When the cocci spread into the surrounding tissue after injection, or from wounds in the skin, etc., they apparently at first frequently follow the course of the lymph channels. In the case of injections, as in Lumin's cases, we find at the seat of injection a central mass presenting a yellowish appearance, due to the presence of large numbers of leucocytes and cocci infiltrating the injured parts, this central yellow mass being surrounded by an inflamed area, in which are also leucocytes and micrococci. At the margin of the inflamed area the cocci are seen to be multiplying and penetrating into the surrounding tissue in all directions, the mode in which they spread varying according to the density of the tissue; thus, where the tissue is fairly dense, they spread in masses, while in the loose cellular tissue they form small groups and chains of four to six members. The cellular tissue attacked soon loses its fibrous appearance, the fibrille swelling up and a homogeneous mass forming, this mass ultimately undergoing liquefaction, just as in the case previously described. Beyond the area of infiltration with organisms a layer of leucocytes is formed, but at first this layer does not seem to be able to oppose the spread of the organism. In rabbits, however, after about the third—and more especially the fourth—day, their spread begins to be limited, and the zone in which the cocci are penetrating into the tissue becomes thinner. In rabbits, by the ninth day the tissues have, as a rule, completely got the upper hand, and the micrococcal growth is surrounded and limited on all sides by a layer of leucocytes (Ernst). The sequence of events in man is quite similar, but, as a rule, the cocci become enclosed more quickly than in rabbits. I may say that I have here been speaking of the effects of staphylococci; the mode of spread and action

of the streptococci is, as Ogston first pointed out and as will be afterwards mentioned, somewhat different, and these differences apparently bear some relation to differences in the peptonising power of the two species of organisms.

As regards the mode in which the cocci act on the skin, for example, in the experiments made by Bockhardt, the following seem to be the facts. The points at which the pyogenic cocci penetrate into the skin are the ducts of the sweat glands, the orifices of the sebaceous glands and hair follicles, and portions of the skin where the protective epidermis has been scratched or destroyed. If the micrococci penetrate by one or other of these paths into the skin, they multiply either in the wall of the ducts of the sweat glands and the adjacent part of the Malpighian layer, or they penetrate into the external root sheath and into the Malpighian layer at the orifice of the hair follicles, or they develop at some part of the Malpighian layer which has been deprived of the epidermic covering. They multiply rapidly at the seat of infection, and set up violent suppurative inflammation in the neighbouring papilla, the violence of this inflammation being evident from the rapidity with which the pustules appear after inoculation. As a rule, when the micrococci only set up impetigo pustules, they do not spread beyond the epidermic tissue; if they do so we have the conditions necessary for the production of an abscess in the skin; this, however, generally only occurs after coarse mechanical injury to the skin. A boil develops, especially from impetigo pustules which have formed in connection with hair follicles, or with the orifices of the ducts of the sweat glands, in the following manner: After the micrococci have entered these parts and set up the impetigo pustules, they gradually spread in the wall of the ducts until they reach the end of the sweat gland, or sebaceous or hair follicles. Coagulation necrosis occurs around them, and violent inflammation is set up in the vascular tissue surrounding these ducts and glands, with the result that a layer of leucocytes is formed like a wall around the affected epithelial tissue. As the necrosed wall of the duct or hair follicle becomes infiltrated with pus cells, the core of the boil is formed; pus forms around the core, and ultimately the skin gives way and it is expelled.

CAN SUPPURATION OCCUR WITHOUT MICRO-ORGANISMS?

Although it is thus evident that these organisms can cause suppuration, a very important question, and one which has been much debated, still remains for consideration, namely, whether acute suppuration can occur without the action of organisms. It is only in a very few instances that pyogenic organisms have been missed in acute abscesses. Rosenbach failed to find any micro-organisms in two cases of suppurating hydatid cyst, and he was inclined to think that a hydatid cyst could, under certain circumstances, exert a pyogenic property. But the cases of this kind which have since been investigated have always shown the presence of micro-organisms in the pus. The other cases of acute suppuration in which micro-organisms have occasionally been missed are cases of suppurating bubo after soft chancre; in a certain proportion of these cases the ordinary pyogenic organisms have been found just as in bubo after gonorrhœa, but in a considerable number, and more especially in those abscesses which, after being opened, become chancrous surfaces, no organisms have as yet been demonstrated. In this instance, however, the abscess is without doubt caused by the virus of soft chancre, a virus which is, in all probability, of a bacterial nature, but which has not as yet been satisfactorily demonstrated. As this is the case it can hardly be a matter of surprise that organisms have not been found in a certain proportion of these bubos; and that, under certain circumstances, pyogenic organisms are present is only what we should expect as the result of the mixed infection which is so apt to occur. Although, therefore, organisms have not been found in some of these cases, we cannot, under the circumstances, conclude that none are present. With these exceptions we always find that acute suppurations occurring naturally are associated with micro-organisms.

Numerous experiments have been made with the view of ascertaining whether it is possible that suppuration can occur as the result of injuries of a mechanical or chemical nature without the intervention of micro-organisms. As a result it may be regarded as settled that, in the lower animals at any rate, mechanical injuries, though frequently repeated, cannot of themselves lead to suppuration; and, as a matter of fact, the whole discussion at the present time is limited to the effect of a few acrid chemical substances, namely, croton oil, ammonia, and oil of turpentine.

With regard to these substances, a large number of investiga-

tions have been made with contradictory results. On the one hand a number of observers state that one or all of these substances can cause suppuration in animals. I myself came to the conclusion some years ago that croton oil could cause suppuration in rabbits. Omitting the earlier experiments, which were not free from objection, I may mention the method I ultimately adopted with the view of excluding all possible contamination with organisms. I took a mixture of equal parts of croton oil and olive oil, sterilised it, introduced it into sterilised glass capsules, which were then sealed at both ends. An incision was made antiseptically in the muscles of the back of a rabbit, and the tube introduced into the muscles; the wound was then stitched with catgut, and an antiseptic dressing applied. The result was that in a certain number of cases the wound healed by first intention, and the glass capsule remained embedded in the muscles as an unirritating foreign body. After a certain time had elapsed the capsule was broken by slight pressure against the spine, and thus the croton oil was brought into contact with the tissues. In one experiment performed in this way the capsule was broken fifty-four days after its insertion, and the animal was killed twenty-seven days later. On making an incision into the part a quantity of putty-like material was found. In another experiment, forty-five days elapsed between the operation and the breaking of the tube, and the result was the same, except that there was a much less quantity of this putty-like material. No organisms were present in either case.—Councilman and others who have followed the same plan mention similar results, as do also other observers, such as Orthmann, Grawitz and de Bary, etc., who have adopted different methods.

On the other hand, we have a number of experiments, carefully conducted, by a number of independent observers, in which no suppuration has followed the introduction of irritating chemical substances. Thus Straus took especial care that organisms should not be introduced along with the material injected by cauterising the surface of the skin at the seat of injection, so as to destroy the organisms on it, and he is positive that these substances do not cause suppuration. Perhaps the most valuable of these researches is that by Klemperer, who adopted Straus's method with still greater precautions. He states that he has failed to cause suppuration by the injection of these substances except in cases where micro-organisms were present at the same time. I may also mention a research by Ruijs, where the materials were injected into the anterior chamber of the eye, and where the effect could be watched. Here also it was found that if organisms are absent, suppuration does not follow the introduction of these chemical substances.

In weighing the evidence it is clear that most stress must be laid on the negative results. If a number of careful observers have failed entirely to produce suppuration by the injection of these irritating chemical substances, then those who have obtained a contrary result must either have brought some other factor unwittingly into play, or there must be some other explanation of the result.

The explanation of the positive results given by those who hold the opposite view is that organisms were really present in the pus, but were either missed from imperfect examination or had died out before the abscess was opened. Speaking of my own results, I am positive that organisms were not present in a living state when the animal was killed, and although it is quite possible that they may have been present at an earlier period, and have died out before I opened the abscess, I do not think that this explanation is a satisfactory one, for other investigators have examined the seat of injection after a shorter period than I did, and have likewise failed to find micro-organisms; and, besides, the character of the disease induced is different from that caused by micro-organisms. In the latter case we have a progressive suppuration, an abscess which goes on spreading, whereas those who speak of suppuration occurring after the introduction of croton oil, etc., state that it is not a progressive inflammation, and does not resemble that caused by micro-organisms.

On the other hand, it seems to me that we are possibly disputing about the same thing, that what the one set of observers calls pus, the other set looks on as fibrinous exudation, for Klemperer, Ruijs, and others speak of the occurrence of fibrinous exudation containing many leucocytes as the result of their injections. Certain it is that, after the injection of these chemical substances, true creamy pus is not obtained unless micro-organisms are present; the most that one gets is a collection of putty-like material, and it becomes a question whether this "putty-like

material may not simply be a further change in what has been found at an early stage, and has then presented the appearance of fibrinous exudation. Klemperer states that on examining a part into which croton oil has been injected, the tissues at the centre of the irritation are of a yellow colour, infiltrated with fibrinous exudation and large numbers of leucocytes. Where the pyogenic organisms act, their peptonising action rapidly dissolves this original tissue, and prevents the coagulation of the fresh exudation, and thus a cavity, containing fluid pus, is rapidly produced. On the other hand, where these organisms do not act, there are still grounds for believing that the tissues themselves can, very slowly it is true, dissolve and remove the dead material, and thus we may quite well find, as the result of the prolonged action of living cells on the extensive dead mass, a putty-like mass, which has been described by some as pus.

This seems to me to be the most probable explanation of these discrepant statements, but on this view we must admit that these irritating substances cannot cause true acute suppuration when micro-organisms are absent. The result which they produce is a different pathological process, corresponding more closely with the formation of chronic abscesses than with that of true suppuration. For the formation of acute abscesses we apparently require the presence of the peptonising ferment produced by the micro-organisms, or, at any rate, of a chemical substance which prevents coagulation of the exuded fluid. Thus we have to note that both Grawitz and Scheuerlen, the latter of whom denies the occurrence of suppuration as the result of irritating chemical substances, have succeeded in inducing acute abscesses by the injection of cadaverine, an alkaloid separated by Brieger from putrefying flesh; this substance is not only an irritant, but also prevents coagulation.

As a matter of fact, in Nature the only situations where we have to consider the possible occurrence of suppuration without organisms are the surface of wounds and the skin. With regard to the possibility of acute suppuration from a wound as the result of the initiation of the antiseptics applied to it, I must confess that I have never yet seen true creamy pus coming from the surface of a wound without finding at the same time micro-organisms in it, and I suspect that the only effect of the antiseptic substance is to increase the amount of exudation and the number of leucocytes, and thus cause at most a semi-purulent discharge. The only other instance in which I have seen suppuration in man without micro-organisms as the result of the action of chemical substances is on the skin at the margin of the new alembroth dressings, where pustules are apt to occur when the discharge is at all free, the contents of these pustules being a sticky semi-purulent material and not containing any micro-organisms. This is the nearest approach that I have seen to true acute suppuration in man without the action of micro-organisms.

A LECTURE

OR

ANATOMICAL PECULIARITIES IN RELATION TO DISEASE.

*Being one of a Course on Evolution in Pathology delivered at the
Royal College of Surgeons.*

By J. BLAND SUTTON, F.R.C.S.

Hunterian Professor; Assistant-Surgeon to the Middlesex Hospital.

MR. PRESIDENT AND GENTLEMEN,—Not the least interesting investigations in the province of comparative pathology are those which relate to morbid conditions, depending in a great measure, or almost entirely, on anatomical peculiarities. The material at my disposal to illustrate this question is very large, hence, on the present occasion, only the more striking examples will be chosen for description. My first illustration is taken from the lamelli-branches.

Lining the concavity of the shells is a membranous structure, which may be regarded as the integument, and known as the pallium or mantle. The shell itself is the direct result of the excretory efforts of the lobes of the mantle, and is composed of animal matter hardened by deposits of carbonate of lime.

Occupying the space between the mantle of opposite sides, we find the animal proper consisting of branchia, intestines, foot, nervous system, heart, reproductive organs, etc.

These animals obtain their food in a somewhat lazy fashion. The margins of the gills are covered with cilia, which, by their constant movements, set up inhalent currents, which not only serve to oxidise the blood in the branchia, but convey concrete particles, many of which are seized upon by the mussel and utilised as food.

Some lamellibranchs have animals commensal upon them. Commensalism differs from parasitism, in the important fact that an animal commensal on another lives upon the food of its host, whereas a parasite lives in the cavities or tissues of, and draws nourishment from, the blood of its host. It would seem that as long as the animals commensal on a lamellibranch keep within the space between the mantle they are safe enough, but occasionally they are rash enough to penetrate the space between the shell and the mantle.

This trespass is resented by the lamellibranch, and the trespasser is punished by being entombed in shell-tissue, and in some cases by pearl.

A very beautiful example of this has lately been recorded by Dr. Günther (*Pro. Zool. Soc.*, June 1st, 1886). The specimen is represented in the accompanying woodcut, Fig. 1. It had been in Dr. Günther's possession for many years. It is an old shell of *Margarita margaritifera*, in which there is embedded, behind the impression of the attractor muscle, a perfect individual of a fish belonging to the genus *Fierasfer*. The fish is covered by a thin layer of pearl-substance, through which not only the general outlines of the body, but even the eye and mouth, can be seen.

In this case the fish, instead of keeping between the two halves of the mantle, penetrated between the mantle and the shell. The irritation thus caused induced the mollusc to cover the intruder with pearl. The secretion must have taken place in a very short time, at any rate before the fish could have been destroyed by decomposition.

Specimens of this nature arrest attention on account of their novelty, and many similar cases could be adduced. This encysting process may be studied in mammals, particularly in the molars and tusks of elephants. In numerous cases, spear-heads, bullets, and other foreign bodies have from time to time been found completely embedded in ivory. Even in the human subject foreign bodies encysted in connective tissue come under observation.

Fig. 1.—A fish of the genus *Fierasfer* imbedded in a pearl oyster (after Günther.)

The Incisors of Kangaroos.—The dentition of kangaroos is, in many respects, peculiar. In the present case it is only with the

incisors that we are concerned. It will be seen from the drawing (Fig. 2) that the upper incisors are three in number, and present

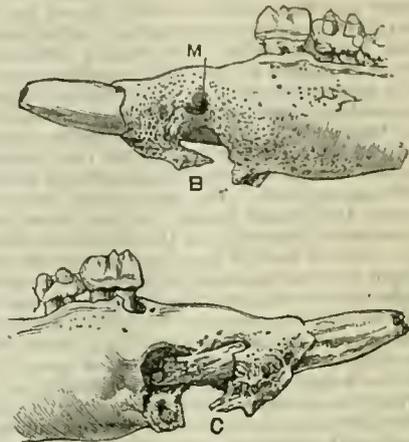

Fig. 2.—The upper and lower incisors of a kangaroo.

little that is exceptional, but the lower jaw possesses only one, and this, in order to antagonise with the upper incisors, is of large size and procumbent, projecting horizontally forward. They are flattened from side to side, and are slightly convex in the outer surface; the inner surface is flat, with a median ridge; the margins are sharp. These incisor teeth are provided with a large and persistent pulp, which extends an unusual distance along the tooth, reaching nearly to its distal extremity.

The points of these teeth, shaped something like a lancet, are exceedingly thin and brittle; as a consequence, the tips are frequently broken, and if only a small piece is detached, the pulp is readily exposed. Kangaroos, like mammals of even high moral pretensions, have domestic differences, which occasionally lead to unpleasant consequences. In the encounter the tips of the incisors are broken, the exposed pulp becomes inflamed, suppurates, and leads to alveolar abscess, which, in some cases, terminates in death. In Fig. 3 two views of the symphyseal portion of the

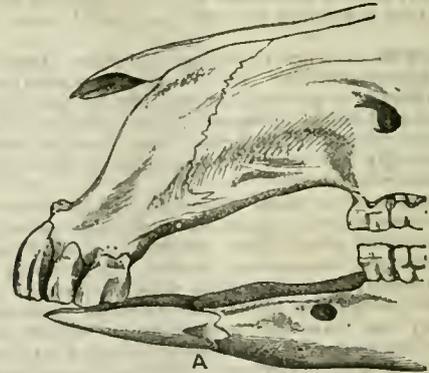

Fig. 3.—Portion of the lower jaw, with the incisor (teeth of a kangaroo, showing the effect of alveolar abscess. M. the mental foramen.

lower jaw of a kangaroo are given, showing the disastrous effects of an alveolar abscess arising in this way. Such cases are by no means uncommon.

The Vermiform Appendix.—In that man has connected with his cæcum a vermiform appendix, he agrees with the anthropomorpha, but differs from all other mammals. This appendix is the vestigial representative of the large cæcum found in very many mammals. Though useless, it is not harmless, as a careful attendance in the *post-mortem* theatre of any general hospital in this metropolis will show. The inconveniences which may arise from the possession of this rudimentary structure are threefold: 1, not infrequently foreign bodies, such as fruit stones, small pieces of pencil, and other similar indigestible substances become impacted in it, induce ulceration, perforation, and peritonitis; 2,

its orifice may become obstructed, and the appendix dilate into a cyst; 3, containing, as is common with vestigial portions of the alimentary tract (vitello-intestinal duct, post-anal gut, etc.) a large amount of lymphoid tissue, ulceration may occur independently of a solid irritant and destroy life.

On the present occasion, however, I am not desirous of drawing many instances from man, but shall deal with one other inconvenience he suffers in common with many members of his class, and even birds; fortunately one that is rarely serious, but interesting nevertheless.

Sebaceous Glands.—The normal anatomy of a sebaceous gland is so well known that it is unnecessary to describe it here, so we may pass at once to a consideration of some of the disadvantages which may arise from their presence. Not infrequently the orifice of the duct of one of these glands becomes obstructed, whilst secretion continues within the alveoli. The acini of the gland thus become distended with the result of their own activity, and a retention cyst is the result. In man such cysts may occur wherever sebaceous glands exist, varying in size from a pin's head to an orange. The walls may be thin and pliant, or laminated, thick, and hard. In man they are very common on the scalp, face, and back; on the scrotum and perineum they are rare. The contents of a sebaceous cyst are epithelial scales, granular fatty matter, and flakes of cholesterol.

The most curious condition associated with a sebaceous cyst is when the contents burst through the capsule, become dry and hard through exposure to the air, and of a brownish-black colour, resembling horn in appearance. If the dried mass is allowed to remain, growth continues at the base, and at length a long cutaneous horn is produced. (Fig. 4.)

Fig. 4.—Cutaneous horns on the face of a woman. The one on the forehead is 5 inches long.

The most elaborate collection of cases illustrating this singular condition is to be found in a small work by Dr. Hermann Lebert (*Ueber Keratose*, Breslau, 1864). He furnishes an account of one hundred and nine cases, with full references, the earliest dating from the year 1300. The horns were found on the scalp, temples, forehead, eyelids, nose, lips, cheeks, shoulders, arm, elbow, thighs, legs, knee, toes, axilla, thorax, buttock, loin, penis, and scrotum. In length they varied from a fraction of an inch to as much as ten or twelve inches, and in circumference some of them measured eight inches. The majority of these cutaneous horns occurred on the head.

An excellent account of human horns is furnished by Sir Erasmus Wilson in his well-known work on *Diseases of the Skin*, 5th ed., p. 653. Besides furnishing details of some good examples of these abnormal appendages a brief but interesting summary of some of the more striking cases is given. The *Transactions of the Pathological Society of London* contain accounts of many curious examples of cutaneous horns, including one which grew from the prepuce of the clitoris. The *Phil. Transactions* for 1791 contain an interesting communication from Sir E. Home, in which some extraordinary cases of cutaneous horns are described. Horns growing from sebaceous cysts are not infrequently seen in the out-patient rooms of large hospitals, but they are as a rule very small in size. Cases such as those described in Home's paper must be very rare at the present time.

Leaving man, and extending our inquiries to lower animals, we

shall find that sebaceous cysts and their consequences are by no means confined to him. They may occur in horses, dogs, sheep, oxen, and birds.

Lebert gives references to cases of cutaneous horns in sheep, he-goats, horses, rams, hares, cows, and dogs. Malpighi described one growing from the neck of an ox, ten finger's-breadths in length, and eight in circumference at the base. Home described in a footnote to the paper already mentioned the case of a sheep about four years old, which had a large horn, three feet long, growing on its flank. It had no connection with bone, and appeared only to be attached to the external skin. It dropped off in consequence of its weight having produced ulceration of the soft parts to which it adhered. On examining it there was a fleshy substance, several inches long, of fibrous texture, filling up its cavity, on which horn had been formed.

In the teratological collection of the Royal College of Surgeons there is a horn three feet five inches in length, and eleven inches in its greatest circumference, said to have grown on the flank of a ram; preserved in a jar near it is the soft core of the same, exactly corresponding to Home's description. The specimen is labelled Hunterian, and I have no doubt it is the one referred to above.

Fig. 5.—Head of a cow with a cutaneous horn.

In the same collection, near it, two other specimens of cutaneous horns are preserved. The first, Fig. 5, a Hunterian specimen, is described as "the head of a cow with a very large hornlike appendage growing from the forehead immediately between the eyes. The second is the head of a sheep, Fig. 6; in this case the horn causes it to resemble the head of a cassowary.

Fig. 6.—Head of a sheep with a cutaneous horn.

Judging from the general character and texture of these horns and the nature of the softer material filling them, I have no doubt they originated in sebaceous cysts. These horns, and that which has just been mentioned as growing from the flank of a sheep, are the largest I have seen or of which I can find any record.

We will now proceed to consider some cases which have been found in birds.

Fig. 7.—A cockateel, *Calopsitta nova-hollandia*, with symmetrical sebaceous cysts on the wings (*Proc. Zool. Soc.*).

It is usual to believe that in birds sebaceous glands are wanting, except in the case of the one over the coccyx, known as the oil or uropygial gland, which is especially developed in water fowl, and serves as a store of ointment in which the bird dips its beak and anoints the feathers in the act known as preening. It is a very significant fact that no known bird ever has its neck shorter than its trunk; that is to say, it is always of sufficient length to allow the bird to reach the oil gland. This structure is not invariably present, for the struthious birds, some of the *Columbae*, and others, lack an oil gland. In the pigeon it is bilobed, of a whitish colour, and a quarter of an inch in length. A duct which is directed backwards has its orifice indicated by a papilla. Such an oil gland as this is described as being nude. In others it is surrounded by a circle of small feathers, and is then described as tufted. The majority of birds have two ducts to this gland. In the hornbill the gland is of a deep orange-yellow colour, which stains very freely things brought in contact with it.

Sebaceous glands exist in other parts of birds' integument, such as the wings, head, neck and breast. They resemble the glands of man in structure, in the tendency to form cysts and in growing horns. Thus in Fig. 7 a cockateel, *Calopsitta nova-hollandia*, is sketched with a sebaceous cyst on the under surface of each wing, and many specimens are preserved in the Museum of the Royal College of Surgeons, occurring in pigeons, partridges, linnets, etc.; some of the cysts are of large size.

The tendency of sebaceous cysts to form horns in birds is as marked as in the case of mammals. Thus in a mule canary a horn of this nature grew from the under surface of the wing, and was curiously curved and twisted. This horn was shed each time the bird moulted, and inquiry seems to show that with birds this is the usual rule. The horn must grow very rapidly to attain such a length in so short a time (Fig. 8).

Fig. 8.—The wing of a mule canary with a cutaneous horn growing from it. Natural size. (Museum of the Royal College of Surgeons.)

Through the kindness of Mr. W. Roger Williams I am able to figure and describe a pretty case of sebaceous cysts and horns in a thrush. In this instance the bird presented a cyst upon its head (Fig. 9), whilst cutaneous horns, as shown in the drawing, were

Fig. 9.—The head of a thrush with a sebaceous cyst. On the leg of this bird two cutaneous horns existed.

attached to its thigh. In this instance the horns were detached when the bird moulted. The thrush was under the observation of Mr. Williams for some time previous to its death.

Sebaceous cysts in birds present characters similar to such cysts in man; in some instances the contents are pultaceous, in others laminated and hard. This is well shown in a cyst growing on the head of a blackbird in the College Museum (Fig. 10).

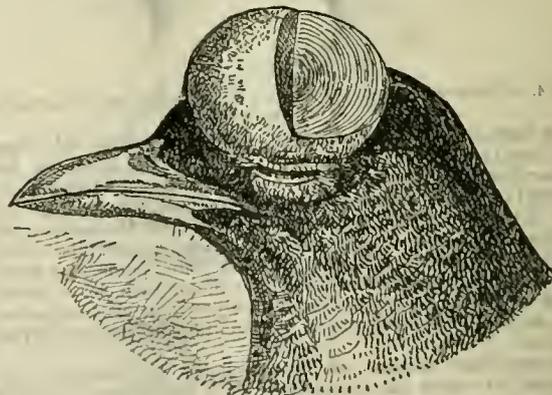

Fig. 10.—The head of a blackbird with sebaceous cyst. The contents are laminated.

Before leaving cutaneous horns it may be interesting to draw attention to a singular cluster of these structures which occur normally on the forearm of *Hapalemur*. These were first described by Mr. F. E. Beddard (*Proc. Zool. Soc.*, 1884, p. 391) in *Hapalemur griseus*; underlying this cluster of cutaneous horns is a gland of oval shape and corresponding in size to the patch of spines. The ring-tailed lemur (*Lemur catta*) presents when adult a curious cutaneous hornlike structure on its forearm, in a situation corresponding to that on the arm of *Hapalemur* (Fig. 11).

This horn or comb-like structure was first noticed by Dr. Jentink in specimens contained in the Leyden Museum. The simi-

larity of this structure with the small spines on the arm of *Hapalemur* induced me to examine the adjacent smooth patch on the forearm of *Lemur catta*, and I had the satisfaction of finding a large collection of glands, the secretion from which, when dried, gives rise to the horny projection in question.

Fig. 11.—Arm of *Hapalemur* with the patch of cutaneous spines on its forearm (*Proc. Zool. Soc.*)

These structures are interesting, inasmuch as they may be regarded as intermediate to the pathological cutaneous horn on the one hand, and the cutaneous nasal horn of the rhinoceros on the other. They also furnish some light as to the nature of the singular patch of hard integument known as the castor on the inside of the foreleg of the horse. In addition, we may use them as physiological types of cutaneous horns which in man only occur under pathological conditions.

ON THE ABORTIVE TREATMENT OF SYPHILIS.

Read before the Medical Society of London, on Monday, February 20th, 1888.

By JONATHAN HUTCHINSON, F.R.S., F.R.C.S., LL.D.,
Emeritus Professor of Surgery at the London Hospital.

For many years past I have been in the habit of assuring patients who came to me with indurated chancres but without any other symptoms, that they would in all probability wholly escape the secondary stage. As years have gone on I have found myself holding out this hope with increasing confidence. My treatment has been almost uniform, and has consisted in giving mercury in the form of grey powder in one-grain doses three times a day, at least, and more frequently if the symptoms did not quickly yield. I have always told the patient that he must take these pills for six months at least. The results have also been very uniform, or have varied chiefly according to the period of the disease at which the treatment was begun. The effect of the medicine in softening the induration is usually quite evident within a week, and may be expected to be complete in the course of a month or a little more. After this the patient remains without symptoms till the end of the course, except, perhaps, some slight persisting enlargement of the inguinal glands. At the end of the six months, if the treatment is left off, there not very infrequently follows in three weeks or a month an erythematous general eruption. This eruption is never severe, never becomes papular or scaly, and always vanishes in a few days if the mercury is resumed. It is never attended by failure of health, and but rarely by sore throat. On account of its frequency after six months' courses, I have lately been in the habit of continuing the treatment for nine or twelve months, and am willing to admit that it might be wise to continue it for still longer periods. As regards relapses at still longer periods, I must state that, in a certain proportion of cases, sores in the mouth or scaly patches in the palms, or a liability to transitory erythema on the skin have occurred, but they have generally been in connection with some special kind of irritation.

The statement which I wish to make quite clear is this: that I believe that it is quite possible, by the early and continuous use of mercury, to suppress the secondary stage—in other words, to make it abortive. In exceedingly few cases where it has been possible to use mercury without interruption in this way have I known a

well characterised secondary eruption or a typical sore-throat to occur. In cases where diarrhoea or sudden pyralism have caused the course to be interrupted, the success has been less complete; but where the patient is careful, and can bear the drug, I may repeat that I believe that it is easily possible, to prevent secondary symptoms. This assertion is not by any means the same as saying that it is possible to cure syphilis, for it does not concern itself with the tertiary stage. It is desirable, I think, in order that we should arrive at sound conclusions, that we should take our problem in parts. In making the proposition which I desire to submit to you this evening, that mercury is a specific antidote for the syphilitic virus, and that by its use the disease may be made abortive, I will divide my argument into several parts.

The first statement shall be one with which all will agree. It is this: that in cases in which induration is well characterised and considerable, it always yields quickly and definitely to the influence of mercury. The very rare apparent exceptions to this which we witness occur to those who in a peculiar manner resist the influence of mercury. We never see sores remain typically hard when the patient is under the influence of mercury.

The next is that in cases in which high temperatures have been observed in syphilis they always abate under the influence of mercury.

Thirdly, I believe that all will agree that when a patient receives no treatment until his eruption is well out, the use of mercury will usually in the most definite manner cause the eruption to disappear. There is but little less certainty about this than there is as to the disappearance of induration in the sore, and the exceptions occur only when the treatment disagrees, and has to be interrupted.

If these several propositions be true, if mercury always causes induration when present to soften down, fever when present to subside, and an eruption when present to disappear, I cannot think that any will see much improbability in the assertion that if used before the fever, rash, etc., have shown themselves, and steadily continued, it will prevent their development. It would be extraordinary if these symptoms should develop *de novo* under the very conditions which all but invariably secure their removal when extant.

Those who object to the statement that mercury is an antidote to syphilis, and decline to employ such terms as "specific," "abortive treatment" and the like, do so because, as they allege with truth, it can seldom or never be asserted that the disease has been wholly or, at any rate, permanently cured. This is, however, I cannot but think, putting a too strong meaning on the words. It may easily be the fact that we have not yet hit upon the best method of using the remedy so as to secure permanent results. It is not fair to demand of a "specific" that it shall always prove its efficacy without regard to differences in the mode in which it is employed. A remedy may be fairly called "specific" if it always and invariably manifests its power over the phenomena of a disease. It is for the prescriber to find out how so to use his specific as to bring about an actual cure. As regards the term "abortive treatment," its appropriateness may surely be justified in any case in which it is designed to cut short the development of a malady and prevent the evolution of its natural stages. We must not strain the word to make it mean absolute annihilation of the thing concerned. If a scheme of treatment of syphilis, begun in the primary stage, is planned to prevent the secondary phenomena, and usually does so, it may, I think, be fairly styled "abortive" in contradistinction with others which make no pretence to prevent the ordinary evolution of the malady. Abortion, as regards preventing tertiary symptoms, is, as I shall endeavour to show immediately, another matter. It is possible that in our present modes of use of mercury we neither begin early enough nor continue long enough to secure that result.

The term antidote, when used in reference to mercury as against syphilis, must be sustained by resort to more hypothetical reasoning as to the nature of the disease. In the year 1860, in a paper read before the Hunterian Society, I first ventured to claim a place for syphilis amongst the exanthemata, and argued that in its phenomena as regards stages, period of incubation, and other points, it resembled the diseases which we attribute to specific animal poisons. Amongst those who took part in the debate on my paper were Mr. Acton, Mr. De Méric, and others who at that time were the leading authorities on the subject. Some years later I read before the same Society another paper, claiming for mercury, on much the same grounds that I have this evening advanced, the position of a specific. My views were on each occa-

sion warmly opposed, but I believe that the progress of investigation since then has done much to facilitate their acceptance. For myself, I may say that I have always, in speculating about the cause and evolution of syphilis, held firmly to the belief that it is due to a specific particulate virus, just as small-pox is, or in the language of to-day, to a living microbe. Other observers, with most praiseworthy zeal and industry, have occupied themselves with the endeavour to bring this microbe to actual demonstration, nor have I the slightest doubt that their search will some day be crowned with success. In the meantime, if we would understand the disease we must, I think, take its existence as granted. It is in reference to this as yet hypothetical microbe, that we justify the assertion that mercury is an antidote; we know how powerful that drug is in preventing the development of plant life, and that which we know fits well with what we observe of its efficacy and its failures in the treatment of syphilis. It is antidotal to the virus, and so long as present it prevents its manifestations of activity. In some cases, but by no means in the majority, it probably kills it outright. The more usual result is a repression of vital activity in the virus, which lasts as long as the drug is used. This repression, if continued for long periods, would appear to amount to a very important modification of power, for I believe that if the secondary phenomena be kept in abeyance for many months, their subsequent development, if then permitted, will never be severe. If continued long enough it will wholly prevent the secondary stage, and yet I fear it is true that even in these the patient may be liable to tertiary affections.

If it be rejoined that no remedy can claim to be antidotal or specific respecting which it is admitted that it does not prevent tertiary sequelae, a reply is yet possible. There is a sense in which, without any hair-splitting, tertiary symptoms may be said not to be syphilis at all. There is neither proof nor probability that the microbe or virus is present in their lesions. They do not develop symmetrically, and they are not contagious; they are due to processes of inflammation occurring in tissues which have formerly been under the influence of syphilis, and have been modified by it. If this be their true position, it will easily be seen that no antidotal treatment directed to the killing of the microbe can prevent them, unless it is commenced before the system has been contaminated. If we wait till the sore is well developed, the patient feverish, and the eruption on the eve of appearance, we have waited until the patient has had syphilis through him, and though we may then proceed to cure the disease by killing the poison, it is too late to prevent its remote effects. In saying this, do not let me be understood to say that the use of mercury late makes no difference as to proclivity to tertiary symptoms. On the contrary I believe, although it is impossible to prove it, that it does make them both less common and of milder type.

The practical questions which come, then, before the surgeon are these—In what manner and at what stage ought mercury to be given so as best to secure its antidotal efficacy?

The verdict that mercury given in short courses is not preventive of the development of syphilis has been recorded in unmistakable terms by the surgeons of the past generation. Mr. Judd, indeed, whose reports are full of interest, and contain proof alike of ability and of candour, thought that such courses favoured the absorption of the virus, and made the disease eventually more severe. His courses were, however, of a fortnight, a month, or six weeks at the most, and were always attended by free ptyalism. The modern introduction of the small-dose system, with the avoidance of ptyalism, makes it necessary that we should investigate the whole question anew. I do not suppose that there is much difference, as to the special preparation of mercury which is employed, though it will not do to take this for granted. Some of the records of M. Diday as to his failures to prevent symptoms would add to the suspicion that the iodide of mercury, as employed by him, is less efficient than the mercury only, in the form of grey powder. The great point is that a preparation should be used which can be pushed without producing symptoms which necessitate its temporary discontinuance. Its efficacy may be taken as proved by the prompt disappearance of the primary induration. The dose which is efficient to this result will, if steadily persevered with, probably be efficient in preventing the development of other symptoms.

The question arises, I think, naturally, at this point of our inquiry as to whether it may not be advisable in the future to attempt the abortion of the primary stage itself. I am not aware that any large amount of evidence is in existence as to the possibility of preventing the development of induration in a chancre by using mercury before it occurs. Ever since the recognition of

the fact that some chancres are not infecting, and that the phenomenon of induration is the most valuable one by which to diagnose the true or infective chancre, we have been in the habit of waiting till the character of the sore declares itself before beginning to use the specific. Many, indeed, especially those of the French school, have advocated waiting till constitutional symptoms in the form of eruption occur. Our forefathers, we well know, did not so wait. For them a venereal sore was a chancre, and they poured in mercury as soon as the patient presented himself, and often within a week or two of the contagion. It may have been that in many cases they succeeded in aborting syphilis as a whole, and in preventing alike the primary and secondary stages. It is to be feared, however, that their success was but too often prevented by the manner in which they prescribed the antidote. They were accustomed to give large doses during short periods, and were constantly obliged, by the occurrence of ptyalism, to interrupt the treatment. Indeed, as a rule, a short treatment was all that was contemplated, and the production of free ptyalism was regarded as essential. As I have already suggested mercury may sometimes, when given in this way, possibly prove an abortive treatment—that is, it may kill the virus. Facts, however, would seem rather to point to the conclusion that it only temporarily suspends its activity, and that in many cases a severe outbreak follows soon after its suspension. It is otherwise, I think, when small doses are long continued.

I wish to avoid giving any exaggerated impression of the extent and kind of evidence upon which my statements are based. It is not my intention to produce before you any statistical evidence, nor even to quote individual cases. To do so would be very easy, for I hold in my hand a large number of extracts from my notebooks which bear upon the matter. To read them to you would however be very monotonous, and I think unprofitable. They are for the most part repetitions of the statement that the patient came under my care with a well-indurated chancre, that I advised a long course of small doses of mercury, that the induration melted away, and that nothing else ever followed. There is a weak point in many, but by no means in all, and it is this, that I have no record as to the patients beyond the first six months or so. My practice has for many years, in respect to primary syphilis, been solely in private, and it is of course not practicable to compel patients to come and report after they believe themselves well. I feel sure, however, that this negation of evidence is in itself of considerable strength. For long, as I have said, I have been in the habit of holding out hopes of immunity, if the remedy were persevered with, and I assume that if my foretellings proved fallacious, I should in the majority of cases hear of it. On the contrary, so far as my own observation of primary syphilis has for many years past been concerned, I should certainly never have discovered that an eruption on the skin was a usual part of the malady. I have of course seen plenty of secondary eruptions in those who had not been under treatment, but in those whom I had myself prescribed for in the primary stage scarcely any. I could count on my fingers the number of cases in which during the last five years I have watched the patient from his primary sore through a well-marked syphilitic eruption on the skin. A few I have seen, probably because not sufficient mercury was given, and more in which some very slight and transitory eruption showed that the poison, though restrained, was struggling to show its powers. Of really troublesome eruptions, such as are common enough when mercury has not been used, I may say confidently that I have seen none.

I must admit that the gross total of cases of primary syphilis which have been under my care has not been so large as that which falls to the share of specialists, particularly those holding hospital appointments. More patients come to me in the secondary, or later stages, than in the primary. Still, my experience has been considerable, and justifies, I think, the general statements which I have ventured to make to you this evening. It is to be clearly understood that I have been speaking only of cases in which the induration was characteristic, and in which an interval of from five to seven weeks had occurred since the exposure. I have never allowed myself to diagnose a sore as infectious, or to begin mercury, except under these conditions.

There is another class of cases which bear testimony which I think, very valuable as regards the antidotal efficacy of mercury. I allude to those in which the patient comes under care with his rash fully out, and having as yet had no treatment. The possibility of aborting the rest of the malady in these is less certain, yet I think we may generally expect it with much confi-

dence. If such patients will take mercury their symptoms will disappear, and if they will continue it there will be no relapses.

In conclusion, I may express my hope that it will have been clear to all that my object in this paper has not been to claim credit for any particular method of treatment, far less to make boast of personal success. My wish has been to draw attention to a clinical fact which, although hitherto much ignored, or even denied, must have been for long more or less under the cognisance of all engaged in the treatment of syphilis according to modern rules. The fact to which I refer is that the early use of mercury does not only greatly shorten the duration of the primary phenomena, but that it also much modifies, and in many instances entirely prevents, those of the secondary one. I have indeed ventured to assert that, when circumstances favour, the febrile stage of the exanthem, syphilis may be rendered wholly abortive. If we can accept this proposition, I feel sure that we shall have gained a step in the orderliness of our future work, and in reference to this the following problems seem to lie before us.

What plan of treatment is most successful in suppressing the febrile or secondary stage?

Does the suppressing of this stage tend to prevent what are called reminders, or those minor, and for the most part local, symptoms which often intervene between the febrile stage and tertiary phenomena?

Are those in whom the febrile stage has been aborted by artificial means more or less than others liable to tertiary phenomena?

Is it possible by anticipatory treatment to prevent or abort the phenomena of the primary stage; and, if this be done, what is the influence upon the further course of the disease?

It has been well said that all men use syllogisms, whilst but few have studied logic; and in like manner I may remark that most of us have been practising more or less completely the abortive treatment of syphilis, though without giving it that name.

CLINICAL MEMORANDA.

TUMOUR OF THE INTESTINE: SYMPTOMS SIMULATING BILIARY COLIC.

COLONEL M., aged 45, who had lived in India for some twenty years, was seized about 2 A.M. on 4th June with agonising pain referred to the right side of his abdomen. An injection of morphia gave relief. But in the course of the following night the pain returned with even greater intensity, so much so, that recourse was had to chloroform inhalation. The case seemed obviously to be one of gall-stone colic, and directions were given to wash the fæces through muslin. On the 6th June the patient passed what he thought was a "piece of flesh," but which was a lymphoma of nearly square outline, measuring about one inch and a-half along each side, and a quarter of an inch in thickness. This is not the place for a description of the tumour. As the textbooks give no warning of this source of error in the diagnosis of biliary colic, it seems worth while to place the case on record. Regarding the patient's subsequent history, a dull pain in the abdomen, chiefly on the right side, continued for some days, at the end of which he regained his usual excellent health. There has been no recurrence of symptoms up to date.

J. LEWTAS, M.D.Lond.

Henrietta Street, W.

PUERPERAL APHASIA.

THE interesting remarks made by Dr. Bateman on the above subject in the JOURNAL of February 4th lead me to record the following case.

In April, 1886, I was called to see, in consultation with Dr. Maguire, of Chesterton, Mrs. B., aged 35, who had given birth to her tenth child ten days before. For some time she had suffered from anæmia with a hæmic murmur, but had improved in health before her confinement, which was quite natural; and she went on perfectly well, suckling her child until the tenth day, when she sat up in a chair for the first time. She was suddenly taken speechless and helpless, the right side being completely paralysed. In this condition I found her. Like Dr. Leith Napier in his case, quoted by Dr. Bateman, we attributed the symptoms to occlusion, by embolism, of the left cerebral artery. Mrs. B. was perfectly conscious, and understood everything said to her. There was no increased flow of milk; in fact it went the same night after the

attack. The use of the arm and leg was soon regained, so that in five weeks she was enabled to walk about the house, and in five months to walk a distance of some miles. In June, 1887, I saw her at Llandudno with Dr. Dalton. We then detected no hæmic murmur. Her general health had greatly improved, but her speech remained very defective; and, as it has not improved much, if at all, since then, I fear it never will.

