report for last year is no exception to this rule, and, in addition to the usual information, has some valuable remarks bearing on lunacy legislation which ought to be of service to our legislators at a time when the Lunacy Acts Amendment Bill is before the House of Commons. It is gratifying to observe that Dr. Campbell's Committee are fully alive to the importance of the subject, and have forwarded a copy of Dr. Campbell's remarks to the Lord Chancellor.

A WELL-KNOWN resident of Calcutta has offered 10,000 rupees towards the building or purchase of suitable accommodation for the Lady Dufferin Zenana Hospital for Women and Children, provided the Bengal Branch of the National Association can find 15,000 rupees for the same object. It is stated that without special help the Bengal Branch will not be able to find so large a sum, its small capital being barely sufficient to raise an income for the maintenance of the present establishment and scholarships.

ILLUSTRATIONS OF NERVOUS DISEASE.—A new journal devoted to nervous diseases has appeared in France, with the title *Nouvelle Iconographie de la Salpêtrière*. It is edited by MM. Paul Richer, Gilles de la Tourette, and A. Londe, under the general supervision of M. Charcot. It will be published twice a month, and will be profusely illustrated. The publisher is M. Lecrosnier.

The publication of a new journal for nurses is announced by Messrs. Sampson Low and Co., bearing the title of the *Nursing Record*. It will be published weekly, price twopence.

MACROOM UNION.—The report of Colonel Spaight, Local Government Board Inspector, for the past six months is of a satisfactory nature as regards the general management and condition of the workhouse. He, however, states that the drainage of the infirmary and separation wards is not in a proper condition, and he recommends that the guardians should consult a competent authority as to the best means of remedying this defect.

THE PEAK HYDROPATHIC AND THERMAL ESTABLISHMENT AT BUXTON.—This establishment, which has been considerably enlarged and remodelled throughout, was opened on Monday, when a dinner, concert, and dance were given by Dr. and Mrs. Hyde.

ADULTERATION OF MILK.—A few such fines as that inflicted recently on a Govan milk-seller should have a considerable effect in reducing milk adulteration. The offender in this case was fined £8 for selling milk adulterated with 10 per cent. of water.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.

MEDICAL SOCIETY OF LONDON, 8.30 P.M.—Dr. Ord: A case of Ulcerative Endocarditis. Mr. Astley Bloxam: On the Treatment of Syphilis by Intramuscular Injection of Mercury.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN, 8 P.M.—Dr. Stretch Dowse: On some Practical Points in Relation to the Physiology and Pathology of the Fifth Pair of Nerves. Dr. George Cunningham: A Statistical Inquiry as to the Results of the Immediate Treatment of Pulpless and Abscessed Teeth. Dr. Campbell: Casual Communication.

SOCIETY OF ARTS, 8 P.M.—Mr. Richard Bannister, F.I.C., F.C.S.: The Cattle Lectures on Milk Supply and Butter and Cheese Making. Lecture I.

TUESDAY.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8.30 P.M.—Mr. Herbert W. Page: A case of Double Nephro-Lithotomy in which Lateral and Median Lithotomy had been previously performed, with Remarks on Sympathy between the Kidneys. Sir T. Spence Wells, Bart.: Remarks on Splenectomy, with a Report of a Successful Case.

WEDNESDAY.

BRITISH GYNECOLOGICAL SOCIETY, 8.30 P.M.—Dr. Robert Bell: On Intra-uterine Medication. Dr. Richard T. Smith: Cystic Disease of the Cervix and Endometrium. Specimens will be exhibited.

HUNTERIAN SOCIETY, 8 P.M.—Dr. Dundas Grant: On Tinnitus Aurium. Mr. De Berdt Hovell: Therapeutic Reminiscences. Dr. A. Davies: A Case of Paralysis.

ROYAL MICROSCOPICAL SOCIETY, 8 P.M.—Dr. R. H. Ward: Fasad's Test Plate. EPIDEMIOLOGICAL SOCIETY OF LONDON, 8 P.M.—Mr. John Spear: The Danger of Specific Contamination of Water during its Distribution, illustrated by a recent Epidemic of Enteric Fever, with certain other points in the Etiology of that Disease.

FRIDAY.

CLINICAL SOCIETY OF LONDON, 8 P.M.—Mr. R. J. Godlee: Case of Acromegaly. Dr. Hadden and Mr. Ballance: Case of Acromegaly. Dr. West: Cases of Acute Periosteal Swellings in several Young Infants belonging to the same Family, perhaps Ricketts nature. Mr. Wainwright: Case Illustrating the Advantage of Early Incision and Drainage as opposed to Excision of Joint. Dr. Hale White: Case of Perihepatitis.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 5s. 6d. which should be forwarded in stamps with the announcement.

BIRTH.

FENOULHET.—February 13th, the wife of J. Peter Fenoulhet, Esq., Horley Surrey, of a daughter.

MARRIAGES.

JONES—WILLIAMS.—At Llanberis Church, by the Rev. D. Jones, Rector, on 28th March ult., Dr. Richard Jones, M.B., C.M., Blaenau Ffestiniog, to Miss Mary Walsh Williams, Erw-Fair, Llanberis.

MACKENZIE—HAMILTON.—On April 4th, at St. Mary Abbot's, Kensington, Rev. E. Kevill-Davies, Lewis Mackenzie, to Augusta Catherine Hamilton.

THORBURN—MELLAND.—On Wednesday, March 28th, at the Congregation Church, Withington, by the Rev. Principal Scott, LL.B., William Thorburn, M.D., F.R.C.S., of Manchester, to Augusta, daughter of W. Melland, Esq., of Moorfield, Withington, near Manchester.

TREVOR—MORPHEW.—On 28th February, at Christ's Church, Rawal Pindi, Punjab, India, by the Rev. Gerald Nichols, Henry Octavius Trevor, Army Medical Staff, son of James Trevor, of Nether Stowey, Somerset, to Alice Marion, second daughter of Augustus Morpew, Army Medical Staff.

DEATHS.

LOOLE.—On April 6th, 1886, suddenly, Cosmo Gordon Logie, M.D., F.R.S., F.S.A., Surgeon-Major Royal Horse Guards (Blue). In memoriam.

PROCTOR.—On the 27th March, at Tunstall, Staffordshire, James Procter, M.R.C.S., of angina pectoris, aged 57 years.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY.....10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's (Ophthalmic Department); and Royal Westminster Ophthalmic.—2 P.M.: Metropolitan Free; St. Mark's; Central London Ophthalmic; Royal Orthopaedic; and Hospital for Women.—2.30 P.M.: Chelsea Hospital for Women.

TUESDAY.....9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's; St. Bartholomew's (Ophthalmic Department); St. Mary's; Royal Westminster Ophthalmic.—2 P.M.: Westminster; St. Mark's; Central London Ophthalmic.—2.30 P.M.: West London; Cancer Hospital, Brompton.—4 P.M.: St. Thomas's (Ophthalmic Department); 10 A.M.: National Orthopaedic.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: Middlesex.—1.30 P.M. St. Bartholomew's, St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: London; University College; Westminster; Great Northern Central; Central London Ophthalmic.—2.30 P.M.: Samaritan Free Hospital for Women and Children; St. Peter's.—3 to 4 P.M.: King's College.

THURSDAY.....10.30 A.M.: Royal London Ophthalmic.—1 P.M.: St. George's.—1.30 P.M.: St. Bartholomew's (Ophthalmic Department); Guy's (Ophthalmic Department); Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Central London Ophthalmic; Hospital for Diseases of the Throat; Hospital for Women.—2.30 P.M.: North-West London; Chelsea Hospital for Women.

FRIDAY.....9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.15 P.M.: St. George's (Ophthalmic Department).—1.30 P.M.: Guy's; Royal Westminster Ophthalmic.—2 P.M.: King's College; St. Thomas's (Ophthalmic Department); Central London Ophthalmic; Royal South London Ophthalmic; East London Hospital for Children.—2.30 P.M.: West London.

SATURDAY.....9 A.M.: Royal Free.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: King's College.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Middlesex; Royal Free; Central London Ophthalmic.—2.30 P.M.: Cancer Hospital, Brompton.

HOURS OF ATTENDANCE AT THE LONDON HOSPITALS.

CHARING CROSS.—Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; Skin, M. Th., 1.30; Dental, M. W. F., 9.

GUY'S.—Medical and Surgical, daily, 1.30; Obstetric, M. Tu. F., 1.30; Eye, M. Tu. Th. F., 1.30; Ear, Tu. F., 12.30; Skin, Tu., 12.30; Dental, Tu. Th. F., 12.

KING'S COLLEGE.—Medical, daily, 2; Surgical, daily, 1.30; Obstetric, Tu. Th. S., 2; o.p., M. W. F., 12.30; Eye, M. Th., 1; Ophthalmic Department, W., 1; Ear, Th., 2; Skin, Th.; Throat, Th., 3; Dental, Tu. F., 10.

LONDON.—Medical, daily, exc. S., 2; Surgical, daily, 1.30 and 2; Obstetric, M. Th., 1.30; o.p. W. S., 1.30; Eye, W. S., 9; Ear, S., 9.30; Skin, Th., 9; Dental, Tu., 9.

MIDDLESEX.—Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; o.p. W. S., 1.30; Eye, W. S., 8.30; Ear and Throat, Tu., 9; Skin, Tu., 4; Dental, daily, 9.

ST. BARTHOLOMEW'S.—Medical and Surgical, daily, 1.30; Obstetric, Tu. Th. S., 2; o.p., W. S., 9; Eye, Tu. Th. S., 2.30; Ear, Tu. F., 2; Skin, F., 1.30; Larynx, F., 2.30; Orthopaedic, M., 2.30; Dental, Tu. F., 9.

ST. GEORGE'S.—Medical and Surgical, M. T. F. S., 1; Obstetric, Tu. S., 1; o.p., Tu., 2; Eye, W. S., 2; Ear, Tu., 2; Skin, W., 2; Throat, Th., 2; Orthopaedic, W., 2; Dental, Tu., S., 9, Th., 1.

ST. MARY'S.—Medical and Surgical, daily, 1.45; Obstetric, Tu. F., 1.45; o.p., M. Th., 1.30; Eye, Tu. F. S., 9; Ear, M. Th., 3; Throat, Tu. F., 1.30; Skin, M. Th., 9.30; Electrician, Tu. F., 2; Dental, W. S., 9.30; Consultations, M., 2.30; Operations, Tu., 1.30; Ophthalmic Operations, F., 9.

ST. THOMAS'S.—Medical and Surgical, daily, except Sat., 2; Obstetric, M. Th., 2; o.p., W., 1.30; Eye, M. Th., 2; o.p., daily, except Sat., 1.30; Ear, M., 12.30; Skin, W., 12.30; Throat, Tu. F., 1.30; Children, S., 12.30; Dental, Tu. F., 10.

UNIVERSITY COLLEGE.—Medical and Surgical, daily, 1 to 2; Obstetrics, M. Tu. Th., F., 1.30; Eye, M. Tu. Th. F., 2; Ear, S., 1.30; Skin, W., 1.45, S., 9.15; Throat, Th., 2.30; Dental, W., 10.30.

WESTMINSTER.—Medical and Surgical, daily, 1.30; Obstetric, Tu. F., 3; Eye, M. Th., 2.30; Ear, M., 9; Skin, Th., 1; Dental, W. S., 9.15.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS respecting editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

In order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the office of the JOURNAL, and not to his private house.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL, are requested to communicate beforehand with the Manager, 429, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication. CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

TO CORRESPONDENTS.

OUR correspondents are reminded that prolixity is a great bar to publication, and, with the constant pressure upon every department of the JOURNAL, brevity of style and conciseness of statement greatly facilitate early insertion. We are compelled to return and hold over a great number of communications chiefly by reason of their unnecessary length.

QUERIES.

MR. RICHARD RICE (Harwen, Stevenon, Berks) asks where a woman who is slightly deaf could receive a course of training qualifying her for monthly nursing.

POST-PARTUM HÆMORRHAGE.

FELIX has to attend a lady who in her three previous confinements has suffered from severe flooding following the expulsion of the placenta. The labours have been otherwise in every respect natural, and most favourable in character. All goes well until the conclusion of the process, when complete atony of the uterus seems to take place; and it has been with the greatest difficulty that any of the usual means aroused the apparently exhausted organ to sufficient action to control the continual oozing or gushes of blood. It proved immaterial whether delivery was hastened or retarded, whether the placenta was removed by hand, or left to Nature. Flooding followed, no matter what was done. Hot water injections seemed to do some good on the last occasion.

With respect to ergotine, will some member give his experience, and state the best preparation for hypodermic use? As to Schieffelin's pills of ergotin, can anyone give experience, and state how long they take, after administration, to produce contraction? Would the administration of iron, etc., for some weeks previous to confinement, be of any probable advantage in combating the tendency to hæmorrhage?

ANSWERS.

R.M.B.—We do not recommend individual practitioners.

TREATMENT OF HEARTBURN.

DR. E. H. WARNER (Barton Hill House, Bristol) writes: I gather from "A Member's" query in the JOURNAL of March 24th that his case is one of chronic gastric catarrh, with dilated stomach, the contents of which, being never thoroughly evacuated downwards into the intestines, are retained, and undergo acid fermentation. I would, therefore, recommend him first of all to ensure a daily evacuation of the contents of the stomach by means of a warm solution of Glauber's or Carlsbad salts, given in the morning before any food is taken. In combination with this treatment, in order to check fermentation, and give tone to the coats of the stomach, he will probably find the following formula useful, namely: R Acidi carbonici (liquid) miv; tinct. iodi mxvi; tr. nucis vom. ʒi; aquæ menth. pip. ad ʒiv. M. Sig. ʒss every two hours. If "A Member" has the opportunity of reading the German Clinical Lectures published by the New Sydenham Society, he will find some valuable practical hints as to the treatment of gastric disorders.

F.R.C.S. writes: In reply to "A Member," who asks for "suggestions for the treatment of obstinate heartburn," let his patient try a tumblerful of milk.

SEA-SICKNESS.

DR. J. R. STOCKER (Board of Trade Office, Glasgow) writes: The observations recorded by Drs. Leiser, Stockman, and Prentice (JOURNAL, March 24th), as to the relief afforded in sea-sickness by forced inspiration, are by no means new. In a paper published in the Lancet, December 17th, 1881, when I was medical officer to the royal mail steamship Servia, I referred to this in support of my views upon the etiology of the sickness.

VITAL STATISTICS OF CONVICT PRISONS.

MR. R. POWER (Portsea) writes: Medical statistics of convict prisons are printed in the annual Blue Books, published by Eyre and Spottiswoode, and can be ordered of any bookseller.

PRACTICE IN AMERICA.

DR. JAMES J. O'BRYEN (Lower Sydenham) writes, in answer to "Stars and Stripes": 1. American States: Arizona, Arkansas, California, Colorado, Columbia, Connecticut, Dakota, Idaho, Illinois, Indiana, Iowa, Kansas, Massachusetts, Michigan, Minnesota, Mississippi, Missouri, Nebraska, Nevada, New Hampshire, New York, North Carolina, Ohio, Oregon, Pennsylvania, Rhode Island, Tennessee, Texas, Washington, West Virginia, and Wisconsin. Canadian States: British Columbia, Manitoba, New Brunswick, Nova Scotia, Newfoundland, and Quebec. 2. No. 3. Yes. 4. The cost varies from five to ten dollars, according to the State registered in.

M.D. (U.S.A.) writes: In answer to the four questions asked by "Stars and Stripes" in the JOURNAL of March 31st: I would say, in answer to the first, legally speaking, none. 2. The laws of many States require all medical practitioners (American or British) to register their diplomas before they can legally practise medicine. In other States no registration is required, but the person (American or British) practising medicine must be duly qualified and hold a diploma, otherwise the authorities would soon be on his track, and provide a comfortable (?) home for him for a period of from two to seven years, according to the requirements of the case. 3. All persons graduating at any American Medical College must satisfy the professors of same that they have a sufficient knowledge of medicine, surgery, and obstetrics to successfully practise the same, otherwise they do not receive a diploma; therefore, should the person not have the knowledge, the "ordeal" would be trying. 4. The cost of registering in the States is the same to both British and American physicians, varying in amount according to the laws of the State where the physician desires to reside—say from four to eight shillings. I would here mention that, as regards the State of New York, all persons who have graduated outside that State must, before they are allowed the privilege of registering their diplomas, get the same endorsed by one of the medical colleges of that State; the fee for which is 24. Also, in case any medical college has reason to think that the person presenting the diploma to be endorsed is not qualified, they have the power to examine him, and, if found incompetent, to reject him, but it is very rarely done. Lastly, for the edification of any of your readers, I would say that all British registered medical practitioners

tioners are allowed the same privileges of registration and the rights to practise medicine in America on an equality with American physicians; and it is to be sincerely hoped that Her Majesty's Privy Council will, in accordance with the provisions mentioned in the Medical Act, 1858, extend similar privileges to any duly qualified American physician who may be desirous of practising medicine in Great Britain.

INDUCTION OF PREMATURE LABOUR.

PERPLEXED asks for advice in the following case. A lady, whose last confinement was attended by very great peril, has applied to him under these circumstances. She is pregnant some five or six weeks, and at a consultation of four medical men in the last confinement, it was advised that the future fetus should not be allowed to come to maturity. Would it be safer to cause expulsion of the early fetus, or allow the case to go on to the seventh month, or when? It is preferable to have recourse to the former for various reasons.

On adequate medical grounds it is acknowledged that the course of pregnancy may be interrupted under skilled advice. The determination as to whether, in any particular case, this course is called for, can only be settled on formal consultation.

We are asked to state that the gentleman who so generously offers to purchase immediate presentation to the St. Anne's Schools for one of the children, provided that £20 be subscribed before May 31st, is a member of the medical profession.

THE TREATMENT OF SNAKE-BITE.

DR. C. R. ILLINGWORTH writes with reference to a paragraph published on March 10th, p. 549: The symptoms of poisoning by the snake-bite were salivation, bronchorrhœa, and cyanosis. These symptoms, in my opinion, contra-indicate the administration of ammonia. I should think that full and frequently repeated doses of the perchloride of iron would answer well, because of the very evident diminution of the fibrin-forming power of the blood in such cases. In any case it might be tested by experiment upon the lower animals.

FURROWS ON FINGER-NAILS.

DR. J. B. DICKINSON (Stalybridge) writes: Respecting the above subject, mentioned in the JOURNAL of March 21th, I beg to state that thirteen years ago, after suffering from rheumatic fever, I found all my finger-nails furrowed transversely, at the lunula; the furrows gradually grew to the end of the nails, and disappeared after about six months' duration. About a year and a half after, I had a horse which suffered from rheumatic fever; he had also his hoofs distinctly furrowed, the furrows growing further and further down, until ultimately they were set away by the blacksmith, and thus disappeared. Since that time I have seen several cases of furrowed finger-nails following rheumatic fever. Other diseases may produce the same phenomena, but my observations have been confined to rheumatic fever cases.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE "BRITISH MEDICAL JOURNAL."

Seven lines and under	£0 3 6
Each additional line	0 0 4
A whole column	1 15 0
A page	5 0 6

An average line contains seven words.

When a series of insertions of the same advertisement is ordered, a discount is made on the above scale in the following proportions, beyond which no reduction can be allowed.

For 6 insertions, a deduction of	10 per cent.
" 12 or 13	20 "
" 26	25 "
" 52	30 "

Special terms for occasional change of copy during series:
 20 per cent. if not less than 26 pages be taken } or their equivalent
 25 " " 52 " " } in half
 30 " " 104 " " } quarter pages.

For these terms the series must, in each case, be completed within twelve months from the date of first insertion.

Advertisements should be delivered, addressed to the Manager at the Office, not later than noon on the Wednesday preceding publication; and, if not paid for at the time, should be accompanied by a reference.

Post-Office Orders should be made payable to the British Medical Association, at the West Central Post-Office, 11th Holborn. Small amounts may be paid in postage-stamps.

CLINICAL LECTURE

ON

LEITER'S ENDOSCOPE IN THE TREATMENT OF VESICAL DISEASE.

Delivered at University College Hospital, March 25th, 1888.

By SIR HENRY THOMPSON, F.R.C.S.,

Surgeon-Extraordinary to H.M. the King of the Belgians; Consulting Surgeon and Emeritus Professor of Clinical Surgery to the Hospital.

GENTLEMEN,—Some important improvements have been recently made in endoscopic apparatus for examining the various cavities of the body. During the thirty years that I have been connected with the hospital, I have from time to time demonstrated here the various contrivances which have been adopted for this purpose. They have long been used for the more accessible cavities, notoriously for the throat, ear, and vagina; but they have been also used for cavities which are more difficult to enter, such as the bladder, and more recently the stomach. The first instrument that I brought here, some twenty-five years ago, was the well-known endoscope of Desormeaux, of Paris, and it was employed in the wards under my care. It was used not only for the bladder and the urethra, but occasionally for the rectum. I cannot say that I think it was of much service; but it was, of course, desirable and necessary that in a great medical school men should see such inventions tested. Then Dr. Cruise, of Dublin, improved the illuminating power of the instrument, and we found it better than the other. We had also a small endoscope designed by Mr. Warwick, which was much less costly than the others, and answered nearly every purpose. After this no great change took place in endoscopic appliances until 1879, when it was reported that Mr. Leiter, of Vienna, the well-known and skilful instrument maker there, had devised a very remarkable apparatus for examining the bladder and stomach. I made it my business that autumn to visit Vienna, and had the advantage of using Leiter's instrument in the Allgemeine Krankenhaus, with my friend Professor Dittel, the distinguished surgeon there. I found it difficult to use successfully, although far more efficient than its predecessors. I therefore ordered one, and exhibited it for the first time in the theatre here in April, 1880, on living patients. It was a large and cumbersome machine, but by means of it an incandescent wire heated by electricity was introduced into the interior of the bladder. In all preceding instruments the source of light had been outside, and a ray was thrown by a mirror or a prism into the bladder, the observation being made only by transmitted light. But Leiter, with whom was associated Dr. Nitze, succeeded in illuminating the bladder by direct rays. The heat, however, arising from the incandescent wire rendered it necessary to provide a current of cold water constantly flowing in a minute channel round the instrument, from the outside to the extreme end of the sound, and returning to make an exit through the handle, otherwise the bladder would have been injured. This involved a very costly and complicated apparatus. Moreover, it was too unwieldy to be carried about in a carriage, a condition which limited its usefulness considerably. But more recently Leiter has succeeded in simplifying the process and the machine, and now without difficulty a tiny Swan lamp, sufficiently small to lie within the apex of a hollow sound not more than No. 22 or 23 in size (of the French scale), can be introduced into the bladder. Moreover, no constant supply of water is now required to reduce the temperature; but it is still necessary to follow certain rules in order to ensure safety and to obtain good results.

In the apparatus now before you the electric current is supplied by a battery of four or six cells (a bichromate is employed), besides which there are the connecting wires with two sounds, one supplied with an opening to show the anterior wall, sides, and floor of the bladder, and one to show the posterior wall.

The first step is to move the handle of the battery, which sinks the elements of each cell into the exciting fluid and furnishes the current. The rheostat must then be adjusted so as to produce the

maximum of resistance, that is, to diminish the current as much as possible before making contact with the little electric lamp, which would be destroyed by too large a charge. The amount of light displayed will show you whether you require more, and if so you will move the slide until sufficient brilliancy is attained. The apparatus is now ready for action.

But certain rules must be followed in order to employ the apparatus safely and efficiently.

First, it is necessary that the bladder should contain fluid; the light cannot be employed in an empty bladder, as a considerable degree of heat is produced; a quantity not less than six ounces is desirable, eight or ten may sometimes be better.

Secondly, the fluid must be transparent; it is desirable to remove all cloudy urine, and, more especially if any source of hæmorrhage exists there, to wash out the bladder so gently as not to excite, if this be possible, any fresh flow of blood. Since the examination is, as we shall presently see, chiefly useful for the discovery of papillomatous growths, or for ascertaining the fact of their absence, the greatest care and gentleness must be employed in every step of the process.

Thirdly, this having been done, the sound No. 1 must be carefully passed into the bladder before the circuit is completed and the light produced; otherwise injury might be inflicted on the urethra by passing the lighted sound along the canal. For the same reason the light must be extinguished before the sound is withdrawn from the bladder. The best way is to pass the sound before attaching to it the connecting wires, and to do this latter only when it has been placed in proper position.

Fourthly, when the beak of the sound is felt free within the partially distended bladder, it should be pressed in nearly as far as it will go, and then the wires attached connecting it with the current; after this the little handle is moved which completes the circuit, and then if all is right, the light instantly appears. If the fluid is clear, the observer will, on looking through the external end of the sound which contains a small telescope, obtain a distinct view of the anterior part of the vesical wall. This view is obtained by means of a small prism situated at the angle between the shaft and beak, so that the rays of light are transmitted from the surface to the observer's eye. By gentle movements, which must be learned by practice, and cannot be verbally taught or described, different portions of each lateral wall and of the floor can be observed at pleasure. But the posterior third of the cavity is outside the sphere of vision through sound No. 1. No. 2 must be introduced, and be managed in the same manner as the former, if it is required, employing for it the little telescope removed from the first instrument for the purpose. Mind also that you do not forget when the lighted sound is within the bladder, that the beak should not be permitted to rest at any spot for more than a few seconds in close contact with the wall of the cavity, lest it should be slightly injured thereby; it is wise to keep the beak gently moving. And when the sound is removed from the bladder, should it be relighted, the beak must be placed in a vessel of water, otherwise the Swan lamp or the crystal covering it, may suffer from undue heat. The light should never burn above one minute in air. If it is not wanted for a minute or two, turn off the current or put the light under water.

[A male patient, about 60 years of age, was now brought in under ether, whose case was a suitable one for exploration. Eight ounces of warm water were introduced into the bladder after withdrawing the urine. Seated between the patient's lower extremities, which hung over the end of the operating table, the lecturer introduced the sound and, having lighted it, was able after a minute or two to say that the fluid was clear, no trace of blood having appeared, that the mucous membrane presented a healthy tint of pale pinkish yellow, but that there was an unusual amount of fasciculation of the muscular fibres in every direction, probably caused by some obstruction of the prostate to the natural outflow. This, indeed, was very well marked; no other morbid condition was present. This description was verified by a number of persons present who in turn examined the organ through the endoscope. This done, the lecturer proceeded.]

You will naturally ask, In what cases is it likely that the instrument will be chiefly useful? Certainly before all others in the case of those small bleeding tumours, respecting the presence of which, but more especially the extent of their development, it is often difficult to arrive at an accurate conclusion. I refer especially to the papillomatous tumours, the distinguishing character of which is their history of

repeated attacks of hæmaturia during a considerable period of time. They may develop slowly for two, three, or four years before the loss of blood becomes considerable. They are often for a long time unaccompanied by pain or by frequency of passing water. The way by which you generally arrive at a positive knowledge that the bladder contains such a tumour is not by sounding as for stone, because the sound is not capable of appreciating a small soft tumour. The mode of determining the fact is to search for a tiny shred of the growth expelled with the urine, and it is very strange indeed if you do not find one after the expenditure of a little time and patience, and are able to identify the structure of papilloma, which is quite characteristic. When you have found this you may be certain that there is more or less of the morbid product there. But you cannot tell whether you have to deal with one growth or two, or more, or whether it is large or small, because neither the sound in the bladder nor the examination by the rectum will afford you any information whatever on these points. In such cases it has been sometimes necessary to make an incision into the urethra by the perineum in order to obtain these data, and I think this will still be necessary in some examples; but in others, perhaps in most, we may now be able to ascertain the facts by means of this instrument. Still when, as not infrequently happens, the tumour is so vascular that the introduction of the instrument produces a considerable outflow of blood, it is useless to pretend that the endoscope will enable us to realise the number or size of the growths in the cavity. If, on the other hand, we succeed by very gentle manipulation in washing out the bladder, clearing it of all opaque matters, and introduce six or eight ounces of fairly clear water, then I think the instrument will enable us to obtain the information required.

One word more in relation to tumours. So far as cancerous vesical growths are concerned—those tumours which you can feel the presence of from the rectum and elsewhere—little or no occasion exists to use an endoscope; and it would mostly be the means of inflicting suffering without adequate advantage to the patient to examine the cavity. Thus, I do not say that it might not be of use sometimes, but, as a rule, that is a condition in which the proceeding might well be spared.

[The second patient brought in was one from whom a considerable portion of the prostate had been excised by suprapubic operation about a fortnight before, by Mr. Christopher Heath, who was present and joined in the examination of both patients. The external wound had nearly healed; nothing, however, could be seen, from the patient's inability to retain more than four ounces, and owing to the presence of blood oozing from the prostate, although the sound passed without any difficulty.]

Here, then, you see an example of the effect of blood to interfere with visual examination, just referred to; and it is a condition commonly met with in cases of papillomatous tumours.

There is another class of cases for which the apparatus may possibly offer on rare occasions some service. We now and then meet with foreign bodies introduced into the bladder, of which, for some reason or other, a clear history is not always obtained. I have met with several instances of foreign bodies, in my time, most of them broken catheters, and have rarely had any difficulty in removing them; in one only was it serious; it occurred in this hospital more than twenty years ago. A hairpin lay right across the bladder, so that I could not move it when seized by the lithotrite. I then did the high operation, and removed the hairpin with some difficulty. I found it lying transversely right and left, with its pointed ends embedded in the mucous membrane, so that it was impossible to remove it by the natural passage. Sometimes, as I have said, only a doubtful history is furnished; there is some reason for reticence, both in regard to the body supposed to be in the bladder and the method by which it arrived there. I remember a case in the country in which a boy had introduced an ear of oats or rye, the spikes of which lying in the right direction ensured its rapid progress to the cavity. In another case in this hospital I cut out a piece of sealing-wax. The history of this was not clear, and we did not quite believe the story given, but sounding revealed the presence of a hard mass. I performed median lithotomy, removing a phosphatic calculus, with an inch of sealing-wax for its nucleus. I may say that I have twice removed sealing-wax thus, and also twice removed a hairpin. In cases of this kind, when you are uncertain as to the fact and desire further information, you may ascertain the nature of the foreign body by this instrument.

Then occasionally there may be a suspicion of impacted calculus. This is a very rare condition, and should not be too

readily suspected to be present. Yet here, too, the endoscope may sometimes throw valuable light—literally—on the situation.

How much it may be necessary to use the instrument for the urethra is a matter of individual opinion. I should say that it is very easy to use it unnecessarily. If, however, you propose to employ it in any given case, it will be generally desirable first to apply a solution of cocaine, of 4 or 5 per cent., for some eight or ten minutes, in order to prevent pain. The urethra is a very delicate tube, and only now and then wants inspection. I do not think you ought to require the instrument for stricture, unless in cases of exceptional difficulty; for all ordinary cases are managed with the least amount of irritation to the passage when treated with simple instruments by a sensitive and intelligent hand. I have never yet, throughout my experience of urethral stricture, met with a case in which I have derived the slightest advantage by inspection. This, of course, refers to the old endoscopic appliances, and I will not say that the present may not be superior in this respect. But I know the urethra well enough to be aware that the introduction of a tube disturbs the relations of the minute orifice, and is by no means so advantageous in practice as by theory it appears to be. The kind of handling which I have found invariably successful for the narrowest and most difficult stricture cannot be adopted when the canal is occupied by a metal tube. But there are other conditions besides stricture for which the endoscope may render some service. The passage is sometimes the subject of little papillomatous growths and congested conditions, which may be removed by an application, say, of some caustic, and you may ascertain the particular spot with ease, and touch it at the same time, by means of this instrument.

In conclusion, I think you will have already arrived at the conviction that it will not be necessary very frequently to employ the apparatus I have shown you in the diagnosis of vesical disease. For the fact is not to be altogether overlooked that its employment taxes the urethra and bladder more severely, for example, than the ordinary operation of sounding for stone, and should, therefore, not be resorted to without adequate necessity. In relation to the presence of papilloma and some other obscure conditions, it may sometimes render essential service; but do not regard it as an instrument that is in any case to be used for diagnosis, except as a special resource when other and ordinary resources have failed. Do not give up in any respect the simple means of prosecuting diagnostic research hitherto employed; but by all means keep it in reserve for certain exceptional cases when other usual methods have been tried and have proved unsuccessful. You may then occasionally find it a valuable ally.

CORK (Population, 81,200). *Decreasing Prevalence of Typhus.*—Dr. Donovan states that the mortality returns for 1886 are very satisfactory, and bear favourable comparison with those of other towns. There was a marked improvement in the death-rate of the city compared with other years. The annual death-rate from all causes was 20.8, the infantile death-rate 2.4, and the zymotic death-rate 0.9. Typhus fever, which has always been very prevalent in Cork, only caused 5 deaths during the year, 83 cases being the total number reported. In 1881, 1,261 cases of this disease had come under notice. Dr. Donovan attributes the decline of this fever to the reduction which has taken place in the overcrowding of congested districts, the improved condition of tenement houses, and the system of regular inspection to which these houses are subjected. Typhoid fever was unusually prevalent, and caused 17 deaths. The precautions taken proved effectual in preventing the spread of the disease, which at one time showed signs of becoming epidemic. Scarlatina was much less fatal than in 1885, the deaths being nearly 50 per cent. less than in that year. Many instances were met with during the year where patients suffering from scarlatina were lying a few feet from pans of milk exposed for sale; and in one case the manager of a large dairy in the city was removed to the hospital suffering from the disease. In all these cases the sale of milk was immediately stopped. Dr. Donovan has devoted a considerable portion of his report to the question of domestic scavenging. If his efforts are successful in securing the removal of the offensive privies and middens, and the general substitution of water-closets, the health of the city will undoubtedly be benefited.

NOTES

ON
A CASE OF CEREBRAL SUPPURATION
DUE TO OTITIS MEDIA
DIAGNOSED AND SUCCESSFULLY
TREATED BY TREPHINING
AND DRAINAGE.

By ARTHUR E. BARKER, F.R.C.S.,

Surgeon to University College Hospital, and Teacher of Practical Surgery at
University College.

If any example were required to illustrate the perils of inflammation of the middle ear, and the need of the most careful study of them by physicians and surgeons, the following case would furnish it. It supplies, on the other hand, fresh evidence of the advance of operative surgery to the rescue of cases hitherto considered altogether hopeless, and suggests the possibility of still further progress. Apart from its intrinsic interest, this case is of importance from the contrast it offers as to pathology and symptoms with a case of abscess in the temporo-sphenoidal lobe published by myself in conjunction with Dr. Gowers in the *Journal* of December 11th, 1886, in which trephining and drainage were also followed by complete recovery. If the present case was, as I believe, primarily one of fairly localised meningitis, the difference of its symptoms from those of the first case are easily explained.

A. G., aged 33, an engineer, was admitted into University College Hospital on January 21st, 1888, under the care of Mr. Heath, who, knowing my interest in such cases, kindly transferred him to my care.

The patient's family history was excellent. When 7 years old he had scarlatinal otitis media, which soon healed, but the right ear has discharged more than once since, and before the last attack. Up to the age of 21 he enjoyed good health. At that time he suffered from some epileptiform seizures, and was treated for them for a few days in University College Hospital. At 24 he states that he was under treatment for gastric ulcer in an infirmary. At 29 he had a bad fall, and injured his spine, after which his right arm and leg were more or less paralysed for eighteen months, with partial anaesthesia. For this he was treated by Dr. Beevor at the Queen Square Hospital, and recovered completely. In May, 1886, he contracted gonorrhoea, and was an in-patient at University College Hospital for prostatic abscess. At this time he began to complain of weakness, and a sensation of coldness in the right leg, which he dragged in walking. The left leg was strong; ankle-clonus was well marked on the right and absent on the left. Knee-jerk was exaggerated on the right and well marked on the left. There was some localised anaesthesia on the dorsum of the right foot; *tâche cérébrale* was well marked.

On August 25th, 1886, the patient came under the care of Dr. Gowers, whose notes record exaggerated knee-jerk on both sides, with ankle-clonus on the right but not on the left; also tremors in the right upper limb on movement, but only slight in the left. Slight nystagmus on movement was doubtful. The pupils were dilated, and reacted sluggishly to light, but well to accommodation. There was tenderness from the fifth to the eighth dorsal spines, but no prominence. Dr. Gowers's diagnosis was lateral sclerosis, and under his treatment for this the various nervous symptoms mentioned disappeared one by one; but, on December 4th, 1886, neuralgic attacks in the right side of the face were noted.

After March, 1887, he ceased attendance, and appeared, from his own account, to have been quite well until the present illness. The latter began on December 5th, 1887, with a purulent discharge from the right ear, for which he became an out-patient under Mr. Bilton Pollard. The right membrana tympani showed a large perforation an eighth of an inch across in the anterior segment, and from this the discharge escaped freely. The treatment consisted in thoroughly mopping out the latter, and dressing the inflamed surfaces lightly with iodoform powder.

On December 28th great pain set in over the whole of the right side of the head. At this time I was asked to see the case, and found the ear as just described, and that there was no evidence of caries of any kind, or of pent-up matter in the middle ear. With Mr. Pollard's concurrence I passed a stream of quinine solution through the middle ear and down the Eustachian tube into the throat, showing that there was a free passage for discharge in two directions, inwards or outwards. There was no trace of redness or swelling over the mastoid, or other evidence of mischief in this process at this date or up to the present moment. The pain was neuralgic in character, and felt most severely over the branches of the trifacial nerve. The optic discs were quite normal, and the pupils equal and normal in reaction to light and accommodation. The temperature was 101°.

Viewing the case as a whole, we both agreed that it was more like one of neuralgia, such as is not infrequent in the course of acute inflammatory ear disease than anything else. From this time the pain continued to increase, and was worse at night, reaching its maximum towards the morning, and preventing sleep.

On January 18th a carious tooth was extracted, but without relief. On the night of the 20th the patient vomited twice, and on the 21st he was admitted into hospital. The condition of the right ear was as before; the left membrana tympani was also perforated, but the middle ear was not inflamed. In addition to the symptoms already enumerated, there was great superficial tenderness on tapping over the right side of the skull; this was most severe just behind the mastoid process and over the right lobe of the cerebellum. There was no trace of redness or swelling anywhere in these regions, or over any part of the scalp. The patient wore a dazed look at this time, apparently from intense pain, and was difficult to deal with in the matter of obtaining accurate information from him, though, as since proved, a very intelligent man. He says now that his sight was at no time in any way affected; but I am sorry to say he was not specially examined for hemianopia at the time.

His temperature on admission was 100°. Until the evening of the 23rd the most marked symptom was intense pain in the head, the temperature varying between 99° and 100°. At 6 P.M. on this day the patient had two epileptiform fits within an hour, preceded by vomiting, during which he ground his teeth, and the right side of his body was very much convulsed. The last fit began as described by the sister of the ward, by his fidgetting about with his right hand, and breaking therewith two ward basins, then extending to the whole side. The latter part of this fit was seen by Mr. Herring, the house-surgeon, who also noticed that the right side was chiefly affected. At the same time the breathing was stertorous and the pupils widely dilated. The eyes were turned first to the right, and then upwards and backwards to the left. After this he slept fairly well, the temperature rising to 100.2° at 7 A.M. next morning.

When I saw him at 2 P.M. on the 25th, the symptoms were as before. His pulse was increased in frequency, and he was groaning with pain in the head. On rising to walk into the next ward, for ophthalmoscopic examination, he was rather unsteady in his gait, inclining to stagger to the left. The optic discs were normal. The pupil on the right was now smaller than on the left. The patient's general aspect and demeanour at this time gave the impression that he was highly neurotic and inclined to magnify his troubles, a fact suspicious in itself, as I have known this condition present in similar cases of grave intracranial mischief, ultimately running a fatal course. On this day, in order to make sure that there was no pus confined in the middle ear, and to cleanse the latter thoroughly I trephined the mastoid in the usual way. Little or nothing was found, but the tympanum was thoroughly washed out through the opening. The wound was dressed with boracic acid fomentations. The next day, the 26th, the condition was unchanged, except that the temperature had fallen to 99° in the morning; it was 100.4° in the evening, and his breath was noticed as very foul. On the 27th there was a rise from 100.2° in the morning to 101.2° in the evening. On the 28th he was sick all night, and more drowsy, and much less observant; temperature 100.2° in the morning, to 100.6° in the evening. For the next few days I did not see the patient, being myself confined to the house. During this time his condition was practically unchanged, except that the temperature was generally a little lower, from 100° to 98.8°. But on seeing him again on February 1st, I noticed great wasting of the whole body, and that the skin was of a dirty yellowish, earthy colour. Mr.

¹ Read at a meeting of the West Surrey Branch on March 29th, 1888.

Herring also recorded a slight loss of power in the left facial muscles. The patient had also begun to pass his motions and urine involuntarily in the bed. Still he could be roused to speak rationally, but quickly lapsed into a stupid heavy state, and was constantly groaning and complaining of intense pain over the right side of the scalp, which was also acutely tender. On the 2nd he was noted as very dull and sleepy, not taking notice of anything around him, but he could still answer questions when roused. His eyes were kept constantly closed tightly, the pupils dilating widely when the lids were raised. The right pupil was now larger than the left. There was greatly increased knee-jerk and ankle-clonus on both sides, and very little plantar reflex on the left. During the preceding night he was first noticed to have lost power in the left arm, and later it was found that the latter was almost powerless, and rather rigid. There were also occasional twitchings about the wrist and fingers. The paresis was most marked in the extensors, the "drop wrist" being very plain. The facial palsy was also more marked than before; temperature 98.8°; pulse 64. In the evening I endeavoured to examine the optic discs, but found it impossible to get the patient to fix the eyes for more than an instant. He would do so when shouted at, but almost immediately the eyes would roll upwards, and remain so till shouted at again, in a way that looked like perversity. When held open with the finger they still turned upwards, but whether unconsciously, or wilfully to avoid the light I cannot say. When remonstrated with, he replied in a dreamy way that he could not help it, that he would do anything to obtain relief from his torturing pain. His breath had at this time the most intensely sickening odour, and his body was extremely emaciated. The paresis of the left arm and face was more marked; micturition and defecation were quite involuntary.

It now appeared to me that a point had been reached in the case at which there were definite symptoms of local cerebral inflammatory effusion for which I had been on the look out, and that its locality was fairly indicated. I also thought that the six other serious conditions which I always teach may likewise arise from otitis media (vide *Lancet*, 1887) might now be excluded as complications in this case, though this could not be done earlier. Putting the matter shortly: (1) Mastoid cell abscess had already been excluded by the operation of January 25th, and the subsequent persistence and aggravation of the symptoms; (2) plastic phlebitis of the lateral sinus, with thrombosis, appeared also to be negated by the course of the temperature, the absence of rigor, and of any swelling in the course of the deep jugular vein and side of the face. The temperature, raised before the opening of the cells, and thorough cleansing of the tympanic ramifications, had shown a general inclination to fall slightly but steadily; (3) pyæmia was negated much in the same way, also by the absence of secondary deposits, as well as by the general aspect of the patient; (4) subdural abscess, besides being less likely to form in an adult, and especially in one who had no evidence of definite caries in the ear, would probably have led by this time to oedema of the overlying skin, which was conspicuously absent, and would probably have been ushered in by a rigor, and have kept the temperature steadily higher than was the case; (5) cerebellar abscess, besides its relative rarity, seemed improbable from the history of the case, that is, the character of the ear mischief and the absence of caries of the tym-

panum; and although it was suggested that the right-sided fits at the commencement of the intracranial complications might be explained by cerebellar disease, the gradual onset of facial and arm paralysis, with twitchings of the wrist, appeared to me to give a clear indication of the situation and nature of the lesion as near the motor areas of the cerebrum; (6) abscess in the temporo-sphenoidal lobe again seemed alone to be insufficient to account for all the symptoms present now. In another case, alluded to above, in which I operated for the latter lesion with the best results, the most noticeable feature was an almost complete absence of special nerve symptoms, although they were carefully watched for, and in the present case these were abundantly present. In the former case, too, the temperature had been usually subnormal after the first onset of the acute attack in the middle ear, though there had been a second sudden elevation, with rigor just before the operation on the brain. The pulse, too, had been constantly slow (*circa* 52), unlike the present case in its earlier stages, although here, also, it gradually slowed down at the last to 64, with the onset of pressure symptoms. With the purely temporo-sphenoidal abscess there was for a time a dull aching in the temporal region, which ultimately passed off. In this present case there was from the first violent, deep-seated headache in the temporal region, with extreme hyperæsthesia all over the right side of the head. This was followed by vomiting, then convulsions with transient coma, followed by intensification of the pain. Later on there was partial left hemiplegia, with twitching of the left wrist, and some rigidity of the arm, together with exaggerated tendon reflexes, and ankle-clonus symptoms entirely absent in the first case, except one attack of vomiting just before the operation.

A consideration of all these facts seemed to me to point to the presence more or less of localised meningitis rather than any of the other six conditions mentioned. Further, it seemed that the locality of the inflammatory effusion was sufficiently clearly indicated for a working hypothesis. The paresis had started in the left side of the face, and had spread to the left arm, and there were twitchings in the left wrist; the leg was unaffected, except

as regards the reflexes. This ought to indicate a lesion in and about the junction of the middle and lower third of the right ascending frontal and parietal convolutions, a lesion which apparently commenced with inflammatory irritation, and had gone on to inhibition, probably from pressure. In one or two cases dying of meningitis due to ear disease I have observed *post mortem* that the inflammation has appeared to concentrate itself about the bifurcation of the Sylvian fissure, and to have spread by preference from this up along the fissure of Rolando. On these grounds, therefore, I decided to trephine over the arm and face centres on the right, and hoped thus to evacuate the materials of a localised meningitis pressing upon them. This operation was accordingly done the next morning, Friday, February 3rd, at 10.30, after I had briefly, in a few remarks to the class present, given some of my reasons for arriving at the conclusions just indicated. Immediately before operation defecation had taken place involuntarily.

Operation.—After the usual shaving and cleansing of the head, the main fissures were marked out on the scalp with an aniline pencil, Reid's method of measurement being adopted. A semilunar flap, including scalp and periosteum, the base about 3½ inches long and parallel with the "base line," was then raised from over

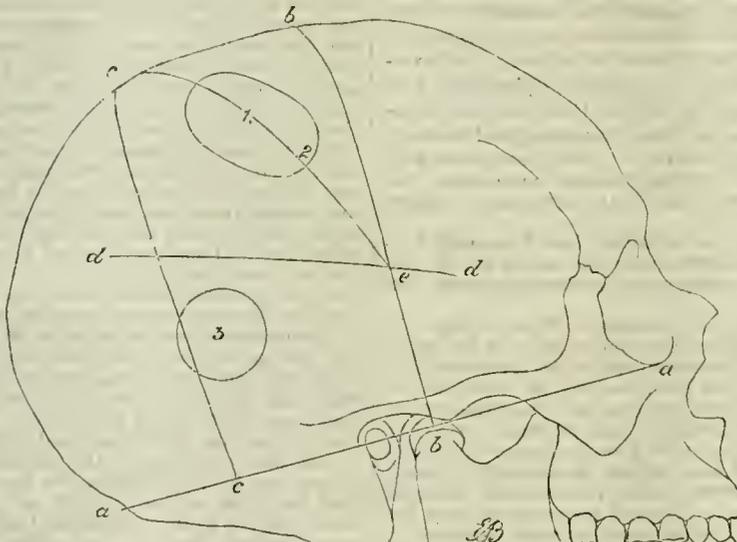

Fig. 1.—From a photograph by Mr. Marriott of a skull, with the markings on it given in the text, and the trephine openings made exactly as in the operation. Exactly one-half the natural size. *aa* Reid's "base line;" *bb* vertical line from latter in front of the tragus, or from tubercle of superior maxilla; *cc* second vertical line from posterior border of mastoid process to sagittal suture; *dd* line marking Sylvian fissure; *ee* line indicating Rolando's fissure; 1 and 2 first trephine opening over motor centres for head and face (the figures indicate the points of puncture in their order); 3 second trephine opening over first temporal convolution, 1½ inch above "base line," 1 inch behind centre of long meatus of ear. The figure 3 indicates the point of the third puncture and drainage opening.

the middle of the motor area, its upper tangent being 2 inches from the middle line of the vertex or sagittal suture. The pin of an inch trephine was then placed over Rolando's fissure (Fig. 1) $1\frac{1}{2}$ inch above the Sylvian fissure, and a disc of bone was removed. The dura mater was at once noticed to bulge markedly outwards. A second disc was then removed above and just touching the first on the same line. Here, too, the dura mater bulged, but not so much. The angles of bone between the two rings were then cut away, and the dura mater was slit up in the middle line of the resulting oval opening of the bone. The surface of the exposed convolutions was now seen to be apparently healthy, but there was considerable bulging and a distinct sense of deep fluctuation under them. I therefore punctured the brain with a large hollow needle in the middle of the oval opening (Figs. 1, II, and IV, 1), and at right angles to the surface, but though the needle entered an inch deep no fluid escaped. The needle was then again entered at the lower border of the opening (Figs. 1, II, and IV, 2), and thrust downwards and inwards into the exposed convolution. When it had penetrated to the extent of $1\frac{1}{4}$ inch, thick, turbid, yellow serum began to flow out, and was received into a test tube to the amount of nearly two drachms.

A third trephine opening was now made, the centre of which was $1\frac{1}{2}$ inch above the base line and $1\frac{1}{4}$ inch behind the centre of the bony meatus of the ear. Through the middle of this third opening (Figs. I, II, and III, 3) the needle was pushed inwards and forwards for $1\frac{1}{2}$ inch from the surface of the bone towards the point at which fluid was struck in the last puncture. On reaching this spot a quantity of thin, white, odourless pus flowed away and was received in a glass to the extent of nearly half an ounce. The dura mater at either side of the puncture was now split up, and a sinus forceps was thrust into the latter as the needle was withdrawn. When the blades of this instrument were slightly separated more pus came away; then a rubber drain-tube was thrust into the open track for an inch and a half from the surface of the bone, through which more pus flowed off freely, especially when the patient struggled, which he did once or twice at this moment, being but lightly anaesthetised. The flow was also observed to increase when Mr. Herring pressed with a sponge on the convolutions under the upper opening. Altogether half an ounce of pus was actually collected in a glass, and quite as much escaped through the drain-tube, so that not less than one ounce was evacuated. On its escape the convolutions under the upper opening were observed to sink down considerably over the area which had before bulged.

The bleeding from the scalp was now finally arrested, and a small vein in the diploë was closed with a Paquelin's cauterizer; then the edges of the incision in the dura mater were united with five fine silk sutures after the opening had been lightly dusted with iodoform in fine powder. The flap was finally dried, similarly dusted, laid down, and stitched all round with eight silk sutures without drainage. Before this was done, however, a small portion of the whole thickness of the scalp was cut away over the lower and posterior trephine opening to admit of free drainage through the rubber tube lying in the brain, which was brought out of this opening. A sal-alembroth gauze dressing laid over the whole scalp after dusting with iodoform completed the operation, which had lasted an hour and a quarter. The ear-bolic spray and all other conceivable precautions were taken to ensure asepsis.

Throughout the whole procedure the respiration, face, and pupils were specially watched by our Resident Medical Officer, Dr. Arkle, and the pulse and left arm by Mr. Jecks, to whom I am indebted for the following notes:—

"Chloroform was administered at first on the corner of a towel, later by means of a Junker's inhaler through the nostril. The condition of the patient was most critical. At the moment of administering the anaesthetic the pulse was only 36 per minute, of only moderate strength, and compressible. It was irregular in force and rhythm, with pauses of three and even four seconds between successive beats. In about ten minutes the pulse rose to 44 and 48 per minute, improving a little in character, and remained like this during the first part of the operation. The respirations were slow and shallow, about 18 per minute. The patient took the chloroform well, and only struggled a little, both sides of the body moving, but the right more freely than the left. While struggling he could not raise the left arm higher than the manubrium sterni. On exposure of the dura mater by the removal of the first disc with the trephine the respiration altered, becoming deeper and more frequent. There was no sudden appreciable alteration at this time in the pulse; but, on the opening up of the dura mater, it was noted as 60 per minute.

"Shortly after the punctures through the motor areas there was some clonic spasm in the left arm and hand, none in the face, leg, or foot. This was repeated several times when the sponge was pressed on the convolutions, but not constantly. Immediately after the pus was struck the pulse became very weak, rapidly reaching 100, and, a little later, 120. It was small, regular, and very compressible. An enema of brandy was given but was not retained long. Before the operation was over the condition of the patient appeared to be most alarming. The breathing again became very shallow, and the pulse was 160 and running; the face was pale and sweating, and the lips a little blue. Fifteen minims of ether were injected under the skin of the præcordium with manifest advantage. The patient was only kept lightly under the anaesthetic during the whole operation, and very little chloroform was used."

When I next saw the patient, three hours later, he was already better,

and stretched out his right hand and shook mine warmly, speaking quite rationally. His pulse was still very rapid, and he had just been sick, but at 9 P.M. I thought him in a very critical condition. His pulse was very weak and variable—140 to 160, temperature 100° ; he had been constantly sick. The dressings, which were slightly soaked with blood and serum, were now changed, but the drainage-tube was not disturbed.

The next morning, February 4th, he was decidedly better. The sickness had ceased, the pulse was 120, the temperature 97.8° . The facial paresis had improved, but there was still great weakness in the left arm. Faeces and urine were still passed involuntarily.

February 5th.—Better in every way. Pulse 112, temperature 97.8° . Takes food fairly well. Second dressing as before, at which a silver drainage-tube, made from a No. 12 English catheter, was substituted for the rubber one. It was pushed in along the track of the latter for one inch and three quarters from the surface of the skin, and in a direction inwards and forwards from the opening. It had a slight curve upwards and forwards. The urine and motions were passed voluntarily from this day onwards. The facial palsy was nearly gone, and the arm much improved. There was no optic neuritis. The pains in the head, though better, were

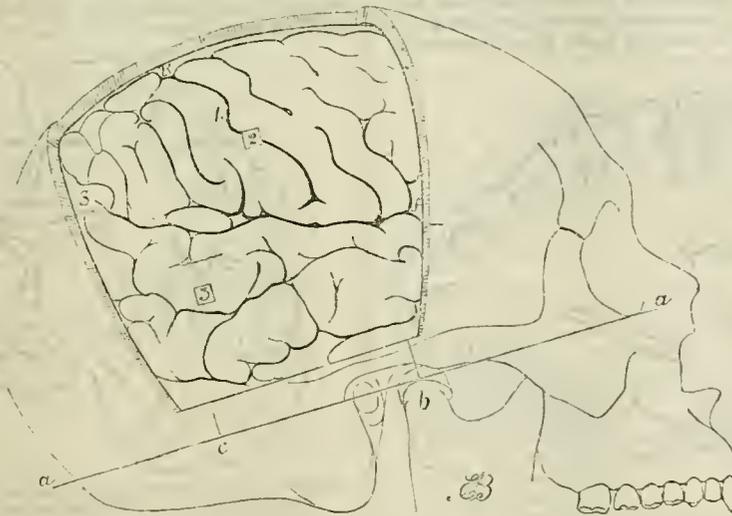

Fig. II.—From a photograph by Mr. Marriott of the same skull with the brain exposed, showing the position of the punctures, which had been previously made with small wooden rods without opening up the dura mater. One-half natural size. *a a* base line; *R* fissure of Rolando; *S* Sylvian fissure; 1 indicates the spot at which the first puncture was made for an inch, from which nothing came; 2 first wooden peg, lying exactly in the fissure of Rolando, passes downwards and inwards, and indicates where the second puncture reached turbid fluid; 3 second peg passes through the first temporal convolution inwards and forwards to meet the first, and indicates the spot at which the drain-tube was inserted.

still severe, but the patient's general aspect had much improved. Pulse 82, temperature 98.6°.

February 6th.—Has slept fairly well. Pain in the head much better. Pulse 82, temperature 98.6°. Three grains of calomel were ordered. The track of the tube was washed out with a warm saturated solution of boric acid; this did not produce any nerve symptoms. The silver tube, dusted with iodoform, was replaced, and the wound was dressed as before.

From this time there is little to note except uninterrupted recovery. The facial and arm paresis disappeared in a few days completely. The breath became less offensive, and the appetite normal. The bowels required to be opened occasionally with a few grains of calomel; there was still an occasional slight tremor or twitch in the left wrist for some days, but this, too, disappeared soon.

On February 9th, he drew attention to a feeling of "pins and needles" in the fingers of the left hand, and slightly in the left leg, and a sensation as though a string were tied tightly round his tongue. On the 10th, the pain in the head was gone. On the 11th, the "pins and needles" were gone, but he noticed that his tongue was still sore.

On the 12th, a shorter and smaller drainage-tube was used, as there was very little discharge from the brain. Two days later a still shorter one was inserted. Humming tinnitus was noticed. Pupils equal. Great tenderness all over the left side of the body was complained of on this day, but especially over the thorax. The dynamometer registers 45 with the right hand, 40 with the left.

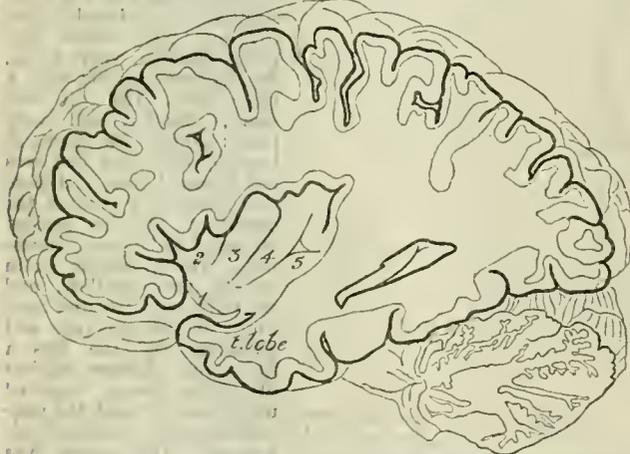

Fig. III.—From one of Dalton's photographs of an imbedded brain, reduced to exactly half size. The section is vertical and longitudinal to expose the space in which the island of Reil lies. 1 2 3 4 5 the convolutions of the island of Reil; the position of the figures 4 and 5 would indicate as nearly as possible the spots reached by my two punctures in the operation; t. lobe temporo-sphenoidal lobe; only the inner part remains.

On February 15th the patient was practically convalescent. His bowels were regular, appetite good, and he was cheerful and intelligent. There was not much pain in the head, and the colour of the skin was much better; the drain-tube was finally dispensed with. The scalp wound healed everywhere by first intention, except at one angle, where slight moisture escaped up to February 20th. On the 21st all the stitches were removed. The patient was out of bed on and after the sixteenth day after the operation, and was very cheerful and bright in spite of occasional neuralgic pains over the branches of the trifacial nerve, probably aggravated by the very severe weather. The knee-jerk on both sides remained, though less than before, and ankle-clonus was still present, though diminished. G. left the hospital on March 8th for the Convalescent Home, where he still is.

It would be interesting did space permit to discuss the pathology of this affection, and to analyse the symptoms present at greater length, as well as to deal more fully with the purely surgical features of the case. But the mere record of the essential and salient facts of the case has carried me already too far, and these questions must be left for future consideration. This record, however, would not be complete if I did not state my belief as to the exact nature of the inflammatory collection, and the position it occupied in the brain.

Reasons alluded to above were briefly given before the opera-

tion for my belief that this was a case of more or less localised meningitis in and about the middle of the Sylvian fissure, and extending up over the motor centres of the face and arm on the right side. But on trephining over the latter, the arachnoid was seen to be healthy, though the cortex fluctuated. The introduction of the hollow needle, however, downwards and inwards (Fig. IV, 2), evacuated thick, turbid, odourless serum. This experience shook my faith for the moment in the correctness of my diagnosis; but the result of the next puncture (Fig. IV, 3) through the posterior and lower trephine opening, in which the needle should have nearly met its fellow at about $1\frac{1}{2}$ inch from the surface of the skin, brought me back to my original conviction, that this was a case of localised meningitis, which I now hold with a very slight modification. It is quite clear that the collection of inflammatory fluid tapped did actually lie in the Sylvian fissure, and was not a temporo-sphenoidal abscess. But instead of extending up over the external surface of the brain, as I at first thought, it accumulated, I believe, among the convolutions in the deeper part of the fissure between the island of Reil (Fig. III, 1, 2, 3, 4, 5) and the overhanging motor convolutions, and pressed the latter outwards against the skull (Fig. IV). This explains the fluctuations of the motor gyri under the first trephine holes, and also their collapsing on the evacuation of the fluid through the third trephine opening below. If the abscess had been seated actually in the white substance under the motor centres, the arm and face would hardly have recovered so rapidly as was the case here; whereas if a collection of

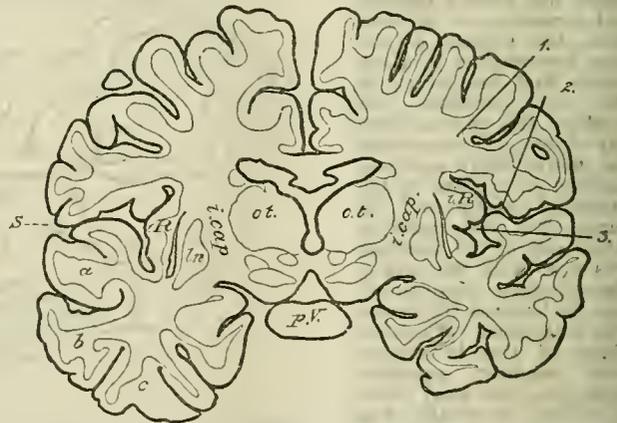

Fig. IV.—From one of Dalton's photographs of an imbedded brain, reduced exactly to half size. The section is vertical and transverse, in the region of the punctures made in the operation. The right half of the brain is apparently a little shrunken. S Sylvian fissure; a b c first, second, and third temporal convolutions; p pons varolii; i cap internal capsule; o t optic tract; l n lenticular nucleus; i l island of Reil; 1 first puncture, directly vertical to surface of brain, which gave no result; 2 second puncture, downwards and inwards, which reached turbid fluid; 3 third puncture, inwards and forwards, through the first temporal convolution, into which a drain-tube was inserted; drained the same space as that reached by No. 2 puncture.

fluid lay in the deeper parts of the fissure of Sylvius around the island of Reil, it could act doubly upon the motor centres, on the one hand by forcing the overhanging convolutions outwards against the skull, and on the other by pressing directly through the island upon the motor fibres of the internal capsule (Fig. IV, i. cap.) lying underneath, and after its evacuation the functions of the parts around would quickly be resumed. But the matter is put beyond question by the performance on the dead body of exactly the same operation, taking every possible precaution as to accuracy of measurement.

In doing this, I selected an adult skull of the same dimensions, within a small fraction, as the patient's. In this skull the dura mater was exposed with the trephine, exactly at the same point (Fig. I, 2) as in G.'s case. I then took a slender lucifer match, pointed it and cut it to the length of $1\frac{1}{2}$ inch. This was then thrust through a puncture in the dura mater, and into the brain, at exactly the same spot, and in precisely the same direction downwards and inwards, as was the needle which struck the first turbid fluid. A second similar match, $1\frac{1}{2}$ inch long, was then pushed through a puncture in the dura mater under the lower trephine hole (Fig. I, 3), in a direction inwards and forwards, as in the case of the needle at the operation. The outer ends of both these rods were now flush with the cortex and concealed by the

dura mater. The skull was then photographed by my friend Mr. Marriott (Fig. 1), after which the right side of the calvarium was removed. On cutting open the dura mater, the outer end of the first rod was seen, exactly in the fissure of Rolando (Fig. 11, 2), that of the second rod in the superior temporo-sphenoidal convolution (Fig. 11, 3), as seen in a second photograph. A vertical section of the hemisphere exposing the whole length of the first match was now made, and then a horizontal, exposing the track of the second. When the posterior half of the hemisphere was now lifted off, the points of the two rods of wood were seen to be almost in contact in the space overlying the island of Reil, and touching the latter (Fig. 1V, 2 and 3). The first had passed between the ascending frontal and ascending parietal convolutions (2), the second through the superior temporal convolution (3). Had the collection of fluid been a temporo-sphenoidal abscess, it is quite obvious that it would not have been reached by the first puncture, which evacuated fluid $1\frac{1}{2}$ inch from the surface of the cortex, at the junction of the middle and lower third of the fissure of Rolando. Nor would it probably, unless very large and high, have been reached by the second puncture, which met the first and travelled quite above the body of the lobe. It must be remembered, further, that one ounce of fluid among the convolutions over the island of Reil would press the former asunder more or less, and would produce a larger space than that represented in the drawing, so that without actually touching each other, the two needles might easily empty it. I am careful to clear up this point, less as a mere operative question (because of course one would evacuate the pus wherever the needle reached it), but rather as bearing upon the wider question of treatment of septic meningitis by operation, which for some time past I have looked forward to as possible. It would of course be unwise to dogmatise as to the exact limits occupied by the pus in this case, and as to whether it was produced primarily by a leptomeningitis or encephalitis, or, possibly, by the giving way of an abscess. The patient is now alive, and we cannot settle the matter by dissecting his brain; and although I have approached as nearly as possible to proving, by operation on the dead body, what actually was the locality involved, still I wish to put forward the above view only as the most reasonable hypothesis deducible from a careful and anxious clinical study of this and several allied cases for which I have had exceptional opportunities now for many years, and also from numerous pathological data accumulated in the *post-mortem* room.

All those who have given close attention to this whole subject will feel that, in the matter of operative treatment of non-traumatic intracranial suppurations, we are but on the threshold of a new region common to medicine and surgery, and most will be unable to divest themselves of a feeling of dismay at its complexity. It is comforting to us all, however, physicians and surgeons alike, to reflect that already this region has shown itself fruitful, and that one more group of fatal diseases has been brought within the reach of surgical operation.

Note.—I have thought it better to give reduced copies of Dalton's beautiful photographs of sections through an imbedded brain in Figs. III and IV, rather than drawings of my own dissections. Without a large material and special apparatus for embedding and section, it is difficult to make an accurate representation of the relation of parts of the brain, which soon sinks down when the skull is opened and it is cut. I have therefore transferred to Dalton's sections the lines of puncture observed in my own dissections; this leaves as little room for error as possible.

March 30th. The patient returned from the country on the 28th. He still complains of pain in the head, but looks well and eats, I am told, remarkably well. I shall continue to observe him, and report later if anything further of interest should be noted.

THE 105th annual report of the Hull Royal Infirmary shows the number of in-patients for the year to have been 1873, the number of out-patients 10,772—the largest number that has ever passed through the hospital in any one year. The average cost of each in-patient for treatment, nursing, and maintenance was £2 19s. 10d. The estimated cost of each out-patient was nearly 1s. 8½d. The alterations and improvements in the main building have been satisfactorily completed, and it was hoped the south-east block would shortly be available for patients. With a view of providing better accommodation for the nursing staff, it was decided to proceed at once with the conversion of the Watts Wards into a home, and by this means provide the nurses the comfort due to their position and the exhausting nature of their duties.

ON SOME HITHERTO UNDESCRIBED SYMPTOMS IN THE EARLY HISTORY OF OSTEO- ARTHRITIS.

(THE SO-CALLED RHEUMATOID ARTHRITIS.)¹

By JOHN KENT SPENDER, M.D. LOND.,

Physician to the Royal Mineral Water Hospital, Bath.

Few things are so apt to cause a feeling of drowsy despair at a medical meeting as the prospect of an academic discussion on the etiology of osteo-arthritis. The fields seem barren; the harvest is small, even after every scrap has been gleaned; one master says one thing, and another master says another; so that the self-styled practical man cries out in his confusion, How have all these speculations helped me? Two wants, he exclaims, I ask to have supplied: such sure notes of a disease that I may, if possible, know it at once when I see it, and trustworthy landmarks to its treatment at a time when treatment is available. The practical man has some ground for his dolorous plaint. It is certain that if scientific questionings about the nature of a disease do not help us to do people good somewhere or somewhere, those questionings will soon lack interest and be forgotten. Three common but wholly distinct maladies affect the same structures; the patient cannot distinguish his malady, and naturally requests his medical adviser to do so; but he is prone to lose himself in vague generalities, and probably falls back on that old-fashioned, ghostly, thing called "suppressed gout." Now, is it not an enormous gain if we can at the earliest moment give a verifiable diagnosis—not merely a fancy or an opinion? When so much depends upon the issue, time is everything. Such is the plea for my paper to-night. It is my aim to strengthen those landmarks which tell of early danger, because they proclaim with unerring precision what the disease is. To be able to identify osteo-arthritis in its very cradle, and to sharpen the lines of boundary between it and all other things which resemble it, is surely worth a little time and trouble.

Bath has been called a museum of living osteo-arthritis; but this conveys no adequate idea of the wealth of our clinical material, which I believe to be without a parallel in its kind. In our Mineral Water Hospital, nearly half the cases belong to the osteo-arthritis group; and a crowd of so-called rheumatoid people flock to our spa from all parts of the country. Among our residential population there is no osteo-arthritis worth speaking of; nor are any of the influences present which would favour its development. But this procession of suffering pilgrims—what a challenge to our therapeutic skill! In the presence of an overwhelming quantity of the same sort of trouble, the tendency of the mind is towards apathy and almost weariness. A ceaseless iteration of the same phenomena dulls the faculties and dims the senses. We see, and yet we do not see; curiosity is dead, for there is nothing to be curious about; what happened yesterday happens again to-day, and (for aught we know) will happen again tomorrow. All interest perishes in the everlasting sameness. In this shroud of mental torpor no man ever discovers anything, because there is no enthusiasm and no inward light.

It has been said by a writer of distinction that there is nothing which may not be found if we start on an inquiry with the intention of finding it. It is sound advice to inquire without expecting, and without even the desire of finding; and it is plain truth when I say that some "hitherto undescribed symptoms" of early osteo-arthritis were so little expected that even when found, after a careful induction of nearly a thousand cases, the feeling of wholesome scepticism was long in clearing away. "Was it not a mere coincidence?" asked the casuist; and his logical appetite suggested that there were a hundred little pitfalls scattered here and there. So it required some hardihood of mind to think at last that certain signs, when present, connote osteo-arthritis in its earliest phase, and demonstrate beyond doubt that the disease cannot be anything else.

1. Dividing roughly all cases of osteo-arthritis into slow and quick forms—the first sometimes occupying decades of years in its chronic ruin, the other maiming and crippling in forced marches—we find that a great number of the latter class are characterised almost from the beginning by an increased velocity and tension of the heart's action. Quoting from cases the history of which was traced from an early date, the pulse may go up at once to between 80 and 90, and remain so for years. But we

seldom see at Bath these twilight beginnings of the disease; people come or are sent when it is developed, and we are startled by counting a steady pulse of much tension, varying from 90 to 110. Beyond this point are the rare cases to which I request special attention. The pulse quickens synchronously with the earliest objective signs of osteo-arthritis; it increases in frequency until 110, 115, or 120 are reached; any variations lie within quite a narrow range. There is no hæmic murmur, and no sign of the heart being in any way affected. In one instance, unique in my experience, a young lady was entrusted to my care (last July) whose pulse was uniformly above 140, and as incompressible as it was rapid. The body is absolutely non-pyrexial, and the icy purple coldness of the hands is often a striking fact. This is not the place to speculate on the cause of this remarkable symptom, nor have I time for doing so. Easy it is to discourse eruditely on the withdrawal of the inhibitory influence of the pneumogastric nerve; but I do not see how this lands us nearer any satisfactory theory of what osteo-arthritis is, or how its complex neural relations are thereby unfolded. And it is strange that the cardiac tumult often does not subside even in these many cases in which the osteo-arthritic phenomena become, so to speak, "tamed down."

2. The next point of mark is the disturbance in the chromatogeneous function of the skin. This symptom has been of unfailing interest to me for the last three or four years, nor do I understand why it seems to have escaped the attention of so many keen observers. Concentrated in the form of patches more or less large, the pigmentation assumes many hues, and affects many parts of the body. Across the forehead it often runs as a light-bronze smear, always more pronounced over the temporal fossæ; thence it extends under the lower eyelids, deepening the pigmentation of an already pigmented area, and generally shading off into the natural colour on the cheeks and the sides of the face. Sometimes the predominating tint on the face is lemon or orange, and sometimes there are fawn-coloured patches on the cheeks. The yellow tinge is nearly always discernible on the backs of the hands, as yellow circles around the finger-joints, and especially around the matrix of the finger-nail. In people of dark complexion the discolourment of the face and neck may be so swarthy as to call up recollections of supranasal melasma; and the white luminosity of the eyes stands out in brilliant contrast. But I desire to lay special stress on the occasional deep pigmentation of far advanced osteo-arthritis, representing what has been termed multiple xanthoma. In this extreme form large, dirty-brown blotches appear between the knee and the ankle, connected by longitudinal streaks, which are intensified in colour by paroxysmal pain. Tropic changes in the texture of the skin occur on the soles of the feet and the palms of the hands, which become rough and horny, and bright with the hue of marigolds. Finally, the nails of fingers and toes separate from their respective phalanges, and are torn and twisted from the matrix by an accumulation of dry chalky material. In this condition of things a patient dies sooner or later from some intercurrent malady, probably an extension of the already grave neurosis. I have now drawn the outlines of an actual patient, entrusted to me in 1884 by Dr. Morton, of Guildford, and who was my constant care until her death more than two years afterwards.²

That form of disseminated pigmentation which goes by the common name of "freckles" is a very frequent accompaniment of early osteo-arthritis. A multitude of little yellow specks may now and then be discerned on the foreheads of many light-haired women and not a few men, appearing at the commencement of what they call their "rheumatic gout;" bigger specks come faster and faster, until the whole face may be covered with spots of every size, which extend to the neck and ears, and are often of a blackish-yellow colour. Now look at the hands. Not only on the backs of the hands do the freckles cluster near the knuckles, but they extend far up the arms, along divers nerve-lines; and even to the elbows, if these joints chance to be involved. Patients are much puzzled by these freckles appearing on parts not exposed (as they say) to sun or artificial heat; and why do they come? is a question which I am often asked, but find it difficult to answer.

3. The next noteworthy symptom is the vasomotor disturbance, which causes local perspiration. Taking the hand of a hospital patient, a middle-aged woman, extremely rheumatoidal, I found it so wet that I said, "You have just put your hand into water." "No, sir;

my hands are nearly always like that." There are many degrees of this morbid sudoræa. It may be a mere dampness, scarcely more than that which exists in many chlorotic people whose circulation is feeble, and who always have chilblains during the winter; or the sweating may be only on the palms of the hands, the natural furrows being so many rivulets which drain the parts around. The sweating process is generally intermittent, and there is most moisture when and where there is most pain. A lady sent to me in the autumn of 1886 suffered thus: every morning, at about 2 o'clock, a severe neuralgic attack came on in both lower limbs, and, at the same time, there was such excessive perspiration that the whole bed felt wet, and a thick layer of flannel was put under the thighs and legs to absorb the fluid which streamed from them. Other upsetting of vasomotor proprieties is shown in erysipeloid swelling of the hands; in transitory feelings of great heat, as if the hands were "parboiled," said one patient, or being "stung all over with nettles," said another; and a very common sensation in both hands and feet is that of being "scalded," as if the textures all through were submitted to a fiery ordeal.

4. There yet remains the large and subjective phenomenon of pain, which follows the course of certain nerves in such a manner as to deserve the title of essential neuralgia. In the early synovial stage of osteo-arthritis there is pain more or less localised in the affected joints; but the warnings and foreshadowings of which I now speak are altogether different, and are due to a perverted innervation of a large nerve-plexus, or of a large area of nerve-supply. The earliest prophetic note of the coming storm is pain in the muscles of the ball of the thumb, with sharp pangs on the inner side of the wrist, which I venture to call the "ulnar area" of this specific neuralgia. Later on the pain is massive and diffused, and not always to be identified with the chief nerves of a limb. Thus a middle-aged lady had a painful condition of the whole right arm, acute and paroxysmal. Pressure along the course of the ulnar nerve and over the brachial plexus was badly borne. Now what was the meaning of all this neural disturbance? It was a beacon warning of coming evil. Already there were the pathognomonic signs of enlargement of the first and second metacarpophalangeal articulations, and a trivial disclerment of the skin; and it was clear that if our whole therapeutic thought had been addressed to the neuralgia as such, we should have missed the very point of the case. What we imagine to be sciatica pure and simple is now and then a note of osteo-arthritic disease having begun in the tarsal articulations, or perhaps in the knee. But the specific neuralgia of the lower limb which I am now describing is, so to speak, pain in bulk; the sufferer clasps the thigh with a fervid grip, and says that the pain is all round, engaging the anterior crural and obturator nerves, no less than the sciatic. An exhaustive surgical examination of the hip-joint may discover that an osteo-arthritic lesion has already begun in it, justifying the old name of "hip-ache," often applied when it was doubtful whether the joint or the nerve were the mere affected. We profess to have more perfect instruments of diagnosis than our forefathers; but it is certain that while we are meditating how to treat a supposed exclusive pain-storm, another and deeper pathological mischief may be creeping on unperceived.³

There are many collateral facts which show how far-reaching are the disturbances which may be roused by that profound nerve-quake (if I may so term it) which is at the root of the true neural arthritis. I have seen two cases (both middle-aged women) in whom the phenomena of the so-called gastric crises, precisely as in locomotor ataxy, were the earliest signs of rheumatoidal disease.

In another case the battle began with symptoms of asthma; and a long dreary prelude of migraine-headache is very common indeed.

Dr. Johnson, of Tunbridge Wells, sent me, three months ago, a patient who exemplified in a striking form the waves of cerebral sympathy which may be stirred by a progressive osteo-arthritis. A lady, aged 75, has the usual nodular joints in the fingers and knuckles; she has an orange tint on her forehead and face, with red cheeks; the fifth nerve expresses its partnership in sorrow by intense supra-maxillary pain; the equilibrium of the glosso-pharyngeal nerve is upset, and queer tastes are frequently perceived; there is intense deafness, and now and then visual ver-

² A full account of this case was published in the JOURNAL of March 7th, 1885.

³ I am indebted to my friend Mr. C. T. Griffiths, resident medical officer at our Mineral Water Hospital, for much help in the collection of data for the purposes of this paper. I owe a great deal also to medical men in London and various parts of the country for sending me cases of interest for private treatment.

tigo. And just now another patient, a lady of middle age, having an intensely pigmented face, suffers from inco-ordination of the pharyngeal muscles to such an extent as to suggest to her medical attendant the possibility of glosso-labial paralysis, so great was the difficulty of swallowing.

There are links which bind together osteo-arthritis, tabetic arthropathy, and the arthropathy of hemiplegic limbs. I venture to put forward the theory that the term "osteo-arthritis" will be found to include several kinds of joint lesion. There is what is commonly called the acute type, and there is the chronic type, and in both the anatomical changes are the beginning and end of the whole thing. But I contend that there is a large and hitherto undescribed group in which the pathology of joints is merely one sign of a profound nerve disorder. We call it conventionally an arthritis; but really the arthritis is only one neural symptom among many others, and possibly not the most important. Synthetically we do not build osteo-arthritis out of pulse, pigment, perspiration, or pain; the special morbid anatomy must be there; but one or more of these symptoms may eclipse the arthritis so far as to make it insignificant in any given case. A new name seems to be wanted for a complex state in which the neural and trophic phenomena of the body are so curiously upset and confused; but I do not venture beyond my allotted province of merely recording what I have seen and heard.

To sum up. A patient (male or female) walks into our consulting room with a slightly forward attitude, spare habit of body, and very likely a halting walk from something wrong in the lower limbs. We note the ovoid face, the melasmic tinge around the eyes, or the shining yellow pigment on the forehead; we feel the cold wet hands, and glance at the nodular fingers; and our diagnosis is made—made, I affirm, beyond the possibility of doubt or failure; and if there be besides the hard quick pulse, one more element is added to the diagnosis already assured. Our ancient friend, the practical man, is now certain to be pleased; he can begin his treatment without hesitation and without fear; he knows, or ought to know, that time lost in applying his remedies is time which cannot be recalled.

I have refrained from touching many minor points, and from travelling along some interesting by-paths, because I desire the main outlines of my theme to be vivid and unblurred. Fallacies of observation and induction beset all human inquiries; and with every caution and reserve I offer for the judgment of this veteran Society some material for the elucidation of an obscure and almost malign disease.

ON SOME POINTS CONNECTED WITH CONCOMITANT CONVERGENT SQUINT.¹

By W. ADAMS FROST, F.R.C.S.,

Assistant-Surgeon to the Royal Westminster Ophthalmic Hospital;
Assistant Ophthalmic Surgeon to St. George's Hospital.

In man, and probably also in other animals whose eyes command a common visual field, the two eyes are intimately associated in the act of vision; not merely in the sense of doubling the intensity of a visual impression, but, the two retinæ transmitting to the sensorium impressions which differ from each other much as the two sides of a stereoscopic slide, the mind is enabled to fuse these into a single mental picture, from which impressions of solidity, depth, and distance are obtained with much greater certainty than could be obtained from a single retinal image. Perhaps the simplest way of demonstrating the advantage of stereoscopic, or, as I shall hereafter call it, "binocular" vision, is by means of Hering's test. A horizontal string is held at the level of the eyes at a distance of about two feet, and small bodies such as beans are dropped from a height of a few inches either on the proximal or distal side of the string, and close to it. With both eyes open there is not the slightest difficulty in seeing on which side of the string the object falls, but with one eye alone it will be found impossible, even with the closest attention, to be certain.

Binocular vision cannot, however, be obtained of all points in the visual field simultaneously, but only of such as fall upon certain parts of the two retinæ, which are for that reason said to be "corresponding areas." The yellow spots correspond, and if the retinæ be divided into quarters by lines meeting at this point, the right upper, left upper, right lower and left lower sections in

one eye would correspond with those of the same name in the other. The result of this is that when the visual axes are directed to any point (so that its image falls on the fovea in each eye), images of other objects in the same vertical transverse plane as the object fall on corresponding areas, while those which are at a greater or less distance have their images on non-corresponding areas. In the latter case double vision, or "diplopia" results if the mind takes cognisance of both images. The impressions, however, produced by retinal images at a distance from the fovea do not force themselves on the consciousness; and although, by a little practice, most people can convince themselves that this diplopia really exists, we are as a rule as unconscious of it as of the existence of the blind spot. If, on the contrary, the object to which the attention is directed has its image on the fovea in one eye and on some other part of the retina in the other, then diplopia is produced.

The whole function of the ocular muscles is to direct the visual axes to the object on which our attention is fixed. Partly, no doubt, from the anatomical fact that the centres which govern accommodation and convergence are in close connection, and partly from the physiological fact that the accommodation and convergence have from the first dawn of vision been associated in action in order to obtain binocular vision, both in the individual and through an innumerable succession of generations, it comes to pass that on accommodating for a given distance, the visual axes are converged to meet at that distance, instinctively and without conscious effort. But the power of adaptation to environment is a characteristic of organised beings, and if from any cause the conditions are so altered that binocular vision can only be maintained by an alteration in the normal relation between convergence and accommodation, that alteration may be made unconsciously if it does not exceed certain limits. This may be illustrated by placing prisms or lenses before the eyes.

Within certain limits, then, the desire for binocular vision will lead to binocular fixation. It remains for us to consider under what conditions continuous binocular fixation either demands a conscious effort or becomes impossible.

Now, in the first place, having regard to the variations in the conformation of the face, in the shape and size of the orbits, and the degree of prominence of the eyeballs, it is not to be expected that the range of the ocular movements should be the same in all cases. The admirable investigations of Motais have shown that the limitation of movement of the eyes depends on the parts of Tenon's capsule which form the check ligaments, and that these are called into play not merely when the limit of movement is reached, but that they exert a continuous and increasing control during the whole range of movement. It would seem probable, therefore, that the variations in the power of moving the globes depend less upon actual differences in the power of the muscles than upon the anatomical connection of the ligamentous processes, although, of course, when there is feeble muscular tone, an impediment would be noticed which might otherwise be unimportant.

For much of our knowledge of the variations that exist in the relative amount of convergence and divergence we are indebted to Landolt. Adopting the metrical notation, and taking parallelism as zero, we may say that the normal condition is a power of divergence (negative convergence) which would cause the visual axes to meet at a point one metre behind the base-line connecting the centres of rotation (that is, one metrical angle — 1 M a); and of convergence (positive) to a point distant one-ninth of a metre (+ 9 M a), the range of convergence being thus ten metrical angles. Now it is evident that this may vary in many ways. The range may remain unaltered, but it may be displaced towards the positive or negative side, or it may be shortened at the expense of either positive or negative end, or of both. A consideration of these varieties would be beyond our present purpose, and I must refer those of you who are interested in it to Professor Landolt's paper, of which an excellent translation by our late clinical assistant, Dr. Law, appeared in the *Ophthalmological Review*, July and August, 1886.

It is evident that any great departure from the normal condition will render binocular fixation difficult or impossible, according to its degree. In the former, the use of the eyes upon near objects for long periods will cause the symptoms classed under the term "asthenopia" with which you are familiar in hypermetropia, a symptom which has been well defined as "a strike for less work or better tools." In the higher degrees of abnormality binocular fixation may be impossible, and then we get a squint

¹ An abstract of two lectures delivered February 14th and 21st at the Royal Westminster Ophthalmic Hospital.

developed. When binocular fixation is only performed under protest, as it were, and in order to avoid diplopia, a squint may be said to be latent, and it will become manifest if anything happens to prevent binocular vision, or to impair its value. A latent squint may therefore artificially be rendered manifest by covering one eye, or by causing vertical displacement of one retinal image with a prism, for, since the eyes can only be moved together in the vertical meridian, fusion of the two images then becomes impossible. The best test object for this latter examination is the well-known one of Graefe, a vertical line with a dot in the centre. When binocular fixation occurs for the distance of the object the lines are fused; in other conditions two complete lines are seen, too great convergence being shown by divergence of the images, too little by their crossing.

A latent squint may also be rendered manifest by impairment of the vision of one eye. So far we have considered the interference with the normal relation between convergence and accommodation from the side of the former function, but it may of course depend on defects in the latter. Myopia acts thus by requiring less accommodation, and hypermetropia by requiring more; the tendency in both cases is to equalise the use of the two functions, and therefore of myopia to cause either spasm of the accommodation or defective convergence, and of hypermetropia to cause either defective accommodation or excessive convergence.

Lack of time prevents me from saying much as to the treatment of these conditions of disturbed relation between convergence and accommodation without actual squint. If the amount of positive convergence is defective, the symptoms can be relieved by the following methods: 1, the use of prisms with their bases inwards; 2, tenotomy of one or both external recti; 3, advancement of one or both internal recti; 4, a combination of several of these. Prisms alleviate the symptoms without removing the condition to which they are due; the weight of the stronger prisms and the chromatic aberration that they cause limit their usefulness. The choice between 2 and 3 will depend upon the relative amount of negative and positive convergence; 2 diminishes the former, while 3 increases the latter.

We will now pass from latent to actual squint, still confining our attention to cases in which there is no paralysis, and which are called "concomitant" because the eyes, although always too convergent or divergent, accompany each other in all their movements in the normal manner.

Concomitant convergent squint is most commonly caused by hypermetropia. The mode of causation is probably well known to all of you. The hypermetrope has to use an excessive amount of accommodation in order to see; he has, therefore, three courses open to him: 1. He may dissociate his convergence and accommodation, and use the necessary accommodation with only the normal amount of convergence; he would, *a priori*, seem more likely to do this if his hypermetropia were of low degree. 2. He may not use the necessary accommodation, and be content to have defective near vision; it was formerly assumed that this actually occurred in the higher degrees of hypermetropia, although this is theoretically possible, but I think that it is much more probable that a hypermetrope who may be unable to neutralise his defect always endeavours to do so. 3. He may facilitate the use of accommodation by employing his convergence at the same time. We are now concerned only with this last.

To Donders we owe the discovery of the connection between hypermetropia and strabismus, and his theory has been universally accepted till recently. Lately, however, two objections which have been urged against it seem to have shaken the faith of some. One is that, according to it all hypermetropes should squint; the second is the alleged immunity of the higher degree of hypermetropia from squint. The first I believe to be unreasonable and the second untrue.