REPORTS

OF

HOSPITAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN, IRELAND, AND THE COLONIES.

ALBANY GENERAL HOSPITAL, GRAHAMSTOWN, SOUTH AFRICA.

A CASE OF HYSTERECTOMY.

(By J. B. GREATHEAD, M.B.Édin., M.R.C.S.Eng., Surgeon to the Hospital.)

J. A., aged 33, a spinster, was first seen on September 5th, 1886. She had had persistent metrorrhagia and menorrhagia for twelve months, and had become very anæmic. The abdominal tumour had grown more rapidly for three months, and, from its size and weight, caused much inconvenience. The cervix was obliterated; and the os externum, somewhat patulous, was pressed forwards against the upper edge of the pubes. The sound could not be passed, but with the aid of a gum elastic catheter the uterine cavity was found to extend eight inches upwards and forwards in front of the main portion of the tumour.

On September 22nd, 1886, chloroform (with ether at intervals) having been administered, a preliminary incision four inches long between the pubes and umbilicus was made. When the diagnosis had been satisfactorily confirmed, the abdominal incision was gradually enlarged until it extended from the pubes to within an inch of the ensiform cartilage. Only then could the tumour with difficulty be brought through the opening. An elastic tourniquet was placed round the uterus just where the vaginal walls joined it. With a large trocar and cannula a pint and a half of black fluid blood was drawn off from the highest part of the tumour. The broad ligaments were next tied in sections and divided as low as possible; but, in order to reach the lowest portions, it was found necessary to cut into the uterus and remove a large portion of the tumour. In this way the pedicle was more readily handled. The uterine arteries were tied with silk and divided. The uterus was next transfixed just above the junction with the vaginal walls, and tied in two portions with strong silk ligatures. The remainder of the uterus was now amputated half an inch above the last ligatures, a small posterior flap of uterine tissue and peritoneum being reserved for the closing in of the end of the stump (pedicle). After all hæmorrhage was well controlled and the tourniquet removed, the flap was brought forward and firmly sutured (with five silk sutures) to the anterior edge of the uterine wound. The loose peritoneum was gathered in with a continuous catgut suture, and closed over a neat stump. The abdominal cavity having been cleansed with warm water and all fluid sopped up from the pelvic cavities, the abdominal wound was closely sutured with silver wire in the customary way. A dressing of lint and carbolic oil (1 to 20), with a liberal supply of cotton wadding, was used.

On September 24th the evening temperature was 99.6° F., the pulse 120. On September 26th the wound was entirely healed; the evening temperature was 99.6° F. On September 28th the evening temperature was 101.6° F. On October 3rd the evening temperature was 102° F., and the pulse 114. Flatulence caused pain, and was relieved by an enema of soap and water. On October 4th the evening temperature was 101.6° F. After this date the temperature gradually became normal, and on October 13th the patient was considered convalescent, and allowed to recline in a semi-recumbent posture. On October 28th and 29th she menstruated, with all her usual symptoms. On November 17th to 19th she menstruated again, with usual sensations. The patient wrote saying that she had again menstruated on December 8th and 9th. She had been in the habit of menstruating every three weeks before this illness.

* NOTE.—Owing to absence from home I have not had an opportunity of hearing whether menstruation occurred after December, but its reappearance on three occasions with a certain degree of regularity after the removal of uterus and appendages seemed to me to be of sufficient importance to warrant the publication of a few notes of the case. I am quite aware that such a phenomenon has been observed after double ovariectomy. The specimen of uterus and ovaries is now in the Museum of St. Bartholomew's Hospital.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, FEBRUARY 21ST, 1888.

Sir JAMES PAGET, Bart., F.R.S., F.R.C.S., President, in the Chair.

Parasitic Fetus.—A Hindu, aged 17, presenting a large parasitic foetus, was exhibited to the Society by Mr. BLAND SUTTON and Mr. S. G. SHATTOCK; a full description of the foetus was read by the latter gentleman, who stated that the parasite was incapable of spontaneous movement, but sensations were perceived; urine was passed through the penis of the parasite; the penis was capable of erection; the parasite perspired when the boy perspired; the surface temperature was low (95° F.). The report, in discussing the origin of such parasites, favoured the theory that they were due to an abnormal cleavage of a single ovum. [A fuller description and illustration is published at page 436.]—The PRESIDENT asked whether spontaneous or reflex movement, or movement in response to electrical stimuli, had been noted in this or other cases.—Mr. DORAN inquired whether in other instances the parasite had suffered from visceral disease; such an occurrence would probably have an injurious effect on the autosome. He observed that in this case there was certainly one kidney, and the report stated that intestine also was present.—Mr. SHATTOCK stated that no spontaneous or reflex movements had been observed.

Periosteal Lipoma.—Mr. D'ARCY POWER exhibited a specimen of a comparatively rare form of congenital fatty tumour, to which the name "periosteal lipoma" has been applied. The patient, a boy, aged 9, under the care of Mr. Thomas Smith, presented a soft, painless, elastic swelling, occupying the outer aspect of the upper third of the left thigh; the skin was freely movable, but the superficial veins were distended. The tumour was incised and removed; it was firmly attached to the periosteum, just below the lesser trochanter; it weighed 15 ounces, and measured 6 by 5 inches. It was only partially encapsuled, and consisted of several lobes held together by areolar tissue; the growth was very firm, and on microscopical examination was found to consist of collections of fat cells, with thick intervening bundles of connective tissue. Mr. Power referred to Mr. BATHIN's opinion that such growths commence as fibrous or fibro-cellular tumours, the formation of fat being a later change, and suggested that there was no special reason why lipomata should not spring from the periosteum, since they are connective tissue growths which might commence as localised proliferations of cells, which rapidly became infiltrated with fat. He also commented on the absence of a capsule over the greater part of the growth, and stated that whereas the fat in the encapsuled portion was mingled with so much fibrous tissue that the growth might in this part be regarded as a fibro-lipoma, in the diffuse portion it was simple fatty tissue.

Mixed Tumour of Parotid.—A specimen of mixed tumour of the parotid containing cartilage cells was shown by Mr. CHAVASSE. The patient was a woman, who first noticed the tumour at the age of 15. It was the size of a pea, and did not enlarge much for fifteen years; then it grew rapidly, and still more so after an ineffectual attempt at removal. The tumour was successfully removed subsequently, and weighed 20 ounces. The growth consisted mainly of lobuli of fibro-adenoma with acini in certain parts; there were areas of cartilage; in others the matrix was undergoing myxomatous change, which was probably a secondary degeneration. As to the origin of the cartilage, Mr. Chavasse thought that it was due to misplaced aural cartilage, which, acting as an irritant, had led to adenomatous growth from the parotid. He thought that the prognosis in these so-called enchondromata of the parotid was favourable, except where the sarcomatous elements predominated.—Mr. STEPHEN PAGET supported the

theory of their embryonic origin, and referred to a paper by Mr. Jacobson in the *Guy's Hospital Reports*. Most of the cases recorded had been women.

Congenital Mitral Stenosis and Pulmonary Endarteritis.—Dr. G. F. CROOKE showed specimens from the case of a man, aged 34, who had had scarlet fever when a child; and rheumatism in one shoulder at the age of 29. There was no history of syphilis, and his occupation was not laborious. About eighteen months before admission he began to suffer from pain in the left side and shortness of breath. When admitted there was œdema of both legs, and a loud systolic murmur was heard at both bases and at the aortic area; the urine contained albumen and hyaline casts. He died somewhat suddenly after slight exertion. The *post-mortem* examination showed pericardial effusion, pulmonary dilatation, incompetence of the tricuspid orifice, and narrowing of the mitral orifice, but no evidence of valvular lesion. The right side of the heart was hypertrophied and dilated. The mitral stenosis was probably congenital; the subdivisions of the pulmonary arteries in the lungs and the vessels were found to be the seat of endarteritis and atheroma.—Dr. WILKS had seen two such cases. They negatived the theory that atheroma did not affect the pulmonary artery and its branches. There was always great hypertrophy of the right ventricle where there was this pulmonary arteritis and mechanical causes were at work. He did not think that it was a sequence of congenital mitral stenosis or of such stenosis occurring in early life, that led to imperfect growth of the lungs, so that the chest and all the pulmonary organs were dwarfed.—The PRESIDENT asked whether there was extensive clotting in the diseased vessels.—Dr. CROOKE said there were no clots in the larger vessels.—The PRESIDENT said that he had described in papers contributed to the *Transactions of the Royal Medical and Chirurgical Society* some forty years ago the occurrence of clotting in arteries, and had expressed the opinion that the process was exactly analogous to thrombosis occurring in veins, that, in fact, it was due to arteritis. It was a curious instance, he thought, of intellectual blindness that the possibility of embolism had never occurred to him during that investigation; several of the cases would, now that our eyes were open to the possibility, at once suggest embolism.

Complex or Vertical Hermaphroditism.—A specimen of complex or vertical hermaphroditism was shown by Mr. C. STONHAM. The child had died after an operation for the relief of a hernia, which was found to contain a uterus. On the right side was a hernial sac, containing organs which appeared to be those of a normal female, but the apparent ovaries were found to be testicles; there was a uterus ending in a vagina, which was in relation with a prostate gland; there was a well-formed bulb; no vesiculae seminales were seen. The external organs were those of the male, with undescended testicles; there was partial hypospadias; the bladder was normal in size and shape, and its neck was surrounded by the prostate; the uterus was well formed, and opened into the vagina; the testes were attached to the cornua of the uterus; immediately below the testes was the Fallopian tube; the epididymis lay below the testis. The mother had had fourteen children and eight miscarriages; the fifth and six children presented a well-marked penis and scrotum, but no testes; one of the mother's sisters was reputed to be an hermaphrodite, but had borne a child. Mr. Stonham referred to the literature of the subject, and said that Foerster had figured a very similar case in his *Atlas*.—Dr. WILCOCKS mentioned a family in which one boy had hypospadias, while a younger child, aged 3½, a girl, had large mammae, hair on the pubes, and had menstruated four times.—Mr. BLAND SUTTON said that the case belonged to the class of free-martins; it showed that the theory that the prostate represented the uterus was a mistake, and that at most it represented only the cervix.—In reply to Mr. JONATHAN HUTCHINSON, jun., and Mr. C. B. LOCKWOOD, Mr. STONHAM said that the bladder was not pulled down, that there were no muscular fibres representing the gubernaculum, and that in using the term "vertical hermaphroditism" he had followed Sir J. Y. Simpson.

Papilloma of both Fallopian Tubes and Ovaries.—These specimens were exhibited by Mr. ALBAN DORAN. They were removed from a woman aged 31, married twelve years, and sterile. Seven years ago she had a severe attack of pelvic inflammation; a tumour was noticed, but it disappeared. Twelve months ago it was again discovered. Ultimately Dr. Bantock performed an exploratory operation. Two tumours were found and removed. They proved to be cystic ovaries united to cystic tubes. Both tubes and ovaries bore abundant papillomatous growths. There was no free

fluid in the peritoneum, and no papillomata were diffused beyond the cysts. The patient recovered. She had menstruated till within a month of the operation in December, 1887, although both tubes and ovaries must for long have been degenerate. The disease appeared to represent a form of atrophy due to old chronic inflammation, resembling in this respect the most frequent form of tubo-ovarian cyst. Only two other cases where papilloma of the tube constituted a distinct disease had been described. In the first, the tube was unobstructed at its ostium, and the peritoneum was filled with fluid; in the second, the tube was closed, and there was no peritoneal effusion. The latter conditions existed in the present case, which differed from the others in being bilateral and involving the ovaries.—Dr. HORROCKS inquired whether there was any history of gonorrhœa or syphilis.—Mr. DORAN said that in the first case infection was impossible, in the others it was possible but not very probable.

Card Specimens.—Mr. C. STONHAM: Tumours of Bone: (1) Spindle-Celled Sarcoma of Femur; (2) Cystic Sarcoma of Femur; (3) Cystic Myeloid Sarcoma of Femur and Tibia; (4) Spindle-Celled Sarcoma of Tibia; (5) Spindled-Celled Sarcoma of Humerus with Fracture.—Mr. JOHN C. LUNN: Special Meningitis following Disease of Ear.—Mr. T. F. CHAYASSE: Vesical Calculus.—Mr. S. G. SHATTOCK: Dermoid Cyst of Neck.—Mr. H. A. LEDIARD: Enchondroma of Hand.

MEDICAL SOCIETY OF LONDON.

MONDAY, FEBRUARY 20TH, 1888.

J. HUGHLINGS JACKSON, M.D., F.R.S., President, in the Chair.

Abortive Treatment of Syphilis.—Mr. JONATHAN HUTCHINSON read a paper on this subject, which is published in full on page 413.—Mr. JAMES BLACK noted the case of a woman who, after having given birth to eight healthy children, became infected, and then had six consecutive miscarriages. She was put under mercurial treatment, and subsequently gave birth to a perfectly healthy child, at term, free from any mark of the disease. He expressed a doubt as to the propriety of commencing the mercurial treatment before being sure of the diagnosis.—Mr. J. ASTLEY BLOXAM expressed the interest he felt in the subject brought before them. The thought had often occurred to him as to when one ought to attack a patient with mercury. The great question was as to whether or not the patient had syphilis. So far as the induration went, an experience of some 90,000 cases had led him to conclude that it was quite without value in the diagnosis. He said that only a general and symmetrical enlargement or hardening of the glands sufficed to place this beyond a doubt. He thought that six months' treatment was altogether inadequate to effect a cure of the disease, many of his patients carrying it on with benefit for from twenty to twenty-three months. So long as the induration of the glands persisted, so long the patient was liable to syphilitic manifestations on ceasing the treatment. With respect to the mode of administration, he had tried pretty well all the plans, but preferred the subcutaneous injections which he had practised since 1884. He had seen many cases in which the secondary symptoms were apparently absent, but maintained that on close examination some manifestations were always to be found, especially in the loins. He agreed that syphilis was probably due to the presence of a parasite, and that the sooner mercury was given the better.—Mr. BERNARD PITTS acknowledged the indebtedness of the profession to Mr. Hutchinson for the diminution in the dose which he had brought about. He mentioned that the advantage of the small doses was the non-liability of the patients to pyralism, involving a discontinuance of the treatment for a time. He observed that it would be hard on the patient to condemn him to a long course of treatment without being sure of the diagnosis. His own plan was to commence the mercurial treatment if the sore resisted local measures, or showed a tendency to spread phagedenically. If the sore yielded at once to the influence of the mercury, he continued it.—Mr. MARMADUKE SHEILD asked Mr. Hutchinson to give a definite opinion as to the merits of excision of the primary sore. He also asked for an opinion as to the combination of iron and quinine with the mercury, to combat the anæmia and debility which often followed the use of the latter.—A FELLOW said he was the first to suggest excision of the primary sore when a surgeon in the army. He had been led to suggest this by observing the good results which followed excision in cases of sores, complicated with phimo-sis. Cases where this operation was practicable were of course rare, but the results obtained by the sur-

geons who systematically excised were better than those obtained by the others. He added that in the army it was often impossible to carry out an uninterrupted treatment, but even with an intermittent treatment the results were far better than when no treatment at all was resorted to. He said that the best preparation of mercury was the one which caused least irritation, and attributed intolerance either to too large doses or to error in the form or time of administration. Mercury was a tonic, and when it produced debility it was advisable to stop.—Mr. H. DE MÉRIC said he had never seen a case of syphilis in which mercury had absolutely prevented secondary symptoms. He did not attach much importance to induration of the sore; induration did not necessarily imply syphilis, nor syphilis induration. The great point was the induration of the glands.—Mr. MALCOLM MORRIS said that surgeons generally waited for the appearance of secondary symptoms before resorting to mercury. He suggested that as induration of the glands indicated elaboration of the poison, the effect of the early administration of mercury in stimulating metabolism might really aid in the prompt dissemination of the virus.—Mr. JONATHAN HUTCHINSON, in reply, pointed out that in his opinion the infection of syphilis consisted in a specific microbe. Mr. Morris's views as to the possible effect of mercury on the glands in facilitating dissemination of the poison required to be put to the test of experience. He thought that the character of the sore afforded much more information towards a diagnosis than the glands, respecting the condition of which he had often been in doubt. Well-marked induration of the sore, in his experience, meant syphilis, but he added that many specific sores did not show this induration. He had admitted that slight transitory eruptions might be found even in the most successful cases, but nothing that could be compared with the ordinary secondary symptoms. Although some of his patients had been apparently cured in six months, he did not consider that this period was sufficient in the general run of cases. He thought iron might be given where required, but he objected to quinine, because it prevented pyralism, and might be supposed to oppose a resistance to the action of the mercury. With reference to excision, he thought that the operation might be desirable whenever practicable, but its influence would depend largely on the site and age of the primary sore. Once the induration was marked the system was infected. With small doses of mercury, its depressing effects were done away with. He said that the fear of mercury dated from the time when it was the custom to give it in large doses. He did not advocate beginning a mercurial course indiscriminately before a diagnosis could be made: but many patients who were nervously alive to the consequence of syphilis gladly consented to begin it at once, so as to reap the advantages. In any case it should never be postponed beyond the period of induration of the sore. He alluded, in conclusion, to the value of the thermometer as an indication of the approach of secondary symptoms.

HARVEIAN SOCIETY OF LONDON.

THURSDAY, FEBRUARY 16TH, 1888.

WILLIAM SEDGWICK, M.R.C.S., President, in the Chair.

Some Cases of Hysteria.—Dr. STEPHEN MACKENZIE read a paper on some cases of hysteria, with remarks on the nature of hysteria. He narrated two cases. The first was that of a girl, aged 21, with emaciation and profound anæmia, complaining of constant and severe pain, increased by food. There had been much vomiting. There were no physical signs of organic disease, and it was regarded as hysterical. Food was regularly and, if necessary, forcibly given; iron was administered, and sedatives withheld. The patient made a slow but steady recovery, the corpuscular richness increasing from 50 to 93 per cent., the hæmoglobin increasing from 30 to 70, and the body weight from 4.2 to 6.7 stones. The patient had remained well two years, in all except the non-return of the menses, which had disappeared before the commencement of the disease. The second case was that of a young lady, aged 19, who, from gastric pain, had gradually ceased taking food until she was reduced to a condition of extreme emaciation and weakness. The cases were regarded as apepsia and anorexia hysterica. The term "hysterical" being employed occasioned the author to explain what he understood by the term. He thought the current view in the profession, as well as out of it, was that hysteria was "a want of self-control," "a giving way to the feelings." The author pointed out that this, though in his

opinion correct, was a purely metaphysical explanation. He thought that the term "hysteria," though etymologically incorrect, misled nobody nowadays, and it was a convenient label, distinctive not descriptive. It was admitted by all that hysteria was sometimes seen in the male. The greater frequency of hysteria in woman was due to education and the whole circumstances of their lives favouring the development of their emotional nature. Passing to the physical aspect of the question, he pointed out that, whether regarded from the psychical or the physical side, hysteria afforded an illustration of the doctrine of dissolution formulated by Herbert Spencer, and extended by Hughlings Jackson. He drew attention to the widely representative character of the physical basis of the emotions, so that when these were powerfully excited there occurred the most widely spread and varied movements of the muscular system, not only in the whole muscular system, but in the vascular and secretory. On the other hand, there were still higher arrangements of the nervous system which "inhibited" the nervous arrangements (called centres for convenience) forming the anatomical substrata of the emotions. This was clearly admitted by the expression "the control of the emotions." In hysteria there was a suspension of function of the so-called inhibitory "centres," which occasioned the negative element—loss of inhibitory power (psychically, loss of control), and the positive element—overaction of the nervous arrangements constituting the physical basis of the emotions (psychically, outburst of the emotions). This "suspension of function" of some of the highest nervous arrangements which inhibit the nervous arrangements forming the physical basis of the emotions, might be brought out by all kinds of debilitating influences, including organic disease. The practical bearings of these views were pointed out, but the gist of the paper was to put on a physical basis the metaphysical theory that in hysteria there was a want of self-control, and a "let go" of the emotions.

Cases of Hysteria.—Dr. LEES narrated two cases of hysteria in boys. The first was a boy of 8, who had vague pains, capricious appetite, asserted inability to swallow and to walk, with some tonic spasm of the muscles of the lower limbs, especially in the adductors of the thighs. There was marked increase of the knee-jerks, normal cutaneous reflexes, no spine disease, and no anaesthesia. The treatment was mainly moral, and the boy was practically well in three weeks. The second case was of a different type. It was that of a boy, aged 11, intelligent and patient, who had severe headache, patches of anaesthesia, amblyopia of the right eye, and defective hearing in the right ear, but no motor weakness, and no spasm. The anaesthesia changed its site several times during six months, affecting different areas, sometimes in the right side, at others in the left. The amblyopia was found to be due in part to posterior polar cataract, but only in part, for it amounted to mere perception of light. One day it was found that he had double temporal hemianopia, the temporal halves of both retinae being insensible to light, but the next day this condition had vanished, and so had his auditory defect and much of his anaesthesia. He improved considerably under treatment, and when last seen had lost his headache, and almost lost his anaesthesia. No doubt these two cases must both be classed as "hysterical," and yet they differed from each other completely. In the first the affection was mainly a moral one, and the objective symptoms were purely motor; in the second there was no moral element, and the symptoms were entirely sensory, and discoverable only by clinical investigation. Yet it seems likely that the difference in symptoms may have been a result simply of the different brain-areas affected, and that a similar condition, a kind of torpidity of some of the nervous centres, may have existed in both.

Death with Symptoms of Hysteria.—Dr. MAGUIRE and Mr. STILCOCK reported a case of death from functional neurosis, in which the symptoms at one time resembled those of hysteria. The patient had complained of pain in the back of the head and falling sight for twelve months. Two months after a blow on the back of the head sight was lost almost entirely. On admission into hospital the gait was tottering, memory impaired, speech slow and drawing. There was no loss of power or of sensation, and the knee-jerks were exaggerated. No change could be detected in the fundus or media of either eye, nor was any other physical sign of disease discovered. The patient became restless at night, and three days later was found comatose, not responsive to any form of stimulation, lying with the mouth open, and breathing stertorously. Copious perspiration was observed on the right side of the face and neck, none on the left, and the pup-

of the right eye was slightly contracted. No diaphragmatic respiration could be detected. The patient died about twenty-four hours later; and at the *post-mortem* examination, after the most careful search, no morbid condition, macroscopic or microscopic, was found. Dr. Maguire related two similar cases which had been followed by recovery. The patient, a medical man, was comatose for more than two months, and during this time had a temperature never below 100° F., and occasionally reaching 102°. Perfect recovery followed; but a second and similar attack followed, four years after the first. Dr. Maguire considered that at the present time such cases as these were of the utmost importance, in that grave organic disease, for which possibly operative treatment might be proposed, was so closely simulated by purely functional disturbance.—Mr. LLOVELL advocated an improvement in the terminology of the subject, and described a state to which he thought the term "neurokinesis" was applicable. He also suggested a more rational and considerate treatment of those who were usually considered to be hysterical.—Dr. HUGHINGS JACKSON said many so-called cases of hysteria were cases of nothing, and a number of cases were narrated to illustrate this proposition.—Dr. GRANT HEWITT thanked Dr. Mackenzie for his lucid exposition of the mechanism of the hysterical derangements. His own experience of hysterical cases in women had taught him the fact that general malnutrition was almost invariably present, and probably the basis of the whole case. Certainly the uterus showed signs of this malnutrition in such cases, its tissues being soft and deficient in normal firmness to a remarkable degree. Probably the central nervous system was in like condition of malnutrition, and thus there arose increased liability to reflex disturbances. He had observed several cases of hysterical convulsions in women, where the excitation plainly came from the uterus, as was proved by the cure of the convulsions by appropriate treatment of the uterus. As regards the pain described by Dr. Mackenzie in his first case, he had seen a case very like it where the pain was undoubtedly due to antelexion and version of the uterus.—Dr. FITZPATRICK thought that during the last fifteen years hysteria had become less prevalent, and attributed this to the better hygienic conditions under which young ladies lived.—Dr. SQUIRE agreed with Dr. Hughlings Jackson that it was necessary to distinguish between hysteria and shamming: the former class was characterised by an absence of motive, the latter had originally a motive.—Dr. EWART thought nerve inanition was an important factor in hysteria, and ought to be especially treated.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

WEDNESDAY, FEBRUARY 15TH, 1888.

JOHN SMITH, M.D., President, in the Chair.

Successful Trephining over Motor Areas for Arrested Development of Limbs and Complete Loss of Functional Value; Commencing Return of Functional Activity.—Dr. FELKIN showed a girl, aged 17, on whom, at his suggestion, Mr. Hare had operated, with a view to the recovery of lost functional activity in the right arm and leg. When a young child, the patient had sustained serious injury to the head. Apparently as a result of this, an arrest of development had taken place in the right arm and leg, while there was an almost complete disappearance of functional activity. In many of its features the case simulated poliomyelitis anterior acuta. Dr. Felkin, into whose hands the case had fallen but recently, was able to trace a slight depression in the scalp over the left motor areas. He consulted Mr. Hare, who, after careful examination, agreed with Dr. Felkin that it was a case for operation. Mr. Hare accordingly operated three or four weeks ago. On exposing the skull, they discovered evidence of the existence of an old depressed fracture, over whose site Mr. Hare trephined. Two complete circles of bone were removed, while additional portions were removed by means of Hey's saw. From the space thus exposed a cyst was found to project. This was evacuated and its connections disturbed. Projecting internally from one of the portions of bone removed was a horn-like process of bone, which doubtless had been the cause of additional irritation. The dura mater was not incised. Small portions of bone were planted on the exposed surface of the dura, and the wound closed, a small catgut drain being inserted. The wound healed by the first intention, and the patient did not present a bad symptom from first to last. No rise of temperature occurred. Careful examination with the dynamometer revealed distinct evidence of returning functional activity, while certain movements of the forearm were

accomplished for the first time. In addition to the great interest of the operation itself, the additional interesting problem was raised as to how far they might look for an improvement in the state of arrested growth of both upper and lower limbs.

Animal Tuberculosis in Relation to Consumption in Man.—Principal WALLEY, of the Royal Dick Veterinary College, Edinburgh, read a paper on this subject. After dwelling on the comparative neglect with which this important subject had been treated, he sketched the history of the pathology of tuberculosis. So early as 1872 he had been inclined to think that tuberculosis in cattle must be due to some specific poisonous principle, and this opinion he had indicated in an essay published that year. The bovine tribe were most liable to the disease; sheep showed a remarkable immunity. As to the horse there was some difference of opinion. It was sometimes said that the horse was not attacked. Certainly there had been confusion, as there had been in considering the question as a whole, through the confounding of lymph adenoma and tubercle proper. Some of the cases described as cases of tubercle in the horse were undoubtedly lymphadenomatous. His colleague, Professor MacFadyean, however, had recently had opportunity of studying a true case of tubercle. There was also some difference of opinion regarding the pig. It was usually regarded as easily affected, but a recent authority had contradicted this view. In the dog it was a very rare occurrence, as in the cat. Water fowl were seldom attacked, while barn-door fowl were very liable to it. Wild animals were far less prone to it, in their native state, than domesticated animals. Speaking of the chances of propagation, Professor Walley indicated his belief in the possibility of congenital tuberculosis. A number of observations pointed to this, while theoretically there seemed no difficulty in supposing it possible for the tubercle bacilli to pass from mother to foetus in the same way as it was admitted that the bacillus anthracis did. It had not yet fallen to his lot to observe a case, but several such were on record, both abroad and at home. Propagation might further result from the ingestion of various affected foods (meat, milk, etc.), and by inhalation. Experimentally it had been induced both by the subcutaneous, intravenous, and intraperitoneal methods. Professor Walley then discussed fully the different secretions and organs which became affected, and illustrated his statements by exhibiting a large collection of morbid specimens. In opposition to the statement that the trachea and bronchi were never primarily affected he was able to show specimens. Turning to the practical side of the question, he deprecated the statement of the *Lancet* that veterinarians had been apathetic on this subject. He was of opinion that a charge of apathy might be lodged with much greater justice at the door of the medical profession. As to the identity of bovine and human tuberculosis, he thought there was now no room for reasonable doubt. All the lines of evidence pointed in this direction. The immediate practical issue was what should they do with a view to minimising the possibility of infection from animals to man? There was no doubt that the milk from tubercular cows was distinctly dangerous. The work of Professor Bang and others had proved this conclusively. He was inclined to believe with many observers that there was danger from the milk of such cows only as showed tubercular sores on the udder. They must have powers granted to them to condemn cattle which were manifestly tubercular. This was a most important department of hygiene, in connection with which he held that medical men ought to combine with them in asking from the Privy Council that such powers be granted to their inspectors. As inspector for the city of Edinburgh, he occupied the happy and unique situation of being allowed by the Lord Provost and magistrates to exercise his own discrimination in the matter.—The PRESIDENT congratulated the Society on being the recipient of so important a paper. The subject was one worthy of their fullest consideration. Their thanks were due to Principal Walley.—Professor MACFADYEAN, of the Royal Dick Veterinary College, congratulated the Society on taking up this important subject. In his opinion, the identity of bovine and human tuberculosis was clearly established on an experimental and a histological basis. Alleged differences in size of the specific bacillus in the two cases were capable of satisfactory explanation. Infection might be conveyed from cattle to man by the ingestion of meat and milk. It was their duty to endeavour to obtain such regulations as might be expected to meet so serious a danger. Human and comparative pathologists would find mutual benefit by combined action. In illustration, he referred to Dr. Philip's recent work on certain morbid products obtainable from tubercular ex-

creta, and suggested the possibility of obtaining these in larger quantity from their public abattoir.—Dr. WOODHEAD thought Principal Walley rather hard on the medical profession. Discussing the question of identity, he thought too much had been made of mere difference of size. They all knew that the same organism varied somewhat under different conditions of growth. Further, he had prepared, in exactly similar way, specimens of the bacillus from human and bovine sources, and had submitted them to a number of qualified observers, and not only could they not say which specimen came from a given source, but it was impossible to find any difference in the series. Regarding the difficulty of inoculating certain animals from certain others, they must bear in mind the difference of temperature which existed among different species of animals. Much had been made of the comparative influence or non-occurrence of tubercular mammitis in the human subject. But the conditions were very different. The udder of the cow was made to afford milk considerably beyond the normal period of lactation, and it was submitted to less delicate handling.—Dr. LITTLEJOHN spoke of the importance of this question from the point of view of public health. He found, for example, that of forty-two cows slaughtered in Edinburgh on account of disease, seventeen had suffered because of tubercular disease. They ought to combine with their veterinary colleagues and petition the Privy Council for powers to destroy all animals manifestly tubercular. But they must remember such a measure could not be a local one, else Edinburgh would become a sink for all the tubercular animals of the country. The whole thing became a question of money, as compensation must be granted to the owners of such cows. With regard to the question of infection by sewage, it became an interesting problem whether the Craiginny meadows (which receive much of the concentrated Edinburgh sewage) might be unsuited as pasture ground. A practical difficulty occurred as to the date at which they should condemn animals. It was matter of common observation in the human subject that phthisis was curable, as was proved by *post-mortem* examination. Doubtless the same curative process occurred in animals. In addition to all this, there was need for the utmost care in the inspection of byres and dairies.—Professor GREENFIELD thought Principal Walley had unduly magnified the work done by the veterinary profession in comparison with what had been effected by the medical profession. He should have been inclined to reverse the order. As to the main issue, he felt inclined to say that, in spite of much that had been stated and written, no satisfactory points of difference between human and bovine tuberculosis had been established. While they could not expect to have the more exact experiment undertaken—the inoculation of the human subject directly from the cow—much important assistance might be afforded by a series of experiments in which inoculation of the calf was attempted from the human subject. He did not wish to say too much, but he was doubtful if they could expect all the good results suggested by the compulsory slaughter of cattle.—Dr. JAMES admitted the identity of the two affections. But in both instances the nidus was the more important factor. The bacillus was probably ubiquitous. It depended on the state of the individual whether it became noxious or not. In other words, improve the vital activity of the tissues and the bacillus remained harmless either to men or animals. Their preventive treatment of phthisis illustrated this. It was further suggested by the comparative rarity of tuberculosis in the more active horse and dog, as distinguished from the sedentary cow. Their best line of treatment of the present evil lay in improving the sanitary conditions under which their cows lived. The mere stamping out of the diseased animals would do no lasting good.—Mr. CATHCART and Dr. PEEL RITCHIE also took part in the discussion.—A vote of thanks was accorded to Principal Walley.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

FRIDAY, FEBRUARY 3RD, 1883.

CHARLES F. MOORE, M.D., President, in the Chair.

President's Address.—The PRESIDENT delivered an address on the importance and advances in preventive medicine.

The Coachford Poisoning Case.—Dr. C. YELVERTON PEARSON (of Cork) read a paper on the medico-forensic aspects of the Coachford poisoning case. The history of the case was shortly related, then an account was given of the *post-mortem* examination, and the various points of interest and peculiarity in it were discussed at

some length. A very full description followed of the different steps of the chemical analysis, and some of these were specially commented on. Such evidence as was necessary for a medical consideration of the case was then related, such as the symptoms observed during life, the nature of certain drugs found in the house of the accused, the purchase of poison, and the destruction of some drugs by the prisoner's sister, etc. The theory of the case as presented by the Crown was briefly described, and certain omissions pointed out, after which the weak nature of the defence was commented upon, and numerous matters raised were dealt with in a critical manner. It was argued that there was nothing in the evidence that was necessarily inconsistent with the termination of life by strychnine.—The Rev. Dr. HAUGHTON said Dr. Pearson had taken the straightforward, manly, and wise course in appealing from the newspapers and the lawyers to a court of his brother medical men, who were the competent judges of the manner in which he had discharged a most responsible and painful duty. It was a difficult thing to avoid mistakes in a complex case, and Dr. Pearson had made one which would teach him not to trust to memory before lawyers, though nothing but the art of lawyers could distort his evidence into the statement that two and three-quarters or three grains of arsenic were found in the liver. But suppose he had stated he found three grains in the liver itself; that was a perfect possibility. It was not generally known that had Palmer (who was hanged for poisoning his horse-dealing friend with the, in his time, new poison, strychnine) been acquitted, he would have been placed in the dock again on a charge of poisoning his mother with antimony. Both arsenic and antimony made for the liver, and he had himself weighed in London a packet of antimony which was taken from the liver of Palmer's mother, and it sealed between six and seven grains. If the arsenic was slowly administered such a quantity as three grains in the liver was exceedingly possible. He had, however, more experience of strychnine poisoning than of metallic poisoning. In conjunction with Dr. Apjohn and Dr. Emerson Reynolds, he had the task of ascertaining whether or not the celebrated greyhound, Master Magrath, had died of strychnine, and he established the fact that he had not died of strychnine. In other cases he established the fact to which Dr. Pearson had called attention, namely, that strychnine was an indestructible poison for many weeks, in fact, remained absolutely perfect, undisturbed and intact in the bodies of animals that had lain ten weeks in their graves. The strychnine part of the poisoning in Mrs. Cross's case was, however, a difficulty in his mind. There was no solution for the screams. But suppose, when he found his wife would not die, he adopted a practice known in his (Dr. Haughton's) native county of Carlow, of putting a pillow on the objectionable person's face and sitting on it for ten minutes, she would give a scream first; and it was quite possible that in Mrs. Cross's case a pillow was the immediate cause of death and not the strychnine. In any case, he was certain the whole world was convinced that a righteous judgment was come to.—Sir CHARLES CAMERON said, from the conclusions drawn from his experiments, he thought Dr. Pearson had conducted the investigation in an admirable manner, and that the results were such as any competent chemist would have arrived at under the same conditions. He agreed with Dr. Haughton as to the length of time strychnine might remain in the stomach and viscera and body generally of an animal. In the case of a Mr. King, who was poisoned at Limerick, it was necessary that the viscera of a dog should be examined, and he produced nearly half a grain weight of strychnine from the body fourteen days after death. A dog had been given some bread and butter, and the animal died shortly afterwards. Four months later an inspector of constabulary brought him the dog, and, having operated on the animal, he extracted more than a quarter of a grain. With regard to the Palmer poisoning case, there was no strychnine detected, and Professor Taylor was subjected to very strong animadversions on that account. He did not agree with the statement in Meymott Tidy's *Medical Jurisprudence*, that when arsenic was taken in small quantities extending over a lengthened period there were greater lesions.—Dr. PEARSON observed that the statement was that when taken for a long time the intestines were more apt to be affected.—Sir CHARLES CAMERON said he met with a case in which a very small quantity of arsenic was taken by cows, and four or five died from arsenical poisoning. They had been given each about a pound and a half of Glauber salts, containing 0.47 per cent. of sulphuric acid. A very small dose caused death, but no lesions were detected in the stomach. Being interested in the fact that the one-hundredth part of a grain could be weighed, he asked whether

any crystalline bodies from muscular tissue might possibly be included in that very minute quantity. He had often found crystals of sulphur assuming the form of crystals of arsenic, so as to deceive him. Sulphur gradually precipitated in the crystalline form, and he had been deceived in the appearance of crystals, thinking they were arsenic until he found they were nothing more than crystals of sulphur.—Mr. DOYLE said he was one of the minority who as yet did not see evidence brought forward on which to condemn Mr. Cross. A witness was sworn to tell the truth and the whole truth, and therefore he should give all the facts connected with the case; and yet Dr. Pearson now stated he found in the body ptomaines, of the discovery of which he did not tell the jury at all. They all knew that ptomaines constituted a most deadly poison—the most deadly poison they knew of, which was formed in their own bodies. Suppositions should be put out of the question in a matter of life or death. There was the supposition about using arsenic as a cosmetic. Dr. Pearson supposed that, if used as a cosmetic, it must have been in the liquid and not in the solid form. But they knew that, even if used in the liquid form and applied externally to the body, it was a curious fact that it always made to the stomach, and would be found there. As to the absurdity of Mr. Cross not recognising typhoid fever, there were hundreds of medical men who would not recognise a case of typhoid fever. There might have been typhoid and the poisoning too. The two conditions were not incompatible.—Dr. TICHBORNE said there was no difficulty in detecting strychnine. The only difficulty was in getting chloroform sufficiently pure to stand the reaction of the sulphuric acid. As regards the arsenic, while he did not like to dogmatise, he doubted about the liver being able to absorb 3 grains. At the same time Dr. Pearson stated there were 1.20 grains. He wished to know did that mean As or As₂O₃.—Dr. PEARSON: It is the oxide.—Dr. QUINLAN thought the case was a plain one. The idea that Mrs. Cross took arsenic for her complexion, as was the custom of women in the eastern parts of the Austrian Empire, was not entertained, for Mrs. Cross was a woman of mature age. The next hypothesis was that it was administered medicinally. From his own experience, arsenic was always given in the fluid form in minute doses, and it would be impossible in that way to produce the crystals in the stomach and duodenum. Moreover, the condition of the arsenic in the undissolved state showed that the quantity found must have been administered in the last few hours. As regards Dr. Haughton's view, he did not believe the "Carlow method" had been used, or Mrs. Cross would have exhibited symptoms of suffocation.—Sir CHARLES CAMERON asked whether the ptomaine was not an oily ptomaine, and quite unlike a crystalline body such as strychnine.—Mr. BROOMFIELD did not see any force in the argument as to how the arsenic was administered. Mr. Cross would not be more likely to give it in the crystalline form than any other medical man to prescribe it, or conversely, he would be just as likely as any other medical man to administer it in the fluid form.—Dr. QUINLAN suggested that it could be easily administered in sago or other food.—Mr. KENNEDY inquired whether there was anything in the evidence pointing to the way in which the strychnine was administered—for instance, any found in unfinished food.—Dr. PEARSON—There was no evidence on that point.—Mr. McCULLAGH, without questioning the justice of Mr. Cross's sentence, said he knew of ladies taking arsenious acid diluted, again and again; it was quite common.—Dr. PEARSON, in reply, said most of the criticisms would not have been called for had he read his paper, *in extenso*. That Mrs. Cross's screams were due to smothering, as suggested by Dr. Haughton, he did not believe. Mr. Cross was a man over six feet high and extremely powerful, and if he were to employ force he would not be likely to do so in such a way as to allow a weak woman to continue screaming four or five minutes. Therefore, in assuming smothering, the screaming was out of the question. But there were two possible explanations. The screaming might be due either to the painful convulsions produced by strychnine if administered at the time in a poisonous dose, or the arsenic might have caused convulsions at the close. He did not swear she died of strychnine poison. The quantity he found was a medicinal one. But assuming the strychnine was not given with the intention of shortening life, it must be accounted for in another way. He accounted for it as having been given accidentally. Mr. Cross did not keep his medicines in a very careful manner, and the strychnine might have been left knocking about the surgery. In like manner, if the evidence went to show that the lady died from a single dose of arsenic, Mr. Cross could never have been convicted; because it might be shown she took it by accident. But

the symptoms described by Miss Jefferson, commencing on the 10th of May, precluded the idea of arsenic having been administered in medicinal doses or taken by accident. Mr. Doyle had observed that it was his duty to have mentioned to the jury that there was a ptomaine. But a ptomaine could not possibly be confounded with strychnine, and was to be regarded as a product of putrefaction, as he believed it was, and therefore a normal product of the body; so that he might as well be expected to tell the jury he found fat and all the other components of the human body. He had satisfied himself that he also found strychnine, with which no ptomaine could be confounded, having regard to the manner in which he tested for strychnine, as described in his paper. Mr. Doyle had also suggested that arsenic applied externally produced the physiological effects on the stomach; but did he suggest that external application would cause white arsenic to be present in the solid form in the intestines?

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

THURSDAY, FEBRUARY 2ND, 1888.