Why do not all hypermetropes squint? Is there any opposing influence? Surely the desire for binocular vision in this case, as in those we have already considered, will tend to prevent the development of a squint. If binocular vision exists, the immediate effect of loss of binocular fixation will be diplopia, and the choice has to be made between the inconvenience of diplopia and that of dissociating accommodation and convergence. It is true that most children who squint have no diplopia, but then we seldom see them until the habit of squinting is well established, and children learn very early to disregard or "suppress" one of the retinal images. I do not think it surprising

that children do not oftener mention the diplopia; they are generally very young when they commence to squint, and are not accustomed to mention subjective sensations unless they are painful; but I have met with many instances in which it has been complained of, and in some of these I have had an opportunity later of finding that it had entirely disappeared. Given the tendency to squint, it is evident that anything that lowers the value of binocular vision will remove an obstacle to that tendency. Squint will, therefore, be the more likely to occur if the vision of one eye is defective; the same effect will be produced if one eye has a higher degree of hypermetropia than the other, for since the accommodation can only be used equally in the two eyes, the more ametropic must have blurred images when the hypermetropia of its fellow is neutralised. Now, as a matter of fact, we do find in the majority of cases of squint that the squinting eye has either a higher degree of ametropia, an inferior visual acuity, or both. It used to be supposed that the impairment of the vision was the result of the squint, and was due to the constant suppression of impressions received from it. I cannot now examine the evidence bearing on this; my own belief is that there is, in such cases, an original inferiority of one eye, but that this is largely increased by the habit of voluntary suppression. Eyes which present this amblyopia in a high degree, often possess a very fair amount of indirect vision, but the vision of the central portion of the retina does not show that marked superiority over the peripheral, which is the normal condition, and is often obviously inferior to it. There is a class of cases in which the two eyes are equal, and in which it seems to be a matter of utter indifference to the patient which eye he squints with. In these cases of "alternating" squint also diplopia is absent when the squint is fully developed. It is not unlikely that in such cases there is an original preponderance of the internal recti.

It remains for us to consider the alleged immunity, comparative or absolute, of the higher grades of hypermetropia from squint. The explanation usually given that those affected with extreme hypermetropia, being unable to neutralise it, give up the attempt, always seemed to be *a priori* improbable, and has no foundation in fact. It is strange that this statement has been generally accepted without question of its accuracy. When some learned philosophers disputed as to the reason why a dead cod-fish weighed more than a live one, it occurred to someone to test the fact, with the well-known result. Low hypermetropia is exceedingly common, while high degrees (over 6D) are comparatively rare; therefore among cases of squint we cannot expect to find a preponderance of high over low hypermetropia, but I believe that it will be found that the proportion of the former is much greater than among the non-squinters. Last year I went over my notes, in order to ascertain whether this was so or not. I found a record of 123 cases in which the refraction had been tested. The following table shows the relative proportion of the different degrees of hypermetropia (when the eyes differed the refraction of the working eye is given).

	Under 1 D	8.13 per cent.
From 1 to 2 D	16.03	" "
" 2 " 3 D	18.5	" "
" 3 " 4 D	17.5	" "
" 4 " 5 D	15.3	" "
" 5 " 6 D	12.7	" "
Over 6 D	11.9	" "

I suppose no one will contend that 11.9 per cent. is the proportion in which H. of over 6D occurs in comparison with other degrees, but this is not all; squint is a prominent symptom, and a large proportion of the cases are brought for advice, H. without squint in the child often produces few symptoms, and therefore only a minority of the cases are brought. These facts are quite consistent with the view that the liability to squint is proportionate to the amount of hypermetropia.

If defective vision of one eye, or preponderance of the internal recti, is present in most cases, you may ask why should not they alone be held responsible for the squint? For the simple reason that the very large majority of cases of squint in the early stage can be cured by correcting the hypermetropia with convex glasses. At first, and sometimes for months, the squint will return the moment the glasses are removed, but eventually a permanent cure will result in most instances. The best test of the curability of a squint with glasses is the effect of atropine; if there is no squint when the accommodation is rendered impossible, there will usually be none when it is rendered unnecessary. It is not always so, for habits that have been acquired may persist after

the original cause has been removed. I know that some authorities are sceptical as to the cure of squint with glasses, but positive evidence must be allowed to outweigh negative, and those of you who have followed the practice of this hospital can have no doubt on the subject. I would go still further, and say that in many cases the glasses may subsequently be laid aside, if binocular vision exists, without the squint relapsing.

Of the operative treatment of squint I will not here speak, but I wish to direct your attention to a method of producing or restoring binocular vision when binocular fixation has been obtained. This in this country has been much neglected; we are too apt to think that, when we have cured the squint, we have done our work, while in reality we have but scamped it. It is true that a deformity has been remedied, but the correction of the squint in the majority of cases does nothing towards restoring binocular vision. Of this you can easily convince yourself by means of Snellen's coloured letters.² You will find that the patient can, if each eye has good vision, see after a little practice either set of letters at will, but seldom both at once. He is not, therefore, really cured, for he does not see as in the normal condition. We owe much to Landolt in the matter of the treatment of affections of the muscles, but in my opinion his greatest achievement is that he has taught us how binocular vision may be restored in a large number of cases of squint. For this purpose a modification of the stereoscope is most useful. In the ordinary instrument the picture before each eye is, by means of a prism with the base outwards, projected to the same point on the middle line and a little further from the observer than the actual picture, so that a slight amount of convergence is used. For our purpose it is necessary that we should be able to regulate the amount of convergence required in order that such pictures may lie on the foveæ centrales. Accordingly the prisms must be capable of rotation, by which means their effect on convergence can be gradually altered. There must also be an arrangement by which either the distance of the object or the strength of the lenses can be altered, in order that the amount of accommodation can be regulated. The objects before the two eyes should be dissimilar, but capable of being fused into a single picture. A bird on one side and a cage on the other make a very serviceable slide.

If the vision of one eye is defective, it must be improved as much as possible by practice, and a more conspicuous object chosen for that eye. In most cases, it is at first necessary to attract the child's attention to the picture before the eye that squinted by covering the other. Even when both images are seen simultaneously, it is seldom that they are fused, usually at first there is homonymous displacement, which must be overcome by rotating the prisms, and, if necessary, by adding others.

When once the patient has succeeded in fusing the images, and understands what is required of him, he should be encouraged to practise with other slides, and to amuse himself daily with it. From time to time Hering's test should be used to see whether any progress has been made towards habitual binocular vision. This mode of treatment has been little practised hitherto owing to the difficulty of procuring a stereoscope which would be within the means of hospital patients. Messrs. Pickard and Curry have, however, now manufactured an instrument after Dr. Landolt's model which will, I believe, obviate this difficulty; and it is not unlikely that by this means many more squints will be cured without tenotomy than has hitherto been possible.

² Transparent letters of complementary colours, arranged alternately, and viewed through similar glasses—one before each eye. Since each glass quenches the light which has passed through the letter of its complementary colour, each eye can only see the alternate letters.

SATISFACTORY information as to the decrease of small-pox at Sheffield continues to be received. The malady is said to be decreasing both in the number of cases and in the malignancy of the disease.

It is suggested by President Cleveland that the United States Government should prohibit the importation of swine or porcine products from France and Germany, owing to the information received that disease exists among swine in those countries.

STEPS have been taken by the friends of the late Dr. Adey to connect his name inseparably with the Hastings, St. Leonard's, and East Sussex Hospital. A meeting with this object was held at the hospital on Thursday, March 29th, to consider the question of raising some permanent memorial to this physician, whose name is deservedly held in high esteem by the inhabitants of the district.

THE VALUE OF ELECTRIC ILLUMINATION OF THE URINARY BLADDER (THE NITZE METHOD) IN THE DIAGNOSIS OF OBSCURE VESICAL DISEASE.

By E. HURRY FENWICK, F.R.C.S.,

Assistant Surgeon to the London Hospital; Out-patient Surgeon to St. Peter's Hospital for Urinary Diseases.

THE new incandescent-lamp cystoscope has been before the profession for more than a year,² and sufficient knowledge has been acquired of the capabilities of this instrument, and of its predecessor, the Nitze-Leiter cystoscope of 1879, to warrant the discussion of certain important questions bearing upon the subject of vesical endoscopy. There can be no dispute as to the immense advantage which would be gained by a visual examination of the interior of the bladder in certain cases of obscure uro-vesical disease—cases in which neither the sound nor the microscope nor a careful estimation of the symptoms afford any clue to the nature and site of the disorder. Nor can there be, as far as the mere examination of the bladder is concerned, any difference of opinion, as to the superiority of a successful cystoscopy over a digital exploration by the *boutonnaire* operation. The questions which merit our consideration relate to the means at our command of obtaining a successful inspection of the interior of the bladder without a cutting operation. They may be thus formulated: Is the electric cystoscope of practical value? What rank will the instrument acquire as a diagnostic agent?

The former question can be readily answered by a reference to the work already done. Obscure vesical symptoms, in which an efficient cystoscope would prove of practical utility, may be elicited by foreign bodies (other than stones), latent and accumulated calculi, various forms of ulceration and vesical growth which cannot be diagnosed bimanually or otherwise. It is in the inferior zone of the bladder that these conditions are mostly to be met with. Given an incandescent-lamp cystoscope in good working order and well lodged in the bladder, a clear medium, a practised eye and hand, and it can be affirmed beyond dispute that the entire inferior zone can be thoroughly searched without a cutting operation by means of electric light. The following briefly described cases from the literature and my own notebook will serve as illustrations.

Foreign Bodies.—No case could be more conclusive as to the practical value of the cystoscope than the following, which came under the care of Dr. Nitze, the able introducer of this brilliant innovation. F. S., aged 35, had left-sided ovariectomy performed by Martin; the pedicle being secured by several stout silk ligatures. Two years after the operation the patient was suddenly seized with acute cystitis. A calculus was discovered and partially crushed, a silk ligature being subsequently passed along with calculous debris. The patient then came under Dr. Nitze, who performed litholapaxy. In attempting to remove the lithotrite, it was felt to be firmly held by something in the bladder. It was withdrawn with an effort, and a silk ligature was found entangled in the jaws of the instrument. All the stone was removed. The electric cystoscope was introduced, and the ends of a thick glistening white ligature were seen projecting from a deeply congested pit in the mucous membrane of the left wall of

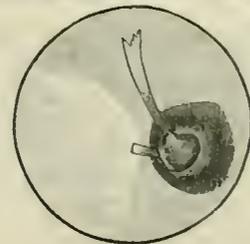

Fig. 1.

the bladder (Fig. 1). The lithotrite was introduced and the liga-

ture cleverly caught and dragged out. This and the other ligatures had evidently ulcerated their way through, producing the cystitis and consequent calculous formation.³ Nicoladoni⁴ was able to demonstrate a needle sticking in the right half of the anterior wall of the bladder to a large class of students.

Calculus.—Dittel, finding a difficulty in removing a stone by the lateral incision, introduced the cystoscope, and found that the calculus was projecting from the mouth of a diverticulum. Although the cystoscope will never supersede the sound, yet stones are very easily found by means of the light, and that without much manipulation. They form beautiful objects. I tried the instrument in two cases lately before using the sound, and in both the stone was immediately recognised.

Case 1.—H. H., sent by Mr. Molson, of Plaistow. The patient had had frequency and straining for four years; no hæmaturia; no characteristic pain; residual urine eight ounces. The cystoscope revealed a large irregular brownish coloured calculus, with a flocculent surface lying on the right side of the base of the bladder. Subsequently verified by the lithotrite.

Case 2.—M. C., aged 66, sent by Mr. Hichens with the diagnosis of calculus. The patient had suffered characteristic pain and profuse hæmaturia; a large intravesical collarette of prostatic growth was present. Cystoscope showed the calculus as a brilliant white object, lying in a clot of blood behind the prostatic outgrowths. It was removed suprapubically.

Vesical Growths.—**Case 1.**—N. C., male, aged 70, under the care of Mr. Eve. Patient had been a heavy drinker. Sixteen months before death a profuse hæmaturia appeared, which never subsequently left him, though it was kept under control by hæmostatics. He suffered no pain, nor was he troubled with frequency until the disease was considerably advanced. No growth or stone could be discovered. Microscopical examination of the urine revealed nothing. I was asked to examine him with the cystoscope. The instrument was introduced and turned on to its side, and a sessile lobulated tumour was immediately discovered on the right side of the trigone. The lobes were large and deeply injected. Fig. 2 represents the sketch taken. It was decided to leave it

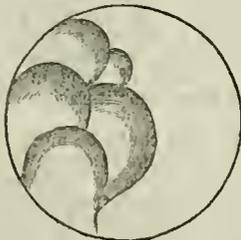

Fig. 2.

alone. Perineal cystotomy was performed a month after drainage, and the growth was then verified by digital exploration. On *post-mortem* examination secondary deposits were found in the liver.

Case 2.—M. B., female, aged 55, under the care of Mr. Heycock. Patient had suffered from intermittent hæmaturia for three years. Usually pain on passing clots. On introducing the cystoscope I detected a walnut-sized tumour on the left side of the base. It was a remarkable object (Fig. 3). Its surface was slightly nodular,

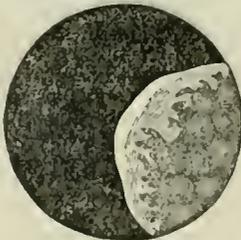

Fig. 3. (The mucous film has been omitted.)

but the cracks and crannies were filled with a glistening white layer of phosphatic deposit. Floating away from, but partially

⁴ Nicoladoni, "Stecknadel in der männlichen Harnblase." *Wiener Med. Wochenschrift*, 1856. Nos. 7, 8.

attached to the summit was a cloak of clear mucus, which wavered and trembled at every current set up by the movements of the instrument. The urethra was dilated, and the position and size of the growth verified by digital examination; an *éraseur* loop was slipped over it, and its thick stout pedicle slowly cut through. It proved to be a fibro-papilloma. The patient made an excellent recovery.

Seventeen other vesical tumours are to be found in the literature, from which I have selected two (figs. 4 and 5) from Dr. Nitze's

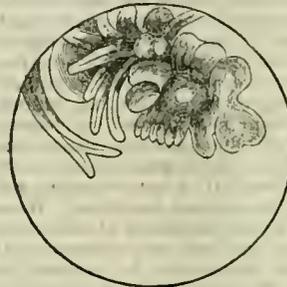

Fig. 4.

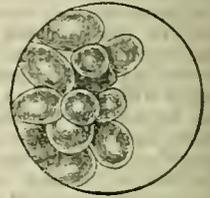

Fig. 5.

work.⁵ Fig. 4 represents a pedunculated villous tumour which Dr. Nitze found hanging over the urethral orifice of the bladder of a man aged 50, a patient of Professor Küster's; it was removed suprapubically. Fig. 5 represents a carcinomatous infiltration very similar to Case 2. It was found on the right side of the urethral orifice by Dr. Nitze in a patient of Dr. Israel's.

What rank will the electric cystoscope assume as a diagnostic agent? It is as yet difficult to estimate its future position, for the instrument has become very popular, and improvements are already on foot. It will never bear comparison in general utility with its kindred, the ophthalmoscope, laryngoscope, or otoscope; for even the slight difficulty attendant on its management and the necessity for a battery will debar it from the wide popularity of those easily-managed instruments for the eye, throat, and ear. It will doubtless become an important atom in the molecule of vesical diagnosis, and in some very rare instances that molecule itself. Without, therefore, weakening the analytical judgment of the symptoms of the case, it will probably be turned to when other forms of investigation have failed. Of its future importance in the differential diagnosis of the site of symptomless hæmaturia and pyuria, I have but little doubt. The ureters can generally be discovered and examined as to the nature of their efflux. I have seen in one case of renal hæmaturia a jet of bloody urine issue from the right ureteral orifice into the artificially cleared medium in the bladder, just as a miniature cuttlefish would squirt out its coloured fluid into the water around. The source of the hæmorrhage was thus at once indicated. In the estimation of the advisability of suprapubic removal of prostatic intravesical outgrowth (MacGill's operation) it may prove of use. I have latterly made a point of examining the prostate by its means. Increased visual knowledge of the living bladder may cause the cystoscope to assume an important prognostic position (as may be judged from Figs. 2 and 5), indicating those growths which are removable, and those which it is the wisest policy to leave undisturbed. Lastly, it will be the arbitrator between the *boutonnaire* and the suprapubic operation for vesical growths; for those which are single, lightly pedicled, and situated close to the urethral orifice may well be treated by the perineal incision, whilst those which are shown to be multiple, sessile, or springing from dimples in the mucous membrane certainly require the wider access afforded by a *sectio alta*.

THE DOSE OF DIGITALIN AND ACONITIN.—The French Pharmaceutical Society have decided not to dispense granules containing more than one-tenth of a milligramme of digitalin or aconitin. Hitherto it has been usual to prepare them with a quarter of a milligramme of one or other of these alkaloids, but owing to the greater activity of the modern crystallised alkaloids, several serious accidents have happened from doses of a quarter of a milligramme, fatal effects in one case having followed the ingestion of this quantity of aconitin.

ON THE ORIGIN AND STRUCTURE OF CERTAIN LOOSE BODIES IN THE KNEE-JOINT.

By HOWARD MARSH, F.R.C.S.,

Assistant Surgeon to St. Bartholomew's Hospital; Surgeon to the Hospital for Sick Children, Great Ormond Street,

In a letter from Professor Humphry in the JOURNAL of March 17th (at page 613), on "Loose Bodies in the Knee-Joint," the following sentences occur: "I am correctly stated to have expressed my scepticism in regard to the possibility of the formation of these loose bodies by the detachment of portions of the articular cartilages." "It must be a very extraordinary and violent accident that would break off into the joint a piece of the articular cartilage, with or without bone, of the femur or the tibia. One can scarcely imagine the occurrence of such an accident, or conceive how it could take place." "We have a ready and sufficient explanation of the formation of loose bodies in the growth.....of tufts or processes of synovial membrane, which.....naturally containing cartilage cells, may become the seat of cartilage-growth and ossification, and by rupture of the pedicle become loose in the joint.....We need not therefore search for other and highly improbable modes of origin." "I can scarcely suppose that anyone really believes that a portion of bone detached by the process of necrosis can be converted into one of these bodies, though such a suggestion is actually made in a recent and important work on surgery."

But for the adjective "important," I should conclude that the work alluded to is one for which I am responsible (*Diseases of the Joints*, Cassell and Co. 1886), for I have stated, at page 181, (1) that "pieces of cartilage, with or without portions of the underlying bone may, after injury, as pointed out by Teale, Sir James Paget, and others, exfoliate and drop loose into the joint, without the symptoms of inflammation usually observed in cases that end in necrosis; or (2) a piece of cartilage, or of cartilage and some of the adjacent bone may be chipped off and fall into the joint." Thus—though perhaps Professor Humphry refers to some other work—I have certainly written in a manual intended for students, as well as surgeons in practice, that which Professor Humphry "can scarcely suppose that anyone really believes." I shall therefore be glad, if space can be afforded me, to say what grounds there are for stating that which Professor Humphry regards as so extremely improbable.

I. As to the formation of a loose body by the breaking off into the knee-joint of a piece of the articular cartilage, with or without bone, of the femur or tibia.

In the museum of St. Thomas's Hospital, Specimen D. 110^t is thus described in the Catalogue (vol. 1, page 140): "Loose body from the knee-joint, removed by Mr. Simon, in 1864. It is a fragment of articular cartilage and bone, apparently clipped off from one of the condyles of the femur." The specimen was shown by Mr. Simon, at the Pathological Society on May 17th, 1864, and is described by him in the following terms (*Pathological Society's Transactions*, vol. xv, page 206).

"Broken-off bit of Condyle loose in the Knee-joint.—A young man who, in falling, had wrenched his knee, came into St. Thomas's Hospital to be treated for some inconsiderable synovitis which followed the accident, and, while under treatment, was found to have a loose body in the joint. As soon as all acute symptoms had subsided (about three weeks after the injury), Mr. Simon operated for the removal of this loose body, and, having removed it, found that it was a broken-off bit of the articular end of the femur, covered on one side with its natural cartilage, and being about the size of a bean. The patient recovered without interruption."

I am indebted to Mr. Shattock, whose opinion on such a question few, I think, will dispute, for the following report:

"The cartilage in Mr. Simon's specimen has every character of healthy articular cartilage, in arrangement of cell-groups and homogeneity of the matrix. There can be no doubt whatever that the loose body is a portion detached from an articular surface."

Fig. 1 represents this body enlarged, for the sake of clearness, to about five times its real size. The bone and the cartilage can be plainly seen. Considering the very definite history which we have direct from Mr. Simon himself, and considering Mr. Shattock's report, I think there can be no reasonable doubt that, in

this instance, a piece of the articular cartilage, with some adjacent bone, was broken off into the joint.

A noteworthy point in this case, in reference to Professor Humphry's opinion, that it must be a very extraordinary and violent accident that could break off a piece of articular cartilage, with or without bone (see above), is that, according to so cautious an observer as Mr. Simon, this injury was produced by a mere wrench of the knee occurring during a fall, and that it was followed only by "some inconsiderable synovitis."

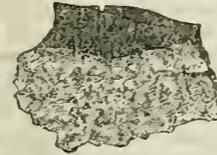

Fig. 1.

2. As to the question whether "a portion of bone, detached by the process of necrosis, can be converted into one of these bodies."

In the museum of St. Bartholomew's Hospital (Cat., vol. i, No. 721) are "two portions of cartilage removed from the knee-joint of a lad, aged 18. They are almost exactly alike in form and size, each resembling such a piece of cartilage as might be obtained by removing that which covers the posterior surface of one of the condyles of a femur, and each, as such a piece would be, is smooth and polished on its convex and rough on its concave sur-

Fig 2

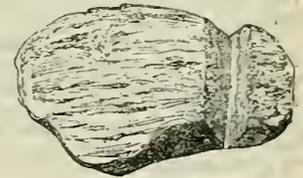

Fig. 3.

face (Figs. 2 and 3). There was an interval of about a year between the operations by which these bodies were removed." In a report on this specimen in the *St. Bartholomew's Hospital Reports*, vol. iv, 1868, p. 257, I said, "On close examination both these cartilages are found to have a thin layer of bone on their concave surface; this presents, under the microscope, the characters of true bone, and is covered with a scanty layer of irregularly disposed fibrous tissue. The arrangement of the cells in the cartilage of both specimens is precisely similar to that of articular cartilage."

The next specimen (722) in the same museum I have described in the Reports (vol. iv, p. 256) as follows:—"It consists of a layer of cartilage and a layer of bone intimately connected with each other. The cartilage is smooth and glistening on its free surface, like ordinary articular cartilage (Fig. 4). In profile it is seen to have the thickness of the layer that encrusts the condyle of the femur in a healthy adult. Its margins are irregular, as if defined by fracture, and recede towards the bony layer. This latter is of less superficial extent than the cartilage, which exceeds it in every direction. At its central, which is also its thickest, part, it measures about two lines. Its surface is irregular and cancellous (Fig. 5). Examined with a microscope the carti-

Fig. 4.

Fig. 5.

lage is found precisely like articular cartilage. In its deeper layer the cells lie with their long axis at right angles to the subjacent bone, while, towards the free surface, they are small, numerous, elongated, and with their long axes parallel with the surface. The bone presents the characters of true osseous tissue."

Dr. Vincent Harris, Demonstrator of Physiology at St. Bartholomew's Hospital, in the course of last week kindly examined these specimens (Nos. 721, 722). He writes: "I have no hesitation in

saying that they consist of spongy bone covered with articular cartilage, and have also submitted them to another competent authority who confirms my opinion."

In the *St. Bartholomew's Hospital Reports* (vol. vi, 1870, p. 1) Sir James Paget, after referring to a paper on "Quiet Necrosis" which he had contributed to the *Clinical Society's Transactions* (vol. iii, p. 183), writes:—"Not long after this case, I had occasion to remove a loose cartilage from a knee-joint. The patient was 16, active, athletic, and, except at his knee, thoroughly healthy. At Harrow he had had many blows and strains of the knee, but he could not refer to any one of them as a cause of special injury. He had had for nearly a year all the usual signs of a loose body in the right knee."

After removal "this body looked exactly like a piece of the articular cartilage of one of the condyles of the femur. It was irregularly oval in outline, about an inch long, half-an-inch wide, and a line in thickness. On one surface it was convex and smooth, on the other concave and rough; and on this surface was a small prominent piece of bone, as if, with the cartilage, a piece of the articular surface of the femur had separated. The borders of the loose body were smoothly rounded off. In agreement with this general likeness to a piece of articular cartilage from a condyle was the microscopic structure of this loose body. In sections through its thickness was found a nearly homogeneous basis-substance, with cartilage-corpuscles, which, in arrangement and all their other characters, were exactly like those of articular cartilage. Thus no character was wanting to make it certain that this loose body was a piece of the cartilage, together with a very small portion of the bone, of one of the condyles of the femur."

"I believe that the explanation of the formation (of such bodies) is to be found in the case of quiet necrosis referred to at the beginning of this paper. These loose bodies are sequestra, exfoliated after necrosis of injured portions of cartilage, exfoliated without acute inflammation, just as the piece of bone was, or as a tooth after a blow may be slowly detached from its alveolus and cast out....."

"The view that certain loose bodies in joints are pieces of articular cartilage, exfoliated after necrosis due to violence, is supported by the fact that they are frequently consequent on injury in perfectly healthy young persons, and that, when a particular injury can be assigned, it is always at some weeks previous to the first finding of the loose body."

When these descriptions were given, neither Sir James Paget nor myself knew of Mr. Teale's paper (*Medico-Chirurgical Transactions*, vol. xxix, 1885, p. 31) in which he describes a "case of detached piece of articular cartilage existing as a loose substance in the knee-joint." In this case a brewer, aged 37, had, a year before, accidentally let a cask fall against his right knee. "Severe pain followed, and he was unable to work for three weeks, after which he followed his employment as usual for nearly twelve months until a few days ago, when he became suddenly lame, and was unable to bear his weight upon the leg. He then for the first time felt a flat substance moving about in his knee-joint." Mr. Teale removed the body, and, unfortunately, the patient, who had been a free drinker, died. "The substance, on being examined, was found to be flattened, circular in form, and irregular or ragged at its border. One of its surfaces had the appearance of cartilage, and was smooth, and slightly convex; the other was concave and rough, from a layer of bone." On opening the joint, "at the under surface of the inner condyle the articular cartilage showed a circular depression, about the eighth of an inch in depth, having a rough surface of bone at its base. On comparing this breach in the articular cartilage with the substance which had been removed, they were found to correspond accurately with each other, and, on placing the detached substance in the cavity in the condyle, the continuity of the articular surface was perfectly restored. It is, therefore, evident that the loose body was a portion of the articular cartilage along with a thin layer of bony substance." Mr. Teale believed that the injured piece of cartilage was cast off into the joint "by a slow process of exfoliation extending through a period of about twelve months" (Figs. 6 and 7).

Here, then, are six loose bodies from knee-joints. One, we are told by Mr. Simon, is "a broken-off bit of condyle," and Mr. Shattock has no doubt that it consists of a piece detached from an articular surface. A second was found by Mr. Teale to exactly fit into and make good a breach in the inner condyle of a femur. A third is minutely described by Sir James Paget, who states:

"Thus no character was wanting to make it certain, that this loose body was a piece of cartilage, with a very small portion of bone of one of the condyles of a femur." The remaining three are in the St. Bartholomew's Hospital Museum, and are pronounced by Dr. Vincent Harris to have the structure of true bone and articular cartilage. All but the first are, I believe, sequestra detached by the process which Sir James Paget has termed "quiet necrosis."

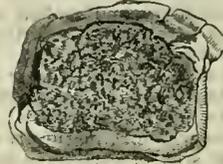

Fig. 6.

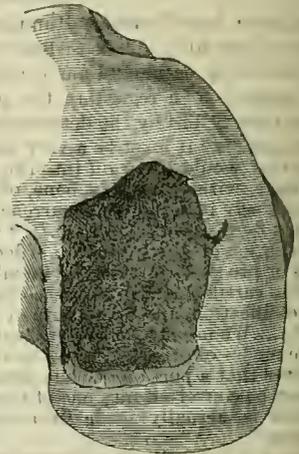

Fig. 7.

In this communication I have kept exclusively to the two chief points raised by Professor Humphry, though there are many others connected with the interesting subject referred to in his letter that would well bear discussion. I will only add that I entirely agree with his view, which no one, so far as I know, would question, that the great majority of "loose bodies" in joints are derived from the synovial membrane in the manner which he has described.

Since the above was written Sir James Paget has directed my attention to No. 647 in the College museum, which is thus described (Catalogue, p. 35): "A large piece of cartilage and bone, of the shape and about half the average size of a patella, removed from a knee-joint. It may be regarded as a portion of one of the condyles of the femur, which, probably after injury, was separated by a process similar to necrosis, but without acute inflammation. The articular cartilage is thinly extended over the edge of the bone. Presented by Sir Everard Home." Mr. F. S. Eve, Pathological Curator of the College, who has kindly examined the specimen microscopically, states: "I believe that in No. 647 the loose body was derived from the articular cartilage."

ON THE RELATION OF SCROFULOUS GLAND DISEASE TO OTHER FORMS OF TUBERCULOSIS: AN EXPERIMENTAL INQUIRY.¹

By FREDERIC S. EVE, F.R.C.S.,

Assistant-Surgeon to the London Hospital; Curator of the Pathological Museum, Royal College of Surgeons.

SOME two years ago, while writing a brief article on scrofula and tuberculosis for a student's Manual of Surgery,² my attention was drawn to the difference of opinion existing on the precise relation of scrofulous gland disease and affections described as tuberculous. I found that some clinical teachers with large experience in diseases of childhood still maintained that the two affections were practically distinct, while among pathologists some taught that scrofula and tuberculosis were synonyms for the same disease; others that in scrofula the tuberculous virus was so profoundly modified as to constitute a special variety. The latter view was strongly supported by some experiments of M. S. Arloing,³ which appeared to prove that inoculation with material from scrofulous

¹ Read before the Pathological Society of London, November, 1887.

³ *Comptes Rendus*, tome xcix, 1884, p. 651.

glands was innocuous to rabbits, while it produced general tuberculosis in guinea-pigs.

The significance of this assertion, if well established, is clear, when it is stated that material from true tuberculous diseases produces visceral tuberculosis in both animals. The results of these experiments seemed of so much importance that I was desirous of testing the matter for myself, more especially as Arloing, in his first two groups of experiments, had only used glands taken from one patient. Further, I had observed such remarkable differences in the naked-eye appearances of strumous glands that it would have been no matter for surprise to have found that two or more diseases had been grouped under a single heading. This could only be tested by making experiments with a series of cases. Structures microscopically characteristic of tubercle and bacilli had been found in some glands; but in many others the histological appearances were indistinguishable from those of simple chronic inflammation, and might even simulate those produced by syphilis in other organs. For example, J. Arnold, who examined ninety cases, found giant cells very rare.

M. Arloing's experiments were, shortly, as follows: A juice was prepared from a single scrofulous gland, caseous in the centre, which was taken from a boy aged 14. This was injected beneath the skin of ten rabbits and ten guinea-pigs. Visceral tuberculosis developed in all the guinea-pigs, but the rabbits remained healthy, except that two showed yellow and caseous granulations at the seat of inoculation.

A second series of experiments were made with a gland subsequently removed from the same boy. The juice was injected into the peritoneal cavity of six rabbits and six guinea-pigs. As before, the guinea-pigs all presented tubercular lesions; the rabbits, on being killed, were found to be perfectly healthy. In two instances, pus from strumous abscesses gave similar results.

Some glands excised from the neck of a young woman produced tuberculosis both in rabbits and in guinea-pigs, but the patient died three weeks after the operation from miliary tuberculosis. Arloing appears to consider this case as outside the general category of strumous glands.

From these experiments he inferred that either scrofula and tuberculosis were nearly allied affections, but caused by different agents, or they were derived from a single virus, of which the activity was modified in the scrofulous form.

In my experiments I used small fragments of the glands prepared with sterilised instruments, and the possibility of infection of the animals with true tuberculosis was negated by the precautions taken. My experiments on rabbits are briefly as follows:—

EXPERIMENT I.—Rabbit inoculated beneath the skin of both ears. Cold abscesses formed at the seat of each inoculation, and remained stationary; but the animal continued well until the expiration of nine months, when, judging it to have escaped, it was re-inoculated in the peritoneal cavity.

EXPERIMENT II.—Rabbit inoculated in anterior chamber of eye with portions of a non-suppurating gland. A large mass of caseous material formed and ultimately projected from the eye (drawing shown). Animal killed three months after inoculation. Tuberculosis of lungs and liver. Brain healthy.

EXPERIMENT III.—Rabbit inoculated in anterior chamber with portions of caseous material and adjoining gland tissue from a strumous gland. No growth formed in the eye. Animal killed in two months and a half. No disease anywhere. Sections were made of these glands, and, after careful staining, no bacilli could be demonstrated. The gland substance had become in great measure transformed into fibrous tissue.

EXPERIMENT IV.—Rabbit, previously inoculated beneath the skin (see Experiment 1), again inoculated in abdomen. Killed after lapse of eleven weeks. Three large caseous glands were found beneath and below liver, and in the latter were yellow threads and stripes, found, on microscopic examination, to be tuberculous. Lungs and other organs healthy. Pus containing many bacilli still existed in the abscesses of the ears, but the visceral tuberculosis may probably be ascribed to the last inoculation.

EXPERIMENT V.—Rabbit inoculated in abdomen. Killed after lapse of four months. Tuberculosis of lungs; other viscera healthy. An enlarged lumbar gland.

Glands from four other patients were also used for inoculation of guinea-pigs, and each time with positive results. Altogether, glands from ten different cases, taken at hazard, were used; but in one (not cited above), in which a rabbit was inoculated in the eye, the animal died in twelve days, and only minute yellow

nodules were found in the liver. The nature of these nodules could not be absolutely determined. Eight of the remaining nine cases were all proved to be tubercular.

As regards the results of the experiments on rabbits with glands from five different subjects, the material from three cases produced visceral tuberculosis; from one case, cold abscesses; and in one instance (Experiment III), in which a rabbit was inoculated in the anterior chamber, it escaped infection altogether; no bacilli could be discovered in this gland. The animal in which cold abscesses occurred was inoculated beneath the skin.

I need hardly call attention to the marked manner in which these results differ from those of Arloing above described. While my experiments were in progress Arloing was pushing his somewhat further in the direction indicated by his first experiments.⁴ Believing that scrofulous glands never produced visceral lesions in rabbits, and that in struma the activity of the virus was attenuated, he sought to find if this could be increased by passing it twice through guinea-pigs. His experiments showed that the passage of glandular scrofula through the guinea-pig in two successive generations did not augment its virulence as regards rabbits. He also found that local tuberculosis of joints and bones only produced cold abscesses in rabbits, but, on passing the virus through a guinea-pig; tuberculosis of the lungs developed in rabbits. "This fact merits," he says, "to be taken into serious consideration at a time when there is a tendency to confound tubercle and scrofula as a single affection. It justifies once more the difference that we have established between the two morbid states. If it is not yet proved that they are the work of a distinct virus, it will be granted that true gland scrofula is yet more removed from the primitive virulence than local tuberculosis. Perhaps it is sufficiently removed to constitute a *fixed variety* analogous to those micro-organisms which, after having lived for many generations in a certain species of animal, have become incapable in consequence (in spite of all known means) of killing the species which had furnished them and among which they made numerous victims."

These later observations I have also repeated, with equally dissimilar results.

EXPERIMENT I.—Two rabbits were inoculated respectively in the abdomen and anterior chamber of the eye with organs from a guinea-pig rendered tuberculous by strumous glands. The rabbit inoculated in the abdomen was killed two months after, and showed tubercles in the peritoneum covering the cæcum (opposite the abdominal wound), caseous lumbar glands, and tuberculosis of the lungs. The other rabbit died after the lapse of five weeks. The portion of tissue placed in the anterior chamber had increased, but there was no visceral tuberculosis.

EXPERIMENT II.—A rabbit was inoculated with portions of the lung of a guinea-pig rendered tuberculous with strumous glands. It died without apparent cause in eleven days; but a caseous abscess and some tubercular material had already formed in the groin, and there were numerous yellowish-white points in the liver.

EXPERIMENT III.—Two rabbits were inoculated in the abdomen with tuberculosis of a guinea-pig excited by strumous glands. One died in seven weeks and the other was killed. Both showed general tubercular peritonitis and general visceral tuberculosis.

In the first and third of these experiments, the virus was certainly intensified by passing it through the guinea-pig, for these are the most acute cases of tuberculosis I have been able to induce by strumous gland disease in rabbits, the tubercles being disseminated over the peritoneum (specimen shown).

Here are the intestines of a rabbit inoculated in the peritoneal cavity with miliary tuberculosis which had been passed through a guinea-pig, and it may be seen that there is very little difference in the result in each case (specimen shown).

It is difficult to reconcile the discrepancies between M. Arloing's results and my own. As in his first series he used glands from only one case, the virus may have been of an exceptionally mild type; or the failure of rabbits to take tuberculosis when the material was injected in solution into the peritoneum may, perhaps, be explained by the virus being absorbed immediately and destroyed by leucocytes. When introduced by small fragments of glands, as in my experiments, a certain amount of inflammation may be excited, and a more favourable nidus obtained for the growth of organisms. This was evident in cases of tubercular peritonitis, for in these a mass of gelatinous granulations on the

⁴ See *Comptes Rendus*, September 27th, 1886, p. 559.

inner surface of the wound in the abdominal wall formed the focus of infection, as shown by the distribution of the tubercles on the peritoneum.

The similarity in point of histological appearances between scrofulous and tuberculous lesions has formed the subject of several excellent memoirs. I have examined sections from most of the animals experimented on, and find no essential differences between them and the same lesions produced by the inoculation of miliary tuberculosis, only slight alterations in accordance with the acuteness or duration of the disease.

Like other observers, I have found tubercle bacilli, although in very small numbers, in strumous glands; but in abundance in those organs which I have examined from the rabbits and guinea-pigs inoculated experimentally. The bacilli in the visceral tuberculosis were generally uniformly stained with even outlines; but in the strumous abscess in a rabbit which had existed for eight months they were nearly all "beaded" or uniformly stained, and often collected in groups not unlike clumps of micrococci. These changes in the form of the bacilli in acute and chronic cases of tuberculosis have been noted by MM. Raymond and Arthaud.⁵

In investigating the relation of strumous disease to other forms of tuberculosis, it was necessary to consider the possibility of its belonging to the form of tuberculosis described as *tuberculose zoogléique* by Malassez and Vignal,⁶ and which has also been observed by Eberth. This disease in its coarse anatomical characters cannot be distinguished from tuberculosis; but, on investigating the lesions microscopically with appropriate reagents, the bacilli of Koch are not to be found, while at the periphery of the caseous centres of the nodules are dense masses of micrococci, usually distributed in zooglæa, but in part in chaplets. The precise relation of this disease to bacillary tuberculosis has not yet been determined. Malassez and Vignal discovered it in guinea-pigs which had been inoculated with a tuberculosis of the skin; and recently Chantemesse⁷ obtained the same disease by inoculating guinea-pigs with portions of sterilised cotton-wool, through which the air of waiting rooms used by phthisical patients had been passed. Malassez and Vignal incline to the opinion that zooglæic tuberculosis may coexist with the ordinary bacillary form. In their experiments bacilli appeared in animals inoculated with a third series of cultures of micrococci, of which each generation had been passed through a guinea-pig. It is even possible that the micrococci may be simply contaminations of bacillary tuberculosis. The subject, therefore, requires further investigation, especially in tuberculous products from man. With the reagents employed by the authors above mentioned I have carefully searched two specimens of strumous gland, and many diseased organs both from rabbits and guinea-pigs inoculated with strumous glands, but have found nothing like zooglæa, except in one gland. Here were some darkly stained granular masses, but the granules were not well defined, and disappeared when the field was fully illuminated by removing the diaphragm. They were probably nothing more than masses of granular caseous material.

In passing I may here state that I have much pleasure in confirming, as regards strumous glands, the observation of Mr. Treves,⁸ which has been combated by high authority, that many of the "giant cells" are clearly formed by lymph coagula lying in lymph sinuses. I may also call attention to a curious condition of the lungs of some guinea-pigs which had been inoculated with tubercle. They are studded with rounded cavities, some larger than a pea, and many of these projected beneath the pleura, looking like bullæ. On microscopic examination they appeared to be formed by the softening of the caseous centres of tuberculous nodules, and by dilatation of the minute bronchi. The occurrence of cavities in the tuberculous lungs of animals has been denied by Chantemesse.

To conclude, while I have shown that the virus of strumous gland disease produced visceral tuberculosis in rabbits as well as in guinea-pigs, yet I admit that the disease in rabbits is not so acute and rapidly fatal as that following inoculation with, for example, acute miliary tubercle. The difference is one only of degree, not of a kind permitting us to infer, with Arloing, that struma is a specialised form of the tuberculous virus. We must, therefore, fall back on another explanation of the clinically innocent course of strumous gland disease; and we find it probably in the locality or soil in which the virus is implanted. Taking cervical gland

disease, if the virus is not inherited from a consumptive or strumous parent, it may be surmised that the common bacillus of phthisis is implanted in the lymph follicles of the pharynx or tonsil, in one of the adjoining mucous membranes on the skin, and is carried direct to the glands. These, acting as filters, arrest its progress permanently, except in some cases in which suppuration and ulceration take place, when the surrounding textures may become implicated, and general dissemination ensue. The malignancy of the virus may be somewhat attenuated under the local influence of the lymph cells and leucocytes in the gland, but to admit that the virus producing the disease is *ab initio* specialised, would be to infer that the strumous disease could only be produced by the virus of struma, and no other.⁹

In conclusion, I would emphasise the objections to the use of the terms "scrofula" and "struma" for lesions resembling tuberculosis.

Teachers must often be asked by students as I have been, What is the difference between a strumous and a tuberculous testicle?

Further, any evidence tending to connect more closely strumous gland disease with general tuberculous affections encourages us to persevere in the practice of early operation (where possible), with the view of completely eradicating the disease.

PERICHONDRITIS OF THE LARYNX.

By R. NORRIS WOLFENDEN, M.D. CANTAB.,
Senior Physician to the Throat Hospital, Golden Square.

A VERY instructive case has recently occurred in my clinic, of which I append the notes. The patient, C. T., aged 43, a big, strong-looking man, by occupation a policeman, applied at the Throat Hospital on September 20th, 1887. He gave the following history. He had been a policeman for sixteen years, had never had any illness that he remembered, except an injury to the knee, which kept him in hospital for fifteen weeks. The father is alive and well, the mother dead fifteen years before from "cancer of the breast;" all other relatives were healthy. The patient himself, though frequently pressed, could give no history of syphilis. At Christmas, 1885, he had caught a severe cold, suffered sore throat, and loss of voice and dyspnoea on lying down in bed. Under treatment he got somewhat better, partly regaining his voice, which, however, never became so clear as formerly. From time to time he caught cold, and suffered extinction of the voice, but was not ill enough to relinquish his work. He attended the Victoria Park Chest Hospital at Christmas, 1886. In July, 1887, he went to Yarmouth, and on returning home continued his work until coming to this hospital in September, 1887.

I saw him first on October 25th, 1887, and then found upon laryngoscopic examination that, situated under the right vocal cord, projecting beyond its edge, and occupying the anterior third of its subglottic portion, was a swelling, smooth and red, having all the appearance of a neoplasm (Fig. 1). The vocal cord of that

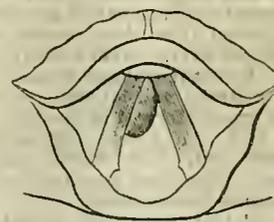

Fig. 1.

side was nearly motionless upon deep inspiration, and its surface was congested. The left cord was well abducted, and presented no abnormal appearance. The ventricular bands of both sides were a little thickened, just as in chronic laryngitis. The voice was hoarse but not extinct. No history of pain in any part could be obtained. Breathing was easy, and the patient's general condition satisfactory.

Bearing in mind the age of the patient, the history of the case, and the resemblance of the subglottic swelling to a new growth, I thought the case might possibly be one of malignant disease of the larynx. I therefore proposed to the patient that on my next

⁸ *Holmes's System of Surgery*, vol. 1.

⁹ For two cases in which the inoculation of circumcision wounds by tubercular virus was followed only by caseous abscesses, see *Lancet*, January 28th, 1888.

visit, three days afterwards, I should remove a portion of the supposed neoplasm, and submit it to microscopic diagnosis. The patient did not come to the hospital until eight days afterwards, when his symptoms had suddenly become urgent. For some days before he had suffered fresh dyspnoea, and was now at the point of suffocation. There was great inspiratory stridor, and extinction of voice; the whole skin was bathed in sweat; the pulse was rapid and feeble; breathing was most difficult, and the patient's expression was most anxious. The imminence of asphyxia rendered tracheotomy necessary on November 1st, 1887. The man was therefore put under anaesthetics, and the operation was performed with skill and dexterity by Mr. Procter S. Hutchinson, the resident medical officer.

Just before the operation I was enabled to make a laryngoscopic examination. Though this was difficult, I was able to make out that all the soft parts of the laryngeal tissues were greatly swollen—the ary-epiglottic folds, the ventricular bands, and the cushion of the epiglottis. The vocal cords were completely hidden, except a small part of their posterior extremities, of which the edges could be seen, quite white, but motionless and fixed. Externally the thyroid cartilage was swollen and enlarged, slightly tender to pressure, and giving some sense of fluctuation. There was very little bleeding during the operation of tracheotomy, and immediate relief was experienced; it was followed, however, by an attack of bronchitis.

The development of the case became now extremely interesting. Two days after the performance of tracheotomy, I obtained a laryngoscopic examination, but could see but little beyond that the whole larynx was occupied by red swellings; no vocal cords could be seen, nor any orifice to serve for respiration. The swelling was covered with frothy mucus, and brushing it off with alkaline lotion exposed a surface, upon which no ulceration could be detected. The odour of the breath was offensive, the secretion smelt also. A good deal of muco-purulent matter escaped through the tracheotomy wound, outside the outer tube. Expectoration was copious, depending of course upon the bronchitis. The secretion through the laryngeal wound continually soaked the dressings and the wound, which was dressed at first with iodoform gauze, looked irritated and inflammatory. Iodol dressings were substituted for iodoform, with great benefit. The temperature chart suggested the presence of pus, and for some days was up and down (Fig. 2).

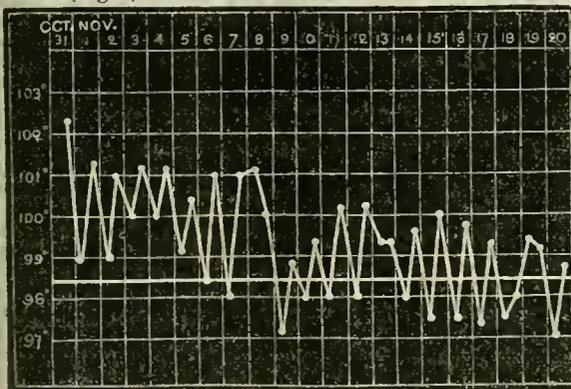

Fig. 2.

On November 10th, a little piece of cartilage was expectorated, and the discharge was lessening in offensiveness and in quantity. On the 14th the thyroid cartilage was enlarged in its whole extent, and especially the left wing, which was fluctuating to touch. An aching pain was complained of, and referred to a spot over the left wing of the thyroid cartilage. The interior of the larynx still appeared almost completely occluded by red oedematous swellings, and only just the posterior ends of the vocal cords could be seen. These swellings were well scarified with the laryngeal lancet with some relief to the patient, who had also been prescribed the vapor pini sylvestris, since the tracheotomy. A slight degree of dysphagia existed at this time. A week afterwards (November 21st) the patient reported that for some days all discharge from the larynx had ceased, and he felt comfortable. The swelling of the thyroid cartilage (externally) had gone down, but he still experienced a constant aching pain at a spot on the lower part of the left wing of this cartilage. An attempt to

obtain a subglottic view, by introduction of a mirror through the tracheal wound, was not successful. At this date (November 21st) the patient was up apparently well, and eating heartily. Cough and expectoration still continued, but the former was relieved by cocaine lozenges, and linctus papaveris. On November 22nd the swelling in the larynx was found to be diminished; but the ventricular bands formed two red tumours, meeting in the mid-line, and the swelling first observed under the right vocal cord could still be seen (Fig. 3). The posterior extremities of both vocal cords

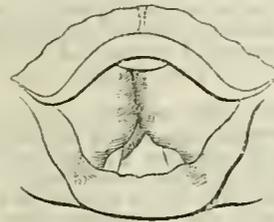

Fig. 3.

could be seen, immobile, but of normal colour.

Nothing noticeable occurred for some time. The patient was greatly improved in every respect, but there was slight discharge by the side of the tracheotomy tube, of muco-purulent character. Insufflations of iodol were daily applied to the subglottic region, through the tracheotomy tube, and had the effect of diminishing the secretion. On December 10th, 1887, the patient was discharged much relieved, and he became an out-patient. On December 14th he visited me again, and stated that there had been some discharge from the tube ever since he went out. With the laryngoscope I saw that there was increased swelling in the larynx, and, though there was a fair respiratory opening, the vocal cords were again hidden by swellings above them. He came again on December 20th, and stated that the day before he had coughed up a piece of bone. The piece was handed to me, and was of the exact size of this drawing. (Fig. 4.)

Fig. 1.

There was bluish-red swelling of both ventricular bands and over both arytenoids, but the laryngeal opening was larger than before. On December 27th I scarified the larynx freely. There had been a good deal of discharge through the tube, and a little dysphagia.

On January 3rd, 1888, he reported himself not so well. Sleep was entirely prevented by a tickling cough, and he then felt "something scratching or pricking" over the thyroid cartilage. The cartilage was much thickened externally, the whole laryngeal cavity was again blocked with red oedematous swellings, and there was a good deal of discharge of offensive pus through the tracheal wound. I was anxious for him to re-enter the hospital. As there was then no vacancy, I directed him to lie down continuously at his own home, and keep an ice-bag continuously applied over the larynx. Ten days after he was much better, and the necessity seemed to have passed away. On January 20th the larynx was not quite so occluded, and the voice was better and the patient stronger. On the 27th the oedematous swellings had still further diminished, and the voice was much stronger.

On February 3rd he was going on well, but some external redness over the thyroid cartilage made me continue the external application of ice. On February 10th all external inflammation had gone down, the voice was fairly strong, but rough, and he could breathe for two minutes at a time with the tube corked up.

On February 17th he was still better, and could breathe for ten minutes now with the cork in the tube. On February 24th he came again, stating that he had had a good deal of inflammation over the thyroid cartilage, with pain, and sharp pains over the clavicle. There was pain on pressure over both ala of the thyroid cartilage, with redness, and a boggy feel. But inside the larynx there was much less swelling, and I could now see into the trachea. There was no dis-

charge now from the tube, and he could breathe for twenty minutes at a time easily with the tube corked up. (I expect he could have breathed for longer, but was nervous.) Ice was again ordered for external application, and four days after (February 28th) the external inflammation had subsided. Internally there was still swelling of the ventricular bands and the cushion of the epiglottis and ary-epiglottic folds, but no ulceration anywhere; the extremity of the vocal cords was quite normal in appearance.

On March 9th, the laryngeal opening was larger, and breathing tolerably easy. He walked about now for several hours with the tube corked up. At this visit I commenced to dilate the laryngeal opening, and passed a No. 7 œsophageal bougie (bent to shape) through it.

On March 13th, 16th, 20th, and 23rd I again dilated it with Mackenzie's three-pronged dilator, and on each occasion passed œsophageal bougies of increased size through the constriction with ease. After each operation he was able to breathe better and for longer with the tube corked up, and now (March 28th) he is able to dispense with the tracheotomy tube altogether. The general condition is excellent, and he has gained in weight. He may now be considered as cured. The tube is entirely removed, and the tracheal opening closed up within twenty-four hours. At the last visit he pointed out to me the cicatrix of an old scrofulous ulcer in the neck, which had been hidden by the beard, and which I had not seen before.

As to treatment, iodide of potassium was, of course, given, at first in doses of 5 grains, afterwards reaching 15 grains; three times a day. This was given without any reference to syphilis. The tracheotomy wound was always dressed with iodol gauze (except just at first, when iodoform was used), and washed with perchloride of mercury (1 in 1,000). Iodol was insufflated into the subglottic region through the tracheotomy tube, and headache was relieved with antipyrin.

A drawing of the condition of the larynx at the present time is here appended (Fig. 5); it was executed by Mr. P. S. Hutchinson

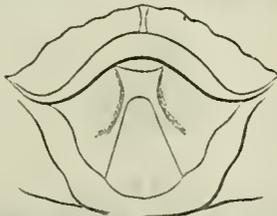

Fig. 5.

who also made the drawings of the larynx reproduced in Figs. 1 and 3. It is seen that the laryngeal aperture is now large enough to permit of easy respiration. All active inflammation has subsided. I quite expect that occasional dilatation will still have to be performed; but the patient may be said to have made a very successful recovery.

Perichondritis of the larynx may arise, as is well known, in the course of typhoid fever, tuberculosis, syphilis, and cancer; it has also been known to occur as a result of chronic laryngitis; to these must be added traumatism, both external and internal. Charles H. Knight, of New York, recently recorded a very interesting case of this kind, the cause of which was injury to the larynx by strangling during a quarrel. He also, in the same paper, recorded a case in which perichondritis followed from swallowing a plate of false teeth during an epileptic fit in a woman. The lodging of the teeth in the pharynx was succeeded by abscess of the posterior wall of the larynx. Perichondritis from deubitus, the pressure of an ossified cricoid cartilage against the vertebral column, has also been described by Gerhardt and Dittrich, and Mackenzie has seen it after cut throat.

The injudicious use of œsophageal bougies in the aged is referred to by Knight as an etiological factor, and there is no doubt that careless or prolonged use of the galvano-cautery to the larynx may give rise to it.

It seems desirable to correct the general opinion that perichondritis must necessarily be caused by syphilis or cancer. The case I have here recorded shows how it may arise out of chronic laryngitis, and the same catarrhal condition which leads to production of innocent neoplasms may also lead to perichondritis of the laryngeal cartilages.

A second case of extensive perichondritis of the larynx has occurred in my practice recently, arising out of chronic laryngitis, and in which there was no question of syphilis. In this case the cricoid cartilage was extensively affected, and formed a large abscess externally, on opening which a large quantity of sero-sanguineous fluid was poured out. The stenosis of the larynx was extreme, and tracheotomy had been performed many months before I saw the case by a surgeon at the Cape of Good Hope. As to prognosis, every case of perichondritis of the larynx, even when extensive, is not necessarily followed by fatal termination. Those due to syphilis, or of traumatic origin, frequently recover, and the case I have here first recorded in detail shows how perichondritis, arising out of chronic laryngitis, may also recover. What influences prognosis most is probably the extent of cartilage involved as well as the patient's general condition; and it is probably true, as all writers on the subject are agreed, that perichondritis of the cricoid cartilage progresses slowly but surely towards a fatal termination. Sufficiently accurate descriptions of the symptoms and laryngoscopic appearances of this disease are contained in many textbooks. I will merely remark that, in cases where there is a possibility of the presence of malignant disease, very little importance can be attached to the examination of the secretions.

A MODE OF OBTAINING VACCINE LYMPH WITHOUT PUNCTURING THE VESICLES.

By W. C. GRIGG, M.D.,

Physician to Queen Charlotte's Hospital.

THE present method of taking lymph for vaccination purposes is coupled with so many inconveniences, not to say dangers, that I feel sure medical men will gladly welcome any suggestion which will dispense with the necessity for puncturing the vesicles at the risk of obtaining a lymph contaminated with blood, or of favouring the occurrence of subsequent inflammation.

The method which I have adopted for some time past for the extraction of lymph from the pock has, so far as my present experience goes, a double advantage, namely, that the supply of lymph obtainable from each vesicle is greater and its efficiency is increased. Out of upwards of 200 infants vaccinated by me during the past few months, I have not as yet had one ill-developed pock nor a single failure of a punctured spot, although many of the cases were from vaccine obtained from very young infants. As a general rule, I only vaccinate in four places, principally on account of the young age of the infants I am called upon to vaccinate. Down to December 31st, 1886, I had vaccinated altogether 2,685 infants, of whom, with one exception, all were successful either at the first attempt or at the second. The unsuccessful case resisted four successive attempts to vaccinate, for which no explanation can be given. The mother had never had small-pox.

A complete failure in all four spots on a first vaccination was comparatively rare, and could, as a rule, be traced to a deficiency in the lymph, for it seldom or never occurred when the lymph was obtained from children of three months old and upwards. It generally happened when the lymph was drawn from an infant less than a fortnight old, at which age the quantity of lymph is very scanty and its efficacy below the normal. It is seldom possible to vaccinate successfully more than a dozen children from one such infant; and failure in one, two, or three spots is not uncommon.

I may remark incidentally that where one or more punctures had failed to take, revaccination of the infant with lymph obtained from its own successful pock generally ensured a satisfactory result, the primary pock or pocks remaining quiescent until the pocks which followed the second vaccination arrived at maturity, that is, at about the eighth day, when they all faded away together. In these cases it was impossible to say from appearances, by the eighth day, which were the primary and which the secondary pocks. In only one case did this method of re-auto-vaccination fail, and no better results were obtained when lymph from other sources was substituted for its own. I had therefore to be satisfied with the two successful primary pocks.

My system of obtaining lymph is as follows: I drop a small bead of pure glycerine upon the centre of each pock, and then gently rub the top of the vesicle with a smooth, blunt instrument (the round glass head of a shawl pin does excellently). After the lapse of two or three minutes the bead of glycerine will have

increased to nearly double its size, especially if the vesicle contain a good supply of lymph. If necessary, a second drop of glycerine may be applied after the first has been used, and even a third.

This plan avoids the risk of drawing blood, which at times it is not easy to escape doing when puncturing the vesicles. Moreover, not having to hold the infant's arm, there is no fear of capsizing the child, the possibility of which adds to the difficulty of arm-to-arm vaccination where many children have to be vaccinated from one.

I should be glad to hear whether, in the hands of other practitioners, the same good results are obtainable. I have only given the method a four months' trial so far, which is perhaps hardly sufficient to authorise any definite conclusion.

CLINICAL MEMORANDA.

HÆMOPHILIA.

THE particulars of the following case are of interest from the very early age of the patient and the symmetrical arrangement of the phenomena.

M. S., aged 38, a primipara (married eighteen years), was on February 14th delivered of a male child after a natural and quick labour. The child was apparently healthy and strong, crying lustily. On the third day a small dark spot was observed on either side of the occiput; the day following the child had two black eyes, evidently due to extravasations of blood, the discolorations extending symmetrically above the eyebrows and on the malar bones. The eyeballs presented an unusually pearly appearance. Next morning the nurse observed a purple swelling on the external aspect of the left humerus, and in the evening the same was to be observed on the right side. The following night the umbilical cord began to bleed, which the nurse arrested temporarily by the local application of brandy and by retying. Hæmorrhage broke out, however, again on the proximal side of the ligature, and the child died from loss of blood before medical assistance could be obtained. DUNCAN R. MCARTHUR, M.D.
Sturminster Newton.

UNDER the above heading Mr. Eagle recorded a case in the JOURNAL of March 10th; and as a very similar case has just come under my notice, I think it worthy of record.

On March 8th I delivered Mrs. P., a countrywoman aged 25, of an apparently healthy male infant. The child was at the full term. It was somewhat jaundiced on March 10th, but better on March 11th. On March 12th the jaundice became more intense, and on March 13th two swellings appeared, one behind each axilla, evidently composed of extravasated blood. During the next two days other swellings appeared on the back, shoulders, front of chest, elbows, and knees. The cord separated on the morning of March 15th, and there was a continual oozing from the umbilicus till the child died at mid-day on March 16th. No treatment was of any avail.

Mrs. P. was delivered of a male infant six years ago at the eighth month. He survived his birth one month, and died much swollen and covered with lumps. Two years ago she aborted at the end of the third month, and lost much blood. I did not attend her on these occasions. Two of her brothers suffer much from epistaxis. GEORGE VINCENT, M.D., M.R.C.S.
Shouldham, Downham, Norfolk.

MULTIPLE SARCOMATA OF THE SKIN.

SARCOMA CUTIS is such a rare disease as to justify the recital of the following case. Koebner reports only two such cases (secondary), whilst Kaposi had only seen five cases of the idiopathic disease (*Nebra on Diseases of the Skin*, vol. iv); in the latter the affection always began in the soles of the feet, and was doubtless a general morbid affection from the very outset.

On October 8th, 1887, I was called to see E. D. G. E. T., a school-mistress, single, aged 32 years, fair complexion, red hair, extremely anæmic, temperature 101° F., pulse over 100 and weak. She was in bed, and could not change her position in the least owing to intense pain in the right hip; she stated that she had come two or three weeks before from near Leeds, where she had been ill and treated for sciatica for six weeks. On examination, I found a distinctly localised oval swelling, four or five inches in length and three inches in width, situated immediately over the upper and back part of the right ilium to which it was attached; the inner

border of the swelling, which was elastic and semi-fluctuating corresponded with the sacro-iliac synchondrosis; the superjacent skin was of its natural hue and consistence, and could be moved freely over the growth, the borders of which were distinctly definable. The growth itself was neither tender nor painful, and of six weeks' duration. There was a history and marks of scrofula in the patient. Was the growth a sarcoma or a chronic painless abscess? Neither a hypodermic needle nor a small trocar could obtain pus. This settled the diagnosis. There was no history of injury, except a fall on "the small of the back" two years before from a gig. On further examination, I found several nodules in the skin of the head, face, and neck, and a few on the body, some of which projected half an inch above the skin level. The nodules varied in size from a split-pea to a pigeon's egg. Some were evidently situated in the deeper layers of the skin itself, whilst the skin could be moved over others; they were mostly isolated, some were firm, others elastic and compressible; over some the skin was of its normal hue, over others white and glistening, whilst on other nodules it was bluish-black, giving the appearance of an enlarged vein. She stated that these nodules developed shortly after she became ill, and that some disappeared entirely, but I could find no cicatrix nor anything else to mark the site of a former nodule. There was no ascertainable evidence of disease in the lungs or liver; there was dysphagia, which was probably due to nodules in the submucosa of the gullet (as in one of Kaposi's cases, in which they also appeared in the lining of the stomach, intestines, and bronchi); the fauces were quite bloodless. Cough and dyspnoea were conspicuous by their absence. The nodules continued to increase in number up to her death, which took place from exhaustion on November 17th, three months and a-half from the commencement of the illness, when no less than sixty or seventy were present on the head, neck, and trunk, the limbs, unlike all Kaposi's cases, being exempt. There was some remission in the sciatic pain before death, but the iliac growth was unaltered. There was no ulceration or gangrene of any of the nodules. The lymphatics were unaffected.

The rapidity with which the nodules developed after the first noticed growth seems to favour the view that the whole of the tumours were due to a primary disease of the blood, and were not the result of secondary infection. I regret not to have been able to obtain a nodule for microscopic examination after death, owing to the great distance (ten miles over moorland) from the patient's house and my other engagements at the time.

Stanhope.

WILLIAM ROBINSON, M.S. and M.D.

THERAPEUTIC MEMORANDA.

PEPPERMINT WATER IN PRURITUS PUDENDI.

EVERY practitioner will have had under his care cases of this troublesome affection, which have been proof against all treatment, especially in the neurosal forms, where the cause of the pruritus, which is, of course, only a *symptom*, is more difficult to remove. No excuse, therefore, is needed to mention a local remedy which will, if the skin be unbroken, either cure the patient, or afford relief whilst the source of the irritation is being treated.

The agent here alluded to is peppermint water, used as a lotion. The B. P. preparation of aq. menth. pip. answers well, but is bulky for carrying about, and is incapable of concentration unless rendered alkaline. This is best done by borax, as being in itself soothing and antiseptic. Patients can easily make their own lotion, as required for use, by putting a teaspoonful of borax into a pint bottle of hot water, and adding to it five drops of ol. menth. pip., and shaking well, the parts affected to be freely bathed with a soft sponge.

If no cracks or sores are present, this lotion will remove the itching, but if there be eczema, etc., or rawness from scratching, it is inapplicable, olive oil, with five grains of iodoform to the ounce, being then more useful. The greatest and most permanent relief is afforded in the neurosal form, especially in the reflex pruritus which often accompanies pregnancy, and which then may take the place of reflex sickness or vomiting. It is also very useful in the pruritus which occurs in the climacteric, or in elderly women, in whom it may be only part of a general pruritus, and also in those cases of women of all ages, where the urine simultaneously becomes of very low specific gravity, without any evidence of having a gouty or granular kidney as a remote cause.

In pruritus due to pediculi, ascariæ, an irritable urethral car-

uncle, an endocervical polypus, early cancer of the cervix, distension of Bartholini's ducts or glands, the leucorrhœa of vaginitis, endocervicitis, and metritis, or the irritating discharges of advanced carcinoma uteri, or to a gouty or diabetic diathesis, the drug excels all others, cocaine inclusive, in affording relief, whilst endeavours are being made to remove the cause.

In two obstinate cases of uncontrollable pruritus of pregnancy, where this remedy only gave temporary relief, the patients were cured by applying iodine liniment to the angry looking cervix uteri, which method has been used successfully by Dr. John Phillips and others for the similarly severe vomiting of pregnancy.

Peppermint has long been used by the Chinese as a local remedy for neuralgia, and has lately been sold here, combined with camphor, as menthol. It appears to act as a local anæsthetic, its effect lasting often many hours, and in some cases of reflex origin a single application of the lotion has cured the patient. The remedy was, I believe, named in a casual communication to the JOURNAL about twenty years ago, but I have failed to find the reference, and though it has been prescribed spasmodically by my father, and perhaps by others, its extreme utility seems known to very few.

AMAND ROUTH, M.D., B.S., M.R.C.P.,

Assistant Obstetric Physician, Charing Cross Hospital.

REPORTS

OF

HOSPITAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN, IRELAND, AND THE COLONIES.

THE CIVIL HOSPITAL, HYDERABAD, SIND, INDIA.

LATERAL LITHOTOMY.

By Surgeon-Major B. C. KEELAN, L.R.C.S.I., L.K.Q.C.P.I., Indian Medical Department, Civil Surgeon of Hyderabad, and Superintendent of the Medical School, Hyderabad, Sind.

THE following table gives a statement showing twenty-four large stone cases which were operated upon by the lateral method of lithotomy during the six months from June 1st, 1887, to November 30th, 1887. Besides these there were sixty-seven other cases operated upon during this period, which will be published hereafter, thus giving a total of ninety-one cases, of whom three were females operated upon since writing my last paper for the JOURNAL.

Table showing the Number and Size of Large and Hard Stones removed by the Lateral Operation from June 1st, 1887, to November 30th, 1887.

Average Size of Stones.	Number.	Sex.	Result.	Ages.
3i 5i	4	Males	Cured	50, 30, 50, and 35 years.
Miss	6	Males	Cured	42, 40, 45, 40, 11 and 50 years
3i	6	Males	45 Cured 1 Died	48, 40, 32, 40, 40 and 32 years
Miss	4	Males	3 Cured 1 Died	60, 50, 50 and 34 years.
5i	1	Male	Cured	42 years.
Miss	1	Male	Cured	24 years.
Ev	1	Male	Cured	29 years.
Miss	1	Male	Cured	48 years.
	24		22 Cured 2 Died	

The following was an important case. An adult male, 48 years of age, was admitted into hospital with severe symptoms of stone in the bladder, from which he said he had been suffering for eleven years, and could endure the pain no longer. He was operated upon by the lateral method of lithotomy, described by me in the JOURNAL of October 16th, 1887. On being removed the stone weighed 6½ ounces. It was of uric acid, and was exceedingly hard and oval-shaped. Round the greatest diameter it measured by the tape 8¼ inches, and round the smallest diameter, which passed through the wound in the perineum, it measured 7¼ inches.

Notwithstanding the large size of the stone, which was very smooth, I had not very much difficulty in removing it by traction upwards and forwards with the bent-bladed forceps, as suggested in my paper. The forceps did not slip even once. I find that the perineum in this direction dilates easily and there is no chance of the tuber ischii or the dense unyielding structures immediately in front of the rectum obstructing the passage, and the rectum is not in danger. There is less bleeding also to be feared by enlarging the wound in this direction. The patient, a stout man, left the hospital quite cured in a month exactly from the date of his admission, during which time his case went on smoothly, and his progress was never impeded by any unusual symptoms. After his discharge there was no incontinence of urine, and there was not even a fistula left behind. His sexual powers were perfect, and his general health was greatly improved.

The other patients made excellent recoveries with the exception of two, one of whom succumbed one month after the operation. He was a weakly man when operated upon, and was 60 years of age. The other man got suppression of urine on the third day after the operation with a tympanitic state of the abdomen, after which he sank rapidly. This man's stone was very peculiar. I have never seen one like it before, nor have I seen a stone similar to it described in any book. It is beautifully smooth, and of a darkish drab colour, and one part of it shines as though it was covered with a layer of varnish, which had become exceedingly hard, and there are two projections, or tears, smooth and shining, like dried up drops of hardened paint of the same colour.

The twenty-two patients who were cured were particularly asked, on being discharged, if they had lost any sexual powers, and I was invariably answered in the negative. This question, I think, has been raised without much reason. It is the testicles that secrete the semen, and as long as that fluid is emitted through the channel destined for its discharge, there can be no proof that lateral lithotomy has a tendency to render persons impotent. Many of these patients had deep perineums, so deep that the finger could with difficulty be passed into the bladder.

There seems to be some mysterious impression, which is very surprising to me, among a few in England that natives of India are weakly attenuated creatures, and, being constitutionally different from Europeans, they are somewhat more amenable to operations. But, from my experience of the Sindhis, the Beluchis, the Afghans, and the Punjaubis, among whom I have daily practice, I can affirm that they are equal in physique to Europeans, and their children are fat and healthy, like the offsprings of English parents. That there are no anatomical differences between the two races is a fact which can be demonstrated daily in the dissecting room. I hope, therefore, that lateral lithotomy may be thoroughly tried, and the operation improved upon, by persons who have equal opportunities with myself of taking up the subject, and developing it. In the JOURNAL of October 16th, 1887, there is an interesting article on the relative merits of litholapaxy and the suprapubic operations in male children. Regarding the latter operation, twelve cases are reported by nine different operators, with one death, of children operated upon under 16 years of age. Eighty-nine cases of litholapaxy have been collected by eight operators without a casualty, except one mentioned in Surgeon-Major Keegan's collection of fifty-eight cases. The article on One Year's Statistics of the Hyderabad Civil Hospital, published in the following page of the same journal, shows a total absence of mortality in one hundred and five successive cases of young people operated upon, some of whose ages did not exceed eighteen months, and many left the hospital completely cured in ten or twelve days. I omitted to mention the great assistance I derive by sometimes using a small curved forceps, if there is any difficulty experienced with the straight pointed forceps in seizing the stone, when operating on young children by my method of introducing the forceps on a small director. Mr. Walsham's paper also shows that the suprapubic operation is not only beset with danger to life as well as with numerous complications, but that the wound takes a longer time to heal. In one case nearly seven weeks, in another nearly ten weeks, a third one took months to heal, in a fourth the little patient died, and in other cases the time is not stated, and no reason is given. In one instance the surgeon who operated said he would not repeat the operation, and this is what I have said in my former paper, namely, that I have tried it and had to give it up.

If the operation is so comparatively unfavourable in children,

how much more so would it be in adults? Mr. Erichsen shows the mortality to be one in three or thereabouts. If this immense mortality is compared to lateral lithotomy on large stones which I can show to be one in twelve, the difference is startling. I will now proceed to quote from Erichsen's *Surgery*, 8th edition, which I believe is the latest, vol. ii, page 988: "...of a gross total of 467 cases of the suprapubic operation in both sexes, there had been 135 deaths, or a mortality of 1 in 3.44; the mortality being about one in three in males."

The mortality is said by Humphry, who collected 104 cases with thirty-one deaths, to be due chiefly to peritonitis and urinary infiltration. So much for the suprapubic operation for the present.

GREAT NORTHERN CENTRAL HOSPITAL.

CASE OF RAPIDLY FATAL CHOREA: DEATH IN 130 HOURS.

(Under the care of Dr. COOK and Dr. CLIFFORD BEALE.)

A. C., aged 9, was brought as an out-patient on October 27th, 1887, suffering from chorea. The mother stated that on October 25th the child had had some difficulty in putting on her stockings, owing to slight loss of control over her right arm and leg. The mouth and eyes had been noticed to twitch next morning, and since then the irregular movements had become general, though most marked on the right side. The child had not taken food well, had slept badly, and been slightly delirious during the night, occasionally screaming and complaining of pain in the left hypochondrium. She had been very thirsty. The evacuations had been normal, and never passed unconsciously. She had been a fairly healthy child, and had passed through an attack of scarlet fever two years previously without any known sequelæ. She had not been frightened, nor had she been in company with other choreic children, nor had any worms been seen.

When first brought under observation, on the 27th, the child was obviously very ill, with flushed face, hot skin, and a terrified expression of countenance. The choreic movements were violent, and according to the mother were hourly becoming more so. The pulse was very rapid, varying between 160 and 170, but the respirations were only slightly increased. She was at once sent into the ward, where, after careful examination, a short systolic murmur could be made out at the apex, which was in the normal position: Only a few scattered crepitations could be detected in the lungs, the breathing being quite regular. The child kept constantly smacking her lips and frequently protruding the tongue, but there was no difficulty in deglutition.

October 28th. She slept very little and was very restless, being sometimes delirious and occasionally screaming. During the day the movements became so violent as to render restraint necessary to prevent injury. The bowels were freely open; the urine was passed involuntarily, but a little, collected, was found to be free from albumen; the tongue was clean and moist, but the lips dry and cracked; the temperature was slightly raised, but never exceeded 101°. The heart's action continued at the same rate or faster, and the pulse at the wrist became almost imperceptible. On the following day some difficulty was experienced in swallowing and the girl became very noisy, frequently screaming and uttering inarticulate sounds; the respiration became irregular and jerky, and she died rather suddenly the same evening, the whole course of the illness having run between the morning of the 25th and the evening of October 30th.

At the *post-mortem* examination both lungs were found to be much congested at the bases, and the left pleura was adherent. The right side of the heart was slightly dilated and flabby, and contained some fibrinous clot and a little dark fluid blood; on the auricular surface of the tricuspid valve were a few punctiform patches of congestion. The left ventricle was firmly contracted, its muscular tissue very good. On the auricular surface of the mitral valve, between the hinge line and the free border, were numerous tiny patches of punctiform congestion, especially marked along the hinge line itself. At the free margin of the valve the attachments of the *cordæ tendinæ* were much thickened by lymphic vegetations, to a few of which slightly coloured fibrinous clots were attached. There was no positive ulceration of the endocardial surface to be detected. The brain and upper part of the spinal cord were healthy, except for an extreme degree of *anæmia* at the pons and medulla. The tissue of these parts seemed quite normal on section. Other organs were healthy.

The case was treated with arsenic, morphine, chloral, and bromide of potassium, but in no case did the action of the drugs

appear to have any influence upon the downward course of the disease.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, APRIL 10TH, 1888.

Sir E. H. SIEVEKING, M.D., President, in the Chair.

A Case of Double Nephro-Lithotomy, in which Lateral and Median Lithotomy had been Previously Performed, with Remarks on Sympathy between the Kidneys.—Mr. HERBERT W. PAGE read this paper. A man, aged 22, entered St. Mary's Hospital in November, 1886. For ten years he had suffered pain in the region of the left kidney, with occasional attacks of left renal colic. In 1882 he began to pass gravel and to suffer from irritability of bladder, and in 1885 a small calculus was removed from the bladder by lateral lithotomy. Symptoms of vesical calculus soon recurred together with pain in the left loin, and his general health became much broken. His urine contained pus and occasionally blood. Left calculus pyelo-nephritis was diagnosed in addition to stone in the bladder, and this was accordingly removed by median incision on December 4th, 1886. On December 15th the left kidney was exposed in the loin, and two small calculi were removed from a large suppurating cyst. The amount of pus, however, did not materially lessen, and towards the end of January he began to have pain in the region of the right kidney, from which it was soon suspected that the pus now came. On February 18th he was attacked with violent pain in the right loin with rigors, vomiting, and high temperature. At the same time the pus almost entirely disappeared, and his urine dropped from forty-two to twenty ounces. It was believed that this urine was furnished by the left kidney only. The symptoms increased, and there was fulness in the right loin: On February 25th the right kidney was exposed; it was found much enlarged and surrounded by stinking pus, and there was an opening into the pelvis, from which an abscess had probably burst into the perinephral tissue. No stones were found. He did well after this operation. The urine steadily increased in quantity, the pus diminished, and his pain ceased. He left the hospital on May 26th, and a few days afterwards he passed four small calculi *per urethram*. From that time he made steady progress towards recovery. The case was of interest from its bearing on the question of sympathy between the kidneys, and it was suggested that in this case the right kidney had in all probability contained calculi, though without giving rise to symptoms, for some considerable time, and that its condition was revealed by the operation on its fellow. In support of this view, the writer referred to a case recently under his care in which the presence of calculi was first made known after the operation of hysterectomy, undertaken by the late Dr. Meadows. Reference was made to other cases in which there was a somewhat similar sequence of events. From another point of view Mr. Page considered this case of importance in its bearing on nephrectomy and preliminary abdominal exploration. Nephrectomy, as time proved, would have been in this case a very wrong thing, but he had never felt quite satisfied that abdominal exploration, by which he would have found an apparently useless left kidney, and a right kidney so enlarged as to be presumably fit for all future needs, its calculi being, moreover, so small as to elude detection, might not there and then have led to nephrectomy. The patient would have been placed thereby in a position of infinitely greater danger when at a future day the right kidney was in its turn *hors de combat*. The case thus demonstrated, with how many precautions and with what consideration abdominal exploration for the examination of kidneys must be made.—Mr. GODLEE congratulated Mr. Page on the success of his treatment, and the many valuable reflections that were to be drawn from it. It confirmed his opinion that it was wise at the time of excision of a stone to leave the kidney from which it was taken, for it might heal, or, at any rate, it would contract, and then would be easier to remove if absolutely necessary. In one of the cases Mr. Page had cited it was a question whether hysterectomy had caused a stone in the kidney, or had merely lighted up inflammation round a pre-existing stone. He thought the first hypothesis very possible, considering how often stones were apparently the results of accidental injury, such as being run over by a cart-wheel, etc. He agreed with Mr. Page in thinking much caution must be used in describing the effects of sympathy

between the kidneys.—Mr. PAGE said, in conclusion, that he had been glad to supplement the paper by showing the patient to the Society that evening in a state of very good health, with his urine normal in all respects. He agreed that mechanical injury might have been the origin of the renal calculus. The sympathy between one kidney and the other was probably not greater than that between one kidney and any other viscus. It was important to remark that in this case abdominal exploration, had he made it, would probably have led him astray, for he was tolerably satisfied that he would, after exploration, have excised the small left kidney—but wrongly, as the sequel of the case showed.

Remarks on Splenectomy, with a Report of a Successful Case.—Sir SPENCER WELLS reported a case where he had successfully removed an enlarged spleen from an unmarried woman, aged 24. He appended remarks upon the details of the operation, especially upon the mode of securing the blood-vessels, and upon the progress of splenectomy before and since the periods of anaesthesia and antiseptics. He added the following table, prepared by Professor Adelmann, to show how in fifty-three cases, recorded up to June, 1887, the result was influenced by the nature of the disease which led to operation.

Disease.	No. of Cases.	Recoveries.	Deaths.
Hypertrophy with leukaemia.....	19	1	18
Simple hypertrophy	14	1	13
Malarial hypertrophy	4	1	3
Wandering spleen	9	7	2
Splenic cysts.....	4	3	1
" hydatid	1	1	—
" sarcoma	1	1	—

He concluded that, as the results of splenectomy had gone on improving during the last thirty years, we might hope that, with increasing knowledge and greater experience, still better results might be obtained; and sufficient facts had already been accumulated to prove that patients who recovered from the operation might live in good health for many years without a spleen.—Mr. W. A. MREDDITH had three times assisted at the operation of splenectomy. In the first case, with Mr. Knowsley Thornton, there had been a cystic spleen, very mobile, and there was no great difficulty in the operation, but a very dangerous moment just after the ligature was applied and before it was divided. There was a good recovery. In the second case, also with Mr. Thornton, the spleen had been very large and very vascular; its attachments were tied with three loops, and death followed in a few hours from the giving way of the middle loop. In the third case, this of which Sir Spencer Wells had just given an account, the method had been excellent; traction on the pedicle had been avoided, and after the main mass of the spleen had been cut away the application of the ligatures had been comparatively easy. In looking back over previous cases he had noticed how those had been most favourable when there had been a long gastro-splenic omentum, allowing much movement of the spleen.—Mr. HAWARD felt, naturally enough, the encouragement given to all surgeons by the record of another success in this department of practice. Mobility of the spleen gave more distress here, but generally it gave more success, perhaps because there was less disturbance to the sympathetic plexuses and easier manipulation. Any great size of the spleen was of course against success in the operation: any reference to the lists of cases showed that those on spleens of smaller size were the most successful, and also those where there was least leukaemia. It was a question whether moderate leukaemia should be held to negative the operation; he gathered that Sir Spencer Wells did not agree in discountenancing the operation if there was only slight leukaemia. The use of pressure forceps were very advantageous. In a case of his own, however, he had found it possible to control the flow of blood from a rent in the brittle substance of the morbid spleen by a sponge.—Dr. ANGEL MONEY remarked that a moderate excess of colourless corpuscles in the blood was generally now called leucocytosis, and was always found in fever. M. Hayem had recently shown that it was universally found in all processes in which there was morbid exudation of blood corpuscles, and in states also such as carcinoma when it was an insufficient reason for the discontinuance of operations.—Mr. GODLEE said he had been puzzled by the record of frequent jaundice before the operation and none after it. Did the tumour displace the bile duct or block it?—Dr. T. M. ROOKE had been the medical adviser of the lady for about ten years, and had always seen an icteric tinge on her face, and observed many attacks of acute jaundice. He agreed that there had been none in the last three months since the operation, but was uncertain in his explanation. He was struck by the little importance of the spleen to the animal economy, and regarded it as acting as a

mechanical diverticulum to the liver.—Dr. A. H. N. LEWERS was surprised that the diagnosis should first have been of a pelvic tumour, and, further, that after the discovery of its true nature the operation should have been continued, seeing that the mortality of splenectomy was 60 per cent. as compared with 25 per cent. for hysterectomy, and 6 or 8 per cent. for ovarian tumours.—Dr. DAY had seen the operation and after-treatment, and remarked that the only period of danger in the latter was on the third day, when Sir Spencer Wells was away, and he found the temperature 103° and the pulse 130. He advised an ice cap and reduced diet, and after that the case did very well. She had only taken as anaesthetic bichloride of methylene Zij , which was given slowly, and the operation was not begun until there was full relaxation of the muscles. Those he considered important points.—Sir SPENCER WELLS, in reply, said he entirely agreed with Mr. Hayward in believing that the smaller the tumour and the longer the attachment, the less would be the difficulty and danger of removal. Of his own four cases this was the only one of wandering spleen with a long attachment. One of his other cases was the largest solid tumour hitherto removed. In two cases there was marked leukaemia. Dr. Lewis's estimate of a mortality of 60 per cent. after splenectomy for hypertrophied spleen was not greater than the general mortality of ovariectomy thirty years ago, and a very great diminution in the mortality might reasonably be hoped for. The cessation of the fever on the fourth day, as described by Dr. Day, he (Sir Spencer) was inclined to attribute, not so much to diet and the ice-cap as to the appearance of the catamenia, and he was strengthened in his belief that the most favourable period for removing any abdominal tumour from a woman was soon after a menstrual period.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, APRIL 4TH, 1888.

JOHN WILLIAMS, M.D., President, in the Chair.

Specimens.—Dr. CULLINGWORTH exhibited a thick-walled cyst behind the uterus, which lay imbedded in the anterior wall of the cyst.

Interstitial Gestation.—A report was read on Mr. Sidney Harvey's specimen of interstitial gestation, exhibited at the January meeting.

Scarlatina during Pregnancy and in the Puerperal State.—The adjourned debate on Dr. Boxall's series of papers was resumed and concluded.—Dr. GALABIN noted the remarkable absence of mortality in Dr. Boxall's cases, but brought forward statistics to show that the general belief in the danger of puerperal scarlatina was not incorrect. The favourable results in Dr. Boxall's series might be explained either as due to the excellent antiseptic precautions, or to the mild type of the epidemic. Experience proved that puerperal scarlatina was sometimes mild where no antiseptics were used; on the other hand, there might be much pelvic complication, and Dr. Galabin had twice seen fatal peritonitis appearing during desquamation. Dr. Galabin considered that evidence concerning the masked form of scarlatina resembling septicæmia was conflicting. There appeared to be a fascinating simplicity in arguing that scarlatina and septicæmia were two distinct specific diseases, the one convertible into the other. Yet septicæmia was not one disease, but a group, comparable rather to all the zymotic diseases together than to scarlatina or erysipelas alone. About twenty microbes had been described as the active agent in different forms of septicæmia, which must be defined as including the effects of all germs except the specific agents in named zymotic diseases. Hence septicæmia did not represent a definite entity like scarlatina. In the latter disease, again, Cheyne found the common microbes of suppuration in the blood not infrequently. Dr. Matthews Duncan had shown that according to the Registrar-General's Reports for London there was no increase of puerperal fever in proportion to that of scarlet fever or erysipelas; this was strong evidence that scarlatinal poison could hardly produce a disease simulating puerperal septicæmia. Dr. Galabin believed that at least the above fact proved that scarlatina was not numerically an important cause of puerperal fever; if it did not account for over 5 or 10 per cent of all cases, it would not be manifest in statistical charts. There was strong evidence of a bacterial relation of erysipelas to puerperal fever, and Dr. Galabin brought forward evidence which tended to prove that scarlatinal poison might produce a disease simulating puerperal septicæmia.—Dr. HORNBOCKS quoted Reports of the Guy's Hospital Lying-in Charity, which showed the rarity of scarlet fever of the ordinary

type in the puerperal state, and he asked how many women were confined during the time that Dr. Boxall's cases were collected. Some of those cases were possibly not scarlatinal, or else represented very mild scarlatina. He believed that the incubation was not shortened when infection took place during labour, but inasmuch as then the poison could generally enter the system at once, the incubation began at once, and so the fever developed within a few days after the exposure. He discussed at length the subjects of Dr. Boxall's series of papers, noting corroborative evidence, and indicating sources of fallacy.—Dr. CAYLEY thought that there was not sufficient evidence that the poison of scarlatina was capable of directly causing septicæmia. Cases of scarlatina following operations, and operations on patients suffering from scarlatina, had usually done well at the London Fever Hospital. Very few cases of puerperal scarlatina had been admitted into that institution, and in two alleged cases, where there were acute septicæmic symptoms, diagnosis was doubtful.—Dr. CHAMPNEYS testified to the great care with which Dr. Boxall had studied his series of cases, never neglecting to trace the history of each case after discharge from hospital. Dr. Champneys noted that the paper contained the analysis of a series which occurred during one epidemic. Different conclusions would probably be drawn from the record of cases seen in consultation, for the very fact of consultations implied picked bad cases. In other words, series should be compared with series. Dr. Champneys then made some observations on the question of scarlatina puerperalis, and criticised the accuracy of Collective Investigation Reports, which represented opinions formed by hundreds of men of different views. Dr. Cayley's valuable evidence was unfavourable to the opinion that the septicæmic variety of scarlet fever existed.—Dr. JAMISON agreed with Dr. Boxall's views; he thought that the best diagnostic difference between scarlatina and puerperal septicæmia was to be found in the retina, for retinal hæmorrhage was an almost constant occurrence in septicæmia and all but invariably absent in scarlet fever. Extreme antiseptic precautions were impossible in ordinary practice, and fortunately scarlet fever was neither very readily communicable to puerperal subjects nor very severe when they took it.—Dr. W. J. COLLINS was no great believer in the absolute specificity of scarlet fever, and hinted that a process of evolution might affect the *materies morbi* of specific diseases.—Dr. HAYES insisted on the entire distinctness of scarlatina and septicæmia, and in his experience puerperal cases were not highly susceptible to scarlet fever.—Dr. WEST distrusted theories about the evolution of diseases, and maintained the specificity of scarlet fever. He had seen much of puerperal fever, but had never come across a case which could be traced to the contagium of scarlet fever, a disease with which he might claim to be very familiar. The pregnant, parturient, and puerperal woman was undoubtedly not highly susceptible to the contagium of scarlet fever. Only two cases, which he related, represented Dr. West's personal experience of scarlatina in pregnancy or after delivery.—Dr. CHALMERS stated that in connection with disturbances in the puerperal condition, he had observed that septicæmia in the lying-in woman was associated with and apparently gave rise to a variety of pathological conditions amongst those in attendance; again, when scarlet fever assailed the mother, Dr. Chalmers found that it never ran its natural course. He did not believe in the absolute specificity of disease, and did believe in the existence of a puerperal septicæmic form of scarlet fever.—The PRESIDENT observed that it must ever be borne in mind that some epidemics of scarlet fever were mild and others severe; that infection from a mild case might give rise to a most malignant form; and that scarlet fever poison might give rise to septicæmia, but in a secondary manner. He compared Dr. Boxall's series with evidence brought forward from other sources in the course of the present discussion. In the latter case, the patients had often been seen but once or twice in consultation or under circumstances where thorough observation was impossible, and accuracy of diagnosis questionable, or where antiseptic precautions were not employed. In Dr. Boxall's cases the course of the disease had been observed throughout, and antiseptic precautions thoroughly and successfully carried out. In the course of an epidemic of scarlet fever, that disease had attacked some of the patients in a lying-in hospital where sepsis had been stamped out, and in every instance had produced scarlet fever, and not septicæmia. On the other hand, we learned that when lying-in patients were exposed to septic infection and to scarlet fever poison, septicæmia was present in all whether scarlet fever was present or not. Since the reading of Dr. Boxall's paper, Dr. Meyer, of Copenhagen, had

published a report of an outbreak of scarlet fever in the Lying-in Hospital of that town. Twenty-one cases were attacked, yet they all ran the usual course of scarlet fever. In support of the view that scarlet fever poison produced septicæmia, not a single case had been noted where this result had been brought about under circumstances where all possibility of septic infection had been excluded.—Dr. BOXALL, in reply, first thanked the Society for the attention bestowed on his paper. He founded his diagnoses on a definite chain of phenomena and not on the rash alone. Turning to the comparative immunity of pregnant and parturient women to scarlatinal infection, he stated that, when Obstetric Assistant at University College Hospital, he visited a recently delivered mother; three of her children lay in her room ill with scarlet fever, and he caught the fever himself, but the woman escaped. He did not deny that the period of incubation might be prolonged in pregnancy, but showed that evidence in favour of the theory was defective. With reference to the severity of scarlet fever in the puerperal state, Dr. Boxall referred to the Collective Investigation Report as evidence of unusually severe cases. He recognised that the cases in his series were of a mild type with one exception, and stated that during the same epidemic, three cases occurred in private patients, two of whom died of the fever. He did not attribute the severe cases to direct inoculation through the pelvic tissues, and the mild to ordinary infection, nor did he believe that of necessity the two forms represented two really distinct diseases. He reminded the Society that very great variations in the character of the fever were well known to exist in children, in men, and in women neither pregnant nor parturient, and until these varieties were explained, the anomalies which occurred in scarlatina during pregnancy and parturition could not be explained. Turning to the septicæmia question, Dr. Boxall maintained that the direct effect of scarlatinal poison was the production of scarlatina and not septicæmia in lying-in women; but the former, like all fevers, was apt to favour the onset of septicæmia at a subsequent stage. Coincidence was readily explained; scarlet fever could not protect a woman in childbed, but that such an association was none other than accidental was borne out by the fact that when the septic element was eliminated, scarlatina and not septicæmia was the result. The contention of Dr. Playfair that the modification of individual scarlatinal manifestations was contingent on the antiseptic treatment of the puerperal state rather than on that state itself, was disproved by the fact that in cases where no antiseptics had been used similar modifications had been proved to exist. The modification, not absence, of individual symptoms did not amount to masking. Eliminating septicæmia, the influence in the puerperal state which really might mask the symptoms, it might be concluded that scarlatina, whether masked or not, bred true, and did not produce septicæmia. As to prophylaxis, it was wrong to suppose that cleansing the hands was the one essential precaution, for the genital tract did not hold a monopoly for the ingress of scarlatinal poison. Though the precautions recommended in the paper were open to criticism on the score of idealism, they were such as Dr. Boxall had consistently carried out in practice; and, though fully aware that their complete adoption in every case was impracticable, they had been put forward by him as embodying the correct principles of treatment. He had omitted from his paper the bacterial question, for the germs themselves were, so to speak, on probation, and the exact relation of different organisms to scarlatina and to septic diseases were not very precisely determined.

MEDICAL SOCIETY OF LONDON.

MONDAY, APRIL 9TH, 1888.

SIR WILLIAM MAC CORMAC, F.R.C.S., President, in the Chair.

Case of Ulcerative Endocarditis.—Dr. ORD read the notes of a case of ulcerative endocarditis. The patient, a young woman aged 16, had been out of health for several years, but had had neither acute rheumatism, chorea, nor scarlet fever. Her main symptoms were a systolic mitral murmur, increasing in loudness under observation, enlargement of the heart on both sides, and signs of some pericardial effusion, enlargement of the liver and spleen, and dropsy of the lower limbs. The urine never contained any albumen, blood, or other indication of renal mischief. The temperature during her stay in hospital was always high in the evening (102° to 104° or more), and from 97° or 98° to 100° in the morning. She died suddenly of syncope after a little more than three months' stay in hospital, never having had hæmoptysis

nor any sign of mischief in the brain. The differential diagnosis was discussed, and the reasons which led to that of ulcerative endocarditis were stated. The heart, carefully prepared by Mr. Shattock, was exhibited. It showed very extensive lesions of ulcerative endocarditis affecting the mitral valve, and extending far into the left auricle. At the *post-mortem* examination large infarcts, recent and old, were found in the spleen, and both kidneys were greatly enlarged and pitted with the scars of infarcts. Dr. Ord drew attention to the remarkable fact that, while the kidneys were so much diseased, the urine presented no sign thereof till the very day of the patient's death.

On the Pathology of Rheumatism.—Dr. MONEY excused the disjointed nature of his remarks on the ground of the short notice he had received. He observed that they had been taught from time immemorial that rheumatism was especially prone to attack the fibrous and serous structures of the body. While he was not disposed to question that view at present, he was prepared to point out certain other affinities of the disease. The difficulty was to define exactly what they meant by "rheumatism." They were only authorised to term rheumatic phenomena those which had been frequently observed in connection with undoubtedly rheumatic manifestations. He said that if there were one thing more characteristic than another of rheumatism it was the fugitiveness and the mutability, the erratic nature of its manifestations. Another feature was that suppuration was distinctly not a result of rheumatism, and when it did occur it was due to collateral and accidental agencies. To show how little had been done in the way of careful, systematic observation, he instanced the lack of information bearing on the variations of function of the cutaneous structures during attacks of rheumatism. In acute articular rheumatism the sensibility of the skin was usually increased, especially in the neighbourhood of the inflamed articulations, but the power of distinguishing sensations was blunted; moreover, great differences were observed as to this. Complete analgesia had at times been observed, though this had been classed as hysterical. Of all the variations of cutaneous sensibility the most marked was that to faradic electricity, which was often scarcely felt, but this was usually confined to the neighbourhood of the inflamed articulations. He remarked also on the differences which presented themselves in the character of the perspiration during the attacks; that fact alone showed how profound were the functional changes in the skin. He passed in review the eruptive and desquamative phenomena which accompanied some forms of rheumatism. Finally, he alluded to the difficulty there was in demonstrating the effect on the spinal cord in rheumatism, though he inclined to the view that the symptoms were of nervous origin. He suggested that rheumatism might be due to the fact that hyperæmia of fibrous tissues led to more permanent changes than elsewhere, from its subsiding less rapidly.—Sir WILLIAM MAC CONRAC asked Dr. Money whether the curious insensitiveness of the skin over the joints to the faradic current ceased abruptly.—Dr. ORD questioned the idea of a rheumatic poison, and asked what grounds there were for believing this. He concurred in the view that suppuration was not a sequel proper of rheumatism. His own view about rheumatism was that a definite tendency existed in certain people to have inflammations of a particular character; that, when tissues became inflamed in certain individuals, they were inflamed in a particular way—a non-suppurative inflammation. Whether it was by reason of poisons generated in the system, or by the operation of the nervous system, was a difficult question to decide. He thought the cutaneous phenomena pointed in this direction.—Dr. MONEY, in reply, said that the insensibility to the faradic current faded gradually off, which was what one would expect from the nerve supply of the skin. He certainly looked upon rheumatism as the result of a blood-poison, though what the poison was he did not know—possibly sarcolactic acid, acting, not directly on the tissues, but through and by reason of its affinity for, the nerve tissue.

HARVEIAN SOCIETY OF LONDON.

THURSDAY, APRIL 5TH, 1888.

WILLIAM SEDGWICK, M.R.C.S., President, in the Chair.

Fibromyomata Complicating Pregnancy.—Dr. JOHN PHILLIPS read a paper on fibromyomata complicating pregnancy and labour, which chiefly referred to the statistics gathered during the past nine years, and compared them with those found in theses on the subject by Lefour and others. The subject naturally fell under three heads, according as the tumour complicated early

pregnancy with non-viable foetus, pregnancy with viable foetus, including labour, or the puerperium. The uterus was capable of division into three zones, a superior and inferior segment and the cervix. Fibroids of large size or multiple in character arising in the superior segment gave trouble during pregnancy often necessitating interference, while their presence in the two latter situations was sometimes only noticed by the pressure symptoms they produced, as at labour, when they were more or less serious obstacles to the progress of the child, on its way through the pelvis. These could with some propriety be called "dangerous zones," the upper, however, being very little less so during pregnancy, both to maternal and foetal life. Unlike pelvic bony narrowing, it was difficult to fix with any precision the size of a fibrous body which could be called an obstacle to labour. The author had collected fifty-nine cases where some difficulty occurred during pregnancy and labour, but in which abdominal section was not required, and forty-seven in which one or other of the varieties of that operation was performed. Special attention was devoted to myotomy in pregnancy, five cases being noted with a mortality of 60 per cent. In Müller's ablation or "abdominal section with removal of the tumour and the uterus containing the non-viable foetus," nineteen cases were recorded with a mortality of 36.8 per cent. Analyses of each case were given in a table, special attention being paid to the reasons for the operation. The author then alluded to induction of premature labour, and related two fatal cases in his own practice, illustrating the remarks with diagrams. Forcible reposition was mentioned, and a warning given of the great dangers which accompanied it. A case of Casarean section was briefly related where a fibroid tumour filled up nearly the whole of the pelvis, and the Porro-Casarean operation was impossible. The various salient points arising during the operation were touched upon, and it was thought that the case was one with which present resources could not cope. The results of twelve other cases were given, and thirteen Porro-Casarean operations occurring in the past eight years, the mortality being the same. The author, in concluding, directed attention to a table showing the very high mortality consequent on forceps version and embryotomy in these cases.—Dr. BRAXTON HICKS thought each case must be taken on its merits. A fibroid of the uterus added greatly to the dangers of pregnancy, especially when situated near the cervix. The tumours frequently got out of the way towards the later stages, and, therefore, he was accustomed to wait and watch. During pregnancy fibroids grew very rapidly, and might entirely block the pelvis. Reposition was sometimes advisable, and, also, tumours near the cervix were always easy to enucleate. Retention of the placenta was another danger caused by fibroids.—Dr. CHAMPNEYS said it was difficult to obtain accurate statistics, rare and fatal cases being alone recorded. Twin pregnancies seemed frequent in cases of fibroids, and these tumours increased the dangers of pregnancy so much, that marriage was to be deprecated. Tumours situated in the posterior wall were the most likely to be attended with ill results, and were less often raised out of the pelvis; hydrostatic pressure, however, often achieved that result. His own cases of version had been successful.—Dr. BANTOCK considered there was great risk of hemorrhage when endeavours were made to replace the tumours. He would generally prefer Porro's operation, which would also obviate any risk of pregnancy. He had three times removed the uterus for fibroids in which it was found that pregnancy was present.—Dr. CORBYN commented upon the dangers of fibroids in pregnancy. Two cases he had watched had been fatal.—Dr. HANDFIELD-JONES emphasised the risks of forcible reposition, and thought the proceeding was seldom justifiable, more especially as there was often adhesion between the tumours and important vessels, and because the endeavour caused bruising of the fibroids. He was inclined to prefer Porro's operation. After Casarean section the uterine wound had been known to give way.—Drs. ROUTH and ALDERSON also joined in the discussion.—Dr. PHILLIPS, in reply, said version was contra-indicated.

BRITISH GYNÆCOLOGICAL SOCIETY.

MARCH 14TH AND 28TH, 1888.

ARTHUR W. EDIS, M.D., F.R.C.P., President, in the Chair.

Electrolysis of Uterine Fibroid, and subsequent Hysterectomy.—Dr. RICHARD T. SMITH exhibited a fibrous tumour of the uterus, removed fifteen days previously by abdominal section. The patient had been suffering from menorrhagia for four years, and

Apostoli's treatment had been carefully carried out. The uterus became very hard, and remained for about twenty-four hours in a state of contraction after each application. He had sent the patient away for three months to see if any benefit accrued, but she returned about a month previously almost dying from loss of blood. The tumour, which was a soft fibroma, rose to three inches above the umbilicus, and as the patient was unmarried and the parts narrow, he was of opinion that if they had attempted to enucleate the tumour they would have lost her. She made a good recovery.—Mr. A. H. REEVES also exhibited a uterine fibroid, which he had removed from a single woman, aged 41, who had undergone the Apostoli treatment without benefit. The tumour in question was pedunculated and impacted in the pelvis. The pedicle was twisted, and the tumour intensely congested and filled with clotted blood. He thought that the electrical treatment, when unsuccessful, might lead to the loss of valuable time. In that case he had removed the tumour after two attacks of peritonitis, and he thought the patient might have recovered had he operated in the first instance. Hysterectomy was a very dangerous operation, and for that reason they ought to give the electrical treatment fair play.

The Action of the Constant Current on Uterine Fibromata.—Dr. J. INGLIS PARSONS read this paper. He thought it was too early to come to any conclusion on the success or non-success of this method of treatment, therefore he had endeavoured to ascertain by experiments how the electricity acted. Electrolysis was found to cause three distinct effects: (1) a decomposition, partial or entire, of certain molecules; (2) a local action at each pole, caused by the collection of acids and bases resulting from this decomposition; (3) the transport of elements through the tissues traversed by the current. Three different experiments were devised to ascertain whether decomposition took place only at the poles or throughout the tissues traversed by the current. The result in each case showed that it only took place at the poles. The electrode, therefore, must come in contact with the tumour to produce decomposition. The chemical action at each pole could be utilised or abolished by varying the method of application. It also explained the different effects produced by each pole, and was entirely local. The positive was, if anything, found by numerous experiments to be more destructive than the negative pole. The third action—the transport of elements—became an important factor when the complex molecule of albumin was split up at the poles. It probably had a modifying influence on the cells of tumours, as they could not recuperate so well as the normal cells of the body. After several experiments the author found it impossible to introduce substances into the body in this way, as described by Munk, Legros, and others. By observing the vessels of the retina on several occasions during the passage of a current, and also the circulation in the frog's foot, the author did not think that any change took place in the vessels, except a local hyperemia due to chemical action at each pole. There appeared to be no contraction of the uterus during the passage of the current, except at the make and break. The author used a large metal electrode with several layers of damp linen; this answered quite as well as clay, and was much less troublesome. He did not agree with Apostoli in laying down a definite rule for the number of applications; each case must be taken on its merits. On one occasion he had given 250 milliamperes for thirty minutes every other day without ill result.—Dr. G. GRANVILLE BANTOCK was much gratified that Dr. Parsons's paper confirmed the views he had formed after a careful consideration of all the evidence. It was only reasonable to expect that any new method of treatment should, if not uniformly successful, at least show a goodly majority of successful results. In this it had completely failed. He admitted the local caustic action of the current. Hemorrhage might be arrested in cases of so-called granular degeneration of the endometrium, so common in association with fibroid tumours, as the result of the destruction of those granulations by that caustic action. But, he contended, where the granular disease was extensive, it was far better to remove the whole at one sitting by means of the curette than by the galvanic chemo-caustic process frequently repeated. Certainly it would be more expeditious. He admitted the production of muscular contractions of the uterus under the influence of the continuous current, but they were only temporary. The action of ergot was of a similar nature. In conjunction with the perchloride of iron the latter remedy was often most beneficial. Apostoli himself only claimed an amelioration of symptoms, and had never seen a tumour disappear under his treatment. Apostoli and his followers had found it necessary to

shift their ground in self-defence, a sure sign of a failing cause. They had recognised the inefficiency of their former method, and now found it necessary to thrust one of the electrodes into the tumour itself; still, they clung to the theory of electrolytic action. The late Dr. Greenbalgh had employed the actual cautery in a similar way, thrusting it into the substance of the tumour through the vagina. There was no essential difference in the principle of the two methods. The object of both was to bring about the destruction of the integrity of the tumour, and the practice might be said to be founded on what was now a well-known fact—namely, that if you could once start the degenerative process in a fibroid tumour, either the active and dangerous process of sloughing or the more gradual and innocent process of absorption, that process would go on until the tumour was ultimately got rid of. It was, however, impossible to control the process.—Dr. HEYWOOD SMITH said that fibroids were exogenous and not endogenous growths starting from a central point. They were therefore buried in the contractile tissue of the uterus, and it was to this external ring that they had to look for the source of absorption. How was absorption to take place if the electrodes were introduced into the centre of the mass?—Dr. FANCOURT BARNES said he had had two cases in his wards treated by this method. In the first case there was a fibroid tumour reaching nearly up to the umbilicus. After many weeks of suffering the tumour disappeared, and she left the hospital. In the second case also the tumour was much smaller, but the patient's sufferings had been great, and she declined further treatment. Comparing the results with those obtained by removal of the appendages, he much preferred the latter.—Dr. MAXWELL MOLLIN said it was not generally understood that electrolysis implied destruction; the word itself had that signification. It was impossible for electrolysis to take place in living tissue. There was no such thing as a modified electrolytic action taking place at a distance from and between the electrodes. Supposing, for the sake of argument, that such action did take place, how was it that the current picked out the morbid tissues only? Dr. Parsons's theory that it was in consequence of the lower vitality of the morbid cell growth, which was influenced in some way by the current, had nothing to support it. In two out of the four cases recently brought before the Society sloughing of the tumour had occurred. He had previously remarked upon the danger from this source, and believed that it was due to the prolonged contraction interfering with the circulation. It was not the result of electrolytic action. Seeing the difficulty of diagnosis, it being in many cases impossible to define the character and position of the fibroid, the treatment was at best essentially empirical.—Dr. AVELING said that electricity could relieve pain, hæmorrhage, and bulk of tumour, the three urgent symptoms for which hysterectomy was performed. If a patient could be thus symptomatically cured, was it not worth trying? He did not agree that there was no electrolytic action between the poles.—Dr. BURFORD raised a protest against the indiscriminate insertion of an unprotected metal rod with currents of high intensity into the uterus. He had lately witnessed the expulsion of the entire cast of the lining mucous membrane of the uterus, which had been in process of discharge for some days. He had also seen a slough detached from the mucous membrane of the cervical canal about the size of a shilling. This had resulted with a current strength of seventy-five milliamperes.—Dr. ROUTH, Mr. LAWSON TAIT, Dr. MACAN, Dr. CHALMERS, Dr. SAVAGE, Dr. STEAVENSON, Dr. RUTHERFORD, Dr. INGLIS, Dr. BEDFORD FENWICK, and the PRESIDENT took part in the discussion.—Dr. INGLIS PARSONS replied.

HUNTERIAN SOCIETY.

WEDNESDAY, MARCH 28TH.

R. CLEMENT LUCAS, B.S., F.R.C.S., President, in the Chair.

Abdominal Puncture in Tympanites.—Dr. R. J. RYLE read a paper on a case of tympanites treated by puncture through the abdominal wall. The patient, a man aged 46, came under treatment in October, 1887, with vomiting, paroxysmal pain, and constipation, of about ten days' duration. Examination of the abdomen showed considerable fulness, but no tumour was felt, and examination by the rectum revealed nothing. Enemata and O'Beirne's tube gave no information. Colotomy was declined, therefore puncture of the intestine to relieve distension was resorted to as the only treatment which promised relief. Eight punctures were made, with considerable relief to the distension, but with the result of setting up an attack of violent peristaltic

contraction about half an hour after it. Three days later it was necessary to puncture again in three places, and two precautions were used to prevent peristalsis, namely, (1) hypodermic injection of morpho-atropine, and (2) use of a larger aspirating needle. A very large quantity of gas was let off. No violent peristalsis followed. Forty-eight hours later the bowels opened. After a fortnight symptoms of obstruction returned, and puncture again became necessary, the same precautions being taken as on the former occasion, and in the course of the following three weeks puncturing was four times repeated. Great temporary relief was gained, but the patient gradually sank and died. A *post-mortem* examination showed an annular stricture of the first part of the rectum, but no evidence of peritonitis or extravasation of feces, and, with the exception of certain small black spots, no trace of the puncture was visible in the wall of the bowel. The points of interest in the diagnosis of this case of chronic obstruction were then discussed; and, secondly, those of the treatment by puncture. As to the latter, the relief afforded by this procedure was of value for three reasons: (1) as checking the respiratory and circulatory difficulties consequent on extreme distension; (2) as diminishing the direct risks of distension, namely, rupture and peritonitis; (3) as favouring the re-establishment of the normal intestinal action. The chief mode, however, in which puncture tended to produce evacuation of the bowel was by exciting brisk peristalsis, and this was a result which, as in the present instance, might require to be guarded against. As to the dangers of intestinal puncture, thinning or ulceration of some part of the bowel might convert a puncture into a rent, or liquid feces might be conveyed from the needle to the peritoneum. But a much less hypothetical danger seemed to be rupture of the diseased bowel by the violent peristalsis set up by puncturing, or if the puncturing was very free. The reality of this risk was shown (possibly) by the history of a case of Dr. Bristow's recorded in the *Pathological Society's Transactions* for 1872, and still more clearly by a case recorded in 1878 in the *JOURNAL* by Dr. Coupland and Mr. Morris, in which rupture was due to peristalsis caused by puncture. If this view of the danger were correct, the proceeding came to resemble the administration of ergot during labour, and the cases most suitable for the treatment would seem to be those which were known to be characterised by healthy bowel and an absence of insuperable obstruction, such as sometimes occurred in obstetric practice or after abdominal operations. Perhaps, too, as had been suggested by Dr. Galabin, this treatment might be of use in commencing peritonitis. The beneficial effects of simple relief of tension in checking the progress of inflammation were shown in periostitis and cellulitis, and probably a few needle-punctures would be less dangerous than continued distension to the peritoneal coat. From similar considerations he suggested its employment in enteric fever, more especially if, as was probable, excessive peristalsis could be prevented by opium. The specimen was shown at the meeting.

Acute Intestinal Obstruction complicating Utero-gestation.—Mr. CORNER read notes of a case of this kind. The patient, a woman aged 27, who had been married four months, was believed to be four months pregnant; during this period she had much sickness and retching. On November 20th, after a hearty supper, she was seized with great pain and violent vomiting. The bowels acted freely several times. Nothing abnormal was felt in the abdomen, and the uterus was of normal size. Vomiting and pain continued, with constipation. On November 26th chloroform was given, and the rectum, vagina, and abdomen were carefully explored, but nothing unusual detected. On the 27th death took place. On *post-mortem* examination the ileum was found constricted five inches above the cæcum by a thick band of adhesion in the middle line above the pubes. The bowel was completely divided. The peritoneum contained a quantity of fecal material. The specimen was shown at the meeting.—Mr. McCARTHY said that he had seen Mr. Corner's case for the first time the day before death. The diagnosis lay between pregnancy and obstruction. There being nothing to indicate the precise nature of the case, he did not advise operation; and, looking at the nature of the case as revealed after death, had this been performed the bowel would immediately have given way, as it had done on the following day. These cases, if seen early enough, especially in hospital practice, and treated by operation, might terminate in a good result. As to puncture of the intestines, he had employed this method in a gynecological case with great relief.—Dr. PYR-SMITH, in discussing the first case, spoke of the difficulty met with in diagnosis, and thought there was nothing to be gained by the passage of a

long tube up the rectum. It often coiled up, and he believed it to be anatomically impossible for it to pass beyond the second part of the rectum. Then as to the classical description usually given of "pipeelay" motions he thought it questionable if a stricture high up could imprint its form on the feces, but that this condition was usually due to some disease of the anus. Cases in point were then described. On the other hand, there might be a stricture low down with no narrowing of the motions; he therefore considered this condition unreliable. Passing to cases of annular stricture due to malignant disease, chronic in their progress and limited to the large intestine, he thought these ought to be diagnosed and treated by colotomy. Cases of this sort would often allow feces to be passed, and he quoted a case of disease in sigmoid flexure in which arrangements had been made for performing colotomy, which was deferred on account of the passage of liquid feces at the time. Death took place next day. Ulceration in these cases, as in Dr. Ryle's, was markedly absent, in contradistinction to Mr. Corner's case. In all such cases he urged operation. As regarded Mr. Corner's case he expressed regret as to the result; if the case reached the gangrenous stage, he thought that an operation took away the last chance of recovery, and as a result death was frequently put down to its performance. Considering the whole question of operation, the more cases he saw the less he trusted the signs; the signs as taught so often failed. Exploratory operation ended in failure in all his cases he had recently looked up. A more loose method of diagnosis than that usually taught he considered useful, and he classified cases under several headings: 1. Acute obstruction in which (a) operation was followed by a good result, as in cases of hernia; (b) treatment by opium and starvation—some of these recovered. 2. Chronic obstruction, like stricture of rectum, treated by colotomy. 3. Chronic obstruction due to impaction of feces, treated for constipation by enemata (this included also that due to gallstones). He agreed with all Dr. Ryle had said as to puncture. He had performed the operation once to relieve excessive distension, and found that peristalsis was excited. The patient passed some feces, and ultimately recovered. He thought it might be performed with greater freedom, and recommended frequent puncture. The needle, however, should not be allowed to remain in any length of time.—Dr. DUNDAS GRANT gave his experience of two cases of cancer of the rectum low down, in which he had used this method of treatment by puncture with great relief to the patient. He asked Dr. Ryle if he had passed the whole hand into the rectum for the purpose of diagnosis. Typhlitis being sometimes accompanied by fecal vomiting and liable to be mistaken for acute intestinal obstruction, he inquired as to what degree of weight should be attached to this sign.—Dr. GALABIN adverted to the criticism by the *Lancet* on the statements made in his manual as regards the method of treatment in puerperal peritonitis being so fatal, the relief given could only be temporary. He quoted cases of this kind, and also one of intestinal obstruction in which puncture had been used with great relief. He also thought that puncture might be used in cases of extreme distension where there was great trouble about to be experienced in abdominal section. The finest tubes only should be used. He had employed fine puncture for the relief of great distension of intestines which had escaped from the abdomen after ovariectomy: a small drop of feces was noticed at the site of each puncture. Finally, he related a case of acute intestinal obstruction with pregnancy at six months caused by volvulus of the small intestine, which terminated fatally. Nothing was done, the patient being moribund when seen.—Mr. SYMONS discussed the increasing difficulty of diagnosis in intestinal obstruction, and related several cases he had had under his care. He always recommended an exploratory operation in these cases, and the success he had met with was certainly encouraging. The use of large enemata, he thought, did not prove the position of the growth. In cases similar to that of Mr. Corner's, Newton's operation was useful as a method of relief short of abdominal section.—Dr. L. E. SHAW had seen Dr. Ryle's case during the second attack, and thought the case an admirable one for operation. He believed that puncture might always be employed in the first place before the performance of operation for the removal of growth—the method appeared to be so innocuous.—Dr. PRY related a case of puncture of the intestines in a man for obstruction due to strangulation of the ascending colon without relief. Colotomy was subsequently performed. In the majority of cases he believed the colon was not full of gas but feces, as in the case just mentioned. A very valuable method of treatment for the relief of symptoms in intestinal obstruction was to wash out the stomach. So, again,

in enteric fever, might not the contact of micro-organisms with the food form gas? From experiments he had made, it was uncertain whether the colon or small intestine was punctured.—The PRESIDENT thought Dr. Ryle's case a typical one for colotomy, and regretted that the patient could not be persuaded to undergo the operation. In chronic obstruction where the position of the disease was a matter of conjecture, he always advised left-side colotomy, and he related two cases in which patients were relieved in this way. In one case there had been symptoms of chronic disease and complete obstruction for thirteen days. He colotomised on the left side, and found the opening was below the stricture; passing in his finger he felt the disease at the splenic flexure, then turned the patient over, and operated on the right side. This patient was alive nearly three years after the operation. As illustrating the use of puncturing, he referred to a case of Mr. Forster's related in the *Guy's Hospital Reports* for 1868, where the patient lived eighty-eight days after complete obstruction.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, APRIL 6TH, 1888.

C. R. B. KEETLEY, F.R.C.S., President, in the Chair.

Cancer of the Bodies of the Vertebrae.—Mr. ROCHE LYNCH again produced his specimen of cancer or sarcoma of the lumbar vertebrae, which he described at the last meeting (*JOURNAL*, March 10th).—In the adjourned discussion the PRESIDENT observed that he had seen a case of secondary cancer of the vertebrae in which the symptoms had been mistaken for those of hysteria.—Mr. LLOYD had seen a specimen of melanotic sarcoma of the spine. The peculiarity of Mr. Lynch's specimen was that it appeared to be a unique specimen of primary cancer of vertebrae.

Rare Congenital Deformity of the Hands.—Mr. PERCY POTTER showed a man in whom the metacarpal bones were so fused that each hand had the appearance of having but two digits and a thumb.—The PRESIDENT, Mr. ALLINGHAM, Mr. BENHAM, and Dr. MANNING took part in the discussion which followed.

Dermoid Cyst Expelled per Rectum during Labour.—Mr. PRIOR MALLAN related this case and exhibited the specimen. A woman who had had two natural confinements previously was taken in labour, and found to have in the recto-vaginal septum a tumour large enough to obstruct the descent of the child's head. In delivering with forceps the tumour was forced out through the anus. It was found to contain serous fluid and some hair. The patient recovered without any bad symptoms.—The case was discussed by Dr. WELLS, Mr. DUNN, and the PRESIDENT.

Perforation of the Eyeball by the Knot of a Whip.—Mr. PERCY DUNN related the case of an attendant at a hippodrome who felt his eye suddenly cut with, as he supposed, a pebble kicked up by one of the ponies who were being trained. He was admitted to the West London Hospital; and on the following day, there being severe panophthalmitis, Mr. Dunn performed enucleation with the best possible result, the man being made an out-patient at the end of eight days. A curious thing was that the man, when struck, was standing beyond the reach of the whip. Mr. Dunn supposed that the thong had become heated, and the knot, detached, had flown off at great speed. It was found to have pierced the ball just below the horizontal meridian of the corneo-sclerotic junction and to have become embedded in the vitreous humour.—Remarks were made by Mr. LUNN and Mr. LANG.

Calculus in a Tonsil.—Dr. ALDERSON showed a hard concretion, about half an inch in diameter, which had sloughed out of the tonsil of a patient aged 72. There was no history of gout or of a calculous diathesis.—Dr. BALL had seen many calcareous concretions from the tonsils, but not one so dense and brown as this.

Large Wen in the Neck treated by a New Method.—In the case of a wen of old standing, and which extended from the jaw to the clavicle, Mr. KEETLEY (President) had operated in the following manner. Removing an elliptical piece, about three inches by an inch and a half, from the cyst wall, he turned out the contents. He then cleansed the cavity thoroughly, first with carbolic acid, then with corrosive sublimate, and finally with boracic acid. The hole in the cyst was then stitched to the hole in the skin, and the cavity of the cyst was plugged with strips of iodoform gauze, which were removed from time to time. At the end of a month the cyst had almost disappeared. During treatment the head and neck had been kept fixed by a proplastic apparatus, which had probably had much to do with the successful result.

Pathological Specimens.—Mr. JOHN R. LUNN: Cancer of the Oesophagus.—Mr. PERCY DUNN: (1) Cyst of Ovary; (2) Nævoid Condition of Brain; (3) Sarcoma of Uterus; (4) Liver from a Case of Peritonitis following Perforation in Typhoid.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF ANATOMY.

FRIDAY, MARCH 2ND, 1888.

ST. JOHN BROOKS, M.D., President, in the Chair.

Brain-growth and Cranio-cerebral Topography.—Professor CUNNINGHAM exhibited fifteen models of the human head. He stated that for some months past he had been endeavouring to determine the relative degree of growth of the several lobes and convolutions of the cerebrum from infancy up to adult life. It could easily be proved that the movement of increase of the subjacent brain did not correspond with the growth of the component bones of the skull. He quoted Féré and Topinard in support of this view, and gave two examples in which it could easily be seen, namely (1) the frontal eminence which overlay a different portion of the frontal lobe of the brain in the adult and child; and (2) the different relations which were observed between the squamo-parietal suture and the Sylvian fissure as first noticed by Foulhouze. The measurements must be applied to the brain itself, and for this purpose some means must be taken to preserve its volume and configuration absolutely unchanged after the cranium was opened. He was now able to prepare the brain so that when it was exposed *in situ* it would remain absolutely unaltered for at least twenty-four hours. But a further step was necessary. A more extensive comparison between the different brains was necessary than that afforded by columns of figures. It was very essential that the parts of the brain should be fixed and retained in their natural form. For this purpose he had had recourse to models which he had prepared immediately after exposure of the brain. Two models were prepared of each head selected for investigation, namely (a) a model of the head before it was touched; and (b) a model of the same head after it had been prepared and the brain exposed. The brain was exposed on the right side, but narrow bars of the cranial wall were left in the lines of the cranial sutures. The models on the table represented the head of a boy 5 years old, a girl of 11 years, a boy of 12½ years, a youth of 15, two middle-aged women, and two adult men. He then briefly alluded to some of the points concerning brain growth which he had observed, but stated that until he was able to obtain specimens under five years old he did not expect to make much advance. In the antero-posterior direction very little difference was observed in the relative length of the frontal, parietal, and occipital lobes above the age of 5 years. What difference there was could readily be accounted for by individual peculiarities. The temporo-sphenoidal lobe, however, showed some interesting changes as age advanced from childhood to adolescence. It was placed more horizontally in the child; in the adult its tip was turned downwards and inwards, so as to give its long axis a curved direction. Again, its vertical depth in relation to the part of the cerebrum above the Sylvian fissure diminished uniformly and steadily as adolescence and adult life was approached. In discussing whether the relative decrease of the outer surface of this lobe could have any functional significance, Professor Cunningham referred to the recent important investigations of Professor Schäfer upon the temporo-sphenoidal lobe. He also indicated that Dr. Symington had suspected that there was such a decrease in the vertical dimensions of the lobe in question, and had accounted for it on mechanical grounds. The question of cranio-cerebral topography came in as a side-issue to the present investigation. There were two distinct methods by which anatomists had determined the relation of the different parts of the brain to the surface of the head, namely, the sutural, which had been followed out with great exactitude by numerous investigators, and that method whereby, by means of certain lines and measurements made with reference to well-marked prominences, the subjacent brain could be mapped on the surface of the head. The latter plan was the one most interesting to the surgeon, and to it only he would refer. Hare, Seguin, and Reid had each developed a method of this kind. For Hare's method he had nothing but commendation. It was easy of application, and as exact as any such plan could reasonably be expected to be. Reid's method was in some measure a modification of Seguin's, and in so far as the fissure of Rolando was concerned, he had found it most unreliable. In none of his specimens did this fissure coincide with Mr. Reid's lines, and in

one model on the table it would be seen that even a trephine with a diameter of two inches would have failed to expose the upper end of the Rolandic fissure had it been applied according to Mr. Reid's rules. It was a method, further, which, although easy of application to a drawing of a head upon paper, was exceedingly difficult of application on the living head.—The PRESIDENT said Professor Cunningham's communication was of great practical utility, especially as it appeared that Reid's method was the one that was regularly taught in many schools. Now that cerebral surgery was beginning to make remarkable strides, the localisation of the different portions of the brain in relation to the outside became of more and more importance, and therefore the confirmation of the results obtained by Hare was of corresponding importance. Hare's method differed from Professor Cunningham's as consisting in removing the whole side of the skull, while Professor Cunningham left bridges of bone along the line of the suture. In another respect, also, their methods differed. Hare used no special hardening method, while Professor Cunningham hardened the brain *in situ* with absolutely no shrinking, so that when the skull-cap was removed the cerebral convolutions were seen tightly applied to the dura mater. At the same time, the results showed remarkable uniformity. Hare was of opinion that the hardening tended more or less to displace the brain and make it shrink. He was also averse to freezing the brain, because when the brain was frozen, unless special means were taken, it was inclined to thaw and become more diffident than ever. What he relied upon was to get the subjects as fresh as possible. He examined them thirty hours after death.—Mr. THOMSON, Rev. Dr. HAUGHTON, Dr. FOY, Dr. NIXON, Mr. SWANZY, and Mr. BENNETT, took part in the discussion.—Professor CUNNINGHAM, in reply to Sir WILLIAM STOKES, said the paper from which he quoted the results of Professor Schäfer's investigations would be found in the last number of *Brain*; and his experiments consisted in removing the temporo-sphenoidal lobe on each side. In each case the monkeys he operated on showed no evidence of loss of hearing, tactile sensibility, or taste. His experiments also tended rather to confirm those of Munk, in which complete removal of both occipital lobes led to total blindness.

Sacro-Iliac Joints in a Pregnant Woman.—Professor CUNNINGHAM exhibited a specimen illustrating relaxation of the sacro-iliac joints in a pregnant woman.—The PRESIDENT, Dr. BENNETT, and Dr. FOY joined in the discussion.

Homology and Innervation of the Achselbogen and Pectoralis Quartus, and the Nature of the Lateral Cutaneous Nerve of the Thorax.—Dr. AMBROSE BIRMINGHAM read a paper on this subject. The points sought to be established in the paper were: (1) that pectoralis quartus is a segmented portion of the great pectoral; (2) that *achselbogen* is a derivative of panniculus; (3) that pectoralis quartus is supplied by the internal anterior thoracic; (4) that *achselbogen* is supplied by the internal thoracic; and (5) that the lateral cutaneous nerve of the thorax is the nerve of Wisberg, associated with more or less of the internal thoracic.—The PRESIDENT and Professor CUNNINGHAM made some remarks, and Dr. BIRMINGHAM replied.

History of the Nerve to the Anconeus.—The PRESIDENT read a short paper on this subject. The history of the nerve involved the morphology of the muscle. The anconeus was usually regarded as a part of the triceps which had wandered downwards from the olecranon process to a more distal point on the forearm. For this view of its morphology two reasons were assigned: (1) continuity with the lower fibres of the triceps; and (2) nerve supply. The author had found in a lizard (*Hatteria*) that the anconeus was separated from the triceps, but formed an integral part of the extensor carpi ulnaris; he found also that the "nerve to the anconeus" supplied other muscles as well (for example, supinator brevis), and then joined the posterior interosseous nerve to take part in the innervation of the extensors of the digits. In the alligator he found the extensor carpi ulnaris absent, its place being taken by a large anconeus with a double nerve supply (from the "nerve to anconeus," and the posterior interosseous nerve). In man he had found a similar double supply for the anconeus in two out of four subjects he had examined; this arrangement had been described by Lusohka. He concluded: (1) that the anconeus was to be regarded more as part of the extensor carpi ulnaris than of the triceps; (2) that the "nerve to the anconeus" originally took a large share in the innervation of the muscles on the extensor aspect of the forearm.—Professor CUNNINGHAM made some remarks.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

THURSDAY, MARCH 29TH, 1888.

M. M. DE BARTOLOMÉ, M.D., President, in the Chair.

Cases.—Mr. SNELL showed a boy who had been operated upon for severe ectopia.—Mr. S. ROBERTS showed a boy with hypertrophy of the gums.

Ununited Fracture.—Mr. PYE-SMITH exhibited an instrument he had devised for use in ununited fractures.

Union of Divided Urethra.—Mr. GARRARD related a case in which a man had fallen on a piece of iron and lacerated his perineum from the sphincter ani into the scrotum. The wound penetrated deeply, exposing the base of the bladder, and completely dividing the urethra near the bulbous portion and tearing part of it away. The proximal end was found, and when the silk web catheter had been passed on into the bladder, the divided ends were two inches apart; they were brought together by thin silk sutures, and a syphon tube was attached to the end of the catheter. The catheter was changed about once a week for six weeks, when the urethra was found to be united, and the perineal wound nearly healed. After this a catheter with a sharp curve was occasionally passed and in three months the perineum was entirely healed, and the man could pass his water as well as before.—Remarks were made by Dr. KEELING and the PRESIDENT.

Massage.—Mr. ATKIN read a paper on massage, in which he discussed its value in certain surgical affections. An opinion was expressed of the uselessness of treating scoliosis, flat-foot, bent legs, and rickets generally by jackets, splints, etc., unless the apparatus could constantly be removed and the parts well shampooed. Attention was also drawn to the use of shampooing in curtailing tedious convalescence, as after a surgical operation. Early massage was recommended for sprained joints and muscles, though not to the exclusion of the physiological rest needed for repair. It was also claimed for massage in certain hysterical affection which simulated surgical diseases, and benefit was stated to have been seen from massage in diseases of the anterior part of the eye.—Remarks were made by Mr. KNIGHT, Dr. HUNT, Mr. JEFFREYS, Mr. SNELL, Dr. S. ROBERTS, Dr. S. WHITE, and Mr. JACKSON.

Terebene.—Dr. MARTIN gave brief particulars of three cases of bronchorrhoea, in the treatment of which he found the use of pure terebene most useful. Ten minims was the dose prescribed, and in each case the beneficial action was immediate, progressive, and persistent. Dr. Martin laid stress on the necessity of inquiring into the condition of the kidneys before ordering terebene.—Remarks were made by Mr. SNELL, Mr. BROWNING, Mr. HARGREAVES, and Dr. CLARKE.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.

WEDNESDAY, MARCH 21ST, 1888.

JOHN URQUHART, M.D., Vice-President, in the Chair.

Occlusion of External Auditory Meatus.—Dr. JOHN GORDON showed a boy, aged 11, with complete occlusion of the right auditory meatus, about half an inch from the auricle. The hearing distance for the watch was $\frac{1}{60}$ and bone-conduction was good

on the affected side. With the probe a bony ring could be made out round the meatus at the blind end. Attention had been drawn to the boy seven or eight months ago, when he became deaf from Eustachian obstruction of the left side. Dr. Gordon intended to operate at a later date.

Exhibition of Electric Apparatus.—Dr. GARDEN exhibited a Schall's battery, suitable for all medical and surgical purposes. He showed Leiter's electric rhinoscope, urethral endoscope, and cystoscope, and demonstrated the mode of using the latter by means of an artificial bladder filled with water and containing various minute objects. An electric mouth-illuminator with tongue-depressor, a laryngoscope, and ear speculum were also shown. Dr. Garden also exhibited Schech's handle for the electric cautery, and its adjustment with the electric loop, and a variety of electrodes. All these appliances were worked by means of the Schall's battery.

Congenital Syphilis.—Dr. EDMOND showed a number of pathological specimens of congenital syphilis occurring in a boy aged 7, who was blind, deaf, and dumb; namely, the skull with large perforations in some places and numerous ulcerative depressions, the sites of gummata, amyloid liver filled with calcifying and cheesy gummata of varying size, and amyloid spleen and kidneys. Dr. Edmond also showed a photograph of several beautifully ex-

cut paper models of cattle, horses, deer, rabbits, etc., which the boy had made.—Professor HAMILTON had observed that the brain was the most highly convoluted one he had ever met with almost approaching that of the cetacean.

Case of so-called Spontaneous Combustion.—Dr. MACKENZIE BOOTH described a case which he had met with. It will be published in full in the JOURNAL.

ERRATUM.—In the report of the proceedings of the Sunderland and North Durham Medical Society, published in the JOURNAL of April 7th, page 749, "Post-aural Branchial Fistula" should have been "Post-oral."

REVIEWS AND NOTICES.

ÉTUDE MÉDICO-LÉGALE SUR LES BLESSURES PRODUITES PAR LES ACCIDENTS DE CHEMIN DE FER. Pp. 118. Par le Dr. CH. VIBERT. Expert près le Tribunal de la Seine, etc. Paris: Baillière et Fils, 1888.

As far as we know, this is the first work which has appeared in the French language on the subject of railway injuries. The author of it appears to have had considerable medico-legal experience, and from the titles appended to his name we gather that he holds an appointment as "medical assessor" in the Paris Courts of Justice. He has thus enjoyed the opportunity of viewing a number of cases from a wholly judicial standpoint, free from any necessity, whether imaginary or real, of supporting particular views in or against the interest of any claimant for compensation for personal injuries. From the medico-legal reports, which are to be found *verbatim* in the book, we should say that the author is well worthy of the confidence placed in him in the official position which he holds. It would be well if in this country, also, appointments of a like character were not unknown.

The injuries received in railway accidents are, as we well know, of singular interest; and nowadays, when both claimants and railway companies alike see the disadvantages of litigation, and amicable settlements are much more common than in times gone by, when medical men are, therefore, able to approach these cases in less of the spirit of contending parties, and more in that of calm judicial observation, it is to be hoped that the results of railway injuries may more closely engage the attention of leading neurologists, who have hitherto rather sought to avoid them, for various reasons which it is needless to name; for the consequences of railway injuries fall especially into the category of neurological work, and they derive their chiefest interest from the light which they sometimes throw upon the close and intimate interdependence of mind and body, of psychical and physical being. Fractures and dislocations, wounds and contusions, received in railway accidents do not differ in the least, either in their immediate symptoms or in their after-consequences, from those inflicted in a hundred other ways; nor is there any evidence that the coarser lesions of brain or of spinal cord, or of other parts of the nervous system, have any special consequences when they have been caused by accidents on railways, by the collisions which we commonly understand railway accidents to mean. To the infliction, however, of all, and every form of, injuries in collisions there is frequently added a disturbing element which is commonly, though not invariably, absent from other and more ordinary accidents; and the course of the after-symptoms is often unusual and unexpected, because of the interference with convalescence which any unsettlement of mind, such as may be induced by litigation, by anxiety as to the future, or by delayed arrangement of claim, is pretty sure to entail. As to that which has influence at the time of the accident, it is well known that considerable importance has been attached, and is apparently by Dr. VIBERT himself, to the *branlement*, or vibration, which is supposed to be communicated by, and at the moment of, the collision to every object of, or connected with, the colliding bodies. It has always seemed to us remarkable that this *branlement* should be so partial in its effects, and unaccountable, moreover, that a vibration, generated by the collision and necessarily communicated to, and diffused through, every particle of, or connected with, the colliding bodies, should exercise a great and injurious influence, say, on one individual, while another individual sitting next him should go scot free.

The different effects of railway injuries, apart from gross bodily lesion, have therefore to be sought elsewhere, and we believe that they are to be found in individual idiosyncrasy, one person suffering largely from the fright incidental to the horrors of a railway

collision, another feeling such effects but little, or it may be not at all. And therefore every variety and combination of results may be met with, as for example: (a) severe bodily injury associated with great mental disturbance; (b) severe bodily injury associated with none; (c) great mental disturbance with slight bodily injury; (d) slight bodily injury with little disturbance from fright, or it may be by none at all. By far the largest number of injured persons fall into the third class (c) thus affording some warrant for regarding *branlement* as the real cause of the symptoms so commonly seen, and for diverting attention from, and paying less heed to, the personal element in railway injuries, and for disregarding the fright, that all potent mental disturbance, either immediate or delayed, which calls the personal element into play.

This is not the place to record the ordinary symptoms of injuries of this class; they may be found in works in our own tongue. It may be well, however, once again to point out that the most recent observations upon railway injuries both in this country and in America have tended to show that it is in the brain rather than in the spinal cord we must look for the lesions, if there be any, which underlie the symptoms of railway injuries; and that "railway brain," rather than "railway spine," would be an appropriate term to apply to the congeries of symptoms with which we are familiar. The work before us is of interest from this point of view, in that the cases recorded, related as they are in detail and with the written "medico-legal" opinions about them, are very largely cases of cerebral injury, with symptoms referable to brain lesion or disturbance rather than to lesion or disturbed function of the spinal cord. The experience of the author appears to have been drawn largely, if not exclusively, from the victims of the well-remembered accident at Charenton on September 5th, 1881. The accident was one of the worst description. Eighteen persons were killed on the spot, five died within a few months, twenty-six received very severe bodily injuries, and some eighty others were more or less hurt. The collision itself was of the most truly terrifying nature, for it became known to everyone that the accident was inevitable; the cry of "Sauve qui peut" was raised aloud, and everyone was doomed to pass through a few seconds of the greatest agony and suspense before the crash came. We are not surprised, therefore, to learn that the great majority of persons suffered from profound mental and emotional disturbance, from nightmare and sleeplessness, from involuntary trembling and severe headache, from grave disturbances of nutrition, and that convalescence was slow and prolonged. We should have been glad to have heard more of the after-history of these patients, but nevertheless Dr. Vibert has made good use of their cases by giving a careful and lucid account of the cerebral troubles which are apt to supervene after railway collisions even in cases where there has been no serious bodily injury nor any true concussion of brain. His account in every way confirms the views now held in this country, and we fail to find anything new in the record.

Differences of opinion seem to exist in France as well as here, and in one of his cases we have the *verbatim* reports of the several surgeons who saw the patient. The views entertained by each appear to us to be alike legitimate and warranted by the recorded facts, and they combine to show how much better it is that the judicial tribunal should be assisted in arriving at a just conclusion by the perusal of such reports than by the oral testimony of witnesses in open court, who run the risk of being subjected there to the taunts and questionings of contending counsel, who may easily lose their presence of mind in such circumstances, and who perhaps at the best may have a difficulty in conveying their opinions on medical matters to lay and uneducated ears and minds, whether of judge or jury.

The author has little to say on the subject of exaggeration and imposture, but his remarks thereon, if short, are judicious and well timed. He rightly cautions against the suggestions to patients which lie in leading questions, and he shows that if the detection of downright imposition is not the difficult thing which it is often supposed to be, it nevertheless may be no easy matter to decide whether a person is or is not exaggerating the symptoms of some real, though very trifling, injury. Experience, however, is of the greatest value in enabling a medical man to say whether the indefinable symptoms which have no physical signs, which are purely subjective, and have no other basis than the statements of the patient himself, are or are not genuine. No book, no account of such symptoms, however accurate and clear, can supply the want of experience in such matters, and those who come to the examination of such cases without experience

would always do well to defer to those who have. We write on the assumption that the expert is a perfectly independent and impartial observer, such as Dr. Vibert seems himself to be, whose opinion would be precisely the same, and given in precisely the same words, be the interest what it may, which he is supposed to serve. Men of this kind have done much to rescue cases of railway injury from the opprobrium which once surrounded them, and to place them on a different footing from that which they had when railway injuries and the disputes arising out of them first sprang into prominence, and when neither medical men nor lawyers knew how to deal with them.

Dr. Vibert says next to nothing as to treatment, but yet treatment may do much for these cases of profound general disturbance of the bodily and mental health such as he records, and such as are so often seen after severe railway collision. Treatment it is true is very often useless because of pecuniary disputes, or at any rate is useless until pecuniary disputes are at an end, and it is obvious that these should be put out of the way as soon as possible, so that proper treatment may be brought to bear on those who are really ill, in whom each function is out of order, whose bodily feebleness becomes extreme, who find work impossible, and who provide the suitable soil for the development of all sorts of hypochondriacal or neurokinetic symptoms, with anorexia of the most aggravated kind. It is in cases such as these that the Weir-Mitchell treatment is often of the greatest service, and one at least of Dr. Vibert's own cases would, in our judgment, have derived benefit from it. How difficult it might be to inaugurate such line of treatment for railway injuries, only those who have had experience can tell; but we can speak of its usefulness in many apparently hopeless cases. Treatment may do much for the patient, but wide experience, tact, judgment, and above all good common sense are necessary first of all to unravel and rightly estimate those mysterious symptoms which may be met with after railway injuries; symptoms which often lie on that slippery borderland between genuine neurotic disturbance and the conscious or unconscious simulation of nerve disorders, when, if we may not call him "hysterical"—a phrase we can surely use without thinking of the womb—the patient nevertheless shows distinct "perversion of the ego," and is very prone indeed to develop perverted notions of the relative value of *meum* and *tuum*, especially if the latter be that of a corporate body, without a soul to be saved.

The author has had no personal experience of injuries of the spinal cord, and he has nothing of his own to tell on this subject, but his book nevertheless has in it much that is interesting and instructive, though nothing that is new, on the cerebral and general nervous derangements which follow railway injuries, and we have no doubt that it will be of much use to the medical profession in the country where most of its readers will be found.

THE MEDICO-CHIRURGICAL TARIFFS, prepared for the late Shropshire Ethical Branch of the British Medical Association. By J. STYRAP, M.K.Q.C.P., etc. The Fourth Edition, revised and enlarged. London: H. K. Lewis, 1888.

THE new edition of these valuable *Tariffs* comes not a moment too soon, for it would be a real loss to the profession if they were to be allowed to remain long out of print. Indispensable to the young practitioner, they are of great value to the more experienced for reference in circumstances a little out of the ordinary routine. Two tariffs for the ordinary work of a general practice are given—one, ex- or inclusive of medicine, one fee being named; the other, distinguishing between the fee for advice and the charge for medicine. There is also a tariff of surgical fees for a long list of operations and manipulations. These *Tariffs* are the only authoritative document of the kind in existence in this country, and their general applicability and justice are further shown by the fact that they have been translated into French. The practical value of these *Tariffs*, and the moderate price at which the pamphlet is published, ought to induce every practitioner to possess himself of a copy for reference. To this new edition valuable advice on the question of professional charges to the clergy and to the relatives of members of the medical profession have been added, and carefully considered paragraphs on the circumstances under which an extra fee for prolonged examinations or consultations have been inserted.

The thanks of the profession are due to Dr. STYRAP for the trouble which he has taken to render these tariffs absolutely reliable: he has not spared himself; and we venture to express the hope, which will be warmly reciprocated by many grateful readers,

that the ill-health which has delayed the appearance of this much needed edition being now a thing of the past, he may be enabled to supervise the issue of many more editions in future years.

SEWAGE TREATMENT, PURIFICATION, AND UTILISATION. By J. W. SLATER, F.E.S. Crown 8vo. Whittaker and Co.

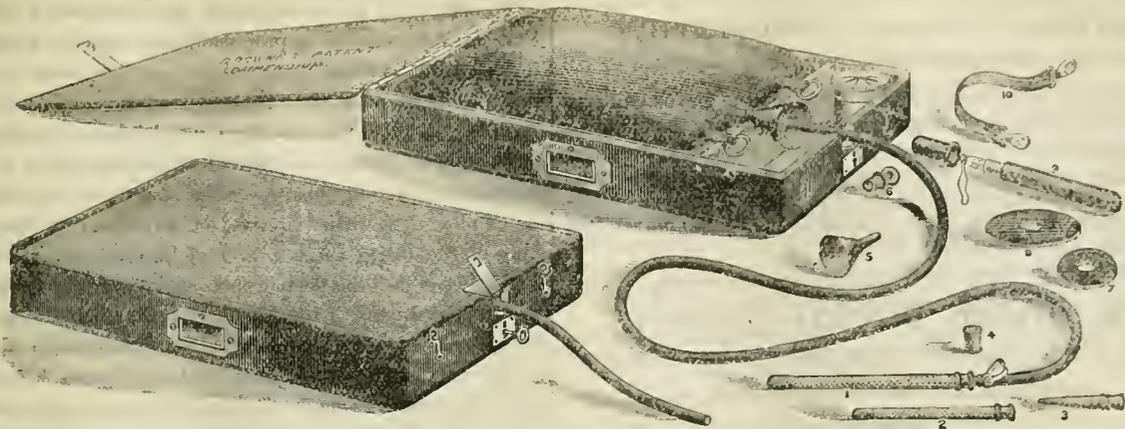

THIS volume appears in the "Specialists' Series," and purports to be a practical manual for the use of corporations, local boards, medical officers of health, inspectors of nuisances, chemists, manufacturers, riparian owners, engineers, and ratepayers. It is, therefore, a work which at any rate aims at appealing to an almost universal class of readers, and it is difficult to understand whether the book is intended for specialists in the disposal of sewage, or whether it is supposed to be written by a specialist in this particular subject. If the latter is the impression intended to be conveyed by the title, we should have been glad to learn with what branch of this very wide subject the author may be regarded to have sufficiently profound acquaintance to entitle him to be thus described. We take it that the author is neither a medical man nor a chemist, it is not our province to decide as to whether he is an engineer. Yet he does not hesitate to discuss the medical and chemical aspects of his subject with a self-confidence and flippancy which would ill-become a veteran in either of these departments of science. The author is a strong advocate of precipitation methods of sewage-treatment, although he is obliged to admit that where a pure effluent is required, it should be supplemented by filtration. But whilst the purest effluent is thus admittedly obtainable by the process of "intermittent downward filtration," the author devotes but ten short pages, principally wasted in irrelevant personalities, to this important subject, whilst a chapter of nearly forty pages is absorbed in discussing processes of precipitation.

Taking, as another instance of the kind of information imparted in this book, the chapter on the detection of sewage pollution—a chapter we take it which is especially addressed to chemists—we find a lengthy disquisition on the evidence afforded by the presence or absence of fish, frogs, and water plants of various kinds, the upshot of which is to show that very little weight is to be attached to such indications. Of chemical or bacteriological methods of detecting sewage pollution, the author appears to have an equally low opinion, but he concludes with "one very simple test, which may be applied to any apparently pure water, is to put a few ounces of the sample in a perfectly clean bottle, close it with a glass stopper, or with a new clean cork, and let it stand for some days at a temperature of 60° to 70° Fahr. If on unstopping the bottle it is found to give off an unpleasant smell, the water must be condemned." This then is supposed to be the limit of our power of diagnosing sewage-polluted water in the year 1888! We cannot help thinking that if the author had taken the trouble to read, mark, learn, and inwardly digest the Blue Books of the 1863 Commission, as well as those of the Commission of 1883, reports which have become the textbooks of the civilised world, he would have compiled a somewhat different volume from the one which we have before us.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS, IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

THE "COMPENDIUM," OR INVALID'S SELF-HELP.

UNDER this name an invention has been registered which seems likely to prove serviceable to invalids requiring a douche for any purpose. A glance at the accompanying illustration will show the chief parts in the apparatus. The central arrangement is a flattened bag made of patent inodorous rubber, which is very durable, and capable of withstanding tropical heat. The bag is filled to any required capacity with water or other liquid, which may be medicated with any required drug, and used at any requisite degree of temperature. A tube, in which is a tap which must at first be closed, is then attached to the bag, and the latter is placed on a spring board in a neatly finished, flattened box, the lid of which is closed on the bag, whilst the tube passes out through an aperture in front. The box being then arranged in any convenient position, the outer free end of the tube is next

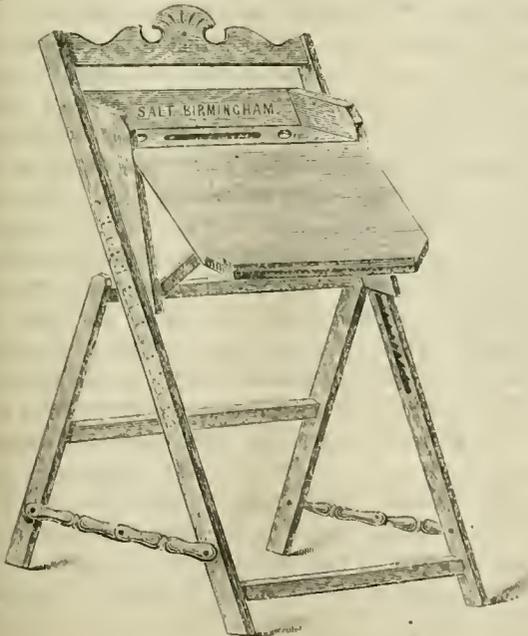

placed *in situ*; and the tap being turned on, the instrument is used. The bag automatically empties itself, and the flow of liquid therefrom is gentle, equable, and easily regulated by the height at which the box is placed, as well as by the degree to which the tap is opened. No effort on the part of the patient is necessary, and the patient may of course be in any convenient position in bedroom, bathroom, or *w.c.* As the liquid in the bag retains its warmth for an hour or two, it may be carried ready for use by doctor or nurse to the patient's house. The "Compendium" may be used as an enema, or as a douche to vagina, ears, nose, or possibly eyes, or for the irrigation of wounds, as bags of any capacity up to two quarts, or even a little more, are made and can be fitted to the instruments. The bags can also be used as hot water bags by screwing in the stopper instead of the efferent tube; and for rectal alimentation the small "Compendiums" appear to be thoroughly adapted.

The apparatus can be purchased (wholesale) of Messrs. A. Hutchinson and Co., 70, Basinghall Street, London, E.C.; of all chemists; and of the inventor and patentee, Miss M. P. Browne, 9, Blandford Square, N.W. The price is one guinea and a half.

SALT'S IMPROVED READING, WRITING, AND DRAWING EASEL.

GREAT and sometimes permanent evils, especially in girls between the ages of 12 and 18, flow from the habit of studying for pro-

longed periods in a cramped and unnatural posture, wherein the head is bent unduly forward, and two or three of the cervical vertebrae

are made to project beyond their proper curve. Much of this evil may be traced to the use of desks whose slope approaches too nearly to the horizontal line, and is incapable of being varied so as to suit the different heights of individual pupils.

Mr. Salt, of Birmingham, has devised a desk or easel (figured below) which appears likely to obviate many of these untoward results; it is eyeable, portable, and inexpensive, and when either folded or expanded for use, forms a pretty and unobtrusive article of furniture.

The flap which is to support the reading, writing, or drawing materials has a bead to prevent them from falling off, and is so arranged that by a pair of quadrant joints, one on either side, it may be raised or lowered from the perpendicular to the horizontal position, or any angle between the two; moreover, by a series of notches, the woodwork carrying the desk can be elevated or depressed, so as to suit the stature of different pupils or the convenience of an individual when sitting or standing. Provision is made for the reception of ink and pens, and the whole apparatus can be folded into a small space so as to be carried.

THE COLLEGE OF STATE MEDICINE.—The following lectures during the summer session will be given in the theatre of the Chemical Society, Burlington House, on Wednesday afternoons, at 1 o'clock:—Introductory lecture, May 2nd, R. Brudenell Carter, F.R.C.S., "The Aims and Objects of State Medicine." May 16th, Professor H. G. Seeley, F.R.S., "Soil in its Influence on Health." May 30th, Inspector-General John M. Macdonald, M.D., F.R.S., "The Organisms occurring in Fresh Water, and the Hygienic Importance of their Presence." June 13th, G. Fleming, Esq., LL.D., C.B., etc., "Some of the more Important Diseases Common to Man and Animals." June 27th, Sir Robert Rawlinson, K.C.B., "The Rise and Progress of Sanitary Engineering within the Present Century." July 11th, Sir J. Crichton Browne, M.D., LL.D., "Responsibility and Disease." All those interested in public health work are invited to be present. Further information appears in our advertising columns, or may be obtained of Surgeon-General Cornish, the Honorary Secretary, 26, King William Street, W.C.

SMALL-POX AMONG THE ARABS.—Some curious details are embodied in a paper by Dr. M. A. Prengueher, of Palestro, on the spread of variola among the Kabyles, a native tribe in Algeria. They practise inoculation by means of an incision between the thumb and the index finger, which not infrequently degenerates into an ulcerated wound, slow to heal, and giving rise to inflammation of the lymphatics and phlegmonous erysipelas. In one instance a native pedlar, on his return from Algiers, developed symptoms of small-pox. Immediately the whole tribe rushed to his tent for the purpose of procuring the material for inoculation, and from this tribe as a starting point the disease rapidly spread among the neighbouring tribes far and wide. Among a population of 13,763, 710 cases of grave and confluent small-pox occurred, with 94 deaths, equivalent to 5.2 per cent. of the inhabitants, and 13.2 per cent. of the cases. Dr. Prengueher recommends compulsory vaccination.

The Medico-Legal Society of New York announce that the time for sending in the competition essays on subjects within the domain of medical jurisprudence or forensic medicine, has been extended to June 1st, 1888.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1888.

SUBSCRIPTIONS to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the West Central District Office, 11gh Holborn.

The British Medical Journal.

SATURDAY, APRIL 14th, 1888.

THE HORSE TAX.

THE proposal of the Chancellor of the Exchequer to impose new duties on horses and vehicles naturally provokes opposition. Taxes which increase the expense of locomotion are not only irksome to those who have to pay them, but they increase the cost of articles—especially heavy ones—which have to be moved from one locality to another. The answer to objections to the proposed new taxes is that the maintenance of roads necessarily involves expenses, which have to be defrayed from some source, and that it is fair that those who use and wear out the roads should contribute to some portion of the cost of their repair. Such an answer is weighty, and it seems impossible to deny that in principle the proposed taxes are fair enough, though their incidence, unless modified, seems likely to be unequal. Many different interests have made themselves heard, each with the object of showing that it is entitled to some relief or exemption, and at present the question as to what exemptions, if any, are to be allowed is still undetermined. We notice, however, with satisfaction that Mr. Goschen seems disposed to view favourably the claims of professional men; and that two classes, namely, country clergymen and doctors, on whom the proposed taxes would press heavily, seem to have a chance of obtaining relief.

It has been rightly urged on their behalf that they use horses not for pleasure, but as a part of the outfit necessary for carrying on their profession, and that a tax on such things is unfair. It is admitted on all hands that things necessarily used in a trade or business should, if possible, be exempt from taxation, and, as regards carts and horses, Mr. Goschen has from the first proposed that those used for farm purposes, though usually heavy, and therefore destructive to the roads, should be untaxed. The case for the county doctor seems at least as strong. There his vehicle is used to convey not goods but himself, but he is required to travel for the benefit of other people, and his carriage, being light, does not cause very much wear and tear to the roads. Most practitioners, if they had their choice, would probably prefer to be visited by their patients in a consulting-room rather than to be obliged to drive long distances, often in bad weather, to see them at their own homes.

No one, as far as we are aware, has disputed, or can dispute that carriages so used by professional men are not generally used for pleasure, and few would object to their claim to partial, if not total, exemption from the proposed taxes. We are glad to be able to point to a precedent which shows that such claim are legally recognised as valid. By the Income Tax Act of 1853 in assessing the duty chargeable in respect of any public office or employment, "the expenses of travelling in the performance of the duties thereof, and of keeping and maintaining a horse to enable the person chargeable to perform the same, are to be deducted before the income chargeable is ascertained." It is, therefore, clear that in some cases locomotion is considered by law as a matter of expense, to be deducted before a man's earnings are ascertained. In fact, and in the public estimation a doctor's carriage is generally as much a part of his professional outfit as his instruments or his library. According to modern economical science, taxes should not be imposed on such things and we venture to hope that Mr. Goschen will be able to carry out his half expressed intention, and to give to struggling professional men the exemption which they need, and which, on principle, they ought to have.

THERAPEUTIC STUDIES.

IV.—RECENT GERMAN LITERATURE OF CHRONIC GASTRIC DISEASES.

THE recent literature of this still unsettled department of medicine has been lately ably reviewed by Dr. Boas in the *Berliner Klin. Wochenschrift*, Nos. 6 and 7, and the views of the partisans interested in the question are fairly rendered. It appears that the Congress für innere Medizin afforded opportunity for reopening the much disputed question of the absence of free hydrochloric acid from the stomach when there is cancer of that organ. This absence has been asserted by so many clinical observers for many years now that it has become a point of great importance. Cahn at the above-named congress remarked on the unreliability of our present rough tests for HCl compared with the titration method, which never failed to give indications of the presence of HCl. The failure of colour tests to reveal HCl depends, in his opinion, upon the accumulation of the products of digestion and the loss of "eliminative activity." This failure, however, is not constant, for Cahn himself has reported a case of hyper-secretion of acid in pyloric cancer. Riegel, von Noorden, and Sticker hold out for the value of the determination of the presence or absence of HCl in the diagnosis of cancer. Moreover, von Noorden and Honigsmann (*Zeitschr. f. Klin. Med.*, Bd. xiii, H. 1) find that the HCl residue, always found to be present even in cancer when the titration method is employed, is due not to free HCl, but to combinations of the latter with albumens. They, therefore, uphold the value of the colour tests. But another difficulty arises, inasmuch as many observers have proved that HCl may be constantly absent in chronic gastric catarrh also, as well as in atrophy of the gastric mucous membrane. Jaworski and Gluzinsky have reported such cases, also Boas *Deutsche Med. Wochenschr.*, 1887, Nos. 24-26, and

Grundzuch (*Berliner Klin. Wochenschr.*, 1887, No. 30). The latter observer found that HCl was constantly absent from the stomach in five out of more than a hundred non-cancerous persons. Wolf and Ewald (*Ibid.*, No. 30) strike a still stronger blow against the theory that the absence of HCl from the stomach is pathognomonic of cancer. In eight persons—some quite healthy, others with only slight gastric disturbance—they found that free HCl was constantly absent, and even the administration of this acid made no difference.

Turning now to the colour tests of HCl, of which there are a great many, Congo-red is declared by Riegel to be a perfectly satisfactory preliminary test; Günzburg advocates phloroglucin-vanillin; and Boas prefers tropæolin paper. But here, again, there is a great disagreement, for Günzburg maintains (*Centrall. f. Klin. Med.*, 1887, No. 40) that the usual colour tests, namely, gentian violet, tropæolin, and Congo-red, are affected by the organic acids also in various degrees of concentration, and Boas specifically states that a 0.03 per cent. lactic acid solution will cause a weak but distinct blue in Congo-red paper. Arlt (*Ibid.*, 1888, No. 3) and Kuhn (Inaug. Diss. Marburg, 1887) argue that this is only true for a watery solution, but Boas replies that the objection is superfluous, as he only referred to free lactic acid. Boas has had a tropæolin paper prepared which discriminates between HCl and lactic acid, and is declared to be highly satisfactory as to cheapness, simplicity, and distinctness of result. A percentage of HCl even below 0.05 is easily recognised thus, and the presence of even 5 per cent. of organic acids makes no difference. Moreover, the degree of coloration with HCl affords an indication of the quantity of the latter present. Günzburg's test is also extremely sensitive and reliable, but less simple. Two parts of phloroglucin and one of vanillin added to thirty of absolute alcohol give a yellowish-red solution. One drop of this in contact with a trace of a mineral acid gives a fine red coloration, red crystals being precipitated. Organic acids, even when concentrated, do not affect this test. In using it, a few drops of a filtrate of the gastric contents (usually obtained by a sound) are mixed with as many of the test solutions, and the mixture is carefully evaporated over a small flame, a bright red colour appears at the margin of the liquid. The test indicates up to 1-20 per mille of HCl. Or a drop or two of the test solution may be added to a few drops of the unfiltered stomach-contents on a strip of paper. On well warming over a flame the red spot indicating HCl appears; it is not affected by ether. As before said, the absence of HCl in gastric cancer cases is attested by so many different observers as to make this sign of importance diagnostically, notwithstanding that a few cases to the contrary are cited, besides many negative cases, that is, cases in which HCl was found to be absent but in which no cancer was present.

Next in interest to absence of HCl comes hyper-acidity of the stomach. This condition is associated with hyper-secretion of gastric juice, according to Boas, who argues that (1) chronic hyper-secretion without hyper-acidity has never been observed; (2) the subjective symptoms are not the result of excess of the gastric juice, but of its abnormal acidity; if this is removed they

at once cease; (3) in general the two conditions go together, increasing and diminishing *pari passu*. The amount of acid juice in a fasting stomach must be about 100 cubic centimètres to constitute hyper-acidity, according to this observer, who lays great stress on the quantity. Riegel and his disciples, on the other hand, maintain that the two conditions are to be entirely separated from each other; Honigmann, in particular (*Münch. Med. Wochenschr.*, 1887, No. 48), states that there is no connection between them; but both Riegel and Reichmann (*Berlin. Klin. Wochenschr.*, 1887, Nos. 12-16) allow that there are transitions.

Taking hyper-secretion apart from hyper-acidity, Reichmann, who has carefully studied this subject, distinguishes continuous from periodical hyper-secretion. The latter is a symptom of derangement of either the central nervous system (tabes), or the whole nervous system (neurasthenic dyspepsia, hysteria), or else is due to local disturbance of the secretory nerves of the stomach. The *crises gastriques* of Charcot, the periodical vomiting of Leyden, and the gastroxynsia of Rossbach come under this category. The typical hemicrania and periodicity point to a central cause, and not to mere irritation of the stomach from accumulation of juice in the fasting condition, as Reichmann would have it. In such cases the acidity is lower than the normal. As to continuous hyper-secretion, this is a condition quite unexplained as yet, for it is no explanation to say that there is "increased irritability," and "lessened absorption" is not a constant accompaniment of this state.

We come now to the etiology of hyper-acidity of the gastric juice, a condition occupying the foreground in recent investigations. Riegel has constantly found an excess of acid when chronic ulcer of the stomach is present, and maintains that the latter is due to hyper-acidity *per se*. The frequency of this coincidence, though it is not absolutely constant, is asserted by so many other observers—Ewald, Korczynski and Jaworski, van der Welden, Rothschild, and others—that it may be regarded as established. Again, Decker, working in Leube's clinic, has made experiments on dogs by injecting small quantities of hot fluids into the stomach (*Berlin. Klin. Woch.*, 1887, No. 21); in one case an extravasation was produced between the mucous and muscular coats, the mucosa being intact; in another case two typical round ulcers were caused, close to the pylorus. Decker thinks that the continual ingestion of hot substances (including liquids) is the most frequent cause of ulcer, and cites a case in support of this. Ritter has experimented on animals in another way, namely, by direct injury to the gastric mucous membrane (*Zeitschr. für Klin. Med.*, Bd. xv, H. 5, 6), but lesions so caused heal too rapidly, as Cohnheim has shown, to allow of any inference from them to chronic ulcer in man. Ritter and Hirsch have recently asserted that hyper-acidity is by no means so common in gastric ulcer as has been supposed (*Ibid.* Bd. xiii, H. 5), for they found this condition only twice in five cases of ulcer; and Boas has seen two cases with all the symptoms of ulcer, but with normal acidity; these cases, however, he declares are exceptional. The test meals selected by Ritter and Hirsch, namely, egg and milk, are said to be unsuitable for ascertaining

the acidity of the gastric juice, as being highly albuminous; starch is the proper food for this purpose, as the results of Ewald, Sticker, and Boas prove.

As to the final results of excessive acidity, Jaworski (*Münchener Med. Wochenschr.*, 1887, No. 7) has followed up several cases of round ulcer, and found that after several months the formation of acid ceased altogether. Boas observed the same result in dilatation of the stomach, but observes that such cases are exceptional, and that the aim of treatment must be, not the prevention of the gastric secretion, but its regulation.

As to atrophy of the gastric mucous membrane, Ewald, Lewy, and Boas have published cases. The latter mentions sharp radiating pains in the epigastrium as important in the diagnosis, also absence of coagulating ferment (besides absence of hydrochloric acid and pepsine). See *Berliner Klin. Woch.*, 1887, No. 4; *Münchener Med. Wochenschr.*, Nos. 42, 43.

Ewald and Sievers have used salol in the diagnosis of dilatation, as this substance passes unaltered through the stomach (*Therap. Monatsh.*, 1887, August). The presence of salicylic acid in the urine was ascertained in about twenty or thirty minutes after giving salol, and at the latest after an hour, so that its absence for a longer period than this would indicate dilatation of the stomach (from pyloric stenosis). The appearance of salicylic acid in the urine was hastened by faradisation of the gastric region. But Sahli throws a doubt upon the certainty of the salol test by his assertion that fission-fungi can decompose salol—in other words, that fermentative changes in the stomach may cause the destruction of salol within that organ. But such changes always require a considerable time.

SEWERAGE OF MARGATE.

THE inhabitants of Margate have at last been brought face to face with the sewerage question; and a thorough system of tubular drainage, as some people term pipe or brick sewers, has been fully determined upon.

Few people who visit Margate year after year had realised the fact until the light of public opinion had been brought to bear upon it in the press, that the only system of sewerage was the cesspools of hygone days. Visitors, indeed, would naturally seldom think of the subject at all, and even many of the residents only discuss it when it is brought prominently before them, and quickly dismiss it again as distasteful.

As was recently stated in our columns, "the reason why the evils attending the cesspool system have not been fully recognised and remedies applied, is that cesspools afford a ready means of getting rid of a troublesome matter, and being out of sight are out of mind, requiring a positive outbreak of disease from bottled-up gases, which must sooner or later occur, to bring about a change. It is only the remarkable salubrity of Margate, and the cleanliness which so generally prevails, that have up to the present time served to counteract the evil results of the cesspool system."

We therefore heartily congratulate Margate that proper drainage of the town has been finally determined upon, and that the

demands of the visiting public, upon whom the trade and prosperity of the town depend, have been acknowledged. As Dr. Rowe pointed out the other day, the immediate welfare of Margate depends upon two classes of visitors—those who go there for pleasure, and those who go there in search of health. These searchers after invigorating breezes demand efficient sewerage coupled, as it must be, with the absence of all bad smells in the streets, and the certainty of obtaining good drinking-water and pure sea-bathing. These three desiderata are absolutely essential and each of them is as much a *sine quâ non* of Margate in the future as they have been in the past. It therefore behoves the inhabitants to pay special attention to and carefully examine any sewerage scheme which may be submitted to the Corporation, so that no plan may be adopted for the sake of economy, which may prove a worse remedy than the disease itself. Whatever is to be done must be done once and for all, and that which is most suitable to the place and its permanent residents will prove most economical in the long run.

The disposal of the sewage is by far the most difficult part of the whole question; failure here would prove disastrous to the town, and we certainly sympathise with the large body of burgesses who demand a more thorough investigation of the subject at the hands of the Council than this point has yet received. The Council, it would appear, have already to a certain extent pledged themselves to the plans of an engineer—certainly an eminent one—who is brother to the borough surveyor, and who, unfortunately, has declared himself in favour of turning the raw sewage without any purification into the sea at no great distance from the town. The majority of those who have given their attention to the subject, on the other hand, do not relish a scheme which is distinguished by a feature which may detract from the pre-eminence which their town has gained for itself. These burgesses would "draw the attention of the Town Council to the extreme desirability of inviting plans for the sewerage of the borough from other eminent engineers than the one selected, and wish their plans submitted to an independent umpire of well-known repute." Moreover, they are willing to pay for this advantage, even though it would involve an outlay in fees of four times the amount of one. In the case of Margate, which is exceptionally placed, we must confess that we quite agree with this expression of opinion, particularly as the selected engineer recommends a plan which, as we have just said, is objectionable to a great majority of the inhabitants.

Two broad points are involved, and must be met and settled:

1. The turning of the sewage in its crude state into the sea, and
2. The cleansing of it through land before discharging it into the sea.

We consider that there ought to be no hesitation in bringing under review the whole question by the comparison of several schemes embracing other treatment than mere discharge into the sea; for it ought not to be forgotten that Margate is situated on the chalk, the absorptive and purifying powers of which are well known, whilst with regard to the discharge of the crude sewage

into the ocean, not only must the burgesses be satisfied as to the currents never washing it back again on to their bathing-ground, but they must bear in mind that the Metropolitan Board of Works is threatening to discharge some 3,000 tons of sludge daily into the sea, off the Nore, and that if they themselves cause a nuisance from the discharge of their own sewage, they will necessarily be unable to resist what appears likely to prove a gigantic wrong to the North Kent watering places.

Details as to whether compressed air or steam should be used to lift the sewage are at present quite out of place; the disposal question, for which everything else waits, must first of all be settled, and we trust that the judicious proposal of the rate-payers will be immediately acted upon by the authorities of the borough.

MEDICAL OFFICERS OF HEALTH AND THE NEW COUNTY BOARDS.

In the labours of the State Medicine Committee of the British Medical Association, in which Rumsey, W. H. Michael, William Farr, Acland, and A. P. Stewart did so much to prepare the basis and mould the form of the Public Health Act, great stress was laid upon the creation of an "Intermediate Authority," for sanitary administration, such as the County Boards, which at length Mr. Ritchie's Bill will create. One of the chief functions of such an authority is its sanitary function, and one of its most important officers should be a medical officer of health. Nevertheless, Mr. Ritchie, actuated probably by the fear to disturb to the peril of his great measure) the *status quo*, has left the County Council without a medical officer or staff. It is alike in the interests of the medical officers and of the county that the medical officers of health should in future hold their appointments under the County Councils instead of the District Councils, as arranged in the Local Government Bill. We are glad to see that the Council of the Society of Medical Officers of Health are prepared to adopt that view, which we have for so many years advocated; and we trust that means may be found to bring it prominently under notice in the House of Commons on the discussion of the Bill.

We are informed that the Galen Club, Sackville Street, will be opened to members after the first general committee meeting, which is convened for Wednesday next, April 18th. The opening dinner is fixed for Thursday, April 26th, and it is desired that early application be made for tickets.

THE hospital which was founded some time since at Bahia (Brazil) for the treatment of beri-beri has recently been closed, in spite of the protest of the local medical men, who urge that, in view of the rapidly fatal effects of this disease, it is unwise to deprive them of the opportunity of studying its etiology, course, and treatment, all of which are at present enveloped in obscurity.

A NURSING SCHOOL IN CAIRO.

A PROPOSAL to establish a Nurses' Home in Cairo attached to the Kasr-el-Ain Egyptian Hospital, and the introduction of a few trained English nurses to control and educate female native

nurses in the performance of their duties, was submitted to the Khedive by Sir Sydney H. Waterlow during his recent travels in Egypt, and met with ready acceptance by His Highness. The necessary money for this year has been promised by the Minister of the department controlling the hospital, and is to be taken from the Reserve Fund. The scheme is to come into operation at once, and the nurses are to be sent out by Sir Sydney immediately he returns to London, early this month, and they are expected to be on duty by May 1st.

MEDICAL WOMEN IN THE METROPOLIS.

We understand that Miss Macdonald, having passed through the recognised course of a medical school, has been admitted by the Society of Apothecaries to examination for its diploma in medicine, surgery, and midwifery. Subject to the same condition being fulfilled, the Society will henceforth admit any lady to its examination.

EPSOM COLLEGE.

THE Duke of Cambridge will be present at the twenty-fourth festival of the Royal Medical Benevolent College, Epsom, which takes place on Tuesday next at the Hôtel Métropole. Of the success of the festival itself as a social event there has for some time been no doubt, but it may be said that those who are prevented from being present can yet contribute to its success from a financial point of view; and we may remind our readers that Dr. Holman, of Reigate, the Treasurer of the British Medical Association, fills the same responsible office in the Royal Medical Benevolent College also.

PHOTOGRAMS OF THE EYE.

IN the recent (sixtieth) Naturforscherversammlung in Wiesbaden both Dr. Claude du Bois-Reymond and Professor Cohn exhibited photographs of the eye obtained by means of the "lightning" illumination (discovered by Herren J. Goedicke and A. Mieth, Berlin, S.W., Ritterstrasse 74). The illumination is so sudden and fleeting that when it occurs in a chamber in previous absolute darkness, the pupil has not time to contract, and thus the maximal dilatation can be represented on photographs. It is hoped that by appropriate arrangements the retina can be thus photographed during life.

THE HORSE TAX.

PETITIONS against the horse tax and increased carriage tax, have been presented during the week by Mr. H. S. Cross, from Dr. John Johnston; by Mr. R. Donkin, from the practitioners of Tynemouth; by Mr. F. B. Mildmay, from the practitioners of Plympton; by Sir E. Reed, from medical men of Cowbridge; by Viscount Curzon, from Burnham and High Wycombe; by Mr. F. S. Powell, from the Wigan medical profession; by Sir R. Temple, from the medical profession of Evesham; by Mr. T. Milvain, from the medical profession of Durham; and by Mr. Round, from Dr. Nicholls, Clacton-on-Sea.

DEFORMITY OF THE HANDS IN GLASSBLOWERS.

At a meeting of the Académie des Sciences, on March 26th, M. Poncet, of Lyons, drew attention to a peculiar deformity of the hand in glassblowers which, according to him, had never before been noticed. It consists in permanent flexion of the fingers on the hand; the little finger and the ring finger are more bent than the middle one or the index; the thumb is not affected. The flexion is most marked in the second phalanx, which is bent almost at a right angle to the first. The deformity is not, according to M. Poncet, due to fibrous bands, but to retraction of the flexor tendons. The phalangeal joints are more or less deformed, and show a tendency to subluxation. Most glassblowers suffer from this deformity, which as a rule gets steadily worse as long

as they continue working at their trade. The deformity is caused by their having to hold a metal tube, over three feet long and weighing about four pounds, which they have to keep constantly turning with their closed hands. They do this on an average eight hours a day, so that it is not surprising that even after a month or two complete extension of the fingers becomes difficult, and in a short time impossible. The deformity when fully established is permanent. It is known among the workmen themselves by the name of *mains en crochets* (hooked hands).

THE LONDON HOSPITAL.

The Lord Mayor, who was supported by the Duke of Cambridge, presided over a meeting, held on Wednesday last at the Mansion House, in aid of the third quinquennial maintenance appeal for the London Hospital. The Lord Mayor, in the course of his speech, observed that while the hospital was spending £50,000 a year, it had a reliable income of only £16,000. At the close of the meeting the Secretary read a list of subscriptions and donations which had been received or promised amounting to £6,500.

HEREDITARY POLYDACTYLY AND ANOMALY OF DENTITION.

In the Naturforscherversammlung recently held in Wiesbaden, Herr Thomas, of Freiburg, brought forward a case of the above-named anomaly, which derived especial interest from the fact that there was also hereditary malformation of the teeth. Polydactyly had existed for several generations in the father's family, and similarly dentitional anomalies affected the mother's side. Some of the teeth were always wanting, and the primary dentition in many cases persisted for a long time. The offspring combined both kinds of irregularity, for one child, aged 11 years, exhibited, besides polydactyly, only two upper and no lower incisors. Milk teeth were present, and there was a corresponding defective development of the jaw. A brother had six fingers on one hand and seven on the other, also six toes on each foot; one pair of fingers had grown together; all the rest, together with the toes, were separate and well formed; the condition of the teeth in this case is not stated.

GERMAN CONGRESSES.

At the seventh German Medical Congress just held in Wiesbaden, the following papers, amongst others, were read: On Wandering Heart, by Herr Rumpf (Bonn); Experimental Investigations of the Mechanism of Respiration, by Herr Verrieh (Jena); an Address, by Herr Liebreich (Berlin); on Combined Degeneration of the Spinal Cord, by Herr Adamkiewicz (Cracow); Experiments relating to the Dietetics of Digestive Derangements, by Herr Jaworski (Cracow); an Address, by the same; the Treatment of Basedow's Disease, by Herr Stiller (Buda-Pesth); the Diagnosis of Renal Tumours, by the same; the Excretion and Solution of Uric Acid, by Herr Emil Pfeiffer (Wiesbaden); the Pathogenesis of the Epileptic Attack, by Herr Binswanger (Jena); on Cryptogenetic Septic Pyæmia, by Herr Jürgensen (Tübingen).—The seventeenth Congress of the German Surgical Society was opened on April 4th, by Professor von Bergmann, in the Aula of the University of Berlin. Geh.-Rath Professor König was chosen Vice-President of the Congress, and he initiated the scientific proceedings by an Address on the Prognosis of Cancer. Professor Gluck will edit von Langenbeck's Lectures.

THE SPREAD OF INFECTIOUS DISEASES.

At a recent meeting of the Clinical Branch of the Preston Medico-Ethical Society, Dr. J. A. Rigby read a paper on this subject, which contained numerous illustrations derived from his own experience of some of the methods by which infectious diseases are propagated in Preston and its neighbourhood. The Preston Fever

Hospital is only open to those able to pay 10s. 6d. per week for their maintenance; consequently the only means of isolation available for the poorer classes of fever patients is that which can be practised in their own overcrowded houses, with the alternative of their removal to the fever ward of the workhouse, should the guardians be willing to admit them. Naturally the hard-working and deserving poor refuse to be pauperised for what is no fault of their own; and the result is the uncontrolled spread of infectious diseases, which is sufficiently evidenced by the high zymotic death-rate which has been characteristic of Preston for many years. It seems almost incredible that the authorities of a town like Preston, which is notorious for its high general death-rate and the excessive mortality which prevails amongst children under five years of age, should have so long disregarded so ready a means of controlling by isolation the spread of infectious diseases. As Dr. Rigby has pointed out in his paper, "in the case of all dangerous infectious diseases, the State or the municipal authorities ought to be prepared to bear the burden of the expense of protecting the remainder of the people, and not expect the infected people themselves to bear it."

LOOSE BODY IN THE ELBOW-JOINT.

In the *Gazette Médicale de Strasbourg* of April 1st, Dr. G. Bœckel relates a case which is of some interest in connection with views which have recently been expressed as to the nature and mode of origin of loose bodies in joints. The patient, a strong healthy man, aged 45, fell from a ladder on his left elbow. Immediately after the accident he lost all power of movement in the forearm. When he came under Dr. Bœckel's care some two months later, movement was found to be very limited and painful, both pronation and supination being accompanied by grating in the joint. Between the olecranon and the external condyle of the humerus a hard body was felt projecting slightly, which could be moved laterally to the extent of some millimètres. Dr. Bœckel was under the impression that he had to do with a case of old arthritis deformans, which the injury had started into renewed activity by displacing an osteophyte. He cut down on the loose body, and with considerable difficulty removed it, when he was surprised to find that it consisted of half the head, with a small piece of the neck, of the radius. The patient made an excellent recovery, and in three weeks from the date of the operation had so far regained the use of his limb that he was able to do light work with it. Dr. Bœckel said that this was the first case he had met with in which the loose body was a fragment of articular surface broken off by violence, and he took the opportunity of formally recanting a different opinion to which he had recently committed himself on the subject. In fact, less than a year ago (*Gaz. Méd. de Strasbourg*, 1887, No. 11, p. 121) he had maintained that such a mode of origin was inadmissible, the loose body being in all cases formed by vegetations springing from the synovial membrane or the articular cartilage.