M. M. DE BARTOLOMÉ, M.D., President, in the Chair.

Small-pox at Swinton.—Mr. W. MAKEIG JONES read a short paper on an outbreak of Small-pox at Swinton, and how it was dealt with. He had long urged the Local Board to make provision for such cases, but it was not till the outbreak really occurred that they consented to do so. The first cases were reported on November 29th, 1887, and on December 3rd was commenced the work of transforming an old hovel of a disused pottery into a hospital. The entire work was designed by the surveyor, Mr. J. C. Haller, M.I.C.E., and under his personal supervision was carried out with such despatch that on December 14th it was completed, and four cases were removed into it, and four more on December 10th. The hospital consisted of a brick building, 30 feet in diameter, divided into two semicircular wards, each 12 feet high, surmounted by one of Boyle's 3-feet ventilators. The administrative department, adjoining the wards, built of double-lined wood, consisted of an entrance passage, kitchen (16 by 14), bath-room (10 by 8) with hot and cold water, and a nurses' bedroom (12 by 10), all 10½ feet high. The cost was: for materials and labour, £128; stoves, water, bath, hot and cold water fitting, £44; 16 beds and furniture for all the rooms, £50 18s.; total, £222 18s. Up to the present only twenty-four cases had occurred, and only two during the last fortnight. In an adjoining village, with rather more than half the population, and where no steps had been taken to isolate the cases, nearly 200 had occurred.

Small-Pox at Sheffield.—Dr. SINCLAIR WHITE related the history of the small-pox epidemic in Sheffield from its commencement in March last up till the end of last year. In the absence of compulsory notification it was impossible to be accurate as to the number that were attacked; it was thought that 10 per cent. were not heard of. In one way or another 2,728 cases had come to the knowledge of the Health Department. Particulars as to vaccination were ascertained in respect of 2,580 cases; 2,198 were said to be vaccinated, and 382 unvaccinated. It might be said that about 90 per cent. of the people of Sheffield were vaccinated; 277 deaths were caused by the disease; in 23 cases it was not known whether vaccination had been performed. Of the remaining 254 deaths, 97 occurred among the 2,198 vaccinated, and 157 among the 382 unvaccinated. These figures corresponding to a death-rate of 4.4 per cent. among the vaccinated, and 41.3 per cent. among the unvaccinated. Taking only the cases occurring in children under 10, much more accurate and striking facts were disclosed. Of the 100,000 children in Sheffield, from official reports it appeared that 95,000 of these were vaccinated, and 5,000 unvaccinated. Among the vaccinated there were 207 cases, and 2 deaths, while there were 146 cases and 70 deaths among the unvaccinated. In other words, among the vaccinated children, 1 in 458 caught the disease, and 1 in every 47,500 died, while among the unvaccinated, 1 in every 34 caught the disease, and 1 in every 71 died. The epidemic showed that primary vaccination should not be relied on after 10, and he alluded to the efficacy of revaccination as exemplified in upwards of 50,000 who had been revaccinated during the last year. He did not think small-pox was to any great extent infectious during the first three days of the eruption; early removal to hospital, and sulphur fumigations had proved in his hands very successful. Referring to the regular periodic epidemics, it was mooted whether, having regard to the fact that small-pox was terribly fatal when contracted for the first time by any race of people, the children of persons who had not

suffered from small-pox were not more liable to the disease than the children of parents who had suffered from it.—Dr. BARRY, Local Government Board inspector, pointed out that the figures quoted with respect to small-pox and vaccination should be accepted with caution, as the returns had not yet been finally verified. From the information which he already possessed he believed that considerable corrections would have to be made in the published figures. Dr. Barry alluded to the statistics of the outbreaks of 1857-58 and 1871-72, showing that in 1857-58, in the north district of Sheffield (the only one he had yet worked out) there were 179 deaths among children under 10 and only 11 at other ages; and in 1871-72 the deaths under 10 were 167, and above 10, 88. In the present outbreak these proportions had been reversed, and up to December 31st, 1887, the deaths under 10 had been 72, and those at other ages 182. It was to be noted that at the first period vaccination was practically voluntary, at the second the Vaccination Acts were badly enforced, and at the third the Acts were efficiently enforced.—Dr. WHITELEGGE (Nottingham) supported Dr. White's contention as to the liability of pregnant women. They had had three such cases out of a total of twenty-three cases at Nottingham. He did not think that the excreta were so infective as some supposed. He entirely disagreed with the assertion that small-pox was not infectious during the first week. It was very infectious then, but might become more so later on. He related cases in support of this.—Mr. E. SNELL (Nottingham) spoke of the advantages of fresh vaccine lymph over stored. He thought the profession should urge on the Local Government Board to instruct public vaccinators to supply fresh lymph—with the source—to practitioners in their towns, and for them to be remunerated for so doing. This was preferable to the present plan of sending it first to the authorities; fresher lymph and proportionately better results would be obtained. Referring to the undoubted popular prejudice in favour of calf over humanised lymph, he thought animal vaccine stations should be established in the provinces, as in London.—Dr. DYSON, referring to the marks after vaccination, remarked that the size of the cicatrices depended a great deal on the temperament of the subject. Information was required as to what constituted "taking" after revaccination in many cases.—Remarks were also made by Mr. A. JACKSON, Dr. BOOBYER (Nottingham), and the PRESIDENT.—Mr. JONES, in reply, said he thought small-pox was not contagious in the early stages. He agreed with Dr. Dyson that the size of the cicatrix depended in a great measure on the patient's constitution—strumous, etc. He did not think that old lymph always failed; he had had good results with lymph five months old, and referred to Dr. Cory's opinion that after a time it recovered its efficacy.—Dr. WHITE also replied.

HALIFAX, NOVA SCOTIA BRANCH.

THURSDAY, JANUARY 12TH.

W. B. SLAYTER, L.R.C.P.Lond., in the Chair.

Bisulphide of Carbon in Pulmonary Diseases.—Dr. DE WITT read a paper on the treatment of pulmonary affections with bisulphide of carbon as a substitute for Bergeon's treatment, and the administration of water impregnated with sulphuretted hydrogen gas. He used 2 to 3 drachms of the bisulphide in 24 ounces of peppermint water, and gave 1 to 2 ounces of this mixture daily in milk. A number of cases successfully treated were detailed. Its action as a microbe-destroyer was supposed to be equal to that of the sulphuretted hydrogen injections. Cod-liver oil and the usual appropriate dietetic treatment were prescribed at the same time.—The Hon. Dr. PARKER stated that he had had but a limited success with Bergeon's apparatus. He cited a case of dysmenorrhœa treated by Sir James Simpson and himself in Edinburgh, many years ago, by injection of the gas *per vaginam*—the first time he had seen it in use. He had no experience of carbon bisulphide.—Dr. CAMPBELL considered carbon bisulphide as one of the hydrocarbon group, others of which, such as kerosine oil and sweet spirits of nitre, had been found equally useful in pulmonary affections.—Dr. SLAYTER, speaking of Bergeon's apparatus in phthisis, proposed at the next meeting exhibiting some preparations showing the action of sulphuretted hydrogen gas on the bacilli in phthisical sputa. In cocaine spray we had a more efficient drug than carbon bisulphide in spasmodic asthma.

Cocaine Poisoning.—Dr. SLAYTER related a case of cocaine poisoning. He had hypodermically injected 15 minims of a 10 per cent. solution of cocaine hydrochlorate into the toe of a patient previous to operation. In ten minutes the patient became cyan-

nosed, and developed an epileptiform fit. This passed off after a few minutes, and the operation was proceeded with, but he remained dazed for a couple of hours, and suffered from pain and smarting in the eyes for twenty-four hours. He had never suffered from epilepsy.

Telephonic Stethoscope.—Dr. SLAYTEN then exhibited a patent stethoscope with a telephonic arrangement for intensifying sounds.

Specimens.—Dr. CAMPBELL showed the following specimens:—A Humerus with a well-developed Hook-shaped Process at the lower end of the internal Border; an Atlas and Axis abnormal in character, there being a Gap of quarter of an inch in the posterior Arch of the Atlas, compensated for by an over development and widening of the spinous process of the Axis; a detached Septum Nasi (due to a blow) removed from a patient on plugging the posterior nares for epistaxis.

Cerebral Lesion in a Heifer.—Dr. CAMPBELL also desired a committee of the Branch to examine and report on the brain of a young heifer which he had lately obtained in the country. The animal, somewhat stunted in growth, but with normal muscular and joint development, had a peculiar gait in walking on the level, with a strong inclination to the left, and a peculiar rotatory motion in descending a hill. He diagnosed a brain lesion or defective development on the left side in the fissure of Rolando, which is supposed to preside over movements of the right hind leg.

PATHOLOGICAL SOCIETY OF MANCHESTER.

WEDNESDAY, FEBRUARY 8TH, 1888.

A. W. STOCKS, M.R.C.S., President, in the Chair.

Rare Forms of Eye Disease.—Dr. MILES showed specimens illustrating the rarest forms of eye disease. Amongst these were examples of ciliary tumours comprising (1) a Ciliary Myoma (Vose Solomon's case, kindly lent by Mr. Priestley Smith); (2) a Myosarcoma of the Ciliary Muscle; (3) a Sarcoma (spindle-celled) of the Ciliary Muscle which had become Extra-ocular; (4) a case of Intra-ocular Thickening of the Sclera, so great as almost to Obliterate the Vitreous Cavity. With these were sections of Two Ciliary Tumours, one of them being from Professor Hirschberg's collection.

Abnormal Shoulder-joint.—Dr. BASIL showed a specimen of Diseased Shoulder-joint, with Fractures of the Clavicle and Acromion Process of the Scapula.

Leucin and Tyrosin.—Dr. J. DIXON MANN showed some preparations of leucin and tyrosin from a case of malignant disease of the liver. He also showed preparations of leucin illustrative of its varied physical appearance in relation to its degree of purity.

Bone Grafting in "Club Hand."—Mr. G. A. WRIGHT showed a specimen from a case of so-called "club hand" in which the radius and thumb on each side were absent. The ulna had been fractured and repaired *in utero*. Bone grafts from another child were implanted in the position of a radius, and were apparently growing, but the child died from intestinal catarrh a fortnight later.

Sloughing Ulceration of the Larynx.—Dr. T. HARRIS exhibited a preparation obtained from a man, aged 52, who had been suffering from incompetence of the aortic and mitral valves. The laryngeal lesion was not suspected during life. During the last three or four days of life his voice was very feeble, somewhat hoarse, and his breath was very offensive; he had also expectorated a small amount of blood; there was no evidence of laryngeal obstruction. At the *post-mortem* examination there was found, in addition to the cardiac lesions, a patch of sloughing on the left side of the interior of the larynx, extending from the base of the left arytenoid cartilage to just below the true vocal cord of the same side, the posterior half of which was destroyed. The patch was about the size of a shilling, was of greyish yellow colour, had clearly defined and sharply cut, but not indurated, margins, and was half an inch deep, extending down to the inner surface of the left wing of the thyroid cartilage, but there was no necrosis either of that or of any other cartilage. The patch was evidently of quite recent and acute origin. The remaining part of the mucous membrane of the larynx was congested, and the ary-epiglottidean folds were œdematous. There was no foreign body in the larynx, nor any evidence of syphilis in any of the organs, neither were there any infarcts in any part.

Sloughing Pharyngitis.—Dr. HARRIS exhibited a rare preparation of sloughing of the pharynx. The disease, which was not

diphtheritic, had extended to the larynx, and rendered tracheotomy necessary. The specimen was from a man, aged 60, and the disease had commenced six days before death.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

THURSDAY, FEBRUARY 9TH, 1888.

G. H. HUME, M.D., President, in the Chair.

Cases.—Dr. BRADLEY showed a man, aged 80, who had amputation of forearm performed for injury. Though the patient was the subject of Bright's disease the operation had been successful.—Mr. BLACK exhibited two boys upon whom he had successfully performed amputation for disease of hip-joint. In one the acetabulum had been perforated by disease.—Dr. LIMONT showed a man, aged 33, suffering from Charcot's joint-disease.—Dr. OLIVER, in the absence of Dr. HEATH showed a patient with deformed tibia. There was a history of injury twenty-six years previously, and again five years before. The disease was regarded as chronic osteitis or pathological hypertrophy.—Dr. CANE, in the absence of Professor PHILLIPSON, exhibited a man in whom empyema had been successfully treated by incision and drainage.—Dr. H. S. BAUMGARTNER exhibited a child with deformed hand, the supposed result of maternal impressions.—Dr. CANE showed for Professor PHILLIPSON a woman subject to epileptiform attacks, who was believed to have a cerebral tumour.

Empyema Treated Successfully by Incision, Perflation, and Drainage.—Dr. OLIVER exhibited a man who had suffered from pyo-pneumothorax. A quart of pus had been removed from his chest previous to admission. An incision anteriorly, also one latero-posteriorly, was made, and perflation by means of carbolic air was carried out. The patient made a good recovery.

Nephrorrhaphy.—Dr. DODD showed a man previously under the care of Dr. DRUMMOND, who gave to the members the history of the case. After experiencing severe strain eight years ago, he had since complained of pain in the back. The right kidney was freely movable; the left also, but very slightly so. Mr. Dodd operated in the usual manner, employing silk sutures. The man made a good recovery, and was fit to follow his employment.

Dislocation of Lens.—Mr. PAGE exhibited a boy whose right lens had been dislocated as the result of accident. There had been rupture of the eyeball. The lens could be seen undergoing changes of colour and texture.

Laparotomy for Extra-Uterine Pregnancy.—Mr. RUTHERFORD MORISON showed a specimen removed in the early months of pregnancy. A cyst-like mass could be felt lying behind the uterus. There was severe uterine hæmorrhage. At the time of the operation hæmorrhage of such a severe character occurred from the sac that plugging had to be resorted to, the operation for the time being abandoned. A few days subsequently, after repeated intercurrent hæmorrhage, the foetus was removed, and the patient recovered.—Dr. MURPHY, who assisted at the operation, alluded to the difficulties encountered.

Museum of Anatomy and Physiology, Newcastle.—Dr. MEARS read a paper on this subject. Three things he thought were necessary for a museum to be complete; (1) a full series of normal specimens, and the notes and histological descriptions; (2) abnormalities; (3) pathological specimens.—The PRESIDENT regarded Dr. Mears's paper as a valuable contribution to the *Transactions* of the Society, and hoped members would aid Dr. Mears in carrying out his scheme.—Dr. MANTLE, Mr. PAGE, Dr. JAMES DRUMMOND, and Dr. OLIVER, made remarks also in favour of the scheme.

Specimens.—Dr. OLIVER showed specimens of Tuberculosis of Heart and Pericardium; and Heart and the Cord stretched transversely across Anterior of Left Ventricle.—Dr. BRADLEY showed an Aneurysm of the Aorta, which had burst into the Oesophagus.—Dr. BRADLEY also showed an Umbilical Cord with True Knot upon it.—Dr. MURPHY showed a Parovarian Cyst.—Mr. DODD showed a Sarcoma of the Tibia.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

PATHOLOGICAL AND CLINICAL SECTION.

FRIDAY, JANUARY 27TH, 1888.

A. S. UNDERHILL, M.D., in the Chair.

Recovery from Paraplegia due to Spinal Caries.—Dr. STICKLING showed a case in which recovery from complete paraplegia, of over two years' duration, due to spinal caries, had taken place

The patient, a man, aged 22, was admitted into the Workhouse Infirmary in August, 1885. He had lost the use of his right leg three weeks before admission, and a week later that of the left also. When admitted he was completely paraplegic, there being ankle clonus and exaggeration of knee-jerk on both sides, with loss of the abdominal reflexes. The epigastric and cremasteric reflexes were present. There was also analgesia of both lower extremities, but no complete anaesthesia. The seventh dorsal spine was prominent, and tender on percussion. During his stay in bed, which lasted two years and three months, he had four plaster jackets put on, wearing each for about three or four months. He had cystitis and bedsores. At the end of two years and three months he could move his toes, and power gradually returned, till in a month's time he could stand, and in another month could walk. The curvature of the spine had increased very considerably, but there was now no pain or tenderness. There was now no ankle clonus or anaesthesia, and the patient walked perfectly well.

Lympho-sarcoma of Posterior Mediastinum.—Dr. CARTER showed a specimen of lympho-sarcoma of the glands in the posterior mediastinum, extending thence into the right lung. The patient was a railway porter, aged 37. His family history and previous history were good. His symptoms dated from a year back, with a succession of bad colds, from which he never completely recovered. Some two or three months before admission to the Queen's Hospital he was troubled with dyspnoea on exertion, constant cough, and abundant muco-purulent expectoration. He began at the same time to emaciate rapidly. At no time had he any pain. At the time of his admission the symptoms and signs were those of progressive consolidation of the right lung, with dilated bronchi; there was some dulness on percussion in the right interscapular region, and slight stridor. A diagnosis of mediastinal tumour was made, which was supposed to have caused secondary broncho-pneumonia by direct pressure on the right main bronchus. He grew weaker, the stridor became more marked, and he died in a paroxysm of dyspnoea three weeks after admission. Dr. Carter also showed a gelatine model of the specimen, which had been prepared according to Professor Cathart's method.

Addison's Disease.—Dr. MACMUNN read a paper on the pathology of Addison's disease, and the functions of the adrenals.

Cerebral Cyst.—Dr. CROOKE showed a specimen of cystic cavity of right cerebral hemisphere.

REVIEWS AND NOTICES.

THE DUTIES AND CONDUCT OF NURSES IN PRIVATE NURSING.

An Address Delivered at the Boston Training School for Nurses.

By WILLIAM L. RICHARDSON, M.D., Visiting Physician of the Massachusetts General Hospital, etc. London: Field and Tuer; Simpkin, Marshall and Co.; Hamilton, Adams and Co. 1887.

SICK nurses, or nurse tenders, as they are perhaps more happily called in Ireland, have received so much indiscriminate praise, that it may well be that a little plain speaking may sometimes be useful; if this be so, it is not to be wondered at that "the lady superintendent of the largest hospital in London," after reading Dr. W. L. RICHARDSON'S address, "at once asked for fifty copies, for distribution among her own staff of nurses." The address was given at the end of a year's course of hospital training, and it is creditable alike to the lecturer and his class; only an accomplished and experienced physician could have spoken so much to the point, and only honourable and earnest women could have been so frankly addressed.

Very wisely, Dr. Richardson spoke first of the nurse's duties in the household: "Always," he said "enter on your new office quietly, as one who is willing to assist, and not as though you were a trained professional who had come to usurp the place of those who are only too anxious to administer to the wants of the patient.....Be especially careful as regards your relations with the servants. They will naturally look upon you as an interloper.....If you have occasion to go into the kitchen for any purpose, make friends with the cook, who will usually be found in an aggressive mood, but who can be very easily persuaded to be your friend." There are, in fact, a great many injunctions as to what not to do in the address, as for instance: "Never have a

prescribed line of duties beyond which you are unwilling to go. It should be a nurse's aim to do whatever can be done to comfort or relieve her patient, to assist the physician, and to help the family." "Be careful never to appear mysterious in what you are doing, and never to whisper in the sick room, a fault which many people have, and which is sure to awaken suspicion in the minds of nervous patients that something is going wrong." "Be careful never to have confidential talks with the physician, the nature of which you afterwards endeavour to surround with mystery." "Never under any circumstances relate your experiences. Educated in a hospital and familiar with the daily incidents of surgical and medical wards, nurses are apt to forget that, to the laity unaccustomed to such scenes, their description is painful and often disagreeable." To this last maxim exception may be taken, it would perhaps be to expect a perfection to which the female sex will never attain, and after all the laity do not always dislike to have their unaccustomed palate tickled by the relation of astounding operations, or awful accidents; too often, indeed, the nurse and the patient have few topics in common, and the wonderful hospital stories are heard with a kind of incredulous interest. "No greater nuisance exists in the sick room than a talkative nurse," Dr. Richardson truly says, but even he allows her to take part in the conversation if the patient leads the way. Some sound advice is given on the duty of a nurse to the physician, and to other nurses in attendance on the case.

If nurses in attendance on private cases would act in the spirit inculcated in this address, we should cease to hear of cases where women technically competent have made themselves dreaded by the household and the physician, for whom or with whom they have been engaged to work. The volume, which is well printed and daintily got up, would form a suitable present for a young woman about to leave the training school and commencing private nursing.

DE L'ÉTAT DE LA DENTITION CHEZ LES ENFANTS IDIOTS ET ARRIÉRÉS. Contribution à l'Étude des Dégénérescences dans l'Espèce Humaine. Avec 32 gravures dans le texte. Par ALICE SOLLIER, née MATHIEU-DUBOIS, Docteur en Médecine, Ancienne Externe des Hôpitaux de Paris et de l'Hôpital des Enfants-Malades. [On the State of the Dentition of Idiot and Backward Children.] Paris: Aux Bureaux du Progrès Médical.

MADAME SOLLIER has taken advantage of clinical work amongst idiot and epileptic children at the Bicêtre, where she devoted herself to the study of the dental pathology of the patients. This work contains over 100 clinical reports. Each report includes a heading which consists of a summary of the family history and the symptoms of the patient, together with a note of the general peculiarities of the dentition; then follows a full description of the teeth, which forms the main part of the report. In some cases good drawings are given. With the general histories we have nothing to do, excepting that we feel surprise at the nomenclature, which is as specialised as in all other forms of special literature. Those useful gentlemen the compilers of dictionaries of scientific terms must be ready to explain the meaning of *Gâtisme*, *Mérycisme*, and *Clastomanie*; for in this case, where the book is meant for dentists, its readers cannot be expected to comprehend the dialect of psychologists. "Gâtisme," it ought to be said, means the involuntary passage of urine and faeces; whilst "Mérycisme" is a term applied to cases where the patient ruminates, not mentally, but literally. Both terms refer to lunatics only.

The authoress finds that idiocy, with or without epilepsy, pre-disposes about 91 per cent. of its victims to dental deformity and disease. Congenital idiocy has no more special influence in this respect than idiocy developed during the first dentition. The deformities and lesions are almost exclusively associated with the second dentition. In Dr. Sollier's experience the first was found to be precocious in eight out of sixty cases, but in a quarter of the whole series the first dentition was retarded. Early casting of the milk teeth was very rare (1 per cent.), whilst in 11 per cent. it was delayed. In 36 per cent. of the series the second dentition was delayed; this phenomenon was commoner in the idiots (26 out of 60) than in the epileptics (10 out of 40). In 14 per cent. there were dwarfed teeth; in 11 per cent. giant teeth. Abnormalities other than giantism and dwarfism were found in 53 per cent.; absence of teeth, excluding retarded eruption at the period of second dentition, was noted in 11 per cent. Giant teeth were

often found where others had not developed; or else they represented ankylosis of two adjacent teeth. In only 2 per cent. were supernumerary teeth discovered. Anomalies of implantation were very common (34 per cent.); but anomalies of actual position in relation to other teeth were very rare and ill-marked. Anomalies in the direction of the tooth—crookedness, obliqueness, etc., were the most frequent of all malformations, and chiefly affected the canines and incisors. Erosion (loss of substance of the enamel over a greater or less area of the surface of the tooth) was often associated with convulsions, but was most frequent in cases where there had been no convulsions; thus Dr. Sollier concludes that idiocy, with or without epilepsy, can by itself cause erosion. In 41 per cent. of the whole series there was longitudinal grooving of the enamel; in 58 per cent. the edges of some of the teeth were notched. Both these peculiarities, especially the notches, more often coincided with convulsions than did erosions. Caries and crustation of tartar were evidently accidental accompaniments of idiocy and epilepsy. The articulation of the upper and lower dental arches was defective in 43 per cent. In 38 per cent. each arch showed deformity. The authoress turns attention to an undescribed anomaly of this class, where the level of the two halves of the arch is unsymmetrical. In 45 per cent. of the series the palatine vault was deformed. Yet Dr. Sollier carefully describes 9 cases of idiocy, and imbecility with epilepsy, where none of the characteristic lesions above described could be discovered. In conclusion, we may say that Dr. Sollier's *Etat de la Dentition chez les Enfants Idiots* is a valuable clinical record, representing one of the best features of French medical literature.

NOTES ON BOOKS.

Annales des Maladies de l'Oreille, du Larynx, etc. (Edited by A. GOUQUENHEIM. January, 1888.)—The present number of this journal contains the following original articles: 1. One by H. Chatellier in the form of a letter on acute otitis media produced by pneumococci, as described by Professor Zaüfal. 2. An article by Dr. Couetoux, of Nantes, on deafness from a medico-pedagogic point of view. 3. A report by Clarence J. Blake of two interesting cases showing the effects of pressure exerted by polypi in the middle ear (between the external tympanic wall and the long process of the incus); and 4. The conclusion of Hooper's memoir on the anatomy and physiology of the recurrent laryngeal nerves. Numerous abstracts, a bibliography, and a supplement containing full particulars of the forthcoming congress for the study of tuberculosis (in man and animals) which is to be held in Paris in July, 1888, complete the number.

REPORTS AND ANALYSES.

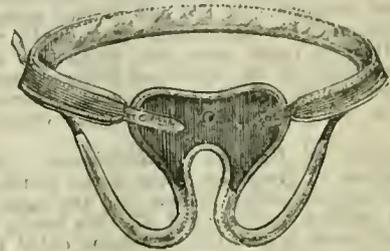

AND DESCRIPTIONS OF NEW INVENTIONS, IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

A TRUSS FOR INGUINAL AND FEMORAL HERNIA OF ONE OR BOTH SIDES.

THE accompanying woodcut shows a form of truss that has been made for the last four years or more, by Mr. Joseph Critchley, 88, Upper Pitt Street, Liverpool, and which I prefer to any other under certain circumstances. It consists of a padded steel plate that covers the pubes and both inguinal and femoral apertures, being held in place by a strap round the waist and two between the thighs. The plate is almost triangular, its upper side with rounded corners lying horizontally above the pubes, but instead of a lower angle there are two wings, and between them a space cut out to fit around the male genitalia, which are thus closely embraced at their root.

The instrument was copied or adapted by Mr. Critchley from a simple one sent to him for repair, and from an illustrated description in some journal, the recollection of which he has quoted to me, but the reference to which neither he nor I have yet found. This truss is not of use for large, unwieldy, or wide-necked herniæ. Nor is it in any sense a spring truss, or one that can by pressure

lead to the curative adhesion of a hernial sac. But it is of value in small, narrow-necked herniæ, femoral and inguinal, of one or both sides; and is an admirable protection when hernia is threatened, but not yet descended. This condition, noticeable in some persons who have a flabby abdomen, is more striking in similar cases where herniotomy has been done, with closure of the sac, whether for strangulation or not. It thus usefully supplements an operation for radical cure in cases where a too obvious impulse threatens a return, and may be an essential factor of success, tardily secured after previous failure without it.

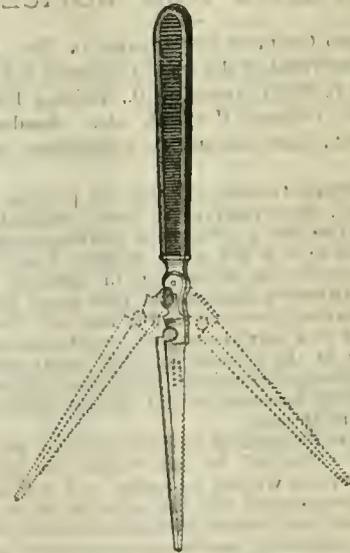

I think very highly of this truss in the selected cases for which it is useful, and take this opportunity of recommending it to those who have not heard of it. By trying on oneself even a casual sample, a good idea of its value is readily had, and a sense of security, protection, and comfort felt in the parts to which it is applied. The weight varies with its strength, but the heaviest are not irksome when in place, and are about the strongest and most durable trusses made. But even these get inevitably worn after prolonged use, in the severe wear and tear of artisans.

In ordering, give the usual circumference round the pelvis, and make a paper pattern roughly fitted to cover the hairy pubes, and cut out below to fit around the genitals in the case of males.

RUSHTON PARKER, Professor of Surgery in University
College, Liverpool.

REVERSIBLE NASAL SAW.

THIS instrument has been designed and made for the removal of cartilaginous and bony obstructions in the nasal passages. The advantages it possesses are, fineness of the blade, and, by means of a screw at the junction of the blade and the handle, a reversibility which enables the operator to work from above or from

below, or at any angle that may be necessary. The serrated edge extends along from half to three-quarters of the blade, so as to avoid injuring the skin of the entrance to the nares. I have hitherto had two sizes made—one for fine, the other for coarser work. The maker is Mr. Young, Forrest Road, Edinburgh.

G. HUNTER MACKENZIE, Edinburgh.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1888.

SUBSCRIPTIONS to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the West Central District Office, High Holborn.

 The British Medical Journal.

SATURDAY, FEBRUARY 25TH, 1888.

DEGREES FOR LONDON MEDICAL STUDENTS.

THE official document which we publish on another page indicates dryly the extent and character of the opposition which is likely to be made to the scheme of the two Colleges, and the status accorded to claimants for alternative schemes. We may say at once that although the discussion of the points at issue by the aid of counsel learned in the law will no doubt do much to clear up various questions of right and justice involved in the issue, we do not think that any merely legal arguments can cover the whole ground, or lead to a result likely to satisfy the interests of the public and the profession. The limits within which legal arguments must necessarily be confined, and the technical character which lawyers instructed by brief are bound to impress on their subjects, are apt to narrow as well as to complicate the broad issues, which are the most important in such a question. What we are all concerned in is that arrangements shall be made by which the most satisfactory elements in the various schemes now before the Privy Council can be fused, and the best possible institution provided for graduating London students of medicine under conditions favourable to the adequate testing of their qualifications as practitioners. Such an institution should be conducted by persons so well in touch with the educational institutions of the metropolis, that the examinations shall have a useful influence on the progress of medical instruction, and not, as often happens, tend to cramp and fetter free development to meet the ever-changing needs of scientific and social progress. Such an investigation, we repeat once more, can only effectually be made by a Royal Commission, and we see with satisfaction that the view which we have steadily urged on this subject has been adopted by the Senate of the University of London. An important and very fully attended meeting of that body was held on Wednesday last, to discuss a motion in this sense standing in the name of Lord Justice Fry. The upshot of the prolonged debate which then took place was a practically unanimous decision that a Royal Commission on the provisions at present existing in London for granting degrees in the various faculties had become a necessity, and Earl Granville, the Chancellor of the University, undertook to urge this view upon the Lord President of the Council. Should it be necessary to bring

the subject before Parliament in order to attain this end, Lord Granville will have the powerful support of the Earl of Derby, the Earl of Kimberley, and Lord Herschell, who are also members of the Senate of the University.

It is unfortunate that the metropolitan medical schools, which are so deeply interested in this question, have been so slow to move. They have at length begun tardily to act, and are only beginning to consider the question at a date when it will be difficult for them to acquire a *locus standi* before the Privy Council, and under circumstances which are otherwise unpromising, and portend, it may be feared, inadequate action.

It is of course obvious that many of the most influential personages on the staff of those schools may consider that their mouths are shut and their hands are tied by their connection with the two Colleges which have taken the first proceedings in the matter; and it is broadly stated that very powerful influences are at work to paralyse their action now, as they have availed to delay them until this late hour. Of course platitudes have been freely used to suggest that inasmuch as a large number of the senior teachers are at one time or another members of the Council of one or other of the Colleges, schools will have an indirect representation in the government of the new graduating University for which the two Royal Colleges seek.

It ought to be a sufficient answer, in the minds of men of common sense, that indirect representation is one of the worst forms under which abuse cloaks itself; still more so, and most of all, when that representation is not a representation *ad hoc* on any fixed principle, but a mere matter of chance combinations devised for altogether other purposes. Without implying any disrespect to the other qualities of the Council and Board of Censors of the Royal College of Physicians, it will not be pretended that they are elected with any reference to the special capacity of their members for the management of medical education or for the organisation of medical schools. On the contrary, it is precisely those persons who have least time, and least direct interest in such matters, who are most apt in their advanced years to have acquired influence and position on various committees of the Colleges. No definite rule could be laid down in this respect in one direction or the other, and the exceptions on either side would probably be as numerous as the examples which would be quoted in favour of either proposition. It is quite obvious, however, if the schools and the teaching bodies of London claim, as we think they should most strongly and justly claim, to be represented as such on the governing body of any graduating institution or university in the metropolis, that representation should be direct, and should have a special reference to its purposes. The representatives should be selected by the schools themselves, should be in direct contact with the teaching bodies which they represent, and responsible to them for the expression of the views of those bodies. All this is well set out in brief in the memorial of the Westminster Hospital School. But it is idle to conceal that not only what are called higher influences are adverse to the bold and definite assumption by the various schools of the position which

they are entitled to take up, but there is apt to be a division of opinion and an inconsistency of action arising out of unexpressed, but still active, jealousies.

The great schools, as they are sometimes called, are not a little jealous of the smaller schools; and the initiative action of King's and University Colleges, however carefully guarded by a formal statement of a full respect for the rights and powers of other institutions, could hardly fail to excite some feelings of alarm and some of jealousy. If, however, laying aside smaller considerations, the schools could satisfy themselves that in a new scheme for a teaching university in London all claims would be fairly recognised, and all rights fairly represented, and all duties equitably enforced, there ought to be no difficulty in such conjoint action as should enable the schools, even at this late hour, to assert themselves before Parliament and before the Privy Council, to aid in obtaining for London a teaching university founded on the widest and most secure basis.

THE BIRTH-PLACE OF CONSUMPTION.

THAT phthisis is cultivated, if it does not actually originate, in overcrowded and ill-ventilated dwellings, is a truism of sanitary science; yet it is very difficult to produce reliable statistics which support this dictum by quite unimpeachable evidence.

The reason of this difficulty is not because there is lack of material for an inquiry, or because there is any want of eager observers to deal with the material existing. It is that there are so many factors to be considered, so many sources of fallacy to be avoided, that the results obtained have hitherto, for the most part, been little better than valueless; nay, in some respects even worse, since they have left the etiology of consumption a hopelessly confused and heterogeneous mass of contradictory facts and deductions, which not even the most industrious and clear-sighted can reduce to order and coherence.

Nothing, for instance, seemed more conclusive than the result of Dr. Buchanan's inquiry into the effect of the drainage of towns upon the death-rate from consumption, and his subsequent and more extended one, in 1867, into the relation existing between the moisture of soils and the incidence of that disease. Yet Dr. Kelly, the Medical Officer of Health for East Sussex, has recently thrown the greatest doubt upon the trustworthiness of Dr. Buchanan's deductions, by showing, in the first place, that a decrease in the death-rate from phthisis had been by no means confined to towns where the drainage has been improved, but was universal throughout England; while in the districts examined by Dr. Buchanan, in his second inquiry, the topographical incidence of phthisis during the period 1861-70 was quite other than it had been in the years 1851-60, the time to which his statistics apply.

We fear, too, that Dr. Arthur Ransome's inquiry into the breeding-ground of consumption must be relegated to the limbo of unreliable statistics, where so many previous efforts have preceded it.

In a paper, read before the British Association at Manchester in 1887, and subsequently published as one of that remarkable

and creditable series, the Manchester Health Lectures, he considered certain portions of Manchester and Salford, and the conclusions to be drawn from an examination of their death-rate. He selected one district of Manchester and two of Salford, as being among the most unhealthy districts of those towns. He first visited each selected area for himself; and then, obtaining from the various health-officers the death-statistics of each region, from these factors he drew the conclusion that such places as these were the actual breeding-ground of consumption.

In Dr. Ransome's first district (Anecoats No. 1) there was a population of 5,600 persons; of these, 150 had died from consumption in a period of five years, giving a phthisis death-rate of 5.3 per 1,000 per annum. In his second district (Green Gate, Salford) there was a population of 2,600, with an annual phthisis death-rate of 6.2 per 1,000. In his third district (Regent Road, Salford) there was a population of 791, and a phthisis death-rate about equal to that of the last-mentioned area.

Dr. Ransome notices, as a first deduction, that the phthisis death-rate in these districts is more than double the rate for England and Wales. This seems to us an extremely unfair comparison. These eminently unhealthy districts of Manchester and Salford should have been compared with the whole city of which they form a part, and again with better sanitated districts of other towns occupied by the same class of workers. Indeed, it appears from some statistics published in volume VI of the *Sanitary Record* by Dr. Ransome himself that during the period 1865-76, while the consumption death-rate for England was only 3.54, that for Salford was 5.12; for the registration district of Manchester, 6.10; and for the township of Manchester in 1874, 7.7. So it appears that the districts selected by Dr. Ransome as the breeding-grounds of phthisis, instead of owning a phthisis death-rate considerably higher than the more healthy regions of the whole area of which they form a part, have really one slightly lower. This seems to us a grave element of fallacy, vitiating all Dr. Ransome's subsequent conclusions.

Of course the generally high death-rate of the inhabitants of Manchester from consumption is at least partly accounted for by the cold and humid climate of Lancashire, partly by the unhealthy occupation of the majority of the inhabitants. In the latter relation some remarks of Dr. Greenhow's made in 1861 still retain their importance. He said that the inhalation of dust in factories was one of the main predisposing causes of phthisis, and that another cause was the working in ill-ventilated and overcrowded factory rooms or workshops. Among the trades and places which he specially instanced as examples of this fact are the cotton-mills of Blackburn, a town having a like industrial population and a like excessive phthisis death-rate with that of Manchester.

Dr. Ransome's further and more important observations on the exact incidence of consumption in special streets and houses of his district are vitiated by this initial fallacy, and moreover possess certain elements of uncertainty of their own. His remaining conclusions are as follows:—

"2. That, although the phthisis deaths are distributed through-

out the [Ancoats] district, yet it is noticeable that at least 15 per cent. take place in the comparatively few houses contained in the same courts opening by passages into the street.

"3. The longest and widest streets in the district are Jersey Street, with ten deaths, and George Leigh Street, with eight deaths; but the number of deaths in these streets is approached by the mortality of eight in Hood Street, which is only half their length, but which is a mere lane, blocked at each end so as to obstruct free ventilation. Silk Street and Primrose Street are each credited with nine phthisis deaths. Again, Henry Street, which is a long thoroughfare, has only four such deaths, while Boord Street, a narrow *cul-de-sac*, only a quarter its length, has seven."

"4. The reappearance of the disease in the same house, as indicated by the occurrence of two or more deaths in them within the space of five years, is also most common in the more confined areas."

In the first place the element of inexactitude is introduced by the use of such comparisons as the relative length of streets. According to Dr. Mapother the smallest and least sanitary houses in Dublin until lately possessed an average population of twelve per house, and even more. A comparison of such a district as this with a larger street whose population was only the normal six per house, would be most inexact, unless this were taken into full account, since the smaller district would contain the larger population. Again the question of occupation intrudes as a disturbing element—it is likely, *primâ facie*, that the larger street would possess some shops, a portion, at least, of whose occupants would be kept out of the cotton factories, while the smaller lanes would be exclusively occupied by inhabitants, almost the whole of whose adult members would be employed in these places.

Again, an examination of the ages of those returned as dying from consumption requires to be made. Are many of them young children? If so, how far does the fact of the employment of their mothers out of the home during the day and their consequent neglect and mal-alimentation while infants enter into the question of the etiology of their deaths? It is certain that during the cotton famine of 1861-5 the infant mortality in the cotton district decreased, owing to the enforced presence at home of the female population.

We by no means seek to impugn the accuracy of Dr. Ransome's conclusions; we only desire to show that they are imperfect. We are strongly of opinion that sanitary statistics, to be of any real value, must be so exhaustive as to exclude any source of doubt or fallacy to the furthest extent, otherwise they are valueless and misleading. Nothing, or very little, must depend on probability, everything on proof.

Dr. Parkes collected in his great work on hygiene a number of accurate and model statistics, which prove that overcrowding and improper ventilation are fruitful causes of phthisis. It is to support and enlarge these that newer statistics are desirable, but at present they remain almost alone.

We require patient and accurate observers, whose observations extend over wide areas and through prolonged periods; who have no bias as to probability of causation, but who will

collect a mass of accurate statistics as to population, both gross and relative, as to ventilation, as to food and clothing, occupation, heredity, climate, and race. Then, and not till then, the etiology of consumption will be made clear, and one of the most fearful scourges of the human race traced to its true breeding ground, and, being so traced, made capable of diminution and perhaps of ultimate destruction.

WE understand that a considerable number of cases of diphtheria have again occurred among the nurses and students at Guy's Hospital.

A LETTER in similar terms to that addressed to the Association of General Practitioners (published at page 434), has been received by all the bodies which have presented petitions relative to the petition of University and King's Colleges, in favour of the creation of a teaching university, to be called the Albert University.

THE LATE SIR GEORGE BURROWS.

WE understand that a Committee has been formed of Fellows of the College of Physicians and others for the purpose of obtaining, with the consent of Sir Frederick Burrows, a replica or copy of the portrait of his late father, Sir George Burrows, painted by G. Richmond, R.A., to be presented to the College, and that a subscription will be opened for carrying out this intention.

POST-GRADUATE COURSE FOR DENTISTS.

WE are informed that arrangements have now been made for the establishment of a post-graduate course at the Dental Hospital, Leicester Square. The course, which will commence in April, will consist of lectures and demonstrations by members of the staff, and will be open to all registered practitioners. The instruction will be as comprehensive and at the same time as practical as possible.

THE PATHOLOGY OF CHRONIC ALCOHOLISM.

AT the end of the meeting of the Pathological Society on Tuesday last, the President, Sir James Paget, announced that the Council had decided to set apart three evenings in the early part of next session for the discussion of the pathological changes produced by chronic alcoholism and the exhibition of specimens relating thereto. Dr. Payne has been invited to open the discussion.

CHARING CROSS HOSPITAL SCHOOL.

A STRONG representation has been received by the Council from the staff of the School, with reference to the urgent necessity for increased accommodation for students, the number of whom has increased from 134 in 1881 to 224. The Council are convinced of the immediate necessity for enlarging the building, and negotiations are now proceeding for acquiring a site on the east side of the school of the Bedford estate, the lease of which has just expired. The estimated cost of the extension is £5,000, towards which special contributions are invited.

THE BRITISH MEDICAL TEMPERANCE ASSOCIATION.

A MEETING of the British Medical Temperance Association was held in the rooms of the Medical Society of London, on Tuesday last, at which Dr. Alfred Carpenter, J.P., read a paper on Difficulties of Diagnosis between Symptoms Produced by Disease and by Drugs. He gave two typical cases in which most serious symptoms of coma were due to the previous administration of alcohol. Dr. Norman Kerr gave particulars of 115 completed cases which have passed through the Dalrymple Home for Inebriates during the last four years and a half; 54 had been under the Act,

and 61 private. Of the 115 cases, 8 per cent. were produced by wine and beer only, the rest took spirits as well, or alone. Eight patients had been expelled. The average time of residence was seven months; 52 cases were reported doing well, 4 improved, 36 had not improved, 1 insane, 4 dead, 18 not heard from.

THE NATIONAL PENSION FUND FOR NURSES.

STEADY progress is, we are informed, being made with this fund. Sir Edmund Hay Currie has been elected a vice-president, and the General Purposes and Finance Committees have now been organised. Twenty thousand pounds has been paid into the Court of Chancery as security for the policy-holders and annuitants, and several thousands of pounds more have been promised for the Bonus Fund. Applications are coming in daily from nurses in all parts of the country to the Secretary at the office, 38, Old Jewry, and some have been received from Malta and one from Australia.

THE MEDICAL SCHOOLS AND THE PROPOSED TEACHING UNIVERSITY FOR LONDON.

A MEETING of delegates of the metropolitan medical schools was held at the Middlesex Hospital on Wednesday afternoon to consider the scheme for a teaching university put forward by University and King's Colleges. The delegates present were Dr. Norman Moore (St. Bartholomew's Hospital), Dr. Mitchell Bruce (Charing Cross Hospital), Dr. Frederick Taylor (Guy's Hospital), Dr. Curnow (King's College), Mr. Frederick Treves (London Hospital), Dr. Coupland and Mr. Pearce Gould (Middlesex Hospital), Mr. Malcolm Morris (St. Mary's Hospital), Dr. R. W. Reid (St. Thomas's Hospital), and Mr. Berkeley Hill (University College). It will be seen that all the metropolitan medical schools were represented at this meeting, with the exception of Westminster (which had already, as was stated last week, petitioned in favour of the proposal of the Association for Promoting a Teaching University) and St. George's Hospital. After considerable discussion the further consideration of the scheme was postponed to a meeting which will be held on February 29th.

ROYAL COMMISSION ON THE BLIND, DEAF, AND DUMB.

A ROYAL COMMISSION is now sitting to consider the educational position of "the blind, deaf, and dumb, as well as such other cases as from special circumstances would seem to require exceptional methods of education." Education is a part of hygienic science, for no brain is likely to work well in social life, and bear without harm the shocks and strains it is sure to receive, unless it be trained and exercised during early years. A knowledge of and the care of these unfortunate children come within the scope of professional work, and lead us to consider these questions of cerebral hygiene. As to the work of the Royal Commission to which we have referred, diagnosis is as important as treatment, the children must be known and selected before they can be submitted to "exceptional methods of education." Diagnosis of the blind, the deaf, and dumb, may be easy, and the teachers and ordinary inspectors may pick out such children; but when we come to the cases of idiots, the feeble-brained children, and other cases which seem to require exceptional methods of education, more knowledge and skill are required to make a wise selection among the children in the school. It is well known that a large class among the school population differ from the average of normal and perfectly strong children, being often unable to attend school on account of frequently recurrent headaches, nervousness, slight chorea—children who are altogether over-mobile; such cases are often unable to follow the ordinary curriculum, and certainly require exceptional methods of education. It is to be regretted that the definition of mental and other brain states is so difficult

to put in words; but after all it is not a wordy definition of certain brain states that we would wish to bring under notice of the Royal Commission, but a class of children whom we can define by what we see in them, though no one term indicates them as a group. As to the exceptional methods of education that such children require, we would rather say upon what principles it should be conducted, than name any "special system." We have seen infant-classes in Board Schools, and the work in the upper classes of schools for imbeciles conducted in very similar manner. It must not be thought that such "exceptional children," as we speak of in schools, are necessarily feeble minded; to be feeble brained is not necessarily to be imbecile; nervousness, headache, over-mobility, over-impassionability, etc., need not prevent mental action being quick, but do prevent a child from running through an immovable curriculum. To exempt such children is not to mend the evil, they ought to be kept in school, in classes suited to their requirements.

THE ILLNESS OF THE CROWN PRINCE.

As so many discouraging rumours have been put about during the past week, we are gratified to be in a position to give an assurance, on the highest authority, which will have the effect of diminishing the public anxiety. The Crown Prince is now beginning to make satisfactory progress; the cause of the unfavourable local symptoms mentioned in the bulletins published at the beginning of this and the end of last week was mainly mechanical. The tube at first inserted into the larynx did not fit well, and there was some delay in obtaining one which could be worn comfortably. Surgeons are familiar with this difficulty, which is often a source of still greater suffering to the patient and anxiety to his medical attendants than in this case. Every individual must be provided with a tracheotomy tube of a size exactly adapted to the contour of the throat and windpipe, which are subject in individual cases to many variations. This difficulty, we now learn, has been overcome; a tube of large calibre, specially constructed in this country, has now been adjusted, and the irritation produced by the ill-fitting tubes has passed away. The Crown Prince is now not only able to breathe through the tube with ease, but by stopping the opening is, we are informed by telegram, now able to speak in a strong, though hoarse, voice, and to carry on a conversation with ease. As the operation was only performed a fortnight ago, this may be considered an extremely satisfactory result. As to the true nature of the disease of the larynx, which has caused the obstruction of the larynx and necessitated tracheotomy, no new light has been afforded, but we learn that the swelling on the right side of the larynx is much less.

THE OFFICIAL REPORTS ON THE ILLNESS OF THE CROWN PRINCE.

THE *Berliner Klin. Wochenschrift* of February 20th refers to the recent publications of Professor Virchow and Sir Morell Mackenzie to the following effect:—"The above publications come at an opportune moment, for both of them are calculated to allay the excessive anxiety of the public caused by the performance of tracheotomy (on H.I.H. the Crown Prince) and the possible consequences of that operation. It is now clear even to the non-medical public that tracheotomy does not constitute a verdict in itself either for or against the previous treatment and opinion of the disease on the part of the surgeons in charge of the case. It is clear, too, that the operation has not come unexpectedly to those surgeons, and that it is by no means a last resource. That everything is being done in the after-treatment—and this is for the present the most urgent part of the task—that human agency can do, is beyond question. We have at least the satisfaction of knowing that our first surgeon, von Bergmann, is present in the case, and we hope that he will not remain apart (*fern bleiben*) in

its further treatment. At first sight the mention by Virchow of 'epidermoidal nests' might raise alarm; but the same conditions are evidently present as those referred to by Virchow in his reports of last year, his address on pachydermia laryngi, and his publications regarding his previous reports. Therefore we may not yet give up the hope of a happy termination of this painful crisis; but no one, and least of all we medical men, ought to be surprised if, in such a tedious and severe affection, various contingencies arise, and one day cannot be prophesied from another."

EFFICACY OF VACCINATION AND REVACCINATION.

THE report by Dr. Sinclair White of the history of the small-pox epidemic in Sheffield from its commencement in March last up till the end of last year furnishes some very striking and instructive figures which ought to convince even the most obstinate opponents of vaccination of the unwisdom of their course. Thus it appears that 90 per cent. of the people of Sheffield being vaccinated and 10 per cent. unvaccinated, 97 deaths only occurred amongst the 2,198 vaccinated persons who were attacked, and 157 among the 382 unvaccinated persons who were attacked, the death-rate among the vaccinated being 4.4 per cent., the death-rate among the unvaccinated 41.3 per cent. This, however, relates to the whole population, including those who, not having been revaccinated, had in adult age lost the protection which revaccination would have afforded, and were but imperfectly protected. If the cases of children under 10 years of age be examined the result is still more striking. Of the 100,000 children in Sheffield 95,000 were officially reported as vaccinated and 5,000 as unvaccinated; among the 95,000 vaccinated children there were only 2 deaths, and among the 5,000 unvaccinated there were 70 deaths. It should be noted that in the outbreak of 1857-8, when vaccination was practically voluntary and not compulsory, the figures were exactly reversed. There were 179 deaths among children under 10, and only 11 deaths among the whole population above that age.

AN OUTBREAK OF DIPHTHERIA AT CHELMSFORD GRAMMAR SCHOOL.

THERE has been a serious outbreak of diphtheria at the Chelmsford Grammar School, as to which contradictory reports have been published. We have received an authoritative statement, from which it appears that two of the pupils, Thompson and Belcher, returned to school on January 24th. On the evening of the same day Thompson was taken ill, but being a weekly boarder returned home in the usual course on Saturday, the 28th. He came back to school on Monday, the 30th, in good health, complained of headache on Thursday, February 2nd, and of sore throat on Friday, the 3rd; in the evening of that day he was driven home in an open trap, and was seen later in the day by his medical attendant, who pronounced the case to be one of advanced diphtheria. He died on the following Tuesday, February 6th. Belcher, who on his way passed through London in a railway carriage with the windows open, had on the 26th sore throat and discharge from the nose, which it is stated bled two or three times. On February 5th Dr. Holland found his throat to be red and injected, but did not, it is said, pronounce it diphtheritic, and the boy returned to his fellow boarders. Dr. Gimson is said to have attended this patient on February 12th, and found him suffering from diphtheria. Another boy, Hardy, was also attacked, but recovered. Tweed, who complained of sore throat, pronounced to be diphtheria on February 5th, died on Sunday, the 12th. There were two other boys, but they escaped. All these five boys were in one dormitory, and all of them were boarders in the house. No case occurred among the day boys. The boys were isolated on February 5th, the day on which Belcher's tonsils were found to be reddened and injected, the master having their throats

examined in consequence of being informed by Mr. Thompson that his son had diphtheria. It is difficult to fix absolutely the date of contagion, but the opinion is held that the disease was imported by the boy Belcher, who it is thought might have contracted it in the railway carriage. The mischief was undoubtedly aggravated by the fact that the disease was overlooked by the head master, and by his failing to call in medical advice; it is felt that Thompson should not have been moved as he was, but for this the father was equally to blame with the master. The case of Hammett, seen by Mr. Carter in his capacity of medical officer of health, has not, as reported in the press, ended fatally. It is satisfactory to hear on trustworthy authority that there are no defects in the sanitary arrangements of the schoolhouse. The school itself has been shut up since Sunday, February 12th, the only boy remaining being Hammett, who is still ill.

THE DONDEERS MEMORIAL FUND.

SUBSCRIPTIONS to the Donders Memorial Fund may be sent to either of the secretaries of the Joint Committee appointed by the Ophthalmological and the Physiological Societies, Dr. W. A. Brailey, 11, Old Burlington Street, W., and Professor Gerald Yeo, King's College, London. As we stated a couple of months ago, the occasion of the memorial is the approaching retirement of the eminent physiologist and ophthalmologist from his professorial chair in the University of Utrecht. Professor Donders attains his seventieth year on May 27th, 1888, and the law requires his resignation to take effect from that date; he has been connected with the University for more than forty years, and is at present Professor and Director of the Physiological Laboratory. It is intended that the fund now being raised shall be devoted to some purpose approved by Professor Donders which shall connect his name in a permanent way with the spot where he has lived and worked for so many years, by the creation of a fund devoted to a scientific purpose, and which shall be known as the "Donders Memorial Fund." The rules and special destination of the fund will be drawn up and fixed with the concurrence of Professor Donders, and will be in full accord with his wishes. It is intended that the co-operation of our countrymen should be rather for the purpose of paying a tribute to the world-wide reputation of Donders than of collecting any large sum of money. It is proposed that the amounts contributed by the several donors be not specified, but that they be grouped into a common sum for transmission to the Dutch Committee for any scientific purpose Professor Donders may choose, and that the names of those contributing be inscribed in a suitable form for presentation to Professor Donders. For this reason, smaller as well as larger subscriptions will be acceptable. The English Committee is working in connection with the committee formed in Holland for the same purpose.

THE HOSPITAL FOR CONSUMPTION, BROMPTON.

IN consequence of cases of sore throat occurring among the nurses and servants in July last, the committee of the Hospital for Consumption, Brompton, ordered a searching inquiry to be made by Mr. Rogers Field, M.Inst.C.E., into the drainage of the old building. Portions of this were found defective, partly owing to bad workmanship and partly to the low level of the portion of the building containing the kitchen, the inmates of which had suffered from time to time from sore throat. The committee, therefore, wisely decided to close the old building for some months, and to execute the necessary repairs which, in addition to a complete new system of drainage, include the building of a new kitchen at a higher level, and two commodious dining halls in connection with the Victoria and Albert Galleries. These works are approaching completion, and half the old hospital has been already reopened for patients. The usual Wednesday lectures and demonstrations are now held at 4 P.M., in the large Recreation Theatre of the new

building, which is specially adapted for clinical demonstrations. Those by Dr. Acland, on Mitral Stenosis, have been largely attended. Dr. Theodore Williams will lecture on February 29th and March 7th on the Pathology and Modern Treatment of Bronchial Asthma; and on March 14th will demonstrate the Uses of the Pneumatic Cabinet in Lung Disease. This instrument, invented by Ketchener, of New York, ingeniously combines both atmospheric rarefaction and compression, and is a new departure in aëro-therapeutics.

THE NEW SMALL-POX HOSPITAL AT SHEFFIELD.

THE erection of the small-pox hospital at Lodge Moor was practically completed on Saturday, February 18th. It is less than three months since the contractors, Messrs. Bissett and Sons, were commissioned to proceed with the work. The electric light has been made use of to expedite the construction of the hospital. The building is entirely composed of wood, and contains a dozen wards, which are faced with red wood, and painted; the roofs are covered with thick tar felt. The walls and roof are constructed of a double thickness of boards, with an air-tight cavity of nine inches, with a thickness of felt under the outer boarding of the walls, and the whole is lined with thick Willesden paper. Each ward is heated by a large stove in the centre; air is admitted by gratings near the floor, and is heated by passing over hot-water pipes. Arrangements have been made for the escape of foul air. At present there is accommodation for 90 patients, which can be increased to 120 if necessary. Each ward building has a space of 12 feet by 12 feet, and a cubic space for each patient of 2,000. Close to the patients' rooms are the nurses' bedrooms, whilst in convenient places are attached to each ward nurses' duty rooms, bath room, lavatory, earth closet, closet for sink, coal, coke, and stores. The situation of the hospital will expose it to cruel blasts in the winter. It is four miles from the Sheffield parish church, but communication by telephone with the town is being established. When the hospital is fully occupied there will be a staff of eighteen nurses and sixteen servants. Dr. J. Pearson has been appointed resident medical officer, and Miss Batchelor matron. This building is additional to the Borough Fever Hospital, which is also available.

THE ASSOCIATION OF FELLOWS OF THE COLLEGE OF SURGEONS.

THE Committee of this Association is about to present to the Lord President of the Privy Council a rejoinder to the "reply" of the Council of the College to the Association's statement previously submitted to his lordship. The rejoinder in full will shortly be published in the JOURNAL. The "reply" appeared in our columns on February 4th. In the rejoinder, the Committee of the Association declare that the reply is so misleading that the Lord President's attention is directed to a criticism of its clauses. With regard to the number of Fellows, the electors of the Council, it is steadily diminishing. Though the Fellowship is a requirement for most hospital appointments in London and the provinces, other important surgical qualifications have recently arisen which may make those who hold them eligible for similar appointments in future; then the supply of Fellows by examination would decline yet more rapidly, and the electorate would thus become too small a body for the proper discharge of its functions. Increase of the Fellows by large annual elections would deteriorate the qualification. Sir Benjamin Brodie is then quoted to prove that the Fellowship was initiated by him and originally intended for the introduction of men of higher professional and scientific education, rather than for electoral purposes. It is not correct to say that any Member of two years' standing may present himself for the Fellowship examination, which demands time and money. The so-called privileges of Members are trifling, and their admittance

to the College Museum rests on Act of Parliament. Members are not eligible on the Court of Examiners, but only to certain junior examinations. The passing of a by-law by appeal to the Fellows and Members would not cause "delay and difficulty," as the "reply" endeavours to make out. The question of the election of the President is then explained, and the rejoinder notes that the recent salutary change is the result of pressure from without, which may not continue; and that, if the Council are the best judges of the qualifications of their own members for the Presidency, they have never exercised such judgment, but have, until eighteen months ago, passed the office round in rotation. The College is truly a political institution, and not private. The results of inquiries recently made by the Council are misleading. The Association justly complained that the complete conjoined scheme was not submitted to the whole body of the College of Surgeons as it was to the Fellows of the College of Physicians, and the "reply" attaches undue importance to a resolution on the scheme hastily passed at the general meeting in 1884, neglecting others of equal importance passed almost unanimously in recent and fuller meetings. It is true that the proposal for wholesale annual elections of Fellows was never discussed at a Council meeting, but this was owing to opposition from the Association; and it is certain that the proposal was made. On the above grounds, and on others which will be open to the perusal of our readers next week, the Association declares that the reply leaves the statement unrefuted. In order to prove that the sentiments of the rejoinder are not unrepresented on the Council, the Lord President's attention is directed to the amendment, which was moved and seconded by Mr. Macnamara and Mr. Willett, at the meeting of the Council at which the reply was settled. We publish the amendment this week. Thanks are cordially due to the two members of Council who proposed and seconded it, and we must all feel satisfaction that there are such bold advocates of reform amongst the elect at Lincoln's Inn Fields, men who are doing their best to make into law the recent improved procedures in respect to annual meetings and the election of the President.

PLAGUES ANCIENT AND MODERN.

AT a meeting held at the Parkes Museum on February 16th, Sir Douglas Galton, K.C.B., D.C.L., LL.D., F.R.S., in the chair, Dr. J. F. Payne gave a lecture on Plagues Ancient and Modern. The lecturer compared the distribution of certain specific diseases over the globe to the geographical distribution of plants and animals. They were native or indigenous in certain centres or regions, from which they had at certain times migrated. The history of their migration was the history of epidemics. From the history of the oriental plague—of which the Black Death in the fourteenth century was the most destructive outbreak—it appeared that this great pestilence was derived from Asia. Contemporary witnesses had observed, and indeed accompanied, its march from the borders of Tartary to Italy. The probability was that its original starting-point was still further East, in China or possibly in India and in confirmation of this it was shown that the true plague, in a form closely resembling the Black Death, still exists or has existed within the last few years in both India and China. The original seat of the disease must therefore be placed in one of these countries, probably in China, and its invasion of Europe in the fourteenth century was an instance of migration from its original home. The historical sweating sickness, which prevailed in England in the time of the Tudor kings, was next spoken of. It was thought to be a disease imported from France by the foreign mercenary soldiers of Henry VII, and owed its extraordinary severity to the fact that it was a new disease in England since diseases often spread in a new country with great rapidity and virulence. Another instance was afforded by the introduction of European measles into the South Seas, where, especially in

Fiji, it had caused an enormous mortality. A disease closely resembling the sweating sickness still recurred from time to time in certain parts of France, and a considerable epidemic of it was observed only last year, when it spread through numerous villages and caused a not inconsiderable mortality. In both these cases the old historical pestilences were to be found still existing in modern times, but at a distance from countries in which their most destructive visitations had occurred.

DOG MUZZLING AND RABIES.

A DEPUTATION consisting principally of members of Parliament representing divisions of Lancashire, introduced by Sir Ughtred Kay Shuttleworth, M.P., waited upon the President of the Privy Council (Viscount Cranbrook), on February 16th, asking that the same regulations with regard to the muzzling of dogs should be enforced in boroughs as existed in other parts of the country. Sir Ughtred Kay Shuttleworth pointed out that the regulations enforced by the county authorities were not adopted by the borough authorities, and consequently the efforts of the county authorities were defeated. Other speakers advocated that an order should emanate which would apply to the whole of England. Colonel Moorson, the chief constable of Lancashire, cited statistics showing decrease in the disease as the result of muzzling regulations being enforced. Viscount Cranbrook said, in reply, that the subject was not so easy to deal with as some persons imagined. The House of Lords' Committee, on the subject last year, found that there would be some 300,000 dogs exempted from registration, but he thought it quite possible that it might be well to give extended powers for the destruction of stray dogs. He thought that Lord Mount Temple had a Bill before the House of Lords, or was about to introduce a Bill, which might make it unnecessary for the Government to introduce one of the kind. No doubt such regulations as had been enforced had done a great deal of good. In London the disease had been reduced materially, the number of cases had been brought down to units where it had been tens. He could not hold out any hope that the Privy Council would take the responsibility of making a law for the whole country, but perhaps the deputation would be satisfied with the assurance that the subject was very strongly before him, and that he was very anxious to assist in getting rid of the disease.

A SELF-SUPPORTING PROVIDENT DISPENSARY.

We have received last year's report of the Battersea Provident Dispensary, and can congratulate that institution on its continued success; it may be fairly considered to be self-supporting, the small amount of voluntary subscriptions (£82 9s. 4d.) not seriously affecting the working of the institution. The rules for benefit members are for the most part well adapted for successful working, and the insisting on a wage limit, with payments in proportion to earnings, is decidedly to be commended; on the other hand, we must emphatically condemn the principle of admitting members when sick on the payment of special entrance fees; this, in our opinion, is altogether contrary to the provident principle. There can be no doubt that institutions of this kind are a boon to the industrial classes of our great cities, and that by their means a large proportion of the working classes are enabled to obtain efficient medical attendance in sickness at a very moderate rate. While, however, duly estimating the great advantage of this to the community at large from a public point of view, it cannot be denied that it bears somewhat hardly on the profession as a class; we do not consider the 11s. 2d., which seems to have been the average confinement fee, adequate remuneration for attendance on midwifery cases by qualified medical practitioners, and we also think that any institution which undertakes midwifery at such low rates competes somewhat unfairly with the neighbouring practitioners. We observe that 25,000 professional visits were made in

the year at patients' own houses, by the five medical officers, for a remuneration of £893, or at the rate of £179 for 5,000 professional visits, which we may assume would have been the amount received by each had the work been equally divided; the payment for work done does not seem very munificent. Many busy practitioners would consider 5,000 professional visits, with corresponding consultations at home or at a dispensary, a very fair year's work; and for our own part we do not think there are many who would have the inclination or the time to do much in addition to this, so that it would seem that the medical staff of the Battersea Provident Dispensary must devote nearly the whole of their time to the duties of their office, and, under these circumstances, we cannot consider the scale of remuneration by any means liberal, although we are told it is 60 per cent. of the entire contributions of the members. On the other hand, it is observed by the able and public-spirited clergyman who is the chief promoter of this flourishing institution, that if the rate be "not liberal," it is the profession itself which reduces it. The Battersea Provident Dispensary is described as surrounded by dispensaries, at which, "Advice, 6d., and medicine, 1s.," is given to persons when sick, and where 10s. is charged for confinements. The medical men of the neighbourhood are said to show great willingness and even anxiety to be put on the staff of the dispensary. It is to be remembered, too, that the medical man gives nothing but his advice. The medicine is made up at the drug store in the building. There is no booking of debts, or collecting them, or unpleasant reception of sixpences and shillings from poor folks. It is stated that a medical officer who was most sought after during the last year, a comparatively young man, received a cheque of about £300 clear for each half year.

SCOTLAND.

SMALL-POX IN PORT GLASGOW.

A CASE of small-pox has occurred in a densely populated portion of Port Glasgow. The Greenock Infirmary authorities refused to admit the case to their institution. In the meantime the case has been isolated, and revaccination has been performed on those who were at the time in the same house.

A DANGEROUS WATER SUPPLY.

THE town of Newmilns, in Lanarkshire, seems to be in a very bad way as regards its water supply. The prevalence of fever in certain districts led to an examination of the water, which is obtained from a number of wells. The report stated that the water of one well was a mixture of 1 part of sewage, with 9 of water; of another, 1 part sewage, with 25 of water; of a third, 1 part sewage, with 3 of water; a fourth, 1 part sewage, with $2\frac{1}{2}$ of water; and a fifth, 1 part sewage, with 4 of water. Four other wells were contaminated to a large extent, and only one supplied water free from sewage contamination. A public meeting is to be called to consider this serious state of affairs.

QUEEN MARGARET COLLEGE, GLASGOW.

THIS College is the only one for women which exists in Scotland on lines similar to that of Girton and Newnham. Some years ago an effort was made to ensure the permanence of the institution by the raising of an endowment fund. The buildings of the College, which cost £12,000, were purchased by Mrs. Elder, widow of the well-known Clyde shipbuilder, but will not be absolutely conveyed to the trustees of the College till the endowment fund reaches £20,000. The effort to raise that sum was allowed to pause for a time owing to the extreme depression of business, but it has been again revived, and a sum of nearly £12,000 has now

been reached. During the few years in which the institution has existed its value in affording educational facilities to women has been abundantly proved, and the advantages it offers have been extensively made use of. It is to be hoped that the endowment fund will soon reach the desired amount, and that by the endowment of chairs and the addition of new lectureships, the value of the institution may be still more increased.

ST. MUNGO'S COLLEGE, GLASGOW.

THE prevailing impression with regard to the Bill for the erection of the Glasgow Royal Infirmary into a College of the University is that there is not the remotest prospect of its being advanced to any considerable stage. It is believed that this session the Government means to push forward the Scottish Universities Bill in earnest, and that the chances of a Universities Act coming into existence are better than ever before. Obviously, the question of the affiliation or erection of colleges is one which should come before the Commissioners appointed under such an Act. The satisfactory thing is that university reform, so long talked of, is likely, in part, at least, to be soon realised; and it will be in every way advantageous that the universities as they are be reformed from within before they become extended by the addition of new colleges.

DIPHTHERIA SUBSEQUENT TO MEASLES.

EDINBURGH has recently been visited by a somewhat severe epidemic of measles, and in several cases croup or diphtheria has supervened or complicated the disease. Two or three cases of the latter have required the operation of tracheotomy.

CHAIR OF BOTANY, EDINBURGH.

THE following are the candidates for the Chair of Botany in Edinburgh University (vacant by the death of Professor Dickson), from whom applications and testimonials have been received: Isaac Bayley Balfour, Sherardian Professor of Botany, Oxford; James W. H. Traill, Professor of Botany, Aberdeen University; William Ramsay Macnab, Professor of Botany, Royal College of Science, Dublin; Patrick Geddes, Senior Demonstrator of Botany, Edinburgh University, and Lecturer on Botany, Heriot Watt College; and George R. M. Murray, Senior Assistant, Department of Botany, British Museum, and Examiner in Botany, Glasgow University. The curators of Edinburgh University are the patrons of the Chair, and will probably make an appointment to it this week.

OVERCROWDING AND FEVER IN GLASGOW.

AT a meeting of the Glasgow Town Council held on Monday, a most interesting report was presented by Dr. Russell, medical officer of health, bearing on the relation of overcrowding to the production of the exceptionally large number of cases of enteric and typhus fevers which have occurred in Glasgow during the past fortnight. The number of cases of fever registered was thirty-nine, as compared with twenty-six, namely, twenty-two cases of typhus and 17 of enteric fever. This is the largest number of cases of typhus registered in one fortnight since December, 1885. As usual, the first cases were certified and admitted as enteric fever. The first case, a boy, aged 11, was admitted to hospital on January 16th, but in two of the families from which cases were next removed there was evidence of previous illnesses of children dating back to the new year. It is a frequent experience that typhus begins with the youngest children, and passes unrecognised among the frequent illnesses of children in these localities. Of the fourteen families infected, nine occupied houses of one apartment, four of two apartments, and only one of three apartments. This latter was a case in which a respectable old couple had the services by day of a girl aged 14, who slept in an overcrowded house of one apartment in Richard Street. This was one of the houses in which the appearance of recognised typhus was

preceded by sickness in a child. The girl and the old lady she served both sickened with typhus on the same day, which gives almost a demonstration that typhus was in the house and was transplanted by the servant to the mistress, so as to take root in both at the same time. That is the only assured case of individual infection traced. The circumstances of the other cases are the commonplace ones of overcrowding and dirt. Special house-to-house inspection revealed great overcrowding in certain streets. The want of compulsory power to effect removal to hospital is most felt. There is no other way of getting the clothing of such persons disinfected. One young man thought so much of his new suit of clothes as to abscond with them.

MEDICAL OFFICERSHIP OF HEALTH, ABERDEEN.

THE public conscience of Aberdeen is greatly exercised at present on the subject of the duties of the medical officer of health, and the extent to which the individual who is appointed to that office should devote himself to its duties. A public meeting for the discussion of the subject was held in Aberdeen on Saturday last, and a resolution was adopted to the effect that the medical officer of health should devote his entire time to the duties of the office, and that he should either reside at the city hospital, or that regulations should be made whereby frequent visits might be made to the hospital so as to secure ample medical supervision and general efficiency at the institution. The same topic was the subject of a prolonged discussion in the Aberdeen Town Council on Monday. It was resolved that the salary to be paid should be £300 per annum, and that the medical officer of health should visit the City Fever Hospital at least twice a day, but that he need not necessarily reside there. The Public Health Committee had recommended that the officer should reside in the hospital, but by twelve votes to nine the above resolution was adopted. As a sequel, Dr. Maitland Moir, convener of the Public Health Committee, intimated his resignation of that office.

IRELAND.

DR. CROKER KING.

THIS gentleman, who has been suffering from gangrene of the foot, is somewhat better. A definite line of demarcation has formed, and it is hoped that the result will be satisfactory.

NORTH DUBLIN UNION.

A sworn inquiry was held at the North Dublin Union on Tuesday, February 21st, regarding the quality of meat supplied to the paupers. Dr. Kenny, M.P., one of the medical officers, said he had often rejected meat as unfit for human food. He had found pieces actually green. On one other occasion he found the meat too fibrous and fat. On one occasion he rejected the whole of the meat for the inmates of the new buildings. Dr. Minchin said he had never observed the meat to be bad.

MERCER'S HOSPITAL.

AT a meeting of the Hospital Fund Committee last week, a motion was passed omitting Mercer's Hospital from the list of hospitals entitled to a share of next year's grant. This action was proposed by the Rev. Dr. Haughton, and there were only one or two to say a word in defence of the hospital. It was pointed out that the inevitable result would be that the Corporation would also withdraw its grant. An ex-governor stated that he was dissatisfied with the management, and particularly with the intention to spend some thousands on new wards while it was found impossible to keep all the existing beds open. Finally, the Committee adopted Dr. Haughton's proposal with but one dissentient. A morning journal calls loudly for the retirement of those governors who have never given a penny to the funds. As to the

expenses incurred by the late investigation, it says: "We think that these expenses ought to be borne by the individual members of the Board, and that those who have so long posed as philanthropists at a cheap rate ought now to put their hands in their pockets, and pay up the costs involved by their own incompetence and mismanagement." This is the general opinion.

FOOD-POISONING.

A NUMBER of adult inmates and children of the Belfast workhouse have suffered poisonous symptoms after eating portions of buns supplied to them. The medical officer found twenty-three children on the floor vomiting, and some of them screaming. Ten of the men had to be removed to the hospital, but all have recovered. The guardians have directed an analysis of the remaining buns to be made.

THE DISMISSAL OF DR. MAGNER.

A MEETING of the Timoleague Dispensary Committee was held recently, in reference to a communication from the Local Government Board relative to Dr. Magner, who had been elected a few weeks since to the post of medical officer of the district. The letter stated that the conviction and sentence of Dr. Magner, for criminal conspiracy, having been confirmed on appeal, the Board declined to sanction the appointment of Dr. Magner as medical officer to Timoleague dispensary district; and requested the committee to appoint another person as medical officer. The committee adjourned until this week to consider the matter.

DEATH OF THE PROVOST OF TRINITY COLLEGE.

THE death of the Rev. J. H. Jellett, Provost of Trinity College, occurred on Sunday evening, after a few days' illness; it has caused widespread regret. He was a very distinguished mathematician, but in medical circles his loss will be most felt, because of the enlightened encouragement which he gave to the development of the medical school connected with his university. He died of acute pyæmia. On Thursday he complained of sore throat, followed by rigors. On Saturday an abscess had developed near the elbow, and it was at once opened; but he gradually sank, and died on the following evening. His funeral was very largely attended.

ALLEGED DEATH FROM STARVATION.

Mrs. CROOKE, of Coachford, County Cork, who was arrested on a charge of having caused her husband's death, has been allowed out on bail until the trial takes place. The following is the evidence of Dr. Crawley, who made a *post-mortem* examination of the deceased with Dr. White:—The body was greatly emaciated, in fact it was a mass of skin and bone. There was hardly any subcutaneous fat, and only a trace in the omentum. The bladder was contracted and empty; the lower bowel was also empty; the intestines were empty and collapsed; the stomach contained some gas and a small quantity of some coloured fluid and a little mucus; the coats were thin; the kidneys were healthy, no surrounding fat; liver small, but healthy; gall bladder greatly distended. On opening the chest some old pleuritic adhesions were found, and in the upper portion of the lungs a number of caseous deposits; all the organs were bloodless; the heart somewhat enlarged, with a tendency to fatty degeneration; the right ventricle contained a small quantity of blood, the other chambers were empty; the aortic valves were defective. In his opinion the cause of death was due to starvation in a man reduced by chronic pulmonary disease; he believed if he had had proper treatment and diet he might have lived for a number of years.

THE MEDICAL SERVICE AND THE INTERESTS OF THE PLANTERS AND COOLIES IN BRITISH GUIANA.

WE have already on several occasions referred to the agitation against the new constitution of the medical service of British Guiana, which has indirectly led to a political crisis in the colony. The main issue has been obscured by the introduction of a variety of collateral interests and subsidiary incidents, but the broad facts, as they appear in the official reports of the colony, are of sufficient importance to warrant further reference to them here.

The Medical Service.—By the passing of the Medical Ordinance in August, 1886, the position of the Medical Service underwent a complete change; in particular the Immigration Medical Service ceased to be a sub-department of the Immigration Department, and became an integral part of an independent Medical Department, which, among other duties, was responsible to the Government for the medical and sanitary state of the immigrants.

Immigrants.—The immigrants are chiefly coolie labourers from the East Indies, who enter into indentures to work for five years on the sugar estate for which they are required. At the end of that time they are free to move to other estates or to leave the colony, but cannot claim a free return passage until after the expiration of ten years in the colony. It will be admitted to be the duty of the Government to see that the rights of the coolies are maintained, since they have themselves no constitutional means of asserting them.

Constitution of the Colony.—The constitution of the colony is peculiar and obsolete. Legislative authority is exercised by the Court of Policy, a body of ten members, divided into two sections—(1) the official section consisting of the Governor and the four heads of the principal Government offices, and (2) the elective section consisting of five persons, who must be owners of land in the colony, chosen by the Court from a double nomination sent up by seven persons who form a body called the College of Electors holding office for life. The elective section thus represent the planters, and from the perusal of official reports and of the local newspapers it may be gathered that Sir Henry Irving, the Governor, who has just retired, when advising improvements in the sanitary and other surroundings of the coolies and of the free labourers, has frequently found himself in conflict with the elective members of the Court of Policy and with the organs of planter opinion in the press.

The Medical Inspector's Report.—In 1886, as has been stated, the medical and sanitary care of the immigrants was among the duties taken over by the Medical Department; it therefore became the duty of that department to make itself acquainted with the existing state of the dwellings on the estates, and of the hospitals required to be provided on each estate. The office of medical officer to the Immigration Department having been merged in that of medical inspector under the new Medical Ordinance, this officer (Dr. A. D. Williams) undertook to make, during the course of his inspections, a detailed report on the medical and sanitary state of the immigrants. Some idea of the magnitude of the human interests involved may be gathered from the fact that the population of the estates inspected was estimated in the middle of 1886 at 70,312, the total population of the colony at the same date being estimated at 274,311. The report pointed out a number of particulars in which the planters were represented to have failed in their duty. With regard to the *Estate Hospitals*, overcrowding, especially in the wards for women and children, imperfect ventilation, bad latrines, general faulty design, and insufficient supply of bedding and clothing were among the chief defects noted separately or simultaneously in a large proportion of those inspected. With regard to *dwellings*, bad design, disrepair, defective ventilation, absence of any provision for removal of excrement, defective drainage, contamination of water supply by excremental products and surface drainage, were defects found very frequently to exist. With regard to *immigrant ships*, defective ventilation and inadequate hospital accommodation are noted. The report concludes with a number of statistical tables and comments thereon.

The *death-rate* among indentured immigrants is stated to be 27.4 per mille, which, when it is remembered that the immigrants are young adults selected in Calcutta as healthy, is undoubtedly high; it must however be noted that in another part of the report it is stated that a large proportion of them are affected by chronic visceral and intestinal diseases when landed; the death-

rate in hospital was equal to 18.8 per mille of the estate population; of the deaths occurring on the estates, but out of hospital, a very large proportion, estimated at 6 to 10 per cent., were due to accidents or other forms of violence. Suicide and wife murder account for a certain number, and the majority of the others were attributed to unprotected machinery and faulty construction of tramways.

Villages.—Dr. Williams's report stated that the larger villages, inhabited chiefly by the negroes born in the colony, had been greatly improved by main drainage, but that many of the smaller villages where this had not been done were worse than the estate dwellings: the most exaggerated insanitary conditions were found in certain free coolie communities squatting on uncultivated parts of sugar estates.

The Indignation of the Planters.—The elective members of the Court of Policy, representing the planters, denied the general accuracy of the statements in the report, and asked Dr. Williams to substantiate them by giving specific details. Dr. Williams was about to leave the colony on leave of absence, but in consequence of the demand made by the elective members of the Court of Policy, the Governor, Sir Henry Irving, required him to stay for another month, in order to furnish explanations to the Government. At the end of this period, and having discharged this duty, Dr. Williams was allowed to proceed on leave. The elective members took great umbrage at this, and demanded that Dr. Williams's report should be withdrawn. The Governor offered to furnish to them the additional particulars reported to him by Dr. Williams, in explanation and extension of his previous report. The elective members, however, being exasperated by what they considered the unconstitutional course of the Governor, withdrew from the Court of Policy, and thereupon ensued a deadlock in the government of the colony. Appeals were made to the Colonial Office by both parties; the Secretary of State decided that the report could not be withdrawn, but directed the Governor to make public all the information in his possession bearing on this subject. The further facts and details which Dr. Williams had been required to furnish were then published, and the elective members subsequently resumed their duties; before this however, Dr. Grieve, the surgeon-general of the colony, who had been absent on leave, returned, and in a report dated October 24th, which he has forwarded to us, had stated that the requirements of the immigration ordinances, and the regulations under them, had not been enforced in their entirety and, passing in review the various heads of Dr. Williams's report, confirmed their general accuracy. We are informed that Mr. Alexander, the immigration agent, has recently issued a report on Dr. Williams's report, in which he enters into a minute analysis, and traverses a large proportion of the statements, but this has not reached us.

Present State.—Improvements have already been made in the Estate Hospitals. Addressing the Surgeon-General on November 3rd, 1887, the Government Secretary writes: "As regards the sanitary condition of the immigrant population on the estates, the report of Dr. Williams appears to disclose a state of things which is prejudicial to health, and which, in the event of an invasion of epidemic disease, might be productive of serious consequences.....The conclusion to be drawn from Dr. Williams's report is, that there has been more or less sickness and mortality among the immigrant population which is preventable, being due to causes which are remediable, the chief amongst which causes are insanitary conditions." Dr. Grieve is requested as soon as possible, to satisfy himself as to the actual sanitary condition of the estates. Sir Henry Irving's term of office having since expired, he has been succeeded by Viscount Gormanston, and we may venture to express the hope that the new Governor will hold the balance true between the pecuniary interests of the planters and the welfare of their coolie labourers.

ROYAL COLLEGE OF SURGEONS.

At the extraordinary meeting of the Council of the College, on January 19th, after the reading of the reply of the Council to the statement presented to the Lord President of the Privy Council by the Association of Fellows, the following amendment was moved by Mr. Macnamara and seconded by Mr. Willett, but was lost, two members only voting in its favour:

"That paragraph 5 and all the succeeding paragraphs be omitted, and that in place thereof the following be inserted:

"5. The Council desire to state that they are in accord with the four resolutions passed at the meeting of Fellows and Members on

the 24th March, 1884, which are set out in paragraphs 9 to 12 of Mr. Pellock's statement to the Privy Council.

"6. The Council believe that the authority and influence of the College would be enlarged and strengthened if the proposed supplementary charter contained clauses giving effect to those resolutions.

"7. The Council are of opinion that the precedent established in 1843, when in the charter obtained in that year provision was made for calling an annual meeting to elect members of Council, should be followed now that the Council have decided to call an annual meeting to which a report from the Council shall be presented.

"8. Seeing that the practice of annual election of the President by seniority merely has ceased to exist, the present President being in his third year of office, the Council are ready to consider whether the continuance of this altered custom should not be ensured by empowering the Fellows to elect the President and Vice-Presidents on some scheme of the candidates for those offices being nominated by the Council and the Fellows. Such a scheme, when settled, would require to be enacted by the charter, as it would entail the calling of an annual meeting of the Fellows.

"9. The Council recognise the fact that, unless the calling of the annual meeting of Fellows and Members and the alteration in the customs of electing the President are made obligatory by the terms of the charter, there is a risk of these concessions becoming inoperative, inasmuch as at present their continuance depends only on the decision of the Council.

"10. The Council regret that, when issuing a circular to the Fellows in 1887, with the object of obtaining their opinion on the questions of Members of the College being empowered both to vote at the election of members of Council and to be eligible for seats in the Council, they did not address inquiry to the Fellows with the object of learning their opinion as to the Fellows electing the President; but, seeing that during the four years the agitation of this subject has lasted no remonstrance from any Fellow has been received by the Council, it may be assumed the Fellows at large really desire this change. Moreover, it would appear inconsistent to speak of the Fellowship representing a higher grade than the Membership, and to admit the qualification of the Fellowship as an elective body for the membership of the Council, and yet to doubt the capacity of the Fellows to elect their own President, or, if capable, to infer that they are not to be trusted with the duty. The Council feel that this change will have the effect of approximating the constitution of the College to those of all the Royal Colleges of Physicians or of Surgeons in England, Scotland, and Ireland, in every one of which, with one exception (namely, the Royal College of Surgeons of Ireland) the Fellows meet at stated periods in their respective Colleges to discuss and approve the acts of the Council."