THE PHENOMENA OF DEATH BY DROWNING.

At the recent Congress for the Advancement of Science at Oran (Algeria), Dr. Paul Loye brought forward some observations made by him, bearing on the phenomena which precede death by sudden immersion. The first stage of deep inspirations lasts about ten seconds, followed by a reaction caused by the resistance to the entrance of water into the bronchioles. This lasts for a minute and is succeeded by arrest of respiration and loss of consciousness. Finally, the scene closes with four or five respiratory effort—the last. Immersion causes an immediate rise in the blood-pressure, with slowing of the heart-beats. The action of the heart remains slow but strong till death ensues. The pressure gradually lessens, but rises just before death, to fall to zero immediately afterwards. The heart sometimes continues to beat feebly for

April 14, 1888.]

about twenty minutes. The result is the same in animals which have been tracheotomised; the period of respiratory resistance is, therefore, due to the respiratory muscles, and not to spasm of the glottis.

NATIONAL PENSION FUND FOR NURSES.

A FEW words will sum up the finance of this fund. Some people seem to think the annual payments needed to secure pensions and provide against sickness rather heavy. We give at p. 815 the analysis of the figures in some details. Briefly, a pension may be secured on this fund at rates 7 per cent. lower than in the Post Office (Government) annuities. Further, the Government payment is a maximum and devoid of bonuses; the Nurses' Pension Fund gives him as a minimum and will provide bonuses. Further, the Nurses' Pension Fund is wholly "mutual," so that if there should be a surplus the insurers receive the whole benefit. It may be added that the generous donors who have provided the deposit of £20,000 also provide that the dividends thereon shall be devoted to the payment of working expenses; and the Council of managers are unpaid; they comprise the names of leading city authorities as well as eminent medical men. So such opportunity can be again anticipated for women of the nursing profession to provide for themselves by reasonable and moderate payments. The medical profession will, we are convinced, not fail to impress upon those nurses with whom they come in contact the duty of self-help, and the importance of availing themselves of the thoughtful munificence and well-devised administration which is now provided on their behalf. Many medical men, we are glad to see, are taking opportunities of bringing the matter under the notice of the nursing staffs of the hospitals to which they are attached. They could render them to greater service. Hospital committees, it may be pointed out, might provide for their nurses the whole annual sum necessary by instituting a just and useful reform in the external economy of their institutions by providing the nurses with washing free, which would set free for the purpose of providence at least £4 a year for each nurse. Some of the best managed hospitals do this already. Documents may be obtained from the offices of the fund, 18, Old Jewry, E.C.

ANOTHER SPECIAL HOSPITAL SCANDAL.

IT is one of the many lamentable features connected with the multiplication of special hospitals that many of them are the seats of continually recurring dissensions and scandals. Comparatively recently we have had the resignation almost *en masse* of the staff of the Throat Hospital, and the creation of a new special hospital by the dissenters. Then came the Jubilee Hospital suit, and the charges brought against the administration of the St. John's Hospital, following upon various secessions in that staff. We hear now of a fresh incident of a similar kind in connection with the Cancer Hospital. The alleged cause of the trouble is a difference of opinion among the staff as to the performance of a particular operation; but that such differences of opinion should lead to suspensions or dismissals, resignations and legal proceedings are among the peculiarities of the atmosphere which seems to pervade special hospitals, and which tend so often to render them sources of professional discredit. The multiplication of special hospitals has always been regarded in the profession as a source of mischief and danger, and has been more than once the subject of grave protest by leading medical authorities. The frequency with which these disagreeable incidents of administration have attracted public attention will have a good effect if it does something to lessen in the future the multiplication of useless establishments of the kind, and to impress upon the charitable public the necessity for a more stable, sound administration of the minor medical charities, which are so often multiplied without due thought or any real public reason for

existence, but rather in obedience to selfish impulses and to further personal objects. So many of the little hospitals nowadays are created rather for the purpose of the staff than to meet a public necessity or to fill any felt want, that it can hardly be surprising that institutions commenced with egotism should end in disrepute.

THE WOKING CREMATORIUM.

THE Duke of Bedford, the Duke of Westminster, Mr. Arkwright, Mr. Budget, and Mrs. Crawshay have each forwarded a cheque for £100 in furtherance of the erection of a chapel, waiting-rooms, and lodge at the crematorium of the Cremation Society of Great Britain. The proposals and plans for the erection of these desirable buildings at the crematorium were put before the Council of the Society by the President, Sir Henry Thompson, at the meeting of the Society held on Tuesday, at which Sir Spencer Wells, Bart., Dr. Cameron, M.P., Dr. Farquharson, M.P., Sir Douglas Galton, C.B., the Rev. Mr. Haweis, and others were present. It was announced at the same time that, whereas the number of cremations that had taken place at this crematorium up to December was only twenty-five, during the last three months there have been no fewer than eleven cremations. A sum of £5,000 will be required to erect the proposed chapel and waiting-rooms. It is highly satisfactory to note, in the interests of public health, that cremation has made so rapid progress in public favour since the publication of Sir Henry Thompson's last paper on the subject answering the objections urged, and reiterating the many arguments in favour of urn burial. The example of persons of so much social influence and sober judgment will, no doubt, go far to accentuate the rate of progress, and it is much to be hoped that the proposed chapel may be provided by public liberality with as little delay as possible.

"A SEA VOYAGE."

THE prescription "a voyage in a sailing ship" is sometimes too lightly given to patients suffering from pulmonary disorder. Some of the discomforts as well as the actual dangers to such patients, which must be run, are well described in a letter recently addressed to his physician by a medical man in delicate health who sailed for New Zealand last autumn; he says:—

"I think it would be a matter of much importance to point out to medical men how much depends on the ship in sending patients for a long sea voyage. Many of them—London medical men—are quite unaware of the risk and actual hardships that have to be undergone on board sailing ships not purposely fitted up for the comfort of passengers. Most people now travel by steamer, and so but little care is taken regarding the victualling and furnishing of the sailing ships. The hospital ships as they are called—the *Sobraon*, for instance, of the Devitt and Moore line—are, of course, exceptions, and by them invalids should go, or perhaps by the other ships specially fitted for the passenger trade. Besides not carrying food of quality and variety suited to invalids, ordinary ships go much too far south for chest cases. We were for about five weeks between latitude 45° and 47° S., and though it was midsummer the cold was intense, and the heavy sea and wet decks obliged us to keep below for a great part of this time. On one occasion a heavy sea broke over the ship and flooded the saloon and cabin, everything was wet, and for a week or more the place was very damp, and the stove-heat caused constant steam. You may imagine how the invalids suffered. I mention these particulars to enable you to form a judgment of what happens in the usual southern course of the sailing ships. The ships I mentioned above, *Sobraon*, etc., do not go south beyond the Cape, after passing which they at once steer north again, and go to the east in latitude 30° to 40°, so that they never have cold, bleak weather the whole way to Australia. In fact, my experience amounts to this; that invalids lose as much during the latter part of the voyage to New Zealand as they gain by the early part (in the ordinary ships). I am sure you will believe me when I say this is a strictly accurate account. I am not actuated by any feeling of disappointment in my own case, but merely by a desire to warn other invalids of the risks so little known."

A NEW METHOD OF OBTAINING VACCINE LYMPH.

In puncturing vesicles for the purpose of obtaining a supply of lymph for vaccination, there is always some risk of causing an admixture of blood, which is undesirable and even dangerous under certain circumstances. A plan is suggested by Dr. Grigg which obviates this risk, and at the same time practically increases the supply of vaccine material. He drops a little glycerine over the ripe vesicle, and this, by a process of osmosis, withdraws the lymph from its interior without any solution of continuity in the delicate membrane which contains it. The lymph thus obtained appears to be fully as active as ordinary lymph, and failures in primary vaccinations were of extremely rare occurrence. It would seem from Dr. Grigg's observations, which we publish elsewhere, that lymph obtained from very young infants, under a fortnight old, for example, is not only very scanty in amount, but is deficient in power, unsuccessful punctures not infrequently following vaccination with lymph derived from this source. Another point of interest, although it is one which has already been observed by others, is that in cases where only one or two punctures out of several prove successful, it is generally possible to secure a more satisfactory result by reinoculation from those vesicles which remain stationary until the maturation of the second crop, when they all fade away together.

THE EMPEROR OF GERMANY.

WE are informed by special telegram from Charlottenburg that there is no change in the condition of the Emperor's throat. His Majesty's general health, however, has, we regret to learn, suffered to some extent during the past week, owing to his enforced confinement within doors and want of exercise. It is probable also that the cares of State and worries of a more personal kind have somewhat overtaxed the strength of the illustrious sufferer. We are requested to contradict the statement that Dr. Norris Wolfenden visited Berlin professionally; we are informed that he went there on business of a purely private nature. On Monday, April 9th, the Emperor conferred on Sir Morell Mackenzie the Hohenzollern Order of the Second Class and Star, in recognition of his great and distinguished services to His Majesty; Mr. Mark Hovell received the Crown Order, Second Class, at the same time. In handing the insignia of the Order to Sir Morell Mackenzie, the Emperor addressed him in the following significant terms: "When you first came to Berlin I had confidence in you, because you were recommended to me by my German doctors; but I have since learned to appreciate your skill myself. I have much pleasure in giving you this Order, in recognition of your valuable services, and in remembrance of my accession to the throne."

TEA-DRINKING.

THE habit of tea-drinking is becoming more and more thoroughly national in the British islands as the century draws to a close. Eighty years ago, the practice was looked upon as a sign of effeminacy, a well-known patriotic ballad in praise of roast beef lauding the good old days, "ere coffee and tea, and such slip-slops were known." Cobbett, in his *Advice to Young Men*, said, "let me beseech you to resolve to free yourselves from the slavery of the tea-and-coffee and other slop-kettle." He thinks that his model young man should devote to the study of arithmetic one-half of the time "usually wasted over the tea-slops." In 1888 tea-drinking is universal. The poor and the rich have long been tea-drinkers; it is amongst the lower middle classes that the habit has recently spread to so marked a degree. Young men beginning life and the great army of elder men, so well known in great cities, whose duties involve much going about from one quarter of the town to another, are steadily recognising the fact that tea is better than alcohol at lunch. In real society and sham society the "afternoon tea" affords to that beverage the powerful sanc-

tion of fashion. The chief evil of tea-drinking amongst the poor is the practice of taking tea whilst it is very hot, so that it act both directly and indirectly as a cardiac stimulant, causing pleasurable feelings to the drinker, but at the same time irritating the gastric mucous membrane. At the "afternoon tea" of polite society, too much is often consumed by the same person who may pay half a dozen visits before the dinner-hour. Well bred people hate excess, and dislike to be seen eating and drinking, nevertheless they are often automatic in their doings, so that the fact that somebody is sipping tea often causes everybody else in the same room to accept the offer of a cup, which is the simplest, tidiest, and least demonstrative way of refreshing the inner man or woman. The evils of tea-drinking have long been recognised, or, at least, we know certain bad results, though it does not follow that others have not been as yet overlooked. The acute objective symptoms of an overdose of tea are relatively trifling compared with opium-poisoning or alcoholic intoxication yet amongst them is vomiting, and violent sickness under most unfortunate circumstances may be the result of dining or smoking too soon after taking tea. This accident may happen even to a strong-stomached person, at a "high tea," "severe tea," or "tea-dinner," for, as Dr. Lauder Brunton has shown, the tannin of the tea interferes with the digestion of fresh meat, whilst Dr. J. W. Fraser has observed that it does not interfere with the digestion of ham, tongue, and other cured and dried flesh. Hence a slice of tongue is better than a cut off the best joint at a "high tea," as at breakfast. Again, severe and intractable dyspepsia may follow tea-drinking, especially between lunch and dinner. Under these circumstances the tannin and the special alkaloid of tea mix with the half-digested food and gastric juice, the products of this abnormal mixture remaining till food is swallowed at dinner, or at least irritating the stomach so as to render it unprepared for the digestion of a good dinner. Several living physicians have shown, on the evidence of experience and of chemistry, that tea cannot be served up free from tannin, even if it be filtered during the process of infusion, like coffee, and poured into a teapot free from leaves. What distant evil effects may be caused by tea-drinking, physicians have not yet determined. Yet we know that it often sets up dyspepsia, which may cause several deadly visceral disorders; it also impedes assimilation, and the resistance to cold. More interesting is the question as to whether it may not induce disease of the circulatory organs by affecting the blood-pressure. On the nervous system, both as understood by physiologists and by hypochondriacs, the habit may exercise a very bad influence. A true tea-vice is not unknown; even certain business men feel, at five o'clock, an irresistible desire to break off important duties in favour of the tea-cup. In hysterical subjects this vice is often a most serious symptom. Though tea too soon before dinner causes dyspepsia, dinner [unexpectedly delayed for many hours after a heavy draught of tea, sets up in some persons very severe nervous symptoms, especially marked by tremulousness and an inability to keep the attention fixed on any subject of duty, pleasure, or conversation. In short, the rules of all things in due season, and not too much of anything, apply to tea quite as much as to flesh diet and to alcohol.

POSITION OF SANITARY INSPECTORS.

WE are glad to see sanitary inspectors recognising the importance of their duties, but there are occasions when they appear to claim a position which is not accorded them by law, and which their previous training does not fit them to occupy. Thus, Mr. C. Eason, of Tottenham, recently read a paper before the Association of Sanitary Inspectors, in which he is reported to have said that the inspector "must be a clerk; must know something of trades, manufactures, and furnaces; must have practical knowledge and be a judge of the quality of articles of food sold by butchers,

culterers, fishmongers, fruiterers, greengrocers, millers, bakers, and dairymen; must have a fair knowledge of plumbing and of building construction, and should, withal, know something of chemistry, and of the diagnosis of zymotic diseases." Perhaps Mr. Eason could not have adopted a better course if he had desired to make his claim ridiculous. The diagnosis of zymotic diseases is often one of the most difficult duties that has to be undertaken by medical men, and an error may easily lead to loss of valuable life. To trust this duty to an officer who has had no medical training is, on the face of it, absurd. While Mr. Eason exalts his own functions, he has no high opinion of those of the medical officer of health, for he argued that this officer should be paid by fee, and only called in for expert opinion in special cases where the ordinary sanitary inspector's knowledge fell short. We should not have thought that Mr. Eason would have admitted that the ordinary sanitary inspector's knowledge ever could fall short. Indeed, endowed with such general information, he could surely place not only the medical officer, but the authority beside. It would, indeed, much simplify proceedings if the law were re-arranged to permit Mr. Eason and those who think with him to diminish the authority at such times as they might think necessary. There would be a vast saving of labour if all sanitary administration were entirely in the hands of such competent persons.

SCOTLAND.

THE GLASGOW MEETING OF THE BRITISH MEDICAL ASSOCIATION.

THE magistrates of Glasgow have intimated their readiness to entertain the members of the Association present at the approaching meeting in Glasgow, at a *conversazione* in the Corporation Galleries, and also to grant every facility for the visitation of any of the works or buildings connected with the municipality, or which they have an interest.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

At the meeting of the Edinburgh Medico-Chirurgical Society on April 4th, 1888, Professor T. R. Fraser showed a female patient presenting the interesting condition of inversion of the abdominal and visceral organs. Papers were read by Dr. W. W. Ireland, on a case of Cerebral Injury from a Fall, and by Dr. G. Dods, on Tropical Malaria and its Sequelæ.

PROFESSOR RUTHERFORD.

PROFESSOR RUTHERFORD, of Edinburgh University, whose return was anticipated for the conduct of the Second Professional Examination, still remains absent. Dr. Caton of Liverpool, formerly lecturer in physiology at Edinburgh University, has conducted the examination, in conjunction with Dr. Noël Paton, the present professor.

ROYAL SOCIETY OF EDINBURGH.

At the last meeting of the Royal Society of Edinburgh, a paper by Professor His, of Leipzig, was communicated by Sir William Turner. The paper consisted mainly of a discussion of the principles of animal morphology. The importance of observation was emphasised, as opposed to logical theories and the scholastic methods. Attention was also drawn to the great importance of elementary mechanical considerations in accounting for morphological connections.

NATIONAL REGISTRATION OF PLUMBERS: EDINBURGH BRANCH.

THE movement in furtherance of the National Registration of Plumbers continues to make progress in Edinburgh. Periodical

meetings of the Registration Committee have been held, when applications in considerable numbers have been received and discussed.

DR. THOMAS KEITH AND THE EDINBURGH ROYAL INFIRMARY.

THE managers of the Royal Infirmary of Edinburgh have adopted the following minute regarding Dr. Thomas Keith's retirement from the surgical staff:—"The managers, in accepting with regret the resignation of Dr. Thomas Keith, desire to record their sense of the importance and value of the work which, in conjunction with Mr. Skene Keith, he has done in the wards under his charge. They beg to convey to him their thanks for the skill and success with which he has performed his duties as extra surgeon for the treatment of ovarian diseases, the result of which has been much relief to suffering females, increase of credit to the Royal Infirmary, and enhancement of the reputation of the Edinburgh Surgical School."

ST. MUNGO'S COLLEGE BILL.

A DEPUTATION attended the last meeting of the Town Council, from the managers of the Royal Infirmary, to ask the support of the Council for this Bill now before Parliament. The spokesmen of the deputation, Mr. Hugh Brown, Dr. McVail, and Dr. W. G. Blackie, stated that they did not appear in any antagonistic spirit to the University; they merely desired that a new college should be erected in the east end of the city, to utilise the great amount of material for clinical teaching at present lost, and relieve the enormous classes at the University. Lord Provost King assured the deputation that the arguments would receive the careful attention of the Council. The Trades House, at a special meeting, unanimously agreed to petition Parliament in favour of the Bill.

CITY MANURE AND INFECTION.

DR. PRIDE, of Neilston, read a paper at the Glasgow Philosophical Society on the Spread of Enteric Fever, and possibly Diphtheria, in Rural Districts by the Use of City Manure for Agricultural Purposes. He related a number of cases of enteric fever that had occurred in his neighbourhood, a hilly and healthy district, and attributed them to enteric germs conveyed from the city in manure spread on the hill slopes from which the water used by the patients was collected. He argued also that there was a strong probability of diphtheritic germs being carried by the same means, and suggested the destruction of the city manure in charring furnaces as a remedy.

MEDICO-CHIRURGICAL SOCIETY, GLASGOW.

PROFESSOR GAIRDNER and Dr. Joseph Coats showed three specimens of perforating ulcer of the duodenum near the pylorus, in which an artery was laid open. In one of them stricture of the pylorus was present, and the case resembled cancer of the pylorus. Dr. Coats showed a liver with four hydatid cysts, in one of which true ossification of the cyst wall had occurred. Professor Gairdner showed a man suffering from choreiform spasms of certain facial, cervical, and abdominal muscles. Mr. Clark showed an epithelioma of the penis from a patient aged 25, and reported a case of successful trephining of the skull for abscess of the brain. Dr. Middleton showed sections of the muscles from a case of pseudo-hypertrophic paralysis, and Dr. Pollock showed sections of sebaceous cysts of the eyelids, and of dermoid cysts of the orbit.

THE UNIVERSITIES (SCOTLAND) BILL.

GREAT activity has been aroused by the appearance of the Universities Bill. All the interested parties are indulging in free criticism of the measure. The general result shows an unexpected unanimity of feeling in its favour, which cannot fail to afford

grateful encouragement to its authors. Both the Court and Senatus of Aberdeen University have expressed approval of the Bill, subject to slight modifications in detail. St. Andrews University expresses its satisfaction with the Bill in general. In particular it approves cordially (1) of the enlarged constitution of the University Court, and of the transference to that body of the management of the finance of the universities; (2) of the power given to the Commissioners to incorporate the University and Colleges of St. Andrews into one body, while retaining their position as Colleges within the University; (3) of the proposal to admit women to the teaching and graduation of the universities; and (4) of the affiliation or incorporation of University College, Dundee, with the University of St. Andrews. Opinion in Edinburgh and Glasgow appears to be rather more divided, and a fear has been expressed lest the prestige of the universities may suffer through the proposed affiliation of colleges. Probably Edinburgh and Glasgow Universities will finally adopt some conjoint line of procedure. With a view to further combined action, deputations from the other three universities met representatives of Edinburgh University on Saturday last, under the presidency of Principal Caird, Glasgow. The proceedings were private, but it is understood that a committee, including the Principals of the four Scottish Universities, was nominated, for the purpose of expressing the views of the conference to the Secretary for Scotland, and generally to watch over the interests of the universities. The only expression of determined opposition comes from the Town Council of Edinburgh, who have resolved to petition against the Bill. The chief ground of their objection lies in the re-constitution of the University Court, whereby the influence of the town authorities in university matters is curtailed.

THE GLASGOW UNIVERSITY CLUB.

THIS club has been formed with the design of promoting the reform of the University from within, in order to save her from the less friendly offices of outsiders. The principle of reform laid down in the constitution is expansion within the organisation of the University, and under the control of the University Court; and the constitution goes on to specify the direction which such reform should take, namely, towards enlargement of the University Court, increase of the teaching staff, a wider range of the subjects of study, and closer contact with secondary education in schools, and with the general intellectual life of the country. Other objects of the Club are to aid in securing endowments for new chairs, to promote social union among members of the University, and to hold periodical meetings for the discussion of University subjects. The adoption of a general fee fund, the appointment of junior professors and lecturers, vesting of financial administration in the Court instead of the Senate, and larger representation to the University Council and to public bodies in the Court are suggested as means to the attainment of the objects of the club. The mere mention of these various parts of the constitution of the new Club and of the ideas of its promoters suggests that the indoor reformers are rather late in the day, and that it is not likely, now that the whole machinery of State legislation has been set in motion to accomplish the chief of these purposes by parliamentary enactment, that the movement will be arrested at the call of a few who think reform will be more mildly effected from within. The Club may be useful for promotion of social union among members of the University, supposing such social union to be possible, and useful for the discussion of University topics. The social side of the Club was the one exhibited on April 6th, when the inaugural dinner was held in the Grand Hotel, Glasgow, under the chairmanship of Mr. Jas. A. Campbell, M.P., the Honorary President. In proposing the health of the University, Dr. A. B. McGrigor trusted that they would not seek on the one hand to sink their University into an academy,

nor, on the other hand, turn it into a simple board for conferring degrees. The Club has already a membership of 100.

IRELAND.

Dr. C. H. ROBINSON has been appointed Lecturer on Medical Jurisprudence in the Ledwich School of Medicine.

THE LECTURESHIP ON MEDICAL JURISPRUDENCE, TRINITY COLLEGE.

At a meeting of the Provost and senior Fellows of Trinity College on Saturday, April 7th, Dr. A. Bewley was elected Lecturer on Medical Jurisprudence for the present session. Dr. Bewley was formerly assistant to the Professor of Institutes of Medicine, Dr. Purser, and is Assistant Physician to the Adelaide Hospital. It is stated that the only remuneration will be the class fees.

THE KING AND QUEEN'S COLLEGE OF PHYSICIANS. THE legal proceedings between the College of Physicians and the Apothecaries' Hall have terminated. The plaintiffs having failed to obtain an injunction to restrain the defendants from carrying out an examination conjointly with the College of Surgeons, they have now resolved not to proceed with an appeal to the higher Court. The Apothecaries are thus admitted to be within their rights in the arrangement which they have entered into. It is not impossible that hereafter the Physicians may join in an examination held by the three bodies, but, judging from their present temper, even that is remote. The victory of the Apothecaries is complete, but it is only truth to say that it does not cause general satisfaction, even to those with whom they are now associated. But the error of recognising them, if error it were, was committed too long ago to hope for its correction now.

THE COST OF PAUPER LUNATICS.

A DISPUTE exists at present between the Cork guardians and the governors for the Cork District Lunatic Asylum in reference to the payment for pauper lunatics sent to the asylum by the guardians. The latter have refused to pay for them, but it should be borne in mind that district asylums, though intended for the insane poor, are not necessarily open to every poor lunatic. The Privy Council rules have, as pointed out by Dr. Nugent, all the power of the original Lunacy statute, and give to the governors of the asylum the selection of applicants for admission. Subsequent Acts authorise the direct admission, or by the Lord Lieutenant, the inspectors, and by magistrates, when parties are duly certified to be of unsound mind and dangerous. So far back as 1831, the Cork guardians sought the admission of twenty-five lunatics from the workhouse into the asylum on an engagement to pay £8 per head per annum for each, which sum was less than the cost of their maintenance in the union. This contract was carried out, and also a similar proposal in May, 1835; but, singular to state, the guardians appear disinclined to pay for the last batch of lunatics sent to the asylum from the workhouse.

At a special meeting of the Abbey Parochial Board, Paisley, it was agreed to erect a hospital for the sick poor, capable of receiving one hundred patients.

WITHIN the last few days there has been a serious outbreak of small-pox in Oldham, beginning on Friday morning last with some nine or ten cases sent into the infectious diseases hospital. The number had increased to forty up to Wednesday night.

THE trial of Dr. Middleton for the murder of the gipsy guide who attempted his life at Cordova has resulted in a verdict of acquittal.

DR. MIDWINTER, on the occasion of his leaving Fleet to reside at Penge, was presented with an illuminated address and a handsome silver inkstand, together with a silver-mounted blotting book, as a mark of esteem.

THE REPORT OF THE BROWN INSTITUTION FOR 1887.

Rabies.—The report of Mr. Victor Horsley, the Professor Superintendent to the Committee of the Brown Institution, contains his year the usual interesting details as to the work carried on in the hospital and in the laboratory. The remarkably beneficial effect of the muzzling order and the destruction of stray dogs is again pointed out, only one case having been noted during the year among all the dogs, over one thousand in number, treated at the hospital, and none in the other animals. Distemper, which is generally communicated by the secretions of the air-passages, also very much diminished after the muzzling order was put in force; but the Professor Superintendent anticipates that both will again increase now that the authorities have been compelled to relax their vigilance. The statistics furnished by Lieutenant-Colonel Moorson as to rabies in Lancashire are very striking. In the nine months from January 1st to November 6th, 1887, seventy-five cases of rabies in dogs were reported, thirty-seven persons had been bitten, and nine had died of hydrophobia. On November 6th, 1887, the muzzling order was issued, and in the following three months nine dogs only were reported as having rabies, and no person had been bitten by a rabid dog. Mr. Horsley states that rabies, which is always prevalent in Surrey, is now beginning to work its way into the metropolis, and we can endorse his opinion that it is very greatly to be regretted that a most ignorant sentimentalism has been allowed to throw obstacles in the way of the adoption of universal measures by the Government. A good deal of work has been done in the laboratory in connection with rabies; in the first place, twenty-three cases have been investigated with the view of establishing, by the result of test inoculation of rabbits, whether animals or human beings, supposed to have died from rabies, had really suffered from that disease, these applications came from many parts of the country, and in the case of two cows, one horse, and four human beings, the answer was in the affirmative; of the sixteen dogs it was found that only eleven had died of rabies. The test inoculations, which established conclusively that the malady from which the deer in Richmond Park were dying was rabies were made at the laboratory by the Professor Superintendent, as were also the searches for the Committee on Pasteur's prophylactic, appointed by the Local Government Board in 1886; the report of this committee was fully discussed in these pages on its publication last year. Mr. Dowdeswell has also made a series of experiments on the virus of prophylaxis of rabies, which also bear out M. Pasteur's statements. He brought out the further fact that the issues of an infected animal do not become virulent till towards the close of the incubation period, and failed to find any drug which had any constant effect on the result of infection in the rabbit.

The Medical Department of the Local Government Board.—Several series of experiments were performed for the Local Government Board under the general direction of Dr. Klein; the results, so far as they have yet been made public, were published in the report of the medical officer to the Board, and have already been fully dealt with in these pages.¹

Various Researches by Mr. Ballance and others.—Mr. Ballance's searches with Mr. S. G. Shattock on the presence of micro-organisms in healthy tissues were incidentally stated in a report to the Scientific Grants Committee of the British Medical Association.² It is stated that Mr. Ballance is continuing his researches on the pathology of the ligature of arteries undertaken along with Mr. Walter Edmunds, and has commenced with Mr. Lingard a research on the infectivity of tetanus, and with Dr. Hadden experiments on the motor area of the cortex of monkeys by stimulation and ablation.

Researches on the Central Nervous System.—Dr. Beevor and the Professor Superintendent have made three sets of experiments on the functions of motor areas; a minute analysis of the representation of movements in the so-called motor region of the cortex cerebri has yielded, among other interesting results, the fact that the focus of representation of the great toe is practically as nearly lineated as that of the thumb, and is situated in front of the per end of the fissure of Rolando. This special observation has

already been of use as a guide for the operator in trephining for epilepsy. The same experimenters have ascertained by faradisation of points in the internal capsule that the fibres in it are arranged in the same relative order and position as the centres projected on the cortex cerebri of the same hemisphere. Dr. Mott has made some experiments on the cauda equina in monkeys by limited total destructions; when the posterior roots were thus destroyed a well-marked degeneration of the posterior median columns occurred throughout the cord. In three cases where the anterior roots were destroyed, there ensued not only degeneration of the muscles, but a rarefying osteitis in the ilium, femur, and leg bones.

Portal Thrombosis.—Dr. Wooldridge's curious observations on the artificial production of portal thrombosis, published in the *Proceedings of the Royal Society*, were also made in this laboratory. As has been previously stated in these pages, he has discovered a proteid body in the thymus gland and other situations, which, when injected into the jugular vein of a rabbit, causes death from complete intravascular clotting. In the dog, injection of small quantities leads to thrombosis of the portal vein and hæmorrhagic infarction of the liver. The clot in the portal vein gradually disappears; the hepatic infarctions are succeeded by areas of overgrowth of connective tissue, leading to cirrhosis. The injection of this proteid material, moreover, determines a temporary condition resembling that seen in the hæmorrhagic diathesis, extravasations of blood occurring in any part of the body which may be slightly injured.

Puerperal Fever.—Dr. W. R. Smith has completed a research on puerperal fever, which will shortly be published.

Pathology of Epilepsy.—Magnan showed many years ago that absinthe rendered an animal insensitive to pain, but provoked an epileptic fit. In conjunction with Dr. Hughlings Jackson, Mr. Horsley has made use of this fact to prove that the lowest motor centres were incapable of generating any convulsion. In an etherised animal the spinal cord was divided above the atlas, and artificial respiration maintained. Injection of essence of absinthe into the jugular vein evoked a characteristic epileptic fit entirely limited to muscles innervated from centres above the section.

NATIONAL PENSION FUND FOR NURSES.

THE National Pension Fund, as now constituted, will consist of two classes—members and policy-holders. The members are those who subscribe £2 2s. per annum, or make a single payment of £25, or who are nominated by hospitals and other similar institutions subscribing £5 5s. annually, or making a single payment of £50. The policy-holders will be nurses and hospital officials, who take out policies for annuities or sickness allowances. Under the constitution the members cannot receive any profit, not even interest on their money. All benefit must go to the policy-holders. The business of the fund will be carried on by the Council, and the policy-holders have the right to elect from among themselves eight members to the Council, thus ensuring that their views shall be fully represented. This provision disposes of the criticism which has been heard in some quarters, that the independence of the nurses will be destroyed if they have their affairs managed for them.

The most important question at present is: Are the rates charged safe, and at the same time moderate, when set against the benefits for which they are to be paid? The report of the consulting actuary states the basis on which the rates have been calculated. Setting aside the sickness allowance, the recently published experience of the Government annuitants has been used for the pensions. The policy-holders of the fund will consist mainly of females, and under the rules the pensions will commence at a comparatively early age, 50, 55, and 60. The longevity of such persons is proverbial, and although no doubt the life of nurses is often a hard one, yet when they enter on their pensions they will obtain rest, and then the mortality among them will probably not be greater than the average with their sex. It is interesting to compare the rates of the National Pension Fund so calculated with those charged by Government for precisely the same benefits. The following are the annual premiums in each case for an annuity of £15, to commence at age of 60:

Present Age.	Pension Fund Rate.	Government Rate.
	£ s. d.	£ s. d.
20	1 13 8	2 2 6
25	2 10 0	2 13 9
30	3 5 8	3 10 0

JOURNAL, Vol. ii, 1887, p. 1,296, *et seq.*, The Etiology of Scarlet Fever (Dr. Klein), Mode of Action of Pathogenic Organisms (Dr. Wooldridge), Attenuation of Perchloride of Mercury (Dr. Klein), Tuberculosis of Bone (Dr. Klein and Lingard).
 JOURNAL, vol. ii, 1887, p. 930.

The pension rates fund minimum benefits are then at least seven per cent. lower than the Post Office charges for maximum benefits. Rates are reasonable and moderate, and these figures supply a complete answer to the complaint that the Council are asking more than is necessary and fair. Although very few insurance companies now grant annuities, because the business is unprofitable, yet it is possible that some company might be found willing to compete with the National Pension Fund for business by offering lower, and, therefore relatively unsafe, rates. It must be remembered that Government and insurance companies will pay only the bare pension stipulated for, while the National Pension Fund already has handsome provision for bonuses, and, being a mutual society, all the nurse's savings will be returned to her ultimately with interest.

It has been said that nurses will be pauperised by the bonus element, but the object of the promoters is to encourage thrift and self-reliance; but, recognising the difficulties of the nurses as a body, they ask them to entrust to their keeping such periodical sums as they can afford to invest or save, and it is only the nurse who so exercises self-denial who will reap any advantage from the fund which has been organised to enable her to secure, by her own exertions, a modest competence for her declining years. It is thought that hospital managers and committees who employ nurses will find that this fund, by making the staff of nurses they employ contented and free from anxiety as to the future, introduces an element of permanence and contentment now often wanting. With the view of encouraging the hospitals and kindred institutions to induce their nurses to join the Pension Fund, it has been arranged to give a rebate of 2½ per cent. on all premiums received officially through recognised institutions.

Medical men, who already possess a flourishing fund of their own, are doing much to foster the Nurses' Pension Fund. The medical officers of some institutions have convened meetings of the nursing staff with the view of explaining the objects of this fund, which they hold to afford to nurses an opportunity for good not likely to recur if the present opportunity is lost. It is probable the announcement will very soon be made that one thousand nurses have joined the fund, this being the minimum number that must be reached before the nurses will be able to avail themselves of the munificence of the City princes, who have conditionally given £26,000 as a nucleus for a bonus fund. The office of the Fund is at 38, Old Jewry, E.C.

SOCIETY FOR THE STUDY OF INEBRIETY.

The annual meeting of this Society was held in the rooms of the Medical Society of London, Chandos Street, on Wednesday, April 4th, Dr. Norman Kerr in the chair.

A paper by Mr. Clark Bell, the President of the Medical-Legal Society of New York, on the Medical Jurisprudence of Inebriety, was read by Dr. Joseph Smith. Mr. Clark Bell pointed out as to civil relations that intoxication was regarded by the common law, when complete and characterised by unconsciousness, as a species of insanity. Delirium tremens, which resulted directly from habits of intoxication, was in civil matters considered to be a form of insanity, and this had been repeatedly held by the courts. "It had always been a well-settled rule of law that no person could make a contract binding upon himself while he was wholly deprived of his reason by intoxication. This would be true as to deeds, wills, all instruments and obligations of every kind. This rule was not changed where the intoxication was not procured by the other party to the contract, but was voluntary on the part of the drunkard. An intoxicated person was rendered incompetent as a witness, and the American statute law usually classified such intoxicated persons as lunatics, and the provisions frequently applied similarly to each and both. In the marriage contract the sound general rule had been that if the party was so far intoxicated as not to understand the nature and consequences of the act, this would invalidate the contract. By English law, the Lord Chancellor, as the direct representative of the Crown, had always exercised the right of assuming the custody and control of the persons and estates of all those who, by reason of imbecility or want of understanding, were incapable of taking care of themselves. Writs *de lunatico inquirendo* were issued in cases to inquire whether the party was incapable of conducting his affairs on account of habitual drunkenness. This principle had been exercised and adjudicated upon in Kentucky, in Maryland, Illinois, Indiana, and North Carolina. In many of

the American States the habitual drunkard even was classified and treated under the same provisions and in the same manner as the lunatic and the idiot, notably in Pennsylvania, New Jersey, Maryland, Illinois, New York, and many other States. In New York it had been held by the courts that all contracts made by habitual drunkards who had been so adjudged in proceedings *de lunatico inquirendo* were void, and that the disability continued after the committee had been appointed, even when he was perfectly sober and fully aware of the nature and consequences of his acts. It had also been held that habitual drunkenness being established was *prima facie* evidence of the subject's incapacity to manage his affairs. Medical men should keep in mind the distinction running all through the law between insanity and irresponsibility. The medical view that irresponsibility should follow where insanity exists had nowhere been conceded by the law. Responsibility was a different matter, and this was more severe. Some judges held that intoxication was an aggravation of a criminal offence, but most held that it was simply no excuse. In some cases the frenzy of delirium tremens had exempted from responsibility. The law did not as yet recognise inebriety as a disease.

A paper by Dr. T. D. Crothers, of Hartford, Conn., was read treating of the study of inebriate criminals, in which it was laid down that the medical history of the accused should be first studied, then the crime.

Dr. Arthur Jamison read the recommendations of the New South Wales Intoxicating Drink Inquiry Commission, to the effect that an inebriate home should be opened at the public expense besides a hospital for the treatment of quasi-criminal inebriates the evidence having shown that punishment had been a failure and that inebriety was a disease demanding remedial treatment.

THE REPORT OF THE DIRECTORS OF CONVICT PRISONS FOR THE YEAR 1886-87.

The latest Report of the Directors of Convict Prisons is now before us, and, as usual, the medical statistics present, as judged by the death-rate, an exemplary standard of sanitation. For some reason or another, probably economy, which is the present craze in Government circles, the medical report is much curtailed. It is, however, improved in form: instead of, as heretofore, separate reports from the medical officers of the different prisons, these have been amalgamated and analysed by the head of the Medical Department, and so presented as a whole to the public.

"The chief causes of mortality," so runs the report, "were pulmonary phthisis, 18 cases; and heart disease, 13 cases. It is noteworthy there were but three deaths from acute inflammatory diseases of the respiratory organs, namely, one from acute bronchitis, and two from acute pneumonia. With the exception of a single death from enteric fever at Dartmoor, there were no deaths from any eruptive fever in any convict prison."

This is very satisfactory, and, taken with the death-rate, shows a low mortality. The report does not, however, say whether the single death from typhoid was due to general exemption from the disease, or from the skill of the medical officers in their treatment of an epidemic. The existence or non-existence of important diseases, such as small-pox, diphtheria, acute rheumatism, etc., is passed by in silence; nor are we informed as to the nature and extent of accidental injuries, beyond the fact that one death resulted from a compound fracture of the leg.

Taking, however, the report as it stands, we learn that 11,127 prisoners were accounted for during the year, giving a daily average of 7,573. The entire number of natural deaths (there was one suicide, not included) was 86, giving a death-rate of 11.3 per 1,000, which was slightly in excess of the average, 10.5, of the past eight years.

In analysing the death-return, which is given in satisfactory detail, we find that, of the 86 deaths, only 36 of the patients were or appeared to be, in good health on reception, the remainder being more or less unsound; it is also noticeable that 62, or over 72 per cent., had been previously convicted, in most instances more than once, and in several more than ten times. In two instances, the causes of death being Bright's disease and hepatitis, the unfortunate victims had been convicted each no less than sixteen times, one being at the date of death only 40 years of age, the other, the Bright's case, but 50.

The greater proportion of the deaths from phthisis were at the prime of life or early manhood, ranging from the age of 20 up to

46, only four deaths being recorded at the ages of 50 and upwards, the average of all ages being 36.8.

Turning to the reports, or rather extracts from the reports, of the medical officers themselves, they are meagre in the extreme. We gather, however, that at Chatham there was a mild epidemic of diphtheria in the officers' barracks, which did not spread to the prisoners; and at Portsmouth some cases of typhoid and scarlet fevers, which were also confined to the officers' quarters. According to both these reports there seems to have been an unusual sick and death rate, which is accounted for by the closing of Woking Invalid Prison, referred to in the Directors' report, and consequent distribution of the invalid inmates to these prisons. In the report of the medical officer of Wormwood Scrubs Prison it is not a little amusing to notice the anxiety on account of one possible case of scarlet fever in a prisoner, as compared with the feeling expressed in the relation of the epidemic amongst the warders' children.

On the whole, it is to be regretted that the report is not a little more expansive. It is good as far as it goes, and shows, especially when confirmed by previous experience, that there is nothing in the medical statistics of convict prisons that need fear to see the light. It would add materially to the value of these reports if the medical statistics of the whole establishment were included.

Prisoners are so isolated from external influences that it is difficult to make a useful comparison between them and the community at large; but whilst the prison staff with their families are presumably under the same conditions as the prisoners with regard to house sanitation, ventilation, sewerage, and water supply, they are, as regards age, food, clothing, and risk of contagion or infection, on a par with the rest of the population. If, on investigation, it should turn out that the same high state of sanitation prevails amongst them as within the prison walls, an exemplary proof would be afforded to our sanitary authorities of the necessity for enforced cleanliness and properly-constructed dwellings, with a plentiful supply of fresh air and pure water.

AN APPEAL.

An appeal is now being made to raise a fund sufficient to enable a medical man of good position, who has been reduced to absolute destitution, through no fault of his own, to buy a small practice, and thus make a living for himself and his wife. A good opening at a watering place can be secured at very small cost, and contributions towards the purchase money will be received by Dr. Farquharson, M.P., Migvie Lodge, Porchester Gardens. Amounts already subscribed:

Sir William Jenner, Bart. ...	£ 2 2 0	Sir Andrew Clark, Bart. ...	£ 8 8 0
Sir James Paget, Bart. ...	6 8 0	Dr. Broadbent ...	1 1 0
Sir Joseph Lister, Bart. ...	20 0 0	Dr. Hare ...	1 1 0
Sir Henry Thompson ...	5 0 0	Dr. Farquharson, M.P. ...	1 0 0
Sir Spencer Wells, Bart. ...	1 1 0	British Medical Benevolent Fund ...	5 0 0
Dr. Ramskill ...	4 4 0		

THE CLIFTON LUNACY CASE.

OUR readers are aware that, at the assizes recently held in Bristol, two members of our profession, Dr. Henry Marshall and Dr. J. E. Shaw, of Clifton, were subjected to the annoyance and worry of an action for damages for certifying a lady to be insane. Although they were completely successful in defending their conduct, yet, in addition to the loss of time and anxiety necessarily attendant upon such an action, they are left, on account of the plaintiff's impecuniosity, to pay their own heavy costs.

It has been generally felt by those more especially acquainted with the circumstances that the case is a particularly hard one, and that many members of our profession, any of whom, in the present state of the law, are liable to a similar prosecution in the course of their daily duty, would be glad to contribute towards a fund raised for the purpose of relieving Dr. Marshall and Dr. Shaw to some extent of the heavy pecuniary fine incurred, and at the same time of expressing their sympathy with them in a practical manner.

Dr. E. Long Fox has consented to act as treasurer of the fund, and subscriptions may be forwarded to him at Church House, Clifton, or to either of the undersigned.

J. MICHELL CLARKE, M.B., 2, York Buildings, Clifton } Honorary Secretaries.

ASSOCIATION INTELLIGENCE.

COUNCIL.

NOTICE OF MEETING.

A MEETING of the Council will be held at the Offices of the Association, No. 429, Strand (corner of Ager Street), London, on Wednesday, the 18th day of April next, at 2 o'clock in the afternoon.

The following Committees will also meet:—

Tuesday April 17th, 1888.—Relative Rank Committee, 3 P.M.—Premises and Library Committee, 4 P.M.—Branch Organisation Committee, 4.30 P.M.—Scientific Grants Committee, 5 P.M. Wednesday April 18th, 1888.—Therapeutics Committee, 10 A.M.—Journal and Finance Committee, 11.30 A.M.

FRANCIS FOWKE, General Secretary.

April 11th, 1888.

NOTICE OF QUARTERLY MEETINGS FOR 1888.

ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Meetings of the Council will be held on April 18th, July 18th, and October 17th, 1888. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before each meeting, namely, June 27th, September 26th, and December 28th, 1888.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No member can be elected by a Branch Council unless his name has been inserted in the circular summoning the meeting at which he seeks election.

FRANCIS FOWKE, General Secretary.

COLLECTIVE INVESTIGATION OF DISEASE.

THE Report upon the CONNECTION OF DISEASE WITH HABITS OF INTEMPERANCE, which was presented to the Section of Medicine in the Annual Meeting of 1887 will shortly be published in the JOURNAL.

Reports upon the two remaining inquiries, namely, that into DIPHTHERIA, and that into the GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES, are in preparation, and will be published as soon as ready.

The following inquiry only of the first series remains open, namely, that on the ETIOLOGY OF PHTHISIS.

A fresh inquiry into the ORIGIN AND MODE OF PROPAGATION OF EPIDEMICS OF DIPHTHERIA has been issued.

Memoranda upon these subjects, and forms for recording observations, may be had on application to the Secretary of the Collective Investigation Committee, 429, Strand, W.C.

BRANCH MEETINGS TO BE HELD.

METROPOLITAN COUNTIES BRANCH: EAST LONDON AND SOUTH ESSEX DISTRICT.—The next meeting will be held on Thursday, April 19th, at the Hackney Town Hall, at 8.30 P.M. The chair will be taken by F. M. Corner, Esq. A paper on the Surgery of Abscess will be read by Howard Marsh, Esq. Visitors will be welcome.—J. W. HUNT, 101, Queen's Road, Dalston, Honorary Secretary.

NORTH OF ENGLAND BRANCH.—The spring meeting will be held at the Infirmary, Sunderland, on Wednesday, April 25th, at 3 P.M. Members intending to read papers or show specimens are requested to communicate at once with the secretary. The dinner after the meeting will take place at the Queen's Hotel, at 5 o'clock. The following papers are already promised:—Dr. Hume: A Case of Congenital Fistula of the Stomach, Cured by Operation. Dr. Coley: On the Treatment of Effusion into the Pleura in Children. Dr. Murphy: A Man 229 Days after Gastrotomy. Dr. Oliver: Notes on an Unusual Case of Hematuria. Mr. Morgan will move a Resolution on Quack Advertisements. Mr. Rutherford Morrison will read Notes of two cases of Gall-Stones: (1) Operation on Dilated Gall-Bladder: Removal of Stones: Drainage: Cure. (2) Abdominal Section for Intestinal Obstruction: Discovery of Gall-Stone, Incision and Suture of Intestine and Removal of Stone. Specimens exhibited. Mr. Morgan will show (1) a Girl disfigured by Cancer of the Ovary; (2) specimens from a case of Tubercular Peritonitis simulating Cystic Disease of the Ovary. Dr. Drummond will exhibit some Pathological specimens. Dr. Lindsay will show a patient suffering from Paralytic Agitation.—G. E. WILLIAMSON, F.R.C.S., 22, Eldon Square, Newcastle-on-Tyne, Honorary Secretary.

—ABERDEEN, BANFF, AND KINCARDINE BRANCH.—The April meeting of the Branch will be held at 198, Union Street, Aberdeen, on Wednesday, April 18th, at 8 P.M., the President, Dr. Smith, of Kinnairdy, in the chair. Business: (1) Minutes, nomination of new members, etc. (2) Ballot for the admission of Dr. James Cravie, Newburgh, Aberdeenshire. (3) Exhibition of patient: Case of Senile Chorea, by Dr. Gordon. (4) Motion by Dr. Wight: "That the Branch petition the House of Commons against the taxation of horses of medical practitioners, as proposed by Mr. Goschen in the Budget, and also recommend individual members to use their influence with Members of Parliament to attain the above object." (5) Case of Labour obstructed by Fibroid Tumour of Uterus in Pelvis, by Dr. Aymer, Bervie. (6) Report of Standing Committee on Post-Graduate Courses for 1888, by Dr. Edmond, Convener. (7) Exhibition of specimens: 1. Exhibition of Lungs, with casts, in a state of Chronic Interstitial Pneumonia and Bronchiectasy, by Dr. Gibson. 2. Dissection of Hammer-toe, by Dr. Mackenzie Booth.—ROBERT JOHN GARDNER and J. MACKENZIE BOOTH, Honorary Secretaries.

BORDER COUNTIES BRANCH.—The next meeting of this Branch will be held at Cockerhous on Friday, May 4th, at 3.15 P.M. The Secretary will be glad to receive intimation of papers for reading.—H. A. LEDIARD, 31, Lowther Street, Carlisle, Honorary Secretary.

BATH AND BRISTOL BRANCH.—The fifth ordinary meeting of the Session will be held at the Grand Pump-Room Hotel, Bath, on Thursday, April 19th, at 7.50 P.M., Dr. G. F. Burder, President. A discussion on Diphtheria will be opened with a short paper by Dr. A. B. Hrabazon, Medical Officer of Health, Bath.—R. J. H. SCOTT and E. MARHAM SKERRITT, Honorary Secretaries.

NORTH OF IRELAND BRANCH.—A general meeting of this Branch will be held in the Royal Hospital, Belfast, on Thursday, April 18th, at 11 A.M. Dr. John Strahan will read a paper on Turpentine in Whooping-Cough and some other affections. Dr. O'Neill will show (1) Two patients on whom he operated for Congenital Inguino-Scrotal Hernia (Radical cure), and read notes of the cases. (2) An Ovarian Cyst successfully removed. Professor Sinclair will report upon a Successful Jejunocolic Enteroctomy performed on the day of the last Branch meeting, and exhibit the segment of intestine excised. Dr. Burden will show a series of Microscopic Preparations of Tumours. Dr. Byers will show an Ovarian Tumour which he successfully removed. Dr. Esler will bring forward a communication on Injection of Carbolic Acid in Hydrocele. Dr. Whitla will show a case of Abdominal Aneurysm.—JOHN W. BYERS, M.D., Lower Crescent, Belfast, Honorary Secretary.

SOUTH-EASTERN BRANCH: WEST KENT DISTRICT.—The next meeting of this District will be held at the Hospital, Gravesend, on Friday, April 27th, at 4 P.M., R. J. Bryden, Esq., in the chair. The dinner will take place at the New Falcon Hotel at 6.30 P.M. Charge 6s. 6d., exclusive of wine. Gentlemen who intend to dine are particularly requested to signify their intention to the Chairman, R. J. Bryden, Esq., 21, Harmer Street, Gravesend, not later than April 25th. Papers already promised:—Dr. P. Horrocks: On Puerperal Fever. Dr. Tanoahill: On Symmetrical Gangrene. All Members of the South-Eastern Branch are entitled to attend this meeting and to introduce friends.—A. W. NANKIVELL, F.R.C.S., St. Bartholomew's Hospital, Chatham, Honorary Secretary.

OXFORD AND DISTRICT BRANCH.—The next meeting will be held at the Radcliffe Infirmary, Oxford, on Friday, April 27th, at 3 P.M. Notice of papers to be read must be sent to W. Lewis Morgan, 43, Broad Street, Oxford, on or before April 18th. A dinner will be provided for those members who signify their intention to dine to the Secretary two days before the meeting.—S. D. DARBISHIRE and W. LEWIS MORGAN, Honorary Secretaries.

CEYLON BRANCH.

An ordinary meeting was held at the Colonial Medical Library, Colombo, at 2 P.M. on Saturday, January 14th, 1888. The following gentlemen were present: the Hon. Dr. P. D. Anthonisz (in the chair); Drs. Asserappa, Attygalle, Macdonald, Stokes, Vanderstraeten (Hon. Treasurer); Messrs. Aldous, Brito, Eleyatambi,

Fernando, Garvin, Johnson, Schokman, Thornhill, and Keegel (Hon. Secretary).

The minutes of the previous meeting were read and confirmed.

Election of Members.—Mr. THORNHILL drew attention to the irregularity of the election of members at the last meeting, in that the names of members to be elected did not appear on the notice paper. It was decided that the elections be confirmed at the next meeting of the Council.

President's Address.—The Hon. PRESIDENT then delivered his presidential address "On the Progress of British Medicine and Surgery in Ceylon during the last Forty Years."

Mr. THORNHILL proposed a vote of thanks to the President for his address, which was duly carried.

Head Injury.—Mr. FERNANDO, on behalf of Mr. Thomas, of Hambantota, read a paper entitled "Observations on a case of Head Injury, especially as regards Ophthalmoscopic Examinations in such cases."

Postponement of Paper.—A paper by Dr. VAN DORT, entitled "A Translation (with notes) of Dr. Daalmans's Observations of the Diseases of Ceylon and India towards the End of the Seventeenth Century," was postponed to the next meeting for want of time.

The meeting then separated with a vote of thanks to the chair.

A meeting of the Council was held at the Colonial Medical Library, Colombo, at 1 P.M. on Saturday, February 4th, 1888, at which Dr. Van Dort, Vice-President (in the chair), Drs. Loos, Attygalle, Rockwood, Macdonald, Messrs. Van Geysel, Schokman, Thornhill, Nell, and Keegel (Honorary Secretary) were present.

New Members.—The CHAIRMAN proposed, and Dr. MACDONALD seconded, the election of Surgeon-Major Stokes, M.D., M.S., and Mr. W. J. A. Wright, L.C., M.C., to membership of the Parent Association and Local Branch. (Carried.)

New By-laws.—Mr. THORNHILL proposed in terms of notice that the Council, under the authority of By-law 6, pass the following new by-laws:

1. At all elections of members or of officers voting shall be by "voting papers;" such voting papers to be signed and dated by any member of Council voting without being present at the meeting of Council at which the election takes place.

2. That no alteration in the hour, date, or place of meetings, nor any by-law be made or altered, nor any member be elected by the Council, unless written notice of such alteration, or by-law, or election proposed has been sent to each member of Council at least one week before the Council meeting at which such is to be discussed.

3. Council meetings to be held half an hour before each ordinary meeting, and at other times when the President or Vice-President or any two members of Council request.

The second and third by-laws passed *nem. dis.*, but in proposing the first Mr. THORNHILL referred to the wording of the third by-law of the Branch, which required that the election of a member should always take place by the "majority of the whole Council." He felt that this rendered it necessary that the votes of all members of the Council should be recorded, and hence the necessity of giving sufficient notice in order to obtain the votes of all such members as could not arrange to be present.

Dr. Loos, in seconding this motion, said that it was necessary that the tone and character of the Branch should be maintained, inasmuch as this was not an ordinary medical society, but one affiliated to a highly respectable and influential Association. All possible guarantee should be afforded that the election of proper persons would take place in a proper manner. The election should not rest with a few members of the Committee who might find it convenient to attend the meetings in Colombo, but all members of the Council should have the opportunity of voting, and sufficient time for this purpose should be allowed to elapse between proposal and election of new members.

No substantive amendment in Clause 1 was, however, proposed, but the original motion having been put to the vote, was carried by six votes against four.

An ordinary meeting was also held at the Colonial Medical Library, Colombo, on February 4th, 1888, at 2 P.M., at which Dr. Van Dort, Vice-President (in the chair), Drs. Loos, Attygalle, Macdonald, Rockwood, Messrs. Van Geysel, Thornhill, Nell, Schokman, and Keegel (Honorary Secretary) were present.

Diseases of Ceylon and India in the Seventeenth Century.—Dr. VAN DORT read "Translations (with notes) of Dr. Daalmans's

Observations of the Diseases of Ceylon and India towards the End of the Seventeenth Century."

A vote of thanks was accorded to Dr. Van Dort for his interesting paper.

The reading of the second paper was deferred to next meeting or want of time.

Alteration of By-law.—Mr. THORNHILL gave notice that at the next ordinary meeting on March 3rd next, he would propose the following alteration or amendment of by-law 4:

"After the word 'Colombo' to insert 'Kandy, Galle, Jaffna, and Madulla,' to omit the words 'and the following' and also the whole of the fourth and fifth lines, and the word 'Colombo' in the sixth line, and insert the words 'these towns.'"

In doing so he desired to be allowed to explain the object of his motion in order that the members might understand its import, as he might not be able to be present personally at the next meeting. This, however, the CHAIRMAN held to be out of order, although there could be no objection to an informal discussion at the conclusion of the meeting. Notice of motion was accordingly given, and the meeting separated with a vote of thanks to the chair.

BERMUDA BRANCH.

MEETING of this Branch was held on March 14th, PARK B. TUCKER, M.D., President, in the chair. Two members and two visitors were present.

Office Bearers for the Year.—Park B. Tucker, Esq., M.D., President; Dr. Heldon Harvey, Secretary and Treasurer.

Delivery in Arm Presentation.—Dr. TUCKER explained a new, safe, and easy mode of delivery in arm presentations, the child being dead, and turning impossible, by puncturing the thorax of the child, and crushing the bodies of two or three of the vertebrae with tooth or other forceps; the breech descending, by slight traction, the foetus is easily delivered without danger to the mother.

Enormous Number of Calculi.—Dr. TUCKER also exhibited 242 calculi taken from the prostate and bladder after death. The patient was a medical man, who was quite ignorant of the cause of his so frequently suffering from retention of urine, being under the impression that stricture was the cause of his trouble, nor could he be made to think otherwise, as he was often on horse-back, and could ride long distances without inconvenience. Two of the largest calculi, oblong in shape, were taken from the bladder, having been forced there by the sudden introduction of the catheter. His death was caused by an overdose of morphine, taken carelessly, without weighing, to induce sleep.

ERRATUM.—In the report of the meeting of the Shropshire and Mid-Wales Branch, published in the JOURNAL of April 7th, page 762, the name of Mr. J. T. Meek was erroneously printed "Meek."

Hemianopsia Cured by Iodide of Potassium.—*Antifebrin in Epilepsy.*—*Erythrophloëin.*—*The Imperial Royal Society of Physicians.*—*The Vacant Chair of Anatomy.*—*Ligature of the Thyroid Arteries in Goitre.*

At a recent meeting of the Royal Society of Physicians of Budapesth Dr. St. Csapodi brought forward a man, aged 53 years, who, after a sudden attack of giddiness, repeated twice on the same day, had remarked on the following day that he could not see objects situated on his right side. He also suffered from headache of the left side. Examination showed that vision was absent on the right side. No organic changes were found except some signs of endarteritis. Improvement took place under iodide of potassium; a symmetrical scotoma, situated 15° outside of the fixation centre, remained, which did not, however, interfere with vision. The hemianopsia in this case was probably due to hæmorrhage into the cerebral cortex.

Dr. Borosnyói, of Hermannstadt, referring to the use of antifebrin as an anti-epileptic, reports to the use of antifebrin in nine cases of epilepsy (six males and three females) in the lunatic asylum of Hermannstadt, which had been first treated with bromide of potassium, and later on with antifebrin. On comparing the results which were obtained with bromide of potassium

(from 6 to 9 grammes) with those obtained with antifebrin (from 0.25 to 2.0 grammes), it was evident that the former had in all cases a much more powerful effect than the latter. Antifebrin, as a rule, did not seem to have much influence on the disease. Even if larger doses of this drug should be proved to be useful, it would not be advisable to carry out a course of treatment with it, as cyanosis was observed in all cases treated with antifebrin.

At a recent meeting of the Society of Physicians of Styria, Professor Lipp, of Graz, gave an account of the results of his experiments with erythrophloëin on thirty persons. He used Merck's "erythrophloëin muriaticum," and made injections of doses varying from 1 milligramme to 1 centigramme. He had never observed any bad general after-effects, except in the case of a neurotic woman, who, after the injection of one centigramme of erythrophloëin, showed retardation of the pulse and respiration, and was attacked with giddiness. He made the injections under the epidermis, as well as under the skin. In each instance analgesia (not anaesthesia, as tactile sensation remained intact) was established over a large area round the point of injection; the analgesia lasted forty-eight hours. The local appearances were intense redness, swelling, and pain. The intensity of the local symptoms, however, depended more on individual irritability than on the strength of the dose used. The most remarkable feature in the experiments with erythrophloëin, in Professor Lipp's opinion, was the development of peripheral analgesic areas, which persisted in this condition for several hours, and even for some days after the injection. These territories corresponded to those which were supplied by nerve branches taking origin near the seat of injection.

The Imperial Royal Society of Physicians of Vienna held its annual festival meeting on Friday, March 16th, under the presidency of Hofrath Bamberger. The first secretary of the Society, Professor Kundrat, gave a report of the Society for the last year, which is the fifty-first of its existence. The report showed that the number of members, which had increased in the last year from 279 to 306, was again reduced to 285, 5 members having resigned their membership, 4 having changed their domicile, and 12 having died. Thirty-one meetings, with 89 lectures and demonstrations, had been held during the past year.

The committee charged to select names from among the candidates for the vacant second chair of Normal Anatomy in the Faculty of Medicine, proposed Professor Schwalbe, of Strasburg (*primo loco*); Professor Zuckerkandl, of Graz (*secundo loco*); and Professor Rabi, of Prague (*tertio loco*). The general opinion is that Professor Zuckerkandl has the best chance of being called to Vienna by the Ministry of Instruction, though his name only stands second.

Professor Billoth, in the first number (April 5th, 1888) of the *Wiener Klinische Wochenschrift*, the new Vienna weekly medical journal, discusses the utility of the method of ligaturing the thyroid arteries with the view of producing atrophy in goitres—a procedure which was not long ago reintroduced into surgery by his late assistant, Professor Wölfler, of Graz. Professor Billoth first tries to answer the question why we are not content with the very satisfactory results obtained in recent years by the extirpation of goitre, and replies: (1) because we are not able to prevent tetanus, which sometimes supervenes after these operations; (2) because it may occur, even when the greatest precautions are observed, that the recurrent nerve is cut or tied into the ligature; (3) because "cachexia strumipriva" is a not infrequent result in children when the whole of the thyroid gland is removed. Among the operations by which it was proposed to replace extirpation, the method of ligaturing the thyroid arteries deserved the greatest attention. *A priori*, the following statements could be made as to the eventual success of this operation: As, after ligaturing all the four arteries, several small arteries still supplied the goitre with a certain quantity of blood, it was probable that no gangrene, but only a gradual shrinking, would take place, just in the same way as in the case of obliteration of the renal artery. The small arteries, which, in this case, derived their origin from the renal capsule, hindered the occurrence of gangrene after the obliteration of the renal artery, but they were not able to prevent atrophy supervening in the kidney. Though this analogy was very striking, the matter nevertheless required to be verified by experiments on animals and men, which was also done by Wölfler. The indications for this operation were nevertheless limited, as extravasation, calcification, cystic and colloid softening were very often met with in goitres, which, owing to the absence of any circulation in

them, would, of course, undergo no change whatever after the ligation of the thyroid arteries. The question as to whether the fluid contents of cysts were capable of undergoing absorption after operation had yet to be decided. It thus became evident that the method in question would be really successful only in those cases in which no degenerative necrobiotic processes had yet taken place, such as rapidly growing goitres in young subjects. Two points were necessary for the success of this plan: 1. The first effect after ligation of all four arteries was that of a glandular anæmia; the goitre would be smaller and softer than before operation. 2. The second effect was obliteration of the blood-vessels, and the disappearance of the epithelial and interstitial tissue, so that only cicatricial connective tissue would remain behind. Respecting the development of "cachexia strumipriva" in children after complete atrophy of the thyroid gland, Professor Billroth considers that no positive statement could be made on this subject, but that it was possible that such a condition would not supervene, as the atrophic process, in such a case, took some weeks or months to become complete, and the organism had thus sufficient time to get accustomed to the absence of the thyroid gland. As to whether it was probable that the atrophy would be permanent, Professor Billroth holds that, when all four arteries are ligatured, there could be no doubt about this, but that, when circulation still existed in one of the chief arteries, or became established again by the "vasa vasorum," such a permanent atrophy would never occur. This had already been confirmed by experience. Discussing the details of the operation, Professor Billroth states that, in his opinion, the incision on the outer margin of the sterno-mastoid muscle was the most convenient one for ligaturing the inferior thyroid artery; he wished, however, to lay stress on a point which had not yet been mentioned, namely, the extreme thinness and fragility of the inferior thyroid artery. It had occurred to him on three different occasions that this blood-vessel was torn by the manipulations with the forceps or by ligaturing too fast, etc. The hæmorrhage which thus ensued was very considerable, and it was very difficult to pick up the artery, which retracted behind the scalenus muscle. In one case he cut through the scalenus muscle to enable him to seize the end of the artery with a broad clamp. In ligaturing arteries, Professor Billroth usually applied two ligatures in their continuity, dividing the vessel between them. In the above-mentioned operation, however, he contented himself with one ligature, owing to the fragility of the inferior thyroid artery. He had never met with secondary hæmorrhage in such cases. Professor Billroth has performed the operation in question in four cases of common goitre. In all of them there was a slight degree of fever, of short duration, but the absorption of the substance of the goitre was not attended with any ill effect on the general condition of the patients. The impression which the operation had made on him was a very favourable one, and he would repeat it in appropriate cases, but in future he would ligature all the four arteries at one sitting. In one of the cases thus operated upon he observed a slight degree of jaundice, which soon disappeared, and was probably due to absorption of blood. From a cosmetic point of view it had to be borne in mind that the ligation of all four arteries naturally caused four scars, as against the single lateral scar left after extirpation, which could easily be hidden by a small cravat. On the other hand, the attenuated appearance of the neck from which the thyroid had been removed was a still greater disfigurement. Professor Billroth concludes by stating that although ligation of the thyroid arteries was a valuable and interesting addition to our operative resources in the treatment of goitre, it would have a much greater importance if it were attended with similar results in the case of sarcoma and carcinoma of the thyroid gland. The attempt made by him in this direction failed. It was possible that ligation might be successful even in such cases, if done at an early enough period in the development of the disease.

Memorial Celebration in Honour of von Langenbeck.—Transplantation of Mucous Membrane.

PROFESSOR VON BERGMANN opened the Seventeenth Congress of German surgeons in the Aula of the University. The evening before, a memorial gathering in honour of the late Bernhard von Langenbeck had brought the members of the Congress and of the

Berlin Medical Association together in the largest room of the Philharmonic. Langenbeck had been honorary president of both societies. The vast room was completely filled. The family of the great surgeon took part in the celebration; in the boxes were present the Grand Duke of Baden and many ladies. One end of the room was hung with black cloth and magnificent palms, in the midst of which was placed a full-length bust of Langenbeck. After some choral singing, Dr. v. Bergmann delivered the funeral oration, of which I will only give the part dealing with the deceased surgeon's relations with England. "His journey to England increased his inclination for surgery, and decided his career. In London at that time many illustrious surgeons were teaching who kept up the heritage of a glorious past. Scientific collections, never seen or heard of in Germany, were freely open to him; whilst the hospitals gave him occupation for the whole day. Astley Cooper especially attracted him. He had already given up lecturing; but his three nephews, first-rate surgeons, paid much attention to the young German surgeon. Here Langenbeck felt happy and at home. These men were not only distinguished practitioners of the healing art, but they were happy in the unselfish practice of their profession. The impression made on Langenbeck's mind by his visit to the College of Surgeons was deep and lasting. His influence has been of the greatest service in establishing intimate relations between English and German surgeons. When in 1881 he went for the last time to England, to take part in the International Congress of London, he had a most enthusiastic reception wherever he went."

Professor Wölfler (Graz) spoke on April 3rd of the value of transplantsations of mucous membrane. He said that where cicatrices were produced in cylindrical organs of the body, which were lined with mucous membrane, an operation could only be useful, if it were possible, after excision of the scar, to unite the mucosa. But that was impossible in many cases. Therefore he had employed the method of Thiersch (the transplantation of portions of epidermis) with great success. After having excised the thickened and indurated tissue from impermeable urethral strictures, he transplanted mucous membrane from a prolapsed uterus. The operation was completely successful. In the same manner he transplanted mucous membrane from a prolapsed rectum on to the conjunctiva in a case of blepharoplasty. He succeeded even in transplanting mucous membrane from frogs, pigeons, and rabbits with good results.

[FROM OUR OWN CORRESPONDENT.]

Hypodermic Injections of Artificial Serum.—"Growing Fever."—The late Dr. Constantin James.

DR. PREGADIUS has made some interesting observations on the subcutaneous injection of artificial serum. He experimented on a large number of dogs, which, after considerable and rapid loss of blood, revived after having had artificial serum injected into their veins. The saline injection, or artificial serum, is composed of six grammes of pure sea-salt dissolved in one litre of boiled water, and then filtered. Before injecting care must be taken to render the skin as aseptic as possible by washing it with antiseptics. The injection should be made at a point where there is plenty of cellular tissue, from twenty to thirty cubic centimetres of liquid being given as a dose. In all, the quantity injected must be about one-half of the quantity of blood lost. A slight massage aids the diffusion of the liquid. The syringe must be aseptic. The sensibility being deadened by loss of blood, there is not much pain. The immediate results of the injections are renewed sensibility, cessation of contractions and of cardiac pressure, followed by gradual return of vital manifestations. The process is simple, free from danger, and rapid enough even for acute cases. Dr. Pregadius recommends its trial on the human subject.

At the Hôtel Dieu M. Reclus recently gave a lecture on the fever of growing children. He described the case of a young girl aged 19, who, while suffering from febrile symptoms, was suddenly seized with severe pain, especially referred to the left hip. She had been growing rapidly. M. Bouilly was the first to call attention to the subject in a little work published in 1879. In it he described the three important characteristics of this fever, which is rarely met with in infancy, although a case is recorded in which an infant aged 25 months grew 8 centimetres in six weeks. M. Reclus cited two cases of this fever observed in patients aged 20 and 21. The affection usually occurs between the ages of 7 and 13 or 15. It is frequently manifested after extended movements and

ter great fatigue following violent exercise (gymnastics, swimming, etc.). It sometimes appears after pyrexia (eruptive and phoid fevers). The anatomical lesions observed are due to disturbance in the function of nutrition in the region of the connecting cartilages, more particularly in those fibro-cartilages which enrich most bone, such as the cartilage of the upper extremity of the humerus, the cartilage of the lower extremity of the radius and ulna, the cartilage of the lower extremity of the femur, and those of the upper extremity of the tibia and fibula. Faulty nutrition is observed in the epiphyses which furnish most bone, especially in the interior of the lower extremity of the femur. "Growing fever" is never fatal, so there is no opportunity for necroscopic examination. The bone alterations which characterise this affection cannot therefore be thoroughly known. It is certain, however, that it presents a series of osseous lesions closely allied to each other proceeding from simple inflammation or osteo-myelitis. In some cases "growing fever" causes the formation of exostoses on one or more epiphyses. In other cases results in inflammation, which engenders staphylococci aurei or infectious osteo-myelitis. M. Bouilly has described the three principal clinical symptoms of "growing fever" as follows: the first of these is pain of a particular kind; this may be spontaneous and generalised, in which case it is not a pathognomonic symptom; or it may be confined to the epiphyses, when it may be regarded as a characteristic phenomenon. The second symptom is the rapid growth of the patient; a case is recorded of a child of 15 who grew 14 centimètres in six months, and of one of the same age who grew 14 centimètres in two months. The third symptom is fever of a particular kind, which may present three distinct forms: 1, acute and transitory; 2, acute and prolonged; 3, chronic and prolonged. The first form is similar to the fever met with at the beginning of pneumonia. It reappears at night with sudden intensity, being preceded by shivering fits. The temperature reaches 40° and 41° C. (104° and 105.8° F.). There is severe pain in the limbs. This fever lasts one or two days. The patient grows from 1 to 3 centimètres in seven or eight days. The acute and prolonged form is frequently preceded by headache, general pain, epistaxis, singing in the ears; these symptoms are followed by shivering, fever, nausea, vomiting, disturbance in the respiratory function; the spleen is hypertrophied; spots are observed on the body; the tongue is foul; there is diarrhoea, with gurgling in the iliac fossa. These phenomena disappear in five or seven days; the patient recovers, but remains thin for a certain time. In order to ascertain whether these symptoms are the result of "growing fever," the epiphyses should be carefully examined. In the third form the fever is slight; the temperature never exceeds 39° C. (102.2° F.). The fever only lasts a few hours at a time; it reappears from time to time during several months. The epiphyses are painful when pressed; the patient increases in height. Reclus cited cases in which the symptoms of "growing fever" were attributed to coxalgia; similar errors are often made. M. Rissaud lately met with a case of this affection in which the patient, a girl aged 16, grew 8 centimètres in two months. The diagnosis of acute chlorosis, typhoid fever, and tuberculosis had been successively made in this case.

Dr. Constantin James recently died, at the age of 75, of inflammation of the lungs. His professional career began in 1840, and he was well known by his writings on mineral waters. He had also obtained celebrity by his criticisms on M. Pasteur's antirabic method, by his theories on hypnotism and suggestion, and by his controversies on the subject of the experiments made by Drs. Harcot and Luys. He also wrote against the Darwinian theory, and his work on the subject had the honour of being annotated by the Emperor of Brazil. In 1869, on his return from the opening of the Suez Canal, he narrowly escaped assassination, a youth inflicting fourteen blows with a loaded stick upon his head. Even this misadventure furnished material for Dr. James's prolific pen.

APPALLING accounts have been received of the inundations caused in the Elbe district by the accumulation of ice, and the consequent breaches made in the river banks. From a Reuter's telegram we learn that from Wittenberge to Danuenberg and Poitzendorf both banks of the Elbe are flooded for miles. A hundred villages are under water, and there has been some loss of life. The damage done is enormous and the distress terrible. Many cattle have been drowned.

TRACES of gold are said to have been recently found in the waters of the sprüdel at Carlsbad.

CORRESPONDENCE.

THE LOCAL GOVERNMENT BILL AND THE P. H. SERVICE.

SIR,—I should like to say a few words in supplement to your excellent article in the *JOURNAL* of March 31st on the subject of "Public Health Service under the Local Government Bill."

I hold an appointment as medical officer of health to one of the largest uncombined rural districts in the country, with a population of over 50,000, and am, therefore, qualified to state where the shoe pinches, and unlikely, if the new Bill becomes law, to pinch again. I shall only touch upon one or two salient points in connection with rural districts.

First, with respect to the guardians. A parsimonious expenditure of the public money being the one aim of the average ratepayer, the most parsimonious candidate obtainable—a small farmer—is probably returned to the board. Men of this stamp form a majority on most rural boards, and it strikes me that the District Councils will be very similarly constituted. Farmers, because of the straitness of their own circumstances at the present time, are the best possible representatives of a parsimonious policy, and being often, in addition, open offenders against sanitary law, their nominal office as guardians of the public health becomes a most unseemly farce. I have said nothing of their educational unfitness, as this goes without saying. It is commonly supposed that the "ex-officio" seen on the lists are effective guardians. This is for the most part an error, as county magistrates, for various reasons, seldom attend the meetings.

The appointment of a superintendent medical officer of health for the county is advocated by you and many others, but it seems to me a much easier way out of the difficulty would be to vest the appointment of all medical officers of health in the County Council, leaving the Local Government Board, as in many other matters, still the superintending authority; the tenure of office, under such appointment, to be also "during good behaviour." The amalgamation of the duties of analyst and pathologist with that of superintendent medical officer of health in a large county would involve more work than any one man, however able and energetic, could effectively do. A great deal of detail in public health matters must still be left to simple evolution; but the present system of appointing sanitary medical officers, which it seems the intention of the Government to perpetuate, is a radical error and evil. There could be little danger of the medical officer of health abusing the power and status given him by the elective arrangement suggested above. Local influence and control would be too strong for this, though not so powerful and paralysing as it often is under the present system. The redistribution of sanitary areas upon a scale sufficiently liberal to allow of the exclusive appointment of pure medical officers of health would be, I fear, too large an order for the Government or County Councils to undertake.

I may add, as a remark applying especially to rural districts, that the inspector of nuisances, by whomsoever appointed, should be directly subordinate to the medical officer of health. This does not follow from the L. G. B. order (1872), but is a most necessary provision.—I am, etc.,
NOTTS.

DENTAL DEPARTMENTS OF HOSPITALS.

SIR,—The thanks of the dental profession are due to Mr. Newland Pedley for his practical paper in the *JOURNAL* of April 7th, and it is to be hoped that the subject may not be allowed altogether to drop until reforms of the kind proposed have been generally adopted. They would confer benefits not only upon medical and dental students, but upon vast numbers of the suffering poor, who now either go unrelieved, or submit to the barbarous operation of extraction for the relief of curable dental diseases. These diseases, the most common and universal of maladies, are much neglected because they rarely endanger life, and yet, in great numbers of instances, they render existence as miserable as it can be made by any form of physical suffering. Many years' experience of hospital dental work convinced me that it would not be possible to deal with the entire mass of dental disease existing among the poor by any organisation however extensive, but very much more might be accomplished than is now done if measures such as Mr. Pedley advocates were systematically carried out. I, however, go further than he does. I long ago formed and expressed the opinion that every hospital, and particularly those with medical schools attached, ought to have a completely

equipped dental department in which dental surgery might be as fully practised and taught as at the dental hospitals. No special hospital could be more free from even the suspicion of abuse than the Dental Hospital of London. It has done and is doing work which could not have been done elsewhere. But not to speak of notorious evils and abuses which sooner rather than later seem to become associated with most special hospitals, it is appearing more and more evident that, with rare exceptions, these institutions might with advantage in every respect be merged into special departments of general hospitals.

Instead of founding a dental hospital, had it been possible from the first to divide the staff and students and to organise well arranged dental departments at a few of the leading London hospitals, many of the complaints that Mr. Pedley justly makes would have been now uncalled for. If during the last twenty-five years dental operations had been fully demonstrated daily at general hospitals, a large proportion of medical practitioners, to whom such an accomplishment is valuable, would have gained knowledge and skill in dental surgery, and the medical profession would have become more thoroughly enlightened as to the scope of dental science, and the value of conservative dental surgery. There seems no room to doubt that in a very few years there will be so great an increase in the numbers of medical students taking up dental surgery as a profession that the Dental Hospital will be quite inadequate to accommodate them. The qualified dentists on the *Register* number only a few hundreds, and there are besides three or four thousand unqualified practitioners registered by virtue of being in practice prior to the passing of the Dentists Act. This latter class is decreasing, and must of course more and more rapidly disappear as years go by. They can be replaced in future only by qualified men. Owing to the elevation of dentistry in consequence of its recognition as a legitimate special branch of the medical profession, and the gradual enlightenment of the public as to the value of dental surgery, the demand for qualified dentists must increase, whilst under these circumstances the crowded condition of the medical profession must, I repeat, lead many medical students to adopt the speciality as a calling. The expenses of a dental department in a large hospital are, as Mr. Pedley shows, comparatively trivial. There could be no difficulty nowadays in finding full staffs of highly qualified dental officers to provide daily attendance and teaching. I believe that if general hospitals would organise such departments so as to furnish special instruction equal to that given at dental hospitals, there would soon be attracted enough students to efficiently work the department without putting an undue strain upon the officers or calling upon them for unnecessary sacrifices.—I remain, etc.,

HENRY SEWILL, M.R.C.S., L.D.S.,

Wimpole Street, W., April 7th.

COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES.

SIR,—The letter from Dr. Alfred Carpenter, in the *JOURNAL* of April 7th, might lead the casual reader to suppose that some private motives had dictated the prosecution of Dr. Dalton for not notifying a case of infectious disease; it is, therefore, incumbent upon me to ask you to place before your readers the real facts of the case.

During the few years that compulsory notification has been in force in Croydon, Dr. Dalton has been the only medical practitioner who has refused to comply with the provisions of the Act of Parliament. In this refusal he has been persistent, notwithstanding official and private remonstrance from myself, couched, as I think, in the most friendly terms.

Owing to the difficulty of obtaining evidence of the existence of infectious disease without the testimony of the medical attendant, it has not been possible to prosecute Dr. Dalton until the occurrence of the case referred to. There the patient died, and in accordance with law Dr. Dalton gave the registrar of deaths a certificate, stating the cause of death as scarlatina. An inquiry was then made, which gave Dr. Dalton an opportunity of explaining his omission to notify, if any explanation had been possible. In answer to that inquiry the right of the Corporation to require notification was denied; thereupon a summons was issued, and upon the hearing of the summons, for the first time the defence was raised that an informal notification had, in fact, been given to the sanitary inspector. It appeared, however, that this informal notification related to a previous case, and not to the case under discussion; a conviction therefore followed, as was inevitable.

Under these circumstances, I think your readers will see that the Corporation, unless they were prepared to allow the Act of

Parliament, obtained with considerable trouble, to be set at naught, were bound to take proceedings to enforce it. Other medical men in the borough who were notifying had just cause of complaint if, whilst they fairly carried out the provisions of the Act, one of their professional brethren should be allowed to set them at naught.

All medical men will understand that a prosecution of this sort is distasteful to those who have to embark in it, but both before and after the issue of the summons private attempts were made to get from Dr. Dalton an undertaking that in future he would comply with the provisions of the Act, and an offer was made to him, both before and during the hearing of the case, to withdraw the summons if such undertaking was given. He, however, absolutely refused to give any sort of undertaking, and apparently relied upon being able to upset the proceeding upon technical grounds. In this he was unsuccessful, with the result known to your readers.

It is hardly worth while to discuss what might have been if the case had borne the aspect suggested by Dr. Carpenter. The facts, however, as will be seen, differ entirely from those related in Dr. Carpenter's letter. I have been on friendly terms with Dr. Dalton for many years, and hope that these proceedings, in which I had no alternative but to appear, will make no difference in those friendly relations.—I am, etc.,

CHARLES W. PHILPOT, M.D. Lond.,
Medical Officer of Health, Croydon.

SIR,—The medical profession generally have reason to thank Drs. Dalton and Carpenter for standing out in opposition to those who wish to make us responsible for the delinquencies of other people. Let but regulations of a like nature be forced upon clergymen and solicitors, and a cry of persecution would be raised immediately. The Kingston Corporation at the present time are promoting a Bill in Parliament similar to that in force at Croydon; and eighteen of the local medical men, including three out of the four officers of health, have signed a petition in opposition to the clause which seeks to impose a penalty on any medical man who neglects to forward personally a certificate notifying the existence of infectious disease. We are all willing to give a certificate to the householder for transmission, but we decline to act the part of public informers. Moreover, a radical defect in the Bill, and one which we desire to see altered, is that it allows medical men who are engaged in practice to be appointed public health officers. The following reasons will suffice to show, I think, why they should be entirely independent. Though engaged in practice as ourselves, they would be placed on an entirely different footing to their brother professionals, inasmuch as they would have to report to no one, and would be in every way a law unto themselves; and, in the case of their having as patients large owners of property, they would, for fear of giving offence, be inclined to allow nuisances and dangers to the public health to remain uncorrected, which they would not do were they in a perfectly independent position. It is almost impossible in certain instances, however conscientious one may be, not to be biased to some extent by existing circumstances. In order to work any Sanitary Act properly, it is necessary a person should be appointed who is independent of all external considerations.—I am, etc.,

F. P. ATKINSON.

Surbiton.

THE ALLEGED ARREST OF SYPHILIS IN ITS PRIMARY STAGE.

SIR,—I do not agree with Mr. Jonathan Hutchinson or Dr. Drysedale, that there is the slightest evidence that syphilis is due to a microbe "as yet unknown to the microscope." This may be heresy in the present microbial age. I must also say that I was much surprised at Mr. Hutchinson's experience in invariably arresting the sequelæ of primary syphilis, if seen sufficiently early, by small doses of grey powder. I have seen a good deal of syphilis for over twenty years, and my habit has been in all doubtful cases to administer bichloride of mercury with potassium iodide. In some cases thus treated, no matter how early, secondary manifestations occurred, though certainly of a very modified nature, while in others there were no secondary symptoms. My experience goes to show that no one can predicate to a certainty that under any treatment a given sore will not be followed by secondary manifestations.

The subject is, of course, too wide to be dilated upon at any length in a note. The combination of mercury which I employ is

almost invariably the bichloride, dissolved in an excess of iodide of potassium. Ptyalism I consider to be due to the precipitation of metallic mercury in the glandular structures. Mercury dissolved in iodide of potassium is not so precipitated, and in this form ptyalism from mercury is rarely or ever seen. Iodide of potassium further aids the action of mercury by stimulating histolysis, and thus acting on the glandular system. It is thus, in my opinion, that the therapeutic effects of these agents, in syphilis, are to be explained.—I am, etc.,

D. CAMPBELL BLACK, M.D.,

Assistant Physician to Glasgow Royal Infirmary.

Glasgow, April 9th.

ST. ANDREWS UNIVERSITY AND AN M.D. FOR PRACTITIONERS.

SIR,—A petition is about to be presented to the Senate of St. Andrews University, praying that all medical men of ten years' standing may be eligible for the practitioner examination for the M.D. degree, without restriction as to age or residence, and I am enabled to say that the Senate will not oppose such a scheme if it be well supported by a large number of names.

Already one petition to this effect has been lodged, containing the names of representatives of nearly every British university, who, whilst not desiring the change for themselves, support it as a means of justice to others.

The subject was thoroughly ventilated in the JOURNAL some time ago, and I hope those who are in favour of the change will send their names to me at once, and I shall also be glad if those who would be willing to obtain the signatures of their neighbours in large towns would so express themselves.—I am, etc.,

Leigh, Lancashire.

B. JONES, L.R.C.P.Ed.

GAD FLIES ATTACKING MAN.

SIR,—With reference to recent correspondence on this subject in the JOURNAL, the following note may be of interest:—

A friend of mine was engaged for some weeks on a survey up one of the rivers of Venezuela. Soon after his return to Trinidad, a large grub was squeezed from a swelling over his lower jaw. The sore healed rapidly after the escape of the larva.

He gave me the grub preserved in spirit, and I forwarded it to Mr. C. O. Waterhouse, of the British Museum, who kindly sent me the following report by last mail:—

"Your larva is the one known under the name dermatobia toxialis, but there is not at present sufficient evidence to prove that it is the same insect as was originally described under the name *noxialis*."—I am, etc.,

BEAVEN RAKE, M.D.Lond.

Trinidad, March 12th, 1888.

LECTURESHIP ON FORENSIC MEDICINE, TRINITY COLLEGE, DUBLIN.

SIR,—In page 760 of the JOURNAL of April 7th, you mention my name among the candidates for the Lectureship in Forensic Medicine in Trinity College, Dublin, vacated by the death of the late Dr. Travers. Kindly permit me to state through your columns that such is not the case. I have not in any way sought the position in question.—I am, etc.,

F. J. B. QUINLAN, M.D.

29, Lower Fitzwilliam Street, Dublin,

April 7th.

NAVAL AND MILITARY MEDICAL SERVICES.

THE ARMY MEDICAL WARRANT OF 1879 AND MR. STANHOPE.

WE are glad to acknowledge the conciliatory spirit in which Mr. Stanhope replied to Dr. Tanner's question, as to whether it was intended to tamper with or set aside the Warrant of 1879, especially the right of medical officers to retire after twenty years' service. The Secretary of State for War went out of his way to answer the question, which had remained unput for four days on the notice paper. We welcome this changed attitude to a great army department, and to the civil medical profession, who are deeply interested in the rights and status of their military brethren. He intimated that "it is not intended to prevent medical officers retiring after twenty years' service, but it is proposed to require a reasonable service in a given rank before allowing retirement on the rates permitted for that rank."

This statement, which is most important, at first sight seems

clear enough; yet, reflection suggests that much depends upon the interpretation of the term "reasonable service;" and perhaps even more, as regards the medical officer, on what is meant by "that rank." For instance, a medical officer on completion of twenty years' full pay service, acquires a new army rank, in ranking as or with a Lieutenant-Colonel, but does not alter his departmental title of Surgeon-Major; but, on being promoted Brigade-Surgeon, he changes his departmental title without gaining any addition to his army rank.

What, then, is "that rank" to which Mr. Stanhope refers? Is it Departmental, or Army, or both? If the former, then, as the medical officer at twenty years will already have served eight years as Surgeon-Major, the "reasonable service" cannot apply, and he may retire at once; if the latter, then, as the Brigade-Surgeon, who will be at least of twenty-five years' service, gets no increase thereof, he, too, may go at once after promotion.

The "reasonable service" becomes bound up, therefore, in the question of "rank." We gathered from Mr. Stanhope's memorandum on the Estimates that a "reasonable period" was to be exacted in a given rank throughout all branches of the service, and we presume, therefore, the rank referred to must be army rank; if so, how is a medical officer who gets a step at twenty years able to claim retirement at once, and at the same time serve a "reasonable period" in this rank?