The above is published as part of the minutes of the Council which are suspended in the hall of the College. Being of considerable importance, we publish it in full.

MEDICAL DEGREES FOR LONDON STUDENTS.

The following letter has been received by the Honorary Secretaries of the Association of General Practitioners.

59,652.

Council Office, February 17th, 1888.

SIR,—I am directed by the Lord President of the Council to inform you that the Lords of the Council have determined to hear counsel in the matter of the petition of the Royal College of Physicians of London and of the Royal College of Surgeons of England for a charter to incorporate the Presidents and certain Members of those Colleges under the name of "The Senate of the Physicians and Surgeons," with power to grant degrees in medicine and surgery, but that their lordships will not be prepared to do so before Monday, April 16th next. His lordship instructs me to state that you will be duly informed of the day and hour when they are definitely fixed.

The Lord President further instructs me to transmit to you a list of petitioners, together with the names and addresses of their agents, with a view, where practicable, to a joint case being submitted to their lordships.

I am to add that twenty-five copies of the case to be submitted (printed in accordance with the directions contained in the rules established by Order in Council of March 24th, 1871) should be lodged at this office on or before March 31st next.—I am, Sir, your obedient servant,

(Signed) C. L. PEEL.

SENATE OF PHYSICIANS AND SURGEONS.

	Precis of Petitions, etc.	Agents and Others.
From the ● Royal Colleges of Physicians of London and of Surgeons of England.	Petition for a charter to incorporate the Presidents and certain Members of those Colleges with power to grant degrees in medicine and surgery.	Messrs. Field, Roscoe and Co., 36, Lincoln's Inn Fields, London, W.C.
Association of General Practitioners.	Letter requesting that they may have an opportunity of urging their views with regard to the application for the grant of the charter.	H. W. Verdon, Esq., M.D., 414, Clapham Road, London, S.W.
Cambridge University.	Request that they may have an opportunity of making a representation before the charter is granted.	The Vice-Chancellor, St. John's Lodge, Cambridge
London School of Medicine for Women.	Request that in the event of the charter being granted provisions may be made that examinations should be open to women as well as to men.	Mrs. Garrett Anderson, M.D., 30, Henrietta St., Brunswick Square, London, W.C.
Faculty of Medicine of Queen's College, Birmingham, and associated hospitals.	Pray that in the event of the charter being granted the students of Queen's College and other provincial medical schools may be admitted to examinations for degrees.	A. H. Carter, Esq., M.D., 2, Temple Row, Birmingham.
The Owens College, Manchester.	Pray that in the event of the charter being granted the interests of provincial students may be protected.	The Principal, The Owens College, Manchester.
The Victoria University, Manchester.	Pray that the charter may not be granted.	The Vice-Chancellor, The Victoria University, Manchester.
Trinity College, Dublin.	Similar prayer.	Messrs. Law, Hussey and Hulbert, 10, New Square, Lincoln's Inn, London, W.C.
Edinburgh University.	Similar prayer.	Messrs. Dumford and Co., 38, Parliament Street, Westminster, London, S.W.
Durham University.	Similar prayer.	The Warden, University of Durham.
London University.	Request that the charter may not be granted without their having an opportunity of being heard on the subject.	The Registrar, London University, Burlington Gardens, London, W.
University and King's Colleges, London.	Request to be heard before the charter is granted.	The Secretary, University College, London, W.C.
Glasgow University.	Pray that the charter may not be granted.	W. A. Loch, Esq., 3, Westminster Chambers, Victoria Street, Westminster, London, S.W.
Aberdeen University.	Similar prayer.	The Principal, University of Aberdeen.
The Yorkshire College.	Similar prayer.	The Dean of the Medical Department, Yorkshire College, Leeds.
Society of Apothecaries.	Oppose grant except on condition that their Licentiates shall be at liberty to present themselves at the examinations, and that their diploma shall be a qualification for candidates at such examinations.	Messrs. Upton, Atkey, and Upton, 14, Austin Friars, London, E.C.
Royal University of Ireland.	Against the grant of the charter.	The Secretaries, the Royal University of Ireland, Dublin.
Association for Promoting a Teaching University for London.	Request to be heard in the matter.	John Marshall, Esq., 10, Savile Row, London, W.
Oxford University.	Pray that the charter may not be granted, at least until provision is made to ensure that candidates for degrees shall have received a sufficient preliminary education in literature and science.	The Registrar of the University, Oxford.

desirable to raise opposition in Parliament, and to communicate thereon with the Medical Council and with the Privy Council. It will appear from the following statement by the President of the Pharmaceutical Society that amendments have been made in the Bill as now put forward with the object of meeting these objections. In submitting the amended Bill to the Council of the Society he spoke as follows:

The objection to the waiving clause was raised by the Parliamentary Bills Committee of the British Medical Association, who were under the impression that at some time or another the Council might possibly waive everything to everybody with a view to making money. It appeared that that sort of thing had been done by certain medical examining bodies, and consequently it was thought, rather unfairly, that it might be done by a pharmaceutical examining body. To meet that objection the waiving clause had been struck out. Lastly, there was an objection by the Parliamentary Bills Committee of the British Medical Association, which was pressed so far as to result in a visit by the President of the Medical Council to the Privy Council on the subject. That Committee seemed to think there was a possibility in future that chemists and druggists qualified under the Act might be considered medical men, because one of the subjects of the course of study was *materia medica*. This objection seemed rather far fetched, inasmuch as this subject had already been examined in under the Acts of 1852 and 1868. But as there was so much jealousy nowadays, and young medical practitioners, no doubt, like others, felt the struggle for existence very keenly, it was thought as well to pay some attention to these scruples. In the House of Commons *materia medica* meant "medical materials," and perhaps in that House there might not be a clear distinction between an understanding of these things and the practice of medicine. He did not think it was a compliment to the House of Commons to suppose such a thing. The Society had no desire to encourage medical practice among chemists and druggists, its desire being to produce educated pharmacists, and as the better this was accomplished the less likely were such men to attempt to practise medicine, the Committee had fallen in with the suggestion of the authorities of the Privy Council that certain words should be introduced, to the effect that this Bill should be read as one with the previous Pharmacy Acts. Accordingly, in Clause 4 the Committee had inserted the words: "and this Act shall be construed as one with the Pharmacy Acts, 1852, 1868, and 1869." That meant that, as there was in the Act of 1852 a clause which stated that nothing therein contained should entitle the Society to examine in medicine, surgery, or midwifery, that clause would be considered to be incorporated in the present Bill. These were the changes which had been introduced into the Bill of last year to meet the objections which had been raised; but as it was possible that still further objections might be raised during the progress of the Bill, he hoped that the Committee would be empowered to deal with them if they arose.

ROYAL COMMISSION ON HIGHER EDUCATION IN LONDON.

WE have authority to state that Lord Granville, as Chancellor of the University of London, supported by Lord Derby, Lord Kimberley, and Lord Herschell, members of the Senate, will at once urge upon the Government the desirability of appointing a Royal Commission to inquire into the present state of the higher education in London, as well as the claims raised by various bodies to confer degrees in medicine. We may add that, in the meantime, the Privy Council have received no less than fifteen petitions from universities and other public bodies against the application of the Colleges of Surgeons and Physicians of London to grant such degrees, and that on or after April 16th these various bodies will be admitted to appear by counsel before the Privy Council. The question is one of such great complication and importance, that we can confidently assure the Government that the course pursued by Lord Granville is that which will best meet the views of the medical profession.

THE PARLIAMENTARY BILLS COMMITTEE OF THE BRITISH MEDICAL ASSOCIATION AND AMENDMENT OF THE PHARMACY ACT.

The Council of the Pharmaceutical Society has made arrangements for the reintroduction of the Pharmacy Acts Amendment Bill. It will be remembered that, in laying this Bill before the Parliamentary Bills Committee, the Chairman pointed out certain clauses which were objectionable, and to which it was thought

RESORCIN IN DIPHTHERIA.—Dr. Taja has treated 36 cases of diphtheria with resorcin spray, 34 of these recovered. The mortality in the same epidemic, where this treatment was not followed, amounted to 93.28 per cent.

THE CASE OF PARASITIC FŒTUS.

IN the JOURNAL for February 11th we mentioned the case of Laloo, the Indian youth who is now being exhibited in London. Messrs. Sutton and Shattock presented a systematic report on the case to the Pathological Society, at its meeting on Tuesday last. A short account of what is known of Laloo may interest our readers. When the practitioner is called in to a labour, and finds that a monster is born alive, the chance of its living must be a matter of high importance for him to determine. Laloo and A-Kee both lived to be youths, and Laloo lives still in very good health, with a whole trunk hanging from his epigastrium. Bartholin's case, Lazaro Coloredo, of Genoa, born in 1716, lived to manhood with a parasitic fœtus, consisting of a head, trunk, arms, and one lower extremity; the face of the parasite had closed eyes and distinct ears and lips. The mouth bore teeth, saliva continually dribbled from it, and it did not take in any nourishment, yet was said to breathe distinctly. A small beard grew from the parasite's face at puberty. Coloredo was probably the most extreme case of monstrosity who ever lived beyond infancy.

Of double monsters, there is one division where the two organisms are each self-supporting (autosites), and of nearly equal size. The union may be very close, the trunk or even the cranium being more or less fused; such monsters cannot live; or it may be less intimate, the lower part of the trunks being partially united, as in Millie Christine, the "two-headed nightingale;" or, lastly, the union may consist of a mere band joining two perfectly distinct,

well-formed human beings, as in the Siamese twins. In the second division of double monsters, one of the twins undergoes arrested development very early in life, and becomes a "parasite," hanging from its brother the "autosite."

The parasite nearly always consists of trunk and limbs without head, rarely of head and trunk, with arrested development of the lower extremities, very rarely of an ill-formed head alone. The parasite is generally attached to the lower part of the sternum of the autosite (thoracopagus parasiticus, Laloo's case), but it may lie posteriorly, joined to the sacral region (pygopagus parasiticus), or very rarely to the face of the autosite (prosopopagus parasiticus). In pygopagus parasiticus the parasite may be represented by a mere rudimentary limb growing from the sacral region of a well-formed autosite. But there is evidence that the "congenital sacral tumour," even when destitute of any trace of the formed structures of a human body, really represents a parasite. The anomalous sacral appendage in the case which Mr. Owen exhibited at the Pathological Society on February 7th (JOURNAL, February 11th, p. 208), was in all probability a parasitic fœtus. Lastly, the parasite may be entirely subcutaneous; thus an ill-

developed minute fœtus has been discovered in a subcutaneous cyst in the epigastrium of a child not quite 3 years old.

Laloo, of Oudh, is thus an example of thoracopagus parasiticus. From notes taken from a previous report made abroad, and from what we have observed, we learn that he is now 17 years of age. At birth the head of the autosite presented, the hands of the parasite encircling his neck. Laloo's father, mother, brothers (two), and sister were not deformed. His mother was about 25 when he was born, and her firstborn saw the light a year before Laloo. This excludes any theory in the present case of early Oriental marriages as a cause of monstrosity. At the age of 2 Laloo had small-pox; the parasite and autosite are slightly marked. Laloo is short, slenderly made, of very dark complexion, with sharp Asiatic features and straight black hair. He, the autosite, bears no other deformity beyond his parasite. The parasite is firmly adherent to the autosite, at the lower part of the right side of the sternum close to the ensiform cartilage. The woodcuts, from a photograph taken two years ago, give a fair idea of its appearance. The parasite is divided by a very deep groove in the integuments into two parts. The first and smaller part includes both upper extremities and the rudimentary shoulder-girdle, the integument bearing mamme. This part appears as though it were attached to the autosite and to the other part of the parasite by two ball-and-socket joints. The larger division of the parasite consists of the lower part of the trunk, a well-developed gluteal region, which looks forward and to the left, and the lower ex-

tremities. This division appears to be attached to the autosite an inch below and to the right of the smaller part, and is not so freely movable. The skin bears the mark of an old burn from a paraffin lamp. The anterior part of the parasite's body lies towards the autosite, and bears a well-formed penis (shown in the woodcut) surrounded by pubic hair, but no testicles. There is a notch between the glutei, which bears a distinct though rudimentary anal involution of the integument. A rudimentary iliac crest and a diminutive sacrum can be felt. It must be remembered that a parasite is destitute of a vertebral column. This curious deficiency is well shown in specimen 129 in the Museum of the Royal College of Surgeons, Teratological Series. It is a kitten's skeleton bearing a thoracopagus parasite. The latter consists of the bones of the lower extremities, free, and the bones of the upper fused together. A ligamentous band, running to a wide oval fissure in the sternum of the autosite, is the sole representative of anything like a central axis.

The upper extremities in Laloo's parasite can be freely rotated in every possible direction at the shoulders; the autosite can cause them to clasp his own neck, as shown in the woodcut. The right elbow-

joint is ankylosed, the forearm disproportionately short; the hand, which bears four fingers and no thumb, is flexed on the wrist. The left thumb is flexed on the malformed wrist; the fingers are finely formed, but small and webbed. The thighs are well-developed, the knee-joints appear imperfect, the legs are strongly flexed on the thighs, and a sharp fold of redundant integument lies over the popliteal regions. There is talipes varus on both sides; the feet are not disproportionately small. The left toes are perfect, the right foot bears but three.

The integuments of the parasite are not highly sensitive. Urine flows away from the urethra frequently, and the autosite cannot recognise any desire for micturition from the parasite, nor feel any sensation during the passage of urine from the parasite till he feels that fluid damping his body. This we could prove when we superficially examined Laloo; the day was cold, the parasite was exposed naked for ten minutes whilst the autosite was well wrapped up, and felt no desire to make water. The parasite is evidently acardiac, but there is distinct evidence that it has intestine. In a foetal pig with a thoracopagous parasite (Museum R. C. S., No. 123) the parasite has a small piece of intestine connected with that of the autosite by a long narrow gut. Such an arrangement would be a source of danger to an autosite, especially should the parasitic diverticulum be to the least degree pervious where it joins the autosite's intestine. One kidney at least must be present. Whether the presence of a urinary apparatus is or is not a source of danger to the physiological commonwealth of which the parasite and autosite must necessarily consist is a question not easily solved.

These cases of "heterologous union," or "heterodidymus," are developed apparently in a manner succinctly expressed by Mr. Benjamin Lowne: "a second embryo becomes wedged in between the visceral arches or laminae of another before they unite." Hence, the development of the second is arrested. Abnormalities of the viscera of the autosite adjacent to the attachment of the parasite are frequent; thus the liver may bear an unusually large number of lobes, or there may be two gall-bladders.

Of Laloo's adventures we need say little. He was in this country a few years ago, but was prevented from exhibiting at the Indian Exhibition, owing to some question of the right of his guardians to make a show of him. We are informed that at one place where he was displayed to the public his exhibitor was ordered by the authorities to desist, as he constituted an "indecent exhibition." Any attempt to amputate the parasite, or even a part of the parasite, would clearly be dangerous; surgery of this kind is known to be highly unsatisfactory.

A very complete description of parasitic monsters may be found in Dr. A. Förster's *Missbildungen des Menschen*; of Laloo we shall hear more when the next volume of the *Transactions of the Pathological Society*, containing Messrs. Shattock and Sutton's report, is published.

ST. GILES (Population, 45,178).—*Insanitary Areas: Glanders in a Horsekeeper*.—Some years ago, the Shelton Street area, a part of this district, was reported upon as insanitary, and in each successive report has Mr. Lovett drawn attention to its defective condition. In the report for 1886, we again find it referred to as exercising an injurious effect on the death-rate; but during the past session, and since that report was made, Parliamentary powers have been obtained for dealing with this area. In the subdistrict of St. Giles South, which comprises this group of streets, there was an increase in the death-rate, but in both the other subdistricts a considerable reduction. In Shelton Street itself the rate for the year was as high as 53.5 per 1,000. The zymotic death-rate was slightly in excess of that for all London: deaths from measles, whooping-cough, and diarrhoea being above the average. Mr. Lovett states that in no two diseases are the dangerous symptoms more commonly overlooked than in whooping-cough and measles. The latter disease was particularly fatal among the children in the poorer parts of Bloomsbury, especially during the summer months. Many of the nights being unseasonably cold, the disease became complicated with bronchitis and pneumonia, which quickly produced fatal results. Deaths from typhoid fever were very few, and so were those from scarlet fever. Typhus fever attacked four children, members of one family, residing in Nottingham Court. After removal to hospital, no further ease was reported. Towards the end of the year a milk seller's horsekeeper was stated to have died from glanders. Apparently there was no illness among the horses, and a veterinary surgeon had certified to their healthy condition.

ASSOCIATION INTELLIGENCE.

ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No member can be elected by a Branch Council unless his name has been inserted in the circular summoning the meeting at which he seeks election.

FRANCIS FOWKE, *General Secretary*.

COLLECTIVE INVESTIGATION OF DISEASE.

THE Report upon the CONNECTION OF DISEASE WITH HABITS OF INTEMPERANCE, which was presented to the Section of Medicine in the Annual Meeting of 1887, and a further portion of the Report upon OLD AGE have been completed, and will shortly be published in the JOURNAL.

Reports upon the two remaining inquiries, namely, that into DIPHTHERIA, and that into the GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES, are in preparation, and will be published as soon as ready.

The following inquiry only of the first series remains open, namely, that on THE ETIOLOGY OF PHTHISIS.

A fresh inquiry into the ORIGIN AND MODE OF PROPAGATION OF EPIDEMICS OF DIPHTHERIA has just been issued.

Memoranda upon these subjects, and forms for recording observations, may be had on application to the Secretary of the Collective Investigation Committee, 420, Strand, W.C.

BRANCH MEETINGS TO BE HELD.

SOUTH-EASTERN BRANCH: EAST AND WEST SUSSEX DISTRICTS.—A conjoint meeting of the above districts will be held at the Grand Hotel, Brighton, on Thursday, March 22nd. F. W. SALZMANN, M.R.C.S., will preside. Meeting at 3.30 P.M.; dinner at 5.30 P.M.; charge 6s., exclusive of wine. The following papers will be read: Dr. Starling: A case of Fibroid Induration of the Stomach (with specimens). Gentlemen desirous of making any communication to the meeting should write to the undersigned or to Dr. Gostling, West Worthing.—T. JENNER VERRALL, Honorary Secretary, 97, Montpellier Road, Brighton.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT.—The next meeting of the above District will be held at Ashford, on Thursday, March 15th. Dr. Wilks in the chair. Anyone wishing to send communications should inform the Honorary Secretary at once.—W. J. TYSON, 10, Langborne Gardens, Folkestone.

BATH AND BRISTOL BRANCH.—The fourth ordinary meeting of the session will be held at the Museum and Library, Bristol, on Wednesday evening, February 29th, at half-past seven o'clock; G. F. BURDER, M.D., President. The following cases will be exhibited at 7.30 P.M. precisely:—F. St. John Kemm, M.D.: Graves's Disease Treated with Strophanthus. C. A. Wigan, M.D.: Pseudo-Hypertrophic Paralysis. J. Michell Clarke, M.B.: 1. Infantile Hemiplegia (without Atrophy)—three cases. 2. Infantile Paraplegia (with Atrophy). 3. Infantile Paralysis of Muscles passing from Spine to Scapula. E. Markham Skerritt, M.D.: 1. Advanced Bulbar Paralysis. 2. Complete Special and General Hemianesthesia. The following communications are also expected:—H. Ormerod: Spina Bifida, with Specimens. C. P. COOMBS, M.D.: On Splenic Leukemia. N. C. DOBSON: A Case of Hydatid Cyst of the Omentum. C. F. PICKERING: The Treatment of Discharge from the Ear. W. J. PENNY: A Case of Acute Intestinal Obstruction, with Early Operation and Successful Result.—E. MARKHAM SKERRITT, R. J. H. SCOTT, Honorary Secretaries, Clifton.

EAST SURREY DISTRICT: SOUTH-EASTERN BRANCH.—The spring meeting of this District will be held at the Queen's Hotel, Upper Norwood, on Thursday, March 8th, at 4 P.M., W. F. R. BURGESS, M.D., of Streatham, in the chair. Dinner at 6 P.M.; charge, 7s., exclusive of wine. The following papers have been promised: Mr. Noble Smith: On Hip-joint Disease, with diagrams. Dr. P. T. DUNCAN: On Simple Catarrhal Fever. Members desirous of exhibiting or reading notes of cases are invited to communicate at once with the Honorary Secretary, P. T. DUNCAN, M.D., Croyden.

BRITISH GUIANA BRANCH.

THE annual meeting of this Branch was held at the Public Hospital, Georgetown, January 6th, 1888. There were present Dr. GRIEVE, the Surgeon-General, in the chair; Drs. Anderson, Hillis, Wallbridge, Honiball, Veendam, Massiah, Delamere, Rannie, Reid, Hill, Hulton, Law, Fulton, Teixeira, E. G. Leary, Ozanne, and the Secretary.

Letters of apology and telegrams were read from those who were unable to attend.

Chairman's Address.—After the minutes of last meeting had been read and confirmed, the CHAIRMAN delivered a short address,

in which reference was made to the very successful year the French had just closed. A general view of the progress of medicine was taken, special mention being made of the transmission of disease from lower animals to man. The political status of the profession in the colony was touched upon.

Vote of Thanks.—A vote of thanks was given to the Surgeon-General for his address.

Dr. Massiah's Motion.—Dr. MASSIAH brought forward the motion standing in his name; this was seconded by Dr. E. G. LEARY. Dr. LAW moved an amendment to the effect that the Committee should strictly confine itself to the pathological condition of the bone, and after some discussion this was carried by a majority of seven.

Notice of Motion.—Dr. HONNALL handed in notice of motion as to the Surgeon-General being *ex officio* President, and as to voting by proxies.

Specimens.—Notice was read by the SECRETARY of specimens sent by Dr. A. Dickson of Ovarian Pregnancy, Guinea Worm, etc.

SPECIAL CORRESPONDENCE.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

Cocaine Poisoning.—Variations of Microbes under Cultivation.—

Transmission of Tubercle by the Air Passages.—Farcy in Man.

Dr. J. DÉJERINE records an interesting case of poisoning by subcutaneous injections of cocaine. The patient was a young dentist, aged 26. M. Déjerine found him in a semi-comatose state, with generalised muscular contraction of the arms and legs. The arms were slightly bent, the legs were stretched out; the knee-jerk was not discernible owing to contraction. The pulse was quick but regular (120), the breathing hurried; the eyes were closed, the pupils dilated and insensible to light. There was complete unconsciousness. The following lesions were detected on the skin: There was a pustular crusty eruption, consisting of pustules the size of a pea, covered with a blackish-grey dry scab, on the anterior external surface of the two arms and on the anterior part of the legs and thighs. This eruption resembled the scabs of syphilitic rupia. On returning to consciousness the patient rose and walked about, with his eyes closed on account of the painful sensation caused by light on the eyeballs. He gave the following particulars as to the cause of the attack: Six weeks previously he began to give himself subcutaneous injections of cocaine. He began with doses of 1 centigramme, and gradually increased the quantity until he used 50 centigrammes. The injections produced agreeable sensations and sexual desire followed by emission. The evening on which the attack above described took place he had injected 1 gramme of cocaine at 10 o'clock. He employed three syringes and a warm solution. At the third injection he fell down unconscious. The next day Dr. Déjerine again examined the eruption, which seemed to be due to localised gangrene of the cutis, resulting from the injections with cocaine, which the patient introduced into and not under the skin. At the spot where the injections were made there were white patches insensible to the touch. The patient stated that when M. Déjerine pinched him in different places during the state of coma he was aware of the fact, but felt no pain whatever. He was, therefore, sensible to the contact of an external object, but insensible to pain. The patient recovered. M. Déjerine considers that if the patient had not gradually accustomed himself to progressive doses of cocaine the dose of 1 gramme would have proved fatal.

MM. Léon Guignard and Charrin, at a recent meeting of the Académie des Sciences, described the results of their experiments on the morphological variations of microbes, and more particularly of the pyocyanine microbe. This microbe, in broth cultivations, appears as an active bacillus, about twice as long as it is broad. The cultivation, placed in a stove at a temperature of 35° C. (95° F.), becomes covered with a film, beneath which a greenish-blue colouring matter is observed, which gradually turns yellow. The bacilli collect their contents into one or two corpuscles; the membrane swells round these corpuscles, which constitute encysted cells or arthrospores. The microbe may be made to assume various forms by adding different mineral or organic acids to the broth. If a small quantity of carbolic acid or creosote be added, it appears as a bacterium. With naphthol

at 0.25 per 1,000, thymol at 0.50 per 1,000, or alcohol at 40 per 1,000, bacilli of different lengths are obtained. These are either separate or joined together by pseudo-filaments or filaments tangled together, forming a network on the surface of the cultivation. These different forms are transitory, and the normal bacillus shortly reappears. If bichlorate of potassium at 0.10 per 1,000 be added to the broth, the cultivation presents a collection of tangled filaments during five or six days; at the end of this time they are replaced by the normal bacillus. If 3 per 1,000 of boric acid be added, the development of the bacillus is retarded, but it continues to produce pyocyanine. With 5 per 1,000 of boric acid short filaments are obtained; with 6 or 7 per 1,000 of the same substance straight or curved bacilli, crescent or ring-shaped, are obtained. If these bacilli do not divide they assume spiral forms. The microbe then ceases to produce pyocyanine, and gradually reassumes its normal form. Bacilli cultivated in broth, to which 0.75 of creosote, or 2 grammes of salicylic acid has been added, form a collection of durable, spherical cells, which resemble micrococci. These cells constitute a means of reproduction, for when replaced in the cultivations of pure broth they reappear as normal bacilli, and produce pyocyanine. These experiments show how far experimental polymorphism may be carried, and the variety of forms which the pyocyanine microbe may be made to assume. These forms, however, are but transitory, and the normal bacillus which produces the pyocyanine invariably reappears.

At the same meeting MM. Cadéac and Malet gave an interesting description of their experimental reappearances on the transmission of tuberculosis by the respiratory passages. Three series of experiments were made. 1. Forty-six animals (rabbits and guinea-pigs) were made to inhale a portion of tuberculous detritus; of this number two only became tuberculous; the respiratory passages of these animals were irritated by inhalations of bromine. 2. The atmosphere in boxes containing rabbits was saturated with tuberculous fluid. All the animals contracted tuberculosis. 3. Tuberculous substances were introduced into the trachea of some rabbits by means of injections; the animals shortly became tuberculous. MM. Cadéac and Malet conclude from their experiments that when the tuberculous bacillus enters the respiratory passages by means of an inert fluid, these passages constitute a favourable agent for the development of tuberculosis. The bacilli are almost unable to introduce themselves into the respiratory passages when they are incorporated in a fine dust.

M. Bucquoy had a case of chronic farcy under his care. The patient was a man, aged 46, who had suffered from abscesses in the muscles and areolar tissues in different parts of the body for several months. The first of these abscesses proceeded from a wound in the hand, accompanied by lymphangitis of the arm, with suppurating glands in the axilla. Fresh abscesses appeared, the general condition became worse, and the patient died. At the necropsy a number of farcinous abscesses were found, two of them were intracranial, one in the meninges and another in the brain; the mucous membrane at the base of the tongue and glosso-epiglottic folds was ulcerated; this last symptom is regarded by veterinary surgeons as characteristic of glanders. The patient had driven a horse belonging to a stable in which several cases of glanders had occurred. While the patient was alive Dr. Bucquoy made inoculations and cultivations with the virus. He found that asses resisted the action of this virus. M. Bucquoy regards this as one of glanders. The farcinous character of the affection and its marked appearance were probably due to the quality of the virus, its mode of transmission, or the medium in which it developed.

VIENNA.

[FROM OUR OWN CORRESPONDENT.]

Pilocarpine in Bright's Disease.—Thoracocentesis in Empyema.—

The Chair of Anatomy in the University of Vienna.

Drs. D. Benezúr and S. Csáthy, assistants to Professor Wagner in the medical faculty of Buda-Pesth, give in a recent number of the Hungarian medical periodical, *Orvosi Hetilap*, the following summary of a series of articles on the effect of pilocarpine chloride in Bright's disease, published in that journal: 1. The patients become accustomed to the pilocarpine, and even large doses, such as 6 centigrammes, do not at a later period produce such disagreeable after-effects as doses of 1 centigramme at the beginning of the treatment. The injections of pilocarpine should not be discontinued in consequence of symptoms which had been con-

sidered as being dangerous. 2. The effect of pilocarpine on the daily secretion of saliva, sweat, and urine, as well as on the daily oscillations of the amount of hæmoglobin in the blood, is in most cases regulated by the stage of the disease and by the quantity of liquid which had been taken. 3. The œdema disappeared the more rapidly the larger the dose of pilocarpine given, and the less the quantity of liquid which the patient has taken. 4. Pilocarpine considerably increases the density of the blood for from four to five hours. 5. The hydræmia in Bright's disease does not depend on the amount of the œdema. 6. The quantity of hæmoglobin in the blood diminishes, that is to say, the hydræmia increases when the general condition of the patient becomes impaired during the course of the disease. 7. When used according to the above-mentioned principles, pilocarpine will be found in most cases of Bright's disease, even when hot baths and other diaphoretics prove useless, always to diminish dropsy to such an extent that the patient is more or less protected against dangerous uræmic suffocative attacks. In this way it may be possible to obtain a relative cure; that is, in secondary granular contracted kidney.

Professor Wölfler, of Graz, recently communicated to the Society of Physicians of Styria a case of empyema cured by simple puncture. The empyema had developed spontaneously, and was probably due to tuberculosis. Puncture was performed with a trocar between the sixth and seventh ribs, on the left side, and the pus was evacuated by siphon drainage. The lower end of the india-rubber tube communicated with a bottle filled with anti-septic fluid, and was left in till no more pus escaped. Healing took place very rapidly, and this method was apparently preferable to extensive resections of ribs. Professor Wölfler had lately successfully treated three patients by this simple method. They were instructed to carry the bottle, together with the drainage-apparatus, until no more pus escaped.

The professional body of the Vienna Medical Faculty appointed, at a recent meeting, a committee to choose from among the candidates one to be recommended for the chair of Normal Anatomy vacant by the death of Professor v. Langer. The committee consists of the dean of the Medical Faculty (Professor Kundrat) and Professors Billroth, Albert, Meynert, and Jolkt.

SAN REMO.

[FROM OUR OWN CORRESPONDENT.]

THE condition and progress of the Crown Prince has been the one absorbing topic here for the past ten days. The dyspnoea to which I alluded in my last letter increased so much on Wednesday night, that on Thursday morning Sir Morell Mackenzie requested Dr. Bramann to perform tracheotomy. Dr. Bramann asked that a few hours should be given in order to see whether the breathing might not become less embarrassed, and Professor von Bergmann, according to arrangement, was telegraphed for. During the day, however, the stridor increased, and at 3.30 the operation was skilfully performed without any complication occurring. I understood that Sir Morell Mackenzie was opposed to the administration of chloroform; but finding that Dr. Bramann invariably used this anæsthetic he advised the Crown Prince to submit to it, so that the statement telegraphed by the Berlin correspondent of the *Times* that "the Crown Prince consented to take chloroform in spite of the opposition of Sir Morell Mackenzie" is quite without foundation.

The after-treatment has been entirely in the hands of the German surgeons Professor von Bergmann and Dr. Bramann. It is said there has been great difficulty with the cannulas, several different tubes having been tried, but all of them causing irritation of the mucous membrane of the trachea; and, up to the present time, the mucous discharge continues to be tinged with blood, but the physicians in charge are very reticent on this point. There is a good deal of coughing at night, due to tracheal irritation; and narcotics are administered, but they are not altogether effectual; so that the Crown Prince has all the disadvantages of this class of remedies without the usual benefit. In this way it is feared his general health may suffer, and the recovery from the operation may be long and tedious. On closing the cannula the breathing is found to be much more free than before the operation. The voice also is considerably stronger. The patient is never left without a medical man, Sir M. Mackenzie and Professor von Bergmann taking their turn of watching with the rest.

The Crown Prince rises at 11 o'clock and remains up until 9, and is frequently to be seen at the window of the villa bowing to the people. His appetite has quite returned, and he has shown throughout this trying time, with the Crown Princess, the greatest bravery and fortitude.

At the frequent consultations that have been held the essential nature of the malady from which the Crown Prince is suffering has never been made the subject of discussion, so that the supposed differences between the English and German medical men on this point have no foundation whatever.

Sir Morell Mackenzie is remaining, at the urgent request of both the Crown Prince and Princess; but his position at the present moment is more that of a spectator than an active participator, and it is stated that he is not at all satisfied.

The Grand Duke and Duchess of Baden (sister of the Crown Prince) are staying here.

The Prince of Wales arrived on February 20th at the Victoria Hotel, and San Remo is very full, never certainly having had so many Royal and distinguished visitors at one time before. The picture painted by the Crown Princess and sold at the recent art exhibition for the benefit of the Home for invalid ladies, realised £65, and was finally purchased by Dr. Schidrowitz, the London correspondent of the Berlin *Tageblatt*. The institution benefited to the extent of over £100 by the exhibition. After over a month of fine weather we have had a short spell of sharp cold, but it is now warmer, and, heavy rain having fallen, the early Italian spring is to be anticipated.

SWITZERLAND.

[FROM OUR OWN CORRESPONDENT.]

Railway Medical Service.—Students' Duels.

As the *Intelligenzblatt für Stadt Bern* (February 3rd) says, all the stations on the Amalgamated Swiss Railways (*Vereinigte Schweizerische Bahnen*) have recently been supplied with the so-called *Sanitätskisten* (manufactured at the well known International Dressing Materials Factory at Schaffhausen), that is, with cases containing all necessary articles (bandages, splints, drugs, etc.) for first aid in cases of accident. Each case also contains printed directions how the appliances are to be used. Practical instruction has also been given to the officials at each station.

The absurd and barbarous custom of duelling, which still survives with astonishing pertinacity amongst German students from one generation to another, has recently given rise to two sad accidents in Bern. One of the combatants had the whole of his nose slashed off, while another, who was on the point of taking his M.D. degree, had his right arm so entirely disabled by a foil that his medical career has come to a premature end. These accidents, however, did not prevent another series of duels, which took place on February 4th (that is a couple of days after the above mentioned accidents), in Bern, between several members of the Corporation Helvetia, and as many students from the University of Zurich, who had come to Bern expressly for the purpose. We learn from the *Berner Stadtblatt* of February 7th, 1888, that this time no noses were lost and no limbs were maimed, though a good many flesh wounds were inflicted. The police, acting on "information they had received," succeeded in surprising one set of combatants in the morning, and in confiscating the weapons and other fighting gear. This did not, however, cool the ardour of these noble "sportsmen," who managed to bring off some exciting "events" at another place the same afternoon.

CORRESPONDENCE.

THE ELECTRICAL TREATMENT OF UTERINE TUMOURS.

SIR,—In the last number of the *Birmingham Medical Review*, for February, 1888, there is a report of a meeting of the Midland Medical Society, at which Mr. J. W. Taylor read an important paper on the Use of Electricity in Gynecology. A discussion followed, in which, as a matter of course, Mr. Lawson Tait made himself conspicuous. Taking it for granted that his prejudices were realities, and jealous that any one should make an advance in gynecology beyond his own standpoint, without his sanction or assistance, he latched out into a reiteration of assertions about my treatment of uterine tumours, in which caution and

error are so intermingled that I feel obliged to contradict and expose him.

1. Mr. Tait declares that my method "is full of dangers, and we shall hear in future of some of the disasters which are occurring from this treatment of to-day. Six deaths were known to have occurred in a single month in patients who were under Apostoli's care."

There is here as much misrepresentation as it is possible to put into so many words. In the month of August last, I gave, at Dublin, a full and complete account of the statistics of my practice. Not one case was omitted. I may safely affirm that since then, the innocuousness of my treatment, as I have carried it on myself, has been uninterrupted. Not a single "disaster," so far as I am aware, has happened. I call upon Mr. Tait to bring forward proof of what he says.

I wish that the fullest light should be thrown upon the unwarrantable insinuation, which I defy him to substantiate. And, that he may have no excuse on the ground of imperfect information, I offer to present to any honourable and competent delegate he may choose to send over all my patients without exception, and to facilitate in every possible way any researches he may wish to have made, so that he may obtain an independent report upon the results of my practice from the year 1882 to the present time.

Science is never advanced by equivocal statements. Incontestable facts are what is wanted, and on this score I am conscious that I stand upon unassailable ground.

But how is it that Mr. Tait lets himself fall into monthly self-contradictions? On the 10th of December last the honoured Thomas Keith announced in the JOURNAL that, following my example step by step, he had made no fewer than 1,200 applications of the electrical treatment of uterine tumours on 100 patients in less than five months, with success. He finished his remarks by saying: "So strongly do I now feel on this subject that I should consider myself guilty of a criminal act were I to advise any patient to run the risk of her life—and such a risk—before having given a fair trial to this treatment."

Mr. Tait's comment (JOURNAL, December 17th, 1887) upon Keith's words is this: "That the great point of Dr. Keith's important paper is the evidence he gives for at least the primary success of Dr. Apostoli's treatment. With such a witness, the conclusion is inevitable that the treatment must be tried, no matter what difficulties may be encountered in the task."

On December 17th, then, he (Tait) must have been in total ignorance of my reputed "disasters" (the six cases of death in one month), which he brought up in array on January 29th, 1888, as an utter condemnation of my system—the same system which a month before he had pronounced it to be an inevitable duty to put on trial.

His attack upon me personally thus refuted, Mr. Tait would probably fall back upon a denouncement of the treatment as practised by others. But who will believe his prognostications of danger, when it is known that my method has been adopted and applied some thousands of times by the most enlightened British gynaecologists, who are not unknown to Mr. Tait and among the Americans, by such men as Engelmann (of St. Louis), Mundé, E. K. McGennis (of New York), A. H. Buckmaster (of Brooklyn), W. Baker and John Homans (of Boston), Franklin Martin (of Chicago), J. H. Kellogg (of Montreal), and many others whom I might mention.

Assuredly everything badly done in medicine is dangerous, and women have died after uterine or even vaginal examination. But is this equivalent to saying that such practices are lethal in themselves? My cauterising operations are much the same thing as massage or scraping of the uterine mucous membrane, everyday performances not in the least jeopardising life. Will any one presume to characterise them as *ipso facto* dangerous operations? Yes; such they may be, supposing them to be done by dirty and unskilful hands.

Would anyone in his senses think of holding me responsible for all the stupidities done in my name? I have written and laid down rules for the practice of my method; they ought to be observed. If, from ignorance or wilfulness, they be neglected, neither I nor the electricity ought to be blamed. On this question I think my long experience of so many thousand cases gives me a right to speak with some authority.

However, if Mr. Tait still remains unconvinced, I will give him another means of calming his unnecessary fears. He shall have the names of every surgeon, either in France or abroad, and more

particularly in England, to whom my electrician, M. Gaiffe, has supplied batteries and instruments. It may be concluded that by this time they have put them to use. Let Mr. Tait inform himself of the consequences of what they have done. There may have been some malpractice, but I am persuaded that, upon a review of the whole of the skilled work, Mr. Tait will be forced in honour to admit that he has exaggerated the perils of my procedure. I expect no more than this, and I certainly am indifferent as to whether he recants his oburgations, or professes a repentant conviction of the excellence and all-sufficiency of my method.

Perfection does not exist in medicine, and I, at least, have no such exalted notions. I am modest enough to be satisfied, and shall feel myself fully compensated if I see electrotherapy take an honourable place in gynaecology side by side with the knife.

2. Mr. Tait adds a reproach which I need only mention to show its absurdity. He ironically says that, till the present time, I and my system were unknown to my compatriots. It is true I have never sought an illegitimate notoriety, but have contented myself with scientific approbation. If Mr. Tait's "leading Parisian gynaecological entertainers" refrained from mentioning my name in his presence, knowing the susceptibility of their guest, it is only a proof of their tact and good sense, and shows that neither I nor they were offensively fussy. But, after all, what does my obscurity matter? What was known of Mr. Tait fifteen or twenty years ago? It would have been inexcusable if I had prematurely asked for adhesion to my views.

3. "Skilled electricians assured him (Mr. Tait) that the galvanometers used by Apostoli are absolutely worthless as indicators of dosage." This is really frivolous, and Mr. Tait again shows how easily he can be led into error. The galvanometers made by Gaiffe, medically speaking, give an exact dosage, with an outside deviation of from one to five milliampères, which actually is of no practical importance. If my word be not sufficient, I will send the galvanometers I have in use to be tested by Mr. Tait's own "skilled electricians."

4. Mr. Tait repeats the old tale of Dr. Althaus having practised my method before my time. Really there are some blunders which are irrefragable. I thought that my letter (JOURNAL, November 26th, 1887) to Dr. Althaus, whose merits in electro-therapeutics all acknowledge, was conclusive. Not so, it appears, to Mr. Tait, though it is for me, seeing that Dr. Althaus (the imputed though silent father of the electrical method of treating uterine fibroids) has publicly (JOURNAL, December 3rd, 1887) waived his claims to the said priority, and admitted my priority in this particular application of electricity in gynaecology.

In all the correspondence on this subject, the contradictions of Mr. Tait and Dr. Althaus stand out most prominently:—(a) He (Mr. Tait) maintains that he and Dr. Althaus employed a current stronger than any I name. Dr. Althaus denies this (JOURNAL, 29th October and 3rd December, 1887), pointing out that his battery was defective, and that he had no such current as mine. (b) Mr. Tait pretends that the practice of Dr. Althaus was better than mine. Althaus again deposes against his own colleague, and admits that his method was imperfect and fell short of mine. He candidly closes his observations by an assurance that "if I should by the use of higher currents and greater attention to details, prove my case to the satisfaction of the profession, no one would be more delighted than myself."