We advise Mr. Stanhope to clear up all the doubts and difficulties created by the late miserable tampering with the rank and status of medical officers before modifying the right of retirement. The War Secretary further admitted that retirement at twenty years was undoubtedly granted as an "inducement to candidates" to enter the service; and that "no restrictions" would be placed "on retirement on £1 a day." Good; but, if so, why at the same time speak of requiring a "reasonable service" in each rank before retirement? A continuation of service beyond twenty years will clearly be a "restriction."

His announcement that an officer's "vested rights," according to Lord Penance's Royal Commission of 1876, "are limited to the rank he holds" is no doubt good law as applied to the question of compensation in the curtailment of prospective advantages; but we would venture to think this decision does not bear on the right or justice of limiting the vested rights in a given rank, deliberately created by Royal Warrant, by merely setting them aside, at convenience, in another Royal Warrant.

The further developments of Mr. Stanhope's plans will be watched with much interest.

THE BURMAH MEDAL.

A CORRESPONDENT complains that the officers and men on board the hospital ship during the late Burmese war have been refused the medal, whereas medals were granted to those on board similar ships during the Abyssinian, Ashantee, and Egyptian expeditions. The official grounds of refusal were that the ship did not cross the frontier—a physical impossibility. But we believe the authorities maintain with no little force that the Burmah ship was so far removed from the scene of hostilities in Upper Burmah, that it was not on all fours with the ships in the other expeditions, which were located directly on the seaboard of operations.

ADMINISTRATIVE MEDICAL OFFICERS OF THE ARMY AND THEIR RESPONSIBILITIES.

WE regret to learn of the retirement from the service of a surgeon-general owing to a decision recently arrived at by the military and medical authorities. Judging from the facts of the case, this appears to mean that an administrative medical officer in visiting a hospital is personally responsible for the correct diagnosis of every case in it, whether reported to him or not, which is certainly a new departure. If this be so, we are strongly of opinion that the sooner the medical regulations of the army are revised the better, both in the interest of the soldier and of the medical officer; as at present, by all existing regulations, the senior medical officer specially appointed to the charge of the hospital is held responsible for this duty.

This strange decision as regards responsibility appears to us contrary to the spirit of the Queen's Regulations for the Army, and the "chain of responsibility" thereto laid down, and also to the usages of the medical and military professions, and to the true interest of the sick or wounded soldier. It is the more unjust and inexplicable in this case as the Secretary of State for War, while declining to alter the decision of the authorities, at the same time officially and "fully recognises the excellent services performed" by this medical officer. The surgeon-general referred to holds seven special letters of approval and thanks for his services received at various times up to the date of leaving the army, at home and abroad, from as many directors-general and

general officers, which were submitted to the Commander-in-Chief. This is, to say the least, a strange manner of encouraging medical officers to do their duty under all circumstances of difficulty and danger.

DUTIES OF ACTING SURGEON OF VOLUNTEERS.

M.D. asks: 1. What are the duties of an acting surgeon of volunteers? 2. Where can I obtain the best information about conducting an ambulance class or ambulance drill for volunteers? 3. What uniform does an acting surgeon of volunteers wear?

*. 1. Duties of acting surgeons of volunteers: (a) Proficiency examination (Volunteer Regulations, 1887, Part I, Sec. II, Para. 144). (b) Camps with Regular Forces (Volunteer Regulations, 1887, Part I, Sec. IV, Para. 405; Medical Regulations for Army, 1885, Part I, Sec. III, Para. 55 to 82).

2. Training of Stretcher Bearers (Queen's Regulations for the Army, 1885, Sec. XIV, Para. 80; and Volunteer Regulations, 1887, Part I, Sec. VI, Para. 517).

3. Uniform (Volunteer Regulations, 1887, Part IV, Sec. III, Para. 1044).

ARE BATTALION SURGEONS NONCOMMISSIONED OFFICERS?

DR. WALTER PEARCE, Acting Surgeon, Artists R.V., writes: Volunteer surgeons have substantive rank (Volunteer Regulations, 1887, Part I, Sec. II, Para. 124 and 125), and are commissioned. Acting surgeons have no substantive rank, are not commissioned, and their appointments cease whenever the corps to which they belong is called out for active service.

PRECEDENCE OF ARMY MEDICAL OFFICERS IN INDIA.

AN ADMINISTRATIVE OFFICER writes: In the JOURNAL of February 18th, page 379, you published a letter on this subject. I now enclose a verbatim copy of the orders relating to precedence.

By the first, paragraph 1360, vol. vi (The Medical Regulations), you will see that medical officers are only to be members of medical boards, and should, in all other cases, attend to give evidence. If this rule were adhered to, there would be no ground for complaint, as if the president acted as described in your correspondent's letter, he would do so on his own responsibility, and it would be evident on the face of the proceeding that the medical officer's opinion had not been asked for or recorded.

It happens, however, that in paragraph 1139, vol. ii of the Indian Army (Discipline) Regulations, power is given to the Government (really to the headquarter military staff) to nominate medical officers as members of mixed boards, and, when this is done, to my certain knowledge the medical officer is invariably nominated last, and has, therefore, to "sit and sign" junior to all the other members of the board.

Two instances have quite lately come under my observation, as principal medical officer of the division in which this has been done. In one case, a surgeon-major of twenty-five years' service, with rank as lieutenant-colonel of five years' standing, had to sign below a junior captain; and in the second, a surgeon-major of twenty-three years' service had to sign below a subaltern. In both these cases the medical officers appealed to me, but my advice to them was (considering they were both rapidly approaching their turn for promotion) to accept the position, and "don't kick up a row."

Will no member of our profession take this matter up in the House, and call on the Secretary of State for India to amend the regulations to such an extent as to give medical officers their proper position on all boards?

Army Regulations, India (Medical), vol. vi, p. 1360.—"Medical officers will be detailed as members of medical boards only. Should a medical opinion be required by any other board, reference will be made to the medical officer detailed to attend it, who will, if necessary, furnish his report in writing, or give evidence in person."

Army Regulations, India (Discipline), vol. ii, p. 1139.—"When committees are convened by Government composed of military and medical officers, or of these and civilians also, the relative precedence of the members is to be that in which they are named in the order convening the committee. In such cases the president may belong to any branch of the Service."

*. It seems to us the military authorities in India (and elsewhere) stick at nothing in their extravagant endeavours to deprive medical officers of any semblance of army rank and status. We have no difficulty in realising the utterly unworthy spirit which works in such a paragraph as 1139, Indian Army Regulations; but what is past our comprehension is that such an order can be promulgated without drawing a vigorous protest from the heads of the Medical Service in India. We never hear of any such protests.

THE NEW WARRANT.

NEMO writes: The more the Warrant on the Reserve of Medical Officers is studied the more insidious do its terms appear; he considers the Warrant has been issued to afford the authorities a powerful lever against the regular service, should that again become unpopular; he trusts the influence of the British Medical Association will frustrate any such scheme; he thinks no medical man of any standing could accept the "Reserve" terms at the risk of ruining his civil practice.

A CORRESPONDENT, signing himself "Beware," thinks the Warrant creating the Army Medical Reserve of Officers "another mean fly-trap of the most approved War Office pattern;" and says that medical men should be careful before they walk into it; the terms offered, he thinks, are beneath professional dignity.

REGULAR MEDICAL STAFF writes: The Royal Warrant for the establishment of an Army Medical Reserve will be read with interest by all who have long recognised the necessity for such provision being made. It only remains to be seen how the new Warrant will be accepted by the medical staff of the Auxiliary Forces, who it is presumed will carefully weigh all the conditions of service before joining.

The Secretary of State's instructions are practically the Warrant. In the light of these instructions, what does a medical officer gain by joining the Reserve.

1. According to Paragraph 1, a medical officer may presumably be unfit for service in the Reserve, yet fit for service with the present corps. Clearly he had better remain with his corps.

2. Publication of his name in an Army List, however useful to the Government, is no advantage to him.

3. Compulsory service as a surgeon-major up to the advanced age of 65, is certainly a doubtful advantage, yet no provision is made for any higher rank, which means higher pay.

4. If a real great national emergency should occur, all the auxiliary forces will naturally be called out, when the medical officer of a corps will necessarily draw the pay and allowances of his rank, and will have a better chance of serving with his regiment, instead of being knocked about the country as a Medical Reserve officer.

5. To a question whether the terms offered are sufficient remuneration for the duties to be performed, most officers of the regular Medical Staff acquainted with these duties will say most decidedly they are not.

6. Prior claims to hard work and insufficient pay can hardly be considered an advantage.

7. Would appear to be a provision for medical officers retaining their present regimental appointments. Should they join a reserve, they would soon find out that they would be sent just wherever their services were required.

Finally, the Warrant is clearly an attempt to play off a medical reserve against the present Medical Staff. Whether our professional brethren will come to the assistance of a Government which has persistently treated the regular medical officers of the army with flagrant injustice and scant courtesy, whether they will accept terms all the advantages of which are on the side of the Government, and whether they will not be far wiser to wait until the emergency arises, when bearing in mind the treatment now being experienced by the Medical Staff, these terms will be what the medical profession chooses to demand, are questions deserving the careful consideration of those now being tempted to join the Medical Reserve.

As a Medical Reserve, the provision made by the Warrant is utterly inadequate, and does not bring us one step nearer to the solution of the questions how to provide for one or two army corps in the field. A more unstatesmanlike Warrant was never issued. One thing is certain, that with the present strength of the regular Medical Staff, our first small war will have to constitute in the opinion of the authorities a great national emergency, and the new Medical Reserve will be called on to give up practice and home, and undertake duties for which the remuneration is totally inadequate. Let medical men, more particularly at this moment, bide their time if hereafter they wish to serve the Government; their market value will be three or four times what the Government now offers.

CIVIL OR MILITARY?

DR. J. RUXTON (Blackpool; late 17th Regiment and Army Medical Department) writes: I have lately wondered whether my old comrades in the Army Medical Staff are to be considered civil or military; the order removing the aiguilletes from the uniform of honorary surgeons to the Viceroy of India, on account of "exception having been taken by the military authorities to the honorary surgeons of the Viceroy wearing an aiguillette," compels one to ask the question. For my own part I consider that army medical officers are as much military as those of any other branch of the service. Wherein, therefore, lies the nucleus of the order?—evidently in the jealousy of the so-called combatant officers. Surely this is small. If medical officers are not military they must trust to civilians to look after their rights; but I observe Mr. Stanhope considers the action of the British Medical Association in finding out the grievances of the Medical Staff, contrary to military discipline. How will the Royal Warrant for reserve and army medical officers affect those now on full pay and those aspiring to the Medical Staff; will the elastic "exigencies of the service" curtail home service, and rob military surgeons of their last chance of a year or two at home, after the extended period of six years abroad?

We medical men are all indebted to Dr. Farquharson and others for bringing medical officers' grievances to the front, and we must ventilate them as it individually strikes us. We have a common welfare as a profession; the well-being of military medical men is ours.

THE ARMY MEDICAL STAFF.

UNION IS STRENGTH writes: The time has come when the medical officers of the army will have to offer, in the defence of their own interests, the most strenuous opposition to the proposed changes in the Medical Department contained in the memorandum recently issued by the Secretary of State for War. Their vested rights are seriously threatened, and if they do not now speak out, they will have only themselves to blame if the proposed changes be carried into effect. These changes mainly refer to conditions of service, pension, and the formation of an Army Medical Reserve, the latter to be composed of retired officers, officers of the auxiliary forces, and civilian surgeons. Naturally, they are calculated to excite the gravest apprehensions in the minds of medical officers, affecting as they do most seriously their privileges and prospects.

The Medical Service has been already transferred by a recent order from the War Office to the Horse Guards, who, following their old traditions, may be expected to treat our grievances with scanty consideration. In this struggle for the recognition of our claims combined representation is denied us, and individual representation, though allowed, is perilous; hence we have to depend altogether on external support, and on the influence which can be most powerfully exercised in our behalf by the various licensing bodies, the universities, and the members of the British Medical Association.

Under the present system there is already intense dissatisfaction existing as to the very short period of home service permitted to medical officers; and if the proposed scheme of the addition of an extra year abroad to each tour be adopted, the inevitable result will be such an increase of prolonged and continuous service in tropical climates as will leave us practically no home service to recruit our health. What is the good of life under such conditions of perpetual exile? And what are likely to be the consequences? The answer is easy: a greater amount of sickness, temporary half-pay on the expiration of six months' sick leave, followed six months later by removal from the service, with a small bonus for permanent ill-health, and an increase in the death-rate of the medical officers, already considerably higher than that of the combatant branch, together with the loss of all the advantages conferred by the Royal Warrant of 1879 while serving in India. This is a sorrowful outlook. Do Mr. Stanhope and his advisers think a medical officer requires no rest in England after frequent and prolonged tours of service in unhealthy climates? Do they think he has no bones to be racked by fever, and no inside to be rent by dysentery?

No arrangement is entered into between them in the signed agreement as to fees for attending and giving evidence at inquests and courts of justice, the point not having been mooted by either A. or B. at the time of signing the deed. B., nine months afterwards, considers he is entitled to these fees, though he did not claim them at first. A. has conceded so far as to give B. the fee when both A. and B. have been required and received a fee each, but declines in the matter of inquests and *post-mortems*, holding that B. was engaged to represent him during his absence, and relieve him of a portion of the work, and that the giving of evidence and making *post-mortems* is only part of his duty in the carrying on of the practice which he has agreed to do. Which is in the right?

"* Taking a common-sense view (based, moreover, on the customary provisions made in all carefully and practically drafted deeds of medical partnerships) of the points specified in our correspondent's communication, we are clearly of opinion that the view of the matter as expressed by "A." is in strict accord with right.

A QUESTION OF DAMAGES.

M. writes: For more than two months I have been attending a child who had fallen down an open cellar-door and received injuries to head and chest. The father of the child has recently threatened to sue the owner of the cellar for damages. Yesterday, without acquainting me, another practitioner, at the request of the owner of the cellar, visited and examined my patient, and this I consider a breach of professional etiquette. If he had called on me, I would have had no objection to his examining my patient, or even accompanying him. I think that the first duty of a medical man in such a case is to ascertain from the medical attendant if the patient is in a fit state to receive such a visit.

"* The duty which devolved upon the interviewing practitioner is clearly laid down in the following rule:

"When an employer or other person becomes anxious and apprehensive in regard to the illness of an *employé*, or in the case of an impending action for damages, and the like, and for his personal satisfaction requests his own family or another doctor to visit the patient and report to him thereon, it is a duty incumbent upon the deputed practitioner to point out to the employer or other interested party their respective ethical obligations in the matter; and, prior to making such visit, to solicit and obtain the sanction of the medical attendant in the case; otherwise, he will commit a grave breach of professional etiquette, and justly subject himself to severe criticism and reproof."

PAYMENT OF FEES TO SUBSTITUTE.

A. is engaged to attend a lady, who has a very quick confinement, so that the patient's mother sends for a doctor (B.) who lives close at hand. B. has left before A. arrives; still the patient requires an attendance of two hours and a half, owing to impending collapse, such having been her condition after her last confinement. Frequent visits were necessary during the following twelve days, and medicine was supplied. B. demanded half the fee, which was two guineas. A. wishes to know who ought to pay it—the patient or A.?

"* The only rule within our knowledge that bears on the point submitted by our correspondent is the following (12) extracted from the *Code of Medical Ethics*, 2nd edition, page 71:

"When a practitioner is called in or otherwise requested to attend at an accouchement for another, and completes the delivery, or is detained for a considerable time, he is entitled by custom (except in the case of illness, etc., provided for by Rule 3) to one-half of the fee, etc."

At the same time, we are of opinion that, under the circumstances related, the patient in question may fairly be called upon to pay the half fee demanded by B., and especially if the fee of two guineas includes the "frequent visits and medicine which were necessary during the twelve days following the confinement," in reference to which latter point A. will, we think, do well in his own interest to consult the explanatory note (No. 11) on "Midwifery," in the new edition of the *Medico-Chirurgical Tariffs*, page 14.

HEAVILY HANDICAPPED.

A. writes: In my absence urgent cases have been sent on to B.; he has retained them, and I have not taken any notice of it. But if B. happens to be out when a message comes for him, his servant comes round to me with B.'s card, requesting me to see the case for B. Thus, he not only keeps the patients that have sent for him and I have seen, but gains those who would have been my patients if I had been in. I wish to do whatever is professional; but this is rather heavy handicapping.

"* Under the circumstances related by our correspondent, he may, we think, not only justly regard himself as (to quote his own language) "heavily handicapped," but unfairly so, in the matter in question. The following is the rule extracted from the second edition of the *Code of Medical Ethics*, page 69, by which practitioners should in similar cases be strictly governed:

"When a practitioner is called to an urgent case, either of sudden or other illness, accident, or injury, in a family usually attended by another, he should (unless his further attendance in consultation be desired), when the emergency is provided for, or on the arrival of the attendant in ordinary, resign the case to the latter; but he is entitled to charge the family for his services."

THE CONSEQUENCES OF CATCHING SCARLET FEVER.

T. S. J. writes: (1) I was subpoenaed to give evidence as principal medical witness in a case for X. v. an Accidental Insurance Company, at assizes in Ireland, on March 16th, the terms arranged being first-class expenses and £3 3s. a day, also £2 2s. for a statement of the cause of death, and reasons for my opinion, etc. On March 9th I got scarlet fever, and consequently could

not attend. On the day of the trial the company compromised, giving £75 instead of £1,000 claimed. I may add that X. relied almost solely on my evidence, which was opposed to that of the jury. Knowing that I would have to go to the trial, I was unable to take any permanent appointment (which was offered), and was out of work for over three weeks, by which I calculate I lost £20. Am I entitled to claim this £20? I have been paid for the statement.

(2) I was acting as *locum tenens* for fifteen days, at rate of £3 3s. per week. On the tenth day I was attacked with scarlet fever, which I got from my patient. Am I entitled to the pay for fifteen days or for ten days?

"* (1) Apparently all the services actually rendered were in making the report, which has been paid for. No fees are ordinarily payable to witnesses unless they attend for the purpose of giving evidence. They might be payable under a special contract, but such contract does not appear in this case to have been made.

(2) The engagement being a definite one for a definite period, the agreed remuneration is payable for the whole time. Illness contracted in the performance of the duties is no reason for refusing payment.

MEDICO-PARLIAMENTARY.

HOUSE OF COMMONS.—Thursday, April 5th.

Retirement of Army Medical Officers.—DR. TANNER asked the Secretary of State for War whether the Royal Warrant of November, 1879, which gave officers of the Army Medical Staff the right to retire after twenty years' service, was about to be interfered with or set aside; whether the condition of retirement was intended as an inducement to medical men to enter the service; and whether the provisions under the said Warrant, if interfered with, would affect the retirement of those medical officers who entered the service since the Warrant was issued.—MR. E. STANHOPE replied that it was not intended to prevent medical officers from retiring after twenty years' service, but it was proposed to require reasonable service in a given rank before allowing retirement at the rates permitted for that rank. The power of retiring after twenty years' service was undoubtedly held out as an inducement to candidates to come forward; and as regards that retirement of £1 a day, no restriction would be placed upon it. The last paragraph of the question touched on vested rights. These, as in all other branches of the service, must be regarded as governed by the rule enunciated by Lord Penzance's Royal Commission in 1874, that an officer's rights are limited to the rank he holds, and this rule was embodied in the preamble to the Royal Warrant.

Friday, April 6th.

Pharmacy Acts Amendment Bill.—DR. FARQUHARSON moved the second reading of this Bill.—MR. J. R. KELLY opposed the Bill, on the ground that it would alter the whole status of chemists' assistants, who would, if this Bill passed, be entirely deprived in many cases of all chance of becoming chemists or druggists. The Bill simply placed the chemists' assistants bound hand and foot in the power of an irresponsible body called the Pharmaceutical Society.

The Horse Tax.—MR. MOZIER asked the Chancellor of the Exchequer whether he could see his way to permit medical men to keep, at least, one horse each free of horse tax.—DR. FARQUHARSON said, before the question was answered, he should like to say whether horses used by medical men for professional purposes might not fairly be considered as horses used for trade purposes.—THE CHANCELLOR OF THE EXCHEQUER said, in reply: I find that there is a precedent for such an exemption as the honorable member suggests. Up to 1869-70, when the horse tax stood at one guinea, doctors and ministers of religion paid only half that duty, and this continued till the duty was reduced to 10s. 6d. for everybody. The question whether one horse ought to be exempt in the case of doctors and ministers of religion is receiving the consideration of the Government; but it must not be forgotten that exemptions are almost always of an invidious nature, and that it is difficult, when once you begin making exemptions from any duty, to know where to draw the line. There is some force in the observation of the hon. member opposite that doctors in country districts do, to a certain extent, come under the definition of traders. I must take this opportunity of reminding the House that the question of exemptions from horse or wheel tax, and, indeed, the question of these taxes generally, is one between the interests of persons using horses and carts and that of the general body of ratepayers. It is not a question between the former and the National Exchequer. I mention this because I see that in many quarters the idea still prevails that these taxes are in some way connected with the reduction of a penny in the income tax.

April 14, 1888.]

the same time, the Government feel that it is essential that the taxes, purely local as they are, should be placed upon the lightest possible basis.—Mr. CHANNING inquired whether the taxes used by farmers would be exempt.—The CHANCELLOR of the EXCHEQUER said the principle which he wished to carry out was that horses used for purposes of luxury should be taxed, and those used in any particular trade should be exempt. He would refer the point raised by the hon. member to his most careful consideration.

Monday, April 9th.

Medical Practitioners.—Mr. A. MORLEY asked the Vice-President of the Committee of Council whether registered medical practitioners in the United Kingdom were afforded privileges of acting in the United States of America; and whether any steps had been taken or were in contemplation by the Privy Council, under Section 17 of the Medical Act, 1836, in the direction of similar privileges being given to legally qualified American practitioners who might be desirous of practising medicine in the United Kingdom.—Sir W. HART-DYKE replied in the negative to both questions.

Thursday, April 12th.

Medical Practitioners and their Horses.—Mr. KNATCHBULL-EGGENSEN asked whether medical practitioners were now allowed to deduct the expenses of their horses in the calculation of income tax, as being necessary for the carrying on of their business.—The CHANCELLOR OF THE EXCHEQUER: Yes, Sir, if the horses are used solely in the exercise of their profession, they would be exempt in the manner suggested.

OBITUARY.

THOMAS HITCHCOCK, M.R.C.S.

WE have to announce the death of Mr. Hitchcock, who died at Leek on March 14th, in his seventy-ninth year, from heart disease. He was born in 1809, and became a pupil of Mr. C. Mayo, of Winchester. He afterwards studied at St. Thomas's Hospital, becoming a Licentiate of the Apothecaries' Society in 1830, M.R.C.S. in 1831, extra-Licentiate of the Royal College of Physicians in 1845, and Licentiate in 1859. For many years he practised at Winchester, where he gained the esteem and respect of all. In 1851 he was appointed Physician to the County Hospital, a post which he held for twenty-eight years; on resigning it he was appointed Consulting Physician. He held the appointment, up to within six months of his death, of Medical Visitor to the Westbrook House Lunatic Asylum, Alton. At the time of his death Mr. Hitchcock had retired for some years from active practice. In 1871 he was appointed county magistrate, having been previously appointed to the Commission of the Peace. The deceased gentleman was fond of sport, and was ever foremost in giving a helping hand to philanthropic, charitable, and other objects. He leaves issue one son, Colonel T. B. Hitchcock, and two daughters.

GEORGE YATES, M.R.C.S.ENG., L.S.A.

WE regret to announce the death of Mr. George Yates, late of Perry Bar, Birmingham, who died at Leamington, after prolonged illness due to renal disease, on April 2nd, aged 66. Mr. Yates was Mr. Alfred Baker's first pupil at the Birmingham General Hospital, and from that time until his death was an earnest worker. He obtained the diplomas of M.R.C.S.ENG. and L.S.A. in 1844. He was a member of the Paris Medical Society, and became Resident Surgeon to the Bedford General Infirmary. Afterwards he was honorary Surgeon to the Birmingham General Dispensary. He contributed papers of great interest to the *Dublin Quarterly* and *Midland Quarterly Journals*; he read many papers to local medical societies, and was a constant debater at their meetings. He was a good classical scholar, and deeply interested in physiological questions. He has ended a long professional career generally esteemed by his professional brethren as a true friend and honest gentleman.

ROBERT TRAVERS, M.B.T.C.D., F.K.Q.C.P.I., Professor of Medical Jurisprudence, Dublin.

MR. ROBERT TRAVERS, whose death on March 27th we have already announced, was Professor of Medical Jurisprudence in Trinity College, Dublin. He graduated in 1832 and became professor in 1844. He did not devote himself to practice, but rather to purely

literary work. In 1841 he became assistant in Marsh's Library, and he was thus enabled to indulge the tastes which were so strong in him. He, however, still maintained his connection with medicine, and, in addition to his other occupations, he lectured on medical jurisprudence in the Ledwich School of Medicine. His lectures were well worked up, full of interest, and instructive, but they were peculiar in style, and some of his laughable class stories, told in quaint and stilted language, are the common property of medical society. To the general body of the profession he was not known, for his habits were essentially those of the recluse. He had a remarkable knowledge of anonymous literature, particularly in that of a theological or patriotic character, and he was always prepared to help any inquirer from the vast stores which he had accumulated. His illness was of short duration. When asked what faith he held, he declared "Christianus sum; I die in the faith of the three creeds." To the many students whom he taught and who survive him, his death will cause much pain, for they all had for him a strong personal affection and admiration.

UNIVERSITY INTELLIGENCE.

UNIVERSITY OF CAMBRIDGE.

It is expected that the magnificent new Chemical Laboratory which has been erected in Downing Street will be partially ready for occupation this term. The laboratory course in pharmaceutical chemistry for the second M.B. examination will be held there daily, beginning on April 23rd.

Dr. Annington, Medical Officer of Health for the Borough, and Secretary of the State Medicine Syndicate, and Mr. Robinson, Assistant to Professor Liveing, announce for the ensuing long vacation a course in Practical Hygiene, suitable for candidates for the Diploma in Public Health Examination in October. The course will include analysis of air, water, and food, and the demonstration of sanitary models. Details may be learned on application to Dr. Annington or Mr. Robinson, at the Chemical Laboratory.

Professor Macalister announces a course of lectures on the Rudimentary Structures in the Human Body, beginning on April 24th.

PUBLIC HEALTH

AND POOR-LAW MEDICAL SERVICES.

PIT BURIAL IN SCOTLAND: AMENDMENT OF THE BURIALS ACT.

At a recent meeting of the Glasgow Philosophical Society, Dr. Eben Duncan, President of the Sanitary Section, proposed and carried the following resolutions: "That the Society memorialise the Secretary for Scotland to take steps for the amendment of the Burials Act, so as to place the private cemetery companies of Scotland under the regulations issued by the Home Secretary in 1883 for burial grounds under the Burials Act," and "That it be remitted to the Council of the Sanitary Section to consider what other reforms are required on our present methods of disposal of the dead, and to report."

After referring to the horrors of pit burial in vogue in all the private cemeteries round Glasgow, Dr. Duncan showed that these cemetery companies were not affected by the Burials Act. That Act, passed in 1855, provided that every local authority should take compulsory powers to secure ground for the proper interment of the people, but, unfortunately, there was one clause introduced into the Act which had prevented any benefit being derived from it in Scotland. It was enacted that local authorities could make an agreement with private cemetery companies to inter their poor for them in any way the cemetery companies thought proper. The cemetery companies were under no regulation whatever; they could do exactly as they liked. The amendment that he proposed would enable local authorities to deal with these cemeteries, and put a stop to pit burials or other nuisances. At present, if a local authority wished to put down such nuisances, it required to act under the Public Health Act, and to prove to the satisfaction of the sheriff that there was an immediate danger to health. Moreover, country local authorities had never paid the slightest attention to this matter. There were three private

cemeteries outside Glasgow that had continued this system of pit burial in spite of much public criticism, and yet the local authorities had not bestirred themselves in the least to put an end to this crying nuisance. It was therefore time that Government should take up the question, and amend the Act so as to bring these cemeteries under proper supervision.

In the discussion that followed Sheriff Spens stated that the sanitary authorities in rural districts were simply no authorities at all, so far as doing practical work was concerned. The present state of matters was not only an outrage upon public decency, but could not by possibility be consistent with public health.

The President (Dr. J. B. Russell) said the local authority of Glasgow had thought it of so much importance that they had resolved to endeavour to get power under the Burgh Police (Scotland) Bill to make by-laws for the regulation of burial grounds. The whole difficulty was that there was no power in the hands of the local authority to enforce regulations that would prevent such a nuisance arising.

HEALTH OF ENGLISH TOWNS.—In the twenty-eight largest English towns, including London, which have an estimated population of 9,398,273 persons, 3,766 births and 3,584 deaths were registered during the week ending Saturday, April 7th. The annual rate of mortality, which had increased in the three preceding weeks from 20.3 to 21.5 per 1,000 declined again during the week under notice to 19.9. The rates in the several towns ranged from 13.6 in Derby; 14.8 in Brighton, and 15.0 in Halifax and in Sunderland to 23.7 in Salford, 28.1 in Blackburn, and 29.7 in Manchester. In the twenty-seven provincial towns the mean death-rate was 20.3 per 1,000, and exceeded by 0.9 the rate recorded in London, which was 19.4 per 1,000. The 3,584 deaths registered during the week under notice included 141 which were referred to whooping-cough, 51 to "fever" (principally enteric), 48 to measles, 46 to scarlet fever, 41 to diarrhoea, 27 to diphtheria, and 17 to small-pox; in all, 371 deaths resulted from these principal zymotic diseases, against 319 and 338 in the two preceding weeks. These 371 deaths were equal to an annual rate of 2.1 per 1,000; in London the zymotic death-rate was 2.2, while it averaged 2.0 in the twenty-seven provincial towns, and ranged from 0.0 in Sunderland, 0.3 in Newcastle-upon-Tyne, and 0.4 in Portsmouth to 3.9 in Blackburn, 4.6 in Salford, and 5.4 in Plymouth. Measles caused the highest proportional fatality in Derby and Plymouth; scarlet fever in Halifax and Blackburn; whooping-cough in Manchester, Liverpool, London, and Salford; and "fever" in Preston, Leicester, and Nottingham. Of the 27 deaths from diphtheria recorded during the week under notice in the twenty-eight towns, 16 occurred in London, 3 in Birmingham, and 3 in Salford. The 17 fatal cases of small-pox included 14 in Sheffield, 1 in Manchester, 1 in Halifax, and 1 in Leeds. The number of small-pox patients in the Metropolitan Asylums Hospitals on Saturday, April 7th, was 8, of which 3 had been admitted during the week. These hospitals also contained 1,032 scarlet fever patients on the same date, which showed a further decline from the numbers in recent weeks; 62 cases were admitted during the week, against 94, 77, and 70 in the three preceding weeks. The death-rate from diseases of the respiratory organs in London was equal to 5.1 per 1,000, and was below the average.

HEALTH OF SCOTCH TOWNS.—During the week ending Saturday, April 7th, 933 births and 551 deaths were registered in the eight principal Scotch towns. The annual rate of mortality, which had risen in the three preceding weeks from 21.0 to 23.7 per 1,000, declined to 21.8 during the week under notice, but exceeded by 1.9 per 1,000 the mean rate during the same period in the twenty-eight large English towns. Among these Scotch towns the lowest rates were recorded in Leith and Greenock, and the highest in Glasgow and Aberdeen. The 551 deaths in these towns during the week under notice included 51 which were referred to the principal zymotic diseases, equal to an annual rate of 2.0 per 1,000, which was slightly below the mean zymotic death-rate during the same period in the large English towns. The highest zymotic rates were recorded Glasgow and Paisley. The largest proportional fatality of measles occurred in Edinburgh; and of whooping-cough in Glasgow, Aberdeen, and Paisley. Two deaths were referred to diphtheria in Edinburgh. The mortality from diseases of the respiratory organs in these Scotch towns during the week under notice was equal to 5.8 per 1,000, against 5.1 in London.

HEALTH OF IRISH TOWNS.—In the sixteen principal town districts of Ireland the deaths registered during the week ending Saturday, April 7th, were equal to an annual rate of 27.2 per 1,000. The lowest rates were recorded in Sligo and Kilkenny, a the highest in Drogheda and Dundalk. The 188 deaths registered in Dublin during the week under notice were equal to an annual rate of 27.8 per 1,000 (against 29.7 and 31.2 in the two preceding weeks), the rate for the same period being only 19.4 in Lond and 22.0 in Edinburgh. The 188 deaths included 19 which resulted from the principal zymotic diseases (equal to an annual rate of 2.8 per 1,000), of which 6 resulted from "fever," 5 from measles, 4 from whooping-cough, 3 from scarlet fever, and 1 from diarrhoea.

HOSPITAL AND DISPENSARY MANAGEMENT.

THE COTTAGE HOSPITAL, WALSALL.

In contradiction of the statements made in the JOURNAL of March 3rd, Dr. MacLachlan, Mr. John Wood, and Mr. P. Shore, write follows:—

1. There is always a qualified medical practitioner at the outpatient department, which is open on three afternoons in the week.
2. The Sisters do not treat fractures without surgical supervision.
3. There never has been a case corresponding to, or in the least resembling, that related by the "well informed correspondent" of the boy with the fractured fibula.
4. The patients have fish for dinner once in the week, in which cod, fresh herrings, and plaice, play about equal parts in the course of the year. The doctor's instructions as to diet and other matters are, and always have been, faithfully carried out.
5. That "the Sister in charge carries things with a very high hand," is a vague assertion, but that during the whole time she has filled that office, now over nine years, there has never been the smallest friction between her and the three doctors, who now form the honorary staff of surgeons, is only the bare truth.

A HOMŒOPATHIC PEER.

LORD DESART, a believer in homœopathy, has availed himself of the opportunity afforded by the projected enlargement of the Grantham Hospital (of which he is president) to offer £225 to complete the required sum of £350, and £100 a year for the next ten years, "on condition that a homœopathic physician be admitted in the staff of the hospital, with full power of treating patients on that system." The letter came before a meeting of the committee on Monday, but its consideration was postponed. The governors will of course understand that if any such offer is accepted, the medical staff will undoubtedly feel called upon in accordance with the general rule in the profession, and the state of opinion which prevails on the subject, to resign.

MEDICAL NEWS.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the Second Examination in Anatomy and Physiology at a meeting of the Board of Examiners on April 5th, namely:—

T. A. O. Langston, H. S. Thurston, E. F. Snyrett, and H. J. Waring, students of St. Bartholomew's Hospital; G. D. K. Bannerman, of London Hospital and Mr. Cooke's School of Anatomy; F. E. Rogers, of London Hospital; R. N. Daniel, J. W. Mactavish, J. R. Harper, and S. Zeldin, of St. Thomas's Hospital; D. Drew, E. Ringrose, L. Williams, A. C. Stevens, and J. B. Paul, of University College; J. B. N. Vickers and G. M. W. of St. Mary's Hospital; C. Thompson, of Charing Cross Hospital; M. Makalua and J. Wood, of King's College; E. C. Long and C. B. Solymon, of Middlesex Hospital.

Passed in Anatomy only.

E. J. H. Budge, of Guy's Hospital; A. Dalzell, of St. Thomas's Hospital.

Passed in Physiology only.

P. C. B. Swanseger, of Charing Cross Hospital; W. K. Steele, of Guy's Hospital.

Passed in Anatomy and Physiology only on April 6th.

F. M. Mangan, H. W. Richards, A. Queinell, F. M. J. Powell, and W. H. Mallow, of St. Bartholomew's Hospital; E. T. Whitehead and J. S. Cooper, of St. Thomas's Hospital; T. J. Wood and C. B. Turner, of University College; E. A. Roek and H. L. Curling-Hope, of Middlesex Hospital; M. S. F. Monier-Williams, of St. George's Hospital; D. L. Southey, of King's College; E. H. Sharmar, of Liverpool, Edinburgh, and

minster Hospital; A. K. Barrett, of St. Mary's Hospital; J. H. Bryant and H. W. John, of Guy's Hospital; A. W. Allen and A. R. Colyer, of Charing Cross Hospital.
 Passed in Anatomy only.
 H. W. Weekes and E. W. Smith, of University College; H. V. Prynne, of Middlesex Hospital; H. L. Morgan, of Westminster Hospital; A. Thorne, of St. Mary's Hospital; J. L. Blakiston, of King's College.
 Passed in Physiology only.
 R. T. Bakewell and W. F. Chambers, of University College; N. Marder, of St. Bartholomew's Hospital; A. Lawson, of Middlesex Hospital.
 Passed in Anatomy and Physiology on April 7th.
 C. P. Le Quesne, F. Arthur, C. P. M. Swales, J. P. Wightman, and C. H. Langford, of St. Bartholomew's Hospital; H. Burden and E. Du Bois, of St. Thomas's Hospital; A. Crick, of St. Thomas's Hospital and Mr. Cooke's School of Anatomy; K. M. Mackenzie and G. E. T. Haydon, of London Hospital; H. S. Baker, D. J. Jones, and J. B. Williams, of Charing Cross Hospital; P. J. Duffy, P. Evans, and A. J. Chambers, of University College; B. W. Hogarth, of Guy's Hospital; L. Rogers and J. C. Wood, of St. Mary's Hospital; W. F. Adams, W. A. Eden, M. K. Soutter, and J. J. Waddelou, of King's College; F. B. Marlin, R. H. Reynolds, and C. L. Lake, of Westminster Hospital; P. G. Garrett, of Middlesex Hospital.

Passed in Anatomy only.
 A. G. R. Cameron and H. M. Phillpotts, of St. Mary's Hospital; H. J. F. Badcock, of Charing Cross Hospital; A. Kidd, of Middlesex Hospital; J. B. Lemon, of St. Bartholomew's Hospital; G. Pernet, of Edinburgh and University College; F. T. Morris, of University College.
 Passed in Physiology only.
 W. A. Hampton, of Middlesex Hospital; J. W. Davies, of King's College.
 Passed in Anatomy and Physiology on April 9th.
 M. L. Margrave, R. Brown, and H. W. C. Austen, of St. Bartholomew's Hospital; H. E. Girdlestone, W. H. Miller, H. D. Levick, and J. B. F. André, of St. Thomas's Hospital; F. G. S. S. Harvey and V. W. Law, of St. Mary's Hospital; W. B. Morton, of University College; T. R. Hamlen and E. Jones, of Middlesex Hospital; A. Rudd, A. T. Coleman, and H. C. De Renzi, of Westminster Hospital; E. W. M. Higgs, of Charing Cross Hospital; D. W. Samways, of Guy's Hospital.
 Passed in Anatomy only.
 H. Clift and C. A. Covertan, of St. Bartholomew's Hospital; E. J. Finch, of St. Mary's Hospital; C. H. C. Visick and E. B. Allan, of University College; J. B. O. Richards and L. J. Minter, of King's College.
 Passed in Physiology only.
 A. G. Minshall, of University College; F. A. Harsant, of Middlesex Hospital; H. W. West, of London Hospital.
 Passed in Anatomy and Physiology on April 10th.
 A. A. Hewer, P. Furnivall, R. Stephens, C. H. Fowler, A. G. Gane, H. A. Eccles, C. B. Dale, and A. Carney, of St. Bartholomew's Hospital; H. L. Hatch, of St. Mary's Hospital; D. C. Johnston, G. F. Dickinson, F. C. Porter, and F. H. S. Blucke, of Charing Cross Hospital; R. E. S. Krohn, of University College; T. G. Brodie, A. Whitfield, and E. L. Pritchard, of King's College; T. H. Kellock, A. King, and H. T. Jones, of St. Thomas's Hospital; A. W. Harrison, of Westminster Hospital.
 Passed in Anatomy only.
 S. H. Rentsch, of King's College; R. F. J. Gill, A. G. Rider, and T. G. S. Crouch, of University College; H. Kneivitt, of London Hospital; St. J. B. Killery and H. Kerwill, of St. Bartholomew's Hospital; A. Jeffreys, of St. Thomas's Hospital.
 Passed in Physiology only.
 J. Mountford, of Charing Cross Hospital; and C. G. Hoysted, of Charing Cross Hospital and Mr. Cooke's School of Anatomy.

The following Member having passed the necessary examinations on November 24th, 25th, 26th, and 27th, 1886, and having since attained the legal age (25), was at a meeting of the Council on April 12th granted his Diploma of Fellow of the College.
 G. P. Newbolt, date of membership, January 22nd, 1855, M.B. Durham, of Newcastle and St. Bartholomew's Hospital.
 The following gentleman having passed the necessary examinations was admitted a Member of the College.
 E. L. Haynes, of St. Bartholomew's Hospital.

MEDICAL VACANCIES.

The following Vacancies are announced:
BIRKENHEAD BOROUGH HOSPITAL.—Junior House-Surgeon. Salary, £50, board, etc., and extras. Applications by April 16th to the Chairman of the Weekly Board.
BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon. Salary, £150, and £30 extra for cab hire. Applications by May 10th to A. Forrest, Esq., Secretary.
BIRMINGHAM GENERAL HOSPITAL.—Assistant House-Surgeon. Residence, board, etc. Applications by April 25th, to the House Governor.
BOROUGH OF BRIGHITON.—Medical Officer of Health. Salary, £500 per annum. Applications by May 2nd to F. J. Tillstone, Esq., Town Clerk.
BRISTOL ROYAL INFIRMARY.—Honorary Assistant Physician (to out-patients). Applications by May 5th to the Secretary.
DURHAM COUNTY HOSPITAL.—Honorary Surgeon. Applications by April 30th to the Secretary.
DURHAM COUNTY HOSPITAL.—Honorary Surgeon-Dentist. Applications by April 30th to the Secretary.
DURHAM UNION WORKHOUSE.—Medical Officer. Salary, £50, and extras. Applications by April 20th to William Lisle, Esq., Clerk to the Guardians, 35, Sadler Street, Durham.
LIDDELL PROVIDENT DISPENSARY, Jarrow-on-Tyne.—Medical Officer. Salary, £200. Applications to John Christie, Esq., 23, Cobden Street, Jarrow.

LIVERPOOL STANLEY HOSPITAL.—Junior House-Surgeon. Salary, £70, with board, etc. Applications by April 19th to the Honorary Secretary.
LIVERPOOL STANLEY HOSPITAL.—Senior House-Surgeon. Salary, £80, with board, etc. Applications by April 19th to the Honorary Secretary.
NORFOLK COUNTY ASYLUM, Thorpe, near Norwich.—Junior Assistant Medical Officer. Salary, £100, with board, etc. Applications by April 21st to Dr. Thompson, Medical Superintendent.
NORTH-WEST LONDON HOSPITAL, Kentish Town Road.—Senior Resident Medical Officer. Applications by April 23rd to the Secretary.
OUGHTRARD UNION, Cloonbur No. 2 Dispensary.—Medical Officer. Salary, £102 per annum and fees. Applications to Mr. James Higgins, Honorary Secretary. Election on April 17th.
OUGHTRARD UNION, Lettermore Dispensary.—Medical Officer. Salary, £132 per annum and fees. Applications to Mr. John Wallace, Honorary Secretary, Tully, Inveran. Election on April 17th.
PARISH OF TARBAT EUSTEE, Ross-shire, N.B.—Medical Officer. Salary, £115. Applications to Finlay Munro, Rockfield-by-Fearn, Ross-shire, N.B.
ROTHERHAM HOSPITAL.—Assistant House-Surgeon. Board, etc. Applications by April 27th to the House-Surgeon.
ST. LUKE'S HOSPITAL.—Resident Clinical Assistant. Board and lodging. Applications by April 26th to the Secretary.

MEDICAL APPOINTMENTS.

BOWKES, Charles S., L.R.C.S. and L.M.E., L.F.P. and S.G., L.R.C.P., appointed House-Surgeon to the Royal Infirmary, Glasgow.
BRANE, Woodhouse, L.R.C.P., F.R.C.S., appointed Anesthetist to St. Peter's Hospital for Stone, Henrietta Street, W.C.
CLEWOW, Frank G., M.B., C.M.Edin., appointed Resident Medical Officer to the British Seamen's Hospital, Cronstadt, St. Petersburg.
FISHER, Alfred, M.R.C.S. Eng., L.R.C.P. Edin., appointed Honorary Medical Officer to the No. 2 District of the Ladies' Charity and Lying-in Hospital, Liverpool, vice William O. Pugh, M.B. Lond., resigned.
FOURQUEMIN, George V., L.R.C.P., L.R.C.S., L.M.Ed., appointed Resident Medical Officer to the St. Helen's Friendly Societies' Medical Aid Association, vice A. M. Hynes, L.R.C.P., M.R.C.S.
GEMMELL, John E., M.B., C.M.Edin., etc., appointed Honorary Medical Officer to the No. 4 District of the Ladies' Charity and Lying-in Hospital, Liverpool, vice Meyer J. Bernstein, M.D., C.M.Edin., resigned.
HOLMES, Thomas D. H., M.B., C.M.Ed., appointed Assistant Medical Officer to the East Riding Asylum.
MECHAN, Joseph, M.B., C.M., late Resident Assistant at the Glasgow Royal Infirmary, appointed Resident Assistant Medical Officer to the Glasgow Town Hospital.
MILNE, J. B., M.B., C.M., appointed House-Surgeon to the Dewsbury and District General Infirmary, vice Alexander Milne, M.B., C.M., resigned.
McKINSTRY, W. H., M.B., M.Ch., appointed Assistant Surgeon to the Liverpool Dispensaries.
PEDLER, William Frederick, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A., appointed House-Surgeon to the Richmond Hospital, vice W. A. Payne, resigned.
ROLSTON, J. R., M.R.C.S. Eng., appointed Honorary Ophthalmic Surgeon to the Royal Albert Hospital, Devonport.
SIMPSON, Samuel, M.B. and B.Ch. Dub., appointed Second Assistant Medical Officer to the Somerset and Bath Asylum, vice W. S. Barnes, M.D., resigned.
SMYTH, W. J. S., M.B., C.M.Ed., appointed Temporary Assistant Medical Officer to the Essex Lunatic Asylum, Brentwood.
WATSON, Thomas Alfred, M.B., C.M.Edin., appointed Assistant Resident Medical Officer to the Woolwich Union Infirmary, Plumstead, S.E., vice J. M. Caw, M.B., C.M., resigned.
WEBB, J. B., M.R.C.S. Eng., L.R.C.P. Lond., appointed Assistant-Surgeon to the Liverpool Dispensaries.
WHITBY, Charles J., B.A., M.B. Cantab., appointed Resident Assistant-Surgeon to the Liverpool Dispensaries (East).
WILLS, William Alfred, M.B. Lond., M.R.C.S., appointed Medical Registrar to the Westminster Hospital, vice Dr. Syers, resigned.

GUY'S HOSPITAL MEDICAL SCHOOL.—The Michael Harris prize in anatomy, value £10, has been awarded to Mr. J. H. Bryant, of Ilminster; the Beaney prize in pathology, value 30 guineas, to Mr. E. H. Starling, of Bombay; and the Golding Bird prize for diagnosis, value 33 guineas, to Mr. R. D. Mothersole, of Colchester.

ST. JOHN AMBULANCE ASSOCIATION.—We learn from Mr. Hugh Lane, of Bath, that the whole of the candidates of the Bath Ladies Branch of the St. John Ambulance Association obtained certificates of competency at the recent examination.

A TABLET bearing a portrait of the late Dr. Austin Flint, erected in the Carnegie Laboratory by the Alumni Association of the Bellevue Hospital, New York, was recently unveiled by the President of the Medical College.

A BILL has been introduced into the House of Assembly with the object of providing the United States with a national *Pharmacopœia*.

THE will of Dr. Robert Palmer Clayton, of Denby Dale, Huddersfield, has been proved, the personal estate amounting to over £14,000.

THE PARKES MUSEUM, MARGARET STREET, S.W.—His Grace the Duke of Westminster, K.G., has made a donation of £100 to this Museum in aid of its work of practical teaching and demonstrating sanitary science.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.

MEDICAL SOCIETY OF LONDON, 8.30 P.M.—Mr. Damer Harrison, of Liverpool: Cerebral Abscess treated by Operation. Dr. J. Milner Fothergill: Small and Moderate Valvular Lesions of the Heart.

SOCIETY OF ARTS, 8 P.M.—Mr. Richard Bannister, F.I.C., F.C.S.: The Cantor Lectures on Milk Supply and Butter and Cheese Making. Lecture II.

TUESDAY.

PATHOLOGICAL SOCIETY OF LONDON, 8.30 P.M.—Specimens: Mr. Shattock: Rare kind of Pedunculated Body in Knee-joint. Mr. Sharkey: Alcoholic Paralysis of Phrenic, Pneumogastric, and other Nerves. Mr. Bowly: Some Cases of Gangrene. Mr. Doran: Primary Cancer of Fallopian Tube. Dr. G. Griffiths: Tumour in Neck invading Jugular Veins. Mr. Bruce Clarke: Sloughing of Bladder following Cystitis. Mr. Silcock: Cystic Disease in Testis. Card Specimens: Mr. Bowly: Unusual Forms of Loose Bodies from Knee-joint. Dr. Leclard: Enlarged Bursa Patellæ with Outgrowths from Walls. Dr. N. Dalton: Gummata in Liver of an Infant.

ROYAL MEDICAL BENEVOLENT COLLEGE, EPSOM.—Twenty-fourth Annual Festival at the Hôtel Métropole, at 7 P.M.

WEDNESDAY.

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND, St. Bartholomew's Hospital, 4.45 P.M.

THURSDAY.

PARKES MUSEUM OF HYGIENE, 5 P.M.—Mr. Justice Cunningham: On the Public Health in India.

HARVEIAN SOCIETY OF LONDON, 8.30 P.M.—Dr. Braxton Hicks, F.R.S.: Two Cases of Ovariectomy complicated with Pregnancy. Dr. Frankish: On Venesection.

FRIDAY.

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 7.30 P.M.—The Council will present reports on: (1) The Journal of the Society; (2) The Local Government Bill. The following papers will be read: C. A. Watts Parkinson, M.R.C.S.: Notes of an Epidemic of Pneumonia. J. F. J. Sykes, M.B., B.Sc.: Verification and Certification of Deaths.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the announcement.

BIRTHS.

BROWNE.—On April 9th, the wife of Samuel Browne, M.D., late Royal Navy Medical Officer to H. M. Prison, Warwick, of a son.

DARTNELL.—At Rochester, on April 4th, the wife of William A. Dartnell, surgeon, of a son.

GRIFFITHS.—On April 8th, at 18, St. George's Terrace, S.W., the wife of Herbert T. Griffiths, M.D., of a son.

MCCAW.—On April 7th, at Alba House, Portglenone, Belfast, the wife of J. Dysart McCaw, M.D., F.R.C.S., of a son.

MARRIAGES.

ACLAND-GULL.—On April 12th, at All Saints' Church, Margaret Street, London, by the Right. Rev. the Lord Bishop of Lincoln, assisted by the Rev. A. B. Cotton, uncle of the bridegroom, Theodore Dyke Acland, third son of Sir Henry Acland, K.C.B., F.R.S., of Oxford, to Caroline Cameron, daughter of Sir William W. Gull, Bart., F.R.S.

BAUMGARTNER-PATTINSON.—On April 5th, at St. Mary's Church, Gateshead, by the Rector, the Rev. W. Moore Ede. Henry Spelman Baumgartner M.B., M.S., M.R.C.S., etc., Newcastleton-Tyne, youngest son of John Percy Baumgartner, Esq., J.P., of Gorleston, Suffolk, to Ethel Mawson, second daughter of John Pattinson, Esq., Shipcote House, Gateshead.

EVANS-BARTON.—On April 11th, at St. Mary's, Balham, Charles Silvester Evans, M.B., of Shaftesbury, Dorset, son of the late Benjamin Evans, F.R.C.S., of Brixton, to Lilian Mary, daughter of George Mitchell Barton, Esq., of Calcutta.

FLOOD-SPROULE.—On April 4th, at Omagh, by the Rev. W. Colquhoun, assisted by the Rev. — Houston, Surgeon S. J. Flood, Army Medical Staff, youngest son of A. Flood, Esq., M.D., Danesfort, co. Fermanagh, to Marion, only daughter of H. Sproule, Esq., J.P., Irish Land Commissioner, Coolnagarde, co. Tyrone.

HICKSON-DURHAM.—On April 4th, at St. George's, Hanover Square, by the Rev. William Rogers, M.A., Rector of St. Botolph's, Bishopsgate, and Chaplain in Ordinary to the Queen, John Godfrey Hickson, son of the late James Hickson, of Highgate, to Ellen Lucy (Nellie), second daughter of Arthur E. Durham, F.R.C.S., of 82, Brook Street, Grosvenor Square, W.

LYONS-CORMACK.—On January 21st, at St. Paul's Pro-cathedral, Melbourne, Victoria, by the Rev. G. E. Bromby, D.D., Brigade-Surgeon R. T. Lyons, M.D., to Helen Rose, eldest daughter of the late Sir John Rose Cormack, M.D., of Paris.

ROWBOTHAM-ABBOTT.—On April 5th, at St. Mary's, Bideford, Devon, by the Rev. Roger Grauville, M.A., Rector, Herbert Claude Rowbotham, surgeon, Melbourne, Derbyshire, son of the late Dr. Rowbotham, of Woolwich, to Jessie Caroline, daughter of John Abbott, of Bideford.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

THE quarterly meeting of the Council was held on Thursday April 12th, 1888.

The minutes of the ordinary Council on March 8th were confirmed. Mr. Sibert Cowell was appointed Assistant Secretary of the College.

The minutes of the Jacksonian Committee on April 11th were read as the report from that Committee. The Committee having adjudged the Jacksonian Prize for the past year to the author of the dissertation bearing the motto "Thorough," the President opened the sealed envelope bearing the aforesaid motto, and declared the name written therein to be Edwin Hurry Fenwick.

The Council also recognise the merits of the dissertation bearing the motto "Veritas" as deserving of special mention; and it was resolved to open the envelope bearing the said motto, upon which it appeared that the author was Mr. F. A. Southam, of Manchester. Both these gentlemen were invited to attend the next meeting of Council.

The following was declared to be the subject of the Jacksonian Prize for the ensuing year 1889, namely:—The Pathology, Diagnosis, and Surgical Treatment of Intracranial Abscess and Tumour.

A report, dated March 20th, 1888, from the Committee of Management of the Examining Board in England by the Royal College of Physicians and the Royal College of Surgeons was approved and entered on the minutes.

The Committee reported that, in consideration of the necessary additional work which had fallen on the staff during the past year, involving as it did a considerable extension of the office hours beyond those originally contemplated, the Committee has thought it right to recognise their services by awarding to the Secretary fifty guineas, to each of the two senior clerks fifteen guineas, and to the junior clerks ten guineas.

A report, dated April 11th, 1888, from the Committee on the form of the report of the Council to the annual meeting of the Fellows and Members of the College, was approved, adopted, and entered on the minutes.

The report stated that the Committee having, in pursuance of the resolution of the Council of March 8th, 1888, taken into consideration the "form of the report of the Council to the annual meeting of the Fellows and Members of the College," had adopted the following report to the Council, namely:

"The Committee are of opinion that no alteration should be made in the report so far as the materials from which it is framed are concerned; and that, in addition to the returns as to the examinations and the statement of accounts, in which no change, necessary, it should only contain, as heretofore, an actual record of the transactions of the Council; but the Committee recommend that the form in which the report is drawn up should be altered so as to provide that, in the arrangement of the several subjects discussed and determined by the Council, each subject should be within the range of the period to which the report relates, but complete."

A report, dated April 3rd, 1888, from the President and Vice-Presidents on the arrangements for the College lectures was approved and entered on the minutes. This report was as follows:

"The President and Vice-Presidents have to report that, in pursuance of the resolution of the Council of June 9th, 1887, they have taken into consideration 'the propriety of rearranging the lectures annually delivered in the College, and of making them more serviceable to the profession; and that they are not prepared to recommend to the Council that any alteration should be made in the arrangements for the lectures, believing that the plan recently adopted of dividing the lectures amongst several professors has been to some extent successful, as evidenced by the increased attendance upon them, and that it would therefore be inopportune at present to make any change in that plan."

It was also agreed that the experiment of the lectures being delivered at 5 P.M. instead of at 4 P.M. as hitherto should be tried.

Sir T. Spencer Wells, Bart., was appointed the Morton Lecture on Cancer and Cancerous Diseases for the present year.

A letter of March 15th was read from the Privy Council stating that the Government had determined to advise Her Majesty to refer the subject of the grant of degrees in medicine and surgery to Royal Commission.

Deputy Surgeon-General Jeffery Allen Marston, C.B., and Mr. Thomas Annandale, of Edinburgh, were elected Fellows under Section 5 of the charter of the 15th Victoria applicable to Members of the College of twenty years' standing.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

QUERIES.

R. H. C. asks to be recommended where to obtain the best kind of portable commode suitable for an invalid when travelling.

E. N. C. asks if there is any institution for the reception of medical men in delicate health, or any home in which a medical man would receive slight medical treatment. He would be prepared to pay a small amount, say £1 or 30s. a week.

INCONTINENCE OF URINE AND FÆCES.

R. K. C. B. writes: I have a patient, aged 5½ (girl), who from infancy has passed both fæces and urine involuntarily. She is not nervous, enjoys good health, and is well developed, both mentally and physically, for her age. There is no pain or tenderness over the spine. She has been seen by various medical men, and different remedies (including galvanism, which was not applied regularly owing to the patient residing in the country) have been tried, but without any permanent benefit. I should feel grateful for any hints as to treatment and prognosis from those who have had similar cases under their care; also to know of any paper or book which deals with the subject.

ANSWERS.

SURGEON F. M. KNIGHT.—A paper on the determination of proteid bodies in the urine is in type, and will be published shortly.

RUSTICUS.—The case has been inquired into by the officers of the British Medical Benevolent Fund, and the facts are as stated. The circumstances are peculiarly distressing, and the case is stated to be a genuine one.

CONGENITAL BLINDNESS.

H.C.M.G. asks whether there are any institutions for cases of congenital blindness, where they would be taught a trade, such as basket-making, etc.

* * Our correspondent will probably be able to obtain all information from Dr. Armitage, 34, Cambridge Square, Hyde Park, Secretary to the Association for the General Welfare of the Blind. There is also a list of various institutions in Fry's *London Charities*.

TREATMENT OF HEARTHURN.

M.D. writes: In reply to a Member suffering from hearthurn, I would recommend him to try the effect of a piece of the best Spanish liquorice, of the size of a pin's head. It may be repeated as often as he needs it, but not in greater quantity at a time.

PURE WOOL CLOTHING.

A MEMBER asks if there is any way by which irritation of the skin, caused by pure wool clothing may be checked or minimised.

* * The irritation diminishes after the clothing has been properly washed and the skin becomes habituated to the wool. A great deal depends upon obtaining good material in the first place, and in this respect the English, Scotch, or Welsh goods are far superior to their competitors.

GYNÆCOLOGICAL COUCH.

COUNTRY MEMBER will find the Rotunda Couch, advertised by Stewart and Co., Newgate Street, meet his requirements.

TREATMENT BY ANTICIPATION OF POST-PARTUM HÆMORRHAGE.

DR. A. H. NEWTH (Hayward's Heath) writes: I have found the following plan of treatment remarkably successful in several cases in which severe flooding has previously and repeatedly taken place, and the patients have made good recoveries.

For some days or even weeks before give a mixture containing dilute sulphuric acid 10 drops, liq. strychnie 4 minims, with a little sulphate of magnesia if there is constipation. Just before labour sets in give 5 minims of liq. strychnie with a dose of ergot, unless the pains are strong. Then use constant pressure on the uterus during the passage of the child. I like a towel folded cornerwise, with a knot tied at the back. Directly the placenta is expelled, wash out the uterus with a large quantity of warm, almost hot, water containing Condy's fluid. Put on a binder or tighten the towel with a firm pad over the uterus.

DR. G. ARMSTRONG ATKINSON (Newcastle-upon-Tyne) writes: In reply to "Felix," I fear the account he gives of the stages of labour is too brief to indicate the manner in which he conducts them, especially as regards the third stage. In his case obviously one ought very carefully to keep grasping the uterus during the birth of the child and the placenta, the latter being removed only after the lapse of at least half an hour from the conclusion of the second stage. The bladder ought to be emptied shortly before the child is born. After delivery the uterus must be kept within the hand and the organ steadily compressed, from time to time making firmer pressure. If necessary the other hand may be introduced into the vaginal canal or uterus, so as to compress the organ between the two hands. As a rule, however, I regard the use of hot water injections as detailed by Athill, Emmett, and more recently by Milne Murray, preferable if further means be required.

As to the use of ergot or ergotin in labour, I regard any pills as quite useless. The Pharmacopœial hypodermic injection of ergotin is as convenient a preparation, and one giving as satisfactory results, as any yet formulated, but one must always bear in mind how very variable ergot is in quality, and also that it deteriorates, however carefully it be preserved. In the case under discussion, I would inject the ergotin as soon as the head was born. Any treatment which would raise the patient's tone before labour would be of great advantage.

DR. C. T. BROOKHOUSE (Brockley, S.E.) writes: In reply to "Felix," who asks for suggestions in the treatment of anticipated post-partum hæmorrhage, I

would suggest the administration of my liq. strychnie twice a day for a month prior to the expected confinement, and the immediate application of electricity after the birth of the child, should normal contraction not take place. This can easily be done by means of a Gaiffe battery, price 21s., one sponge being pressed above the pubes and the other introduced by the hand to the cervix. The sol. ergotin hypoderm. B. P., is a very reliable preparation; it may be injected deep into the gluteal region, and repeated if necessary.

MR. GEORGE EATON STANGER writes: In reply to the query of "Felix" in the JOURNAL of April 7th, I have long been in the habit of administering liq. strychnie my ter die for a month before the completion of the term.

DR. JOSEPH THOMPSON (Nottingham) writes: If "Felix" will give his patient 5 minims of liq. strychnie in tincture of orange peel three times a day for a month or six weeks before her confinement, I think she will have no hæmorrhage.

AMICUS writes: In answer to the inquiry of "Felix" as to the treatment to be adopted in a case where post-partum hæmorrhage has occurred after three previous confinements, may I suggest to him a trial of strychnine, in doses of 4 or 5 minims of the official solution, three times a day, with or without iron as advisable? In two cases in my practice, where such hæmorrhage had occurred twice and four times respectively in former labours, this treatment during two months before the expected time was most satisfactory. The uterine contractions were more forcible, and no atony followed the expulsion of the placenta.

PRACTICE IN AMERICA.

YANKEE writes: In reply to "Stars and Stripes," I beg to state that he can practise in all the States, with the exception of New York, Pennsylvania, and Illinois. These States demand an examination which is rather severe, particularly for an Englishman. It would be a great advantage for anyone contemplating locating in the States to possess the M.D. degree. The registration fee is thirty dollars (about £8) in the States requiring registration.

TREATMENT OF TRACHEAL COUGH.

MR. LOCKHART STEPHENS (Emsworth) suggests inhalations of pinol, 20 to 30 drops to be placed on a pledget of absorbent cotton in the hot water of an ordinary form of inhaler, to be used for ten or fifteen minutes three or four times daily. During the past six months he has had under close observation four cases of incipient phthisis, in which the cough was the most prominent symptom, and in all the cough ceased after using these inhalations for from four to six days; all the patients are doing well, and are very grateful for relief afforded. He adds that in these cases sedatives had had full trial, and had failed. No remedy, in his personal experience, gives such relief as pinol inhalations. The makers of pinol are Messrs. Burroughs, Wellcome and Co., Snow Hill Buildings.

NOTES, LETTERS, ETC.

THE BUDGET.

MEDICUS writes: The classing a doctor's horses as "pleasure horses" and his carriages as used for purposes of luxury is very unjust. I doubt if they are so used in any sense on half a dozen occasions in the course of the year. Owing to our practice being in a mixed suburban and country district ten miles from town, my partners and myself are obliged to keep two horses each, and, owing to the distances we have to travel and the often heavy state of the roads, it is sometimes necessary, in order to get over the ground quickly, to drive a pair. Our rents and local rates are very heavy, so that this additional taxation will press on us with increased severity. I see that already letters from medical men in protest have appeared in the lay press, and I feel confident that any measure so injurious to the interests of a hard-worked and poorly-paid profession will be opposed by the leaders of the British Medical Association.

THE LATE MR. J. TEEVAN.

MR. A. TEEVAN (Ballarat, Victoria) writes: There was a slight mistake in the obituary notice of my uncle, the late Mr. James Teevan, which appeared in the JOURNAL of November 26th, 1887. He had three brothers in the profession instead of two, namely, William Teevan, of Bryanston Square (father of the late Mr. William Frederick Teevan, of Portman Square, Dr. Henry Teevan, of Dunedin, New Zealand, and myself); John Teevan, of Woodside, Croydon; and Michael Teevan, of Kensington, both of whom had at the time of their death retired from practice.

A CASE OF DISTRESS.

Second List of Donations.

Further donations in aid of the family will be gratefully received by Dr. George C. Jonson, 16, South Eaton Place, S.W., or by Dr. John M. Bright, Park Hill, Forest Hill, S.E.

OLD CLOTHES: AN APPEAL TO THE BENEVOLENT.

MR. EDWARD EAST (16, Upper Berkeley Street, Portman Square, W.), Honorary Secretary of the British Medical Benevolent Fund, writes: I am in urgent need of some cast-off clothing of any sort for men, women, or children, and shall feel very much obliged if any kind friends could help me by sending a few articles to me at this address. I can assure their being well used and most thankfully received. Great-coats and warm clothing for men, jackets

CLINICAL LECTURE

DISEASES OF THE TONGUE.

Delivered at University College Hospital.

By CHRISTOPHER HEATH, F.R.C.S.

Holme Professor of Clinical Surgery in University College, London.

GENTLEMEN,—I propose to-day to speak of the diseases of the tongue. Of course the tongue is constantly looked at simply as an index of disease elsewhere; and, as far as that is concerned, I do not propose to deal with it to-day, but to confine my observations to the surgical diseases of the tongue. I think you will admit that the simplest way to consider these will be under three heads, namely, the inflammatory affections of the tongue, the ulcerations of the tongue, and, lastly, deposits in the tongue. Of course you will find them given differently by different authors, but, on the whole, I think that it is perhaps as convenient a way of putting it as any other.

First, as regards the inflammatory affections of the tongue, here is, of course, such a thing as acute glossitis, but, it is very rare, and you have not had an example of it before you, that I know of, of late—at all events, not in my practice. Still you may meet with such a case, and it is well to know that patients are liable to a sudden great enlargement and inflammatory swelling of the tongue, which looks very formidable for the first few hours, and may sometimes prove dangerous to the patient's life by inducing suffocation. You may occasionally meet with it coming apparently idiopathically, but more often it seems to be connected with the administration of mercury. A patient has been taking mercury for some reason; and, it is difficult to say why, he gets acute glossitis. Under these circumstances you find the tongue enormously swollen, filling up the mouth of the patient and almost suffocating him, and naturally requiring to be relieved immediately. The treatment is extremely simple—by making an incision on each side of the median line of the tongue. Do not mind a little free bleeding. Bleeding relieves the affection, and then with a little fomentation and simple gargles the whole thing subsides in a few hours. It really is not a very important affection, although it looks very alarming when you first see it.

What I want to speak more particularly about to-day are the chronic affections of the tongue. We get chronic inflammation of the tongue from various causes. Perhaps one of the commonest is the form which is due to smoking, for there can be no question whatever that tobacco has a deleterious effect upon the mucous membrane of the tongue. If you must smoke, and I suppose in the present day it is difficult for any young man not to smoke, may smoke mild tobacco, and do not use pipes which are saturated with oil, and which, perhaps, have been smoked by other people.

Now, with regard to the chronic glossitis which is produced by the tobacco affection, you will find that authorities differ about it, but I agree with Mr. Barker in his essay in *Holmes's Surgery* that there is a condition of reddened tongue which is an early stage of chronic glossitis. When that has passed away you find a later stage where you have a development more or less complete (it varies, of course, in different patients) of a white patch. This may be simply a loss of epithelium—that is, a common condition which is sometimes known as "glazed tongue"—but you find in addition to that sometimes a development of white tissue in the tongue, of which you see a very good example in one of the illustrations in Mr. Butlin's book. We happen to have a patient who has been in No. 1 ward lately for an anal affection. I have invited him out to you when you have gone round, as a remarkably good example of what is dignified by the name of "leucokakia" or "leucoma," and I will now bring him before you; and let me remind you that when you examine a tongue, the first thing to do is to dry it. I will dry this man's tongue, and then you will see clearly a white patch, which is partly the cicatrization resulting from an operation performed upon it. Here we have a good example of the results of chronic glossitis, which at one time seemed likely to run into more serious disease. We have

here a growth developed in the white patch, which at one time looked exceedingly like epithelioma, so much so that the man was admitted into the hospital in 1886 with the view of having part of the tongue removed. It was not removed quite so promptly as it would have been but for a Fellowship examination which was coming off, and we wanted the patient to be shown. I postponed the operation, therefore, and during the fortnight or so that he was waiting here the tongue improved so much under simple treatment that I made up my mind that it could not be epithelioma, and accordingly I simply scraped away the disease which had sprung up in the white patch, or beneath it, and the result, as you see, is that the man is now well. He has a perfect tongue instead of having lost part of it, and it is quite clear that it was not a case of epithelioma developing in a patch, but was simply hypertrophy of the submucous tissues, the result of chronic inflammation. Let me at the same time warn you that there is no doubt whatever among those who have carefully observed these cases, that a patient who has a white patch is more liable to epithelioma than the patient who has not a white patch. I do not like to put it more strongly than that. I do not say that every such patient will have epithelioma, but his chances of having it are greater than those of a patient who has not a white patch.

The white patch may of course go on and develop into a sort of warty growth, as you see here in one or two of these pictures, or it may develop into a condition which is sometimes badly called psoriasis; or again, it may develop by still greater irritation into what is sometimes called ichthyosis of the tongue. They are all degrees of the same disease. Ichthyosis was the name given by Mr. Hulke, who first called attention to it; and it is undoubtedly much nearer epithelioma than the white patch. There is a drawing here in Mr. Clarke's book which illustrates it very well. It is a very good representation of a highly hypertrophied and roughened mucous membrane. An ichthyotic tongue is so near epithelioma that it is just a question whether you should remove the tongue at once, or wait until there are positive signs of epithelioma. I think myself, if I had a well developed ichthyotic tongue, I should prefer to have it out at once rather than run any further risk.

Now let us take another class of case, where you have a chronic change in the epithelium due to syphilis. You may have a primary chancre. The early enlargement of the glands under the chin and jaw is very characteristic of chancre; but do not suppose that you will find that induration which we see so commonly on the penis, because you will not any more than you do on the lip. The cases of primary chancre on the tongue are extremely rare; but you must bear in mind that a patient may most innocently get a primary sore upon the tongue from another. If a patient hands, from a mouth which has mucous tubercles in it, a pipe, which must necessarily have some syphilitic saliva upon it, to another person who has a little sore or crack on the tongue, it is conceivable that the tongue may become affected, and the patient may have a primary chancre. Much more common than that, but still rather rare, are mucous tubercles. You find that a patient who has syphilis in the system sometimes develops mucous tubercles about the tongue, particularly on the back part of the organ.

But the most common syphilitic affection of the tongue is another form of glossitis—chronic glossitis with cracks in the tongue—which is well recognised as the result of secondary syphilis. The picture in my hand shows it well. You see the loss of epithelium in the centre of the tongue, and round the sides you see a cracked, cicatrised tongue. Those deep cracks, sometimes running quite far into the tongue, are as characteristic as anything you can have of secondary syphilis. Then, if you go further and follow out syphilis, of course you may have gummata in the tongue; but I shall put these under the head of deposits, and I will say a word now with regard to the treatment of that which is so common an affection.

The question arises, in the case of such a tongue as I have described, will you give mercury or iodide of potassium? Certainly, in a tongue like that you had better give small doses of mercury. It is true the patient may have had mercury before; but I find that these patients do better with small doses of mercury—which you can, if you like, combine with iodide—in the form of biniodide, or you may give it separately as liquor hydrargyri perchloridi. The thing I lay most stress on, however, is the local application of mercury. These tongues do well if you only pickle them in a mercurial lotion. It is of no use to tell the patients to use a mercurial mouth-wash and

then spit it out. They should be told to hold it in their mouths ten minutes by the watch, and breathe through their noses, so as to get the tongue thoroughly pickled with the lotion. As to the strength of the lotion, I advise you to begin with a quarter of a grain (afterwards getting a little stronger) of perchloride of mercury, with a little honey to make it more palatable, in an ounce of water. If the process of "pickling" is repeated twice or three times a day, the effect produced on the tongue is astonishing; the ulcers will heal under the mercurial treatment, the tongue will cicatrize, and the patient will recover a perfectly useful tongue, in which there will be no risk, so far as I know, of any future development of epithelioma. It is longstanding diseases that develop into epithelioma; but if you cure the disease and make the tongue healthy, or comparatively healthy, the patient will be no more liable to epithelioma than any other person.

Now let us go on and take the forms of ulceration, which we have from three different sources. You may have the syphilitic ulceration, you may have the tubercular ulceration, and you may also have the epitheliomatous ulceration. Syphilitic ulceration I have already mentioned in connection with superficial inflammation of the tongue. It is well that you should remember that there is another form of ulceration connected with syphilis, that is the ulcerated gumma. Some months ago we had in the hospital an old man, a foreigner, with very well marked ulcerated gumma on one side of the tongue. I took him in because he could not be attended at home, and he got steadily better under good treatment. He was here a week or two ago to show his tongue, and I then called your attention to how very much it was improved. The treatment of these ulcerated gummata is of course a little different from that of the ulcers occurring in the earlier stage of syphilis. Where you have ulcerated gummata of the tongue, it would be unwise to push mercury. You give iodide of potassium, and improve the patient's health in every possible way; and if you use the mercurial wash, not stronger than a $\frac{1}{4}$ to a $\frac{1}{2}$ grain to the ounce, you certainly get those tongues better.

The tubercular ulcer of the tongue is not a very common thing, and you see it more often in private practice than in the hospital. It usually occurs at the tip of the tongue, and is I believe very often determined by irritation from the teeth; at all events, I have found that by covering the teeth with gutta-percha, so as to prevent the tongue being rubbed against the back of the teeth, I have been able to get these tongues very much better. Here is an example in Butlin's book of a well-marked ulcer of the tip of the tongue, and where you find an ulcer in that condition you will generally find some evidence of tubercle in the lungs or other parts of the body. An ulcer like that you must treat as you would treat an ordinary tubercular ulcer elsewhere, namely, by scraping away all the diseased tissue. You may or may not find tubercle bacilli in it. I am not prepared to say which is more common, but at all events you should scrape the ulcer, and then dress it with iodoform, and treat the patient with cod-liver oil and by general anti-tubercular remedies.

Then we come to the third form, which is the malignant or epitheliomatous ulcer. Now, why does a patient get epithelioma of the tongue? Invariably, I believe, from some irritation. Patients with perfectly healthy tongues do not get epithelioma. But if you have a patient who has a white patch beforehand, which is a little irritable, perhaps scratched by a tooth, and which is kept in a state of irritation by the constant application of tobacco juice, one can easily imagine that developing into epithelioma. But as far as my experience goes, the greater number of cases of epithelioma are simply due to the local irritation of a ragged tooth cutting into the tongue; nothing has been done to relieve it, and then at last a development of epithelioma takes place. During the last winter I have seen two middle-aged gentlemen, both of whom had the very smallest patches of epithelioma that I have ever seen on the tongue from that cause. They both had sharp pointed teeth, and they were conscious that those teeth had been irritating their tongues. They went on, however, until at last they began to find something wrong, and then they took advice. In both cases I cut out the piece, and it was simply mucous membrane that was affected by the disease, which did not go down into the muscular fibre of the tongue at all; but still in both cases there was well-marked microscopic evidence of epithelioma. One may hope that by such an early removal as that, the patient may be completely relieved of the disease. Still, the great thing is to prevent the occurrence of such cases. I am happy to say that dentists are becoming better instructed every day; they are more

alive than they were to the importance of irritation caused by teeth, and they do send on cases at once, when they find anything suspicious about the tongue, to medical men and surgeons to see what the matter is. Too often, however, patients themselves are content to let the thing go on; and then at last they come with a ragged ulcer, which is undoubtedly epitheliomatous.

I quite allow that the very early stage of epithelioma is a little difficult to recognise; but when the ulcer is well developed, and the induration at its base has become well formed, no one can hesitate for a moment. Here we have three examples of epithelioma. An epitheliomatous ulcer is not simply an ulcer, but an ulcer with a growth, a growth springing up at the edges of the base and forming a protrusion, sometimes a distinct protrusion, as in this particular case, but more often like this other case, an indurated base of the ulcer with well marked granulations coming up into the cavity. Unfortunately, you have seen many of these cases, because we have a great many in the hospital at various times, and in hospital practice they do not come until very late, so late that generally the glands are enlarged. But in private practice we see them rather earlier, before the glands are enlarged, and I want particularly to impress upon you the importance of not waiting for the glands to become affected. It is very absurd that a surgeon should think to himself, "This cannot be cancer because there is no enlargement of the glands," and then deliberately wait and watch to see whether the gland become affected or not before he makes his diagnosis. That is a very good as regards diagnosis but very bad as regards the patient, and the patient who is waited for in that way is hardly treated, for you ought, if possible, to get rid of the cancer before the glands become affected.

Let me now say a word about diagnosis, because that is really the important point. How will you diagnose a case of epithelioma when you see it? In the first place by the position. It is more generally at the edge and side of the tongue than anywhere else, and the history is pretty conclusive. You will find that for weeks or months the patient has had some irritation about the tongue; he has had an ulcer which has too often been constantly irritated by the application of nitrate of silver, and has developed more and more until there is the characteristic growth in the base and edge of the ulcer which I have mentioned. Then there may be tenderness of the glands of the neck. The pain, too, is characteristic; the patient tells you that it shoots up into the ear. I always dread that phrase, and never prompt a patient to use it, but as sure as he does so it is a case of cancer of the tongue.

Lastly, we have the deposits in the tongue, which I have mentioned incidentally, and which are of two kinds, the epitheliomatous, which always follows the ulcer and extends beneath it, and the gumma, which develops, as a rule, in the central portion of the tongue, and is apt to break down and give rise to a formic-like-looking ulcer, as already described. Unquestionably a ulcerated gumma may develop into epithelioma, and it is these mixed cases which apparently improve for a time under iodide of potassium, and yet prove malignant after all.

What, then, is to be done for cancer of the tongue? Undoubtedly to palliate these cases is merely to lose valuable time, and the so-called "cancer cures" are simply swindles on the public. Chian turpentine stands on a different footing altogether, and I have used it where I thought it right as an adjuvant to surgical treatment, but I confess that I have never seen any benefit from it whatever. I have even sent a patient on whom I had operated and who had a return of the disease, by his own wish, to Dr. Clay, of Birmingham, that he might himself carry out the treatment; but the patient died under the treatment, just as he would have done without it, and in about the same time, without having received the slightest benefit. I do not think there is any special cure for cancer, and the only chance for the patient is to get rid of it as early as possible.

That brings me to the question of operations on the tongue. Of course there are many, but I am not going to trouble you with them all; it will be sufficient to tell you what we do here at the present time. We have all come, in most cases, to removing the tongue with scissors. Years ago, as you will find if you look in the records of the hospital, the galvanic *écraseur* was used, but we gave it up because it led to secondary hæmorrhage. The answers well for the time, if the battery is in good order, and you can remove the tongue without bleeding; but you are apt to get secondary hæmorrhage a few days afterwards, when the slough comes away. After the galvanic *écraseur* we used the wire *écraseur*. The best way of using it is Mr. Baker's modification of the oper-

tion—namely, to split the tongue down the middle, to loosen it from all its attachments beneath, and then divide with the *éraseur* far back, taking one-half of the tongue at a time. Of course in many cases you remove only half; it is not necessary to remove the whole. We have most of us now given up that operation and gone to the intrabuccal operation with the scissors, generally known as Mr. Whitehead's operation. It is extremely simple. All you have to do is to gag the patient thoroughly—it is important to have a good gag; then, getting a firm hold of the tongue, with the scissors you divide the mucous membrane under the tongue and the muscles, and, drawing the tongue well forward, next divide it at the root, cutting steadily through till the lingual artery is exposed, when you can often pick it up before dividing it. Having done one side, you go to the other, if you remove the whole tongue, and treat it in exactly the same way. The result is that you get the tongue away as far back as you like with very little hæmorrhage.

Let me say, on the subject of hæmorrhage, that I myself introduced an improvement in the operation about the tongue some years ago, which I find most surgeons have adopted, namely, that when there is hæmorrhage and you require to stop it, you simply put your fingers down the patient's throat and hook up the base of the tongue and the hyoid bone. I found that out when assisting my colleagues in removing the tongue. We used to have occasionally sharpish hæmorrhage. It was my business to help to pick up the arteries, and I found that by putting the fingers well down I could stop the bleeding, making the tongue bloodless, and pick up the arteries quietly, as you might pick up an artery in a limb.

But then supposing you have disease of the tongue with enlargement of the glands, should you or should you not operate upon them? For myself I am not particularly fond of removing glands, yet I am obliged to do it from time to time. Where I find a patient has an ulcer of the tongue which is distinctly cancerous with infiltration in the submaxillary glands, I do not hesitate to make an incision and take the glands out. It becomes a little different when the glands of the neck are affected. In my experience cases where the submaxillary lymphatic glands are not affected and the glands under the sterno-mastoid are affected are the worst possible cases. If you cut out one gland, you find very soon afterwards that another becomes affected; and those patients, as a rule, have very short lives. Cases where you can remove the glands under the jaw merely do fairly well, as well perhaps as any of these cases. Because, after all, you must remember that recurrence is almost invariable, and one hardly knows of a patient with *bonâ fide* epithelioma living more than two years. Then in these cases where the glands are affected you may have seen some of my colleagues do a very large operation called Kocher's operation. You make an incision into the neck, turn up a large flap, and get down upon the glands; you then get hold of the tongue, and you can undoubtedly remove numerous glands and extensive disease of the tongue through that incision. I am not particularly favourable to it. It seems to me that in cases in which there is such extensive disease as to warrant an operation like that, we had better not interfere with the neck, but content ourselves with removing the tongue. That, however, is my individual opinion.

You saw me in the beginning of last session do an extensive operation on a man in the private ward, No. 1. He was sent up from the country with extensive disease of the tongue and of the submaxillary tissues. He was in a miserable state, and anxious to have something done. I told him plainly that I would operate if he wished, but I could not promise him anything more than temporary relief. On November 2nd I operated on him. The disease was so extensive that I thought it better to do tracheotomy first. I do not usually do tracheotomy in these cases; I do not hold with preliminary tracheotomy in ordinary operations on the tongue; but this was so extensive a case that I thought it right to do it. I was then able quietly to remove the whole tongue down to the hyoid bone, and a piece of jaw right up to the masseter on each side, and all the infiltrated submaxillary tissues. It is not the first time that I have done an extensive operation like that. The first case I had was in 1876, and the result of it is in the museum. The patient lived certainly four years after the operation, but he did not appear to have many weeks to live at the time I operated.

Still these extensive operations are not very satisfactory. This very patient, before he was really well, had a recurrence. The operation was on November 2nd, and he went out on December 2nd convalescent from the operation, but having already evidences

of a return of the disease. I heard from the friends that he had a recurrence, but I have not heard whether he is dead: the poor fellow cannot have long to live.

The satisfactory cases are those where the disease is entirely confined to one part of the tongue, where you can get well behind that portion and remove it at once, and where there is no infiltration of the glands. It rests with you, who will see these cases early, to insist upon the patients having an operation in early days if there is evidence of disease. When we get that sufficiently insisted on, unquestionably our rate of mortality and our rate of cure will very much improve.

The Registrar-General has pointed out that cancer is much on the increase. There are two or three explanations. No doubt many cases are put down as cancer which formerly were not recognised as such. Still even if that be so, I think, from my own observation, there can be no doubt that we do see more cases of cancer of the tongue than we did twenty or thirty years ago. One explanation is, I believe—you will excuse my saying so—the greater spread of smoking; and another, I think, is the greater spread of syphilis. Those are the two main elements which have to do with cancer of the tongue being so much on the increase. I hope that we shall be able to diminish it, and that by taking the cases early and by removing the diseased part thoroughly, we may be able to hold out some prospect to the patient of prolongation of life—we cannot honestly do much more than that at present.

THE PROCESS OF COMPENSATION AND SOME OF ITS BEARINGS ON PROGNOSIS AND TREATMENT.

By BYROM BRAMWELL, M.D., F.R.C.P. EDIN.

Assistant Physician to the Edinburgh Royal Infirmary; Lecturer on the Principles and Practice of Medicine in the Extra-Academical School of Medicine, Edinburgh; etc.

MR. PRESIDENT AND GENTLEMEN,—When my old friend, your esteemed Secretary, asked me in the name of your Council to read a paper and introduce a discussion at this meeting, I felt that it was impossible to refuse such a complimentary invitation, for which I now beg to return you my warmest thanks; but I did not, I fear, sufficiently appreciate the difficulties of the task to which I was committing myself; indeed, it was only after I had accepted your courteous invitation, and when I came to look about me for a subject, that those difficulties became fully apparent. After much consideration and not a little hesitation in coming to a decision, the subject which finally commended itself to me was "the process of compensation and some of its bearings on prognosis and treatment;" and I trust that in selecting this subject my judgment may have guided me correctly, and that it may prove both acceptable to you and the source of a good debate.

Speaking generally, and using the term in its widest sense, compensation may be said to include all those processes by means of which Nature endeavours to repair a damage done by disease or injury, to protect herself against the injurious results of disease, or to relieve, reduce to a minimum, and make bearable those results.

The basis of all compensation is the fundamental fact that the human organism as a whole, and each of its individual parts in particular, is, in ordinary circumstances—and granting, of course, that the condition is one of health—working below its full strength; that, in short, it possesses a large balance or reserve on which it can fall back when any sudden or unusual demand is made upon it.

Now the success of the result—in other words, the completeness of the compensation—depends upon several factors, the most important of which are:

1. The amount of the reserve.
2. The suddenness and extent of the call; or, in other words, whether time is allowed for the realisation or development of the reserve.
3. Whether the demand is temporary or continuous; in other words, whether the lesion is stationary or progressive.

I may perhaps be able to make my meaning clearer if I make use of a financial illustration.

* A paper read before the Border Counties Branch of the British Medical Association at Carlisle on February 24th, 1888.

Suppose, then, in the *first* place, that a call is made upon a trader which exceeds his reserve, the result will, of course, be bankruptcy or financial death. The same result may follow when a demand for a sum, well within his reserve, is made so suddenly that he is unable to realise his resources and so to meet the call which is thus unexpectedly made upon him. In the latter case, the risk of bankruptcy will, of course, be greater when the reserve is already partly mortgaged and tightly tied up.

Now both of these conditions have an exact parallel in disease. A severe case of malignant scarlet fever, which rapidly proves fatal, and in which, from the intensity of the attack, the case is clearly hopeless from the first, may be taken as an illustration of the former; while the latter is exemplified by the fact that sudden destruction of a comparatively small portion of the motor cortex of the brain will produce paralysis or loss of function—bankruptcy of the muscles, as we may term it—while much more extensive destruction, provided that it is slowly and gradually established, or, in other words, provided that time is allowed for compensation or realisation of the reserve, may be unattended with any paralysis (see Figs. 1, 2, 3, and 4).

In the *second* place, a heavy call made upon a man in a large way of business and who has an ample reserve, may severely tax his energies and resources for the moment; but, provided that he is able to keep himself afloat and to tide over the great and sudden strain which is placed upon him, his position is ultimately little, if any, the worse. For a time, it is true, he may be debilitated and shaken; but his business is so sound, his credit is so good, in other words, his vitality is so great, and the local damage which is left behind is comparatively speaking so slight, that he soon makes up his loss, and is ultimately in no way deteriorated. As examples of this condition, acute croupous pneumonia and those inflammatory and febrile diseases, such as typhus, which leave little or no permanent local damage, may be mentioned.

In the *third* place, a demand, which falls short of producing bankruptcy, may so seriously reduce the trader's reserve and so materially damage his credit that it leaves him permanently crippled. Under such circumstances, a wise man appreciates the difference in his position, reduces his expenditure, is careful to avoid risks and hazardous speculations, and above all, to guard himself as carefully as possible against a repetition of the conditions which produced his previous reverse. Permanent compression of the lung, the result of a pleurisy with effusion or an empyema, destruction of one kidney by suppuration, and syphilitic disease of the larynx with resulting stenosis, may be mentioned as cases in point.