The question between Mr. Tait and Dr. Apostoli is now before your readers. Let them form their own conclusions.—I am, etc.,
Paris, February 20th. G. APOSTOLI, M.D.

VENTRAL NEPHRECTOMY FOR HYDRONEPHROSIS.

SIR,—In answer to my criticism on the above named case, wherein I suggested that the patient should first be allowed the chance of recovery by simple aspiration, and illustrated it by the usual practice in hydrocele, Mr. Hunter replies that "there is no analogy between hydrocele and hydronephrosis, either in their pathology or treatment." As regards treatment this is incorrect, since both affections have been known to be permanently cured by simple tapping, and I carried the analogy no farther.

As regards pathology I did not suggest analogy, but where the resemblance breaks down the advisability of tapping a hydronephrosis becomes the more apparent, for in this affection we are seldom dealing with a perfectly closed sac as in hydrocele, and tapping gives a chance for the temporary obstruction to be removed. That such an operation is harmless, and that it has

proved effectual, should be a strong argument for its adoption as a step preliminary to nephrectomy.

I am not one to decry operations, however complicated or severe, provided the ends to be obtained justify the means employed. But it is scarcely reasonable to pass through the peritoneum to reach an organ that lies altogether behind that membrane if the organ can be removed through the loin. That the latter is the safer operation recent experience abundantly proves. Mr. Hunter thinks his case could not have been removed through the loin, but the report of the case does not convey to me that impression.—I am, etc.,

"THE OATH OF HIPPOCRATES."

SIR,—In a book entitled *Uriconium*, by Thomas Wright, F.S.A., I have found a translation of a remarkable oath preserved in Greek, and attributed to Hippocrates, which in early times all students were obliged to take before they were allowed to practise. Do you not think it would be a good thing if we were obliged to subscribe to some modified form of this oath? Would it not perhaps prevent that column of complaints about medical etiquette which appears weekly? If you think it is of enough interest, I shall be glad if you would print it.—I am, etc.,

FRANK BROADBENT, M.D.

South Collingham, near Newark, February 10th.

"I swear by Apollo the Physician, by Æsculapius, by Hygeia, and Panacea, and all the gods and goddesses, calling them to witness that I will fulfil religiously, according to the best of my power and judgment, the solemn promise and the written bond which I now do make. I will honour, in the same degree as my parents, the master who has taught me this art, and endeavour to administer to all his necessities. I will consider his children as my own brothers, and will teach them my profession, should they express a wish to follow it, without remuneration or written bond. I will admit to my lessons, to my discourses, and to all my other methods of teaching, my own sons, and those of my tutor, and those who have been inscribed as pupils and have taken the medical oath, but no one else. I will prescribe such a course of regimen as may be best suited to the condition of my patients, according to the best of my power and judgment, seeking to preserve them from anything that might prove injurious. No inducement shall ever lead me to administer poison, nor will I ever be the author of such advice; neither will I contribute to an abortion. I will retain religiously the purity and integrity both of my conduct and of my art. I will not cut anyone for the stone, but will leave the operation to those who cultivate it. Into whatever dwellings I go, I will enter them with the sole view of succouring the sick, abstaining from all injurious views and corruption, especially from any immodest action towards women or men, freemen or slaves. If, during my attendance, or even unprofessionally in common life, I happen to see or hear of any circumstances which should not be revealed, I will consider them as a profound secret, and observe on the subject a religious silence. May I, if I religiously observe this oath, and do not break it, enjoy good success in life, and in the practice of my art, and obtain general esteem for ever; should I transgress and become a perjurer, may the reverse be my lot."

. Although this so-called Oath of Hippocrates is in many respects a most excellent one, we do not recommend its compulsory adoption by the General Medical Council. The day of Test Acts is past, partly because the feeling of the age is against such compulsion, principally because they have been found utterly inadequate to accomplish their aim. The man, for instance, who would perform any of the dishonourable actions mentioned in "the oath," would not hesitate to take it without the least intention of keeping its promises. The only persons who would object to it are those men of tender and merbid consciences, who would be quite incapable of wrong-doing, but who would scruple to take the oath.

We regret as much as our correspondent the unsatisfactory relations too often existing between members of the same profession, who should be as brothers. But we see the remedy for this condition of things, not in oaths and assertions, but in the cultivation and inculcation of a noble spirit of mutual trust and toleration, which we trust will be impressed upon the students of the coming generation by their teachers, both in word and example.

In proportion as homœopathy and other quackeries are relegated to obscurity; as every member of our profession devotes himself

to the cure of disease, rather than to pleasing his patients; as we become men of science and gentlemen, an end to squabbles and disputes will be found. Meanwhile, how far courts of honour, subscribed to by members of our profession, before which cases of difficulty and wrong could be brought, would be of use is a matter for controversy. We recommend rather the old-world precepts for the conduct of members of our profession: To love one's neighbour as oneself, and to do to all men as we would like them to do to us.

THE APPOINTMENT TO HAYWARD'S HEATH ASYLUM.

SIR,—Both your correspondents have failed to grasp the true significance of the recent appointment of medical superintendent to Hayward's Heath Asylum, and I think that your note appended to H.'s letter is quite aside from the question at issue. I appeal on behalf of the assistant medical officers of English asylums against the insult inflicted upon them by the gross injustice of this appointment. Although the terms of the advertisement excluded a large number of otherwise good candidates, still there were several who possessed the necessary qualifications, and these gentlemen, from want of personal influence with Chancery Lunacy Commissioners, have been superseded by a candidate whose only recommendation, if we except his age, was the energetic support of certain Commissioners, no part of whose duties consists in active interference in such appointments. There is little encouragement in the results of this appointment to men who are devoting the best part of their lives to obtaining a practical knowledge of insanity and the management of asylums if such appointments, for which they are most eligible, are to be given to men with no such experience. It is gratifying to note that the Medico-Psychological Association intend taking the matter up and have called a special meeting to discuss the question in all its aspects.—I am, etc.,

I.

SIR,—With reference to your editorial note underneath a letter referring to the above matter in the *JOURNAL* of February 18th, I should, with your permission, as a matter of simple justice to the present generation of assistant medical officers, like to point out that at least six of their number (all of whom were candidates) actually more than satisfied the exceptionally restrictive requirements of the Sussex committee as to medical degrees and qualifications. A list to verify this statement accompanies this letter. A public announcement that these men included those who have had many years' experience at such asylums as Bethlem, Colney Hatch, Rainhill, Northampton, and Devon is sufficient answer to any statement as to the age of the present regulations, and it is surely all that is required in the way of criticism as to the extraordinary nature of the recent appointment.—I am, etc.,

A MEMBER OF THE BRITISH MEDICAL ASSOCIATION.

February 18th.

RULING OF THE JUDGES IN CASES OF INSANITY.

SIR,—Having been subpoenaed as a witness during the past week in two murder cases in which the plea of insanity was raised, it might be interesting to state the different view entertained by the two judges who tried the cases.

I attended at Maidstone on Thursday, in the Ramsgate shooting case. Mr. Justice Mathew presided. The medical men who tendered their evidence were asked whether at the present time the accused was of sound or unsound mind? On their answering that he was of unsound mind and unable to plead, the jury so found.

On arriving at Leeds the same evening, I found that Mr. Justice Day had refused to allow the experts to state whether they considered the prisoner of unsound mind; he said they could only state facts, and that he would not allow any medical expert to usurp the functions of a jury. The jury were, Mr. Justice Day remarked, the proper persons to decide this question. Such contradictory ruling makes it awkward for those professional gentlemen who are summoned as experts, and there should be a meeting of the judges, as in Macnaughten's case, to decide what questions a medical expert might answer in a court of law.—I am, etc.,

L. FORBES WINSLOW, D.C.L. Oxon.

70, Wimpole Street, Cavendish Square, W.

SUCCESSFUL VACCINATION.—Mr. T. Garrett Horder, L.R.C.P. Ed., has received the Government grant for efficient vaccination in the Cardiff District of the Cardiff Union.—Mr. W. Duncan, public vaccinator for the Nunney District of the Frome Union, has received the Government grant for efficient vaccination.

MEDICO-PARLIAMENTARY.

HOUSE OF LORDS.—Thursday, February 16th.

The Pharmacy Acts.—The Earl of MILLTOWN presented a Bill for the amendment of the Pharmacy Acts, which was read a first time.

Friday, February 17th.

The Safety of Theatres.—The Earl of STRAFFORD, in asking the Government whether there was any objection to produce the report made by Captain Shaw in 1882 upon the condition of the London theatres, and their probable safety from fire, referred to the fact that there were 50 theatres in London, with a holding capacity of 70,000 persons, and upwards of 475 music halls, 31 concert halls and so-called palaces, with a holding capacity of 445,000. Within the last few years there have been some terrible calamities from the burning of theatres; the Ring Theatre at Vienna, the Opéra Comique at Paris, the principal theatre at Exeter, the Grand Theatre at Islington, the theatre at Bolton, had all suffered in this respect; and it was clear that better precautions ought to be adopted for the security of the audiences.—Lord MAHERONNE, as Chairman of the Metropolitan Board, stated that every theatre in London had been thoroughly and efficiently inspected. In his opinion the publication of the report would produce unnecessary alarm, because it had been considered and acted upon, and many of the defects which it pointed out had been remedied. Some theatres had been shut up because they were not in a proper condition as to safety, and every new theatre had been thoroughly inspected. Many music halls had been dealt with, and others were still under the consideration of the Board.

Monday, February 20th.

Sanitary State of Dublin Barracks.—Earl BEAUCHAMP moved that the return of all cases of febrile disease in the Dublin garrison since January, 1881, ordered to be printed September 9th, 1887, be continued to December 31st, 1887. Taking the return for 1884, he found, in regard to enteric fever, that Dublin showed the greatest number of cases and the highest ratio of admissions to hospital per 1,000 men.—Lord HERSHELL said he had reason to believe that matters were not in the slightest degree better during the last part of 1887 than they were during the earlier part of the year. The fact that the remedy would be costly was no justification or excuse for sending men to a place where they must contract a serious and dangerous disease.—Lord HARRIS said the Government did not shut their eyes to the serious condition of the barracks in Dublin. The report which had been received from Dr. Grimshaw and Sir C. Cameron showed conclusively in what an insanitary condition the barracks, and especially the Royal Barracks, were.—The Duke of CAMBRIDGE thought it was possible to exaggerate the condition of these barracks. He had lived in them himself for years. Enteric fever was exceptionally prevalent just now, and Dublin barracks were having a share of it. He agreed, however, as to the importance of inquiry to see what was the reason why the barracks were less healthy now than they were formerly, and of measures being taken to remedy the evil as far as possible. In future the difficulty would be met to some extent by the new barracks now in the course of erection.—Earl BEAUCHAMP expressed his readiness to substitute in his motion the medical report for the return.—Lord HARRIS assured their lordships that the present Government, having the information of the experts, did not intend to delay dealing with a matter of so much importance.—The motion for the production of the medical report was agreed to.

HOUSE OF COMMONS.—Thursday, February 16th.

Rabies in Dogs.—Mr. RITCHIE, replying to Viscount CURZON, said that the subject of rabies in dogs was receiving the attention of Her Majesty's Government, and the Privy Council Office were in communication with some local authorities with reference to the restrictions which might be necessary in connection with it. If it should be considered that further powers were required, they would be asked for. The average annual number of deaths in England and Wales during the ten years referred to was 40, and the average number in London from 1878 to 1887 was 7. The total number of deaths in England and Wales from hydrophobia in 1885 was 60, of which 27 were in London; in 1886 it was 26, of which 9 were in London. The number of deaths in London in 1887 was 2. He was unable to supply the total number in England and Wales for 1887.

Organisation of the Medical Department of the Army.—Mr. E. STANHOPE, in answer to a question put by Sir W. BARTELOT, said the whole question of the organisation of the Medical Department of the army had been engaging his earnest attention. Several points of detail were still under consideration; and on introducing the Army Estimates he would endeavour to explain fully the arrangements contemplated.

The Safety of Theatres.—Mr. MATTHEWS, replying to a question put by Sir S. NORTHCOLE, said the Government had under their consideration the question of the greater safety in construction of theatres, both in London and the provinces, and the expediency of introducing a Bill dealing with the subject.

Friday, February 17th.

Vaccination.—Mr. RITCHIE, in reply to questions by Mr. BRADLAUGH and Mr. PICKERSGILL, said that the Order of the Local Government Board dated October 31st, 1874, relating to prosecutions in vaccination cases, was not binding upon boards of guardians. The Order was merely a communication, and it rested entirely with boards of guardians to exercise their discretion in the matter.

Saving of Life at Sea.—Sir J. FERGUSSON informed Mr. H. VINCENT that it was the intention of the Government shortly to introduce in the House of Lords a Bill for the better saving of life at sea.

Monday, February 20th.

The Water Supply of the Country.—Sir H. ROSCOE called attention to the printed correspondence which has appeared from eminent authorities as to the possible danger of a water famine occurring during dry summers, and asked whether, in view of the vast importance of the question of the proper storage of water throughout the kingdom, the Government would consider the advisability of appointing a Royal Commission to inquire and report on the whole subject.—Mr. W. H. SMITH, in reply, admitted the seriousness of the question, but thought it impossible for any steps to be taken now which would affect the water supply of the ensuing summer. Looking to the fact that large sums of money had in late years been borrowed by local authorities for the purpose of providing water, the Government hardly thought a Royal Commission, such as suggested, advisable.

Measles in the Island of Lewis.—The LORD ADVOCATE, in replying to a question of Dr. CAMERON, stated that in Stornoway burgh there were a large number of cases of measles, and 4 deaths; Stornoway parish, many cases and 18 deaths; Barvas parish, nearly 300 cases and 1 death; Lochs parish, 300 cases and 16 deaths; Uig, 2 cases and no death. The disease has been on the whole of a mild type, and in all these places medical attendance was given and the sick supplied with medicine and such necessaries as were ordered by the medical men. Isolation, wherever practicable, was insisted upon.

Wednesday, February 22nd.

POLICE AND SANITARY LEGISLATION.

On the motion of Mr. STUART-WORTLEY, it was resolved that the Committee of Selection do appoint a Committee, not exceeding nine members, to whom shall be referred all private Bills promoted by municipal and other local authorities, by which it is proposed to create powers relating to police and sanitary regulations which deviate from, or are in extension of, or are repugnant to, the general law; that Standing Order 173A be applicable to all Bills referred to the said Committee; that the Committee have power to send for persons, papers, and records; that five be the quorum of the Committee.

NAVAL AND MILITARY MEDICAL SERVICES.

PRIZE OFFERED FOR PUBLIC COMPETITION BY HER MAJESTY THE EMPRESS OF GERMANY.

On the occasion of the fourth International Conference of Red Cross Societies, which was held at Carlsruhe last year, in the month of September, the Empress of Germany generously placed at the disposal of the meeting a sum of 6,000 marks (about £300), together with three gold and nine silver medals, to be employed as prizes in any competitive undertaking which the conference might consider likely to be useful in promoting Red Cross work. After full discussion of the subject, it was decided at the conference to devote Her Majesty's gift to a competition on "the best interior arrangements of a portable hospital, that is to say an indication of the most suitable articles and the best means of procuring them, for furnishing and carrying on the work of a portable hospital calculated for a fixed number of sick and

wounded patients." It was also settled that the Central Committee of the German Red Cross Societies, of which Count von Stolberg is the president, should undertake the arrangement and publication of the detailed programme for the competition. This programme has now been issued, and we are requested to make known the conditions agreed upon for the competition. They are too lengthy for us to publish them *in extenso*, but an indication of the leading points among them will suffice, as it is announced that information in all particulars regarding the competition may be obtained by inquiries addressed to the Central Committee of the German Associations of the Red Cross, No. 73, Wilhelmstrasse, Berlin.

1. It is assumed that hospital accommodation for 60 patients has to be provided rapidly, and that to meet this urgent need, 3 huts have been erected, each 15 metres long by 5 wide, with walls 2.25 metres high, and an elevation of 3.65 metres to the top of the roof. Each hut can contain 18 or, in case of need, 20 beds. One or two other huts, with interior partitions, are destined for the accommodation of a staff of 2 surgeons, 2 purveyors or stewards, 1 cook, and 6 attendants on the sick. The question is how to dispose of these erections to the best advantage, keeping in view the attention to be given to the needs of the sick and wounded patients. All objects intended for the purpose named must be capable of being readily packed and transported, either by railway, or by country vehicles. Attention must, therefore, be given to reduction of bulk and weight as far as possible.

2. The objects above mentioned have reference to the bedding and all the furnishing of the space reserved for the patients, including the means of heating and lighting, the utensils for the sick, surgical instruments, medicaments, bandages, linen, clothing, cooking utensils, table articles, and, lastly, aliments and beverages necessary for three days. All articles must be furnished of their natural size, but only a single specimen of each. Models of reduced dimensions will not be admitted.

3. Each competitor will furnish a description of the objects he exhibits either in German, French, English, or Italian, and, if needed, explanatory drawings. The description must include (a) a plan of the constructions intended for the steward's duties; (b) a list of the different objects for the service, and an indication of the number of the sick and of the *personnel* they correspond to; (c) the precise cost of the various articles, where they are procurable, how they are to be packed, and the cost of packing; and (d) an approximate estimate of the number, dimensions, and weight of the packages, with a statement of the number of vehicles required for their conveyance.

4. Objects intended for the competition must be sent to Brussels before August 15th, 1888, and should be addressed: "Au Comité Exécutif du Grand Concours International des Sciences et de l'Industrie, Rue du Palais 22, à Bruxelles." Each competitor must send to the same address a notice specifying the amount of space he will require before July 15th next. This space will be allotted free of cost.

5. An international jury will be appointed to award the prizes.

6. The exhibition of the articles sent for competition will take place in an annexe to the Brussels Universal Exhibition, and will last from September 1st to the 30th, 1888.

It may be remembered that an international exhibition of hut portable hospitals took place in Antwerp in the autumn of the year 1885, in competition for a prize of 4,000 marks and a gold medal, which the Empress of Germany at that time placed at the disposal of the Red Cross Societies. The present competition, if it excites the same interest and attracts as many competitors as the competition of 1885 attracted, will complete the humane and valuable undertaking which was then commenced.

AN AMBULANCE COMPETITION TROPHY.

The suggestion made by Sir Guyer Hunter, M.P., at the Mansion House, last Saturday, on the occasion of the distribution of certificates to the successful candidates of the Ambulance Department of the Volunteer Medical Association, was one which if carried into effect would be likely to do much to create a healthy rivalry, and, as Sir Guyer Hunter observed, "be of service in increasing and making more perfect the work of the Ambulance Department." He expressed the hope that in course of a short time they might be able to obtain a shield, or some other similar object, which might be as the Elcho Shield was to the volunteers. The suggestion met with ready approval, and the Lord Mayor testified his concurrence by offering to give five guineas towards the object, an example which he hoped would be followed by others.

THE NAVY.

INSPECTOR-GENERAL JAMES NICHOLAS DICK, C.B., has been appointed Director-General of the Medical Department of the Navy. His commissions are thus dated:—Surgeon, August 17th, 1853; Staff-Surgeon, September 27th, 1861; Fleet-Surgeon, August 14th, 1863; Deputy Inspector-General, February 26th, 1869; and Inspector-General, February 27th, 1884. From the *Royal Navy List* we learn that he was Assistant-Surgeon during the Russian war in 1854-55, and served in *President*, flag of Rear-Admiral Price, being present at the attacks on Petropaulovski by the combined English and French Squadrons on August 31st and September 4th, 1854, when he was specially mentioned for his care of the large number of wounded. In September, 1854, he was also present at the capture of the Russian vessels, *Sitka*, of 10 guns, and *Anadir*, of 4 guns. In April, 1862, as Surgeon, was present in the boats of *Flying Fish* at the capture of a slaver in Rio Nunez, West Coast of Africa. In July and August, 1868, when in *Satellite*, was Senior Medical Officer in charge of the naval forces and Indian troops; in the operations on shore against pirates in the Nicobar Islands, Bay of Bengal. Was Senior Naval Medical Officer during the Abyssinian war, 1867-68, and for his services was specially promoted to the rank of Fleet-Surgeon (Abyssinian medal). During the civil war in Spain, when Fleet-Surgeon of the *Lord Warden* flag-ship in 1873, he proceeded into Cartagena during the bombardment as a volunteer to assist the wounded. Received from the Admiralty an expression of their high estimation of the zeal, energy, and skill shown by him in the performance of his duties in connection with the Royal Naval Hospital, Malta, of which he was the principal officer during the Egyptian campaign, 1882.

The following appointments have been made at the Admiralty:—T. D' A. BROMLOW, Fleet Surgeon, and G. T. COLLINGWOOD, Surgeon, to the *Impérieuse*; W. H. O'MEARA, Surgeon, to the *Cambridge*; J. H. DAWE, Surgeon, to the *Griffon*.

The following gentlemen who competed at the examination recently held at Burlington House, for appointment as Surgeon in the Royal Navy, have been granted commissions:

	Marks.		Marks.
Acheson, J. H.	3,130	Collingwood, F. W.	3,020
McElwer, J.	3,130	Levinge, R. T. A.	3,020
Fraser, P. W.	3,100	Ferguson, J. C.	3,010
Harvey, D'A.	3,045	Mowriyan, E. P.	2,990

THE MEDICAL STAFF.

SURGEONS P. J. B. O'SHAUGHNESSY and J. F. McMILLAN, who are serving in Bengal, have passed the examination in Burmese by the elementary standard.

THE INDIAN MEDICAL SERVICE.

SURGEON H. A. SHEPPARD, of the Bengal Establishment, has been superseded for absence without leave. He entered the service April 1st, 1886.

SURGEON U. N. MCKERJI, Bengal Establishment, is appointed to the officiating medical charge of the 5th Native Infantry, *vice* Surgeon C. J. Bamber, who has been transferred to civil employ.

SURGEON D. O. WÄRLIKER, Madras Establishment, has passed the examination in Burmese by the higher standard.

SURGEON-MAJOR G. BOMFORD, M.D., Bengal Establishment, is directed to officiate as Secretary to the Surgeon-General and Sanitary Commissioner with the Government of India during the absence on leave of Surgeon-Major A. Barclay, M.B.

SURGEON-MAJOR G. KING, M.B., Superintendent of the Royal Botanical Gardens at Calcutta, has leave of absence on private affairs for 2½ days.

BRIGADE-SURGEON C. SIBTHORPE, Madras Establishment, Fort Surgeon and Acting Surgeon at the General Hospital, is appointed to be Surgeon at the General Hospital.

SURGEON-MAJOR H. ALLISON, M.D., Madras Establishment, Assistant-Physician at the General Hospital and Acting Fort Surgeon, is appointed Fort Surgeon, with fort and marine duties.

SURGEON T. H. POPE, M.B., Madras Establishment, Civil Surgeon at Negapatam, is appointed Assistant-Surgeon at the General Hospital.

MEDICO-LEGAL AND MEDICO-ETHICAL.

CASEY v. THE GUARDIANS OF ST. GEORGE'S-IN-THE-EAST.

(Before Mr. BARON HUDDLESTON and a special jury.)

THIS action was brought under Lord Campbell's Act by a widow, for herself and her children, to recover compensation for the death of her husband. The case as opened by the counsel for the plaintiff was to the effect that it had become necessary to restrain the deceased, who was at the time an inmate of the workhouse infirmary, but that, the straps not being properly fixed, he got loose and threw himself out of the window. The case for the plaintiff was that the guardians were guilty of negligence by their servants in not having the deceased properly secured in the condition in which he was known to be at the time.—Mr. Baron Huddleston asked whether the point raised in this case had not been before him previously.—Mr. Finlay replied that it was before his lordship sitting without a jury. The Court of Appeal thought there was no case of negligence made out against the guardians.—Mr. Baron Huddleston: I thought there was.—Mr. Finlay: Yes.—Mr. Baron Huddleston: That was the case of a window not being properly barred?—Mr. Finlay assented. The question of law as to whether an action would lie in such a case was not decided in

that case. Lord Justice Bowen said the question was one of very great difficulty. It had been decided in the Irish case of "Brennan v. the Limerick Poor Law Union." The deceased had in that case been suffering from delirium tremens. The decision showed that no action lay against the guardians, on the ground that they were acting ministerially in the matter, and that by the Poor Law Acts such a liability is not imposed upon them. There was, he supposed, no substantial difference between the Irish and the English Poor Law.—Mr. Baron Huddleston said that case was not quoted when the point was previously before him.—The evidence of some of the nurses and doctors having been heard, the learned judge ruled that there was no evidence of negligence in this case, and by his lordship's direction the jury found a verdict for the defendants.

MEDICAL AID SOCIETY.

A CORRESPONDENT writes to us with regard to the action of the Medical Aid Society at Hanley. In the JOURNAL of January 14th we gave our opinion of the character of this Society, and advised medical practitioners desirous of maintaining the dignity of the profession to have as little to do with it as possible.

Complaint has also reached us as to the system of "fouting" for patients alleged to be practised by agents of the London and Manchester and other insurance societies; it is stated that they not infrequently call on the patients of different practitioners and persuade them to leave their own medical men, and to employ the services of the medical men of their society for a small additional premium payment.

It has always been considered legitimate for insurance agents in the way of business to call on members of the public in the hope of getting them to take policies in their respective offices; but if, under the pretence of *bond fide* insurance business these societies are through their agents simply carrying on a wholesale traffic in cheap medical attendance, we cannot but think such practices worthy of the strongest reprobation of the profession.

W. J. B.—Our correspondent was well advised in leaving a situation for which he was admittedly unqualified, and continuance in which would probably have brought him into difficulty. Without a full report of the proceedings we are unable to form an opinion whether the decision of the county court judge was right or not. The solicitor, if properly retained, might be liable for negligence in failing to appear to conduct the case.

INDIA AND THE COLONIES.

NINETEENTH ANNUAL REPORT OF THE SANITARY COMMISSIONER FOR BENGAL (DEPUTY SURGEON-GENERAL R. LIDDERDALE, M.D.) FOR THE YEAR 1886.

IN the year under review there was a marked reduction in the prevalence of cholera, as compared with its incidence in 1885. In 1886 the deaths from this disease amounted to 118,363 persons, among a population numbering 66,163,884, that is, at the rate of 1.78 per 1,000; while in 1885, 173,767, or 2.62 per 1,000 of the population perished from this cause. The disease attacked 21,567 villages, or 2.33 per cent. of the total number of villages in the province, against 29,239, or 12.61 per cent., in 1885. In the urban circles 9,935 persons died of the disease, at the rate of 4.12 per 1,000 of the population; in the rural districts 108,433, or 1.70 per 1,000 of the population. As usual, the rainfall exercised a powerful influence on the prevalence of cholera. In 1885 the province was severely inundated, so much so that a large portion of it was kept under water to a late period; this, in the opinion of the Sanitary Commissioner, has the effect of materially reducing the usual severity of the winter prevalence of cholera in that year, and this abatement was prolonged into January and February of 1886. The first four months of the year had a rainfall below the average of several preceding years, but this was not followed by any marked exacerbation above the usual seasonal increase of deaths. March, April, and May have a smaller mortality than 1885.

There was heavy rain in May, June, July, August, and September, attended by a very considerable diminished mortality, but the winter prevalence of the disease was high, and culminated in severity in December.

It appears that the Government of India directed a table to be prepared, showing the meteorological peculiarities which obtained during defined periods of cholera outbreaks in certain selected thannas and towns. The Sanitary Commissioner does not seem to think that much, or indeed any, useful information has resulted. He thinks the whole subject has already been exhaustively considered by Drs. Lewis and Cunningham, and he adds the following significant paragraph: "We already know the conditions which

foster the disease, and what the Sanitary Department requires is more and more money to remove them, leaving to savants to puzzle out the problem of causation, while in the meantime we save useful lives." It is certain that until the health officers of Calcutta and the other great cities have either "more powers" to deal with the known causes which foster cholera, or the obstructive municipalities are by some means made to cease from obstruction, the death-rate from this disease will continue to be what it is, and Calcutta will continue to be what it is—a terror to Continental nations. Again and yet again we have warned the Government of India that unless some stringent measure in the direction indicated is taken, Continental Governments will take steps to protect themselves by international action that will affect the commerce of India very seriously. At this time a measure of municipal reform from Bombay is under consideration there, and it is a lamentable fact that great pressure is being brought to bear on the Government by nearly the whole of the wealthy and educated native community to emasculate the measure, by striking out the clauses which are intended to promote the health of the community, or indirectly to effect the same bad end by restricting the power of health officers. Cities that have grown up, no matter where, without knowledge of the laws of health, can only be made even tolerably wholesome to live in by a considerable expenditure of money under the supervision of sanitary engineers, and this is exactly what municipal bodies in India, under the almost sole guidance of wealthy but, as regards sanitation, ignorant native gentlemen will not permit. Has the governing race lost the art of governing? Has it become so emasculated in India that it must "lie low" at the bidding of the ignorant governed?

REGISTRATION IN CEYLON.

A REGISTERED PRACTITIONER writes: In the JOURNAL of January 7th it appears that an Order in Council has been published extending the provisions of the second part of the Medical Act, 1886, to Ceylon. That this is a step in the right direction is unquestionable, but, at the same time, I venture to hope that the privileges which are associated with the act of registration will be extended to us in their entirety, and that thereby we shall be enabled to overcome satisfactorily the present unjust and undignified restrictions that are imposed upon the medical men of the Ceylon Medical Service by the Government in the matter of fee-charging. At the present moment, no medical man in charge of an out-station is permitted to demand a fee from any Government servant who draws a salary under £25 a month. The largest number of my patients consists of Government servants with salaries ranging from £10 to £22 a month, and the majority of them are, in addition, landed proprietors, and yet, by reason of this grossly unfair ordinance, I am forced to attend upon them and their families without the smallest remuneration. Now, why should this be so? The "free" patient and the medical officer are both servants of one and the same Government, with the important difference though that, in my case, I am registered, hold a British qualification, and am privileged to claim a monthly salary of £7 4s. only. This being the case then, wherein lies the necessity or the justice of drawing this fine distinction?

It strikes me very forcibly that the "free patient" derives a considerable amount of gratuitous benefit by this curious arrangement. Without entering into a lengthy recital of the wrongs that are thus inflicted upon medical men drawing a meagre salary, I may mention that any number of instances could be cited where medical officers have had to go some distance to attend Government servants for fractures, typhoid fever, etc., and who, on forwarding their account for payment, have received the terse and pithy reply of "I am a Government servant." It is therefore only to be hoped that the Council will take into consideration the existing state of matters, and that, before extending the Act of Registration to Ceylon, it will exert its powerful influence to amend the anomalous position which medical men in the island are forced to occupy.

THE *Indian Medical Gazette* states that Sir James Hanbury, K.C.B., will shortly be gazetted Principal Medical Officer, Madras, and will probably be the successor of Surgeon-General Madden as Chief Medical Officer of the Forces in India.

MEDICAL MAGISTRATE.—Surgeon-Major Keogh, J.P. for Co. Kildare, has been placed on the Commission of the Peace for the Queen's County.

UNIVERSITY INTELLIGENCE.

UNIVERSITY OF OXFORD.

MAINTENANCE OF THE PHYSIOLOGICAL DEPARTMENT.—At a meeting of Convocation held on February 21st, the ordinary motion was made to continue the grant of £500 per annum for the expense of the Physiological Department, a minimum which Professor Fowler said Dr. Burdon Sanderson had eked out by an annual payment of £100 from his private purse. Professor Freeman opposed the grant as an antivivisectionist; so did the Bodleian Librarian, who reviewed the history of the contest over the Physiological Department, and complained of the inequity with which an important minority had been treated. Mr. Macray said that he and others would feel bound to vote against grants to the department so long as the University left the question of vivisection unrestricted by its statute. The grant was carried by 102 votes to 22.

UNIVERSITY OF CAMBRIDGE.

OUR Cambridge correspondent telegraphs:—The following were, on February 23rd, admitted to the degree of M.B.:

Harrison, H. L., B.A. (St. John's); Light, E. M. (Clare). Mr. Light was also admitted to the degree of B.C.

UNIVERSITY OF BRUSSELS.

At the recent February examination the following gentlemen, having passed successively the first, second, and third Doctorates Examinations required by the University, were admitted to the degree of M.D.:

Des Voeux, H. A., M.R.C.S. Eng., L.R.C.P., L.S.A.; Dyer, S. G., M.R.C.S. Eng., L.R.C.P., L.S.A.; Hubbard, W. L., M.R.C.S. Eng., L.R.C.P., L.S.A.; Mathews, W., M.R.C.S. Eng., L.R.C.P. Ed., F.R.C.S. Ed.

OBITUARY.

PROFESSOR WAGNER.

THE death of Professor Wagner, the distinguished pathologist, on February 10th, is announced from Leipzig.

Professor Ernst Leberecht Wagner was born in Dehlitz in 1829, obtained his degree at Leipzig in 1855, was made extraordinary professor in 1859, and in 1863 ordinary professor of general pathology and pathological anatomy. After Wunderlich's death Wagner took over the direction of clinical medicine in the University of Leipzig. His profound pathological acquisitions were evidenced by numerous publications—for example, *On Uterine Cancer* (Leipzig, 1858), *On Fatty Metamorphosis of the Heart* (1864), *On Lymphadenoma Resembling Tubercle* (1871), and these labours throw his clinical activity into higher relief than is usually the case with physicians. "Of his many-sided and profound knowledge of pathology" (*Berliner Klinische Wochenschrift*, February 20th) "his distinguished exposition of Bright's disease is a witness; of his comprehensive medical culture his *Handbook of General Pathology*, a truly classical work, of which Uhle was co-editor. Subsequently to 1860 Wagner edited the *Archiv der Heilkunde*, which, in 1878, gave place to new undertakings. Wagner was distinguished as a diagnostician and teacher, and in general character, and his work will ever be remembered far beyond the scene of his activity."

PUBLIC HEALTH

AND

POOR-LAW MEDICAL SERVICES.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

WITTINGTON URBAN (Population, 21,000).—Dr. Railton's account of the incidence of epidemic disease during 1886 in the four townships comprised in this district is very interesting. The year's mortality was low, although two rather extensive epidemics of fever prevailed, which, but for the mildness of the disease, might have proved very disastrous. Measles also prevailed to a great extent in Chorlton-cum-Hardy in the early months of the year, and especially in the month of April. Six cases of diphtheria were reported, and of these 5 proved fatal. They were quite unconnected one with the other, the milk supply being from a different source in each case. Dr. Railton devotes a fair portion

of his report to a consideration of the mortality at the various age periods. Deaths of infants were at the rate of 9 per cent., which is slightly lower than in 1885. All the deaths from diarrhoea occurred in children under 5 years of age. The general death-rate was very low—12.0 per 1,000.

KENSINGTON (Population, 173,500).—*Hospitals of Asylums Board: Notification of Disease: Disease in Post Office Officials.*—Dr. Dudfield's annual reports may be regarded as exhaustive treatises on sanitary science, of which he not only expounds the theory, but relates the practice. His influence and interest are widespread, and acting under his advice the vestry of St. Mary Abbots, has become a real power in promoting improvements, and in controlling sanitary legislation. Dr. Dudfield has always attached the greatest importance to the work of the Metropolitan Asylums Board in connection with hospital accommodation, and may justly claim credit for originating many useful features of its present system. He for many years contended for the free admittance of all infectious cases upon the application of sanitary officials or of registered practitioners, and it was mainly at his instance also that the plan of removing small-pox patients out of London was adopted, and that the hospital-ships were instituted. His report for 1886, especially that part which deals exclusively with the prevalence of zymotic diseases in the district, shows that there was not a great deal of epidemic sickness during the year. Measles, whooping-cough, and diarrhoea were the most fatal, but the number of deaths in each instance was below the decennial average. Diphtheria was the only one of these diseases which showed a mortality in excess of the average. This increase, Dr. Dudfield thinks, may be apparent rather than real, and is possibly due to greater accuracy in diagnosis. The decline in the prevalence and fatality of certain diseases is taken as evidence of the beneficial results of the system of voluntary notification. The action of the postal authorities in reference to the notification of several cases of scarlet fever in the families of letter-carriers, etc., did not quite satisfy Dr. Dudfield's requirements, information having been withheld until the services of the disinfecting staff were called into requisition at the termination of the respective illnesses. The death-rate for the whole parish was 15.9 per 1,000, compared with 15.5, 15.1, and 16.1, in the three preceding years, being 1.4 per 1,000 below the decennial average, and 4.0 below the metropolitan rate. The infant mortality was lower than in some recent years, the number of deaths under one year of age being 686, or 15.4 per cent. of the total registered births.

CHELSEA (Population, 97,716).—*Diphtheria: Typhus Fever: Conviction for Careless Dispensing.*—The number of deaths registered in this parish during 1886, including the three subdistricts, was 1,909. The death-rate, therefore, was equal to 20.4 per 1,000. No deaths were recorded from small-pox, and there were only 7 deaths from scarlet fever. Dr. Edward Seaton states, as a curious fact, that exactly the same number of scarlet fever deaths occurred in each of the two preceding years. Diphtheria caused 28 deaths—a high mortality, as compared with other urban districts. Dr. Seaton's experience leads him to the conclusion that defective house drainage has very little to do with the production of this latter disease. "It is beyond question," says Dr. Seaton, "that many outbreaks of diphtheria, like scarlet fever, have been traced to milk, and it is also beyond doubt that in these cases the milk has not become contaminated by human agency, or by a polluted water supply. As in the case of scarlet fever, there are facts which point to a disease of the cow as the source of the mischief." People are careless about measures of isolation and disinfection in connection with diphtheria; but Dr. Seaton insists very strongly on the need for treating the disease as one of an infectious character. Some cases of typhus fever occasioned considerable anxiety, occurring as they did in a court occupied by poor people, necessarily living under unfavourable sanitary conditions. The utmost precautions were taken, and the patients removed to the hospital, and Dr. Seaton procured the assistance of the guardians and of other charitable societies in relieving cases of distress, which would otherwise have fallen ready victims to the disease. The new disinfecting station afforded valuable help, and its usefulness is becoming more generally recognised. One of the chief events of the year was the successful prosecution of a chemist and druggist for carelessness in dispensing a medicine.

POPULAR (Population: South district, 58,530; North district, 115,900).—*Prevalence of Measles and Diphtheria: Cutting off*

Water supply.—Measles was the only zymotic disease that was seriously epidemic during 1886. In each division the deaths are reported to have been excessive. So prevalent was the disease in the south district during the month of December that Mr. Corner caused a special inspection of houses to be made, with the view of ascertaining if defective house sanitation were contributing to the fatality. The results, however, showed that such was not the case generally. Dr. Russell Talbot's explanation is, perhaps, more probable: that sufficient means for isolation were not available. No death occurred from small-pox during the year, and only 6 cases were recorded. Diphtheria and croup were fatal in 36 instances in Poplar and 14 each in Bow and Bromley. Bad storage of water, the presence of sewer gas in houses due to faulty drains and fittings, want of water to closets, and defective or absent traps, were not infrequently found in connection with the cases. In a fatal case at Millwall the suspicious connection of want of water and diphtheria was shown. The premises had been without water three days, the company having cut off the supply to enable alterations to be made. Twenty-four deaths occurred from enteric fever, 16 in the north and 9 in the south district. One death, undoubtedly due to defective sanitary conditions, was specially lamentable, the victim, the head of the house, having, on entering it nine months previously, expended money freely with the object of securing a healthy home; a daughter, who sickened later on, nearly lost her life. The deaths in Poplar were 1,043, and in Bow and Bromley 2,481. Diarrhoea prevailed but little during the summer.

HEALTH OF ENGLISH TOWNS.—During the week ending Saturday, 18th February, 5,516 births and 3,764 deaths were registered in the twenty-eight large English towns, including London, which have an estimated population of 9,398,273 persons. The annual rate of mortality per 1,000 persons living in these towns, which had been 21.9 and 22.2 in the two preceding weeks, declined during the week under notice to 20.9. The rates in the several towns ranged from 14.1 in Birkenhead, 14.2 in Sunderland, and 15.4 in Bradford and in Cardiff, to 26.7 in Norwich, 26.8 in Preston, 29.3 in Manchester, and 29.4 in Wolverhampton. The mean death-rate in the twenty-seven provincial towns was 21.2 per 1,000, and exceeded by 0.6 the rate recorded in London, which was 20.6 per 1,000. The 3,764 deaths registered during the week under notice in the twenty-eight towns included 405 which were referred to the principal zymotic diseases, against 507 and 491 in the two preceding weeks; of these, 170 resulted from whooping-cough, 61 from scarlet fever, 40 from "fever" (principally enteric), 38 from measles, 37 from small-pox, 35 from diphtheria, and 24 from diarrhoea. These 405 deaths were equal to an annual rate of 2.2 per 1,000; in London the zymotic death-rate was 2.6 per 1,000, while in the twenty-seven provincial towns it averaged only 2.0, among which it ranged from 0.2 in Bradford and 0.3 in Hull, to 3.6 in Nottingham, 3.8 in Oldham, and 6.0 in Sheffield. Measles caused the highest proportional fatality in Wolverhampton, Nottingham, and Plymouth; scarlet fever in Halifax, Oldham, Preston, and Birkenhead; whooping-cough in Brighton, Salford, and London; and "fever" in Nottingham and Norwich. The 35 deaths from diphtheria in the twenty-eight towns included 18 in London and 5 in Liverpool. Of the 37 fatal cases of small-pox recorded during the week under notice 30 occurred in Sheffield, 2 in Bristol, 2 in Leeds, 1 in London, 1 in Nottingham, and 1 in Manchester. The Metropolitan Asylums Hospitals contained 6 small-pox patients on Saturday, February 18th, of which 1 had been admitted during the week. These hospitals also contained 1,395 scarlet fever patients on the same date, against numbers declining steadily from 2,600 to 1,453 in the eleven preceding weeks; there were 104 admissions during the week. The death-rate from diseases of the respiratory organs in London was equal to 5.9 per 1,000, and was slightly below the average.