In the *fourth* place, instead of, as in the former cases, a single call being made, the demand may be repeated from time to time, or it may become more or less continuous. At first the effect may be unnoticed, for, the call being small in proportion to the reserve, it may excite no anxiety or apprehension. But frequent repetitions of the call may so reduce the reserve that ultimately a period may arrive when the reserve is exhausted and the income is only just sufficient to balance the expenditure. Under such circumstances, a trifling extra demand, which formerly would have been laughed at because of its insignificance, may now be sufficient to upset the balance, to throw the trader into great difficulties, or even to produce bankruptcy. Illustrations of this group are numerous in disease; perhaps the best that can be cited is a slowly progressive cardiac valvular lesion, such as aortic regurgitation.

Turning now to actual disease, let me mention some of the chief means by which compensation and compensatory protection are effected in the human subject.

In the case of doubly or bilaterally represented organs, when one is disabled or destroyed, compensation is effected by enlargement or true hypertrophy of the remaining sound organ on the opposite side. Familiar illustrations are the hypertrophy of one kidney or of one lung which follows destruction of the kidney or lung on the opposite side.

The very important practical bearing which the condition of the remaining and apparently sound organ has, both for prognosis or treatment, is self-evident. The success or failure of an operation for the removal of a diseased kidney to a large extent depends upon the condition of the kidney on the opposite side.

And here I would raise a practical point, and ask whether there is any other means than palpation and percussion of the kidney

(in other words, than the presence of localised pain or tenderness on pressure, or of distinct enlargement of the organ), by which it is possible to ascertain the condition of the kidney which is to remain. The condition of the urine discharged *per urethram*, is an uncertain guide, for, representing as it does the products of both kidneys, any abnormal constituents which it contains may, of course, be derived from the diseased kidney. I would like to ask whether it may not be possible, by the aid of the electric endoscope which Mr. Hurry Fenwick has recently described, to catheterise the ureters in the male, and by obtaining the urine direct from either kidney, to ascertain the functional condition of each organ individually.

The relative value of life after one of two bilateral organs, such as the lung or kidney, has been destroyed or removed, is a question of distinct practical importance, and one which, so far as I know, has not yet received the attention it deserves. The subject is one which might I think be profitably taken up by the Collective Investigation Committee of the Association.

It is quite obvious that the life of an individual who has lost one lung in consequence of an empyema or a long standing and badly treated pleurisy with effusion, or of a patient who has lost one kidney either as the result of a pyelitis, or in consequence of its having been excised by the surgeon because it was the seat of a tumour, or affected with hydro-nephrosis, hydratid or cystic disease, is a bad one, quite apart from the risks entailed by the diathesis or special pathological tendencies of which the original disease was a manifestation. A limited pneumonia or a small pleuritic effusion, which in a normal individual would be a comparatively trifling condition, is, as we all know, attended with the greatest danger when the opposite lung is useless. But irrespective of such obvious and well-known risks, does not, I would ask, the increased strain and functional activity which is thrown upon the remaining sound organ, when its fellow has been destroyed, entail special risks, and predispose it to disease? When, for instance, one kidney has been destroyed or removed, is not the risk of Bright's disease greater than it would be in the same individual, provided that he had two kidneys? I would ask the members of the Branch to give us their experience on these points—to detail, for example, the life-history of cases in which one lung has been rendered useless, by a previous pleurisy or empyema.

Compensation in Brain Lesions.—There is perhaps no organ in which the results of unilateral damage are more interesting, or require more careful observation than the brain. Consisting as it does of two hemispheres or halves, the different portions of which (areas or centres of grey matter) are, as modern investigation (experimental and clinico-pathological) has shown, endowed with special functional activities, it is a most interesting and important question to determine whether the corresponding centres in the two hemispheres are functionally separate and distinct, or whether they are so related that when one, say a centre in the right hemisphere, is destroyed, the damage may not be compensated, in other words, the function taken up and carried on by the corresponding centre on the opposite (say the left) side.

The question is a difficult and complicated one, and the facts which we at present possess are not sufficient to enable us to give a definite answer in all cases. The result would appear to depend chiefly upon two factors, namely (1) the function of the centre which is destroyed, and (2) the age of the patient at the time when the destruction takes place.

The motor centre for speech in right-handed persons is, as we all know, located in the posterior end of the lower or third left frontal convolution. Destruction of this centre is followed by motor aphasia, but the permanence of the speech derangement depends to a large extent at least, upon the age of the patient. In children the aphasia is usually of quite temporary duration, and in young adults the condition may be entirely or to a large extent recovered from, but in old people recovery is usually very imperfect; indeed, in many cases after the temporary disturbances (speech defects) due to shock, inflammatory oedema, and cerebritis have subsided, the aphasia which is due to the actual destruction of nerve tissue (that is, to the lesion itself, and not to the temporary disturbances in its neighbourhood) remains, and little or no improvement in the condition subsequently takes place.

Now in those cases in which Broca's convolution has been destroyed, and in which recovery from the aphasia takes place, compensation is in all probability effected by the corresponding centre on the opposite side (posterior part of the right lower frontal convolution) taking on the function of the part which has been de-

² The paralysis which follows a sudden but small lesion of the motor cortex may be, in fact usually is, merely temporary.

stroyed. That this is the manner in which compensation is effected in such cases seems proved by a case of great interest and importance which Barlow has recorded; the chief details of which are as follows. A boy, aged 10, affected with aortic disease, was suddenly seized with right hemiplegia and aphasia, the paralysis chiefly affecting the face and arm. The aphasic symptoms soon passed off, and at the end of a month he had apparently quite recovered. He was then seized with left-sided hemiplegia, which chiefly affected the face and arm. There was now complete aphasia, with paralysis of all the muscles of the face and tongue, reflex movements, such as deglutition, being, however, unaffected. The aphasia continued until the time of death, which resulted from the cardiac lesion. At the necropsy a lesion was found in exactly the same situation in each hemisphere, namely, a yellow softening of the posterior part of the middle and lower frontal, and of the lower end of the ascending frontal convolutions. In this case, therefore, destruction of the left motor speech centre produced aphasia, which was soon recovered from, while subsequent destruction of the corresponding part in the right hemisphere (destruction of which, it will be observed, does not as a rule produce any aphasic disturbances in right-handed persons) was followed by complete and permanent aphasia, and, in addition, by paralysis of the facial and tongue muscles (*JOURNAL*, July 28th, 1877, p. 103).

In the case of the motor centres more strictly so called, the result (that is, whether compensation will or will not take place) seems to depend largely upon the fact whether the movements which are represented in the centre which is destroyed are in the habit of being performed bilaterally or unilaterally.

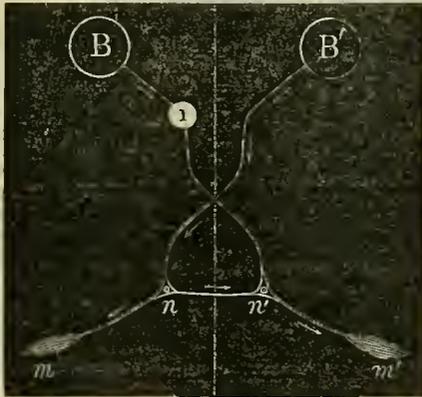

Fig. 1.—Diagram illustrative of the manner in which paralysis is compensated in the case of muscles which are in the habit of acting in association. The letter B points to the right, and B' to the left, cerebral hemisphere; n and n' to the nerve nuclei in the spinal cord, for the muscles m and m', which are in the habit of acting together. A lesion, in the position of 1, will arrest the motor nerve force, passing down from B to m' through n'; and will therefore cause paralysis of m'. Compensation is effected, and the paralysis recovered from by the motor nerve force from B', passing through n and n' to m', as shown by the arrow.

The movements of the two eyes, of the two sides of the face, chest, and trunk are, for the most part, performed in concert. We laugh, for example, with both sides of our faces, and although some persons are able, by means of a voluntary effort, to put each individual muscle of expression into separate and independent action, for most of us this is impossible without long practice. Many people even find it difficult to wink with one eye alone.

In short, there is every reason to suppose, from the observation of muscular action in the healthy man, from the results of experimental investigation on the brains of monkeys, and from observation of spasms due to localised cortical irritation in the human subject, that those muscles on the two sides of the body which are in the habit of acting in true association or concert may be thrown into action from either hemisphere.

Possibly this associated bilateral action is effected, as Broadbent has ingeniously theorised, by means of commissural fibres connecting the nerve cells of the trophic nerve nuclei in the pons Varolii, medulla oblongata, and spinal cord. (See Fig. 1). But be that as it may, there can be little doubt that when a cortical centre which innervates muscles which are in the habit of acting in concert with corresponding muscles on the opposite side of the body is destroyed, compensation is effected and permanent

paralysis prevented by the function of the destroyed centre being taken up and carried on by the corresponding centre in the opposite hemisphere of the brain.

The more highly specialised movements, on the other hand, seem, so far as we at present know, to be represented only in one—the opposite—cerebral hemisphere. If this is so we should expect that complete destruction of the cortical centre, say, for the muscles of the forearm and hand, would be followed by permanent paralysis, and that such is actually the case seems proved by the experiments of Ferrier, Horsley, and Schäfer, in the monkey, and by the results of disease (destroying lesions) in the human subject. In those cases, for example, in which hemiplegia results from a lesion in early life, though the leg regains a considerable amount of power—indeed, in some cases, almost completely recovers, the muscles of the hand and forearm may, and often do, remain markedly paralysed. Such cases seem to prove conclusively that the motor centres for the muscles of the hand and forearm of one side are only represented in one, the opposite, hemisphere; and that when the muscles concerned in the production of the highly specialised movements of the hand are paralysed, compensation cannot be effected by the corresponding centre on the opposite side of the brain taking up and carrying on the function of that which is destroyed.

Cases are occasionally met with which seem at first sight, at all events, to form exceptions to this law. The most remarkable case of this kind with which I am acquainted is one which I have reported in the *Edinburgh Medical Journal* for February, 1879, page 693. In it, a large sarcomatous tumour, almost the size of the closed fist, had apparently destroyed the greater part of the motor area on the right side. So far as one could judge with the naked eye, the whole of the motor centres for the face and upper extremity were destroyed (see Figs. 2, 3, and 4), and on microscopical examination the grey matter in this region seemed to have completely disappeared. And yet there was absolutely no trace of paralysis.

Cases such as this suggest at all events the possibility of substitution being in some rare cases effected, even when the movements paralysed are highly specialised and differentiated by the corresponding motor centres in the opposite hemisphere.

A more probable explanation is, however, that which supposes that the grey matter in the affected area was not entirely destroyed. In considering cases of this description, it must be remembered that the different cortical centres are not sharply defined and separated one from the other, that to some extent at all events they run one into the other. Such an overlapping has been clearly demonstrated by Horsley and Schäfer in the case of those centres which are situated on the inner side of the cerebral hemisphere (that is, in the marginal convolution).

The importance of this overlapping, and the possibility of compensation being effected by undeveloped or embryonic nerve-cells in the immediate neighbourhood of a centre which has been destroyed has been clearly set forth by Victor Horsley. "Since," he says, "in a complete piece of mechanical apparatus we find that loss of function is in proportion to the amount and seat of the injury inflicted on it, analogy will surely lead us to imagine that unless it is specially provided with a reserve of embryonic tissue in every part, the nervous system is no exception to this general rule. Although the purport of this paper is briefly to discuss the scientific value of the theory of substitution or compensation, it is impossible to go further without referring to the saving clause above mentioned, namely, the possible existence in the cerebral cortex at least of numbers of small nerve-corpuscles, connected with the veteran corpuscles of well-marked centres, but which have not yet themselves subserved psychical function. The existence of such corpuscles has been assumed by several writers at the present day, and with fair ground, seeing that in the first place the gradual accretion of knowledge by the child, and in the second place the intellectual acquirement of some new subject late in life, are both best explained theoretically on the assumption that fresh tracts are opened up with each new and complete idea. The bearing that this view has on the question of substitution is of course of fundamental importance, since, supposing it to be true, it is very easy to imagine that if a centre be destroyed, the elementary corpuscles in the uninjured area around having within themselves a faint echo of the nerve disturbance which before was normally existent in their immediate neighbourhood can be educated gradually so as to replace the part injured" (*Lancet*, July, 1884, p. 7).

In order to illustrate this theory of substitution, and to show

the important difference that there is between rapid and slow destruction of a motor centre, I am in the habit of making use of the following simile: Supposing a peal of bells, each rung by a ringer especially trained to ring his own bell and that bell only (the bell-ringers representing the discharging motor centres in

of whom may be able to establish lateral connections, and to train themselves to carry on the work of their disabled colleague. In the case of the sensory cerebral centres, compensation by the action of the opposite hemisphere seems to occur much more readily.

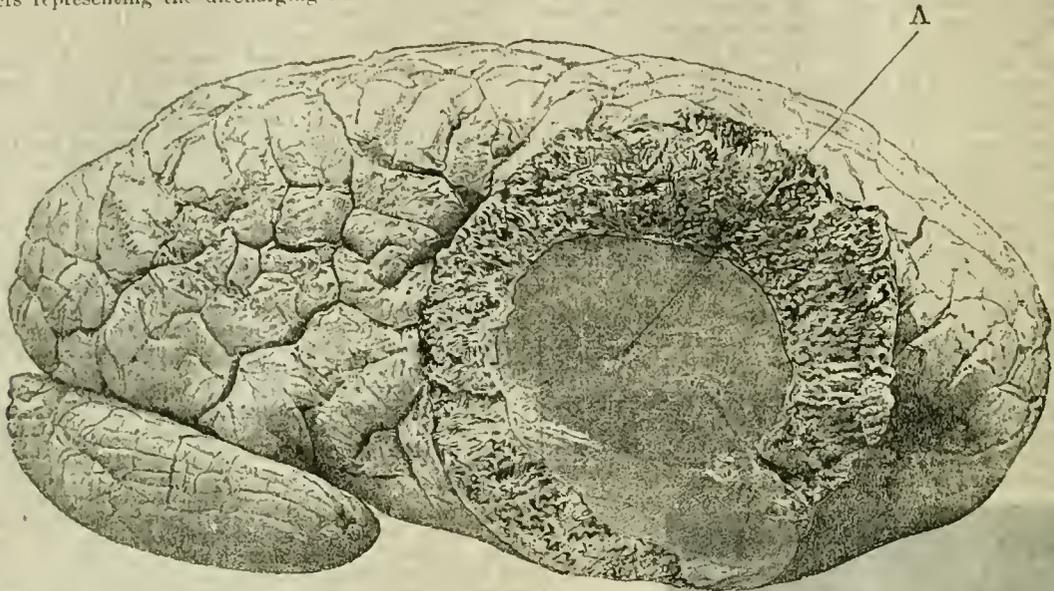

Fig. 2.—The outer surface of the right hemisphere of the brain in the case of M. D. (large sarcoma growing from the dura mater, which had produced extensive atrophy of the motor centres, but was unattended with paralysis) showing the tumour *in situ*. (Copied from a photograph, and somewhat reduced in size.) The letter A points to the outer surface of the dura mater over the centre of the tumour. The leading features of the case are detailed in my work on *Intra-cranial Tumours*, page 11.

the cerebral cortex, the bell-ropes the conducting fibres of the pyramidal tract, and the bells the muscles); and suppose that one of the bell-ringers or discharging centres is suddenly disabled—say, killed or put *hors de combat* by an apoplectic seizure—paralysis of the bell or muscle, which he, and he only, has been trained

The tactile centre (which according to Ferrier is situated in the hippocampal region, and according to Schafer in the gyrus fornicatus as well as the hippocampal lobe) appears in the adult, at all events, to be distinct and separate from its fellow on the opposite side; but it is doubtful if its complete destruction in the child is

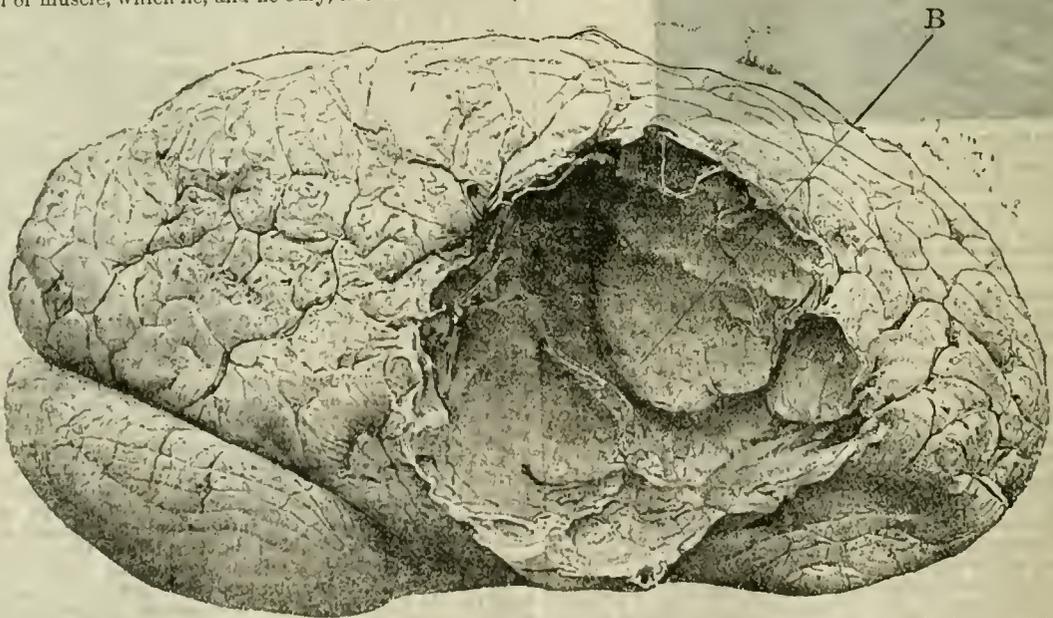

Fig. 3.—The outer surface of the right hemisphere of the brain in the case of M. D., showing the brain after the tumour was removed. (Copied from a photograph, and somewhat reduced in size.) The letter B points to the extensive depression on the surface of the brain into which the tumour fitted.

to ring, will necessarily result; but if instead of being suddenly destroyed, one of the ringers is gradually and slowly disabled by some chronic disease—say cancer of the stomach—he will be able to communicate his failing condition to his fellow ringers, some

ever followed by permanent hemianæsthesia; in other words, it would appear that the tactile centre in one hemisphere can, in the child, take up and carry on the function of its fellow on the opposite side. The extensive connections which the tactile centre

has with the other portions of the cerebrum, and the important fact that when one sense is placed *hors de combat*, compensation may be effected by one of the other senses supplying the place of that which is destroyed, are shown by the facts that blind persons may be taught to read and that they may be largely educated by means of the sense of touch, and also by the most interesting and remarkable circumstance that in some cases in which there is complete word-blindness, in which the patient is unable to decipher a single word or letter by the aid of sight, he is able to read, when he writes the letters or even when he traces the letters with his finger in the air. In the latter case the loss of vision is compensated by means of the muscular sense.

In the case of sight, destruction of the posterior part of the occipital lobe—the half vision centre as it has been termed—seems to be followed in the adult by permanent loss of vision towards the opposite side (that is homonymous hemianopsia). Whether this is so in the child, in other words, whether the half-vision centre in one occipital lobe is able, even in the child, to take up and carry on the function of the half vision-centre in the opposite occipital lobe, has not been as yet ascertained.

Central vision seems to be bilaterally represented, so that complete destruction of the whole of the visual centre in one hemisphere need not destroy the acuity of vision, since central vision is bilaterally represented. It is said, however, by Munk, and his observations on this point seem supported by Schäfer, that destruction of the half vision-centre in both hemispheres is followed by complete and permanent blindness.

It seems certain that the special senses of hearing, taste, and smell are bilaterally represented, but the exact position of their respective cerebral centres is not yet definitely decided, Schäfer's recently published observations being opposed to some of Ferrier's observations on this point. Clinico-pathological observation in man has as yet failed to throw any very certain light upon the subject. Loss of hearing, taste and smell, very rarely, if ever, result from a localised lesion such as a tumour in either cerebral hemisphere,³ though a peculiar form of loss of hearing, "word-blindness," does seem to result from a lesion of the first temporo-sphenoidal convolution in the left hemisphere. The fact too,

that localised lesions in the temporo-sphenoidal lobe are in some cases attended with an auditory or olfactory "aura" a noise or a smell, seems to support the view that the auditory and olfactory centres are situated in this region. It would appear, therefore, that the cortical centres for hearing, taste, and smell in one hemisphere can take up and carry on the function of the corresponding centres on the opposite side.

As regards the mental and intellectual defects which result from localised lesions in parts of the cerebral hemispheres other than those parts or centres which have just been referred to, our knowledge is also somewhat indefinite; but there is reason to suppose that localised destruction of the prefrontal lobe on one side can, to some extent at least, be compensated by the action of the corresponding centre on the opposite side. In this, as in other cases, the compensation is more perfect in those cases in which the lesion is slowly and gradually established, and in which the patient is young. The size of the lesion or the amount of de-

struction is also, of course, a most important factor in determining the result.

Extensive lesions of the prefrontal lobe are probably, in the adult, attended with lasting alterations in the mental faculties and disposition; small localised lesions may, in all probability, be compensated to some extent; but in investigating such cases it is necessary to remember that slight mental defects and alterations are difficult to detect, and may therefore easily pass unnoticed. In dealing with purely mental symptoms, in other words, with cases of localised brain destruction in which there are no motor or sensory derangements properly so called, the greatest caution is required. We can only determine whether any mental defect has resulted from a lesion (in other words, whether perfect compensation has resulted or not) when we are in a position minutely to compare the mental condition after recovery with the mental condition before the occurrence of the lesion; and it is unnecessary to say that in most cases we are not able to make such a comparison founded on our own personal knowledge. We have in most cases to rely upon the statements of the patient's friends and relatives—in many cases an uncertain and unsatisfactory method of ascertaining the normal mental condition of the patient, even when dealing with educated and intelligent people. That severe lesions of the prefrontal lobes

which produce no obvious motor or sensory disturbances do produce permanent mental alterations, in other words, that such lesions are not compensated, in the adult, at all events—and the same also applies to the child—is abundantly proved by clinical observation. The extraordinary case, which is known under the name of the "American crowbar case," shows how profound these mental symptoms may be; and at the same time illustrates the enormous reserve which Nature possesses, and the marvellous recoveries which sometimes take place after the most serious injuries. The details of this remarkable case (I quote from Ferrier) are as follows:

"The subject of the lesion was a young man, Phineas P. Gage, aged 25. While he was engaged tamping a blasting charge in a rock with a pointed iron bar, 3 feet 7 inches in length, 1½ inch in diameter, and weighing 13½ lbs., the charge suddenly exploded. The iron bar, propelled with its pointed end first, entered at the left

angle of the patient's jaw, and passed clean through the top of his head, near the sagittal suture in the frontal region, and was picked up at some distance covered with 'blood and brains.' The patient was for the moment stunned; but within an hour after the accident he was able to walk up a long flight of stairs and give the surgeon an intelligible account of the injury he had sustained. His life was naturally for a long time despaired of; but he ultimately recovered, and lived twelve years and a half afterwards. Unfortunately, he died (of epileptic convulsions) at a distance from medical supervision, and no *post-mortem* examination of the brain was made; but, through the exertions of Dr. Harlow, the skull was exhumed and preserved. Upon this the exact seat of the lesion can be determined. The line of union of the cicatrices of entrance and exit, however, allowed a pretty accurate estimation of the track of the bar during life, and Dr. Bigelow did so with considerable accuracy.

"Dr. Bigelow, who examined the man two years after the accident, thus describes the appearances presented: 'A linear cicatrix of an inch in length occupies the left ramus of the jaw near its angle.....The eyelid of this side is shut, and the patient is unable

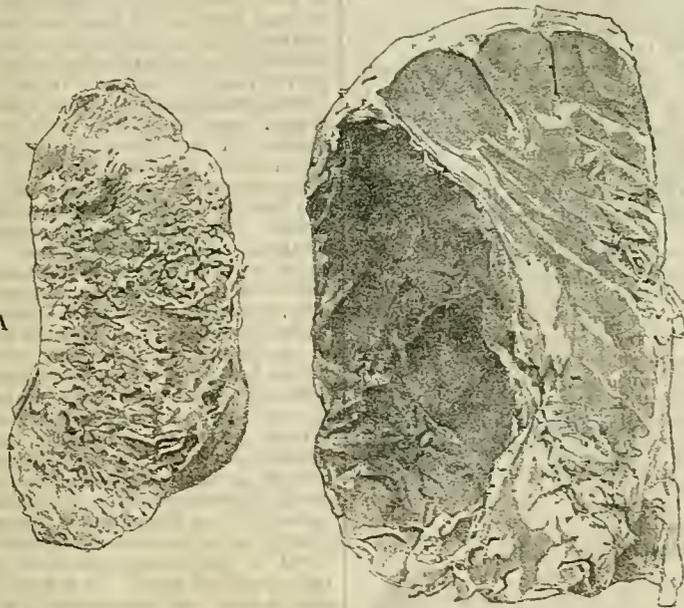

Fig. 4.—Transverse vertical section through the right hemisphere of the brain in the case of M. D., showing the tumour in section, and the depression in the brain tissue produced by it. (Copied from a photograph, and somewhat reduced in size.) The letter A points to the tumour; B is placed on the inner (left) side of the right hemisphere, which has been separated from the opposite (left) hemisphere by a section made from before backwards, in the middle line.

³ Loss of hearing of course may result from a localised cerebral lesion, such as a tumour, which presses upon the auditory nerve.

to open it; the eye considerably more prominent than the other. ... (Vision lost.—Harlow.)... Upon the head, and covered by the hair, is a large unequal depression and elevation..... A piece of the cranium of about the size of the palm of the hand, its posterior border lying near the coronal suture, its anterior edge low on the forehead, was raised upon the latter as a hinge, to allow the egress of the bar; it still remains raised and prominent.'

"From his examination of the skull itself, Dr. Harlow thus describes the track of the bar: 'The missile entered, as previously stated, immediately anterior and external to the angle of the inferior maxillary bone, proceeding obliquely upwards in the line of its axis, passed under the junction of the superior maxillary and malar bones, comminuting the posterior wall of the antrum, entered the base of the skull at a point the centre of which is an inch and a quarter to the left of the median line, in the junction of the lesser wing of the sphenoid with the orbital process of the frontal bone, comminuting and removing the entire lesser wing with one-half of the greater wing of the sphenoid bone, also fracturing and carrying away a large portion of the orbital process of the frontal bone, leaving an opening in the base of the cranium after the natural efforts at repair by the deposit of new bone of one inch in its lateral, by two inches in its antero-posterior, diameters.' (See Figs. 5, 6, and 7.) Dr. Harlow does not describe the further track of the bar through the frontal bone, but you will clearly see from the figures that the whole lesion is situated anterior to the coronal suture. If, now, you will compare the track of the bar through the skull and brain with the diagram before you (Fig. 8), showing the relations between the skull and the brain, you will, I think, have no doubt in convincing yourselves that the whole track is included within that region of the brain which I have described as the prefrontal region, and that, therefore, the absence of paralysis in this case is quite in harmony with the results of experimental physiology. The only other region which the bar could have injured is the tip of the temporo-sphenoidal lobe and the outer root of the olfactory bulb. Respecting the condition as to smell, nothing is, however, said either by Bigelow or Harlow. This case is generally quoted as one in which the man suffered no damage bodily or mental. But hear what Dr. Harlow says as to his mental condition: 'His contractors, who regarded him as the most efficient and capable foreman in their employ previous to his injury, considered the change in his

Figs. 5, 6, and 7.—Illustrations of Dr. Harlow's case of the passage of an iron bar through the head. (Copied from Ferrier.)

mind so marked that they could not give him his place again. The equilibrium or balance, so to speak, between his intellectual faculties and animal propensities seems to have been destroyed. He is fitful, irreverent, indulging at times in the grossest profanity (which was not previously his custom), manifesting but little deference for his fellows, impatient of restraint or advice when it conflicts with his desires, at times pertinaciously obstinate, yet capricious and vacillating, devising many plans for future operation, which are no sooner arranged than they are abandoned in turn for others appearing more feasible. A child in

his intellectual capacity and manifestations, he has the animal passions of a strong man. Previous to his injury, though untrained in the schools, he possessed a well-balanced mind, and was looked upon by those who knew him as a shrewd, smart, business man, very energetic and persistent in executing all his plans of operation. In this regard, his mind was radically changed, so decidedly that his friends and acquaintances said he was "no longer Gage".'

(To be continued.)

ON A CASE ILLUSTRATING THE PROGNOSTIC SIGNIFICANCE OF THE BLOOD PRESSURE IN ACUTE RENAL DISEASE.

By W. H. BROADBENT, M.D., F.R.C.P.,
Physician to St. Mary's Hospital.

It is well known that kidney disease is attended with increase of tension in the arterial system. This is most marked in the contracted granular affection of these organs, but it is present in almost every form of renal disease. I have, however, met with cases in which the arterial tension has been much below instead of above the normal average, and all such I have watched with unusual interest. I have twice seen low tension when the character of the urine, the age, antecedents, and condition of the patient have indicated cirrhosis of the kidney; in both the disease proved fatal with unusual rapidity. In acute renal dropsy I have found persistent pulse of low tension more frequently, and it has always been associated with an intractable character of the disease. A fatal case of this kind was the subject of a clinical lecture some years since.

In acute renal dropsy the artery is usually at first full between the beats, and rather large, but the beat is short and easily arrested. This corresponds to a period of temporary dilatation and weakness of the left ventricle. In the course of a week or ten days, however, the heart recovers itself, and the pulse acquires the character of moderate tension, which, in a case ending favourably, is sustained up to the time of complete recovery. I have learnt, therefore, to look for the supervention of a certain degree of tension in the pulse as an indication of favourable progress; but as has been said, already, in some cases it is missing. The defect of tension may be due to persistent weakness of the heart, the capillary or arterio-capillary resistance being present, but the driving power on which the degree of pressure in the intermediate arteries ultimately depends being deficient. That weakness of the central organ of circulation is of unfavourable prognostic import is easily seen, but the low tension is not always so caused; there is sometimes diminished resistance at the periphery; the capillaries and arterioles are relaxed, and allow the blood to slip through them as in pyrexia, and the pulse is not only weak but short. It is not so easy to understand why this should be of bad augury, and it is only by observation that this conclusion has been reached.

The case to which these remarks lead up is summarised in the following account.

J. L., aged 27, a carman, married and having three healthy children, of sober and steady habits, and previously in the enjoyment of good health, was admitted into St. Mary's Hospital on October 29th, 1887, on account of acute renal dropsy. His mother, still alive, was much addicted to drink, which brought her to the workhouse, where she then was. There was no other unfavourable family history.

The patient was born and had lived all his life in London, and had had no illness since childhood, when he had small-pox. He underwent a certain amount of privation two years previously, when he was out of work for four months, but did not apparently suffer in health. For the last eighteen months he had been a carman. Without any special exposure to cold, he had four days previously noticed on rising that his face, arms, and legs were much swollen, and he had a bad cough. He remained at home for two days, and then returned to work, but on the day of his admission to the hospital the scrotum became swollen, and with this the face was pale and swollen, the eyelids puffy, and the extremities—the arms and hands more than the legs—affected by the characteristic firm, waxy œdema of early acute desquamative nephritis. The urine was found to have a specific gravity of

1030, and was almost entirely converted into a coagulum of albumen on boiling and adding nitric acid. It was straw coloured, gave a very slight blood reaction with guaiacum and ozonic ether; no blood-corpuscles were seen, but numerous epithelial cells. The temperature was slightly subnormal, the pulse 64.

I first saw the patient on November 1st, and found the pulse 60, short and very compressible. The heart was normal in size, but the apex beat could only just be felt, and could not be definitely localised, and there was no right ventricle impulse; the sounds were everywhere weak and indistinct.

A week later the dropsy had everywhere increased, and there was a small amount of fluid in both pleural cavities. The pulse was still short, weak, and devoid of tension; the heart somewhat enlarged downwards, the first sound short, the interval between this and the second rather longer than normal, the second sound weak. The amount of albumen in the urine was still very large, the coagulum occupying seven-eighths of the volume; hyaline and granular casts were present.

The prognosis was at once formulated that the case would be of long duration, the basis for this being the defective pulse-tension and weak blood-propulsion by the heart. It was at the same time considered probable that the large proportion of albumen was not due to any specially severe affection of the kidneys, but was in part the consequence of the languid circulation, which would almost permit of complete stasis in the capillaries ramifying between the convoluted tubes in the cortex of the kidneys, and, consequently, in the Malpighian tufts. It was anticipated, therefore, that if the circulation could be improved, the amount of albumen might diminish rapidly.

The patient was, of course, kept in bed. His diet was mainly milk. Tincture of iron with sulphate of magnesia was given at first, to which were added in a few days nux vomica and digitalis; dry cupping over the loins was practised.

At the end of a fortnight, on November 14th, the dropsy had slightly diminished, and there was still much fluid in both pleural cavities. The pulse was short and compressible, the apex beat of the heart just perceptible in the fifth space slightly outside the nipple line. The urine had a specific gravity of 1018, and the coagulated albumen occupied half its volume.

On November 17th the albumen was somewhat diminished.

On the 21st a general improvement was noted in the pulse. The artery could easily be felt between the beats, and rolled under the finger, and was not so compressible. Simultaneously the amount of albumen had fallen, so that it was described as rather more than a trace. The dropsy and pleural effusion were much less.

On November 24th the apex beat could be distinctly felt in the fifth space, three-quarters of an inch outside the nipple line. The first sound was here indistinct and rather prolonged instead of short, as before; the second sharp and louder than normal, the interval still much prolonged; the pulse was long, and not easily compressible; albumen one-eighth; dropsy nearly gone.

Two days later the patient appeared to be so nearly well, that he was allowed by the resident surgeon to get up for a short time. There was at once, December 5th, some return of swelling in the legs. The apex beat and heart sounds became weaker and the pulse more compressible, while the proportion of albumen rose to one-third.

That this was not an ordinary relapse due to chill was clear from the rapid return to the previous condition of the urine when he was sent back to bed. The explanation was that the heart was not equal to the maintenance of the circulation in the erect position, and with the languid movement of blood so caused came the increased amount of albumen.

He was now kept in bed. He took his food, slept well, remained free from dropsy, and had only a varying trace of albumen. Before it was considered safe again to allow him to rise he had an attack of tonsillitis, in which the temperature rose to 103.8° on January 23rd, and the urine was now of a dark blood-purple colour, and contained four-fifths of its volume of albumen. Under the microscope, however, there were scarcely any blood-corpuscles. The blood and albumen rapidly disappeared, and were succeeded three days later by uric acid crystals in large quantity. The attack was, in fact, one of hæmoglobinuria. The patient is still in hospital, but his subsequent history possesses no points of interest.

The imperfect development of blood pressure to which I have called attention in this case is not to be looked upon as the cause of the slow recovery or of the complications observed in the course

of the disease; it merely reveals the constitutional weakness to which they are to be attributed, and shows that the patient is made of poor stuff. In doing this, however, it fulfils a useful purpose, as it throws light on the prognosis. The occurrence of hæmatolysis and hæmoglobinuria in the course of an attack of tonsillitis was an interesting confirmation of the opinion formed as to the feeble powers of resistance possessed by this young man's constitution.

The development or non-development of pulse-tension in the course of acute renal disease appears to me again to furnish some guidance in treatment. To raise the tone of the circulation is a help towards recovery when this is defective.

CASE OF SO-CALLED "SPONTANEOUS COMBUSTION."

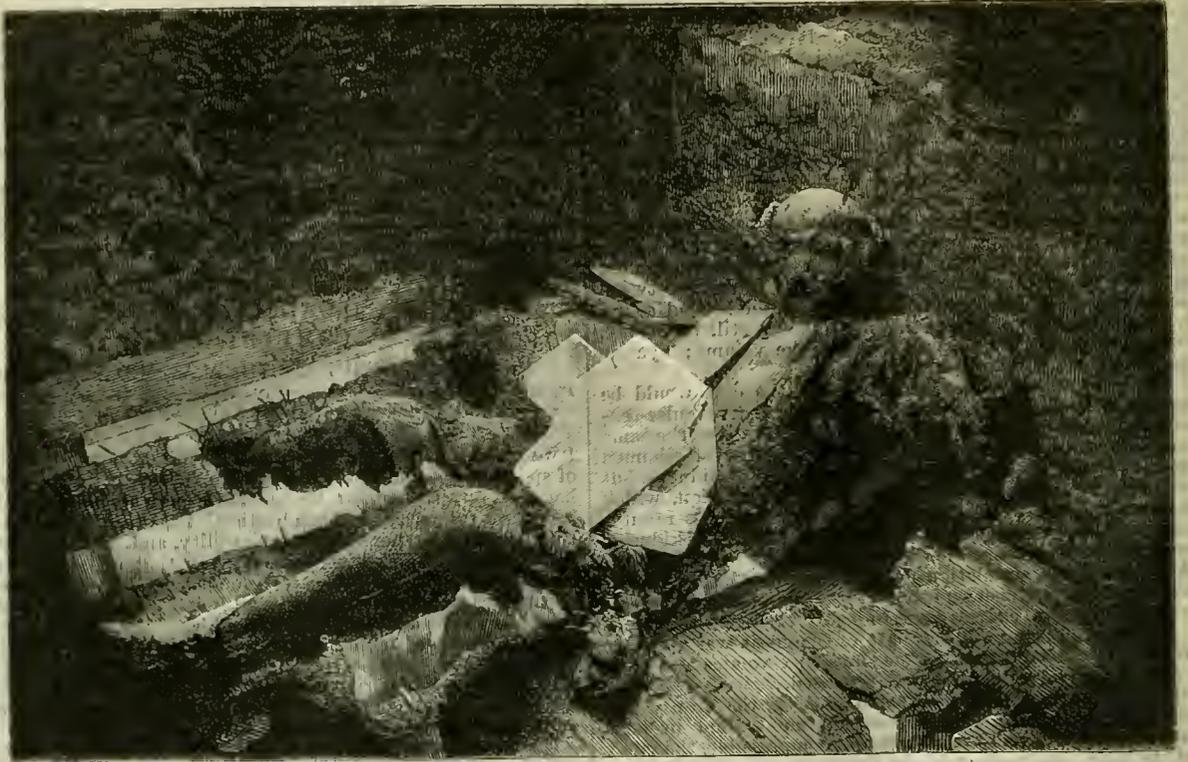

By J. MACKENZIE BOOTH, M.A., M.D., C.M. ABERD.,

Physician to the Aberdeen General Dispensary, and Lecturer on Diseases of the Ear and Larynx in the University of Aberdeen.

I was lately called to a case which vividly recalled the old tales of spontaneous combustion, and more especially an article that I had read on that subject by our late President, Professor Ogston. The term "spontaneous combustion" has been applied to two conditions: first, spontaneous ignitability, and, secondly, increased combustibility; and I need hardly say that it is to the second category that the present case belongs. As Dr. Ogston remarks on these cases, the subjects were all found dead, their bodies, their clothes, and the articles in their neighbourhood being partially or entirely destroyed by fire, the only remarkable thing about them being that the bodies were burnt and charred out of all proportion to the neighbouring objects, and to an extent which seems incapable of being accounted for by the heat of the burning clothes and objects in the vicinity.

On the morning of Sunday, February 19th, I was sent for to examine the remains of a man, A. M., aged 65, which were found in a hayloft off Constitution Street. This man, a pensioner, of notoriously intemperate habits, had been seen at 9 o'clock the night before to enter the stable below in an intoxicated condition, and he asked the lad and girl who saw him to shut the stable door after him, which they did. They then heard him ascend the ladder leading to the loft above, and afterwards saw the skylight of the loft lighted, and later still the light put out. Between 8 and 9 o'clock next morning the wife of the proprietor of the stable, living near by, happening to look out of the window, observed smoke issuing from a hole in the roof of the loft. She informed her husband of the fact, and he, on entering the stable, was horrified to see through a hole in the loft floor the remains of the old soldier perched on the joists above, and leaning against the wall. The police were at once communicated with, and I was sent for to attest the accident. On arriving I ascended to the loft, and found the charred remains of a man reclining against the stone wall, and kept only by one of the joists and the burnt remnant of the flooring under him from falling through into the stable beneath. What struck me especially at first sight was the fact that, notwithstanding the presence of abundant combustible material around, such as hay and wood, the main effects of combustion were limited to the corpse, and only a small piece of the adjacent flooring and the woodwork immediately above the man's head had suffered. Several of the slates had fallen in over the corpse, making a small hole in the roof above it, and a small piece of the flooring had fallen through immediately round him into the stable below, leaving the hole through which he had been first seen. The body was almost a cinder, yet retaining the form of the face and figure so well, that those who had known him in life could readily recognise him. Both hands and the right foot had been burnt off and had fallen through the floor among the ashes into the stables below, and the charred and calcined ends of the right radius and ulna, the left humerus, and the right tibia and fibula were exposed to view. The hair and scalp were burnt off the forehead, exposing the bare and calcined skull. The tissues of the face were represented by a greasy cinder retaining the cast of the features, and the incinerated moustache still gave the wonted military expression to the old soldier. The soft tissues were almost entirely consumed, more especially on the posterior surface of the body, where the clothes were destroyed, and the pos-

¹ Read at a meeting of the Aberdeen, Banff, and Kincardine Branch on March 21st.

[From a Photograph by Mr. W. REID, 100, Holburn Street, Aberdeen.]

terior surfaces of the femora, innominate bones, and ribs exposed to view. This was doubtless in a measure caused by the falling of the slates on the body, and a more perfect cinder would have been found had we arrived earlier on the scene. Part of the trousers on the anterior aspect of the legs that had escaped the impact of the slates was still represented in cinder.

Regarding the condition of the internal organs, I regretted much having been denied the opportunity of investigating their condition, as wishing to have a photograph taken of the remains prevented me at the time, and on my return from other work later on I found that the whole had been removed. The bearers told me that the whole body had collapsed when they tried to remove it *en masse*. From the comfortably recumbent attitude of the body it was evident that there had been no death struggle, and that, obfuscated by the whisky within and the smoke without, the man had expired without suffering, the body burning away quietly all the time.

So much for the condition of the corpse. The strange fact remains that while round about in close proximity were dry woodwork and hay, loose and in bundles, these had escaped, and the body of the man was thoroughly incinerated. The exceeding stillness of the night (for it was remarked by the policeman on the beat that there was not a breath of wind) would only in part account for the facts.

To return to Dr. Ogston's paper. That increased combustibility exists cannot be denied, though at first sight it is not so clear to what it owes its existence. The question has given rise, as has been already seen, to numerous hypotheses, all of which, with one exception, are manifestly untenable, and it is owing to the wildness and illogicality of these hypotheses and deductions surrounding the subject that the whole question has come to be treated as a half-forgotten fable. In the doctrine that increased combustibility in bodies is due to excess of fat, Dupuytren has advanced the only explanation capable of setting the subject at rest, and on a true basis explaining rationally and philosophically the cases of so-called "spontaneous combustion."

When we consider the amount of fat some bodies contain, the subject grows even clearer, and a review of the cases demonstrates that the incineration was always most extensive in the skin and subcutaneous adipose tissue, and other places where fat is abun-

dant, and least marked in organs and regions with less fat. The fatty degeneration of various organs and structures, the intermuscular and subcutaneous adipose tissue, along with the masses deposited on other parts of the body, all present a body of oleaginous matter amply sufficient to account for the combustion, and which, once ignited, would tend rather to burn *in situ* than to flow out, thus explaining the greater destruction of the corpse than of objects in the vicinity.

Regarding the influence of alcoholic indulgence in these cases, it has been conclusively proved that tissues soaked in alcohol do not burn more readily than others not so treated, and that it is only as a stupefying agent and in its tending to the deposition of fat in the body that alcohol aids in increasing its combustibility.

THE DETECTION OF PROTEID BODIES IN URINE.

By SIDNEY MARTIN, M.D., M.R.C.P.,

Pathologist and Registrar, Victoria Park Chest Hospital; and British Medical Association Research Scholar.

The test ordinarily applied for the detection of albumin in the urine is, as is well known, that of boiling and acidulation. This test is taken as indicative of albumin alone; it does not distinguish between albumin and paraglobulin, and, moreover, does not indicate the presence of those proteids which occur more rarely in urine, as for example, the albumoses and peptones. Of late years the methods for distinguishing and separating proteid bodies have greatly improved as our knowledge of their properties has advanced.

The object of the present paper is to discuss these more modern methods of the separation and detection of the proteids in the urine—methods which are not universally applicable in bedside clinical examination, but which are necessary for the elucidation of doubtful cases. The bodies which I shall consider are:

1. Albumin: serum-albumin, egg-albumin. 2. Globulin: paraglobulin (serum, fibrino-plastin). 3. Albumoses (globulin, hemialbumose, propepton). 4. Peptones.

As was stated above, the heat test does not distinguish between these bodies. This test may be applied in two ways as follows: a small quantity of dilute acetic acid may be added to the urine

in a test tube, and the upper stratum of liquid boiled; or the liquid may be boiled first and rendered strongly acid with nitric acid. The first method is more delicate, provided too much acid is not added so as to convert albumin into acid-albumin; it also prevents the precipitation of phosphates. In the second method, phosphates, if present in excess, are precipitated by heat and redissolved by the acid. The picric acid test has no advantage over the heat test carefully applied.

In ordinary cases these tests are quite sufficient, but when it is a question of the presence of globulin or albumoses or peptones, other tests are necessary.

In the first place, if the proteid is present in only small quantity, it ought to be obtained in a concentrated solution before tests are applied to it; and even if present in large quantities in the urine, it ought to be separated and redissolved if its nature is of a doubtful character.

Precipitation of Proteids in an Unchanged Form from the Urine.—This is readily done for most proteids by saturating the urine with neutral ammonium sulphate $[(NH_4)_2SO_4]$. After powdering the crystals in a mortar the salt must be added to the urine in a flask, and shaken well with the hand until no more is taken up by the liquid. This operation takes only a few minutes. By this means albumin (serum and egg), paraglobulin, and albumoses are completely precipitated, whether the liquid be acid, neutral, or alkaline; while peptones remain in solution.

The precipitate obtained is amorphous, and rises to the surface of the liquid; it is readily removed by filtration. When on the filter it may be redissolved by adding a small quantity of distilled water, or, if it is requisite to obtain the proteid in a state of great purity, it may be washed twice with a saturated solution of ammonium sulphate before adding the distilled water. The proteid or proteids are now in concentrated solution containing ammonium sulphate, the presence of which does not interfere with the ordinary test for proteids. The filtrate, after saturation with ammonium sulphate, may contain peptones, and these are to be tested for in the manner presently to be described. We shall now consider the tests for the individual proteids.

Albumin.—In the great majority of cases the precipitate obtained by boiling urine after acidulation is due to serum-albumin. But in a smaller number of cases it may be due to egg-albumin, paraglobulin, or to hemi-albumose. It is, therefore, not possible by this test to distinguish between serum-, egg-albumin, or paraglobulin, even if the temperature of heat-coagulation be carefully taken, inasmuch as they are all precipitated at about $75^\circ C$. The behaviour of heat to the kind of hemi-albumose which has been found in urine is peculiar, and is suggestive of its presence. If urine be not acidulated, the albumose is precipitated on gently heating, but redissolves on further heating, being reprecipitated on cooling. If the liquid be acidulated with acetic acid, it is not precipitated by heat. Further details of this reaction will be given further on.

Egg-albumin is distinguished from serum-albumin by the addition of ether, which coagulates it. Before this test is applied, however, the proteids ought to be separated by saturation with ammonium sulphate in the manner described. If it is a question of the presence of serum-albumin or paraglobulin, or both together, the tests for paraglobulin must be applied.

Paraglobulin.—This may be found in urine by itself (globulinuria) or in association with albumin when there is pus or blood present. It is indicated by the following tests:

1. Urine containing it gives a precipitate on acidulating and boiling, which precipitate is not soluble in an excess of acid; that is, it is coagulated proteid.

2. Saturation of the liquid with magnesium sulphate precipitates the paraglobulin. Before doing this test the urine must be perfectly clear. If there is a deposit of mucus, urates, or phosphates, the clear superstratum of liquid must be poured off, and if the urine is turbid it must be filtered till clear. Two or three drops of dilute acetic acid are then added to the urine in a test tube, and magnesium sulphate added to the liquid, which is to be well shaken with the thumb placed over the mouth of the tube. The amount of salt that it is necessary to add is about equal to half the bulk of the liquid. Complete saturation at the ordinary temperature does not occur unless the liquid be shaken three or four hours, but for ordinary purposes simple hand-shaking for a few minutes is sufficient to cause the precipitation of most of the globulin. The precipitate is readily removed by filtration, and after dissolving it by adding distilled water the ordinary tests for proteids can be applied to the solution. This test distinguishes

paraglobulin from serum-albumin, which is not precipitated by magnesium sulphate; but it does not distinguish it from hemi-albumose or any of the albumoses presently to be described. There is only one albumose which is precipitated by heating; this is called hetero-albumose, and this is the albumose found by Kühne and others in the urine. As has been stated, this body is precipitated at a low temperature, and is dissolved on further heating. Moreover, the precipitate by heat is readily dissolved by adding a drop of dilute acetic acid—an important point of distinction from paraglobulin, which when precipitated by heating is rendered insoluble in acid.

If this heat test is doubtful the clear urine must be saturated with magnesium sulphate, and the precipitate with the liquid poured off from the sediment of salt into a clean dry test tube. This precipitate and liquid must now be boiled and several drops of acetic or nitric acid afterwards added. If the precipitate dissolves it is albumose; if it does not dissolve it is paraglobulin. These tests may be confirmed by the following: To a small quantity of the original urine, or, better still, to the magnesium sulphate precipitate dissolved in water, a drop of one per cent. solution of copper sulphate is added, and then an excess of liquor potassæ; the albumose gives a pink colour (biuret reaction), while the paraglobulin gives a violet colour (ordinary proteid reaction). These reactions taken together distinguish paraglobulin from serum- and egg-albumen and albumose. Sodium chloride also precipitates paraglobulin and most of the albumoses, and it has been stated that saturation of the liquid with ammonium sulphate precipitates globulin, leaving albumin in solution. But besides the doubtful character of this reaction, some albumoses, if present, would be precipitated with the globulin. It is only necessary to perform these distinctive tests between paraglobulin and albumoses when there is an indication of the latter being present. To the detection of these we shall now pass.

Albumoses.—These are bodies which are formed during peptic digestion, and are considered as intermediate between globulin and albumin on the one hand and peptone on the other. To those derived from albumin the term "albumose" has been applied, and to those from globulin the term "globulose." These two classes, however, bear so close a resemblance to each other in their reactions and properties that, in the present state of our knowledge, it is more practical to use the term "albumose" for both. The reactions to be described apply to both albumoses and globuloses.

Albumoses are of three kinds, and they may be considered as a row of bodies linked at one end by their properties to globulins or albumins (undigested proteids), and at the other end to peptones (digested proteids). They are named hetero-, proto-, and deuterio-albumose. They differ in the following manner. Hetero-albumose is soluble only in saline solutions (1 to 15 per cent. sodium chloride), and not in distilled water. It is precipitated from solution by heat, and by saturation with sodium chloride or magnesium sulphate, but only partially; it is thrown down also by dialysis.

Proto- and deuterio-albumose are soluble in distilled water, are not affected by heat, and are not thrown down by dialysis. Proto-albumose is, like hetero-albumose, partially precipitated by saturation with sodium chloride, but deuterio-albumose only if 20 per cent. of acetic acid be added. All the albumoses are precipitated by saturation with neutral ammonium sulphate in the manner which has been previously described, and they all give a characteristic reaction with strong nitric acid. Nitric acid added to a solution of hetero- or proto-albumose causes a precipitate, which dissolves on heating, is reprecipitated on cooling, redissolves on again heating, and so on. Deuterio-albumose only gives this reaction when a few crystals of sodium chloride are added to its solution in a test-tube. All the albumoses are precipitated by adding acetic acid and the ferrocyanide of potassium to their solution. The precipitation by ammonium sulphate, and by acetic acid and ferrocyanide of potassium, and the peculiar behaviour of the nitric acid precipitate, serve to distinguish albumoses from all other proteids. Like peptones, they all give a pink colour with copper sulphate and potash.

All these albumoses have not been described as occurring in urine, very probably because their distinctive tests have not been applied.

The albumose first described by Bence-Jones, and later by Kühne and others, as occurring in the urine, was probably hetero-albumose. The specimen of urine examined by Kühne ("Hemi-albumose im Harn," *Zeits. für Biologie*, Bd. xix) gave a proteid precipitate between 43° and $50^\circ C$. (109.4° and $120^\circ F.$), the pre-

precipitate dissolving on further heating. If a small quantity of acetic acid were added to the urine, no precipitate was obtained by heating. Sodium chloride to saturation gave a precipitate, and the precipitate with nitric acid behaved in the manner peculiar to albumoses. The sediment in the urine partly consisted of albumose. These reactions are similar to those given by hetero-albumose in urine, as I have ascertained by applying them after dissolving some of the proteid in normal urine. Further researches will show whether the other albumoses occur as abnormal urinary constituents. At present it will be sufficient to state that an albumose is indicated in urine by the following reactions.

1. The precipitate by heat comes down at a lower temperature than that of paraglobulin and albumin. The temperature of coagulation may be accurately taken by means of a very simple apparatus. A portion of clear urine is placed in a test tube, in which an accurate thermometer is also put, and the test tube allowed to rest in the neck of a small flask containing distilled water. The water must be above the line of the urine. The flask is then gradually heated, while the urine in the tube is stirred by means of the thermometer. The temperature at which the urine becomes cloudy is the lower limit of coagulation; the liquid is then heated further until a precipitate occurs; this is the higher limit of coagulation. For paraglobulin and albumin the lower limit is about 73° C. and the higher 75° C.; for hetero-albumose the lower limit is 43° and the higher 50° C. If hetero-albumose be suspected, the urine must not be acidified previous to heating; but in the case of paraglobulin or serum-albumin, one or two drops of dilute acetic acid must be added.

It is important to emphasise the fact that a specimen of urine containing hetero-albumose (without paraglobulin or serum albumin) will give a precipitate with heat only when no acetic or other free acid is added.

2. Nitric acid added drop by drop to the urine causes a precipitate if albumoses are present, which behave in the characteristic manner already described. This reaction is distinctive of albumoses. It is not given, it must be remembered, by deutero-albumose, unless solid sodium chloride be added to the urine.

Peptones are closely allied to albumoses, especially to deutero-albumose. A urine containing them alone would give no precipitate on boiling, and none with nitric acid, even if sodium chloride be added. Such a urine would, however, give a pink colour with copper sulphate and potash. This test (biuret reaction) would indicate the presence of peptones if the heat and nitric acid tests proved negative. A small quantity of proto- and deutero-albumose would, however give the biuret reaction, and be in such small quantity as to give a doubtful reaction with nitric acid. The biuret reaction cannot then be taken as absolutely demonstrating the presence of peptones, even when applied after the heat and nitric acid tests. It is best to apply the following: saturate the urine with neutral ammonium sulphate in the manner described above, and filter off the precipitate, if any, which occurs. The precipitate will consist of globulin, albumin, or albumose, if they be present, and the filtrate will contain the peptones, for these are not precipitated by saturation with ammonium sulphate. To the filtrate then add a drop of 10 per cent. copper sulphate solution and a large excess of potash; if a pink colour is produced peptones are present. Or add two or three drops of nitric acid, boil and add liquor ammoniac after cooling; if the liquid turns brown peptones are present. This method of saturation with ammonium sulphate is the only certain one of testing for peptones in urine.

A method which has been commonly applied is to filter the urine after concentration into a large excess of alcohol; the peptones are thrown down, and may be collected on a filter and dissolved in water. If such a solution gives no precipitate on heating, or with nitric acid, or with acetic acid and ferrocyanide of potassium, or on saturation with ammonium sulphate, and yet gives a brownish colour on heating with nitric acid and adding ammonia, and a pink colour with copper sulphate and potash, the urine contains no proteid but peptones, and the case is one of simple peptonuria. But in every case it is best to saturate the urine first with ammonium sulphate, as by this means all proteids are readily separated from peptones.

PROFESSOR CACCIOPOLI recently performed extirpation of the larynx and six rings of the trachea for sarcoma on a woman, aged 50, in the Hospital for Incurables at Naples. This is the thirteenth case of laryngectomy in Italy.

ON THE TREATMENT OF STERILITY IN WOMEN.¹

By THOMAS MORE MADDEN, M.D., F.R.C.S. Ed.,

Obstetric Physician, Mater Misericordie Hospital, Dublin; Physician to the Hospital for Sick Children; Consultant National Lying-in Hospital; Ex-President Obstetric Section Royal Academy of Medicine, Ireland; President-elect Obstetric Section British Medical Association; sometime Vice-President British Gynaecological Society; formerly Examiner in Obstetrics, Queen's University; etc.

THERE are few gynaecological questions of greater practical interest, and none which have been more frequently brought under my notice in the course of a somewhat extensive clinical experience in hospital and consultation practice, than those connected with the subject of sterility in women: I therefore now venture to submit the following observations on this topic, not merely for the purpose of expressing my own views, which I believe to be well-founded, but also in the hope of eliciting the opinions of other practitioners on a matter of much importance, and one involving not only the physical health of our patients, but, moreover, in many instances also intimately affecting their social interests and the happiness of conjugal life.

Etiology of Barrenness.—As in every other morbid condition, so with regard to sterility, our first aim must be to ascertain its cause in each instance. Of the various factors in the causation of infecundity, some—such as the absence or arrested development of any of the organs essential for conception, namely, the uterus, Fallopian tubes, or ovaries—being beyond remedy need not here occupy consideration. In the great majority of instances, however, sterility, when occurring in women within the period of ovarian functional activity, admits of effectual treatment, provided that treatment be rationally directed to the special exigencies of each case.

For convenience of description, in the following observations I have followed the example of the majority of writers on female sterility, by whom, under this term, is also included the subject of impotency or sexual incapacity. Strictly speaking, however, the latter term should be restricted to those cases in which marital intercourse is prevented by some physical impediment, such as vaginal or vulvar occlusion, imperforate hymen, vaginismus, etc., whilst sterility, or reproductive inability, is commonly the result of some structural lesion, malformation, displacement, or deficiency of either the uterus or its appendages, although it may also be due to certain morbid constitutional conditions, as well as be occasioned by other causes, such as sexual incongruity or irrespoudence of a moral rather than of a physical kind.

Stenosis of the Cervical Canal.—This is not only the most common of all the causes of sterility just alluded to, but is, moreover, according to my experience, the one which proves most amenable to appropriate treatment. Until a comparatively modern period, however, atresia of the cervical canal was generally regarded as irremediable, and this opinion continued to prevail very generally for years after the period when Dr. Mackintosh, of Edinburgh, by his revival of the ancient but long-disused method of dilating the cervical canal when occluded, proved the curability of that condition. Practically, the modern treatment of cervical stenosis was initiated a quarter of a century later, when Simpson brought the subject prominently before the profession, and proved the feasibility of treating stenosis by incision with the metrotome, as well as by dilatation with sponge and laminaria tents. This, however, is not the place to trace the progressive history of the improved procedures by which the crude operations resorted to half a century ago in the treatment of obstructive dysmenorrhoea and sterility have been now replaced. My present object is a more practical one. Believing as I do that, though both dilatation and incision of the cervix may be successfully employed in many cases, I also know that both these plans very often fail in permanently overcoming the natural contractility of the cervical structures, and that after each operation the canal too commonly rapidly resumes its former condition, and frequently from cicatricial contraction becomes still less permeable than before the operation. Hence I now desire to direct attention to the advantage I have observed in the treatment of such cases from a method of procedure and the use of instruments by which the parts are so forcibly separated and torn

¹ Read in the Section of Obstetric Medicine at the Annual Meeting of the British Medical Association, held in Dublin, August, 1887.

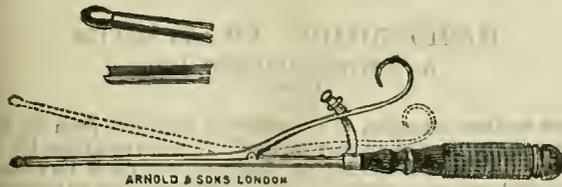

apart, rather than cut, as to reduce any risk of their speedy reunion.

Operative Treatment of Cervical Stenosis.—As the method which I employ in such cases differs in some respects from that generally adopted, I may perhaps be permitted to refer to the details of a plan of treatment which within the past session alone has been employed in eighty-two of my hospital cases of stenosis, and in many of these with the co-operation of my friend Dr. Duke. The total number of cases on which I have operated during the past ten years now exceed five hundred instances in cases of cervical stenosis productive of obstructive dysmenorrhœa or sterility.

In such cases the operation should, if possible, be undertaken a few days after the catamenial period, and should be preceded by daily hot water syringing for some time previously. For its satisfactory performance the patient should be fully etherised, and placed in ordinary semi-prone position on a suitable gynæcological table. Then the cervix being exposed by a duck-bill speculum, the anterior lip is drawn down by a strong vulsellum as near to the vulva as possible. The sound should be now used, or, if this cannot be introduced at first (as happened in a case of stenosis on which I recently operated in England), a very small flexible probe may be passed, and followed by a larger one, until the ordinary uterine sound can be introduced. This being removed, I then pass in, up to the fundus, my uterine director, which you perceive is a long probe-pointed instrument, with ball and socket adjustment in handle, and rather less bulky than the common sound; and along its groove the button of the triangular guarded, blunt-edged knife, now exhibited, is forced, with the cutting surface directed backwards into the uterine cavity. It is then rotated, and withdrawn in the opposite direction. The edge of this instrument is thick and blunted, so as to crush apart or tear, rather than sharply divide, the parts through which it is forced, and thus to diminish the risk of hæmorrhage at the time, and to prevent the subsequent reunion of the separated surfaces.

These instruments have now been used with satisfactory results in upwards of a hundred cases in my hospital and private practice during the past session. But for twenty years previously I have employed, and in many cases still use for this purpose, Simpson's original metrotome, which I regard as a far better instrument than any of the more recent metrotomes, and in every respect superior to Sims's or Emmet's, or any other intra-uterine knife.

Whether the metrotome or my knife be used, I think matters little, at least when compared with the importance of maintaining the permanent permeability of the passage by whatever means this has been restored. This, I believe, may be best secured by the use of the dilator now shown.

Immediately after the completion of the incisions I employ this instrument, not merely with the view of thoroughly expanding the canal and its orifices in the most effectual manner possible, but also for the purpose of tearing the divided tissues and vessels, and thus arresting any excessive hæmorrhage. The extent to which this dilatation may be carried must, of course, be largely determined by the special circumstances of each case. As a rule, however, in ordinary cases I pass the instrument well into the uterine cavity, and then, by means of the screw adjustment, separating the points to their full extent (that is, one inch and a quarter, and then not redneible by any external pressure to less than three-quarters of an inch), I withdraw the expanded blades forcibly through the canal, so as to expand the canal in the natural direction from within downwards and outwards, and not, as most other dilators, which act in the opposite direction; reintroducing it, and repeating the same manœuvre in opposite directions, until the passage is so expanded that I can readily pass my finger into the uterine cavity, which is then thoroughly washed out with a hot carbolicised injection. In the next place, I pack the cervical canal with a long tampon of compressed absorbent cotton, saturated in dilute glycerine of carbolic acid, and fill the underlying vagina with a

large glycerine plug. The latter is removed in twenty-four hours, and the former in sixty hours, if not sooner expelled, being then replaced with a large-sized, soft rubber stem, also previously well carbolicised, or else by Dr. Duke's ingenious ball and socket intra-uterine stem, which causes no irritation and requires no additional support, and which I direct to be worn, if possible, until the next monthly period passes over. For a fortnight or ten days after operation the patient should be kept in bed, and the uterine cavity daily washed out with hot water, plain or medicated. Before allowing the patient to leave her bed I invariably secure the uterus *in situ*, and lift its weight off the ligaments by a properly adjusted Hodge pessary, which to a considerable extent obviates the occurrence of the possible after-troubles that might otherwise be consequent on this operation. Moreover, I desire the patient to remain in bed during the next menstrual period, which is generally attended with some pain and increased discharge. She should then wear a soft rubber stem until the approach of the subsequent period, after which, and never sooner, she may return to marital intercourse.

These precautions and directions may perhaps be regarded as superfluous after an operation which has been described by some who ought to know better as "one of the simplest and safest of all gynæcological procedures." This certainly is not my opinion, and I ascribe the success which has attended my treatment of stenosis chiefly to their adoption. For although any tyre armed with a metrotome may lay open a contracted cervical canal easily enough, the operation may probably prove worse than useless if it be rashly and needlessly undertaken or carelessly performed, being extremely apt to be followed by ill consequences, such as hæmorrhage, pelvic cellulitis, endometritis, and above all by permanent cicatricial occlusion of the canal, when abused by those who disregard these details and precautions which are essential for its safe and successful accomplishment.

Vaginal Aphoria or Incapacity.—In reference to the causes of sterility, the condition of the vagina also requires consideration, it being obviously essential that this canal should be capable of receiving, retaining, and transmitting the spermatic fluid. These requirements may be variously defeated. Thus the vagina may be wanting, as I have seen in one instance, wherein the urethra opened on the perineum directly. The vulvar orifice may be occluded by morbid adhesions from vulvitis or congenital atresia; the vaginal canal may be abnormally narrowed, or—and more frequently—it may be occluded by membranous septa consequent on former parturient injuries or inflammation, of which I have recorded several cases, one of which is at present under my care in the hospital.

Infecundity from Vaginismus.—Conceptive incapacity, or female impotency, is, according to my experience, very frequently traceable to vaginismus or excessive sensibility of the vaginal orifice and adjaent parts, attended with such spasmodic contraction of the sphincter vaginae as to form an impediment to marital intercourse. This occurs chiefly in patients of a hysterical temperament, and is generally occasioned by neuromata, confined to the parts supplied by the superficial perineal branch of the pudic nerve. In all such cases constitutional treatment by nerve tonics and sedatives should be combined with the simple plan of local treatment, which I have generally found efficient in relieving the most intense dyspareunia thus caused, without any operative interference beyond the forcible dilatation of the vaginal canal, and stretching of the pudic nerve by a method fully described in a recent paper of mine. In some instances, however, these measures fail, and we must then fall back on Sims's and Emmet's operations for the cure of vaginismus. It sometimes happens, that even in cases of vaginismus, so intense as to render complete marital intercourse impossible, the disease is not necessarily a barrier to impregnation. Thus, in one instance under my observation, so extreme was the local hyperæsthesia as not only to prevent the possibility of complete cohabitation, but also to prevent the patient submitting to any local treatment for relief of the morbid condition. Nevertheless conception occurred, and I was subsequently called in to deliver her at full term, and, in doing so, was obliged to incise the still unruptured hymen by which delivery was obstructed.

Sterility from Uterine Flexions.—The various displacements of the uterus by which sterility may be occasioned have been fully discussed by recent writers. For my own part, I am inclined to think that an undue degree of importance is attached by Dr. Graffy Hewitt and his followers to the influence of anteversion and antelexion in the causation of infecundity. In my own

practice, at least, I have not often met with cases of sterility assignable to anterior deviations from the normal position of the uterus, and I have seen early pregnancy coexistent with marked antelexions. On the other hand, I have often traced sterility to retroversion, and again still more frequently to retroflexion, by the latter of which not only is the permeability of the canal mechanically constricted at the point of flexion, but, moreover, as in cases of retroversion, and also of prolapsus uteri, the vaginal retentive capacity was necessarily interfered with. In each and all of these three latter conditions I have generally found that the reposition and maintenance *in situ* of the uterus by a properly adjusted Hodge pessary sufficed, if the canal itself was permeable, to cure the sterility thus occasioned; otherwise, the operation of opening, by incision and dilatation, the cervical canal is also necessary, more especially in cases of flexion with elongation of the cervix, where, from long-continued pressure at the angle of flexure, much absorption of tissues has taken place. In such cases the result of incising the cervix, which should always be divided backwards, is, as Dr. Emmet observed, to bring the neck of the uterus to a more natural length, and it then becomes straighter, shorter, and thicker. This change in the neck is brought about, it is supposed, by the action of the longitudinal fibres after the circular ones have been divided.

Endometritis and Sterility.—Chronic endometritis is incompatible with fecundity, and as long as that disease exists to any serious extent the patient must remain barren. This fact, to which I called attention many years ago, is one of great practical importance, and is too generally ignored in practice. I have known many instances in which patients were subjected to active surgical treatment to overcome some supposed mechanical obstacle to impregnation, and who nevertheless remained childless, no attention having been paid to the existence of chronic cervical inflammation, on the subsequent cure of which pregnancy has followed. In such cases not only is impregnation mechanically obstructed by the viscid glairy secretion by which the os and inferior segment of the cervical canal is sealed in all cases of endocervicitis, but also, as Mr. Whitebread long since pointed out, the inflammatory action, going on within the uterus may prevent the formation of the membrana decidua; and hence the ovum, even though impregnated, is unable to attain the fertilised state. Secondly, the diseased condition of the lining membrane of the uterus may be extended to the Fallopian canals, and obliterated for a time their internal orifices, so as to oppose an insurmountable barrier to impregnation. Thirdly, the uterine secretions, in cases of endometritis, may be inimical to the active existence of the spermatozoa.

Hence, agreeing as I do with Mr. Whitebread's views, I may also recapitulate briefly the conclusions on this subject which I published several years ago in the first volume of the *Dublin Obstetrical Transactions*, and which have been confirmed by my more recent experience, namely: 1. That congestive hypertrophy of the uterus, and especially of the cervix uteri, is a very common cause of sterility. 2. That these conditions are, in the majority of cases, occasioned by constitutional causes, and in the most frequent of which is the serofulous diathesis. 3. That these diseases require constitutional as well as local treatment; and in this connection I therefore would again urge the benefits derivable in such cases from certain mineral and thermal waters, the uses of which are fully described in my work on *The Health Resorts of Europe*.

Ovarian and Tubal Sterility.—Ovarian inflammation is one of the most frequent consequences and accompaniments of endometritis. In these cases the inflammation extends from the uterus along the Fallopian tubes to the ovaries, and this to a great extent accounts for the fact just mentioned, that patients suffering from endometritis or endocervicitis are invariably sterile. In such cases the inflammatory action is generally attended by a viscid exudation, by which the tubes, and especially their uterine orifices, are mechanically sealed against the possibility of impregnation. Independently, however, of its frequent sequence on endometritis, tubal obstruction, productive of dysmenorrhœa and of sterility, may also arise from those possibly graver, but, according to my experience, comparatively exceptional diseases, namely, idiopathic salpingitis and pyo-salpinx, in the treatment of which operative procedures, involving loss of all future conceptive ability by the complete removal of the uterine annexa, are now so readily resorted to by some practitioners. For my own part, having in not a few cases seen all the supposed symptoms of pyo-salpinx subside completely without any surgical interposition

whatever, it would seem to me quite as rational to amputate the breast for an ordinary mammary abscess as to remove the Fallopian tubes merely because they may be the seat of serous or purulent exudations. In some cases of the latter kind there is, as I can vouch from clinical experience, no absolute impossibility of reaching and removing such collections by aspiration or even by catheterisation of the Fallopian tubes.

Many years ago, having occasion to use the sound in a patient suffering from dysmenorrhœa and sterility, I was surprised, there being no enlargement of the uterus, to find the sound pass in up to the handle, and on palpation discovered that obviously it had entered the right Fallopian tube. A year subsequently that lady gave birth to her first child, after eight years of married life. Since then I have more than once succeeded in accomplishing by a little careful manipulation what in the first instance was but a happy accident. And hence I endeavour to impress on those who attend my hospital practice, the fact that the catheterisation of the Fallopian tubes, when employed by a practised hand and with due caution, is a feasible, and in some exceptional instances may possibly prove an effectual, method of treating certain cases of dysmenorrhœa, sterility, and other morbid conditions.

Sterility may also arise from causes irrespective of any physical lesion; and although impregnation in no way depends on the sexual orgasm, unquestionably it may be prevented by strong mental emotion or personal dislike. In some instances, however, sexual incongruity productive of sterility coexists with conjugal affection. Thus, I have more than once been consulted by sterile patients, happily married, desirous of offspring, and not suffering from any physical disability, who informed me that, though warmly attached to their husbands, not only were there absolutely sexual indifference, but even positive repugnance to coition, any attempt at which in one of these cases invariably produced nausea. In that case I may add that the last-mentioned symptom was allayed by the use of cocaine suppositories.

Still more commonly is sterility dependent on abuse or abnormal irritation of the sexual organs, and hence the general sterility of prostitutes. It is hardly necessary to observe that in such cases long period of abstention from all sexual stimulation affords the only hope of curing the *impotentia generandi*.

In the treatment of infecundity, independent of any local disease, malformation, or displacement, or of any obvious derangement of the general health, or other tangible cause, and in which the mineral waters already referred to have either been tried without benefit, or are contraindicated or not available, a course of sea-bathing, whatever may be its *modus operandi*, is a prescription the occasional efficacy of which in such cases I have seen proved by experience.

HÆMORRHAGIC PHARYNGITIS.

By ARTHUR JAMISON, M.D.,
London.

I WISH to draw attention to a condition I may call, from its chief symptom, "hæmorrhagic pharyngitis." It is not mentioned in our textbooks. I have found it very obstinate to cure if its cause overlooked, and also because I have found amongst patients suffering from it some of the greatest grumblers at medical men whom I have ever met. And no wonder. Five out of eleven very marked examples of this condition were thought to be, or were become, victims of phthisis, had got no benefit from medical treatment, and before they came under my care had drifted, by the advice of friends, to the tender mercies of quacks, who promised to cure their consumption, and had made themselves worse by pocket and digestion by swallowing many bottles of tarry emulsions. Three other patients, whom I saw when at the Riviera, were wandering from one town to another there, at great inconvenience to their work in life, and without any benefit to their ailment. Let me give a case fairly typical of them all, as much as possible in the patient's own words.

Mr. B. came to see me, and, almost before I had time to say a word, produced his pocket handkerchief, and, with a voice expressing the deepest concern, said, "Doctor, what's this? Is it serious? Is it a return of consumption?" I saw on the handkerchief several masses of dusky, red-stained expectoration. He told me that, preceding this attack for several days, he had a sensation of constant tickling in his throat, and an equally tormenting desire to clear it; and his throat felt dry and burnt, and this burning feeling was greatly increased by swallowing

anything pungent. He told me he generally got his first warning whenever sherry felt burning as he swallowed it. After about two days of great discomfort he got relief by being able to hawk up very frequently dark, blood-stained lumps of phlegm. This he kept constantly doing all day long for about a fortnight. He at the same time had a good deal of pyrosis and great mental depression. As the attack wore off the blood-staining got less and less; and, as he invariably examined each mass of expectoration, he got cheered by seeing it become yellow; then the yellow mixed with something clear and gelatinous, with what he called dark spots in it. He very strongly emphasised the fact that he got no benefit from coughing; that only by hawking, in which he was quite an expert, did he bring the secretion up easily and quickly. This gentleman was of an intensely nervous, anxious temperament, seemed to be in fairly good health, not intemperate in any way—indeed, far too careful to keep up his tone, and had not got any thinner, felt himself very low, was very liable to be bilious, and in cold weather liable to attacks of extremely painful diarrhoea, passing many copious, offensive, white-coloured motions. An attack of this diarrhoea seemed to relieve his throat for some time afterwards, and the sanguineous expectoration stopped for awhile. He never had piles, and when a boy had many attacks of epistaxis.

Another interesting case was that of a young gentleman, a Mr. McK., aged 27, who was brought to me by his father, having been old by their family doctor that his son was suffering from an attack of hæmoptysis, which indicated commencing mischief in his chest and urged him to take a long sea voyage, or a stay on the Riviera. This young gentleman had had frequent free epistaxis when a boy, and was frequently bilious. Another case was that of a Mr. R., aged 52, of portly size, and, being a man of leisure and means, had been to a fresh physician for each recurrence, and now thought he would try me just to give me a chance. He had epistaxis when a boy, and told me also that he remembered getting innumerable powders in childhood, as his liver was said to be perpetually out of order, and his motions never pleased his mother or nurse either in colour or consistence, being always called pasty. The least indulgence in the good things of life gave him a bilious headache, and he had been told his heart was weak.

The diagnosis of all these cases rested on the fact of the entire absence of lung mischief, and on the microscopic characters of the sputum. The clear portion of the secretion consisted of large mucous epithelium from the mouth, and many small round cells from the entrance to the larynx, and a few pus corpuscles, the yellow portion of pus and fat cells, a few blood corpuscles, and in great abundance the large spheroidal cells from the pharynx, and a few cubes of common salt—when the phlegm was dark red, of course quantities of blood corpuscles and crystals of hæmatin. There were no elastic fibres nor any distinctive epithelium from the alveoli or bronchial tubes. Two of the cases came under my notice since the discovery of the tubercle bacillus, and I need hardly say I could not find it. I may mention that as most of these cases were very nervous people the microscopic examination seemed to reassure them very greatly, and I would like to advise every practitioner as a routine thing the microscopic examination of the sputum. I have found nothing equal to it in obtaining the patient's confidence. There was nothing unusual to be seen in the pharynx except that it looked frequently anæmic in the early stages with enlarged veins coursing over it. Afterwards there were patches, especially laterally, of a very deep dusky-red colour. There were no signs of follicular disease, and the larynx was normal in every case. In nine out of the eleven cases the liver was slightly enlarged and tender.

Now what causes this condition? Is it catarrhal? I think not. I am inclined to think it hepatic in its cause. The epistaxis that most of these cases suffered from in childhood is, we know, associated with hepatic disturbance. There was a fairly continuous history of biliousness and liver engorgement, and as there were no piles, it seems to me that pharyngeal hæmorrhage of a passive character replaced the ordinary rectal leakage.

At first, thinking I had to do with a local disease, I used various stringent pigments and sprays chiefly of iron and tannin, but no benefit was derived from their use. I have found most relief in the irritative stage from painting the pharynx with a solution of carbolic acid and glycerine (3ss to ℥j), and using Allen and Hanbury's pastilles of chlorate of soda. As most of the cases were men of a flabby condition in addition to their biliousness, I have found a combination of nitric acid and extract of bark of the greatest value if continued for several weeks, adding a little tincture of

nux vomica if much flatulence troubled the patient; also limiting the amount of fluid taken to about half a pint with each meal, and the avoidance of cold bathing or sponging helped to maintain the gain derived from the mixture. The effect of alcohol was very marked in its positive injury. It was noticed by several that if they had been out to dine and had taken more wine—especially champagne or port—than usual, they knew that next morning their expectoration would be bloody. One gentleman noticed that he invariably had a relapse when abroad after taking *café noir* and cognac the night before.

I found in obstinate cases when the nitric acid failed, the somewhat old-fashioned prescription of sulphates of magnesia and iron with dilute sulphuric acid of great use. The use of a saline aperient, especially if taken after a little blue pill the night before, was extremely useful, and latterly I have always started the treatment with it. Thus it will be seen that as I treated the throat less and the general condition of the patient more, and, to use an old medical phrase, "looked after his liver," the better the result. Many times I have heard patients say that they could not get their medical men to do this. It seems to me that this important organ has gone out of fashion with the profession nowadays, and bacilli and endless neuroses absorb all its energies, greatly to the gain of the endless makers of pills and mineral waters; the numbers of aloetic pills and glasses of waters containing chiefly sulphate of magnesia, that are swallowed—too often unwisely—by the public is hardly realised by medical men.

THE COMMUNICABILITY OF TUBERCLE THROUGH COW'S MILK.

By LOUIS PARKES, M.D., D.P.H.Lond.

Assistant to the Professor of Hygiene, University College, London.

THAT cow's milk is not uncommonly a vehicle for the transmission of infectious disease to the human subject is now well understood. The evidence in support of such a mode of propagation is in many cases incontestable. Enteric fever, scarlet fever, diphtheria, and a disease resembling the foot-and-mouth disease of cattle are known to have been spread by means of the milk-supply. There is one other disease, tuberculosis, in which cow's milk has not been definitely proved to have served as a carrier of contagion; but amongst those who have made a study of the subject the view in favour of such a mode of propagation is regarded as containing the elements of extreme probability.

Cattle are very susceptible to tubercle, and stall-fed dairy cows in towns are not infrequently found to be affected. Indeed, Professor Fleming has asserted that at least 25 per cent. of all dairy cows kept in towns are the subjects of this malady. These animals are stalled day and night in stables often uncleanly or badly ventilated, and they are perpetually being drained of large quantities of milk. Prolonged lactation in the human female is well known to be a frequent precursor of phthisis, and it is not to be wondered at that, under such circumstances, and with the additional factors of confinement, want of exercise, and bad air, cows should succumb to a malady to which they are in a high degree susceptible.

It has been found by experience that the best bred animals, which are also usually the best milkers, are those which are soonest affected. In the early stages the symptoms of the disease are ill-defined, the health of the animal is apparently not interfered with, and the milk secretion is as abundant as ever. It is not until the disease is well established that nutrition is interfered with; and even then, unless the amount of milk is seriously lessened, the dairy farmer continues to keep the animal in stock. So far as known at present, the milk of tuberculous cows is free from tubercle bacilli, unless there has been—as is sometimes the case—a deposition of tubercles in the glands of the udder.

It would be extremely interesting to know in what percentage of cases the mammary glands are involved in the process of tuberculation, and at what stage of the disease such involvement usually commences. Milk which contains tubercle bacilli, when given to guinea-pigs and rabbits, causes tubercular deposits in the lymphatic follicles lining the intestinal walls, followed by tubercles in the mesenteric glands, peritoneum, liver, spleen, and general tuberculosis (Klein). Milk which is free from tubercle bacilli, although derived from undoubtedly tubercular cows, has

not so far been found to be productive of tuberculosis in calves and other animals to which the milk was given.

It may be fairly assumed that in many of those cases of primary tubercular ulceration of the intestines or of tuberculous of the peritoneum and mesenteric glands (tabes mesenterica), which occur in the human subject, the tubercular virus has been introduced with the food, and the absorption of the virus has taken place through some part of the digestive tract. These diseases are usually primary in young children; in adults they are mostly secondary to tubercular disease of other organs, especially of the lungs. On referring to the Registrar-General's Summary it is seen that in the ten years 1871-80 tubercular peritonitis and its allied disease, tabes mesenterica, caused amongst children under 5 years of age an average mortality of 2.55 per 1,000 per annum, which approaches closely the average mortality from measles (2.57 per 1,000) in the same period, and is more than twelve times as great as the corresponding mortality from these diseases of any other age-period of five years, from the age of 5 up to 100. Primary tubercular disease of the lungs in children under 5 years of age is a comparatively rare event. The average annual mortality from phthisis of children under 5 years for the decennium 1871-80 was only 0.77 per 1,000, and possibly some of the cases so registered were really secondary to primary tuberculous of the abdominal organs. The extreme incidence of primary tubercular disease of the abdominal lymphatic system on young children is at once seen from these figures. In the matter of dietary there is one great distinguishing feature between this age period and all others. Under 5 years of age, milk—usually unboiled—forms the staple food of children.

Whilst not denying that the tubercular virus may find other means of reaching the digestive tract than through unboiled cow's milk, it appears to me that there are no sufficient safeguards in the management of town dairies to warrant us in assuming that milk from cows in an advanced stage of tuberculous has no chance of being mixed with the milk of other healthy cows. In every dairy of any size there will probably be tubercular cows, some of them, perhaps, with tubercular deposits in the udders; and as it is the common custom with dairymen to mix together the milk yielded by different cows, it is not too much to assume that tubercle bacilli may be widely distributed in the milk supply of any town. It has been said that the tuberculous of cattle is not the same disease as the tuberculous of man, and that the absence of any proof of the human variety having ever been dependent upon ingestion or inoculation of the virus of the bovine variety tends to strengthen such a belief. To this it may be replied that the bacilli of bovine tuberculous are identical—according to all bacteriological methods at present known—with those found in tubercular formations in the organs of man, and that although the disease presents anatomical differences in man and cattle, these differences may be explained as being due to differences of soil in the human and bovine tissues, the bacilli ingrafting themselves in those tissues which present conditions most favourable to their growth and development. Secondly, absence of proof may only mean want of observation or recorded data, and cannot be held to imply that at no future time will satisfactory evidence of the dependence of the human disease upon a bovine source be brought to light.

Having regard to all these considerations, surely the time has arrived when a radical change in the present methods of milk production and milk consumption is urgently needed. In the first place it should be rendered illegal for cows known to be suffering from tuberculous to be kept in stock by dairymen and farmers for milking purposes; and, secondly, in no household should unboiled milk be consumed, more especially by children. No other animal food is consumed by civilised nations in an uncooked state; and by the light of our recently acquired knowledge it would appear that there is as much, or more, danger connected with the practice of drinking unboiled milk as of eating raw flesh.

Exposure to the heat of boiling water for five minutes destroys the life and action of the tubercular virus (Klein); and the same is true of the other specific disease poisons. By such simple means, then, is it possible to guard against an ever present source of danger, as well as to obtain protection from those possibilities of the introduction into our bodies of the viruses of enteric fever, scarlet fever, and the like, which the experience of past epidemics has taught us to be latent possibilities in milk, with powers of development at the most unexpected periods. If medical practitioners generally recognised the importance of these views, and

were careful to enforce them upon those entrusted with the care of delicate children of scrofulous diathesis or with hereditary tendencies to tubercle, a commencement would be made in the right direction, which would gradually extend itself through all classes of society.

CEREBRAL ABSCESS TREATED SUCCESSFULLY BY OPERATION.

By DANER HARRISSON, M.K.Q.C.P.I.,
Honorary Surgeon to the Liverpool Northern Hospital.

THE case was one of traumatic origin, the injury having been received eleven years before urgent, and ten years before even slight, symptoms appeared.

The patient, a boy, aged 15, was admitted into the Northern Hospital, Liverpool, on December 22nd, 1887, with partial right hemiplegia and severe pain in the head. His parents gave the following history: Eight days before admission, he received a blow upon the right side of the head, which another boy accidentally inflicted with a pair of tongs. Three days afterwards, he was suddenly attacked with convulsions of the right side of the body. These appeared first in the arm, and then spread to the face and leg. When they had ceased, the patient found that he had lost more or less power on the whole of the right side of the body, especially in the right arm. During the succeeding four days, he had eight similar attacks. These convulsive fits were accompanied by giddiness and pain in the head, but by no loss of consciousness. The pain in the head had increased in severity, and the paralysis had also increased, especially in the face and leg. Vomiting had occurred two or three times.

On admission into the hospital, there was marked paralysis of the right side of the face and neck, the right arm and the right leg. In the arm the extensors of the wrist were principally affected, the biceps next, and the deltoid only slightly so. In the leg the quadriceps extensor and the long extensors of the toes were the muscles chiefly paralysed.

There was very severe pain over the top of the head, not referred to one side more than the other, and the intellect was dull. The tongue was protruded towards the right side. There was impairment of vision in the right eye, but sensation over the surface of the body was quite normal.

The reflexes on the right side were as follows:—Superficial plantar markedly diminished, abdominal diminished; deep: knee-jerk much exaggerated, no ankle clonus. Numerous moist rales and sonorous rhonchi were heard over the right apex, and bronchophony was marked posteriorly on the right side.

Soon after admission all the paralysed muscles were convulsed for about five minutes. Upon examination of the head no spot tender to pressure or percussion could be definitely discovered, but a cicatrix was observed on the left side covering a somewhat uneven surface of bone, and a further inquiry from the patient's friends elicited the following history: Eleven years before, when between 4 and 5 years old, he had received a severe blow upon the left side of the head, causing a wound from which bone was removed; this injury was followed by no severe symptoms. During the last twelve months twitchings in the right arm had been observed, which were confined to the flexors of the wrist, the biceps and the deltoid. There had, however, been no fits except those already described.

From the history of the patient and the personal observations have related, my colleagues and I came to the conclusion that there was probably an abscess of the brain, situated in the motor region of the cortex, and an operation was determined upon.

On mapping out the side of the head by Thane's method the cicatrix was found to correspond in position to the upper part of the left ascending frontal convolution, and the centre of the cicatrix was therefore chosen as the site of operation; and on December 23rd an inch disc of bone was removed, the centre of the trephine hole being three-quarters of an inch in front of the fissure of Rolando. The bone removed was very adherent to the dura mater, and was found to be of very unequal thickness, a ridge of bone occupying its centre, having evidently pressed in an abnormal manner upon the brain. The whole extent of the ridge not having been removed by the trephine, it was followed up with a chisel close to the middle line and removed, leaving an irregular opening an inch by an inch and a half in extent. Having removed what

might possibly be a source of irritation, and as there was no bulging of the dura mater, I decided to postpone further procedure, in the meantime keeping the wound open, so that further exploration might readily be made.

December 24th. The patient passed a quiet night, with complete relief from pain, and was more intelligent. The plantar and patellar reflexes had become normal. Pulse 60; temperature normal.

December 25th. He had had slight pain in the head occasionally. The plantar reflexes were more marked, the limb becoming firmly flexed, and remaining so for some minutes.

December 26th. He had passed a restless night, complaining of pain at intervals; the right lower limb was tonically half flexed, and could not be extended, the plantar reflex exaggerating this contraction for a few minutes.

December 27th. He was rather more apathetic, and inclined to be drowsy. The temperature during the night 97.2° F., the pulse 45. Paralysis was absolute. The contraction of the right leg was more marked, the patella tendon reflex was absent, and the plantar reflex delayed.

I now considered it necessary that a further exploration should be made. This was effected by a crucial incision through the dura mater one inch in length; then, with a tenotomy knife, a puncture was made into the brain in a vertical direction for one inch and a quarter in depth, until a drop of pus was observed to have made its way along the blade; an incision was then made one inch in extent, through which nearly four drachms of foetid pus rapidly flowed, as if under the influence of considerable pressure. The abscess cavity was syringed out with corrosive sublimate lotion, and a horsehair drain inserted.

December 28th. He slept all night, and had no pain. The patella tendon reflex was just perceptible.

December 30th. He had not been so drowsy. The drainage was unsatisfactory, one drachm of pus having collected. The horsehair drain was removed, and a small india-rubber tube inserted.

January 1st. The right leg had recovered some power; the plantar reflex was much less marked.

January 2nd. The hamstring and quadriceps extensor muscles of the leg had recovered more power; facial paralysis was less marked. On January 3rd, slight movement was observed for the first time in the right arm, and on January 5th he was no longer drowsy, had no pain, and was quite intelligent and quick in answering all questions. The right arm could be rotated outwards at the shoulder. The leg had power of flexion, extension, and adduction. On January 6th, a hernia cerebri protruded from the wound an inch in height. On January 10th he could flex the arm at the elbow.

January 18th. Pressure having been applied to the hernia cerebri, it was observed that upon relief of pressure during the dressing of the wound, the pulse would rise from 60 to 84, becoming again 60 after two hours of pressure.

From this time the history of the case is simply an uninterrupted progress towards recovery. The hernia cerebri, which at one time assumed the proportions of a large walnut, entirely subsided under the influence of elastic pressure. The temperature was generally subnormal, and only reached 100° F. upon one occasion.

The patient was allowed to get up on January 29th, and could walk with some assistance; about a fortnight afterwards the drainage-tube was finally removed.

At the present time, April 15th, the patient is perfectly well—the only difference when comparing the opposite sides of the body, being found in the grip of the hands, the right hand grip being 27, the left hand grip being 25½ kilogrammes. Optic discs are normal.

REMARKS.—The duration of the latent period, eleven years, forms an interesting feature in this case, as I understand that here are not many recorded. The symptoms of localised disease during the latent stage, as shown by the twitchings of the right arm, and afterwards by the convulsions beginning in the arm before spreading to the face and leg, clearly point to the arm centre as the focal area of the abscess. The order in which recovery took place also supports this view. 1. The face and tongue. 2. Neck. 3. The leg. Lastly, the arm.

The localisation was much facilitated by the presence of a cicatrix indicating the point of original injury, but, in the absence of this, the extensive nature of the paralysis, which implicated so rapidly the face, tongue, and neck (the centre for the latter in monkeys being the first and second frontal convolutions), would

have led to the choice of the ascending frontal, rather than the ascending parietal, convolution as the seat of disease.

In diagnosing abscess rather than tumour, the factors chiefly taken into consideration were the original injury and the prolonged latency, afterwards followed by acute symptoms, accelerated by a recent blow, the symptoms bearing the character of a rapidly increasing focus exerting great pressure on surrounding parts.

The operations and after-treatment of the wound were conducted with the most careful antiseptic precautions. I regret that no ophthalmoscopic examination was made on the patient's admission, but his condition at that time would have rendered any satisfactory examination extremely difficult. The horsehair drain was a complete failure, but the india-rubber tube gave perfect drainage, showing that drainage by silver tubes is not absolutely necessary.

OPHTHALMOLOGICAL MEMORANDA.

EYE OPERATIONS: BROMIDE OF POTASSIUM.

THE JOURNAL has recently contained several contributions describing methods of employing cocaine in squint operations, the aim being to render the operation painless. Mr. Browne says: "Squint operation, even on nervous, frightened children, can be done painlessly." Immunity from pain is not enough for the "nervous frightened" child, whose fear must be allayed. Cocaine will not banish alarm. We are all, however, familiar with the soothing influence of bromide of potassium in emotional disturbance, and yet the virtues of this drug do not appear to have been utilised in relation to operations. It is now my practice to give to children who are to undergo operation a full dose of the drug, and operate during the calm which ensues. I now speak not of squint operations merely, but of eye operations in general. The suggestion I make commends itself; it does not need much advocacy. I shall mention only one recent case: C. H., aged 5, had double congenital cataract, a considerable portion of the lens being transparent. For both eyes the procedure was the same—needling, and several days afterwards linear extraction. On each of the four occasions cocaine was instilled, bromide (40 grains for the extraction) administered, the operation performed without difficulty, and followed by sound sleep. I tried to tear the capsule of the second eye without bromide, but the boy was unmanageable.

Manchester.

TOXICOLOGICAL MEMORANDA.

TOXIC ACTION OF EXTRACT OF EUCALYPTUS.

A FEW days ago, a male patient, aged 25 years, took by mistake about five drachms of extract of eucalyptus, at 10.45 P.M., and laid himself down in bed again, after going to attend to a sick relative in the same room. Near 12 o'clock he felt faint and giddy, and as if he was being lifted up by the heels and his heels pulled up over his head. He also began to feel inclined to say all his thoughts aloud, and found some twitching going on involuntarily in his fingers. Thinking dreamily he might be poisoned, he drank a large glass of cold water, but did not vomit. His wife, aroused to his condition, came for me, and at 1.20 A.M. I found him with weak, rapid pulse (120), but quite sensible, and complaining of the above symptoms. Free vomiting (smelling and tasting strongly of eucalyptus) was caused by administration of mustard and water.

On page 840 of Dr. Lauder Brunton's *Materia Medica*, he says: "Eucalyptus acts chiefly on nerve centres; depression of brain, medulla and heart; drowsiness, feeble respiration, lowered blood-pressure, and fall of temperature.....Death from paralysis of respiration." At page 798 of the same book, caffeine is said to—"stimulate medulla and cardiac centres, and raise the blood-pressure."

As I was unable to find in any book, or remember an antidote for eucalyptus, I hastily prepared a hypodermic injection (Martindale and Westcott) as follows: Caffeine, 20 grains; salicylate of soda, 17½ grains; water, 1 drachm. After the emetic had acted, I injected into the arm six minims of the solution. All unpleasant symptoms speedily disappeared, and we sat talking till 3.30 A.M., when I left him apparently recovered.

He called upon me in the evening of the next day, said he was sleepless after I had left him, for a couple of hours, got up at noon; the urine had a peculiar odour, and there was some diarrhoea of a blaekish colour; he had also pain in the end of the penis and the right testicle (which was drawn up). The dose of extract of eucalyptus is about fifteen minims.

ERNEST SHEAF, M.R.C.P., F.R.C.S.E.,
Honorary Surgeon to the Toowoomba Hospital,
Toowoomba, Queensland, Australia.

POISONING BY STRAMONIUM.

J. B., a strong and healthy young woman of eighteen, took by mistake for herbs about half an ounce of stramonium leaves (which her father had left in the cupboard for smoking to relieve his asthma), and having made an infusion with nearly a pint of boiling water, she drank a large teacupful of it off. Characteristic symptoms were developed within an hour, and I saw her shortly after they appeared. Briefly they were as follows: 1. She had no rash, yet (2) there was complete mydriasis, indistinctness of vision, and a staggering gait. 3. There was no stupor, but incessant "fussy" delirium and much "giddiness." 4. The mouth and throat were dry and the fauces insensible to the touch, so that irritation of the pharynx produced no reflex action. 5. She chattered, laughed, and grasped at imaginary objects, and had a tendency to fall over when endeavouring to rise. 6. The pulse and respiration were not seriously affected.

The treatment consisted in the administration of stimulating emetics and five-grain doses of caffeine, at frequent intervals, followed by a full dose of castor-oil. The symptoms subsided in about eight hours; and a partial explanation of their less than usual intensity after such a dose is probably to be found in the fact that the patient, feeling "giddy and queer," as she described it, took a copious tea-meal immediately after the ingestion of the poison.

Tamworth.

J. HOLMES JOY, M.A., M.D.

CASE OF OPIUM POISONING IN AN INFANT ONE MONTH OLD: ARTIFICIAL RESPIRATION: RECOVERY AFTER FORTY-FIVE HOURS.

At 6 A.M. on February 16th I was called to an infant, aged one month, to whom a dose of three drops of laudanum had been administered by its nurse, on the previous night, at 10 P.M. The child was in a semi-comatose condition, from which it could with difficulty be aroused. Two drachms of vin. ipec. had no effect as an emetic, but a hot bath, followed by a cold douche down the back, thoroughly roused the child for the moment, but the sleep subsequently, grew deeper and the respiration fainter, till it gradually ceased altogether.

I at once resorted to artificial respiration, and after about an hour's work succeeded in inducing the child to breathe again. This was maintained by means of constant stimulation with hot flannel for an hour and a half, when another relapse took place. I again had recourse to artificial respiration, and after another hour the child once more opened its eyes. Another hot bath and cold douche had now a good effect, and by dint of constant friction, patting on the back, application of hot cloths, and stimulation with the current of air induction apparatus, we kept her awake for a couple of hours. The effect of the drug, however, had not in the least worked off, though it was now eighteen hours since it had been given, but the infant seemed more under its influence than ten hours previously. Nutrient enemata had been given every hour and retained.

She relapsed for the third time into a comatose state, and artificial respiration was again kept up almost constantly for about three hours, by which time natural breathing was again established; but constant watchfulness was still necessary. The face was wizened, the jaw dropped, and the eyes glazed and heavy; pulse and respiration barely perceptible. In this condition she remained for nineteen hours, fed by nutrient enemata. At about 5 P.M. on February 17th she seemed to wake up of her own accord, and gave a little cry. On being put to the breast she took it and drank heartily. She made a rapid recovery. The child was one of twins, and premature by about a month.

Seaford, Sussex.

WILLIAM PRINGLE MORGAN, B.A., M.D.

LORD JUSTICE BOWEN will preside at the annual festival dinner of King's College Hospital, which will be held in the Whitehall Rooms of the Hôtel Métropole, on Monday, April 30th.

REPORTS

OF

HOSPITAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN, IRELAND, AND THE COLONIES

MIDDLESEX HOSPITAL.

TWO CASES OF LARYNGOTOMY: A SUGGESTION AS TO THE APPLICABILITY OF SUTURES TO THE AIR-PASSAGES IN CASES OF CUT THROAT.

(Under the care of Mr. HENRY MORRIS.)

[Notes by Mr. W. G. NASH.]

CASE I. *A Large Recurrent Myeloid Sarcoma of the Face; Laryngotomy; Removal of the Growth; Recovery.*—W. T., aged 45, a stonecutter, was sent by Mr. Lang into Broderip ward on January 16th, 1888, under Mr. Morris. He was suffering from a large recurrent sarcoma of the right side of the face.

History.—Two years ago he first noticed slight protrusion of the right eye and blocking of the right nostril, followed by a small swelling of the right side of the nose. There was bleeding from the right nostril, the eye became more prominent, and the swelling increased for a period of six months. The mouth was not involved at this time. He went to the Bristol Royal Infirmary, and Mr. Board removed the superior maxilla with the growth. As soon as the wound was healed the tumour recurred. During the next few months a large swelling formed and projected the cheek, but did not involve the eye, and six months after the first operation this recurrent growth was removed. Six weeks after the second operation a swelling formed below the right eye, from which the present disease has gradually developed. He had syphilis at 20. Ulceration of legs for the last twenty years. Has been a great beer drinker. Father died of alcoholism, aged 60. Mother died, aged 70, of unknown cause. One sister died of phthisis. No family history of cancer or tumour.

State on Admission.—On the right side of his face is a tumour about the size of an orange. The skin over it is of a mottled, dark-purple colour, and is ulcerated, and there is discharge of sanious pus and blood. The tumour is firmly fixed to the surrounding structures, and involves the skin from the orbit to the upper lip, infiltrating it for nearly an inch from the margin of the tumour. It spreads upwards as far as the upper margin of the orbit behind the eyeball, and downwards nearly as far as the corner of the mouth. Internally the growth projects against the nasal septum extending forwards to within half an inch of the anterior aperture of the nose. Externally it spreads to within an inch and a half of the ear. Its edge is ill-defined. It is not adherent to the roof of the orbit. The lower eyelid is everted, and the eye is pushed upwards and prominently forwards, thus producing diplopia. There is a very offensive discharge from the right nostril, and frequent hæmorrhage from the tumour. In the mouth there is a large soft swelling, which extends internally as far as the middle line and backwards to the front part of the soft palate. There are no enlarged glands beneath the jaw or in the neck. The patient was in a very distressing and loathsome condition, and was quite willing to undergo any operation which afforded him fair hopes of relief.

Operation, January 24th.—Patient being anæsthetised, laryngotomy was performed and a Hahn's tube inserted. After waiting a few minutes to allow the compressed sponge around the tube to swell, an incision was made beyond the upper and outer margins of the growth along the free margin of the orbit a little below the eyebrow and just over the external angular process of the frontal bone. The tumour and the eye were freed and pushed forwards and downwards with a raspator; the deeper structures of the orbit were divided with scissors, and the whole of the contents of the orbit thus enucleated. An incision was then made downwards along the outer border of the growth about an inch in front of the ear-hole to about half an inch above the angle of the mouth, and another incision inwards above the free border of the upper lip as far as the frenum of the nose. Lastly, a fourth incision was carried upwards to the inner end of the first incision along the right side of the bridge of the nose, ending at the inner end of the right eyebrow. The bones were divided with bone-pliers, and the growth was thus taken away *en masse*. A large chasm remained, the roof of which was formed by the roof of the orbit; its inner wall by the septum of the nose; its outer

wall by the outer wall of the orbit, pterygoid processes, and ascending ramus of the lower jaw. The floor was formed by the tongue and a portion of the soft palate which was left intact. Posteriorly it communicated by a wide opening with the pharynx. The internal maxillary artery bled freely, but was easily controlled. The cut end of the parotid duct opened at the lower and outer margin of the chasm (seen as a dark spot in the woodcut). Paquelin's cautery was freely applied to the stumps

of the muscles and the optic nerve at the apex of the orbit. The mucous membrane of the cheek was sutured to the skin at the edge of the wound. The wound was stuffed with a large soft antiseptic sponge; the cannula was easily withdrawn from the air-tube; and the wound over the crico-thyroid membrane was dressed with carbolic gauze, but no sutures were inserted either into the crico-thyroid membrane or the external wound in the neck. The Hahn's tube acted very well, and allowed of the operation being rapidly proceeded with, without any interruption from hæmorrhage, or difficulty in the administration of the anæsthetic.

Course.—For the first twenty-four hours the patient was fed by nutrient enemata. The subsequent progress was, on the whole, most satisfactory, although it was interrupted on January 27th, and on two or three subsequent days, by swelling and tenderness over the parotid region, and on February 13th, 14th, and 15th by severe headache on the right side. On January 31st, just a week after the operation, the laryngotomy wound was quite healed, and the patient sat up. There was never at any time after the operation either air or mucus discharged through the wound in the larynx. The patient has been greatly benefited by the operation. The outer and lower parts of the chasm have much contracted; the line of the upper lip is perfect. There are no signs of recurrence in any part of the structures; he is quite well, and ready to wear the artificial face with which he will be provided. The microscopic examination showed the growth to be a very vascular myeloid sarcoma.

CASE II. Papilloma of Larynx: Extra-laryngeal Excision: Immediate Healing after Suturing the Wound in the Larynx.—W. G., aged 38, a board-school teacher, was admitted under Mr. Morris on January 24th, 1888, suffering from loss of voice due to a polypoid tumour below the anterior extremities of the vocal cords.

History.—He has had good health until eighteen months ago, when he lost his voice and was treated for laryngeal catarrh. He recovered his voice until October, 1887, when he lost it again. He came to see Mr. Hensman as an out-patient, who has kindly furnished the following account of his case at that time: "W. G. was first seen by me in the out-patient department of the hospital on October 4th, 1887. Patient was a strong, healthy man, though

looking somewhat old for his years. Had for more than twelve months past complained of huskiness and weakness of voice. Latterly he had been obliged to relinquish his duties on this account. Previous to this, however, he had experienced several attacks of 'sore throat,' which had passed away without affecting his voice. He was able to swallow and breathe without difficulty, and had at no time suffered from laryngeal pain. On examining his throat it was clear he was at this time suffering from an attack of catarrhal pharyngitis extending into the larynx. Patient was ordered an inhalation and a throat paint, and was advised to come the following week with a view to a more complete examination of the larynx. On examining the fauces on the following Tuesday (October 11th) the catarrhal attack had subsided, but the voice remained as before, thick and husky. The larynx was apparently healthy, and the vocal cords moved freely and looked quite normal. On placing the mirror far back in order to bring into view the anterior portions of the cords—previously hidden by the epiglottis—a reddish, smooth growth about the size of a pea was observed below and apparently midway between them. In phonation this was observed to be freely movable, a portion of the growth appearing momentarily above the cords, but slipping below them during inspiration, and remaining there during ordinary breathing. The patient subsequently came into the hospital, and remained some weeks under treatment. With the aid of a 10 per cent. solution of cocaine brushed over the parts and the intelligent co-operation of the patient, in spite of a very low isthmus of the fauces, every chance was afforded of dealing by intra-laryngeal methods with the growth. I was, however, unable to remove it or reduce it materially by crushing. The upper portion of the growth was seized and crushed on several occasions, and at one time the voice materially improved. Mackenzie's forceps were used (those with the antero-posterior blades being most easily managed), also Schrötter's forceps (very much curved in order to pass round the pendant epiglottis). As it became evident that a further operation was desirable the patient, after a considerable interval, during which he was under observation as an out-patient, decided to come into the hospital under Mr. Morris to have the growth removed through an external incision."

On Admission.—Patient is a healthy-looking, well-nourished man, complaining of great hoarseness and occasional attacks of difficulty of breathing. On laryngoscopic examination there is seen a small pinkish-white pedunculated growth below the vocal cords at their anterior extremity.

Operation. January 25th, 1888.—Chloroform being administered, Mr. Morris made a vertical incision over the centre of the crico-thyroid membrane and cricoid cartilage, about an inch and a half in length. Several transverse and oblique veins had to be divided, and the isthmus of the thyroid body was found much enlarged. The bleeding being controlled, a vertical incision was made through the crico-thyroid membrane and cricoid cartilage and membrane above the first tracheal ring. The edges were held apart by blunt hooks. A good deal of mucus was expelled by coughing; and then, by the aid of an electric light, a small pedunculated polypus, about the size of a large pea, was very plainly brought into view immediately below the anterior extremity of the vocal cords, a little to the right of the median line. A fine wire snare was passed around it, and, on being tightened up, it brought the tumour away easily. The spot at which the pedicle was attached was touched with the fine point of a Paquelin's cautery. The edges of the wound in the air-tube were brought together by five catgut sutures, passed so as not to perforate the mucous membrane. Two were inserted in the crico-thyroid membrane, two in the cricoid cartilage, and one in the membrane below the cartilage. The upper half of the skin incision was secured with two silk sutures, but the remainder was left open. The wound was dressed with carbolic gauze.

Growth removed from the larynx was examined microscopically by Mr. Hindson, who reported as follows: "This growth is a simple papilloma. It is of roughly spherical shape, and consists of a central portion, from the surface of which spring numerous papillary processes. The central portion is composed of firm fibrous tissue, with numerous nuclei of irregular shape. It contains some dilated blood-vessels, and towards the free convex outer part a deposit of pigment has taken place from these. The epithelium covering it is of the stratified squamous variety, and arranged in a thin layer like that on the normal true cord; the papilliform projections have for the most part broad bases, and in

their centre is a prolongation of the fibromatous structure from the central part of the growth. The epithelium both of the central part and of the papillæ everywhere preserves a regular line, and does not transgress the basement membrane."

After the operation nothing escaped through the wound in the larynx, the closure of which was quite perfect.

January 27th. Patient says he feels "as if he had a very large passage for air in his throat." He is still hoarse. External wound healed. He has a little pain on swallowing, and the fauces were congested. Ordered inhalations of steam and a spray of a solution of chlorate of potash. Liquid diet.

January 28th. Better; got up for an hour.

January 31st. There is a good ring in his voice to-day. Much less hoarseness and soreness of throat. Wound looking well. Temperature 98°.

February 2nd. Silk sutures in external wound removed. Wound healed at the upper half, but not at the lower.

February 14th. Laryngoscopic examination by Mr. Hensman. "Epiglottis is quite normal, vocal cords are still very slightly congested, their action is perfect. The voice is stronger and quite clear. Nothing can be seen below the vocal cords except a congested appearance. There is still a feeling of effort when swallowing saliva." The external wound presented exuberant granulations, which were rubbed down with nitrate of silver.

February 21st. Mr. Hensman again examined patient, and reported "the whole larynx appears normal; the vocal cords are now of their normal colour, and act perfectly in phonation. There is no congestion below the vocal cords, and no sign of any recurrent growth. The voice is normal in the lower notes, but he has some difficulty in the higher notes."

February 28th. The vocal cords now act perfectly; the voice is stronger. Patient is able to resume his duties as a teacher.

March 23rd. Seen to-day. There has remained a minute granulation mass in the middle of the scar from which a short piece of twisted silk was presenting. It was the deep part of the silk suture the knot of which only had been cut off and removed on February 2nd. The wound closed immediately after this.

REMARKS BY MR. HENRY MORRIS.—These two cases, which happened to come under my care about the same time, are reported together because they afford some evidence as to the value of stitching up the opening in the air-passage when made for a brief temporary purpose. In Case I the crico-thyroid membrane was divided transversely as usual in such operations, and it was found impossible to close the wound by sutures. This was due, partly to the very small external wound not allowing the edges of the divided membrane to be seized, partly to the narrowness of the crico-thyroid membrane, and partly to the compression of the edges of the divided membrane, by the withdrawal of the swollen sponge-covered cannula. Though the wound was left unstitched it will be observed that both superficial and deep structures were completely united in a week.

In Case II the incision of the air-tube was much larger and in a vertical direction through the crico-thyroid membrane, cricoid cartilage, and the membrane between the cricoid and the first ring of the trachea. This wound was completely and accurately closed by sutures, and its healing was by immediate union. The portion of the external wound which was sutured united immediately, and there is no doubt the whole of the wound would have as readily healed had sutures been inserted in the lower half also. Still, even then healing would not have been more rapid than in Case I. (The protracted granulation growth in the superficial wound may be ignored in a comparison of the two cases, as it was clearly due to the fragment of silk suture used for the external wound, and had no reference to the catgut sutures employed on the larynx.)

Allowing for the difference in length and direction of the wound in the air-passage of these two cases, we may at least draw this conclusion: that a simple incision in the crico-thyroid membrane, such as is made for convenience and safety in operations on the tongue and mouth can close at once without sutures. It is most probable, however, that a vertical wound will close more rapidly and perfectly by being sutured, and that if sutures are also introduced into the superficial soft structures, the patient will be quicker well than when the tracheal and external wounds are left to granulate. In the vertical division of the cricoid cartilage it would seem that sutures prevent the lateral gaping caused by the inferior constrictor muscles. That this was so in my patient is suggested by the sense of dragging and effort experienced at the wound during swallowing.

Another advantage of primary closure of the wound in the trachea or larynx is the impossibility of stricture or narrowing following; union of the wound which occurs when sutures are used is immediate and not followed by contraction.

In cases of cut throat I think we shall often do well to employ sutures on the air-passage, and close the external wound also, using drain-tubes if they are indicated. In the only case of cut throat under my care this year the air-tube was not opened, and the superficial wound after being sutured healed by first intention. But at the first opportunity in a case where the larynx or trachea is opened, I intend to put this practice to the test of experience. If the edges of the divided air tube be accurately sutured, emphysema would not occur, and there would be no danger of the passage of discharges from the surrounding tissues into the lungs. Cut throat wounds, being usually clean incised wounds, ought to heal by immediate union.

KING'S COLLEGE HOSPITAL.

GUNSHOT INJURY OF RIGHT KNEE-JOINT: RECOVERY WITH FAIR MOVEMENT.

(Under the care of Mr. WILLIAM ROSE.)

[Notes by Mr. G. L. CHEATLE, House-Surgeon.]

C. C., aged 31, a coachman, has always enjoyed good health, and been moderate in the use of stimulants. He was out shooting on November 16th, 1887, near Caterham, and about 5 P.M. he was holding his gun in his right hand by the muzzle, and ramming the butt end down a rabbit hole. It was an old fashioned muzzle loader. He states that the hammer was at half cock, the gun went off, and the charge passed through the outer side of his right knee. He did not suffer much pain at the time, and managed to walk a distance of forty yards to the house, where he was seen soon after by Dr. Eady, who wrapped up the limb in a towel, applied a temporary back splint, and sent him up by train to King College Hospital.

Condition on Admission.—There had been profuse hæmorrhage on the journey up, the dressings being completely saturated. The patient was seen by Mr. Rose at 10 P.M., taken into the operating theatre and placed under an anæsthetic. There was a ragged wound on the outer aspect of the knee measuring $3\frac{1}{2}$ inches from before backwards, by $2\frac{1}{2}$ inches wide. The tissues and skin around were blackened by gunpowder. On examination with the finger the outer third of the patella was found to be shot away, leaving a rough and comminuted surface, and the upper and outer portion of the external condyle of the femur had a portion of the cartilage carried away, and the cancellous tissue exposed about the size of a two-shilling piece. The joint was open, the finger passed easily into the subcutaneous pouch. The external lateral ligament were intact.

A careful examination of the interior of the joint failed to detect the presence of any foreign substance therein, neither skin nor portions of wad; and, from the direction of the fire, there was every probability that the main portion of the joint had escaped.

Mr. Rose proceeded to clip away the ragged and blackened tissues, and smoothed off the irregular surfaces of the patella and external condyle. The whole cavity of the joint, as well as the wound, was next washed out by means of a Higginson's syringe with a solution of carbolic acid (1 in 20) and corrosive sublimate (1 in 500), and one or two articular branches were secured. The washing was most thoroughly carried out for upwards of half an hour, as there was still some oozing. The opening in the subcutaneous pouch was extended downwards to insure complete drainage from the cavity of the joint, which otherwise would have had a tendency to pocket. A medium-sized drainage tube was inserted into the pouch, the wound dressed with iodoform and salicylic wool, and the limb placed on an ordinary back splint. In consequence of oozing, the dressings had to be changed five times in the first twenty-four hours. Temperature 99°; pulse 110.

On the 18th the temperature rose to 101.2°, and the pulse 132; face flushed; tongue white fur. He complained of throbbing pain in the knee, but, on examining the wound, it looked well, and there was no effusion or tenderness of joint.

The drainage tube was removed on the third day, and the limb placed on a carefully-padded Gooch splint, with a side flap opposite the wound, so that the dressings could be changed without disturbing the rest of the limb.

On the following day the knee felt hot, and painful, and there was some redness and swelling, for which an ice-bag was applied.

outside the dressings. These symptoms quickly disappeared, and the after-progress of the case was most satisfactory. After a small superficial slough of fibrous tissue had separated, the wound slowly granulated over, cicatrisation being assisted by occasional skin-grafts. The patient left the hospital on February 9th, with a para-plastic splint fitted to the knee, so as to limit the movements of the joint, which then admitted of slight flexion. The adhesion of the cicatrix to the external condyle rendered it necessary to control the movements of the joint for the present, to prevent the possibility of the wound being torn open.

N.B.—The patient was shown to the Fellows of the Medical Society of London on March 26th.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, APRIL 17TH, 1888.

Sir JAMES PAGET, Bart., F.R.C.S., F.R.S., President, in the Chair.

Pedunculated Body in Knee-joint.—Mr. SHATTOCK showed a specimen of a rare form of foreign body removed from the knee-joint. The lower and other structures were quite healthy except for some fibrous metaplasia. Projecting into the joint on the right side, and immediately below the patella, was a discoidal body 4 centimetres in its transverse diameter, 3.2 centimetres in a vertical direction, and 7 centimetres thick. It was invested by a thin capsule of connective tissue continued into the falciform synovial fold on the right side, which fold was lost on the adjacent borders of the patella in the general synovial membrane. It rested on the posterior surface of the bone, and its upper border was adapted to the lower margin of the articular surface. At first sight it looked like an overgrowth of fat such as often occurred in the alar ligaments. There was an example of such a lipoma in the museum of St. Bartholomew's Hospital. Mr. Barwell had had a case of inter-articular lipoma on each side of the patella. Further inspection of the body showed blotches of orange red, characteristic of extravasation. It was of compact feel and consistency. Histological examination showed a faintly stained structure, with collections of reddish brown granular pigment in trabeculae, variously arranged. The size of the coagulum placed it beyond the pale of organisation. It was evidently due to an old hæmatocele into the alar ligament from contusion or other injury. He mentioned that one form of foreign body was constituted by unorganised substances, such as the ordinary melon-seed bodies. These consisted sometimes of blood, in part, as in a specimen in the University College Museum. The best collection, numbering fifteen, was in the museum of St. Thomas's Hospital. They were laminated in structure, and of a reddish-brown colour. A distinct nucleus was found in these bodies, easily distinguishable on account of its white colour. These laminated bodies might become calcified, and then resembled phlebotoliths.—Mr. BOWLBY alluded to a specimen in St. Bartholomew's Hospital Museum of a hæmatocele which formed a loose body and was removed from the knee of a strong healthy man who had wrenched his knee. The injury was followed by an attack of acute synovitis, which left a chronic synovitis. Three months afterwards the patient, a surgeon, detected a loose body in the joint, and this was removed by direct incision. It was found to be attached by a small pedicle to the synovial membrane. After removal it was seen to consist of a torn portion of synovial membrane, and between its two surfaces there was a considerable extravasation of blood. He then showed another specimen from one of Mr. Marrant Baker's cases, of a loose body starting from a torn fringe of synovial membrane. There was a history of injury to the knee a considerable time prior to the admission of the patient. He had the usual symptoms. It was removed, and consisted of a torn portion of synovial membrane thickened by inflammatory effusion. Another specimen showed apposition of portions of semilunar cartilages removed a few days before. The patient, an athlete, after a football match found his knees swollen and painful, and was unable to play for a time. Subsequently, while playing cricket, one of his knees gave way with a crunching sensation, which disabled him. He recovered from this, but afterwards his left knee gave way in the same manner. A year later he came to the hospital with a loose body in the left knee. It turned out to be a torn portion of the internal semilunar cartilage, which was torn about half-way from

its posterior attachment. He had also brought down two other specimens, one of which was shown by their President to illustrate his Bradshawe lectures on certain rare diseases. The interest in that case was the number of the loose bodies (415) removed from the knee-joint of a man who, six years before admission, had suffered from chronic swelling and pain. He had had three attacks of rheumatic fever. The synovial membrane was rough and vascular, and the joint was packed full of these bodies, only four or five of which had pedicles. The other specimen, which he had already shown to Professor Humphry, was interesting in connection with the possibility of separation in connection with damage to the cartilages of the knee. The patient was a lad, aged 18, with no history of any injury to either knee. On admission a loose body was found in the left knee, and incision revealed a small detached portion of cartilage from the surface of the femur. He made a good recovery. A year later he returned with a similar body in the other knee, identical in its nature with the other.—Mr. LEDIARD sent a dislocated and loose semilunar cartilage.—Mr. RICKMAN GODLEE mentioned that he once had the opportunity of removing a very peculiar body from the knee-joint, diagnosed as a loose cartilage, which turned out to be a broadly pedunculated mass, growing from the internal ligament.—Mr. CLUTTON said that in his case the cartilage did not suggest that it was articular cartilage. The interest lay in the fact that the specimen was symmetrical. In 1885 he removed a body from one knee-joint in a boy, and two years afterwards he had removed another from the other joint.—Professor HUMPHRY said that Mr. Shattock's and Mr. Bowlby's specimens were singularly interesting. The specimens, also, of detached, or partially detached, inter-articular cartilages were not quite new; a similar case was reported in the *St. George's Hospital Reports*. They were generally more or less attached. The specimens showing the large detached portions, loose in the joint, like articular cartilage on one side, and fibrous tissue on the other, had caused him to ponder a good deal, and he had been unable to give any satisfactory explanation of the manner in which they were formed. He discussed the possibility of quiet necrosis of the cartilages leading to separation, and added that the presence of calcareous matter was a difficulty in connection therewith. He said that up to the present time no instances had been adduced of a portion of bone or cartilage being chipped off and forming a loose body in the joint, except the case reported by Mr. Simon, in which, three weeks after a wrench which gave rise to no immediate symptoms of consequence, Mr. Simon had removed what appeared to be a piece of cartilage and bone, considered to have been detached from one of the articular surfaces. It was very difficult to understand how that could be. They must bear in mind that these loose bodies might lie for years snugly hidden in the joint, causing absorption of the bone with which they were in contact, and then in some sudden strain they became detached, and gave rise for the first time to the symptoms of a loose body. That was certainly a very frequent condition.—Mr. HOWARD MARSH said that the only criticism he was disposed to make on Professor Humphry's letter was, that he assumed that there was an adequate explanation, and therefore that there was no necessity to go further in search of one. They ought not, however, to prejudice the case, but form an opinion from the evidence. He thought that Professor Humphry was still unconvinced that a piece of articular cartilage could be chipped off, but he could only refer him to the specimens of Mr. Simon. There was the authority of Mr. Shattock for saying that, however it was produced, there it was. They also had the statement of Mr. Simon of its presence in the joint three weeks after the injury. He was quite convinced of the fact, and did not presume to offer any explanation. Professor Humphry, moreover, evidently did not believe in quiet necrosis, though of this there were at least two specimens. It was perhaps a rare process, but certainly did take place. He thought of all the structures articular cartilage would be the most likely site of quiet necrosis. He referred to the cases of Cline and Teale (of Leeds). The second one he had illustrated in the *JOURNAL* of April 14th; he alluded to the fact that this drawing in the *Medico-Chirurgical Transactions* had been misplaced, and probably overlooked. The history in that case was almost the prophecy of what their President had described as quiet necrosis. A brewer's drayman had an injury, and a year later a loose body was found in his knee-joint. The man died, and on being enabled to compare this loose cartilage with the hole in the femur, they exactly corresponded. Cline's case was inter-

esting in several ways, partly as showing the kind of injury that was necessary to set it going. A young man, aged 36, in perfect health, stepped on a billiard ball, and brought his foot with a sharp bang on the ground. The injury was followed by some inflammation of the joint, and ten months afterwards a loose body was found. Cline removed this, and, unfortunately, the patient got pyæmia and died. A vacuity was found in the surface of the femur, into which the loose body accurately fitted. In reference to Professor Humphry's suggestion, Cline specially mentioned that the vacuity in the femur could not be accounted for on any such hypothesis, because the body fitted so accurately into the vacuity, and the surface of the tibia which faced the cavity, although a little degenerated, was not in any way worn. That case was very much like one of their President's cases in a boy at Harrow. He thought Mr. Bowlby's cases were cases of quiet necrosis.—Sir JAMES PAGET said the credit of the suggestion of quiet necrosis as applied to articular cartilages belonged to Mr. Teale and not to himself. He thought the specimens accumulated showed that they were right in thinking that it was possible that a piece of cartilage might be so damaged by injury as to undergo slow necrosis and separate. He was glad the subject had come up for discussion, especially as it had been questioned, for nothing was more likely to cause evidence to be forthcoming. He referred to a point which he thought was generally accepted in relation to what Professor Humphry said as to necrosis following strain in cartilage or bone. Had time allowed he would have brought a paper to show what he called periostitis from strain. He said that many of the consequences of a strain or jolt were attributable to the periosteum, which became inflamed. There were two or three cases in which the strain upon the muscles had been followed by well marked necrosis at their attachments. He mentioned the case of a young lady who took violent exercise with her arms in a gymnastic institution. Some more than usually violent feats were followed by necrosis of the acromion attachment of the deltoid without any other sign of inflammation of the adjacent parts or shoulder. He had seen several cases of this kind.—Professor HUMPHRY explained that he had not intended to express a doubt as to the possibility of the occurrence of necrosis.—Mr. SHATTOCK, in reply, said that certain loose bodies simulated very closely detached pieces of cartilage.—Sir JAMES PAGET asked whether there was any definite change of structure in the section of the loose body such as one found in articular cartilage.—Mr. SHATTOCK replied that he had not observed.

Alcoholic Paralysis of Phrenic, Pneumogastric, and other Nerves.
—Mr. SHARKEY showed some microscopic sections from the case of a woman who was admitted on August 29th, and died on September 25th. She had been an in-patient six months before for what her husband called "liver complaint with yellow fever." She had been a hard drinker, principally of whisky and beer; had suffered from diarrhoea and hæmoptysis (one attack). She had been losing flesh and strength, and was very weak in her legs. She had also complained of numbness and cramp in her legs. On admission she could understand well enough what was said to her, but was incoherent in her replies. Respiratory sounds harsh, but no evidence of pulmonary disease. Liver enlarged and hard. No albumen in urine. Legs wasted, especially in front of tibiae. She could neither walk nor stand. The legs were tender both superficially and on deep pressure. Temperature normal. Tremors of the tongue and lips. A few days later she had a rigor; her temperature went up to 102.8° F. On September 13th she had two severe attacks of dyspnoea, and it was then noticed for the first time that the diaphragm was completely paralysed. There was a difficulty in swallowing. Respirations 40 to the minute. On the morning of the 15th she began to spit blood. The average pulse-rate 143. On September 23rd the apices of the lungs showed signs of breaking down, and on the 25th she died in a sudden access of dyspnoea. *Post mortem* the diaphragm was found on a level with the fourth rib; slight hæmorrhage beneath pericardium over right ventricle. Tuberculosis of apices. Liver hard and firm, in early stage of cirrhosis. Kidneys normal. Spinal and cerebral membranes healthy; brain normal throughout. In the dorsal and lower cervical regions there was softening which seemed to be pathological and not a *post-mortem* change. The microscope revealed slight general inflammatory vascular changes throughout the whole central nervous system, including the motor convolutions and spinal cord, though the changes were trivial except in the lumbar enlargement. The brain of the disease had evidently fallen on the peripheral nerves,

inflammatory changes being intense in the phrenic, pneumogastric, and popliteal nerves; there were inflammatory changes also in the muscles supplied by those nerves.—Dr. ORMEROD observed that, as a rule, alcoholic neuritis got well when the cause was removed, but some cases did succumb quite suddenly. He mentioned a case which bore on the subject of sudden death through the pneumogastric from the *post-mortem* room at St. Bartholomew's. It was the case of a child under Dr. Andrew, who had just recovered from diphtheria, and was apparently well. Being a weakly child she developed abscesses in the neck, but she was going on well when suddenly she died, and at the *post-mortem* examination it was found, on dissecting up the pneumogastric nerve on one side, that it was involved in the capsule of an abscess, which pressed upon and flattened it. Nothing else was found to account for the sudden death.

Tumour in Neck invading Jugular Veins.—Dr. G. GRIFFITHS showed a specimen obtained from a man who was admitted on October 23rd, 1886, and died in January, 1887. Three months before admission he noticed a small movable tumour, seated in the posterior border of the left sterno-mastoid muscle. It grew gradually downwards in the neck. On admission, there was nothing particular to observe, except that he had certain lung symptoms, with intensely fetid expectoration, pointing to gangrene of the lungs. *Post mortem* the growth was found to have involved the upper third of the sterno-mastoid muscle, extending downwards in the line of the external jugular vein, the lumen of which, and the internal jugular vein, it followed towards the root of the neck; thence it extended into the right side of the heart and into the right ventricle. There was a small, shrunken-like growth, free in the interior of the ventricle, consisting apparently of small masses of fibrin. A similar growth extended along the pulmonary arteries into both lungs, passing along the lumen of the vessels, and giving rise to coagulation of blood. There was a large cancerous cavity in the right lung. Nothing was found in the superior vena cava, nor in the right auricle. Microscopically the growth consisted of fibrous tissue, which did not admit of being classed, in various stages of degeneration. He mentioned that a similar case had been reported by Sir James Paget.—Mr. BOWLBY suggested that the growth should be referred to the Morbid Growths Committee.

Cases illustrating the Pathology of Gangrene from Embolism and Arterial Thrombosis.—Mr. BOWLBY brought before the Society a series of specimens illustrating the pathology of gangrene from embolism and arterial thrombosis. The first was a gangrenous hand from a man, aged 63, who was admitted in 1884. He had always been healthy until just before admission, when he had symptoms of heart disease. A fortnight before, while cleaning his boots, he was seized with pain in the thumb, which became numb and cold, and this condition shortly afterwards extended to the fingers. There was evidence of advanced heart disease. The thumb was black and shrivelled, and the fingers blue and cold. There was no pulsation in radial or brachial arteries. The gangrene slowly spread, and he died a few days later. *Post mortem* the heart was found enlarged and fatty. The mitral orifice very much dilated arteries atheromatous. The brachial artery was normal as far as the bend of the elbow, where it was blocked. The specimen showed exceedingly well a multiple embolism. The second case was that of an old and feeble man, admitted on November 7th. He had pain and tenderness in the left leg. He had rheumatic fever and a history of heart disease. The left foot was gangrenous, and no pulsation could be felt in the arteries of the leg, not even in the femoral artery. This slowly cleared up. On December 12th the patient was suddenly seized with pain in the right leg below the knee. The limb became cold, and pulsation ceased in the right femoral artery. Ultimately the limb became gangrenous, and two days later he had right hemiplegia, soon after which he died. It showed the plugging of the arteries of the brain, and the right femoral was blocked; the left femoral, the first to be affected, was clear. Another case was that of a man who had had rheumatic fever forty years previously. There was evidence of heart disease. On December 9th, 1885, he was suddenly seized with cramp-like pain in the left groin, and the left leg became cold. Gangrenous patches showed themselves on the outer side of the thigh. On December 13th the leg and foot became gangrenous, and the patient died. The heart was found to be extremely diseased, and the right femoral artery was blocked by an embolus. The fourth case was a woman aged 37, who was suddenly seized with pain in the left groin, followed by coldness and numbness of the foot, and ultimately by gangrene. There was a

evidence of heart disease. These were specimens of embolic gangrene. It was rare to see such large vessels blocked by emboli. An embolus generally blocked the artery at a bifurcation, thus occluding two vessels; and secondary emboli were common. In all the cases except one the heart was diseased. He then showed two cases of gangrene from arterial thrombosis, though one of the cases was complicated by embolism. A woman aged 56, admitted in 1885. She was seized, while walking, with pain and numbness in the left leg. She had heart disease, and sank and died. The aorta was completely filled with a large clot, and, on washing this away, a raw patch was found, on which the blood had clotted to the extent of complete occlusion. Plugs were also carried into the arteries of both lower extremities. The other specimen was the hand of a comparatively young woman. Her general health had been fairly good. In December, 1883, she "caught cold," and never recovered from it. Weakness was the prominent symptom. Her legs, feet, and hands were liable to become cold, blue, and swollen, all together. In the first week of February the left hand became more numb, and gangrene set in. No pulsation in the vessels of that arm, which was the seat of a burning pain. The patient gradually became weaker, and the circulation almost imperceptible. She became comatose and died. The heart was found quite normal; in fact, no disease was found anywhere except in the left upper extremity, the arteries of which were completely and evenly filled with clot. This case was unique. It was difficult to assign any definite cause for the thrombosis, yet the history pointed rather to a general than a local cause.

Card Specimens.—Mr. BOWLBY: An unusual Form of Loose Body from the Knee-Joint.—Dr. LEDIARD: Enlarged Bursa Patellæ with Outgrowths from Walls.—Mr. DALTON: Gummata in Liver of Infant.—Mr. TURGETT: Bony Tumours of Buttock.—Mr. PERCY KIDD: (1) Mitral Stenosis with Pulmonary Phthisis; (2) Tuberculosis of Bladder and Urethra.—Mr. CLUTTON: Symmetrical Loose Bodies from Knee-Joint.

CLINICAL SOCIETY OF LONDON.

FRIDAY, APRIL 13TH, 1888.

W. H. DICKINSON, M.D., F.R.C.P., Vice-President, in the Chair.

A Case of Acromegaly.—Mr. RICKMAN J. GODLEE described the case. The patient, a lady, aged 41, had applied to him on account of a great enlargement of the thyroid body, of about nine years' duration, in which a cyst formed which caused neuralgia by pressure on branches of the cervical plexus; this cyst Mr. Godlee opened and drained, with relief of the symptoms. The patient, who had previously been of a slight figure, and the possessor of a good voice, first noticed the disappearance of her high notes, then the swelling of the neck, and then the sudden stopping of the menses at the age of 36. Since that time there had occurred a gradual increase of the thyroid, accompanied by enlargement of the bones of the face and limbs, and especially of the lower jaw and of the hands and feet. The patient came of a gouty and rheumatic family, and had been the subject of rheumatism before the illness developed itself, but not afterwards. The present state was then described. *Bones:* The lower jaw was much enlarged, so that the teeth, which spread out, could not adapt themselves to those of the upper jaw. The head lines were little if at all affected, so that the face had the shape of an egg with the large end downwards, thus differing much from that of osteitis deformans. The clavicles and ends of the ribs were massive, so that the sternum seemed sunk in a hollow. The bones of the limbs were not generally thickened, but all the natural prominences were much exaggerated, and the small bones of the hands and feet much enlarged, so that the extremities had become broad and spade-like. *Spine:* There was marked kyphosis, suggesting caries, and causing considerable diminution of height. The cartilages of the ears, and probably of the nose and larynx, were thick and stiff. The skin was coarse, and with large sebaceous glands in the face, but was natural elsewhere. The subcutaneous cellular tissue was normal, but deficient in amount owing to emaciation. Perspiration was profuse, the skin having been previously not abnormally moist. The muscles were much wasted. *Senses:* Hearing was normal. Smell was much impaired, especially for delicate odours. Tasting was also much impaired, especially for delicate flavours; the tongue was very thick and large. Vision remained good. Touch was normal, the patient being still able to play the organ as well as ever. The voice was harsh, metallic, and monotonous. *Respiration:* There was some dyspnoea, partly due, no doubt, to the

thyroid enlargement. The general condition was one of marked and increasing weakness; she "shuffles about like an old woman." The appetite was poor, but thirst excessive. Pulse rapid. Temperature normal. The urine contained no albumen or sugar. Her intelligence was perfect, and disposition placid. Mr. Godlee then referred to: 1. The connection between this remarkable condition of the bones and the abnormal state of the thyroid noted in most cases, comparing it with cases of serous malignant tumours of the thyroid, which had a tendency to recur in bones. 2. The relation between the abnormal state of the thyroid and the early stoppage of the catamenia, also apparently a common symptom of the disease. 3. The resemblances and differences between acromegaly and osteitis deformans. 4. The superficial resemblance but wide difference between acromegaly and myxœdema.

A Case of Acromegaly.—Dr. HADDEN and Mr. BALLANCE brought forward another case. The first observations respecting it had been published in the *Clinical Society's Transactions* three years previously (vol. xviii). Fifteen months later the attention of the authors was again drawn to the subject by a paragraph in the *Lancet*, headed "Acromégalie," and under this head it was found that Marie had described a condition which tallied with the authors' case (*Revue de Médecine*, April, 1886). Dr. Hadden's patient was a woman aged 37, and the disease dated five years back, when she had rheumatic swelling of the knees, following probable scarlet fever. But previous to this she had suffered from a tingling sensation in the hands, and the catamenia had ceased and never reappeared. The face became enlarged, the nose broadened from hypertrophy of the nasal cartilages, the cheek-bones prominent, the lower jaw square, massive, and protruding, the lower lip thick and everted. There was some fulness beneath the eyes, but no pallor or translucency, and no circumscribed redness over the cheeks. The cranium was not affected. The thyroid gland was distinctly atrophied. There was no indication of enlarged thymus, as shown by dulness over the manubrium. The clavicles were hypertrophied. The hands and feet were enlarged, but not deformed. The enlargement was general, but the subcutaneous fatty tissue was disproportionately thickened. The skin of the extremities, as elsewhere, was in every respect natural. Previously she used to wear 7 gloves, now the circumference of the hand was 9½ inches. The feet were even more enlarged in proportion than the hands. At one time she wore large 4 boots, now she took large 8's. There was no loss of muscular power, and the woman could use her hands as well as ever she did. The forearm and legs were not hypertrophied. The arm was natural. The speech was guttural, not slow. The tongue was hypertrophied. The viscera were natural, and there was no albumen in the urine. The arteries of the extremities were apparently natural. There was complete blindness of the right eye, due to optic nerve atrophy, probably following neuritis. Sensation was good, the muscular power unimpaired, and the muscles not wasted; the intellectual processes were good; there was no excessive perspiration, no undue thirst, and no curving of the spine. The authors then gave an account of the literature of the affection, and among other cases quoted one by Dr. Wilks, mentioned in Fagge's *Medicine*. It would appear that rheumatism was a possible cause, and in four cases at least the catamenia were suppressed at the onset of the disease. Both the sexes might be affected. The disease received its name from the characteristic enlargement of the hands and feet, but the bones of the face become hypertrophied, as also the cartilages of the nose, ears, and eyelids. The long bones, unlike in osteitis deformans, usually remained unaffected. Blindness had been noted in three or four cases, and the authors mentioned that this might depend on hypertrophy of the pituitary body exerting pressure on the optic chiasma and tracts. Enlargement of this body had been found in two or three fatal cases. The thyroid gland also always seemed to be abnormal. Attention was called to the chief points of difference between acromegaly and myxœdema and osteitis deformans. The differences in the shape of the face were very obvious. In addition there were many important features absolutely characteristic of acromegaly.—Dr. WILKS congratulated Dr. Hadden on having so well pursued the investigation of this remarkable malady that now, after four years, he was able to bring the case again before the Society. No doubt many instances of the disease had been observed before Marie had christened it; not only was there Dr. Hadden's own case, but the one he had alluded to as described in Fagge's work on *Medicine*. Dr. Wilks said this was the case of a young lady, aged 28, who visited him for the first time on February 9th, 1869. She had been a tolerably good-looking girl, but her face had be-

come now frightfully distorted. She had been ailing six years with amenorrhœa, pain in the face and back of head, and gradual loss of sight. Her appearance was so disfigured that people would stop in the street to look at her; her ears, nose, and lips having become enormously enlarged, and the whole face elongated. Her hands and feet also had become gigantic, so that she could with difficulty get gloves to fit her. Dr. Wilks saw her several times during the following year, and prescribed arsenic. The pains in the head became less, and she expressed herself as altogether better. She then went into the country, and died shortly afterwards in a state of coma. He believed she had an intracranial tumour. Dr. Wilks said he thought we were right in giving this disease a distinct appellation, as it certainly differed from myxœdema, osteitis deformans, and other maladies to which it had been compared. He remarked that these cases of overgrowth were of very great interest, as they were quite removed from ordinary examples of disease, which depended upon morbid changes in the structures and organs of the body. They had rather a physiological than a pathological bearing, and by their very exceptional occurrence emphasised the great fact so well enforced by Paget, of the necessary exact relation of the different organs of the body for the due fulfilment of the natural functions. These overgrowths showed that from some unexplained cause this relationship might be broken up, so that the bony skeleton might grow enormously, or the fat of the body increase until the patient became of preposterous size, or the lymphatic gland tissue develop to an extraordinary extent, or as in the present instance a sudden sprouting of the extremities take place. In a very interesting case described about a year ago in the *Berliner Klinische Wochenschrift*, the patient, a musician, was obliged to give up a wind instrument, as well as his violin, owing to the enlargement of his hands and lips; he also had headache, and had partially lost his vision. His thyroid also was diminished in size. The writer alluded to other cases, and said that where an opportunity occurred of a *post-mortem* examination, the pituitary body was found much enlarged by new growth. Dr. Wilks said he could quite believe that his patient might have had a tumour of this kind. Virchow had remarked on the resemblance between the thyroid and the pituitary body, and Sir W. Gull, many years ago, had been struck with the similarity of structure between the pituitary body and the suprarenal capsules, and had asked Dr. Wilks to look at these organs in all cases of Addison's disease. He had done so, but never found them affected. It was very interesting, however, to remark on the possibility of "acromegaly" being associated with the pituitary body, since it had a structural resemblance to the adrenals and the thyroid, both of which organs were admitted to have a marked influence on nutrition.—Mr. GODLEE, in reply, said that in three cases of acromegaly he had found, *post-mortem*, some enlargement of the pituitary body. In one case it was as large as a walnut. Erb's paper collected eleven cases of the disease, which, with the two now reported, brought the number up to thirteen. They had occurred between the ages of 15 and 50. The cases recorded by him were very interesting. The first case was in a woman, aged 58. The disease came on at the menopause. This patient suffered from migraine, a not uncommon symptom in this disease. In her case the disease progressed for three years, and then remained stationary for six. The loss of vision in several cases seemed to have been due to opacity of the cornea. Friedreich had described two cases. With regard to the temperature, it was normal in his own case, except just subsequently to the removal of the thyroid body. The long bones were distinctly affected. In several cases the marked enlargement of the lower jaw was absent. In connection with the nails, Erb had pointed out that in his cases they were much affected, as in other recorded cases.—Dr. HADDEN, in reply, mentioned that Dr. Ord had examined his patient, and had said distinctly that it was not a case of myxœdema, the disease with which it was most likely to be confounded.

Acute Periosteal Swellings in several Young Infants of the same Family, probably Rickety in Nature.—Dr. S. WEST read this paper. A child, aged five weeks, was brought by its mother, with the statement that its left arm had "dropped." A swelling, apparently periosteal, occupied the middle third of the shaft of the left humerus. It was exquisitely painful and tender. The movements of the arm were perfect, but the child kept the arm still on account of the pain which movement caused. Similar swellings were found on the right humerus and on the left femur. There were some slight bosses on the ribs, but no other signs of rickets, and the child was well developed

and well nourished, and except for the pain of the swellings seemed in good health. The treatment consisted in the administration of some cod-liver oil and a little iodide of potassium, and the mother's milk was supplemented with cow's milk. In a fortnight the pain had almost gone, and the swellings were smaller. In the course of three months they were hardly to be made out, and they ultimately entirely disappeared, leaving the bones straight. The patient was the fifth child, born at the eighth month, and fed upon the breast only. The first swelling came on the ninth day, the second in the fourth week, and the last two days before it came under observation. Of the other children the eldest was similarly affected at the age of a week. The child, now a lad aged 9 years, was seen, and showed no traces of the old bone affection. The second, a boy aged 7, was never so affected. The third, a girl, aged 5½, and also the fourth, a boy aged 3½ years, were both affected; the former recovered completely, but the latter had considerable rickety deformity. There was no history of syphilis, or evidence of it in the family. The second case was seen in a child of the brother of the father of the previous children. It was a girl infant aged 3 weeks, and had developed a swelling of the left humerus a week before being seen. It was also suckled, and as the mother was strong no medicine was given and no treatment adopted except to keep the arm still by a loose bandage. In about a month the swelling had entirely disappeared. This patient was the fourth child. The first, a girl aged 6, and the third, a girl aged 2, were and had been always well. The second, a boy aged 4, had had both arms and legs affected in the same way at the same age, but had quite recovered. In this case also there was no evidence of syphilis. Dr. West believed that all these cases were rickety in nature, and closely allied to acute rickets, if not actually cases of that disease. From the cases of acute rickets recorded they differed in respect of age, acute rickets being rare in so young children; also in the fact that more than one member of the family was attacked; and lastly in the mortality. That these were cases of early rickets could not, however, be doubted, on account of the evidence of rickets in the family, and of the absence of any other assignable cause. Of syphilis there was no other evidence, and greenstick fracture or injury must also be excluded. Dr. West also referred to another case seen by him, and recorded by Mr. Herbert Page, which was an undoubted case of acute rickets, and that seemed to him to differ from those here described only in degree. The element of scurvy had been supposed to enter into the causation of acute rickets, but that condition was certainly not existent in the present cases.—Dr. BARLOW considered Dr. Samuel West's cases of great value, and could not remember any quite similar group of cases on record. The closest parallel that he could recall was the late Dr. Ormerod's case of a man who was the subject of combined molities and rickets, with remarkable proneness to fracture, and who transmitted his bone proclivities to two of his children; but these children were, according to the history, healthy-born, and did not manifest the tendency to bone fracture until they were a few years old. The special features in Dr. West's cases seemed to be (1) the very early appearance of bone lesions (within a week of birth in one case), and (2) the repeated occurrence in the same family. Dr. Barlow had, by Dr. West's kindness, seen one of the children when these lesions were present, and he quite agreed with the description given of them. He also agreed that there was no evidence of congenital syphilis, but he was unable to accept the view that the cases belonged to the group called "acute rickets" by the Germans, and which group Dr. Cheadle and he had given reasons for believing was a combination of rickets and scurvy. In contrast, Dr. West's cases with the scorbutic cases, he pointed out that the latter had severe cachexia, with much sallowness and pallor and great proneness to hæmorrhage, especially showing itself in spongy bleeding gums or ecchymoses in the gums, but also in subconjunctival and other ecchymoses; that the pain and suffering were very severe, and that the local bone lesions were dependent on hæmorrhage between bone and periosteum, commencing at the area of junction of shaft with epiphysis, and sometimes separating the whole length of the diaphysis, or leading to fracture just above the epiphysal line. In none of the recorded acute rickety (that is, scorbutic) cases had the infant been breast-fed at the time of the appearance of the symptoms. In Dr. West's case, the cachexia was almost nil; there was no proneness to hæmorrhage; there was no suffering, except on pressure; the lesion were in the middle third of the shaft of each long bone; the infants were actually breast-fed at the time. Into what category

then, should Dr. West's cases be put? Dr. Barlow thought the most probable explanation of the lesions was that they were greenstick fractures with some callus round them. He suggested that the infants had been the subjects of intra-uterine rickets from some faulty nutrition of the mother during pregnancy, and that the results of the intra-uterine rickets made the bones easily liable to yield after birth. The ease with which multiple greenstick fracture might occur was sometimes very remarkable. The question might be asked, Was there any reason to believe that true rickets occurred as an intra-uterine disease? No doubt many cases described as foetal rickets were quite distinct from rickets, and depended on an error of development in which the cartilage cells did not proliferate, but the bone was formed entirely from periosteal outgrowth, etc. Thus a malformed fetus was developed, presenting features superficially resembling rickets, but differing fundamentally from that disease. Nevertheless there seemed reason to believe that a true rickety change in the fetus was sometimes present quite comparable in anatomical features with the disease so commonly found in hand-fed children. Some years ago Dr. Barlow had found in several fetuses a slight but definite beading at the anterior ends of ribs, and some recent extensive investigations by observers in Naples and in Vienna had shown the existence of true congenital rickets to be by no means rare. Dr. Barlow had brought to the Society that evening a child aged 9 months who had been under his observation since she was ten weeks old, and whose case, he thought, had some bearing upon Dr. West's paper. This infant had been delivered with head presentation, but the legs were found considerably bent. The lower limbs were found to present an extreme curvature convex forward, the curve affecting both femora and both tibiae, whilst the tibiae were also flattened from side to side. The appearance was exactly like that of many museum specimens of extreme rickety deformity. The lower limbs for some weeks after birth were very tender, but the tenderness gradually passed away, and the curvature had undergone a certain amount of involution. When the infant was one month old a swelling appeared in the middle of the right arm, and for this it was brought to see Dr. Barlow. The swelling was in the middle third of the humerus, was very tender on pressure, but did not yield erepitis. There was subsequently a similar swelling on the left humerus, but it was a little higher up. The swelling referred to gradually subsided, and now a slight bony projection was present, marking, as Dr. Barlow believed, the vestige of a greenstick fracture. Thus in the case a question there was probably intra-uterine rickets, giving rise to deformation of femora and tibiae, and causing these bones to be tender for some time after birth, and the rickety cachexia still showed its continuance from the foetal into the infantile life by the occurrence of the greenstick fracture of first the right, then probably of the left humerus. Dr. Barlow suggested that Dr. West's group of cases might admit of a similar explanation.—Dr. DICKINSON said he had seen several instances of acute periosteal swellings in infants and young children, and connected them especially with rickets and scurvy. He formerly supposed them to have some association with syphilis, but increased experience had convinced him that this was not the case. The association with scurvy was very striking. A child of about four months old was brought to him from the country in a miserable state of pallor and cachexia; it had a large hard swelling round each femur, evidently connected with the periosteum; and it was passing bloody urine. At an early period of its life it had been deprived of fresh milk, which was not thought to agree with it, and fed chiefly on Swiss milk. Under a complete change of diet, fresh Alderney cow's milk being substituted for the Swiss milk, the hæmaturia ceased, the swellings disappeared, and the child got perfectly well. A little iodide of potassium was given for a short time, and in some doubt. He did not think this did any good, and now never gave it in such cases. Whatever scorbutic results presented themselves in infants—hæmaturia was frequent in this relation—fresh milk was the one thing needful. The benefit which ensued in such a case upon its taking the place of less suitable diet was very striking.—Dr. GLOVER mentioned a very similar case which puzzled him very much for a time. The patient was a child a few years old, with painful swellings of the legs and slight hæmaturia. Syphilis being suspected, the iodide was given, but with unsatisfactory result, but the child rapidly recovered with Parrish's food. Dr. Gee, who saw the case with him, was of opinion that the child was scorbutic, a condition which could be attributed to the use of Swiss milk.—Dr. WILBERFORCE

SMITH pointed out that strumous periostitis almost always went on to suppuration, which this disease never did.—Dr. ORMEROD drew attention to the fact that in Dr. West's interesting series of cases the disease affected relatives, and not merely the children of one family, but the children of two brothers. He thought that this fact, unless it were explained as a mere coincidence, did not harmonise with the view that the disease was due to rickets or syphilis.—Mr. R. W. PARKER was pleased to hear Dr. Ormerod draw attention to a very special feature in the cases related, namely, the multiplicity of the lesion, as well as to the fact that the lesion occurred in the families of two brothers; in seeking for a name for the disease, this multiplicity was of considerable importance. In the course of the debate scurvy, rickets, and syphilis had been referred to. As regarded scurvy in this and kindred cases, he would only say this: that, were a hundred sailors exposed to the conditions which were formerly known to produce scurvy, in the classical sense of the word, probably not a single one would escape; on the other hand, notwithstanding that many thousands of children, predisposed to malnutrition both by inheritance and by bringing up, had for years and years past been exposed to what had been described as a scurvy diet, yet these cases of so-called scurvy rickets belonged to the greatest of pathological rarities. Under such circumstances, he (Mr. Parker) could not agree that scurvy, in the classical sense of the term, had anything to do with the disease under consideration. Then, as regarded rickets: it was quite new to him to hear of periosteal complications; the bones suffered quite commonly, but only at the epiphyseal parts of the diaphyses. In Dr. West's cases the stress of the disease fell on the middle of the shafts, a most unusual place for rickety manifestations. To come next to syphilis, the incidence of syphilis was quite the rule during the earliest weeks of life, while rickets, as regarded the long bones, was infinitely rare at this period; the shafts of the long bones, moreover, were the "seats of election" of syphilitic disease, while the multiplicity and uniformity of the lesion were most suggestive of a syphilitic origin, the absence of a syphilitic history notwithstanding. The cases were doubtless peculiar, but the peculiarity was due to some very special personal or family idiosyncrasy of the subjects attacked.—Dr. WEST, in reply, said that he adhered to his original opinion in the absence of any serious reason for altering it. He said he had failed to find the slightest bending of the bone in Dr. Barlow's case. He had only noticed cachexia in a case where there had been a good deal of hæmorrhage. He observed that Mr. Parker begged the question. If the swellings were to be accepted as proof of syphilis, there was an end of the matter, but there were no other signs of its existence, though they had been carefully looked for. With reference to the parentage of the children, he mentioned that none of the brothers were strong, and one was actually suffering from some strumous affection of the ankle-joint.

Living Specimens.—Dr. BARLOW showed a Case of (Partly) Congenital Rickets; Mr. MURPHY, an Infant Recovering from Bromide Rash, the Bromide having been taken by the Mother; Dr. HADDEN and Mr. BALLANCE, a Case of Acromegaly.

MEDICAL SOCIETY OF LONDON.

MONDAY, APRIL 16TH, 1888.

EDMUND OWEN, F.R.C.S., Vice-President, in the Chair.

Cerebral Abscess treated successfully by Operation.—Mr. DAMER HARRISON read a paper on this subject, which is published at page 848.—Mr. BARKER alluded to the immense difficulty of examining the eyes of patients just at the time when it possessed the greatest interest. In some cases there was papillitis, and in others this symptom was absent. In neither of his cases was there any tendency to hernia cerebri. He recommended the use of a metallic drainage-tube, such as a silver catheter split and bent to form flanges, as better calculated to favour a free discharge. He mentioned that cerebral abscess might remain latent for years.—Dr. BEEVOY thought that the tendency of all these cases of cerebral abscess was to confirm Dr. Ferrier's view as to the cerebral centres. He observed that the site of the lesion was evidently the upper part of the arm centre, but it was of large extent, as evidenced by the parts involved. He asked Mr. Harrison in what part of the arm the fits began, whether in flexion or extension, and in what sequence, as this was essential to the localisation of the lesion. He pointed out that abscess, being of rapid growth, might not give rise to optic neuritis, whereas in tumours this was generally present.—Dr. ANGEL MONEY asked what was the

condition of the superficial as compared with the deep reflexes. In brain lesions the deep reflexes were generally increased and the superficial lessened. He mentioned a case at present under his care in which he had diagnosed a tumour in the middle lobe of the cerebellum, evidently pressing upon the pons, interfering with the function of the pyramidal tracts when they passed through the pons. In this case there was practically no cremasteric reflex on the right side.—Dr. MACLAGAN asked whether the absence of pyrexia was common after such operations.—Mr. JESSOP asked what was the extent and the degree of the usual lesions.—Dr. MONEY added that their experience at University College Hospital was that the temperature, in cases of suppuration in the brain, was invariably subnormal.—Dr. BERRINGHAM confirmed Dr. Money's remark as to the subnormal temperature in cases of suppuration in the brain.—Mr. HARRISSON, in reply, acknowledged that he had a prejudice against using metallic drainage-tubes, and said that although the horsehair drain had failed, the india-rubber tube had answered every purpose. He made the trephine hole as far forward as possible on account of the extent of the paralysis. The wound was absolutely aseptic. The first operation relieved the patient's symptoms, probably by reducing the pressure. The first symptoms on the arm began twelve months before the urgent symptoms showed themselves, and he was very careful to elicit the minute history of the case. The first sign was the contraction of the flexors of the wrist and hand. The patient was carefully examined on April 15th, and both eyes were found to be normal.

Small and Moderate Valvular Lesions.—Dr. MILNER FOTHERGILL said that in the consideration of valvular lesions of the heart little or no attention was paid to the discrimination of large and small injuries; all were grouped together, and usually the prognosis of the gravest lesions was given to small injuries producing very little effect upon the organisation. In order to grasp the subject properly the facts of comparative anatomy and of embryology must be borne in mind. They saw the primitive heart a mere pulsatile, muscular sac. It was not till the ganoid fishes were reached that imperfect pouch-valves were developed in the bulbus arteriosus. So in the foetus. At first the heart had no valves; then imperfect valves appeared, and became more complete as the embryo grew. A valvular lesion was the undoing of evolution precisely to the extent of the valve mutilation; and there was all the difference in the world betwixt a small lesion well compensated, and a large one which could not be efficiently compensated. He added that Nature compensated a valvular injury by falling back upon the primitive form of heart—the muscular sac. As in evolution valves economised muscular energy, so in dissolution an injury to the valvular mechanism of the higher heart was compensated by muscular growth—a development of the early lower heart—spoken of as “compensatory hypertrophy.” When they detected a valvular injury they realised that they could do nothing for that; their hopes were centred on the primitive muscle. If by rest and good food, with cardiac tonics, they could aid Nature's attempt to develop the primitive heart, so far so good. A small lesion was easily compensated, and the compensation was well maintained for many years. Where the injury inflicted was large, complete compensation was unattainable; and such compensation as was possible, wore out comparatively soon. Consequently it was of great importance to measure the extent of valve-mutilation in each case, and from that to calculate the chances of the patient. A murmur revealed the existence of valvular injury; but it was dumb as to its extent. For that they must examine the case physiologically, especially in mitral lesions, and test the effect of effort. With a small lesion the patient could run, but not very far; with a moderate lesion he could walk on the flat, but could not get up hills very well, or run; with a large injury all effort was distressing. In strict proportion to the extent of the lesion the organism was crippled and life shortened.—Dr. MONY said that the nodules which formed in rheumatism offered some idea of what was going on in the heart.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

FRIDAY, MARCH 23RD, 1888.

SAMUEL GORDON, M.D., President, in the Chair.

Carcinoma of Liver.—Dr. WALTER SMITH exhibited a specimen of carcinoma of the liver from a woman, aged 35. Three months before admission to hospital she complained of dull pain in the right side and posteriorly. In about a month jaundice super-

vened, increased from day to day, and lasted until her death. At first she vomited, but not subsequently. The motions were white, and the urine was free from albumen, and not very deeply tinged with bile. No increase in the size of the liver could be detected, and there was no ascites until within a few weeks of her death. While in hospital she emaciated rapidly, and later on she vomited blood on several occasions, oedema of the legs and ascites developed, and she died about six weeks after admission. During nearly the whole of her illness the temperature was above normal—on one occasion as high as 102°. On *post-mortem* examination no diffuse peritonitis was found; the spleen was adherent, the liver not materially enlarged. On the upper surface of the left lobe there was a cancerous node about the size of a florin, and numerous other prominences, some of them cupped, on the upper surface of the right lobe; there were a few nodules on the lower surface. The gall-bladder presented itself as a hard, pyriform tumour, and upon incision its coats were found to be greatly thickened and calcified, except at the fundus. It contained some white gall-stones, and a yellow, grumous pulp composed of cholesterin. The cystic and hepatic ducts were enormously dilated. The pancreas was adherent to the liver, and was fused into a mass along with enlarged glands. The kidneys and stomach were healthy. Microscopically, the disease was proved to be polygonal-celled carcinoma.—The CHAIRMAN said it was rather an unusual circumstance to have so much malignant disease without a good deal of enlargement of the liver, and from that peculiarity arose the question whether it was not originally a case of cirrhosis of the liver, in which carcinoma supervened. A most interesting fact was the absence of any disease of the stomach from which carcinomatous disease so often proceeded.—Dr. O'CARROLL mentioned a case which, during eleven months, presented all the signs of continued enteritis, the number of motions having gradually increased to something like twenty a day, while they varied between fifteen and twenty-five during the last five or six months of the patient's illness. The motions came on very suddenly, and were fluid and foetid. The patient never had an jaundice, save a passing tinge in the conjunctivæ during some two or three days, which was merely suggestive of it. He had no ascites or vomiting, and it was more or less constantly a question whether there was any hepatic trouble whatever. The symptom always pointed to enteric trouble. He arrived at a diagnosis of the case rather by the exclusion of other diagnoses than from the actual symptoms, and that diagnosis was afterwards confirmed by the *post-mortem* examination. The liver was found to be simply a mass of encephaloid tumours, which had crushed out all the normal liver tissue. The cancer was primarily in the liver, as far as he was able to make out, for he found no trace of any other tumour in the abdomen.

Acute Pulmonary Tuberculosis.—Dr. C. J. NIXON exhibited the lungs of a man, aged 29, who died after an illness of five weeks in which a deposit of miliary tubercle was distributed uniformly throughout both organs. The patient had been in good health five weeks before his death, when he was seized with a shivering fit. He became feverish, and gradually developed symptoms of gastro-enteric disturbance, which led to his being treated outside the hospital for enteric fever. The chief symptoms during the progress of the case were high temperature without any marked depression; dyspnoea with greatly increased respiratory rate, the respirations averaging 48 in the minute; marked cyanosis, especially about the finger-nails and alæ of nose; a pulse varying between 132 and 148; tendency to profuse sweating; tongue clean and red. The physical signs, on examination of the chest, were minute crepitating râles, heard best at the bases of the lungs, but before death extending over the whole of both lungs; occasional friction sound heard posteriorly; no alteration of sound on percussion. From these symptoms the diagnosis of pulmonary tuberculosis was made.—Dr. M'KEE thought that in almost all cases of tuberculosis—even the most acute—it would be found that there had been some old focus of the disease in the body. Dr. NIXON, in reply, said the point raised by Dr. M'Kee was an important one. In the present case there was no evidence whatever of caseation in the bronchial glands. There was caseation in two or three places at the base of the lungs, but it was an actual caseation brought about by the clustering of the tubercles; and in one of those centres the caseation was evidently a recent production, and the lung was broken down.

Chronic Bright's Disease.—Dr. JAMES LITTLE submitted the following case of chronic Bright's disease. The kidneys weighed rather more than 2½ lbs. The patient was 38 years of age at 1

death. Thirteen years previously he had had an attack of acute nephritis. Afterwards he came under his (Dr. Little's) care in the Adelaide Hospital for acute renal dropsy. He did not know whether it was justifiable to connect the state of his kidneys at the time of his death with that past illness, because they all knew that acute nephritis usually ended either in death or a complete cure; and the man appeared to have recovered from that former illness. After five or six years he became subject to winter cough, of which he had attacks every year; but these were never severe enough to oblige him to seek hospital relief until the winter of 1886-87. He then came under his care for dropsy and general bronchial catarrh, his urine being markedly albuminous. After being four or five weeks in hospital, he went home apparently quite well. There was no record as to whether his urine was free from albumen at the time he left the hospital; but the man himself said that he heard the clerk who had charge of his case say that it was entirely free from albumen before he went away. The matter was one of consequence, because an important point in the case was as to the age of the renal changes that were found after death. About three months ago he came again to the hospital, suffering from extensive anasarca with dyspnoea. At that time he generally passed between 30 and 40 ounces of urine daily; it was highly albuminous, and had a specific gravity of 1012. The diagnosis made was that he had some chronic form of Bright's disease, with general bronchial catarrh. His pulse was always exceedingly soft and weak, his heart-sounds very feeble. There was no evidence of the cardio-vascular changes that were found in some forms of Bright's disease. He fought off death for more than two months in hospital, and the day before he died appeared as if he might recover. On the day of his death he awoke in the morning, after a fair night's rest, with a violent pain low down in his left side. He remained in great suffering during the day, and died in the middle of the night. On a *post-mortem* examination the cause of intense pain was found to be, as they had guessed, acute pleurisy affecting a small portion of the lower lobe of the left lung. It was also found that, in addition to general catarrh with highly emphysematous lungs, he had small cavities in both lungs, and miliary tubercles all through them. His heart weighed 9 ounces, and was soft and flaccid, presenting no sign of enlargement. One of the kidneys weighed 19 ounces and the other 21½. They were smooth and rather pale on the surface; the capsules peeled off very readily, and when each kidney was divided the cortical portion was of a dull, yellowish-white colour, and the pyramidal portion had a vivid red staining. The question was, were these kidneys affected by parenchymatous nephritis since the affection of thirteen years previously. All their knowledge, however, forbade such a conclusion. They must conclude that the last disease was of about a year's duration. The kidneys showed distinct evidence of amyloid change.—Dr. BEWLEY said the kidneys were an example of chronic Bright's disease, every constituent part of the organ being more or less affected. The renal tubes were in some places dilated, and in others diminished; and the epithelium was a most parts fatty, and in many parts low and with jagged edges. The connective tissue was increased in several places, but not to any great extent. The glomeruli were a good deal diseased, being the parts chiefly affected by the amyloid change. The vessels were also affected by amyloid change. The spleen, with its veins, arteries, and capillaries, was affected in the same way; and the Malpighian bodies were also similarly affected.—The CHAIRMAN remarked that the absence of cardiac pain indicated that the disease was not of very long standing.

Chronic Bright's Disease with Cerebral Hemorrhage.—Dr. AMES LITTLE submitted a case of cerebral hemorrhage. About three weeks before a man aged 45 was admitted into the Adelaide Hospital in an apparently unconscious state. The story told of him was that, about a week before, he had violent convulsions, after which he remained in a more or less stupid and confused state in bed. Two days before his admission he had another fit, and then he was brought to the hospital. When first seen he was lying in bed with his eyes open, the pupils being equal in size, but moderately dilated. If spoken to, he made some attempt to answer, but could not speak; but when a little drink was offered to him he swallowed it. He could move both arms and legs perfectly, and there was no sign of paralysis of any of the facial muscles, eyes, or cranial nerves. The only thing of that kind occasionally observable was a very slight twitching of the left angle of the mouth, and of the left occipito-frontalis muscle. On examining his reflexes they found the knee-jerk extremely well

marked in both lower extremities, and also ankle-clonus developed in as high a degree as he had ever seen. On listening over the heart they perceived a deficiency in the first sound, and also a well-marked systolic muscular murmur. He (Dr. Little) concluded that he had to deal with a case of uræmic convulsions, judging by the pulse and cardiac action. His urine had been passed involuntarily in bed, and by means of a catheter a few ounces were drawn off, which were found to be rather highly coloured and densely albuminous. He was carefully observed from that time until his death, and it was noticed that he had no hemiplegia, but moved his arms and legs on both sides; and, beyond the twitchings of the corner of the mouth and of the occipito-frontalis muscle, there were no indications of paralysis. Early the following morning the man jumped out of bed, put his hand to his head, and went into a violent fit of convulsions, in which he died. On *post-mortem* examination the kidneys were found in a shrivelled condition, one a little less and the other a little more than three ounces in weight. The capsules were thickened, and when peeled off, left a rough granular surface. The heart showed very distinctly hypertrophy of the left ventricle. They found nothing to account for the muscular murmur. The whole of the arterial system was very much diseased. A portion of the aorta showed in a very highly marked form the changes that used to be called atheroma, but which were now called endarteritis deformans. The circle of Willis at the base of the brain was the seat of patches of similar change. On the right side of the brain was an enormous hemorrhage, the right lateral ventricle being full of blood; and the hemorrhage appeared to have taken place in the frontal lobe just outside the right lateral ventricle. There had evidently been two hemorrhages—namely, one that must have occurred at the time of the seizure a week previous to his admission, and a second one that, he presumed, occurred at the moment of his death. There was a clot, which had the appearance of being a week or ten days old; and there was also a large quantity of what appeared to be recently extravasated blood. The man had been a soldier, and a very hard drinker at one time of his life. The case presented a specimen of a chronic form of Bright's disease occurring in a person of intemperate habits, and accompanied with the cardiac vascular changes that were conspicuously absent in the preceding case.—Dr. NIXON believed that most of the hemorrhage now seen in the specimen must have occurred at the time of the final convulsion. So far as he could make out from the specimen now, the hemorrhage seemed to have come from the posterior lenticulo-optic artery; and that was just the situation where there would have been the least amount of pressure on the motor part of the internal capsule. A small hemorrhage might have occurred there for some days without its being attended by any paralytic phenomena; but at the time the man sprang out of bed in convulsions there was most likely a disturbance of the clot, followed by the fresh hemorrhage and large amount of blood now visible, which could not possibly have existed previously during the man's life without producing paralytic phenomena.

Corneal Tumour.—Dr. STORRY exhibited, jointly with Mr. SCOTT, a corneal tumour. It was removed from the eye of a boy aged 16 or 17, about ten days before. About four years previously the lad had been in St. Mark's Hospital, under his care, and the growth in the cornea was then in exactly the same state as it was when recently removed. It was a small opaque, yellowish-white body, situated at the upper margin of the cornea, of oval shape, of five or six millimetres in its long, and three or four in its transverse diameter. The colour was somewhat the same as that of the Meibomian glands when seen through the conjunctiva. The tumour was vascular, as blood-vessels could be seen running up to it and over its surface. It occupied nearly the whole thickness of the cornea, reaching from the anterior coat to the posterior surface. The epithelium of the cornea ran smoothly over the tumour, which was not the least raised above the surface of the cornea. He removed only a portion of it, because he believed that if he had removed the whole he would have gone into the anterior chamber.—Mr. SCOTT said the specimen, when examined under a high power, practically represented the whole of the cornea. Under the conjunctiva there was a mass of undoubtedly fibrous tissue, containing a quantity of small round cells, and this had a very large supply of blood-vessels. In one of the specimens seen under a high power, the supply of round cells was greater than in the rest, so much so that if that specimen alone were looked at, they would think the structure more like sarcoma than anything else. It was very difficult to make out how the fibrous tissue

came there. It might have been either a cicatrix from an old ulcer or an old pannus.—Mr. BENSON remarked that in a somewhat similar case which he brought before the Section last year, the tumour, which was present in the cornea, was entirely removed from the sclerotic border, and there were no blood-vessels running into it, nor any evidence of blood-vessels having ever gone into its neighbourhood. The pannus theory would therefore not apply to this case. The growth would rather seem to be a hyperplasia of the corneal tissue itself.—Mr. STONY, in reply, said the tumour in Mr. Benson's case was almost in the centre of the cornea, and there was a perfectly clear cornea between it and the sclerotic. In the present case the tumour was situated at the junction between the cornea and the sclerotic. The case was one in which there had been at one time granular ophthalmia, but not of a very severe character. He had come into the hospital for the state of his other eye, which had entropion consequent on the granular ophthalmia. The slice which he took off the tumour occupied nearly the whole surface of it, but did not go through to the posterior surface of it except in particular places, and there was left a circular depression in the tumour as if a little piece of it had been scooped out. The way in which the healing progressed was remarkable. It progressed from the periphery of the little ulcer equally all round toward its centre, and a fresh little collection of blood-vessels and a fresh pannus sprang up, running not alone from the sclerotic edge, but from the cornea towards the centre of the tumour, which was now the deepest part of the ulcer.

SOUTH INDIAN BRANCH (MADRAS).

FRIDAY, DECEMBER 2ND, 1887.

Surgeon-General G. BIDIE, President, in the Chair.

Syphilitic Keloid.—Drawings of a remarkable example of wide-spread keloid, associated with syphilis, was shown by Surgeon-Major E. F. DRAKE-BROCKMAN. The patient, a Brahmin ryot, aged 27, was admitted into the Eye Infirmary, Madras, with corneal ulceration and prolapse of the iris in both eyes. He contracted primary syphilis at the age of 22; he had a secondary eruption, in several crops, with fever. The only other illness he had had was variola when aged 3, but no marks of that disease were visible. When admitted the whole body was found to be covered with disseminated, indurated, elevated growths, which were distinctly keloid in character. Some parts of the body were more affected than others—namely, the trunk on its ventral and dorsal aspects, and the upper extremities. The lower limbs, as far as the insteps, were also covered with growths similar to those on the trunk, though in a much less aggravated form. In the vicinity of some of the nodules scar-like patches might be seen, in which situation also the skin was in an atrophic state, and had lost some of the natural pigment of its structure. In reference to these atrophic patches the patient stated that they corresponded to the sites of former similar nodosities which had disappeared by a process of shrinking. Besides these markings there were also evidences of a former skin eruption in the form of pigmented patches, varying in size from a small pea to that of a hazel nut. The patient stated that the keloid had made its appearance on the sites of these patches. The etiology of keloid was discussed in reference to this case.—Surgeon-Major BRANFLOO mentioned a case in which keloid growths formed at the site of vaccination.—The PRESIDENT thought that keloid was more often seen amongst convicts, especially Burmese convicts, than in the civil population.—Brigade-Surgeon FOX had frequently seen the growths in convicts, and Brigade-Surgeon SIBTHORPE in sepoys, especially Telugu men, who were frequently burnt on the abdomen when children.

Filaria Sanguinis Hominis.—Brigade-Surgeon SIBTHORPE showed two patients in whose blood filarise sanguinis hominis were present; in one of the cases there was chyluria, and the filarise were only discoverable at night. The blood contained in bugs (*acanthia lectularia*) from the cots occupied by these patients contained filarise, in much larger numbers, moreover, than the blood taken from the finger. Reference was made to Dr. Manson's observation that the intermediate host of the filarise was the female of a species of mosquito.—Brigade-Surgeon PORTER had had three cases of chyluria under his care early in 1887; in one case filarise were found in the blood both by day and night, in another during the night only, and in the third none could be found.—Brigade-Surgeon SIBTHORPE, in reply, observed that cases of chyluria often terminated spontaneously.

Scrofulous Kidney: Uterine Fibroids: Colloid Cancer.—Surgeon J. SMYTH, M.D., related the case of an unmarried lady, aged 40, who was admitted into the Civil Hospital, Vizagapatam. There was a smooth globular tumour on the right of the abdomen, extending from the margin of the ribs to a point two inches below the umbilical level; the tumour was not connected with the liver or uterus; the urine was acid and free from albumen. The patient was also suffering from phthisis, and to it her death appeared to be attributable. At the necropsy, the ascending colon and small intestines were found matted together by firm adhesions and attached to the left anterior aspect of the tumour: A very friable new growth, resembling the roe of fish in appearance and consistence, affected the meso-colon, mesentery, and capsule of right kidney, affecting especially the pelvis of the latter, binding them all together in a solid mass. On tearing open this mass the kidney was found in its centre, considerably enlarged and softened, its capsule enormously thickened, yet fairly separable from its surface. The pelvis and infundibula of the kidney were much distended, and full of a urinous purulent fluid. The interior of this dilated cavity was studded over with granulations in several parts. The parenchyma of the organ was softened and infiltrated in several places with caseous deposits of small size; several large calculi, like masses of dried ginger, occupied the dilated infundibula and pelvis. The uterus and small tumour with the ovaries were removed together. They were not involved in any way in the large tumour. This small tumour, about two inches in diameter, was a sub-peritoneal uterine fibroid, and three other small ones about the size of a grape were now also seen. The uterus, small, only two inches long, was otherwise quite healthy. The right ureter was obliterated about two inches from its pelvis; just at the margin of the mass of new growth. The left kidney was quite healthy.

Infantile Hydrocele.—An adult patient with infantile hydrocele was exhibited by Brigade-Surgeon SIBTHORPE, who stated that there appeared to have been an encysted hydrocele of the cord, which had extended down along the cord into the scrotum.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, APRIL 6TH, 1888.

W. H. RANSOM, M.D., F.R.S., President, in the Chair.

Treatment of Uterine Displacements.—Mr. HATHERLY read a paper on this subject, advocating more attention to constitutional treatment by rest and tonics, with local treatment of accompanying conditions, and less reliance on purely mechanical treatment. He held that in recent displacements, especially such as followed parturition, and were due to deferred involution of the uterus and a relaxed condition of its normal supports, treatment by pessaries was not only unnecessary but sometimes mischievous. It was very often some accidental complication which first directed attention to an antelexion or anteversion, and in such cases the treatment should be chiefly directed to the removal of such complication. Posterior displacements were more amenable to mechanical treatment, but even in them a pessary might be compared to a crutch to a lame man, not in itself curative, but affording a useful support to a weak part whilst Nature was doing her work. He found pessaries often very useful in procidentia, but in extreme cases of prolapsus after the menopause, advised the narrowing of the vagina by operative methods. In conclusion, he enumerated briefly the conditions which contra-indicated the use of pessaries, and the general principles which should govern their use.—A discussion ensued in which Dr. RANSOM, Mr. GERATY, Dr. COLLINS, Mr. WOLVERSON, Dr. MICKIE, Dr. MUTCH, Mr. WHITE, Mr. BOOBYER, and Mr. BURNIE took part.

Swelling of Scrotum.—Mr. CREW showed a case of swelling of the scrotum presenting unusual symptoms.

Proposed Horse Tax.—Upon the initiative of Drs. MUTCH and WOLVERSON, the following resolution was passed: "That in the opinion of this Society the proposed tax upon horses would press unduly upon medical practitioners who use horses in the practice of their profession."

MIDLAND MEDICAL SOCIETY.

WEDNESDAY, MARCH 21ST, 1888.

Surgeon-Major TURTON in the Chair.

Amputation at Shoulder-joint.—Mr. JORDAN LLOYD showed a case of amputation through the right shoulder-joint, with clearing away of the whole of the axillary contents for recurrent carcinoma. The subclavian artery was tied as a preliminary step, and

no blood was lost at the operation. The wound healed in three weeks.

Abortion after Removal of Ovaries.—Dr. LESLIE PHILLIPS showed a remarkable abortion. Two months before aborting, the woman, aged 30, had had a large, pedunculated, uterine myoma, as well as both ovaries, removed by abdominal section. The foetus was of the fourth or fifth month. Pregnancy was unsuspected at the time of operation.

Extra-uterine Fœtation.—Mr. J. W. TAYLOR showed an extra-uterine pregnancy of three or four months successfully removed a fortnight previously.