HEALTH OF SCOTCH TOWNS.—In the eight principal Scotch towns, 781 births and 563 deaths were registered during the week ending Saturday, February 18th. The annual rate of mortality in these towns, which had been 22.4 and 22.5 per 1,000 in the two preceding weeks, was again 22.5 during the week under notice, and exceeded by 1.6 per 1,000 the mean rate during the same period in the twenty-eight large English towns. Among these Scotch towns, the lowest rates were recorded in Greenock and Leith, and the highest in Glasgow and Paisley. The 563 deaths in these towns during the week under notice included 62

which were referred to the principal zymotic diseases, equal to an annual rate of 2.5 per 1,000, which slightly exceeded the mean zymotic death-rate during the week under notice in the large English towns. The highest zymotic rates were recorded in Glasgow, Perth, and Paisley. The highest proportional fatality of whooping-cough occurred in Glasgow, and from measles in Dundee. The 13 deaths from diphtheria recorded in these Scotch towns included 6 in Glasgow and 5 in Edinburgh. The mortality from diseases of the respiratory organs during the week under notice in these towns was equal to 6.5 per 1,000, against 5.9 in London.

HEALTH OF IRISH TOWNS.—During the week ending Saturday, February 18th, the deaths registered in the sixteen principal town districts of Ireland were equal to an annual rate of 28.3 per 1,000. The lowest rates were recorded in Kilkenny and Wexford, and the highest in Limerick and Drogheda. The death-rate from the principal zymotic diseases in these towns averaged 3.1 per 1,000, and was highest in Belfast and Newry. The 175 deaths registered in Dublin during the week under notice were equal to an annual rate of 25.9 per 1,000, which showed a marked decline from the high rates in recent weeks. The 175 deaths included 17 from the principal zymotic diseases (equal to an annual rate of 2.5 per 1,000), of which 7 were referred to scarlet fever, 4 to whooping-cough, 2 to "fever," 2 to diarrhoea, 1 to measles, and 1 to diphtheria.

REPUDIATION OF OVERSEER'S ORDER BY A BOARD OF GUARDIANS.

A COUNTRY MEMBER writes: On October 12th last a boy was brought to me suffering from extremely severe lacerated wound of hand, demanding immediate amputation of thumb. The operation satisfactorily concluded, the mother of the child informed me that neither she nor her husband were in a position to pay for a medical man; so I told her she must get me a "note" from the parish authorities of the Union for which I act as medical officer; this was brought me the following morning in the shape of an overseer's order. I reported the case in the usual manner to the Board of Guardians every fortnight during my attendance, which only ceased, owing to the severity of the injury, about ten days or a week ago.

I hear nothing from the Board on the subject till I send in my bill at Christmas, when I am informed that they refuse to pay me my fee (£2) for attendance on the case, and on my demanding the reason subsequently stated that "they consider A. W.'s case was one in which the overseer should not have given the order, and they decline to confirm it." Can they do so?

* * * Our correspondent should immediately take out a summons against the Board of Guardians, when he will be promptly informed by the county court judge that the Board of Guardians are, under the special circumstances, liable for the claim, and cannot dispute the legality of the same.

CERTIFICATES OF SUCCESSFUL VACCINATION.

M.B., C.M. asks: Can I, after having vaccinated a child brought to me from a distance, subsequently sign a certificate of successful vaccination on the word of the mother, without having myself seen the child? I am practising in a country district, and children are frequently brought to me for vaccination from a distance of six or eight miles. The parents strongly object to bringing the child back for examination on account of the expense to my (the year) bad weather. Similarly they object on the score of expense to my making a visit for the purpose of seeing whether the vaccination be successful or not. Hitherto I have refused to certify without seeing the child, and in consequence have roused the indignation of one or two patients for having, as they said, "refused to take their word." Apparently my predecessor had been in the habit of certifying without seeing.

* * * The intention of the Act is that the vaccination should be inspected. It is only by such means that the operator can be certain of certifying correctly. Read Form (A) in the Schedule, Vaccination Acts, 1867 and 1871.

ALPHA.—The duties of medical officers of health and of inspectors of nuisances have been defined by the Local Government Board, and an application to the Board would doubtless procure for you their memorandum.

MEDICAL OFFICER OF HEALTH.—The best book is, we think, Wilson's *Handbook of Hygiene*, but we are not prepared to state that this book will enable the candidate to reply to every question.

At a meeting held on February 16th, 1888, the Wigan Medical Society unanimously passed the following resolution:—"That it is inadvisable amongst members of the medical profession to issue circulars or to use a systematic canvass for club appointments."

THE LATE PROFESSOR BOHN.—Dr. H. Bohn, Extraordinary Professor of Pediatrics in the University of Königsberg, died on February 5th, after a long illness. His best known works are *Diseases of the Mouth in Children*, *Handbook of Vaccination*, the *Description of the Acute Exanthemata* in Gerhardt's *Handbook of Children's Diseases*, and numerous contributions to the *Jahrbuch für Kinderheilkunde*. Although Bohn had to work under unfavourable conditions, without adequate clinical material, he nevertheless produced scientific results of permanent value.

MEDICAL NEWS.

MEDICAL VACANCIES.

The following Vacancies are announced:

- BIRMINGHAM GENERAL HOSPITAL.**—Assistant House-Surgeon. Applications by February 25th to the House Governor.
- BRISTOL DISPENSARY.**—Surgeon. Applications by March 8th to E. Stock, Esq., 57, Queen Square, Bristol.
- CANCER HOSPITAL, Brompton.**—Registrar. Salary, £50 per annum, with board and residence. Applications by March 6th to the Secretary.
- CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's Inn Road, W.C.**—Two Assistant Surgeons. Applications by March 6th to the Secretary.
- COTON HILL LUNATIC HOSPITAL.**—Assistant Medical Officer. Salary, £100 per annum, with board, etc. Applications by March 10th to the Medical Superintendent.
- DEWSBURY AND DISTRICT GENERAL INFIRMARY.**—House-Surgeon. Salary, £90, with board, etc. Applications by March 6th to the Chairman of the House Committee.
- FRENCH HOSPITAL, Leicester Square.**—Resident Medical Officer. Salary, £90 per annum, with board, etc. Applications to the Secretary.
- LEICESTER INFIRMARY AND FEVER HOUSE.**—Assistant House-Surgeon. Salary, £50, with board, etc. Applications by March 10th to the Secretary, 24, Friar Lane, Leicester.
- LINCOLNSHIRE COUNTY ASYLUM, Bracebridge, near Lincoln.**—Assistant Medical Officer. Salary, £150 per annum, with board, lodging, and washing. Applications by February 25th to J. W. Marsh, Esq., Superintendent.
- METROPOLITAN HOSPITAL, Kingsland Road.**—Junior House-Surgeon. Salary, £40, with board, etc. Applications by February 27th to the Secretary.
- MOUNTMELICK UNION, Coolrain Dispensary.**—Medical Officer. Salary, £115 per annum, and fees. Applications to Mr. P. Kelly, Honorary Secretary, Derryduff, Mountrath. Election on March 5th.
- OUGHTERARD UNION.**—Medical Officer, Oughterard Dispensary. Salary, £112 per annum and fees. Applications to Mr. Robert Mons, Honorary Secretary, Drumnakill Lodge. Election on March 7th.
- OUGHTERARD UNION.**—Medical Officer to the Workhouse, Infirmary, and Fever Hospital. Salary, £70 per annum. Applications to Mr. J. Gillmore, Clerk of Union. Election on March 7th.
- ROXBURGH DISTRICT ASYLUM, Melrose.**—Assistant Medical Officer. Salary, £80 per annum, with board and residence. Applications to Dr. Johnstone.
- ST. GEORGE'S AND ST. JAMES'S DISPENSARY.**—Physician. Applications to S. L. Bunnett, 60, King Street, Regent Street, W.
- TARBAT (ROSS-SHIRE).**—Medical Officer. Salary, £115 per annum. Applications by February 28th to Finlay Munro, Esq., Rockfield-by-Fearn, N.B.
- UNIVERSITY OF GLASGOW.**—Four Examiners in Medicine. Annual fee, £40 or £30. Applications by March 5th to the Secretary of the University Court, G. D. McLellan, Esq., 145, West George Street, Glasgow.
- WEST BROMWICH DISTRICT HOSPITAL.**—House-Surgeon. Salary, £80 per annum, with board. Applications by February 25th to William Bache, Esq., Churchill House, West Bromwich.
- YORK COUNTY HOSPITAL.**—Senior House-Surgeon. Salary, £100 per annum, with board, etc. Applications by March 1st to the Secretary.
- YORK DISPENSARY.**—Three Resident Medical Officers. Salary, £130 per annum, with furnished apartments, etc. Applications by February 29th to S. W. North, Esq., 84, Micklegate, York.

MEDICAL APPOINTMENTS.

- ASHLEY, S. D., M.R.C.S.,** appointed Resident House-Surgeon to the Brixton, Streatham, and Herne Hill Dispensary, *vice* A. G. Peacock, L.R.C.P., M.R.C.S., resigned.
- CALVERT, James, B.A., B.Sc., M.D.Lond., M.R.C.P., M.R.C.S.,** appointed Assistant-Physician to the Royal Hospital for Diseases of the Chest, City Road, London.
- GRIFFITHS, T. R.,** appointed Clinical Assistant to the Birmingham Borough Asylum, *vice* R. J. Fox, resigned.
- HAILES, D. G. Clements, C.M., M.D.Ed.,** appointed Consulting Surgeon-Oculist to the Redland Branch of Clifton Dispensary.
- JONES, E. Lloyd, M.B., C.M., R.A.,** appointed Junior House-Surgeon to the Western Dispensary, Marylebone Road, N.W.
- LUFF, A. P., M.B., B.Sc.Lond., M.R.C.S.,** appointed Assistant-Physician to the North-West London Hospital, Kentish Town Road, *vice* T. Glover Lyon, M.A., M.D., resigned.
- POWELL, H., L.R.C.P.Ed.,** appointed Medical Officer to the Silvermines Dispensary, Nenagh Union, *vice* J. H. A. Hall, L.K.Q.C.P.I., resigned.
- SUGDEN, E. S., M.B.Dur., M.R.C.S.Eng.,** appointed Senior House-Surgeon to the Birkenhead Borough Hospital, *vice* S. Hughes, M.B., C.M.Ed., M.R.C.S., resigned.
- THOMAS, J., M.R.C.S.Eng., L.R.C.P.Lond.,** appointed House-Surgeon to the Glamorgan and Monmouth Infirmary and Dispensary, *vice* Donald Paterson, M.D., resigned.

PRESENTATION TO DR. F. ERNEST POCOCK.—At the half-yearly dinner, on February 16th, of the Brussels Medical Graduates Association, Dr. Henry Lewis, of Folkestone, President, in the chair, a handsome illuminated address, with a gold repeating watch and massive silver centre-piece and soup tureen, was presented to Dr. F. Ernest Pocock, who has been honorary secretary of the asso-

ciation for nearly ten years. The presentation was made jointly by Dr. Jervis, the president, and Dr. I. Beresford Ryley, the founder of the Association, both of whom spoke in the warmest and most cordial manner of the indefatigable energy and acumen shown by Dr. Pocock in carrying out the work of the association. It was entirely owing to Dr. Pocock's efforts that the Brussels degree had been (under the recent Medical Act) placed upon the *Medical Register*. Dr. Pocock suitably responded, and thanked the association for their kind recognition of his services. Dr. Bowles, F.R.C.P., of Folkestone, in replying to the toast of his health, said that Indian medical students were at a great disadvantage in obtaining a degree in medicine, but that he hoped this was soon to be remedied. Among the other speakers were Dr. Danford Thomas, Dr. William Gayton, Dr. Nix, Dr. Barraclough, and Dr. Orwin.

THE WORKHOUSE INFIRMARY NURSING ASSOCIATION.—H.R.H. Princess Christian of Schleswig-Holstein, patroness of the Workhouse Infirmary Nursing Association, has written to the committee: "If I have an opportunity, I will certainly urge the claims of the Trained Nursing Association in workhouse infirmaries. I know from personal experience what good work it has done." The eighth annual report of this association showed that there has been during the past year a steady increase in the demand for nurses trained by the association. Sixty-three have been appointed to twenty-two infirmaries. Seventy-three nurses, of whom fifty-four are in London, and the remainder in the country, are now at work. Four vacancies were filled during the year at new infirmaries. Midwives from the association are at work at the infirmaries of St. Pancras, Camberwell, St. Luke's (Holborn), Marylebone, Kensington, and Hampstead. The Board of Guardians of St. George's-in-the-East have consented to fill the vacancies which occur in their infirmary with trained nurses, under the supervision of Miss Hughes, the matron appointed last year. Miss Louisa Twining has promised a donation of £100 towards meeting the increased outlay of the association in carrying out the work it has set to itself—that of abolishing the old system of pauper nursing, and replacing it by placing trained ladies and nurses in all our infirmaries. It is encouraging to find that fifteen boards of guardians subscribe to the society's funds.

HUNTERIAN SOCIETY.—The following officers of the Hunterian Society were elected at the annual general meeting on February 8th for the ensuing twelve months:—*President*: R. Clement Lucas, B.S. *Vice-Presidents*: Mr. G. J. B. Stevens; Mr. G. B. Hicks; Fletcher Beach, M.D.; Heinrich Port, M.D. *Treasurer*: H. I. Fotherby, M.D. *Trustees*: H. I. Fotherby, M.D.; Mr. D. de Berdt Moyell. *Librarian*: Mr. T. Rowing Fendick. *Orator*: G. E. Herman, M.D. *Secretaries*: F. Charlewood Turner, M.D.; Mr. John Poland. *Council*: Messrs. S. H. Appleford; T. E. Bowkett; P. L. Burchell, M.B.; F. M. Corner; J. S. E. Cotman; H. Gervis, M.D.; Dundas Grant, M.D.; W. Rivington, M.S.; Isaac Searth, M.B.; J. H. Stowers, M.D.; C. J. Symonds, M.S.; R. G. Tatham. *Auditors*: G. E. Herman, M.B.; Messrs. Waren Tay, T. Rowing Fendick, J. S. E. Cotman. *Library Sub-committee*: Messrs. F. M. Corner, S. H. Appleford, Walter Rivington, M.S.; Heinrich Port, M.D.; J. S. E. Cotman. In our notice of the dinner of this Society last week, the name of Buzzard was misprinted for that of Sir William Blizard, of the London Hospital, who in former years adorned the presidential chair, being the first president, and delivered the first oration.

THE WILLIAM F. JENKS MEMORIAL PRIZE.—The first triennial prize of 250 dollars, under the deed of trust of Mrs. W. F. Jenks, will be awarded to the author of the best essay on "The Diagnosis and Treatment of Extra-Uterine Pregnancy." The prize is open for competition to the whole world, but the essay must be the production of a single person, and must be written in the English language, or if in a foreign language must be accompanied by an English translation. All essays to be sent to the College of Physicians of Philadelphia, Pennsylvania, U.S.A., addressed to Ellwood Wilson, M.D., before January 1st, 1889. Each essay must be distinguished by a motto, and accompanied by a sealed envelope bearing the same motto, and containing the name and address of the writer. The Committee will return unsuccessful essays if reclaimed within one year. If the successful essay be published, which the trustees have the power of doing, the distribution of it is to be entirely under the control of the trustees under the deed. If not published, it is to be the property of the College of Physicians of Philadelphia.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.—The following gentlemen have been admitted as honorary members of this Society:—Sir Andrew Clark (London), Drs. Matthews Duncan (London), David Ferrier (London), Alex. Harvey (London), Thomas Keith (Edinburgh), William Bruce (Dingwall), Samuel Davidson (Wartle), Patrick Jamieson (Peterhead), William Lyon (Peterculter), Alexander Manson (Banff), Charles Smith (Kinnairdy).

INTER-HOSPITAL (RUGBY) CUP TIES.—Second round: St. Mary's v. London, resulted in a win for the former by 1 try (10 points) and 3 minors to 2 minors (2 points). The game was almost entirely confined to the forwards, and the result somewhat unexpected. The semi-final round is played this week, the final on March 1st.

INTER-HOSPITAL (ASSOCIATION) CUP.—Penultimate round: St. Bartholomew's v. St. Mary's. Played on February 14th, resulted in a draw, each side scoring one goal. St. Thomas's v. Guy's (holders). Played on February 17th, resulted in a win for the holders by 4 goals to 1.

Professor Brunetti, of the University of Pavia, has just been suspended by ministerial decree on the ground that he incited the students to rebellion against his colleagues.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 P.M.—Professor Walter Hamilton Hilton Jessop, F.R.C.S.: Lecture I. On the Physiological and Pathological Conditions of the Pupil, and Accommodation.

MEDICAL SOCIETY OF LONDON, 8.30 P.M.—Dr. Omerod: Two Cases of Friedreich's Ataxia. Mr. Marmaduke Sheild: (1) Ununited Fracture of Arm. (2) Loose Bodies in Knee-joint. Mr. Black: Case of Syphilis. Cases will also be shown by Mr. Stephen Paget, Mr. Pitts, Dr. Samuel West, and others.

TUESDAY.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, 5 P.M.—Inspector-General Lawson: The Milroy Lectures.—Lecture III. Epidemiological Aspects of Yellow Fever.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8.30 P.M.—Mr. Henry Morris: Some remarks on the Radical Cure of Hydrocele, with notes of two Cases of Excision of the Tunica Vaginalis, followed by Recurrence of the Hydrocele. Mr. A. Marmaduke Sheild: A Case of Neglected Dislocation of the Head of the Humerus, followed by Paralysis of the Nerves of the Hand and Forearm, treated by Excision of the Head of the Humerus.

WEDNESDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 P.M.—Professor Walter Hamilton Hilton Jessop, F.R.C.S.: Lecture II. On the Physiological and Pathological Conditions of the Pupil, and Accommodation.

HOSPITAL FOR CONSUMPTION, Brompton, 4 P.M.—Dr. Theodore Williams: Pathology and Modern Treatment of Bronchial Asthma.

THURSDAY.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, 5 P.M.—Inspector-General Lawson: The Milroy Lectures.—Lecture IV. Epidemiological Aspects of Cholera.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8.30 P.M.—Annual meeting.

PARKES MUSEUM OF HYGIENE, 5 P.M.—Professor G. Sims Woodhead, M.D., on Milk and Disease.

HARVEIAN SOCIETY, 8.30 P.M.—Mr. Mansell-Moullin: The Surgical Treatment of Bimpyema. Dr. Spicer: On the Functions of the Uvula and Epiglottis.

FRIDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 P.M.—Professor Walter Hamilton Hilton Jessop, F.R.C.S.: Lecture III. On the Physiological and Pathological Conditions of the Pupil, and Accommodation.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, 8 P.M.—Mr. Percy Dunn will show Pathological Specimens. Mr. Roche Lynch will show a Specimen of Cancer of Bodies of the Vertebrae. Dr. Eccles will give a demonstration of Massage. Papers: Mr. Lunn: On a Successful Case of Oophorectomy. Dr. Inglis Parsons: The Treatment by Electrolysis of Fibroids of the Uterus.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the announcement.

BIRTHS.

BELL.—On February 18th, at Morehall Bishop, Devon, the wife of Theodore Bell, M.B., B.Ch. (Univ. Dublin), of a daughter.

O'CONNELL.—On January 30th, at Neemuch, Central India, the wife of Surgeon D. V. O'Connell, M.D., Army Medical Staff, of a daughter.

DEATH.

GREENER.—On February 11th, at Riverside, Cardiff, Marjorie Grace, infant daughter of Michael and Florence Greener.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY	10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's (Ophthalmic Department); and Royal Westminster Ophthalmic.—2 P.M.: Metropolitan Free; St. Mark's; Central London Ophthalmic; Royal Orthopaedic; and Hospital for Women.—2.30 P.M.: Chelsea Hospital for Women.
TUESDAY	9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's; St. Bartholomew's (Ophthalmic Department); St. Mary's; Royal Westminster Ophthalmic.—2 P.M.: Westminster; St. Mark's; Central London Ophthalmic.—2.30 P.M.: West London; Cancer Hospital; Brompton.—4 P.M.: St. Thomas's (Ophthalmic Department);
WEDNESDAY	10 A.M.: National Orthopaedic.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: Middlesex.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: London; University College; Westminster; Great Northern Central; Central London Ophthalmic.—2.30 P.M.: Samaritan Free Hospital for Women and Children; St. Peter's.—3 to 4 P.M.: King's College.
THURSDAY	10.30 A.M.: Royal London Ophthalmic.—1 P.M.: St. George's.—1.30 P.M.: St. Bartholomew's (Ophthalmic Department); Guy's (Ophthalmic Department); Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Central London Ophthalmic; Hospital for Diseases of the Throat; Hospital for Women.—2.30 P.M.: North-West London; Chelsea Hospital for Women.
FRIDAY	9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: St. George's (Ophthalmic Department).—1.30 P.M.: Guy's; Royal Westminster Ophthalmic.—2 P.M.: King's College; St. Thomas's (Ophthalmic Department); Central London Ophthalmic; Royal South London Ophthalmic; East London Hospital for Children.—2.30 P.M.: West London.
SATURDAY	9 A.M.: Royal Free.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: King's College.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Middlesex; Royal Free; Central London Ophthalmic.—2.30 P.M.: Cancer Hospital, Brompton.

HOURS OF ATTENDANCE AT THE LONDON HOSPITALS.

CHARING CROSS.—Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; Skin, M. Th., 1.30; Dental, M. W. F., 9.

GUY'S.—Medical and Surgical, daily, 1.30; Obstetric, M. Tu. F., 1.30; Eye, M. Tu. F., 1.30; Ear, Tu. F., 12.30; Skin, Tu., 12.30; Dental, Tu. Th. F., 12.

KING'S COLLEGE.—Medical, daily, 2; Surgical, daily, 1.30; Obstetric, Tu. Th. S., 2; o.p., M. W. F., 12.30; Eye, M. Th., 1; Ophthalmic Department, W., 1; Ear, Th., 2; Skin, Th., 3; Throat, Th., 3; Dental, Tu. F., 10.

LONDON.—Medical, daily, exc. S., 2; Surgical, daily, 1.30 and 2; Obstetric, M. Th., 1.30; o.p. W. S., 1.30; Eye, W. S., 9; Ear, S., 9.30; Skin, Th., 9; Dental, Tu. F., 1.30; o.p. W. S., 1.30; Middlesex.—Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; o.p. W. S., 1.30; Eye, W. S., 8.30; Ear and Throat, Tu., 9; Skin, Tu., 4; Dental, daily, 9.15; St. Bartholomew's.—Medical and Surgical daily, 1.30; Obstetric, Tu. Th. S., 2; o.p. W. S., 9; Eye, Tu. Th. S., 2.30; Ear, Tu. F., 2; Skin, F., 1.30; Larynx, F., 2.30; Orthopaedic, M., 2.30; Dental, Tu. F., 9.

ST. GEORGE'S.—Medical and Surgical, M. T. F. S., 1; Obstetric, Tu. S., 1; o.p. Tu. S., 2; Eye, W. S., 2; Ear, Tu., 2; Skin, W., 2; Throat, Th., 2; Orthopaedic, W., Tu., 2; Dental, Tu., S., 9, Th., 1.

ST. MARY'S.—Medical and Surgical, daily, 1.45; Obstetric, Tu. F., 1.45; o.p., M. Th., 1.30; Eye, Tu. F. S., 9; Ear, M. Th., 3; Throat, Tu. F., 1.30; Skin, M. Th., 9.30; Electrician, Tu. F., 2; Dental, W. S., 9.30; Consultations, M., 2.30; Operations, Tu., 1.30; Ophthalmic Operations, F., 9.

ST. THOMAS'S.—Medical and Surgical, daily, except Sat., 2; Obstetric, M. Th., 2; o.p., W. S., 1.30; Eye, M. Th., 2; o.p., daily, except Sat., 1.30; Ear, M., 12.30; Skin, W., 12.30; Throat, Tu. F., 1.30; Children, S., 12.30; Dental, Tu. F., 10.30.

UNIVERSITY COLLEGE.—Medical and Surgical, daily, 1 to 2; Obstetrics, M. Tu. Th., F., 1.30; Eye, M. Tu. Th. F., 2; Ear, S., 1.30; Skin, W., 1.45, S., 9.15; Throat, Tu., 2.30; Dental, W., 10.30.

WESTMINSTER.—Medical and Surgical, daily, 1.30; Obstetric, Tu. F., 3; Eye, M. Th., 2.30; Ear, M., 9; Skin, Th., 1; Dental, W. S., 9.15.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS respecting editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

In order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the office of the JOURNAL, and not to his private house.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate beforehand with the Manager, 429, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication. CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

QUESTIONS.

CANIS has a case before him now (in advanced life) where a simple enema, though satisfactory enough to empty the bowel, leads to great acceleration of pulse, with loss of all rhythm and rise of temperature. What is the explanation of this; does the injection reverse the peristalsis and react upon the heart?

A MEMBER OF THE BRITISH MEDICAL ASSOCIATION asks: What constitutes the "National Dispensary?" A "cheap" (possibly "naughty" also) dispensary has been opened at Tunbridge recently as the "Tunbridge Branch" of the above.

SUPPLY OF MEDICINES FOR A CHARITABLE INSTITUTION.

A MEMBER asks: What would be a fair sum for a charitable institution, containing seven adult female beds and one cot, to pay their medical officer for the supply of medicines? Professional services are given gratuitously. The cases admitted are non-contagious and suticute ones. Each patient pays 5s. a week towards her maintenance.

ANSWERS.

DR. A. has omitted to forward his name or card.
T. L. L.—Dr. Albin Meunier's products for the treatment of pulmonary affections can be obtained at Roberts's, 76, New Bond Street, London. The general depot is at Paris, Pharmacie Vicario, 17, Boulevard Haussmann.

R. F. (Linfield).—Another point of view is that it is for the respective Colleges to enforce their own by-laws in respect to titles, if they wish to do so, but any infringement of those by-laws should be brought before the properly constituted authorities.

DR. J. N. DEAN (Ardwick).—The case described by our correspondent ought also to be referred in the first place to Mr. East.

GLYCERINE AS AN INJECTION.

DR. C. J. R. MCLEAN (Yeaton) writes, in reply to W. H. B., "I have given glycerine as a rectal injection in a number of cases with very satisfactory results with a common glass syringe such as is used for urethral injections."

MR. WILLIAM PROWSE states that glycerine is quite as effectual in stimulating the rectum when it is diluted with an equal quantity, (or more) of water. He would add that glycerine is no cure for habitual constipation; all that it does is to cause a peristaltic action of the lower bowel (the rectum) only, and certainly does not remove any cause existing higher up; not even in the transverse or descending colon. The injection can easily be made with a small india-rubber bottle, taking care to wash it out and drain.

TOLERANCE OF LARGE DOSES OF MORPHINE.

DR. PHINEAS PITTS LANGFORD asks as to the quantity of morphine which may be given subcutaneously with impunity in a case of carcinoma uteri. He has a case where injections have been given since March last in doses ranging from one-sixth of a grain to twelve grains daily. The latter quantity has been administered for the last three months, 20 minims of a 1 in 5 solution being injected three daily. During the last three weeks beneficial effects seem to have ceased, as far as relieving pain and obtaining sleep are concerned. Ten days since his patient made up her mind to give up the drug, as she seemed to obtain no benefit from it. Strange to say, she has not apparently suffered from its loss, and she is now better than she was two months since. He states that she has had one bad attack of morphinomania which lasted seven days, during four days of which administration was stopped. Before she ceased having morphine this last time she was suffering from incessant vomiting and very great prostration. The vomiting has now ceased, and she has apparently no pain, and is sleeping well, and taking more nourishment than she has done for some time past. She is very much emaciated, but her mind is clear and memory good; no diarrhoea.

* * * It is difficult to fix with precision the degree of tolerance of opium. Idiosyncrasy and habit vary greatly in their influence.

TREES FOR TOWNS.

R. HUGHES (Bala) asks what kind of trees are most suitable for towns, both for sanitary purposes and beauty.

* * * The following is a list of trees and shrubs which have been found to do best in smoky districts, furnished us by Miss Wilkinson, hon. landscape gardener to the Metropolitan Public Gardens Association, 83, Lancaster Gate:

Plane (one of the best for London, but does not thrive in north country towns)	Willow (especially good for moist places)
Poplars (very quick growing)	Thorns of sorts
Birch	Laburnum
Ash	Almond
Maple	Double cherry
Sycamore	Fig (grows well in London and the south)
Silver birch	Mulberry
Lime (is often attacked by vermin)	Lilacs
Horse chestnut	Mountain ash
Beech	Elders of sorts
Purple beech	Alder (grows in moist places)
Tulip tree	

It has been found by experience that for London planting planes, poplars, willows, and in some places silver birch and flowering shrubs grow better than any others.

APPEALS TO THE BENEVOLENT.

DRS. A. M. MACRAE and R. ROSS (Stornoway).—The benefits of the Society for the Relief of Widows and Orphans are, we are informed, confined to subscribers. The case would, however, probably come within the scope of the

British Medical Benevolent Fund, and our correspondent had better in the first place apply to Mr. Edward East, 16, Upper Berkeley Street, Portman Square, London, W., Honorary Secretary for cases.

CONSTIPATION DURING PREGNANCY.

MR. WILLIAM PROWSE, in reply to "Rhubarb," who asks for a remedy for constipation in pregnancy, recommends the administration of 10 minims of the Prussia tincture of colocyth pulp. (with or without the aniseed) in half a wineglassful of water at bedtime twice a week; it is the best remedy for habitual constipation. The dose should be varied according to the age and strength of the patient, and care should be taken not to overdose—sufficient to produce one solid evacuation, and not more.

DR. W. HESBY writes: In reply to "Rhubarb," I would advise him to try cascara sagrada, twenty to thirty minims of the fluid extract, two or three times a day until a regular action is obtained. I cannot speak too highly of the use of glycerine as an injection; I have used it very frequently of late, although my first trial of it was two years ago, when I prescribed one drachm to be diluted with a tablespoonful of water, and used every morning. I now use one drachm with a little water, and use a syringe of vulcanite with a glass barrel; this holds about half an ounce; to this a bona fide enema, similar in shape to that on a child's ball enema, is fastened. The nozzle should be at least two and a half inches in length; an ordinary glass syringe is useless.

DR. J. WALTERS (Reigate) recommends ext. cascara sagrada with pil. rhei co. gr. ii-iii, as he has found it most beneficial against obstinate constipation in pregnancy.

DR. SPENCER SMYTH (Forest Hill) recommends a pill containing cascara, capicum, and olix vomica.

GYNÆCOLOGICAL PRACTICE.

DR. D. A. FRASER (Totnes) thinks "Country Member" would find Fraser's surgeon's combination chair, made by Mr. W. Harris, cabinet maker, Esplanade, Burnham, likely to suit; complete £5 5s. in oak or mahogany.

BISKRA PUSTULE.

T. H.—Duclaux on Biskra Pustule (*Bulletin de la Société de Biologie*, 1888); Chantemesse (*Annales de l'Institut Pasteur*, October, 1887); Poncet (*idem*, November, 1887).

TAXES ON CARRIAGES AND HORSES.

C. J. R. M.—If our correspondent refers to licence for carriage and man-servant, there is no exemption by reason of their being necessary to practice. This is one of the hardships of the carriage tax, as one of the hardships of the inhabited house duty is that full duty is charged on a house where a profession is carried on, whereas two-thirds of the duty only are payable where there is a shop. If he alludes to income tax, the expenses of his carriage, horse and man-servant are a professional expense, and as such may be deducted. See for further particulars Chapman's *Income-tax: How to get it Refunded*, to be obtained at 25, Colville Terrace, W. To send in his accounts to the surveyor, he should get forms for balance sheets, and three years' returns at the same address.

"PSEUDOMANIA."

ALETHES (Cambridge): Lying, like theft, may be a symptom of insanity. Either of them must be taken in conjunction with other symptoms, and the whole condition and all the circumstances of the individual case be taken into consideration. Lying alone, or theft alone, would not constitute insanity. Prichard and others have described cases of so-called "moral insauity" (not a happily chosen name), in which lying (unusual to the patient) was one among other symptoms.

NOTES, LETTERS, ETC.

RECIPROCITY OF PRACTICE.

DR. EDWARD DRUMMOND (Rome) writes: I very much doubt if any good is likely to arise from a petition to the Swiss Federal Government on the subject of permission being given to English medical men to practise in Switzerland.

I had a correspondence some years ago with the Swiss authorities at a time when I thought of alternating my winter work in Rome with summer practice in the Engadine. Although influentially supported by our own embassy, I found that, if I practised in Switzerland at all, it must be *sub rosa*, which my own dignity forbade.

I had a like difficulty about Homburg, where my name was not allowed to appear in the *Kurliste*, and where my right to practise was denied unless I passed a "Staats-Examen." The late Lord Amphilil did his best to procure me a special permission, but in vain, although the shrewd Teutons did not disdain in advertising Homburg to refer to my articles on the baths, climate, etc.

It is not sufficient to have obtained a German degree. The Staats-Examen is essential, and yet half the prosperity of Homburg is due to English money. English visitors would prefer an English physician, but he can only practise under penalty. The German physician practising in England can easily obtain some sort of diploma on easy terms from one of our own corporations, and if he did not he would not be likely to be molested.

The Italian law seems to me the most equitable. No one can attend Italians in Italy without a degree from an Italian university, but any medical man of a foreign nationality can attend foreigners in Italy, provided that he shows himself to be legally qualified to practise in his own country when called upon by the authorities. To this is due the circumstance that whereas when I came to Rome I was the fourth English physician, there are now eight or nine. Still I feel sure the Italian law is the best solution of the difficulty, and might very well be adopted at home.

THE TITLE OF DR.

HONESTAS writes: Your reply to "Anxious One," in the JOURNAL of February 11th, that the Royal College of Physicians of Edinburgh has always discouraged its Members and Licentiatees from using the title of Dr. is quite erroneous.

In 1845, Dr. Grace, of Thornbury, wrote to the Secretary of the College, asking for information on this subject. The official reply was that "he was (as a Licentiate) legally entitled (by the charter) to call himself doctor, and to add the prefix on his door-plate, etc." (see the JOURNAL, February 7th, 1885). This secretary was the distinguished Rutherford Haldane, afterwards a member of the General Medical Council.

At the present time the College undoubtedly discourages the assumption of any other title than that of physician by its Licentiatees, but this does not alter the fact that for many years it gave candidates to understand that the licence carried with it a right to the title of Dr., and in all official communications this prefix was used.

I hope all old Licentiatees and Members will make a note of the law as laid down by the College in their letter to Dr. Grace.

A SOCIETY FOR SUPPLYING CLOTHES TO CHILDREN IN HOSPITALS.

MRS. H. GOODWIN STEPHENSON, Honorary Secretary of the Society for Making Clothes for the Sick Children in London Hospitals, will be glad to receive applications for membership, and to supply rules, patterns, and all further particulars on receipt of two stamps and a letter addressed to her at 26, Dorset Square. There are now over 1,000 members of the society, and parcels of clothes are sent monthly to twenty-five institutions in turn. Each member is required to supply four garments yearly, and to provide her own materials, but no subscription is asked for. The clothes are much valued by the various hospitals.

WOMEN AS PHARMACISTS.

MRS. ISABELLA S. CLARK KEEB, herself a pharmaceutical chemist, recommends pharmacy as an employment for women, in an interesting paper on the subject in *Atlanta* for this month. There are at present ten women pharmacists on the registry of the Pharmaceutical Society, of whom four are in business, three in England and one in Wales; of the others, some hold appointments in hospitals and dispensaries, and one or two give private lessons in pharmacy.

CARRIAGES FOR REMOVING INVALIDS.

MESSRS. H. and J. READING, 14 and 15, Riding House Street, Langham Place, London, write: We notice in the JOURNAL of February 18th an illustrated article from Mr. Richard Davy, of the Westminster Hospital, in the last paragraph of which he states "that until lately no regard has been given to the removal of an invalid," we may beg leave to mention, as must be known to most of your readers, that for the last fifty years our invalid's cot carriages have been used for that purpose, and with such gratifying results that not one single complaint of an injury done to an invalid during transit has been made, among the thousands we have moved to all parts of England, Ireland, Scotland, and to the Continent.

Our carriages have the advantage of conveying an invalid from bedside to bedside without having to be moved off the couch, no matter how far the distance, which obviates the necessity, which occurs in other carriages, of taking the patient out, and transferring him to a railway carriage or guard's van, where he runs a great risk of taking cold and being much shaken.

We may also mention that we never have any inconvenience with the railway companies; on the other hand, they facilitate our object by even allowing our carriage to be placed in the middle of a train to lessen the little vibration that may ensue; but as we have special means of strapping our carriage to the truck, in addition to their arrangements, such vibration is reduced to a minimum.

We shall have the greatest pleasure in showing and describing our carriages to Mr. Richard Davy or any other medical gentleman interested in the object of the removal of invalids, and we are sure that we shall convince them that our mode of removal supercedes all others, and will continue to merit the patronage hitherto bestowed on us by the profession.

IDIOSYNCRASY TO QUININE.

H. G. H. writes: A patient who consulted me the other day after I had prescribed for him suddenly asked me if I had ordered him "quinine" in any form or other, and on informing him that I had not, I asked him the reason. "Why? well," he said, "I really cannot take it. I have tried it several times, and every time it produces the same effect," namely, intolerable itching all over the body, but more particularly the hands, between the fingers, which lasts for about two or three hours. The first time he tried it was about nine years ago, with the same result then as now, and every time that he takes it (unaware, of course, as he will otherwise not take it upon any account) he has this most fearful itching of which he complained. In all "Therapeutics," articles upon quinine, etc., that I have read, I have not seen this mentioned. I wanted him to try a dose or two, with the intention of combining it with some liquor arsenicalis, as a preventive to this most intense itching; but nothing would induce him to try it, although he said he wished so much to be able to take quinine.

COMMUNICATIONS, LETTERS, etc., have been received from:

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE "BRITISH MEDICAL JOURNAL."

Seven lines and under	£0 3 6
Each additional line	0 4 4
A whole column	1 15 0
A page	5 0 6

An average line contains seven words.

When a series of insertions of the same advertisement is ordered, a discount is made on the above scale in the following proportions, beyond which no reduction can be allowed.

For 6 insertions, a deduction of	10 per cent.
" 12 or 13 "	20 "
" 25 "	25 "
" 52 "	30 "

Special terms for occasional change of copy during series:
 20 per cent. (if not less than 26 pages be taken) or their equivalent
 25 " " 52 " " in half or
 30 " " 104 " " quarter pages.

For these terms the series must, in each case, be completed within twelve months from the date of first insertion.

Advertisements should be delivered, addressed to the Manager at the Office, not later than noon on the Wednesday preceding publication; and, if not paid for at the time, should be accompanied by a reference.

Post-Office Orders should be made payable to the British Medical Association, at the West Central Post-Office, High Holborn. Small amounts may be paid in postage-stamps.

REMARKS

ON

ALBUMINURIA A FREQUENT RESULT OF SEWAGE POISONING.

BY GEORGE JOHNSON, M.D., F.R.S.,

Emeritus Professor of Clinical Medicine; Consulting Physician to King's College Hospital.

IT is notorious that a great variety of diseases may result from drain poisons. With our present system of drainage a town sewer may contain, not only excremental matter in various stages of decomposition, but with this may be combined the specific contagia of such communicable diseases as cholera, typhoid, scarlet fever, erysipelas, diphtheria, etc. That typhoid fever, some forms of diarrhoea and dysentery, diphtheria and various forms of sore throat, not presenting the specific characters of diphtheria, may result from defective drainage is a matter of daily observation. I have seen several cases of profuse purulent discharge from the inflamed mucous membrane of the fauces demonstrably the result of septic sewer poisoning. In other cases, with less apparent inflammation of the mucous membrane, the lymphatics beneath the jaw have become swollen and painful, and in one case this resulted in an abscess.

Pleuro-pneumonia is another form of acute disease which not rarely may be traced to the same cause. I have seen many instances of this. Last summer I was asked by a friend to see his groom in a mews at the West End of London. The young man had been in good health until the day before, when, without previous exposure to cold, he was seized with a rigor. I found him with a temperature of 104°, the pulse and breathing were rapid, and he had pain in the right side of the chest. Although the physical signs had not then become developed, I felt sure that the disease would prove to be pleuro-pneumonia, and I at once sent him to the nearest hospital, St. George's, where, under the care of Dr. Whigham, the disease took the usual course, and ended in a speedy and complete convalescence. He had come up from the country with the rest of his master's establishment a fortnight before, and had slept in a room close by a filthy untrapped closet. Looking upon this as the septic source of his disease, I had a double reason for insisting upon his prompt removal to the hospital: first, that he might have better attendance; and, secondly, that he might escape from the poisonous atmosphere in which his disease had been contracted.

The coachman, who had come up at the same time, and who occupied an adjoining room, after feeling unwell for some days, got an abscess in one eyelid.

The coachman's mother, who was acting as housekeeper and nurse, immediately after the removal of the groom, had a rigor, followed by severe pain in the limbs; temperature, 102°. I sent her at once into King's College Hospital, where, in a few days, the pain ceased, the temperature became normal, and she was convalescent.

There can, I think, be no question that these three distinct forms of illness, occurring within a few days of each other, were the result of septicæmia, from the one common source of drain poisoning; and the master, on being informed of the insanitary condition of the premises occupied by his servants, at once gave orders for the defective drainage to be made good.

In addition to other forms of disease, the result of drain poisoning, I have met with a number of cases of albuminuria which have been clearly traceable to that cause, and the main object of this communication is to direct attention to the fact that amongst the many causes of blood contamination and consequent albuminuria, sewage poisoning is a by no means infrequent one.

The occurrence of a case of typhoid or diphtheria in a house would, as a matter of course, excite attention to the drainage and the water and milk supply. I am anxious to show that, in the absence of other probable exciting causes of albuminuria, the possibility of sewer poisoning should be constantly borne in mind. It is needless to insist upon the practical importance of discovering the exciting cause of a disease, and thereby enabling the patient to avoid continued exposure to the morbid agency.