Amputation by Berger's Method.—Mr. BENNETT MAY showed an upper extremity, with the attached shoulder-girdle, which he had removed a few days before by "Berger's method," from a boy aged 17, for sarcoma of the humerus. The patient's condition was in every way satisfactory.

Uterine Myoma.—Mr. LAWSON TAIT showed an enormous uterine myoma, weighing nearly forty pounds, removed from a woman, aged 56. A great part of the tumour had formed a hernia in the abdominal wall, and the overlying skin was ulcerated. The patient was doing well.

Abdominal Section for Peritonitis.—Mr. LAWSON TAIT read a paper on a series of cases of acute peritonitis treated by abdominal section.

Acute Peritonitis successfully Treated with Saline Purgatives.—Dr. SUCKLING showed a man, aged 21, who was admitted into the Workhouse Infirmary on January 6th, suffering from acute peritonitis. He stated that he had had the "bowel complaint" two years previously, but had been well till three days before admission, when he was taken ill suddenly in the early morning with pain in the abdomen and vomiting. He had been constipated before this attack, and had had no motion since. The abdomen was tense and tympanitic, and the abdominal respiratory movements were abolished. There was extreme tenderness all over the abdomen, the legs were drawn up, the pulse small and frequent, and the expression anxious. He had retention of urine and fever. No tumour could be discovered in the right iliac fossa. Vomiting was incessant, and pain about the umbilicus greatly complained of. Dr. Suckling thought that the peritonitis was set up by typhlitis, due to faecal retention. Opium and belladonna were first given, but the vomiting and pain continued. Then half-trachm doses of sulphate of magnesium and sulphate of sodium, with ten minims of tincture of belladonna, were administered every four hours. Improvement soon followed this treatment, several liquid motions being passed. On January 9th the vomiting, pain, and tympanites had passed off, and a distinct fulness could be observed, with increased resistance to pressure in the right iliac fossa. The medicine was continued, with the result that the motions became more and more solid, till on the 14th the patient was apparently quite well, and free from fever. Only small quantities of peptonised milk and beef-tea were given. The patient continued to complain of dragging pain in the abdomen or some time, but in about three weeks he was able to get up, and, five weeks after his admission, was allowed solid food. He had since had two or three slight relapses, which at once yielded to purgatives and proper dieting, and at the present time there was a distinct indurated swelling in the right iliac fossa. Dr. Suckling was of opinion that in this form of peritonitis, and in typhlitis due to faecal retention, saline purgatives, in moderate doses and with plenty of water, were of great value.

MANCHESTER MEDICAL SOCIETY.

WEDNESDAY, APRIL 4TH, 1888.

JAMES ROSS, M.D., LL.D., Vice-President, in the Chair.

Complication in a Case of Femoral Hernia.—Mr. STOCKS described a peculiar complication in an operation for right femoral hernia, where a large mass of omentum accompanied the protruded bowel. The bowel was returned, and the omentum tied and cut off. The patient did not rally, and died three hours after the operation. On examination it was found that the strangulated bowel was ileum, and that the omentum had been tied so close to the colon as to include a small piece of the bowel. The transverse colon had so nearly recovered its normal position that the ligatured stump was found above the level of the umbilicus.

Œsophageal Forceps.—Mr. STOCKS also exhibited an Œsophageal forceps made by Krohne and Sesemann, by means of which a foreign body could be removed almost from the lower extremity

of the outlet without the danger of pushing it further down, as must be the case when using an ordinary probang.

Erythromelalgia.—Dr. MORGAN made some remarks on a case of erythromelalgia, and showed a patient suffering from this affection.

Malarial Fevers.—Dr. BASIL made some observations regarding imported malarial fevers.

The Action and Uses of Nitro-glycerine and the Nitrites.—Dr. LEECH and Dr. R. B. WILD read a paper on this subject, the first portion of which comprised an account of experimental researches to determine the action of various nitrites on the contractile tissues, and the extent to which this could be modified by different bases. The latter portion of the paper discussed the therapeutic uses of the nitrites, the indications for their administration in various diseases, and more especially the danger attending their use in certain conditions of the heart and circulatory system.

REVIEWS AND NOTICES.

THE PATHOLOGY OF INTRA-UTERINE DEATH. By WILLIAM O. PRIESTLEY, M.D., F.R.C.P., etc., Consulting Physician to King's College Hospital. London: J. and A. Churchill. 1887. The lectures included in this volume comprise the Lumleian Lectures delivered at the Royal College of Physicians of London in 1887. The references to the literature of the subject are numerous, and will be found of special value to the student.

In Lecture I the author compares his statistics of abortion with the well-known tables drawn up by Whitehead. An analysis of 400 cases shows that 152, or 38.00 per cent., had not aborted; while 248, or 62.00 per cent., aborted. These statistics are almost exactly the reverse of Whitehead's, and are explained by the difference in age. Whitehead's analysis was made from women under thirty years of age, Dr. Priestley's from women over forty. Ten pages of this lecture are devoted to the effects of high temperature as a cause of abortion, and the results of a series of experiments carried out in the Physiological Laboratory in King's College are shortly recorded. The "heat theory" of Runge is probably the correct explanation of the death of the foetus *in utero*; Houlier's theory of degeneration of the myocardium being untenable. The forcible uterine contractions so frequently observed in cases of abortion during high temperatures are brought about by an accumulation of dark venous blood, charged with carbonic acid, in the uterine sinuses. Undue distension of these sinuses will cause contraction, while the excess of carbonic acid present will bring about a still more vigorous contraction of the uterine muscles. This action of carbonic acid upon contractile tissues was first proved by Brown-Séquard in 1851.

Lecture II treats of the diseases of the fetal appendages, and is full of valuable information. Dysmenorrhœal membranes, resembling "both in external appearance and minute structure" a decidua cast from the impregnated uterus, are capable, as is now known, of being expelled quite independently of pregnancy. Extravasations of blood in the decidua and decidua inflammation are fully considered.

Considerable attention is paid to the morbid changes affecting the chorion; the etiology and pathology of cystic degeneration of this body being specially discussed. The views of Virchow and Ercolani upon this interesting and somewhat rare disease are discussed at some length, with the result that the author confesses himself unable to accept the tenets of the latter authority. Except in exceptional instances, it may be laid down as a rule that cystic degeneration precedes and is the cause of the death of the foetus. To the question: Can cystic or vesicular chorion ever occur in women without conception? a negative answer is given.

In Lecture III the various diseases and anomalies of the placenta are studied fully and adequately. The experience and teaching of the author are opposed to those of Charpentier, who holds that the placenta undergoes only one morbid change. It is now admitted that the placenta may be affected by various diseases, and many obstetricians will be found who entirely agree with Dr. Priestley when he says "the placenta is, in truth, as liable to be affected by a variety of diseases as the liver or the lung." Under the term "phthisis of the placenta," we find described a low form of inflammation, not associated with bacilli as phthisis of the lung is, but characterised by a tendency for exudations to be thrown out into the parenchyma of the placenta.

This exudation may either become organised, and so form fibroid nodules scattered in the organ, or it may break down, and destruction of the placental tissue take place. In either case, if the disease advances beyond a certain point, the result will be the same, and the life of the fetus will be destroyed. With regard to the changes produced in the placenta by syphilis, our present knowledge scarcely entitles us to attribute any specific lesion to that disease alone.

In conclusion, we must note the numerous diagrams and several coloured plates of microscopical sections. The volume is of very handy size and neatly got up. Much of the material contained in it is original, and all of it is extremely valuable, especially to the student of obstetrics. Hitherto no book, so far as we know, has ever been published in which this subject is treated of in the same systematic manner; indeed we believe no attempt has ever been made to collect so much material into one volume. There is still much to be learned, and the author is careful to point out the paths by which many more facts may be gathered. The book should be in the library of every obstetrician.

FIRST AID IN ACCIDENT AND SUDDEN ILLNESS. By GEORGE BLACK, M.B. Edin., C.B. London: Ward, Lock, and Co.

THIS book is very well arranged and excellently written, but it almost reaches the requirements of a manual on minor surgery, rather than of a plain, practical guide to the rendering of help in cases of accident and sudden illness, and a manual for the instruction for ambulance students. The anatomy and surgery of the nose, eye, ear, and larynx cannot be usefully comprised within the teaching of an ordinary ambulance class. No doubt many who take an interest in the work of the St. John Ambulance Association will read this book with interest and profit.

NOTES ON BOOKS.

Modern Theories of Chemistry. By LOTHAR MEYER; translated from the German (5th edition) by P. P. BEDSON, D.Sc., and W. CARLETON WILLIAMS, B.Sc. (Longmans, Green, and Co.).—This volume is a translation of a work which has gained for itself a world-wide reputation, as being undoubtedly the most successful attempt to present to the student a complete survey of the theories of chemistry which have been built up from the vast array of experimental data. The work is one which from its nature appeals mainly to the pure chemist, to whom for a number of years past the German original has formed an almost indispensable companion. The present translation will be welcomed by all whose German scholarship is too limited to enable them to pursue such hard reading as a study of the original entails. We can thoroughly congratulate the translators on the faithful and conscientious manner in which they have performed their task. We notice, however, that some of the matters treated of have not been quite brought up to date; thus, in dealing with the laws governing the incomplete combustion of gaseous mixtures, no reference is made to the important researches made in this country, and published as long ago as 1884.

The Royal London Ophthalmic Hospital Reports. Vol. xii, Part 1, January, 1888. (J. and A. Churchill).—Notwithstanding its extremely emaciated appearance, this number of the Reports contains matter for instruction. Mr. Lawson contributes an interesting case of Sarcoma of the Optic Nerve Sheath. Tumours growing from the optic nerve are extremely rare, although several cases have, however, been recorded in addition to those mentioned by Mr. Lawson, and a few monographs have been written on the subject. The value of the case under consideration is increased, however, by the fact that a thorough examination of the tumour was made. Messrs. Lang and Barrett contribute a paper on Convergent Squint which gives evidence of systematic work extending over a considerable period. We hope to consider this paper in detail on a future occasion. It is sufficient to say here that it shows that in young subjects squint can be completely cured by glasses in about 10 per cent. of the cases, and that the occurrence of squint can be prevented while the glasses are being worn in 33 per cent. No doubt, as suggested by the authors, many in the latter class would ultimately be completely cured; on the other hand, it is not unlikely that some of the cases of complete cure would relapse if the glasses were discontinued for long. The authors promise a further communication on the subject. The

same authors make another short communication on the frequency with which cilio-retinal vessels and retinal pulsation are seen. As the presence of venous pulsation has been not infrequently mentioned as a symptom of glaucoma, it is important to note that it was found in 73.8 per cent. of the eyes examined. It would have been interesting to know whether age has any influence on the frequency of its occurrence. Mr. Collins, the house-surgeon, contributes a paper on Suppuration, Glaucoma, and Corneal Opacity following Cataract Extraction. The facts given are valuable, but when the writer launches into statistics he is unsafe. The cases of complication are collected from several years, while the tables showing the average age of patients, the number of operations in different months, etc., are compiled from one year only. Mr. Collins attributes suppuration to general conditions rather than to local infection; nearly all the facts, however, that he adduces would be equally consistent with the view that such conditions only rendered the eye more susceptible to the influence of septic organisms. Five cases are given in which the injection of a solution of biniodide of mercury (1 in 25,000) was followed by corneal opacity, a matter which is of interest in its bearing on the subject of intra-ocular injections, on which a correspondence recently appeared in our columns. It is difficult to see with what object Mr. Doyne's Observations on Tobacco Amblyopia have been inserted. On the strength of a solitary case, of which the early history is obviously unreliable, and the result admitted to be unknown, and which the writer only observed for twelve days, he has the temerity to found a theory of pathology in support of which he does not produce a single piece of evidence. In propounding this theory, he entirely ignores the pathological evidence which has been collected by others at considerable labour, and on which the commonly accepted view of the pathology of tobacco amblyopia is based. The admission of crude material of this kind will, we cannot but think, do much to damage the high reputation which the *Reports* of the Royal London Ophthalmic Hospital have always enjoyed.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

ANOTHER BINAURAL STETHOSCOPE.

THIS is a stethoscope which I venture to think is worthy of being brought into notice. Its form was suggested to me by that of an instrument for one ear which was described by Mr. R. N. Combes. I have employed it now for about two years, and find it both efficient and exceedingly convenient in use, more especially in comparing different portions of the chest in children. Its portability is a great recommendation, as it can be easily carried in any coat pocket without any case to contain it. It is also cheap. The old-fashioned wooden stethoscope excels it for auscultating thick-walled chests, as of men with strongly-developed muscles; but for all others, especially of women and children, it is entirely satisfactory, contributing greatly to the comfort of both patient and auscultator—of the former by largely diminishing the need for change of position, and of the latter by the avoidance of awkward and constrained attitudes. It is good to carry both instruments, this in the pocket, the other in the hat.

This stethoscope has the chest-piece like that of the common binaural instrument, but about an inch shorter. The tubes are about 14 or 15 inches in length, made of rubber tubing somewhat larger in calibre and firmer than that used for infants' feeding bottles. The ear-pieces are tipped with rubber tubing to make them fit comfortably in the ear, and should be selected so as to fairly well the ear of the auscultator. The ear-pieces are retained with quite sufficient firmness, without any aid by a spring or other contrivance, if they are gently pressed into the meat, giving them at the same time about half a turn of a screw motion.

The stethoscope is sold by Young, Forest Road, Edinburgh, 3s. 6d., and also by the Argyle Rubber Company, Glasgow.
J. W. MILLER, M.D.
Dundee.

SUCCESSFUL VACCINATION.—Mr. William Cooper, of Widnes, received the Government grant for successful vaccination.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1888.

SUBSCRIPTIONS to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the West Central District Office, High Holborn.

The British Medical Journal.

SATURDAY, APRIL 21st, 1888.

SANITARY ADMINISTRATION AND THE LOCAL GOVERNMENT BILL.

A SOMEWHAT remarkable feature of the debate on the second reading of the Local Government Bill has been the inadequacy of the attention that has been given to the public health aspect of the Government proposals. Mr. Stansfeld opened the debate in a very clear and carefully-reasoned speech, in which he pointed out various matters in respect of which the Bill falls short of completeness as a measure of local government reform affecting the health and prosperity of the nation. But, with the exception of Sir Lyon Playfair, the subsequent speakers directed their remarks almost exclusively to those other phases of local administration which, although matters of vital importance, do not stand in such great need of reorganisation as does our system of sanitary administration.

Sir Lyon Playfair, in his able speech, very forcibly exposed the insufficiency of the proposals in the present Bill to secure a removal of the hindrances to sanitary progress which at the present time are in full operation in many localities. Chief amongst these hindrances must be reckoned—as we have on many occasions pointed out—the unsatisfactory system under which medical officers of health are appointed and hold office. At present, as Sir Lyon Playfair observed, the plan of appointing a medical officer of health for a small, insignificant area results frequently in a practitioner being chosen who has had no special training in the science of public medicine, and who, in exchange for a trifling remuneration, gives some fragments of his time to sanitary duties and to preparing reports to the Local Government Board. The less such an officer does the better will his employers be pleased.

“The people would rather have their dunghills and nuisances left alone, as in the time of their fathers, than have them stirred up by the stick of a parish doctor. The officers are paid to do nothing and they do nothing. What is the result? That while our towns have largely improved under sanitary legislation, as they generally possess well-qualified medical officers of health, the rural districts, as a whole, have not shared in this rate of improvement, and their disease and death-rates remain much what they were.”

In contradistinction to this picture Sir L. Playfair points to Cheshire, where much has been done to improve the organisation of the sanitary service, and where the duties of the medical officers of health have been consolidated in respect of large areas. One of these areas has 280,000 acres and a population of 135,000 persons. It has the entire services of an able officer of health, who has a salary of £800 a year. Another consolidated area in the county has 139,000 acres and a population of 84,000 persons, and the medical officer of health has a salary of £635. But the rest of the county has not shown this intelligence, and there remain 213,000 acres, with a population of 420,000 persons, split up among 28 health officers, who, if Stockport be excluded, have salaries ranging from £10 to £75. Combinations exist in other parts of the country where sanitary matters are properly supervised and controlled with benefit to the public health. But, on the other hand, many combinations have been broken up or have crumbled to pieces through the jealousies or quarrels of constituent authorities or individual members. It is clear, therefore, that in practice the system of voluntary combination of districts cannot always be secured, whilst the use of compulsory powers by a central authority is, for obvious reasons, not satisfactory.

At the present time, according to the last report of the Local Government Board, there are some 1,300 medical officers of health throughout the country, and the salaries of these officers range from £3 a year to £900. In Sir L. Playfair's opinion there would be far more efficient sanitation in the country if the number of health officers were reduced to 180, each of these officers having a larger area than at present, and having public health as his sole duty, instead of regarding it as an accidental adjunct to his private practice. If London, and the larger towns that are to become counties in themselves, be excluded, a population of some 18,000,000 remains, and this would form 180 health officers' districts of 100,000 each. Undoubtedly the £130,000 annually spent on medical officers of health would, under an arrangement of this sort, secure infinitely better results than at present. Instead of this considerable sum being frittered away in small honoraria, a thoroughly effective method of sanitary administration would be built up.

The means proposed for putting this matter on a satisfactory footing is to make all officers of health officers of the County Councils, and not, as proposed in Mr. Ritchie's Bill as at present drawn, to make them officers of the District Councils. Each County Council should be required by the Act to appoint a duly qualified Superintendent Medical Officer of Health, who should be responsible for advising on all public health matters in the county, should be debarred from private practice, should be paid a reasonable salary, and should be secured in his office so long as his duties are adequately and faithfully performed. Only under such circumstances can the most useful and unfettered skilled advice be secured, which a county authority must have, if it is to fulfil properly the functions transferred to it from the Local Government Board. Subsidiary health officers would be necessary for special areas or towns in the county, or in order

to deal with cases of emergency, but such officers also should be appointed by the County Council, should act under the Superintendent Medical Officer, and should report to him.

This is a simple, logical proposal which we are glad to find has very general support in the medical profession, and which we feel sure in practice would greatly improve the sanitary service of the country. It is the ideal which the Joint Committee of the British Medical and Social Science Associations on State Medicine advocated in their memorial to Lord Beaconsfield in June, 1877, and it is to be hoped that Mr. Ritchie will see the public advantage of the scheme, and will agree to the modification of his Bill accordingly.

SULPHONAL: A NEW HYPNOTIC.

This substance is "diethylsulphondimethylmethan," an oxidation product of the union of ethyl-mercaptan with acetone, and has, therefore, the composition represented by the formula $(CH_3)_2C=C(C_2H_5)_2SO_2$. We owe its discovery to Professor E. Baumann, of Freiburg, and its therapeutical application, or, rather, some knowledge of its remarkable physiological properties to Professor A. Kast, of Freiburg, who has a long article on the subject in the current issue of the *Berliner Klinische Wochenschrift* (April 16th, 1888), in which he has nothing but praise for this new addition to the materia medica. The term "sulphonal" is due to a happy suggestion of Herren Fr. Bayer and Co., Elberfeld, who supply it. This substance crystallises in large colourless tables, and is perfectly devoid of taste and smell. It dissolves in 18 or 20 parts of boiling water, in 100 parts of water at the ordinary temperature, and is easily soluble in alcohol or alcoholic ether. It is not affected by acids or alkalis, or by oxydising agents either in the cold or warm. Thus, concentrated sulphuric acid with heat scarcely affects it, and it resists fuming nitric acid; and even chlorine and bromine; it is, therefore, a very stable body. Twenty experiments with sulphonal on healthy men showed that doses of three or four grammes were borne by adults without the least discomfort or disagreeable after-effect. Thus, a medical man, aged 28, took 3 grammes (46 grains) at 4 P.M., and at 5.15 P.M. began to feel sleepy, with a feeling of heaviness in the head. At 6.15 these feelings lessened, but at 8.15 they increased somewhat. At 9.15 the subject of experiment went out for the evening, having resisted the inclination to sleep. He passed a tranquil night afterwards, and felt no after-effects of any kind. Another medical colleague sank into a sound sleep two hours after the same dose, the sleep lasting several hours. The time of day and the meals were found to influence the action of sulphonal very much.

Employed medically the drug has been given to 60 patients; and 300 observations of its effects were made (Professor Cramer gave it 200 times in the Marburg Lunatic Asylum). The results, almost without exception, were that the patients sank within from half an hour to two hours into a tranquil and sound sleep, lasting from five to eight hours, and awoke feeling perfectly comfortable. A few felt tired and sleepy next day. The diges-

tion, pulse, and temperature were unaffected, and it is curious that no ataxy of any degree or kind was present, whereas this was the most prominent symptom in dogs after large doses. The ordinary dose for man is two grammes (half a drachm). Professor Kries has examined the effect of sulphonal on the blood-pressure, and has established the fact that in dogs, even after very large doses, the blood-pressure is not lowered. Poisonous doses in dogs, to determine the mode of death, caused severe convulsions, then, after a few hours, a heavy sleep, deepening to coma and ending in death in about ten hours. Spectroscopic and microscopic examination of the blood revealed no alteration of its elements. Sulphonal appeared most efficacious in cases of sleeplessness in nervous subjects, but was given with benefit in all kinds of cases, including even cardiac valvular disease.

ELECTRICAL TREATMENT OF DISEASES OF THE UTERUS.

At the next meeting of the Brighton and Sussex Medical-Chirurgical Society on Thursday, May 3rd, a paper on the above subject will be read by Sir Spencer Wells, Bart. Dr. Apostoli will be present and take part in the discussion. The meeting will be held at the Dispensary, 112, Queen's Road, Brighton, at 8 P.M. Members of the profession are admitted on the introduction of a member of the Society.

SANITARY PLUMBING.

MEDICAL officers of health have consistently and persistently supported the movement now on foot for the reform of plumber work. The medical officer of Liverpool (Dr. Taylor) has recently brought the subject prominently before the Health Committee of the city, and he is, we learn, now taking steps to obtain such support from the architects and plumbers of the locality as will secure the formation of a district council to carry out in Liverpool the examination and registration of plumbers on a national system inaugurated by the Worshipful Plumbers' Company, London. The medical officer of Birkenhead (Dr. Vacher), who has evinced an active interest in the movement from the outset, read a paper on Defective Plumbing at the Royal Institution, Liverpool on Monday, April 16th, illustrating it by some of his own sketches of cases coming under his observation.

THE RESEARCH SCHOLARSHIP OF THE BRITISH MEDICAL ASSOCIATION.

DR. RALPH STOCKMAN has been appointed Research Scholar of the British Medical Association. Dr. Stockman is assistant Professor of Materia Medica in the University of Edinburgh, and received a special training in the modern methods of pharmacological and physiological research in the laboratories of Professors Schiemedeberg and Hoppe-Seyler. He proposes to undertake researches on the following subjects:—1. The chemical changes which menthol, camphor, and similar bodies undergo after absorption; how far these metabolic products affect the organism, and whether they still act as antiseptics. 2. The mode of action of the camphor group on the heart and circulation. 3. The pharmacology of a new body which acts like digitalis. The problems connected with the absorption and excretion of glycerine and of fats. 5. On the connection between chemical constitution and physiological action of some alcohols.

NEW WARDS AT THE SUSSEX COUNTY HOSPITAL.—LARGE detached wards have been built on the site of the museum. The wards are intended to be used for violent patients, or for cases of erysipelas, etc., and a special feature is that those on

top floor constitute almost a separate establishment, having a separate entrance and staircase, as well as bath room and offices. Here there are two large wards—28 feet by 16—and four smaller—16 feet by 12½—all 13 feet high; a corridor 52 feet long and 5 wide separating north from south rooms. The middle floor has six wards, which are either 16 feet by 16, or 16 by 12½, separated by a corridor nearly 90 feet in length. On the ground floor there are four wards, with kitchen, laundry, and other offices. The internal walls of the building are covered with Portland and Keene's cement, trowelled to a smooth face, and all angles of walls and ceilings are rounded off, so as to lessen deposit of dust, etc. The floors are fireproof, and laid with pitch-pine; the grates are "Economisers," and the general appearance of the wards is very bright and pleasant. The closets are fitted with "Unitas" pans, and the ventilation through the window-sills and over the doors is on an improved plan. In the lower rooms are two large beds, with movable sides, for refractory patients, constructed on the model of those at St. Bartholomew's. The museum has been rebuilt, and is well arranged in its new quarters; the *post-mortem* room is equal to the best in light and convenience. Altogether the buildings are an extremely advantageous addition to the professional resources of the institution, and reflect credit on the Committee and the staff, as well as on the architect, Mr. Scott.

EXTENSION OF ST. MARY'S HOSPITAL, PADDINGTON.
We are informed that at a recent Board meeting of St. Mary's Hospital a resolution was unanimously passed arranging for the purchase of twenty-three houses on the north side of Praed Street adjoining the hospital, giving an entrance to the hospital in Praed Street. The new buildings will include a residence for nurses, special wards, and wards for lying-in women. The latter department will obviously be of great value to the clinical work of the hospital as well as an immense boon to the many poor women who frequently suffer at their own homes for the want of the advantages of a special treatment and careful nursing, which they would receive the wards of the hospital. In adopting this resolution, the Board passed also a vote of thanks to Mr. Field, the Dean of the school, to whose energy and warm interest in the hospital much of the success which has attended the preliminary arrangements for this enlargement is due.

A NEW MEDICAL JOURNAL.

A new medical journal, the *Wiener Klinische Wochenschrift*, appeared in Vienna on April 5th. It is to be published weekly, under the editorship of Dr. G. Riehl. The first number contains an article by Professor Billroth on the Treatment of Goitre by Ligature of the Thyroid Arteries, an abstract of which was given in the letter of our Vienna correspondent last week; and other important papers by Professors von Bamberger and E. von Hofmann. The journal is well printed, on good paper, and is altogether more satisfactory to the eye than the majority of foreign journals, whether lay or medical.

DEATH OF PROFESSOR DE CHAUMONT.

We deeply regret to have to announce the death of Professor de Chaumont, who succeeded the late Professor Parkes as Professor of Military Hygiene at the Royal Army School, Netley Hospital. Dr. de Chaumont was amongst the most able and accomplished members of the Army Medical Department. His scientific acquirements, especially in chemistry and physics, and his valuable contributions to the Army Blue Books on the subjects of dietary, hygiene, and ventilation, early marked him out for special employment as a teacher. He assisted Professor Parkes for some years at Netley, and his appointment in succession to that eminent man was recognised as one which did much to fill the void. Professor de Chaumont was also employed by the Privy Council and

the Local Government Board to carry out special inquiries in public health matters. His social accomplishments were hardly less notable than his scientific acquirements, and his personal character was so agreeable, his bearing so courteous and considerate, that he was universally beloved. Professor de Chaumont, whose weak state of health has caused his friends much anxiety for some time past, died suddenly of failure of the heart at his residence at Woolston.

THE SUMMER SESSION.

TRADITION in medical schools disparages the summer session. The first of October is the student's New Year's Day. At once he begins his work in the dissecting room, and, with the exception of a few days' holiday at Christmas, his labours are continued till the end of March. The new requirements of the Conjoint Examining Board will give greater importance to the summer session. The medical schools are shaping their arrangements in accordance with the new order. When the student enters in May, he will enjoy the advantage of getting used to hospital life, and will be able to spend part of his summer vacation in learning osteology. At the end of September he will know how to ensure a "part" in due season. It is, therefore, satisfactory to learn that the Warden of the College at St. Bartholomew's Hospital has issued a notice encouraging the entrance of freshmen in May. The notice advises a student who has passed a preliminary examination in arts early in the year (and has not commenced medical study) to enter in May, and to pursue his studies as follows:

1. In his first summer session to attend chemistry lectures and practical chemistry, with lectures on chemical physics. At the end of this session to pass the examination of the Examining Board in England of the Royal College of Physicians and Royal College of Surgeons in these subjects. He thus goes from his chemistry lecture to the practical study of the subject, and has the direct stimulus in his work of a public examination at the end of the session.
2. In his first winter session to attend anatomy lectures and dissect; to attend physiology lectures and practical physiology classes. At the end of his first winter session to pass the examination of the Examining Board in elementary anatomy and physiology.
3. In his second summer session to attend materia medica lectures and practical pharmacy. At the end of this summer session to pass the examination of the Examining Board in materia medica and pharmacy.
4. In his second winter session to dissect and to study practical physiology, and to attend the advanced course of lectures on anatomy. He may with advantage also attend a second course of physiology lectures. At the end of his second winter session to pass the second examination of the Examining Board in anatomy and physiology. Although systematic clinical work is necessarily deferred until after a student has passed his examinations in anatomy, physiology, and the other elementary subjects, he should from the beginning of his career take every opportunity of learning the rudiments of practical medicine and surgery by attendance as opportunities occur to him in the wards, out-patient rooms, and the *post-mortem* room.

We understand that other medical schools intend to follow the example long ago set by University and King's Colleges, and more recently by St. Mary's, and to encourage the entry of new students in summer.

UNFOUNDED CHARGES AGAINST MEDICAL MEN.

MEDICAL practitioners are, as our readers know too well, liable to have unfounded charges of negligence brought against them, and are consequently are often put to a great deal of unnecessary trouble and expense for their own protection. The fact of charges having been made is sometimes remembered, and perhaps mentioned against a man behind his back, while the more important fact that they were shown to be unfounded is forgotten or ignored. We think it well, therefore, to give publicity to a case in which a member of the profession was enabled recently to vindicate his character successfully. In the County Court at Yarmouth in

March last, a Mrs. Grief brought an action against Mr. C. A. Mayo, a medical practitioner of good standing in the town, to recover damages for injury to her health consequent on abusive and violent language used by the defendant, and on his negligent treatment of her case. In the winter of 1886 she was ill, suffering from rheumatism and pneumonia, and attended by Mr. Mayo. She wanted to call in another doctor, a Mr. Collier, but Mr. Mayo objected to meet him, as he was his junior, and Mr. Meadows was called in instead. The plaintiff alleged that on the morning after the consultation, Mr. Mayo, on paying his regular visit, accused her of having been attended by Mr. Collier, swore at her, using disgusting language, and went violently out of the room, banging the door after him; and that the effect of this conduct was to cause her to spit blood and confine her to her bed for six months. The story on the face of it appears improbable, but the plaintiff took no steps against Mr. Mayo for nearly a year, when she consulted several solicitors successively, and at last found one to bring her case into court. The demand in the first instance was for £20 and an apology for violent conduct and brutal language, and the charge of negligence was subsequently added in order to make a legal course of action. The plaintiff and her witnesses contradicted themselves and each other as to the language alleged to have been used by Mr. Mayo; and Mr. Meadows said that he was satisfied with Mr. Mayo's treatment when he was called in. The judge, Sir F. Roxburgh, decided that the plaintiff's case as to negligence failed entirely, and said that "having heard the witnesses called for her, and also the defendant himself, he was satisfied that no such conduct as alleged took place. As a question of character was involved, he had thought it right to hear the case out, but even if he had considered that the words alleged had been used, he should have decided, in point of law, that they would not support an action. In justice to a medical man, he had preferred to decide upon the facts, and he considered Mr. Mayo had vindicated his character most completely." The result is satisfactory, and should be generally known. That the defendant should have been put to considerable expense and more trouble and annoyance in repelling an unfounded charge is less so. But English law, in its anxiety to refuse justice to nobody, is unwilling to prevent actions being brought where there may possibly be a good claim. It is not till a case gets into court, and the evidence is tested, that its value or worthlessness becomes apparent. Hard though it may be on defendants to have to resist extortionate or unfounded claims, we do not see any probability of the law in this respect being altered, and members of the medical profession, when thus attacked, must be content with the knowledge that they are only under the same liability as other respectable Englishmen, though the consequences of an adverse decision are to a professional man more serious than to others.

INDIVIDUALITY OF CHILDREN AND RESULTS OF TEACHING.

CONSTANT and urgent complaints are made by teachers that, in judging of results, inspectors and managers do not sufficiently take into account the individuality of children. This feeling found strong expression at the annual conference of the National Union of Elementary Teachers. The work of teachers paid by the Government and ratepayers must ever be estimated by results: those who pay must have some security as to what they get for their money. If we visit schools for the blind, the dumb, or the feeble-minded children, we see that different criteria are looked for in each case as indicating "results" of training. The individuality of children differs greatly, consequently the objects and methods of training must be various. The attainments which we desire to see in children of 11 years old are not simply such as are indicated by examinations in grammar, writing, arithmetic, etc., but also the signs of physical growth and healthiness, the

signs of tidiness, intelligence, quickness, and happiness. It is an important but a difficult and complicated question how to estimate "results" of education; the teaching profession might do well to try and give some practical definition of "good results." An assessment of the results of school work must take into account individual differences among children; it is very undesirable that the age of children should in any large degree be taken to indicate what standard in the school a certain child ought to occupy late developments often make very good growth. In framing a statement of results of educational work, allowance ought to be made for the variations of individuality in the children, and this can only be done by those trained to observe individual children, and able to estimate their condition and progress by what they see in them. The results to be sought in a child that is feeble, or 'one of poor development,' differ greatly from those to be expected in children of average growth; a very moderate amount of knowledge, but fairly quick brain action, well under control, is perhaps all that can be expected, but a "good result" has been obtained if such a dull child is made to like the school, if he attend regularly, and is active and obedient. We protest that school results should not be estimated by mere scholastic work, and should not much depend upon lesson work in relation to age. The individuality of children differs immensely, so also does the special character of different teachers. Some method of estimating results must be employed, but it is highly desirable to leave considerable freedom of action to teachers, and they in their turn will be glad that the results of their work should be known and estimated. The real question at issue is not that any of us doubt the varying individuality of children and teachers, but how are we to apply tests as standards of results? This difficulty is less felt in secondary schools, where the parents' opinion of progress and later successes of former pupils in part form a standard of school success.

AWARD OF THE MARSHALL HALL PRIZE.

FIFTEEN years have passed since the Marshall Hall Fund was instituted, with the twofold purpose of commemorating the late Dr. Marshall Hall, and of encouraging research in that branch of natural science which he did so much to develop. The trust provides "that a prize shall be given every fifth year for the best original work done and recorded in the English language during the previous quinquennium in physiological or pathological researches relating to the nervous system, and that the prize shall consist of the simple interest derived during the preceding five years from the amount of the capital fund." The first award was made to Dr. Hughlings Jackson, the second to Dr. Ferrier; and this year the Council of the Royal Medical and Chirurgical Society, whose hands the fund was placed, have awarded the prize to Dr. Walter Holbrook Gaskell, F.R.S., Lecturer in Advanced Physiology in the University of Cambridge. The Council have invited Dr. Gaskell to give some account of his work before the Society, at a special meeting will be convened for this purpose, which will be duly announced.

THE LATE MR. MATTHEW ARNOLD.

THE life and death of Mr. Matthew Arnold have a lesson of hope and a warning for the large number of persons who suffer from heart disease. Twenty-five years ago he consulted Dr.—now Dr. Andrew—Clark, and was told that he had valvular disease of the heart, but advised that if he exercised reasonable care it need not at all interfere with his career. For many years he rigidly adhered to the recommendations as to regimen and exertion which were given to him, and it is interesting and encouraging to recall that nearly all his serious work in criticism, education, and theology was done within the last twenty-five years. His reports and essays on middle-class education, the *Essays in Criticism*, and *Literature and Dogma*, all belong to this period. Such a life is

striking proof that heart disease, even of a type generally accounted serious—for Mr. Arnold had disease of the mitral and aortic valves—need not interfere with the labours or the enjoyments of a successful career, provided only that the limitations and moderate restrictions to which the individual must submit are frankly recognised. Emboldened by long impunity, patients are disposed to come to believe that the precautions have been unnecessary, and to relax their vigilance at the very time when the approach of old age renders all more or less liable to weakness of the heart. The Arnold family are a remarkable instance of family predisposition to disease of particular structures; the father of Dr. Arnold of Rugby, Dr. Arnold himself, and now two of his sons, have all succumbed to chronic heart disease.

THE EMPEROR OF GERMANY.

WE learn, by special telegram from Charlottenburg, that at the end of last week inflammatory swelling of the loose tissue surrounding the windpipe was observed below the tracheotomy wound in the Emperor's throat. His Majesty had a slight shivering fit on Saturday evening, and this was followed by symptoms which made the medical attendants fear that the lungs were becoming affected either by the development of a fresh centre of the disease which has so long existed in the larynx, or by inflammation excited by the trickling of irritating discharges into the bronchial tubes. So far, however, we are pleased to know that no trace of any pulmonary complication has been discovered after repeated careful examinations by Professors Senator and Leyden, whose scientific attainments and practical skill are as fully recognised by the medical profession in this country as they are in Germany. The Emperor's temperature rose to 103° F. on Tuesday, but came down to 101° F. in the evening. On Wednesday it reached 104° F. for a short time, but quickly fell again. Sir Morell Mackenzie believes that His Majesty is at present suffering from pyæmia, a form of blood-poisoning which is, under any circumstances, extremely dangerous, and which, in a patient whose vital powers have been slowly sapped by a lingering and painful illness, must give rise to the worst apprehensions. His Majesty's physique, however, is so exceptionally robust, and his life has been so entirely free from excesses of any kind that could weaken or vitiate the natural soundness of his constitution, that there may still be some room to hope that the present crisis—threatening and almost desperate as it undoubtedly is—may be successfully got over. The worst feature of the case, however, with regard to the ultimate prognosis is the internal condition of the air-passage, which, it appears, became suddenly so much narrower at a point opposite to the wound that it was found necessary to introduce a new tube long enough to reach below the obstruction. We have pointed out more than once that one of the most perplexing features of the case is the extraordinary suddenness with which the disease, after prolonged periods of quiescence, starts into renewed activity. Whether the invading mass be an offshoot from the original cancerous formation in the larynx, as the German physicians are said to be unanimous in believing, or an abscess depending on destructive inflammation of the cartilaginous structures, is now, we consider, a matter of comparatively little practical moment. Probably a patient would have a chance of a longer lease of life with undoubted cancer than with perichondritis of so widespread and severe a character as is postulated in the present case.

SCOTLAND.

THE honorary degree of LL.D. was conferred upon Sir William Mackenzie, M.D., and Dr. W. H. Walshe, by the University of Edinburgh at the annual graduation ceremony on Wednesday last.

GLASGOW UNIVERSITY EXTENSION SCHEME.

THE town of Paisley has taken the lead in adopting the extension scheme recently announced by the University of Glasgow. A largely attended public meeting, convened by the Provost, was held on April 13th, and after the details of the scheme had been fully explained, the meeting unanimously agreed to its adoption. A large and strong committee was appointed to make the necessary arrangements.

SOUTHERN MEDICAL SOCIETY, GLASGOW.

DR. EBEN DUNCAN introduced a discussion on the modes of disposal of the dead, and after reviewing present modes of burial, he pointed out very fully the advantages of cremation. He illustrated this subject by the accounts of experiments made on the bodies of animals, and then discussed the various precautions taken to prevent, at any time, a miscarriage of justice by cremation.

CHOCOLATE CHEWING GUM.

TWO confectioners in Glasgow have been fined £3 each under the Adulteration of Foods Act, for selling a sweetmeat called chocolate chewing gum, and containing 42 per cent of paraffin wax. It was stated for the respondents that the confection was manufactured in Lincoln, and that it was bought by children for the purpose of chewing and then making crackers. Dr. Russell stated that the paraffin wax was insoluble in any of the fluids, and indigestible, and might so irritate the stomach as to cause convulsions in children of tender years. The sheriff said the article had a misleading name, and as children might purchase it for eating the trade must be put down.

DALBETH CEMETERY, GLASGOW.

THE Archbishop of Glasgow has replied to the communication made to him by the local authority in regard to the condition of Dalbeth Cemetery owing to the custom of pit burial. He expresses the willingness of the committee in charge of the cemetery to make such regulations in the method of interment as are indicated in Dr. Christie's report, and intimates that instructions to that effect have already been given. At the same time he states that the Committee, while willing and anxious to meet every proper and reasonable requirement, cannot see that there is any evidence that the methods hitherto adopted have created, or are likely to create, a nuisance. He refers to the exceptionally good health enjoyed by the inmates and attendants of the reformatories on each side of the cemetery, the low death-rate, and the favourable reports of Her Majesty's inspectors as supporting this view, and expresses the opinion that the offensive odours complained of arise from the Tollcross Burn. He, therefore, thinks it a hardship that Dalbeth Cemetery should have been singled out for animadversion, and the managers of it alone called on to alter their method of interment.

FRESH AIR FORTNIGHT FOR CITY CHILDREN.

THE Committee who so successfully carried out last year the idea of giving the poor children from the slums of Glasgow a fortnight in fresh country air, are again taking steps to carry on this important work during the ensuing summer. Their plan consists in boarding the children in the homes of cottagers in healthy country districts. The Committee, however, found last year that children with open sores could not be so boarded out, although they required fresh air even more than the others, and, consequently, nothing was done for them. An attempt is to be made this year to get over the difficulty by providing a special home for such children. We wish the attempt all success, as the work is most necessary, and will assuredly be followed by excellent results.

PATHOLOGICAL AND CLINICAL SOCIETY, GLASGOW.

At the meeting, on April 9th, Dr. Meighan showed a man who had had a piece of metal embedded in his left eye for ten years. The metal was now making its way outwards through the cornea. Dr. Reid showed microscopic specimens from a case of mycosis of the eyeball, in which mycelium tubes and spores were found spreading from the deeper layers of the conjunctiva into the substance of choroid and interior of the eyeball. Dr. Joseph Coats showed specimens of fat-embolism of the lung from a case of simple fracture of the femur. Dr. Fleming showed a portion of ascending colon containing a large concretion, which had caused the formation of an abscess in the right iliac region. Dr. Newman showed a perforating ulcer of the anterior wall of the stomach communicating with an abscess cavity of old standing. Recent rupture of abscess into the peritoneum had occurred.

EDINBURGH UNIVERSITY COUNCIL AND THE UNIVERSITIES (SCOTLAND) BILL.

At the statutory half-yearly meeting of the General Council of Edinburgh University, held on Tuesday, April 17th, the text of the Universities (Scotland) Bill came up for consideration. The Business Committee presented a report on the Bill, which in large part was accepted by the Council. The Committee held that the proposals for affiliation and incorporation of other colleges were needlessly vague. It appeared to the Committee that the term affiliation might be accepted as sufficient. The Committee insisted on their previous contention as to the impolicy of transferring the Botanic Garden to the University, and as to the inadequacy of the proposed grant to the Scottish universities. In other respects the Committee, believing the measure to embody much for which they had long contended, expressed the opinion that, subject to such minor alterations as had been suggested, it should be passed.

SCARLET FEVER AT GARNET HILL, GLASGOW.

SCARLET fever is very prevalent at present in the Garnet Hill district of Glasgow. It appeared first in a dairy in the district, the proprietor of which at once communicated with the authorities. All the other cases have been traced to this dairy. Immediate investigation of the sanitary conditions of the farms whence the milk supply of the dairy was obtained led to the discovery that at one of them—a farm near Eaglesham—there were two cows suffering from sores on the teats and other symptoms resembling the recent Hendon cow-disease. It was accordingly resolved to bring these cows into the city for further and more careful observation. Professor McCall kindly offered accommodation at the Veterinary College. During the last fortnight careful observations have been made as to the condition of the cows, and some young calves and pigs fed with the milk. Bacteriological observations are also being made, and in due course a full report of the whole circumstances will doubtless be given.

IRELAND.

SANITARY CONDITION OF NAAS.

THE Local Government Board have received a report from their inspector, Dr. Burke, in reference to the sanitary state of this town, which they forwarded last week to the Naas guardians. The report states that the sewerage is in a defective condition, and the Board have requested that the matter may receive the attention of the guardians, who are the sanitary authority. The latter, however, are of opinion that they have done all that is necessary, and refuse to have a main drainage scheme for their town. That up to a recent period the sanitary condition was positively disgraceful is shown by a report of the medical officer

of the district, who some time since stated that considerably less than one half of the entire number of houses had any sanitary accommodation whatsoever.

CASE OF HYDROPHOBIA.

IN January last, a workman employed in Guinness's stores, at Limerick, was bitten on the hand by a rabid animal. The wound was cauterised at the time, but symptoms of hydrophobia supervened last week, and he died in Barrington's Hospital, two days after admission.

SIR PATRICK DUN'S HOSPITAL.

A DEPUTATION of the governors of this hospital waited on the Public Health Committee on April 17th in reference to the proposed fever hospital in connection with that institution. After some discussion, the deputation stated that their board would acquiesce in the wishes of the Public Health Committee. A deputation of residents in the neighbourhood of the proposed fever hospital also waited upon the Committee. The following resolution was then agreed upon unanimously:—"That this Committee cordially thanks the Board of Governors of Sir Patrick Dun's Hospital for their public-spirited conduct in agreeing at the request of this Committee and at material cost to abandon their original intention of using the new wing of their hospital for the reception of fever patients, and to devote that wing to the treatment of non-infectious diseases, and that the Committee regard as entirely satisfactory this concession freely made by the Board of Governors in deference to the desire of this Committee."

ULSTER MEDICAL SOCIETY: DISCUSSION ON MEMBRANOUS LARYNGITIS.

A VERY interesting discussion upon the diagnosis and treatment of membranous laryngitis, occupied the attention of the Ulster Medical Society at its last meeting, upon April 11th. The discussion was opened by Professor Cuming, who devoted his remarks mainly to the therapeutic aspects of the question. He deprecated the excessive use of steam, and especially the erection of a tent around the patient's bed to concentrate the vapour, but thought that a warm and somewhat moist atmosphere was desirable. He had seen no advantage from the use of emetics, which were of acknowledged efficacy in simple laryngitis. Sprays of lactic acid, sulpho-carbolate of soda, lime water, and glycerine might be employed, but he did not rely much upon them. As regards internal medication, he had a leaning in favour of mercury, but thought that probably he had seen most benefit from iron and chlorate of potash. Nutrients and stimulants were, of course, most valuable. The important question of tracheotomy was fully considered. He drew attention to the remarkable discrepancy between the results of the operation in different hands and in different localities. Although his own experience of the operation was unfavourable, he had little doubt that if performed sufficiently early it materially improved the very gloomy prognosis usually necessary in membranous laryngitis. He thought that as soon as the existence of a membrane in the larynx was definitely diagnosed, tracheotomy should be at once proposed, lest of time being very perilous. As regards the new procedure of intubation, he had no personal experience of it, but thought that there was a rapidly accumulating body of evidence in its favour. Professor Sinclair, Professor Dill, Dr. McFarland, Dr. Byers, Dr. Wales, Dr. Lindsay, Dr. Dempsey, Dr. M. Connell, Mr. Fagan, and the President, Dr. Esler, took part in the discussion which followed.

THE twenty-second annual report of the Bristol Hospital for Sick Children and Women states that, owing to the system which requires some payment towards the cost of medicines—although 788 women and 2,327 children made 8,113 and 16,929 attendances respectively—the net expense to the hospital was less than £1.

PARLIAMENTARY BILLS COMMITTEE.

Lunacy Acts Amendment Bill.—Tax upon Horses.—Irish Lunacy Laws.—Notification of Infectious Diseases.—Public Health Prevention of Infectious Diseases (Hastings) Bill.—Relative Rank.—Pharmacy Bill.—Coroners Bill.—Burials Bill.—Local Government Bill.

A MEETING of the Parliamentary Bills Committee of the British Medical Association was held on Thursday, April 12th, at the offices of the Association, 429, Strand. The following members were present:

Mr. ERNEST HART in the Chair.

Dr. Bridgwater, Harrow
Dr. Holman, Reigate
Dr. Alfred Carpenter, Croydon
Dr. Langdon Down, London
Dr. Mickle, London
Dr. Grigg, London
Mr. Eastes, London
Dr. C. Orton, Newcastle-under-Lyme

Mr. W. D. Spanton, Hanley
Dr. Walter Dixon, London
Mr. Balding, Royston
Dr. Phillips, Reading
Mr. Wallace, London
Dr. C. E. Glascott, Manchester
Dr. A. J. Harrison, Clifton
Dr. S. H. Agar, Henley-in-Arden

The minutes of the previous meeting, of which printed copies had been circulated among the members, were confirmed.

Dr. BRIDGWATER proposed and Dr. HOLMAN seconded the re-appointment of Mr. Ernest Hart as Chairman, which was carried unanimously.

Letters of apology for non-attendance were received from the President and the President-elect; Dr. Deas, Exeter; Dr. Duffey, Dublin; Dr. Meadows, Market Drayton; Dr. Bruce Goff, Bothwell; Mr. Harrison, Liverpool; Mr. Jeaffreson, Framlingham; Dr. Philipson, Newcastle-on-Tyne; Dr. Ritchie, Edinburgh; Mr. Sibley, London; Mr. Watkins, Towcester; also from Dr. Esler, of Belfast, who sympathised with the efforts made to prevent the taxing of horses of medical men.

The CHAIRMAN said he had asked the Committee to meet at that time, because it was the time at which they usually met to consider the Bills before Parliament, and to consider specially any points in respect to particular Bills or any matter affecting the medical profession. They had a long list of Bills before them, and he suggested that, with respect to any Bill requiring detailed consideration, it might be convenient to appoint a subcommittee to consider the special points, and to refer the conclusions arrived at to a future meeting.

Lunacy Acts Amendment Bill.—This Bill, which had been twice before the Committee had, the CHAIRMAN pointed out, now passed the House of Lords, and he asked Dr. Mickle to report on the further proceedings desirable.

Dr. MICKLE said the Bill was considered by the Committee last year in its amended form, and the present Bill seemed to be very much the same thing. There had been a shuffling of the clauses, still the provisions were very much the same. Some matters in the former Bill had been omitted and a few new matters introduced, but these, he thought, were not important from a medical point of view. He had drawn up a report upon these which he would read if necessary. With regard to registered hospitals, as to which they made representations last year, some of the clauses had been omitted and others retained, and he would be glad to know if Dr. Deas (who had interested himself in this question) was satisfied. He (Dr. Mickle) had also noted the points to which the Committee were committed in previous years, and which still applied in the present Bill. The first was Subsections 1 and 2 of Section 4, which had been introduced, partly in modification of, and partly in substitution for, clauses existing in a former Bill. The provisions, as they had already argued, left it optional with the judge, magistrate, or justice to consider whether or not he was satisfied with the evidence appearing by the medical certificates, etc.; and, if not, he should make such further inquiries as he thought fit. But, if he thought the evidence sufficient, he might make an order forthwith. This was connected with a different section, namely, Section 2, pages 6 and 7, where a number of provisions were made for cases in which the magistrate had not seen the alleged lunatic; and in that case the alleged lunatic might, if he had not been previously seen by a judge, magistrate, or justice, demand, at any time within seven days, an interview with judge, magistrate, or justice. This left room for a good deal of delay; so that he might be certified and yet his case only decided upon a fortnight later; and though when certified he might be extremely

insane, when examined by a magistrate he might have recovered. It was most desirable that it should be made compulsory for a magistrate to see the alleged lunatic before signing an order for his admittance. Then there was the question of the remuneration of workhouse medical officers, as to which there was some little doubt whether the Bill really meant that the workhouse medical officer should receive any remuneration. They recommended that the workhouse medical officer should receive remuneration. They also made a recommendation in respect to the severe penalties attaching to the workhouse medical officer for not reporting cases, which might easily happen from oversight. Dr. Mickle called attention to Section 36, page 22, as to which it had been suggested by their Committee that "the person making application for the discharge of a patient under this section, shall give security for the payment of all expenses." The clause in the Bill read as follows: "An order for the examination by two medical practitioners, authorised by the Commissioners, of any person detained as a lunatic in any asylum, hospital, or licensed house, or as a single patient, may be obtained from the Commissioners upon the application of any person, whether a relative, or friend, or not, who shall satisfy the Commissioners that it is proper for them to grant such order; and on production to the Commissioners of the certificates of the medical practitioners so authorised, certifying that after two separate examinations, with at least seven days intervening between the first and the second examination, they are of opinion that the patient may, without risk or injury to himself or the public, be discharged, the Commissioners may order the patient to be discharged at the expiration of ten days from the date of the order." It was to be anticipated that under this section vexatious and wholly unnecessary proceedings would be instituted, likely to lead to the discharge of patients unfit for discharge. Any person, whether a relative or friend of the patient or not, might apply and get an order from the Commissioners for the patient to be seen by any two medical men, who, after two examinations, may certify that the patient should be discharged. There were, he thought, "black sheep" in the profession who would make it their business to see patients, and certify for their discharge. A patient so discharged would have, *prima facie*, a very strong case if the certifying was recklessly done by persons who were not acting *bona fide*.

It was also suggested that service of medical officers in public asylums should count accumulatively towards pension, etc.

It was proposed that Dr. Mickle's report be accepted and referred for consideration to a subcommittee consisting of Dr. Bridgwater, the Chairman (Mr. Ernest Hart), Dr. Alfred Carpenter, Dr. Langdon Down, and Dr. Mickle, with power to act.

This resolution was seconded and adopted.

Dr. LANGDON DOWN thought it very desirable that the Bill should be carefully watched through Committee.

The CHAIRMAN said the Committee were greatly indebted to Dr. Mickle for the trouble he had taken in drawing up his reports.

Tax upon Horses.—The CHAIRMAN said there had been, as they knew, a considerable feeling raised throughout the profession on the subject, and he had received a large number of communications, practically unanimous, from persons feeling it to be a grievance that such a tax should be imposed. One or two persons however had taken a different view, feeling it undignified on the part of the profession to protest against the imposition of a tax of £1 per year. He (the Chairman) felt that the question of £20,000 or £30,000 a year was an important matter for the profession as a whole, and that there was an obvious objection to taxing horses employed in medical business as pleasure horses. He had had himself some private communication with the Chancellor of the Exchequer, and he (the Chairman) had advised medical men, individually, to address communications to Parliament. They had seen the statement made by Mr. Goschen in the House, which he thought they might accept as practically indicating his willingness to make some considerable exemptions. He did not think, from the tenour of the communications which had been received, that it would be quite abolished, but he thought they might gather from what had been said, that probably one horse would be exempted, and in the same way exemptions would be made as to the carriage tax, which would considerably lighten the existing burden of medical men in that respect. The Chancellor of the Exchequer had intimated that he did not think it necessary that he should receive a deputation from their Committee, because he was already very fully in possession of the views of medical men on the subject, from a great variety of sources, and he was doubtful whether it would add to his information. He further pointed out that the actual provi-

sions of the Bill had not yet been passed. He (the Chairman) thought that, taking the tone of that letter, and seeing they had already a considerable body of Parliamentary assistance in the matter, that it would perhaps be hardly necessary or dignified that, under the circumstances, they should put further pressure on Mr. Goschen, but wait until the actual provisions were introduced in the measure, and if then no concessions were made, he should be allowed to call the Committee together to make a collective representation. A number of petitions had been presented, and members generally had received instructions from their medical constituents.

Dr. HOLMAN called attention to the threefold nature of the undue burden of taxation upon the medical man. There was the increased taxation on his income, upon his horses, and upon his carriage wheels. The average earnings of a medical man in the country were under £300 a year. He could not earn more than that with one horse, and to earn £500 he had to keep two.

Mr. BALDING agreed with Dr. Holman.

The CHAIRMAN thought the statement made by Dr. Holman would be an important element in any further statement they might have to make. The income of medical men was a precarious one; they would have the wheel tax to pay, and the house in which they carried on their business was taxed as if it were a pure dwelling house; so that medical men were hit in every possible way.

Dr. CARPENTER suggested that a letter should be written to Mr. Goschen, stating the views that had been expressed had had that day the support of the Parliamentary Bills Committee.

Mr. BALDING said he knew two or three medical men with a thousand a year practices, who required the use of three horses.

Dr. BRIDGWATER agreed with the suggestion of the Chairman that it would be well that the Chairman should address a further letter to Mr. Goschen, and then they might wait and see the provisions as introduced into the measure before taking further action. This course was decided upon.

Irish Lunacy Laws.—The CHAIRMAN read the following resolution of the Psychological Section of the Dublin meeting, which had been referred to the Parliamentary Bills Committee by the Council.

"It was moved by Dr. Yellowlees and seconded by Dr. Savage:—

"That this Section of the British Medical Association, having had under consideration during the meeting in Dublin the Irish lunacy laws and their practical working, and having strongly felt their grave defects when compared with those of England and Scotland, conclude to bring this subject under the consideration of the Council, in the hope that they will take such steps as to bring under the attention of the Government the urgent need of better regulations and further legislation in regard to this matter. The chief defects are the following:

"1. The modes of admission of patients into asylums, which often involve injustice and injury to the patients, and great danger to the public.

"2. The defective powers possessed by the medical superintendent for the proper and efficient management of the asylums, for example, his having no power to engage or to dismiss the attendants, on whose loyal discharge of duty the welfare of the patients so greatly depends.

"3. The want, in the majority of asylums, of assistant medical officers, so that the medical superintendent is unable to give the necessary time to his strictly medical duties, and large asylums containing some hundreds of lunatics may be left entirely without resident medical supervision when the superintendent is absent."

The CHAIRMAN said he had obtained the opinions of the gentlemen who moved and seconded the resolution, and also of Dr. Mickle, who had drafted a report, as to the necessary reforms. The state of things there disclosed was obviously one which was far behind that of which they complained in England and Scotland.

The following resolution was moved by Dr. DIXON, R.N., seconded by Mr. EASTES, and carried *nem. con.*:

"That the foregoing resolution, together with the memorandum now handed in by Dr. Mickle, be referred to the subcommittee already appointed, with directions to frame a report on the subject, and to circulate it in type before the next meeting." Subsequently, being found to deal fully with the subject, this memorandum was accepted as the report to be so printed for consideration by the Committee.

Notification of Infectious Diseases.—The CHAIRMAN reported the receipt of a letter from Dr. Biddle, of Kingston, accompanied by a memorial signed by a number of medical men residing in that town, calling attention to the fact that in the Kingston Improvement Bill a clause had been inserted requiring concurrent notification of infectious disease; that was to say, notification by the householder and by the medical attendant. The memorialists objected to the latter.

Dr. LANGDON DOWN explained that there was a very strong feeling in Kingston on the subject, the medical profession being practically unanimous in opposing the dual notification, the feeling being that their practices would be worth nothing if they were put in the light of common informers.

The CHAIRMAN pointed out that it had long ago been legally decided that their Committee had no *locus standi* before a Private Bills Committee in respect to any private Bill, and this had been repeatedly stated in the JOURNAL. The local medical men must themselves apply to be represented. The proper course was to instruct a solicitor. They were the only persons who could oppose.

Dr. ALFRED CARPENTER said the question was one of some interest and some importance, though of course he agreed that they had no *locus standi*. In his neighbourhood dual notification prevailed, and medical men, as a rule, did notify; but there were medical men in Croydon who objected to it, and the authorities were just then proceeding against Dr. Dalton to recover a penalty because he refused, and would still refuse, to notify, but would do as he had done in the case referred to, instruct the householder and occupier. And in the above case the householder did notify, and the house was cleansed, but the local authority, for some reason or another—not, he thought, suggested by the medical officer—thought it best to proceed against Dr. Dalton. A second case occurred soon after. The authority recovered, but there was the principle involved that though there was dual notification there had been no notification by the householder, nor could proceedings be taken against the householder because he did not notify, but immediately they got a complaint against a medical man they proceeded against him. It showed the way in which the Act was being worked was not exactly the best to promote the repression of disease, because at that moment in the parish of Croydon there were cases of infectious disease which were being attended by herbalists, who were not called upon and could not be compelled to disclose. The consequence was that disease was being spread because they were not under the care and management of qualified medical men, and no proper measures were taken for preventing the spread of disease. If the law said the medical man was to act as agent of the patient there would be no difficulty whatever, and where there was a determination not to be a so-called informer, he would request the householder to give the notice, and the householder would probably do it.

Dr. Langdon Down was requested to inform Dr. Biddle that the Committee sympathised with his views, but that, as had several times been determined and announced in the JOURNAL, the Parliamentary Bills Committee had no *locus standi* before a private Bill Committee.

Public Health Prevention of Infectious Diseases (Hastings) Bill.—The CHAIRMAN said Dr. Carpenter's observations might be considered an introduction to the consideration of the above Bill. It was a general measure introduced by Mr. Hastings, Dr. Farquharson, Mr. Francis Powell, Mr. Wharton, and Mr. Harcastle. The object of the Bill was to make universal the notification of infectious disease which now existed in about forty-eight cities or towns of England, and the Bill proposed the method to which Dr. Carpenter objected, and to which so many people in the Association objected, namely, the method of dual notification. It was a Bill which he supposed had very little chance of passing. If the Committee proposed to take any such steps as Dr. Carpenter would suggest, it might, he thought, be well for them to appoint a subcommittee to draw up reasons to submit to the promoters of the Bill in favour of or against the provisions of the Bill.

Dr. GRIGG called attention to the fact that in the list of infectious diseases given in the Bill as to which notification was to be made, puerperal fever was included.

The following subcommittee was appointed to draw up reasons for opposing the Bill:—Dr. Bridgewater, Dr. Alfred Carpenter, Dr. Langdon Down, Dr. Grigg.

Relative Rank.—The CHAIRMAN said he had to report on the question of rank that for the moment they might consider it

taken out of their hands, inasmuch as it was still before the Council, who were dealing with the subject. As they would have seen, he was not seeking to give the matter attention, and various questions had been put to Mr. Stanhope. The answer given as to the interpretation of the Warrant was more conciliatory and promising. A considerable number of military members of the House of Commons had sympathised with them. He was sure it would be pleasing to the Committee to know that the course taken thus far by the Committee was exceedingly satisfactory to the Service, and that they were constantly receiving letters from officers of all classes giving their most sincere thanks. One officer, as a testimony of his sense of the great services of their Committee, had forwarded the names of no less than forty new members during the year.

Dr. ALFRED CARPENTER said he thought they owed Mr. Hart a very cordial vote of thanks for the ability and energy which, as their Chairman, he had shown in dealing with the matter of rank.

Dr. BRIDGWATER proposed a cordial vote of thanks to their Chairman, Mr. Ernest Hart, which was seconded, and unanimously accorded.

Pharmacy Bill.—The CHAIRMAN said they would remember that he brought before them certain points connected with the Pharmacy Bill which indicated that, under that Bill, there was a possible tendency to encroach on medical rights, especially in including among the courses of instruction *materia medica*, and to examine therein. The Committee had directed him to write letters to the Privy Council and to the General Medical Council. The General Medical Council adopted their views, and Mr. Marshall and Dr. Quain, on behalf of that body, had an interview with the Privy Council. The Bill as now introduced had been expressly modified to meet their views, and it was satisfactory to know that the resolution of the Committee had had so good an effect.

Coroners Bill: Coroners Election Bill.—The CHAIRMAN explained that the Coroners Bill of the Lord Chancellor proposed to put the election of coroners in the hands of the Lord Chancellor, and the Coroners Election Bill proposed otherwise to amend the Act. The Committee would remember that they had, some years previously, a very elaborate series of reports on the amendment of coroners' law prepared for them and by it, with the assistance of the late Dr. Taylor and other eminent persons. They were all in favour of the abolition of the election of coroners by freeholders, and thought it would lead to great abuses. The objection seen to the Bill as drawn was that, if the Lord Chancellor appointed, he would probably appoint a lawyer and not a doctor; otherwise the Bill seemed to be a good one. The Bill might, he thought, be printed in the JOURNAL, and suggestions asked for.

Dr. CARPENTER said if there was to be an alteration with regard to the law of coroners, they should endeavour to get a plan by which medical assessors to coroners should be appointed, and he suggested for this purpose medical officers of health where their whole time was devoted to their duties. If the Bill was to be seriously considered in this Parliament, he would suggest that a committee should be appointed to deal with the Bill, and to press the question of the appointment of medical assessors upon the attention of the Government.

Mr. BALDING thought if the Bill passed it would be very much to the disadvantage of the medical profession. There were from 400 to 500 coroners in England, and it was proposed to revolutionise a system of appointing coroners which had existed for many hundreds of years. How was the Lord Chancellor to decide on the proper men to hold the office of coroner? He contended that the duties of that office were, in some respects, better performed by the medical man than by the lawyer. One of the most difficult points for a coroner to decide was when to hold an inquest and when to order a *post-mortem* examination. These questions could be much better solved by a medical man than by a lawyer. It was compulsory upon a borough coroner, whatever his profession, to appoint a lawyer as his deputy, but that did not apply to county coroners. He was in favour of a medical coroner being compelled to appoint a lawyer as his deputy, and a legal coroner being compelled to appoint a medical man as his deputy. He thought it would work much better than appointing assessors.

The CHAIRMAN suggested the appointment of a subcommittee, to consist of Mr. Balding, Dr. Danford Thomas, Dr. Carpenter, and Mr. Sibley, with power to call in the assistance of gentlemen not members of the Committee, for the purpose of considering the Coroners' Bill.

Burials Bill.—The CHAIRMAN called attention to the fact that in the Burials Bill, which was otherwise generally approved, there was no provision for supplying a zone around cemeteries or burial grounds. It had frequently come to the notice of sanitary authorities that they were quite up to the very verge of high-ways. It was decided that the Committee should urge the insertion of a clause providing for a zone of unoccupied ground around cemeteries and burial grounds as being important in the interests of public health.

A resolution in accordance with the above was proposed by Dr. HOLMAN, seconded by Mr. SPANTON, and adopted.

Local Government Bill.—The CHAIRMAN, in calling the attention of the Committee to this Bill, said it had always been maintained by their Committee and by the State Medicine Committee of the British Medical Association and by the Council that it was of the utmost importance, first of all, that an intermediary authority, such as the County Boards, should be established for health purposes, and they knew that when the Public Health Bill was framed, they fought very hard to have such County Boards created. Now that intermediary authority had been created, it answered in many respects the desire of the Committee. Although large sanitary powers were given to its Council, it had no sanitary staff, and the medical officers of health were in no relation to it, and the County Boards in cases of epidemics would have no means of communication with the Local Government Board. They had always contended that medical officers of health should be appointed over large areas and have large jurisdiction, and any reduction in their numbers would be more than made up by the efficiency of having officers over a large area. He was glad to see that the Council of the Society of Medical Officers of Health also considered that they should be attached to and should be appointed by the County Councils. He thought that would have the entire concurrence of their Committee. It was entirely in accordance with their traditions, and the only objection that could possibly be raised would be the objection of cost, and he did not think that would be any obstacle. Supposing there were 200 appointed and they were paid £200,000 a year, there would be little or no increased expenditure, with considerably increased efficiency.

Dr. CARPENTER said those were the views which had been so often expressed by the Association at various times, and the time seemed to be at hand at which it would be right to urge those views upon the Government, especially in connection with the Local Government Bill. Dr. Carpenter also called attention to suggestions made at a meeting held at Croydon, to consider the treatment of a medical officer at the hands of the Holborn Guardians, and suggested they should be considered in connection with that matter.

A resolution was passed to the following effect:—

“That an endeavour be made to introduce into the Local Government Bill a clause attaching the medical officer of health to the new County Councils.”

The subject was referred to the same subcommittee as that appointed to consider the Coroners Bill.

SEVENTH GERMAN MEDICAL CONGRESS, HELD AT WIESBADEN.

[FROM OUR SPECIAL CORRESPONDENT.]

THE seventh German Medical Congress was opened by the President, Professor LEUBE (Würzburg), on April 9th. He gave a short historical view of the advance in medicine during the century, and pointed out that in future we must endeavour to find means of treatment corresponding to our progressing powers of diagnosis.

Treatment of Heart Disease.—Professor OERTEL (Munich), whose method has attracted so much attention, both at home and abroad, since the cure of Prince Bismarck by Dr. Schweningen (hence falsely “Schweningencur”), opened the discussion on the treatment of chronic diseases of the heart-muscle. After stating that, in his opinion, Stokes, who first introduced this method, had not found any followers, he said that it had first been employed in Germany by himself, with great success on a relative of his own, who suffered severely from weakness of the heart-muscle in 1875. During the following nine years he endeavoured to give a scientific basis to this mode of treatment by experiments on animals and observations on men, which are to be found in his book *Therapie der Kreislauf Störungen*. He had, however, reconsidered his position, and recognising that his

treatment was not equally suitable for all cases, he would exclude from it advanced atheroma and grave incompetence of the heart-muscle. By a combination of an appropriate diet (animal food containing little water) and exercise obtained by the gradual ascent of mountains (Terraincur), he obtained the following results: 1, diminution of the quantity of fluid in the body, and removal of the condition which he had termed "serous plethora;" 2, oxidation of the fat; 3, compensation between the arterial and venous system; 4, strengthening of the heart-muscle. The method he said ought not to be employed when the dyspnoea was increased by it and the flow of urine diminished.—Professor LICHTHEIM (Berne), his opponent in the discussion, denied the existence of a serous plethora, and cited the recent publications of Bamberger, and of one of his own pupils, showing that the relative amount of red corpuscles and serum was a constant quantity. He considered the method only suited (although then very effectual) for cases of fatty heart in persons of sedentary habit who lived high, and for the removal of dropsical swellings. The chief danger lay in acute dilatation of the ventricles; several of the cases of sudden death recorded were thus brought about.—Dr. KISCH (Prague) mentioned that in cases of general obesity, with or without dropsical swellings, he had found that the proportion of red corpuscles was always constant.

Alcohol as a Remedy.—The discussion of the second day on alcohol as a remedy was opened by Professor BINZ (Bonn), and Professor von JAKSCH (Graz), who considered that recent observations had proved that alcohol was an excellent remedy in febrile diseases (diphtheria, typhoid fever), owing to the multiplicity of its effects in lowering the temperature, stimulating the heart's action, and diminishing metabolism. A healthy man, however, needed no alcohol.—Professor NOTHNAGEL uttered a warning word as to the employment of alcohol in childhood, and expressed the belief that the rapid increase of neurasthenia was one of its effects.

Prevention and Treatment of Cholera.—The third discussion was on the prevention and treatment of cholera. Dr. PREIFFER (Wiesbaden), who gave expression to contagionist views, without, however, bringing forward further evidence, agreed generally with the results arrived at by the Vienna Cholera Conference. Prevention was to be effected by isolating the patient, and disinfecting everything coming from him.—Professor CANTANI (Naples) spoke in German on the treatment of cholera. He confirmed the results laid down in his recent publications by new experiments on animals and new statistical material. The idea that tannin might prove powerful originated in his mind from seeing that tanners were exempt from cholera in the recent epidemics. After experiments on animals he ascertained that his so-called "tannin clyster" (injection of 5 to 10 grammes tannic acid dissolved in 1 to 2 litres 38° to 40° C. warm water into the rectum) fulfilled the following three chief indications: (1) weakening and destruction of micro-organisms; (2) excretion of Brieger's ptomaine by the removal of anuria; (3) removal of the inspissated condition of the blood. He believed that his injections reached the ileo-cæcal valve and even the stomach, for they were sometimes vomited. He warmly recommended also a 6 in 1,000 solution of chloride of sodium as a hypodermic injection.—Drs. HÜPPE and BÜCHNER, both well-known bacteriologists, gave expression to the view that even the recent epidemics had shown the existence of what Pettenkofer called local and periodic influences. While considering the comma bacillus as the cause of the disease, they believed that we were yet far from recognising the whole etiology of cholera.—Professor BRIEGER made some observations on cholera ptomaines.—Dr. ROSENAU (Wiesbaden) urged that the investigations brought forward by a large body of English and Indian epidemiologists, who studied the disease in its home, had not received due attention in Germany. Mentioning the recent Milroy Lectures of Surgeon-General Lawson, he (Dr. Rosenau) thought it possible that by dust winds, so often experienced by ships at sea in tropical zones, which carry an immense amount of organic matter, cholera germs might be widely spread. As prophylactic means he would advise a combination of pepsine with muriatic acid.

Œsophageal Catheter.—Professor LEYDEN (Berlin) showed a permanent catheter (*Dauersonde*), resembling that of Symonds, for cases of stricture of the œsophagus. In one case of cancerous stricture the sound had remained during ten months without any alteration of tissue.

Pathology of Epilepsy.—Professor BINSWAUGER (Jena) reported a new series of experiments confirming those made by Nothnagel fourteen years ago, and showing that epileptic fits might originate

from a centre in the medulla oblongata; both, however, agreed with Hughlings Jackson on the origin of the epilepsy from the motor area of the cortex.

Xanthelasma.—A very remarkable case was shown by Professor LEUBE (Würzburg), of general xanthelasma of the skin, where growths were also met with in the aorta and the substance of the heart.

Local Anæsthesia and Local Anæsthetics.—Professor LIEBRICHT read a paper of high interest, demonstrating that the most heterogeneous substances, even distilled water, might produce anæsthesia on rabbits when injected subcutaneously; this might serve as a caution against the too ready acceptance of the recent experiments on erythrophlein.

Diagnosis of Gastric Diseases.—Professor DEHIO (Dorpat) described a method of examining by percussion the area occupied by the stomach when fasting and when gradually dilated by measured quantities of water, which might prove useful for the difficult differential diagnosis of atony and ectasia.

Pasteur's Prophylactic.—Professor CANTANI reported a large number of experiments after Pasteur's method, which went to disprove the views of Professor von Frisch (Vienna). He showed that the poison of rabies might propagate itself along the course of the peripheral nerves in both centripetal and centrifugal directions.

Many other interesting papers were read and largely discussed. Some were shortly reported in the JOURNAL of April 14th. The meetings lasted daily from 9 to 12.30 A.M., and from 3 to 5.30 P.M.

By a large majority Wiesbaden, the Queen of German watering-places, was chosen as the place of the next meeting, in spite of a considerable number being in favour of Berlin.

ROYAL MEDICAL BENEVOLENT COLLEGE.

THE twenty-fourth festival of this College was held on Tuesday at the Hôtel Métropole, when about 300 guests assembled under the Presidency of the Right Hon. the Lord Mayor. Amongst the guests were His Royal Highness the Duke of Cambridge, K.G.; the Earl of Dartmouth; Sir A. Clark, Bart.; Sir Trevor Lawrence, Bart., M.P.; Sir E. H. Sieveking; Sir A. T. Watson, Bart., etc.

The usual loyal toasts having been duly honoured, THE LORD MAYOR, in proposing the toast of "The Army, Navy, and Reserve Forces," said it was a matter of necessity that the defensive forces should be always kept in the greatest possible state of efficiency. It was not the place for him to mention the great services rendered to the army by the Medical Staff, but they were rendered in some cases with the most heroic devotion.

THE DUKE OF CAMBRIDGE, in responding to the toast, said: My Lord Mayor and gentlemen, the Lord Mayor has done me the honour of coupling my name with the toast of "The Army, Navy, and Reserve Forces." I am always proud to have the honour of responding in a large assembly for the services generally, and for my own service in particular. I believe that, as far as possible, what the Lord Mayor has suggested is at this moment the case. I mean that, as far as our means will admit, the services are as efficient as they can be. But there is a difference in that, because, though the services are as efficient as they can be as far as possible, I do not mean to imply by that that they are as efficient as they ought to be. We are a very powerful and a very influential nation, and every individual, whether in this room or walking in the street out there, ought to be, and should be, interested in the condition of those services, for it is the power of this country that its prosperity must depend, and unless you have that power in these days always more or less ready, depend upon it you never can feel that you are in a safe or in a satisfactory condition. This is the great question that is now occupying very much the public mind, but not a bit more than believe me, it ought. The fact is, we live in times of great difficulty, and, I might almost say, of great anxiety. It is impossible to foresee from day to day, I might almost say at this moment from hour to hour, what the next morning may produce to us or news from distant parts. It is not a moment in which we can shut our eyes to our own especial condition. We live in an age when everything progresses most rapidly. Nobody is more aware of that than the large body of scientific men which I am addressing on this occasion, and who know that in their own profession everything changes, everything progresses, everything advances in a degree, and to an extent which some few years ago would have been thought impossible. But it is possible now, you know it, you appreciate, you see it, and are obliged to deal with it when the moment arrives; and just as in your profession these changes

improvements, and advances take place, so it must be, and is, with other professions, and so it is with the great military profession of the army and navy, for which I have at this moment the honour to respond. This is, perhaps not the occasion when I ought to indulge in my thoughts on this subject, but I can assure you I feel so impressed with the importance and the anxieties which are surrounding this subject, that I never like to get up and speak for these services without bringing to your notice what ought to be done, what might be done, what should be done, and what would be done if we look into this subject, which is not to be thought of or dealt with in a party spirit or a political spirit; for, to my mind, it has nothing on earth to do with politics whatever. What it has to do with is the existence of this grand country, which every one of you, here or elsewhere, is ready to defend with your life, if necessity arises. That being so, I never can shrink from bringing this to your notice in the most forcible manner that I can. Now, gentlemen, I have said my say as regards the special toast to which I have been called upon to respond, and I now will turn to the fact of my being here to-night, not in the chair, but most delighted to support the Lord Mayor, who, with that good taste which is conspicuous on these occasions in all the Lord Mayors of London, is always ready to come forward to do what he can for works of benevolent charity. Gentlemen, I am here to-night at your invitation, also, I hope, with your full concurrence. I think I may claim, to a certain extent, to have a right to be here in this respect, that there is a great affinity between the important service that I represent and the great corporation which you represent here upon the present occasion. The fact is that we army men could not exist without the medical service. I have always felt that most fully. I have always deplored the possibility of occasional little rubs and grinds, which I hope have now entirely passed away, and I sincerely trust that that cordiality and good feeling which ought to exist, and which I hope exists, between the military and naval professions and the great medical profession in all parts of this country is so strong that nothing possibly can shake it in the future. Well, now, gentlemen, when you come to see what I have seen, and what others have seen more than I have, of what military service is, I can assure you that, if it was not for the medical profession armies could not exist in the field. And not only in the field but even in daily life, in our daily avocations. If it was not for the great assistance that we have from the medical profession of the army, which emanates from the great colleges and medical schools which are so largely represented here to-night, it would be impossible to keep our forces in the condition in which they ought to be. Therefore, I think I have a right to claim that I, representing those services, may be assumed to have great sympathy for those institutions which are connected with the profession many of whose members I am at this moment addressing, and therefore I appreciate the compliment that has been paid to me in having been invited to support the Lord Mayor on the present occasion. Gentlemen, there can be no difference of opinion that in every profession there is need of help—I speak absolutely now of help not in a professional sense, but, I am sorry to say, in an economic sense; that is to say, there are members of every profession, who, by circumstances, either by death or accident, or some means, are not in a position to leave their families and friends able to look after themselves. Well, gentlemen, it is right that there should be great institutions, such as the one that we are assembled to support to-night, in which these incidents should be considered; and I am glad to think that there is a feeling of sympathy amongst medical men, as there is amongst all right-thinking professions, that one man ought to support the other when he is in difficulty. That has been the foundation, no doubt, of this institution, which, I believe, owed its origin to Mr. Probert, and the first Treasurer, the late Mr. Hancock. Now you are represented by Dr. Holman, and you have a most influential supporter in Dr. Jenson. It has also been very much aided by the great liberality of Mr. Fry, and though there are many others. I think I have named sufficient to show you that I have taken that interest in the institution which it is right that those who come to support it should appreciate and be able to give to those whom they are addressing. I can only assure you that I for one, and every member of my profession, have the greatest regard and esteem for their medical friends of the army. Sometimes it is said that we do not appreciate you, that there is no cordiality. I can assure you there is nothing of the sort, and if ever there is anything of the sort, depend upon it there is some individuality in the matter which in

every land will occur, and which we all appreciate every day that we exist. There is another point; we in the army are called upon to go to every portion of the world. We have great difficulties of climate to contend with, we have the advantage and the knowledge and experience which you possess and which you acquire in the medical profession in mitigating the dangers, the risks and the anxieties of military life in bad climates. There again we have your valuable assistance. As to war, I need not say that that carries with it its consequences: they are deplorable, but yet they are inevitable, and but for you they would be detestable; your assistance enables that to be passed over with less distress, with less pain, with less anxiety than would be the case otherwise. I believe that there is no profession in the world so ready to do its duty, not only for the sake of its profession, but for the spread of humanity throughout the world. We have men like my friend Sir Joseph Fayrer and others, who have been in India, who have studied all those climatic differences that we have to contend with, and who have given us the benefit of their advice and assistance, and the consequence has been that we have passed through difficulties which other nations have never been able correctly to face. All this justifies me in feeling that I am no intruder amongst you; that the army is not an intruder amongst you; and, as a result, I trust that the cordial feeling which I have endeavoured to express on this occasion throughout the medical profession is reciprocated, and will be more and more reciprocated year by year. In my opinion it is the bounden duty of every man, whatever position he may fill, to try to bring together every element that can produce results beneficial to the great State to which we belong. It ought to be our bounden duty. I can assure you it is my anxious endeavour and desire always to try to be in accord with all my neighbours, under whatever circumstances I find them. I can only say that, if at any time there are differences, they certainly are not created by me, and I do my utmost on all such occasions to mitigate and to assuage, and to try to bring cordiality where there ought never to have been any question of anything else. These are the sentiments which I on my own part and on that of the army entertain towards this great profession; and, having that feeling, I could have no hesitation in at once coming forward and accepting with satisfaction the compliment that you have paid me, and I thank you on the part of the army and of myself for the honour you have done me on this occasion.

Sir EDWARD SIEVEKING, in proposing the toast of "The Houses of Parliament," expressed the debt of gratitude which all who were connected with the Medical College owed to Earl Manvers, its first president.

The Earl of DARTMOUTH, in responding for the House of Lords, claimed that, with any amendment of the House a gentle treatment would be preferable to more drastic treatment.

Sir TREVOR LAWRENCE, M.P., on behalf of the House of Commons, expressed the belief that the House was doing its duty in a satisfactory manner. He was glad that a Medical Bill having been brought in year after year, the House had at last had the good sense to leave to the medical profession the management and settlement of its own affairs.

Mr. C. G. WHEELHOUSE: At the request of those who have organised this banquet, I have been entrusted with the proposal of a toast which I know you will receive with enthusiasm. If I pass over those impolitic and illogical restrictions by which experimental research is hampered and hindered, I think I may venture to say, without fear of contradiction, that at no time and in no other country in the world have the opportunities for the study of medicine and the allied sciences been more abundant or more perfect than they are in our own. Covered as each division of the kingdom is with ancient universities, ancient corporations, and great schools, devoted alike to the study and to the teaching of medicine, and flooded as the country is with zeal on all hands for the promotion of scientific knowledge, it would be marvellous indeed if British medicine and British surgery did not stand in the foremost rank all the world over; and, whether as pioneers or as practitioners of our profession, Great Britain may certainly point with pride and satisfaction to the achievements and reputation of her sons. And if we regard that reputation as it was in ancient days, and only a generation or two ago, and as it is in these present times of ours, where are we to look for the springs and sources of its present improvement but in the training insisted on by our great corporations? Without the guiding hands of our Colleges of Physicians and Surgeons, and of that most excellent and useful corporation the Society of Apothecaries.

if every man had been still permitted, as in former days, to pick up his knowledge and information where and how he could, what could we have hoped to remain but a nation of empirics, where now we stand out as one of scientific and educated practitioners? To the Royal College of Physicians, with her stringent laws, her abundant lectures, the honours and the prizes she offers to her Licentiatees, to her Members and her Fellows, medicine owes well-nigh all her pre-eminence; surgery could never have attained to its present standard of greatness had it not been for similar efforts on the part of the Royal College of Surgeons. Presided over, as these corporations have been, by men whose names have become household words all the world over, they have done their work with singular dignity and efficiency, and have manifested to the world what such corporations ought to be and may be; and the mere mention of the name of Sir William Jenner, beloved at home, and held in veneration wherever true medicine is appreciated, will, I know, call forth your generous enthusiasm. To his successor, Sir Andrew Clark, we look for great things also, and we look with no fear of disappointment. Troublous days seem, indeed, for the moment, to have fallen on these grand old corporations; differences and schisms have arisen among their constituencies, but, gentlemen, they are such that time and reflection will heal them all, and I am one of those who believe and sincerely hope that in the great principle of "union" we shall, ere long, discern the remedy for these evils. Union is, proverbially, strength, and with our Colleges united, their laws consolidated, their requirements assimilated, we shall soon see them working smoothly and harmoniously together, and I am not without hope that even we who are gathered at these tables may live to see arising out of their union yet another corporation, whose great function it shall be to grant to those who aspire to possess them, and who are able to show by the acquisition of superior knowledge, wheresoever acquired, whether in our universities, or in London, or in our great provincial schools, that they deserve them those higher titles and qualifications which it is a legitimate aim and ambition for every man to set before himself. Gentlemen, I propose to you the toast of "Our Medical Corporations," and I couple with it the names of Sir Andrew Clark as the President of the College of Physicians, and of Dr. Amsden as Master of the Society of Apothecaries.

Sir ANDREW CLARK in responding, said he would do all that lay in his power to stimulate the corporation with which he was connected as well as the other corporations to come forward in the support of the Royal Medical Benevolent College in a way that they had not hitherto done.

The LORD MAYOR, in proposing "Success to the College," dwelt upon the great services that were rendered by the medical profession to the community at large, and urged that provision should be made for the support of the widows and children of those who fell in the discharge of their duty. He stated that he had visited the College and saw the good work it was doing, and concluded by appealing to those present and also to the public for increased liberality in the support of this noble work.

Dr. HOLMAN having acknowledged the toast,

The SECRETARY announced that the total sum received that evening, including £20 from the Duke of Cambridge, was £2,574.

The toast of "The Chairman" was then proposed by Dr. HOLMAN, after which Sir Joseph T. FAYRER proposed "The Head Master," which was responded to by the Rev. CECIL WOOD, and the toast of "The Local Secretaries," proposed by Dr. JONSON and responded to by Dr. PURNELL, brought the proceeding to a close.

MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE SOCIETY.

REPORT FOR THE QUARTER ENDING MARCH 31ST, 1888.
PRESENTED APRIL 18TH, 1888.

THE number of proposals received during the past quarter is above the average, namely, 43, as compared with 34 in the previous quarter, and 30 in the corresponding quarter of last year. The total number of proposals received during the four years the Society has been established is 1011. On the other hand, the Society has lost more members than usual during the quarter—2 having died, 2 proposals being declined, 2 having withdrawn with surrender values, and 11 (quite an unusual number) having lapsed by non-payment. If this total (17) be deducted from the 43 new members during the quarter, there remains a net increase of 26, which, added to the 829 members good

on the books at the commencement of the quarter, gives a present available membership of 855. Neither of the two members whose deaths were notified during the quarter had effected life assurances with the Society.

The following is a summary of the operations of the various funds:—

Sickness Fund.—The premium income of this fund has been £1,272 4s. 6d., against £1161 18s. 10d. in the previous quarter, and £1,091 4s. 2d. in the corresponding quarter of last year. The expenditure for sickness pay is £383 5s., as compared with £423 19s. in the preceding quarter, and £337 12s. in the corresponding period of last year. The number of members claiming is 30, and the aggregate period of sickness, 115 weeks 6 days, an average of 3.86 weeks for each claimant. The number of claimants in the preceding quarter was 40, and the aggregate sickness, 129 weeks 6 days, while in the corresponding quarter of 1887 there were 32 claimants, and an aggregate sickness period of 123 weeks 4 days. The claims, which are chiefly on account of affections of the throat and air-passages, include also 2 cases of fever, and 2 accidents. It will be noted the sickness rate continues below the average assumed in the data on which the tables were calculated, and, so far, has not shown the expected tendency to increase as the Society grows older. On the contrary, the ratio of sickness is less now than it was some time ago. If the expenditure be treated as a charge on income, it will be seen that this quarter the proportion is 0.302 of the total, while last quarter it amounted to 0.364, and in the corresponding period of last year to 0.355.

Annuity Fund.—The net premium income to this fund is £601 9s. 1d. as compared with £574 18s. in the preceding quarter. From this the only expenditure is £14, the surrender value of a membership withdrawn. As a number of members will be entitled from March 31st, 1889, to have a proportion of their annuity premiums returned to their representatives in case of death before the age of 65, a larger expenditure from this fund may then be expected.

Life Assurance Fund.—The premium income to this fund has been £216 13s. 4d., compared with £213 6s. 7d. in the preceding quarter, and £197 11s. 11d. in the corresponding period of 1887. There is an expenditure of £200 on account of the death of a member at Norwich, reported last quarter. Payment of this was delayed while the representatives procured letters of administration, and was made immediately on their having done so.

Management Fund.—There is an income to this fund of £256 4s. 6d. From this the expenditure for management, etc., for the quarter is £97 2s. 2d., leaving nearly £160 to be added to the amount accumulated to the credit of the fund as the result of care and economy in the administration of the Society, and the honorary services rendered by the officers and the committees. The defined and limited proportion of 10 per cent. of the premium income for management purposes has thus proved more than sufficient, the amount expended during the quarter under review being only £3 15s. per cent.

General Position.—The position of the Society and the amount standing to the credit of the various funds is now as follows:

	£	s.	d.