CASE I.—The following typical case was seen by me with Mr. Galton, of Brixton, and Dr. Langford, of East End, Finchley, on January 3rd, 1887. Mr. L. H., aged 40, had been ailing on and off since August, 1886, but he had been worse during the last month. There had been soreness of the throat and neck, with occasional rigors and a temperature of 102°. A week before my visit the urine had been tested and found highly albuminous. It was now turbid with urates; specific gravity 1030; contained (as ascertained by Esbach's method) 7 grammes per litre of albumen, and when cleared by warmth many small hyaline casts, with some epithelial and leucocyte casts, were seen. The urine was scanty, the pulse full and throbbing; no œdema. The patient was of temperate habits, he had not been exposed to cold, and in the absence of other apparent exciting cause I expressed my conviction that drain poisoning had been the cause of the sore-throat, occasional rigors, and albuminuria. On subsequent inquiry, it was found that sewer gases had been escaping into his house from two untrapped waste pipes, one connected with a washing basin in a lavatory, the other with a bath, and both going direct into the drain. At the time of my visit the patient was staying at the house of a relative, and he remained there until he recovered. He was treated in the usual way by rest in bed, milk diet, warm baths, and purgatives. In about a week the albumen began to decrease; in three weeks it had entirely disappeared, and it has not recurred. I saw him in May last year and in January of the present year, with Mr. Galton, for another complaint, and on each occasion the urine was found to be quite normal.

It is highly probable that if the cause of this man's illness had not been discovered and removed, continued exposure to the sewer poison would have resulted in an incurable disorganisation of the kidneys, as it had done in several cases that have come under my observation.

I will now give an outline sketch of three of these cases, omitting dates and details, the publication of which might give pain to the relations and others connected with the cases.

CASE II.—A national schoolmaster consulted me at my house. He had been out of health for a year. For six months the urine had been blood-tinged. Now specific gravity 1010, slightly blood-tinged, albumen 3 grammes per litre, many epithelial casts, and some blood-tinged. There was a double aortic murmur at the base and a single systolic mitral at the apex. A modified collapsing pulse (see Chapter xxxv of my *Medical Lectures and Essays* "On the diagnosis of co-existing aortic and mitral incompetence"). The legs were œdematous; there was much dyspnoea; he was pale and emaciated, and hopelessly ill. It is probable that the double valvular disease was a result of uramic endocarditis. He was living in the basement of a schoolhouse, where there was conclusive evidence of a blocked drain in the fact that after a rainfall the area was always flooded. His wife had suffered from dysentery soon after they entered the house four years before, and often since from diarrhoea. The doctor who attended her for the dysentery said they ought not to remain in the ill-drained house. I wrote to the clergyman who sent him to me, and expressed my conviction that the illness of his schoolmaster was caused by the insanitary condition of the schoolhouse. The poor man was a total abstainer, and had been exposed to no other probable exciting cause of disease.

CASE III.—Mr. W., aged 35, had enjoyed uninterrupted good health until two years before I saw him (in December, 1887), he went to live in a recently built house a few miles from London. From that time he began to suffer from disorder of the stomach and bowels, with almost constant diarrhoea. On two occasions, in 1886 and 1887, while he was away in Scotland for three weeks, these troublesome symptoms entirely passed away, but they re-appeared within a few days after his return home. Six weeks before my visit general dropsy appeared, and then the urine, which had not before been examined, was found to contain a large amount of albumen. It was of the rather light colour indicative of chronic disease, specific gravity 1020, and contained fifteen grammes of albumen per litre—the largest amount I have ever found. It deposited a cloudy sediment containing numerous hyaline and oily casts, with scattered oily cells. In the absence of other probable exciting cause of the renal disease, I inquired about the drainage. There were two closets in the small house—one on the ground floor, the other on the first floor near the patient's bedroom. The patient's wife had occasionally noticed a bad smell, and a friend who often visited them had complained of an unpleasant "earthy smell" whenever he

entered the house. A case of typhoid fever had recently occurred on the premises. I expressed a decided opinion that a drain poison was the cause of the renal disease, and advised that the condition of the drainage should be thoroughly investigated.

I have since learnt from the gentleman whom I met in consultation, and from the patient's wife, that after my visit the drainage was examined, with the following result. Peppermint water having been poured into the upstairs closet was at once detected by its odour in the hall; and beneath the hall floor there was found a defective joint in the soil pipe from the closet, so that sewage had escaped into the earth upon which the floor of the hall rested. The sitting room, which was generally occupied by the patient and his wife—they have no children—opened into the small hall. Here then is the explanation of the "earthy smell" which had often been noticed; and I have no doubt that the chronic diarrhoea and the albuminuria were directly due to the same cause. The fact that the health of the patient's wife, who had been even more continuously exposed to the same poison, had not apparently suffered, is quite consistent with this explanation of the husband's illness. We have frequent opportunities of observing that out of a number of persons exposed to the same morbid agency, only a small proportion become seriously ill. Additional evidence that the diarrhoea was excited by the sewer poison is afforded by the fact that this symptom, which had continued until the time of my visit, and for some days afterwards, ceased almost immediately after he left home to stay with a friend for five weeks. The defective drainage was made good during his absence, and during the fortnight since his return home there has been no return of the diarrhoea. His general condition, too, is reported to have improved, and the albumen has diminished by one-third.

CASE IV.—Miss B., aged 35, had been more or less ill since she had undertaken the management of a country hotel six months before I saw her. During the last six weeks the urine, which had not before been examined, was found to be blood-tinged. At the time of my visit the urine was brightly blood-tinged, specific gravity 1012, contained albumen (8 grammes per litre), and deposited granular and hyaline casts and oily cells. The secretion was very scanty. The patient was very pallid and feeble; there was frequent vomiting; temperature 102°; much dyspnoea, with a rapid and feeble pulse. The prognosis was most unfavourable. When I saw her a second time three days later, the symptoms were worse; there was almost complete suppression of urine, and she died on the following day.

This lady was in good health when she took up her residence in the hotel. The drainage was found to be bad, and the drains were opened and repaired while she remained in the house. I have no doubt that the illness, which commenced soon after, and which culminated in fatal degeneration of the kidney, was the result of drain poisoning.

The medical attendant who sent me the account of the defective drainage which was discovered in connection with Case 3, ended his report by saying: "I very much doubt whether the profession at large is sufficiently alive to this subtle cause of albuminuria."

It is hoped that the publication of these illustrative cases may serve to direct more general attention to this frequent, though often unsuspected, source of renal disease.

In connection with this subject, it is not without interest to remark that amongst the numerous diseases which may result from defective drainage and consequent sewage poisoning, diphtheria is, in a very large proportion of cases, associated with albuminuria, a fact which Dr. Wade was the first to make known.

The history of such cases as have been here briefly recorded serves to illustrate a principle which cannot be too much insisted upon, namely, that the treatment of symptoms by drugs forms but a small part of the art of healing, and that one of the main objects of rational medicine is to trace disease to its cause. What a melancholy exhibition of unscientific impotence is the attempt to arrest by opiates and other astringents a diarrhoea, the result of perpetually inhaling a septic drain poison!

It can scarcely be doubted that the diarrhoea and the albuminuria having such an origin are the result of a physiological effort by the bowel and the kidney to eject the poison and its noxious products from the system; and it is obvious that an essential condition of successful treatment in such cases is the discovery and removal, or avoidance, of the exciting cause of the symptoms.

ST. THOMAS'S HOSPITAL was visited by the Queen of Sweden on Tuesday last.

LECTURES

ON SUPPURATION AND SEPTIC DISEASES,

Delivered at the Royal College of Surgeons, February, 1888.

By W. WATSON CHEYNE, F.R.C.S.

Hunterian Professor; Surgeon to King's College Hospital, and to the Paddington Green Children's Hospital; Examiner in Surgery at the University of Edinburgh.

LECTURE II.

We have thus found that these pyogenic cocci are constantly present in suppurative affections; that they can cause suppuration both in animals and in man, as evidenced by experiments, and also by the microscopical observation of the changes which occur at the seat of infection; and, further, that true acute suppuration does not occur naturally when these organisms are absent. It would therefore appear as if, with the discovery of the pyogenic organisms, the etiology of acute suppurative affections was satisfactorily settled. This, however, is hardly the case, for the following considerations, among others, render it evident, that in most cases other factors in addition to the micro-organisms must come into play. Thus we find a great variety of morbid processes caused by the same organisms. The staphylococcus pyogenes aureus can set up a superficial inflammation of the skin, a boil, an abscess, acute ulcerative endocarditis, or even pyæmia; and the streptococcus pyogenes causes sometimes phlegmonous inflammation, sometimes peritonitis, sometimes puerperal fever, and sometimes pyæmia. Then, again, we have the fact, on which I have not as yet dwelt, that, in order to produce these suppurative affections in animals, various conditions, such as the injection of large numbers of the micro-organisms, are essential.

That these organisms are not of themselves able in most cases to set up these suppurative diseases is evident also from the fact that they are frequently present in the blood without producing any suppurative affection. Thus Ogston states that in cases of septicæmia in man the micrococci are present in the blood, and are excreted in a living state in the urine, and he makes no mention of the occurrence of secondary abscesses. Ogston's statement has been confirmed by von Eiselsberg, who examined the blood of almost all cases in Billroth's *clinique* who were suffering from septic fever, and was able to demonstrate the presence of staphylococci and streptococci, most frequently of staphylococcus pyogenes albus, in the blood; and yet apparently no abscesses formed. In the case of acute osteo-mylitis also Garré has found the pyogenic staphylococci in the blood, although the patients did not suffer from abscesses in more than one situation. In connection with acute osteo-mylitis, perhaps the most interesting observations are showing that these organisms may exist in the blood without doing any harm are those in which children have been born suffering from this disease while the mothers, through whose blood only the organisms could have come, have apparently been in good health. As an example of this I may mention a case published by Rosenbach in a paper on acute osteo-mylitis.

E. A., aged 30, was delivered of her fifth child in June, 1858; she had been married ten years, and all her other children were living and healthy when born; she was not aware of having suffered any fright or injury to account for the disease in the child's leg. The latter, a full-grown boy, was born dead at full time, and had apparently been alive quite recently. Attention was at once drawn to the right leg, which was swollen and showed distinct fluctuation both in front and behind. Immediately below the patella there was a bulla on the skin; the whole leg had a marked erysipelatous character, and on making an incision a large quantity of pus was evacuated, and it was then found that the greater portion of the soft parts of the leg was destroyed, and that there was scarcely any muscular substance to be seen. Further investigation showed that almost the whole of the periosteum of the tibia was detached and the bone was in a state of necrosis. At the lower part a small portion of the periosteum was inflamed, but still adhering to the bone; at the upper part the epiphysis of the tibia was almost entirely separated from the

shaft, and was only connected with it by a few membranous threads.

Then we have a very interesting paper by Escherich on the presence of pyogenic cocci in the milk of women suffering from puerperal fever. In a considerable number of these cases he demonstrated the presence of the same pyogenic cocci in the milk from both breasts, and in these cases there was every reason to believe that the organisms had reached the milk from the blood; more especially there was an entire absence of any disease or ulceration of the nipple; and yet in these cases there were apparently no abscesses either in the mamma or elsewhere. Escherich's observations have been confirmed by Longard, and both of these investigators have made experiments on animals which had just brought forth young, which show that very shortly after the injection of these organisms into the blood they appear in the milk.

These pyogenic cocci have also been found in the blood in various febrile diseases, and not necessarily in association with suppuration. Thus, in scarlet fever Loeffler found the streptococcus pyogenes, or an organism indistinguishable from it, in the diphtheritic membrane in cases of scarlatinal sore-throat, and he observed that in some cases these organisms penetrated from the surface into the body. Fränkel and Freudenberg have also investigated the organisms of scarlet fever, and have found that the streptococcus pyogenes is present in the blood in a considerable number of cases, without, however, apparently giving rise to any suppurative or septic affections.

I need not go into further details to show that these micro-organisms do not necessarily of themselves set up suppuration and septic diseases when present in the body; in the following considerations sufficient evidence of this will be brought forward.

CONDITIONS NECESSARY FOR INFECTION.

The conditions which are necessary to enable these organisms to live and act in the body may be considered according as they chiefly affect the body, or according as they chiefly affect the microbe. We have also some conditions—such as temperature, season of the year, locality, moisture, etc.—which must be grouped under a third heading; for, with regard to these, we do not know whether their influence is due to some action which they exert on the body, or to some effect which they produce on the microbe. In considering these conditions, it is not possible to draw a sharp line between the various groups, because a number of these conditions are almost always combined in the same case; but I shall, as far as I can, endeavour to avoid repetition, and at the same time to treat of the various facts under their chief headings.

Had time permitted, I should have liked, before entering on the consideration of these conditions, to have traced the fate of the pyogenic organisms in the body when they fail to get the upper hand. And we should have found that these organisms disappear in a very remarkable manner from the blood; that they are, in fact, apparently rapidly killed in the blood, or deposited from it in various tissues and organs, or possibly excreted through the various excretory glands. The rapidity with which some organisms disappear from the blood is very remarkable; it is in many cases a matter merely of minutes, certainly of an hour or two; and this disappearance of the organisms from the blood must be due to an active destructive action of the constituents of the blood on them; mere unsuitability of soil is not sufficient to account for the rapidity of the phenomenon. We should also have seen that there is good reason for believing that these organisms may be excreted by the various excretory glands, although this is a matter about which there is still considerable dispute. That they are so excreted by the kidneys is shown by various observations; and this is an important point to remember, as probably explaining certain cases of pyelitis occurring in patients who have never had any instrument passed, and whose urethra and bladders are perfectly normal, the occurrence of these cases being explained on the supposition that the organisms had entered the blood in a living state, were excreted by the kidneys, and afterwards, as in the example of which I showed a drawing at last lecture, found a suitable pabulum in the urine and grew in the pelvis of the kidney. As regards excretion from the mamma, I have referred to the observations and experiments made by Escherich and Longard; and these facts are of interest in connection with mammary abscess, as showing that the organisms which set up these abscesses may arrive at the gland from the blood, and either grow in the tissues or in the acini of the gland after excretion; although without doubt the great majority of abscesses of the mamma are

caused by the spread of the organisms inwards, either along the milk-ducts or from cracks in the nipple. We should also have seen reason to believe that the salivary glands, more especially the parotid, occasionally take part in this excretion of pyogenic organisms, thus again offering a possible explanation of the not infrequent occurrence of abscesses in the parotid gland after suppuration elsewhere.

The study also of the exact mode in which the body carries on the battle with the microbes, more especially the study of the investigations which have been set on foot as the result of Metschnikoff's experiments on phagocytosis, would have furnished us with much interesting and suggestive material for consideration, and we should have seen what an important part the leucocytes play in the destruction of micro-organisms and in the limitation of inflammatory affections, although the evidence does not as yet seem to be sufficient to support Metschnikoff's idea that these cells act by taking up the organisms into their interior, and there killing them.

I must, however, omit the consideration of these matters, and pass on to the discussion of the conditions which enable or hinder these organisms to act; and the first condition, and an essential one, which we have to notice, is that an opportunity must be afforded to the organisms of resting for a time in the part in which they exert their action. If they are floating in the blood current they must be arrested at some part, and not only must they be arrested, but, as we shall see, they must find, at that spot, conditions suitable for their growth.

Embolism.—Such mechanical conditions, causing the arrest of organisms, are brought about by embolism, thrombosis, injury, etc. The importance of arrest of organisms has been beautifully shown by Ribbert in some experiments which he performed with a pathogenic species of mucus. When the spores of pathogenic aspergilli are injected into the blood, deposits are formed in various organs, and also in large numbers in the various muscles. In the case of mucus, however, Ribbert noticed that while the spores, when injected into the blood stream, gave rise to deposits in various organs, the muscles remained only slightly or not at all affected. On looking into the matter, it was seen that the spores of mucus were very small, much smaller than those of aspergillus; and Ribbert thought it possible that the reason why masses occurred in the muscles in the latter case and not in the former, was that, on account of the larger size of the aspergillus spores, they were caught in the capillaries of the muscles, while the mucus spores passed through them. He therefore sought to increase the size of the mucus spores before their injection into the blood, and this he did by keeping them for a short time in a nutrient fluid, at the temperature of the body. As a consequence, the spores swelled up and commenced to sprout, and when he found, under the microscope, that this had occurred, he injected the material into the circulation. The result corresponded entirely to his expectations; in contrast to the control experiments, he found that in these cases fairly numerous deposits of fungi were present not only in the organs but also in the muscles of the back and extremities.

Referring, however, more especially to experiments with the pyogenic organisms, we have several facts of a similar nature with regard to their action on rabbits. The injection of moderate quantities of staphylococcus pyogenes aureus into the circulation of rabbits is followed, as a rule, only by abscesses in the kidneys, the other organs apparently remaining unaffected; but a number of experiments which have been made, among others by Ribbert, on the production of myo- and endocarditis in these animals, have shown that abscesses can be set up in other organs if the pyogenic cocci are attached to gross particles, which cannot pass the capillaries of these organs. Thus, Ribbert was able to produce myocarditis by using a cultivation of staphylococcus pyogenes aureus on potatoes if he took care, in removing the cultivation from the surface of the potato, to scrape off also the superficial layer of the potato itself. If this mixture of potato granules and organisms was rubbed up with water, so as to form a fine emulsion, and then injected into the circulation, the result was the production of deposits of organisms in the muscular tissue of the heart, as well as in other organs, leading to myocarditis; if the particles of potato were very fine, only myocarditis resulted, but if they were coarser, endocarditis occurred as well.

Bonomé investigated nine cases of gangrene of the lungs in man, and found in three of them staphylococcus pyogenes aureus alone, in five staphylococcus pyogenes albus alone, and in one both organisms together. He tried to set up gangrene of the

lings in rabbits by the injection of these organisms into the circulation, but he failed to do so if only the cultivations of these organisms were employed. He succeeded, however, by taking pieces of the pith of the elder tree, breaking them up into very fine fragments, mixing these fragments with the cultivation of the pyogenic organisms, and then injecting this mixture into the jugular vein. The result was numerous deposits of cocci in the lungs, leading, as shown in the last lecture, to extensive coagulation necrosis of large tracts of these organs, and, as a consequence, to extensive gangrene. Injection of the fragments of pith alone caused no effect.

In the same way Rujis found that if he injected a small quantity of a fluid cultivation of staphylococcus pyogenes aureus into the uninjured eyes of rabbits suppuration did not result, and he concluded that the reason was that the cocci were carried away too quickly by the lymph stream; for if he soaked sterilised cotton threads in the cultivations, and then introduced portions of these threads into the anterior chamber of the eye, suppurative panophthalmitis occurred.

The last experiment that I shall mention is one by Pawlowsky, who found that, by the simultaneous injection of sterilised cinna- bar, and of cultivations of staphylococcus pyogenes aureus into the circulation, he produced abscesses in various organs—in fact, the typical picture of pyæmia.

The great importance of these facts in explanation of the etiology of pyæmia will be at once evident. Whether cases of pyæmia occur in man, like those described by Koch in the case of rabbits, as the result of the growth of cocci in the blood, their entanglement of blood-corpuses, and the consequent formation of emboli, we do not know; but it is very doubtful if this takes place, for the same cocci which seem to be the cause of pyæmia may, as we have said before, be often present in the blood in considerable numbers without causing abscess or embolism. It is easy, however, to understand that the ordinary pyogenic cocci may cause pyæmia if they enter the blood attached to portions of blood-clot, or other solid material. This, in fact, is evident from the experiments mentioned, and thus the importance of thrombosis and embolism as factors in the production of pyæmia is clearly established. These emboli are not always necessarily emboli composed of detached portions of blood-clot; in some cases, probably, especially where the streptococcus pyogenes is the active agent, the organisms grow in the lymphatic vessels, and the emboli are formed there and arrive at the blood with the lymph stream. Probably in pyæmia other factors also come into play, such as large dose of the organisms, general depression of vitality, possibly also greater virulence of the organism; but it is evident from these considerations, and from the clinical and pathological facts, that embolism must play an important part. Pyæmia must thus be clearly distinguished from multiple abscesses, the so-called chronic pyæmia, where embolism does not probably play any part but where the cocci are able to circulate in the blood and are deposited in some part weakened by injury or other depressing cause.

The mere arrest of these pyogenic organisms in the circulation, although an important factor, is not, however, as a rule sufficient of itself to lead to the production of disease. This is very well seen in the case of rabbits. Inject a considerable number of pyogenic cocci into the circulation of a rabbit, and kill it within twenty-four hours, it will be found that masses of organisms are present in the capillaries of the lungs and other organs of the body; but allow such an animal to live for forty-eight or seventy-two hours, and it will be seen, on killing it, that the organisms have disappeared from the various organs, with the exception of the kidneys (Ribbert). Here we have evidence that, although the organisms had been able to stick in the various organs, the other conditions were not favourable for their growth and action; and in the case of embolism it is probable that the material to which the cocci are attached of itself aids their growth by causing injury to the endothelium of the blood-vessels, and thus leading to the production of a weak spot: in the case of emboli composed of blood-clot the emboli are saturated with the products of the cocci, and are thus still more likely to injure the part. We must therefore pass on to the consideration of other conditions which aid the action of these organisms, and the chief of these is what we may vaguely term general and local depression of vitality.

General and Local Depression of Vitality.—That general depression of vitality can enable these organisms to live in the blood for a considerable time has been shown by a number of experi- ments. For example, I found, in experiments on the presence or

absence of organisms in the living tissues, that while organisms were absent when the animal was in a good state of health, yet if the vitality of the animal was depressed—say, by administering large doses of phosphorus for some time—organisms could be found at times in the blood and tissues of the body. The same conclusion must be drawn from the following experiment. If of a putrefying fluid not containing pathogenic organisms, varying quantities are injected into the circulation of animals, it will generally be found that after twenty-four hours the organisms have entirely died out in those animals which received a small dose, while in those in which a larger quantity—say, 1 cubic centimètre—was injected, in other words, in those whose vitality was depressed by the introduction, at the same time, of a quantity of the poisonous chemical products of these bacteria, organisms may still be found alive. This is a fact which has been confirmed by a number of observers; but as I shall have again to refer to experiments from which similar conclusions may be drawn, I shall pass on to what is much more important for the matter under discussion, namely, the result of local depression of vitality.

A number of experiments show that when the vitality of a part has been lowered by cutting off the blood-current for a comparatively short time, organisms grow in that part much more readily and luxuriantly than if the blood stream had not been interfered with. To mention one or two examples: according to Cornil, a septic nephritis is readily obtained by ligaturing the renal arteries for some hours, and then, after removal of the ligature, injecting pyogenic organisms into the blood.—Heubner's experiments on the artificial production of diphtheria also show, in a very marked manner, the effect of local depression of vitality as the result of cutting off the blood stream temporarily. Heubner arrested the circulation in the fundus of the bladder for two hours by the application of a ligature to the vesical arteries. After removal of the ligature there resulted intense congestion and œdema of the submucous tissue, while, at the same time, as the consequence of the temporary inanition, the epithelial cells died; after the circulation was again restored, there was a great exudation of blood plasma and cells, in fact, coagulation necrosis occurred on the mucous surface. Heubner found that if, at the same time, that the circulation was restored, septic bacteria were injected into the blood, they accumulated in large numbers in the affected part of the mucous membrane of the bladder; and set up extensive disease.—In order to obtain these results, it is, however, necessary that large numbers of bacteria should be present in the blood, and this factor can only very rarely come into play in Nature, where the number of bacteria is seldom sufficiently great. Thus, in this case of strangulated hernia, even where the circulation has been arrested for a considerable time, comparatively little harm is done, and unless actual gangrene of the bowel wall has occurred, bacteria are very seldom found in the fluid contained in the sac of the hernia, nor does bacteric peritonitis occur.

In conclusion, I may mention an experiment of Cornil's, who states that if a slight nephritis is set up, either by cantharides or in some other way, and if then pyogenic organisms are injected into the blood, a septic nephritis occurs. This last experiment leads us to the consideration of a very important factor in the production of local depression of vitality—namely, inflammation.

Inflammation.—Inflammation is frequently looked on as a predisposing cause of these suppurative diseases, and it has been held that inflammation leads to the formation of a weak spot where bacteria can settle and develop; and that, while inflammation can be set up by other causes than micro-organisms, the pyogenic cocci are very apt to become added to it, and then suppurative results. On the other hand, in old times, when wounds were allowed to become septic, it was generally held that the patient was safer when the surface of the wound had become covered with granulations than before granulation had taken place. We have also seen, in considering the anatomy of abscess, that as the granulation tissue increased in amount, so the penetration of the organisms into the body was rendered more difficult, and they remained more and more limited to the interior of the abscess. In the case of erysipelas, the cessation of the inflammation seems to stand in some relation to the accumulation of leucocytes in the part. In the case of tubercles, also, which consist of a central mass of epithelioid cells and an outer wall of leucocytes, I believe that the external circle is purely an inflammatory circle; and is of great importance in limiting the spread of the tubercle bacilli. That preliminary inflammation is not essential to enable the pyogenic organisms to act is shown by many facts, such as Garró's and Boekhardt's experiments on themselves, and similar experi-

ments performed by Grawitz with reference to acne contagiosa of horses, where the organisms which are the cause of the disease produced it when rubbed into the skin.

To explain the facts of the case, I must shortly recall the chief points as regards inflammation. Inflammation which has gone on for some time may be divided into three stages. In the first stage we have the preliminary dilatation (or it may be, in some rare cases, contraction) of the vessels, the increased flow of blood through the part and along with this, increased flow of lymph, soon followed by slowing of the circulation, and ultimately by inflammatory stasis, with, at the same time, exudation of blood plasma and corpuscles. In the second stage the irritation is continued, and the tissue originally attacked by the inflammation is removed and its place taken by granulation tissue. In the third stage the irritation has ceased, and retrogressive changes occur, leading to the formation of a scar.

If we consider the state of the tissues in these three stages we see that in the first stage, as was long ago pointed out by Sir Joseph Lister, the vital activity of the tissue is suspended, the functions of the tissues are, so to speak, paralysed; in other words, the tissue has become an extremely weak tissue, and one unable to resist in any way the entrance of the parasites. In the second stage this weak tissue has been removed, and its place has been taken by young, vigorous, healthy granulation tissue, which has probably great power in repelling the attacks of the organisms. Lastly, in the third stage this granulation tissue is getting older, and becoming converted into less active tissue. The first stage of inflammation is partly defensive and partly reparative, and always occurs after every injury. The second stage may be looked on as a purely defensive stage, the irritant still continuing to act. In the third stage the irritant has gone, and processes leading to permanent repair take place. The relation of inflammation to infection may perhaps be best illustrated by regarding it as an instance of instinctive action. The first effect of the irritant is to damage the part, and the first result is dilatation of the blood-vessels and increased flow of blood and lymph; the part, in fact, is flushed with blood, as if an attempt were being made to wash away the irritating cause (Landerer). This is a process which is probably constantly occurring in our bodies with satisfactory results. If the irritant continues to act it is very soon found that these attempts are ineffectual, and the next instinctive method of protection is to get rid of the injured tissues and to supply their place by young, strong, healthy tissue—granulation tissue. Finally, when the irritating cause has been got rid of, the vigilance of the part is, so to speak, relaxed, and the tissues proceed to develop into a less active and less vigorous tissue, namely, fibrous tissue.

Clinically, the organisms enter during the first and last stages, more especially during the first, and not, as a rule, during the intermediate stage, unless, indeed, while growing outside the new tissue, on the surface of the wound, they can so injure it as to reduce it again to the position of a weak tissue—to the first stage, in fact. This is very well shown in a series of experiments made by Huber on the localisation of virus. Huber performed his experiments on rabbits, and set up inflammation in one ear by rubbing in croton oil, the other ear being left intact for purposes of control; the infective material employed was virulent anthrax bacilli, and these were introduced into the body as far as possible from the seat of inflammation, namely, at the root of the tail. According to the stage of inflammation which he desired to study, Huber applied the croton oil before or after the infection with anthrax bacilli. The result of these experiments was, in the first place, that the bacilli were not found outside the vessels in the tissues of the inflamed part in any stage of the inflammation; and, in the second place, that their presence inside the vessels was dependent on the stage of the local affection. Thus in the first stage, where there was inflammatory oedema, this stage reaching its height in about seven hours and a half, there was a very marked increase in the number of the bacilli in the capillaries of the inflamed part, as compared with the number which were present in a similar part of the opposite ear. As the inflammation passed into the second stage, the number of bacilli in the capillaries of the inflamed part gradually diminished, till, when this stage was at its height—after forty-eight hours—the bacilli had completely disappeared, although they were present in large numbers in the capillaries of the other ear. During the third stage, where the inflammation had subsided, and where new tissue was being formed, bacilli again appeared, and were found in considerable numbers in the newly-formed vessels. Ultimately, when the

scar had been formed, there was no difference as regards the number of bacilli in the capillaries of the scar and the number in the capillaries elsewhere.

It has been found, as regards the pyogenic cocci, that if they are circulating in the blood, the induction of a severe inflammatory action does not lead to their deposit in the part, while if the inflammation is less severe, they can apparently pass out of the blood-vessels and set up suppuration. Thus, Rinne concluded from his experiments on suppuration that a violent inflammatory action did not produce a *locus minoris resistentiæ*, but that the slighter injury caused by the chemical products of the bacteria themselves sufficiently weakened the part to enable the organisms to grow in it.

Acute osteo-myelitis and local tubercular diseasea frequently stand in some relation to injury, but they are not, as a rule, attributed to severe injuries, but usually to some slight blow or sprain. In a phthisical individual fracture of a bone or some other severe injury is not followed by the development of a local tuberculosis, whereas a slight sprain is very commonly mentioned as the exciting cause of such a process, the probability being that the severe injury sets up too great reaction to enable the organisms to act, while the slighter injury simply weakens the part.

Cold.—Another point which has been much discussed, in relation to inflammation and suppuration, is the effect of cold. It is generally assumed that cold is a frequent cause, or at least a very predisposing cause, of inflammation, as, for example, in the production of pneumonia. That cold may play an important part as one of the factors in that disease is very probable, but it is needless for me to say that we are constantly subjected to violent changes of temperature without the production of inflammatory disease, so that it seems as if when a result is obtained some other factor comes into play.

That cold can cause inflammatory affections where the conditions are suitable is evident as regards the external surface of the body from the production of chilblains, the tissue thus weakened being brought into a condition rendering it very liable to attack from organisms.

As regards the effects of cold on the internal parts of the body, some very interesting observations have been made by Lassar. A number of rabbits were shaved, or deprived of their hair in some way or other. These animals, when kept at a suitable and equable temperature (about 20° C.) and well fed, remained in good health. But on being taken out of the warm room and plunged into ice-cold water for from one to three minutes, then dried carefully, chafed, and warmed again, they almost always, in the course of one or two days, showed albuminuria, increasing at a later period, often to a great extent, and accompanied by the presence of hyaline cylinders in the urine; at the same time, the rectal temperature was as much as 1.5° C. above the normal. These animals often recovered from the albuminuria, but were again similarly affected when again exposed to cold. On microscopical examination of the organs, they were seen to be in what Lassar terms a state of "interstitial inflammation;" the organs chiefly affected being the kidneys and liver, but also in some cases the lungs, muscular tissue of the heart, and the sheaths of the nerves. In the organs it was seen that there was no degeneration of the interstitial tissues, but the blood-vessels, especially in the lungs and liver, were often enormously dilated, the arteries filled with thrombi, and large numbers of leucocytes in the tissues in the neighbourhood of the veins. The effect of cold in these experiments seems, in fact, to be the production of what is probably a weak tissue, and one therefore liable to attack from organisms.

As to the relation of pyogenic organisms to animals acted on by cold, I only know of experiments by Grawitz on the relation of peritonitis to cold, but his experiments are not sufficiently satisfactory. He shaved the skin of the abdomen in young animals, covered it for from half to one hour with warm compresses, and then, suddenly removing these, allowed a draught of ice-cold air to play on the part for twenty to forty minutes. This caused no bad effect on the peritoneum, nor was any bad result produced on that membrane when organisms were simultaneously injected into the intestinal canal or into the blood; and in one experiment the cocci were injected directly into the abdominal cavity, also without setting up peritonitis. In the last experiment, however, the cocci were injected three-quarters of an hour before the commencement of the exposure to cold; and it is highly probable that, under the circumstances, they had died or had been removed by the healthy peritoneum before the application of the cold, and this is the more likely to have been the case seeing that the

activity of the peritoneum was probably increased as the result of the warm compresses applied to the skin over the abdomen.

Injury.—An important cause predisposing to the occurrence of suppuration is injury, which probably acts in two ways; in the first place by setting up the early stage of inflammation, and in the second place by leading to effusion of blood, and thus enabling any pyogenic cocci which may be circulating in the blood to pass out of the vessels, and find in the cellular tissue a suitable place for their development.

The effect of injury is well shown in experiments which have been made on the production of acute endocarditis. In order to induce this disease in animals by injection of the pyogenic cocci into the blood, it has been found either that the number of cocci employed must be very large, or that they must be attached to gross particles, as has already been mentioned, or that some injury must be caused to the valves before their injection. Wyssokowitsch and others have performed experiments of this kind, and have found that, by introducing a rod into the jugular vein, they were able to cause laceration of the valves, and that then, on subsequent injection of staphylococci into the blood ulcerative endocarditis occurred. The effect of the injury in this instance is no doubt chiefly to lead to loss of resisting power in the endothelial and connective tissue cells, as the result of the early stage of inflammation induced by it.

The relation of injury to certain inflammatory diseases in man is generally accepted, and I need only instance the case of acute osteo-myelitis, which is frequently attributed to an injury. In experiments on animals, on the production of acute osteo-myelitis, it is, as a rule, necessary not only to inject the pyogenic organisms into the blood, but also to cause some injury to the bone. If this is done, especially where large numbers of cocci are introduced into the circulation, the animals generally die in from twelve to fourteen days, much emaciated, and showing pus at the seat of fracture, pus in the medulla, and necrosis of bone. With regard to man there are several cases on record in which the relation of injury to this disease is very strikingly shown, and the fact that the disease occurs much more often in males than females, and especially in young males, is usually attributed to the fact that injuries are sustained more frequently by boys than girls. At the same time, the number of cases of acute osteo-myelitis in man, in which the direct relation to an injury can be satisfactorily traced is, in reality, comparatively small; and that injury, though it plays a part in some instances, is not an essential condition for the production of the disease is shown by its occurrence after acute fevers, and also by the fact that it is limited, as a rule, to certain favourite seats. When, however, the disease affects bones, or parts of bones, which are not usually attacked, a history of injury or cold can generally be obtained to explain its occurrence in these abnormal situations.—In the case of wounds also we must not forget that the injury done to the surface of a wound during an operation by the knife and the manipulations sets up the early stage of inflammation, and that thus the surface of a wound is, for a few hours at any rate, a weak surface, and unable to resist attacks from organisms.

That one great explanation of the value of injury in aiding the occurrence of suppurative diseases is the extravasation of blood from the vessels is shown in a very striking manner by experiments on symptomatic anthrax, a disease to which I shall have to allude in detail presently. I may say here that this disease is caused by bacilli, but is not set up if the bacilli are introduced into the circulating blood; in order to produce it the bacilli must act in the cellular tissue. After injection of the organisms into the blood the animals remain well, and the bacilli very soon disappear; if, however, shortly after the injection of bacilli into the blood, a bruise is produced in some part of the body, the bacilli pass out of the vessels into the cellular tissue along with the blood, grow there, and soon cause the formation of the characteristic tumours, the spread of the disease, and its fatal termination.—In man it is sometimes seen that bruises in weakly individuals are followed by suppuration, and I have already published the case of a drunkard who had albuminuria, and was in a very low state of health, and who, whenever he received a bruise, developed an abscess at that part. In his depressed state the pyogenic cocci were probably able to live in his blood, and the injuries, by setting up the early stage of inflammation, and thus further weakening the tissues, and also by leading to the effusion of blood containing the organisms, gave rise to the formation of abscesses.

Irritating Chemical Substances.—Another important cause of depression of vitality is the action of irritating chemical sub-

stances. The effect of these chemical substances is probably that, when concentrated, they destroy the vitality of the tissue by their caustic effect, and, when more dilute, they set up the early stage of inflammation, which also occurs in the former case in the vicinity of the dead part.

The effect of these substances in procuring a weak spot at which the organisms can develop is, no doubt, the explanation of Kocher's results with regard to acute osteo-myelitis in dogs. He found that if digestive disturbances were induced by the introduction of large quantities of septic material into the intestinal canal; and if, at the same time, a bone was injured by the injection of ammonia, or other irritating chemical substances, into it, acute osteo-myelitis occurred at the seat of injury; while the injection of the chemical substance alone only produced temporary reaction. These experiments, however, were only few in number, and are not completely satisfactory because it is possible that the organisms spread in along the needle track, and did not reach the part from the blood.—It has also been found that if irritating chemical substances are injected subcutaneously into rabbits, and if at the same time large numbers of pyogenic cocci are injected into the veins, suppuration frequently occurs at the seat of injection, the suppuration going hand in hand with the development of the pyogenic organisms which have reached the part from the blood.

Many of the former experiments on the production of suppuration by means of irritating chemical substances which frequently resulted in growth of micro-organisms in the part and, as a consequence, the occurrence of suppuration, show how the presence of irritating chemical substances placed the parts in a condition which diminished their resisting power against the action of micro-organisms.—Grawitz and de Bary found that if croton oil was injected into rabbits subcutaneously, it caused inflammation and sometimes suppuration; if, however, the pyogenic organisms were also present, suppuration always occurred; although these cocci alone in small numbers are unable to produce suppuration in the normal subcutaneous tissue of dogs or rabbits.

If I may venture to apply these facts to the treatment of wounds, it seems to me that if the views which I have attempted to develop as to the importance of a granulation wall as a barrier against micro-organisms are correct, it is questionable whether, in the case of wounds which have become septic, it is well to wash them out with irritating antiseptics, as is so often done at present. That it is well to remove the decomposing discharge, both by free drainage, and also by washing out the wound in some cases, is of course evident, but, where strong, irritating antiseptics are employed, unless they are able to kill all the micro-organisms present in the wound, and thus render it aseptic, the result of their injection might be, I think, that they will injure the granulation wall, and thus produce a weak spot in which the pyogenic cocci present in the wound can develop, and through which they may be able to enter the body. Thus it has been found that in cases of tubercular disease of joints and bones accompanied by suppuration, general tuberculosis—more especially tubercular meningitis—occurs by far most frequently where the sinuses have become septic, and more especially when, in addition, these septic sinuses have been much irritated by futile antiseptic injections. Hence it seems to me that, except in cases where there is reasonable ground for believing that the injection of these antiseptics into septic wounds will completely eradicate the organisms, it is better to avoid the use of irritating antiseptics such as carbolic acid, and if it is thought well to wash away the discharge, to employ some fluid which will not injure the granulation wall.

Except in the case of wounds, the chemical substances which aid in enabling the bacteria to gain a foothold are the products of the organisms themselves. That various bacterial products are highly poisonous is now well known, and in the case of putrefactive and pyogenic organisms, these products are able not only to cause local trouble, but also to set up fever, to depress the vitality of the patient, or, it may be, even to cause death. With regard to these general effects of the chemical products of bacteria, it is unnecessary for me to enter into further detail, for the fact is now so well known that in most books on surgery we find, in addition to septicæmia and pyæmia, a third group of general septic diseases due to the action of these products described under the title of septic intoxication or, as Dr. Matthews Duncan has termed it, "sapremia." I may therefore at once pass on to the local effects of the products of bacteria and their action in enabling the organisms to live and multiply in the part.

In some experiments which I performed recently with an

organism described by Hauser, under the name of proteus vulgaris—an organism not uncommonly present in putrefying materials—I diluted the growth in gelatine, with a certain amount of water before injection. In some cases, however, I used for dilution, instead of water, boiled meat infusion, in which the same organisms had been growing, that is to say a fluid containing the products of the growth of these bacteria, and I found, for example, that while $\frac{1}{3}$ cubic centimetre of the mixture prepared by the addition of water never killed the animals experimented on, where the dilution was made to the same degree with the boiled meat infusion, they died from the same dose after about forty-eight hours. In the second case a larger quantity of the products of the bacteria, these products being very poisonous, was introduced than in the first case, and to this we must ascribe the difference in the result.—In experiments on guinea-pigs with the cholera bacillus, Hueppe has found that infection occurs more certainly, and with less material if there has been preliminary action on the intestine of the poisonous products of the cholera bacilli, or even of the ptomaines of other bacteria; and Flügge and Wyssokowitsch have shown that bacteria which are not usually pathogenic in the animals employed for the experiments can penetrate into tissues previously weakened by bacterial poisons.

Among the products of the putrefactive fermentation, there are two substances which have been found to be highly irritating, namely, cadaverine and putrescine, and I have previously referred to the experiments made by Grawitz and Scheuerlen, which show that, as the result of the injection of these substances, inflammation and suppuration may occur, according to the strength and quantity of the solution employed. Grawitz found, further, that suppuration certainly occurs if, at the same time that a comparatively dilute solution of cadaverine is injected, pyogenic cocci are introduced.—The chemical products of the pyogenic cocci are also, according to Grawitz, irritating to the subcutaneous tissues of dogs and rabbits, when introduced in sufficient quantity and concentration. Thus, he found that if sterilised cultivations of pyogenic cocci were injected in large quantities into dogs—for example, 4 cubic centimetres of a sterilised cultivation of staphylococcus pyogenes aureus—suppuration occurred, the pus being free from organisms.

As regards the products of these pyogenic cocci, Brieger, who is the great authority on this subject, states that he has been unable as yet to obtain any toxine from the cultivations of these organisms. Cultivations of staphylococcus pyogenes aureus on moist beef or veal yield large quantities of ammonia, as does also the staphylococcus pyogenes albus; the latter produces, in addition, considerable quantities of trimethylamine. Streptococcus pyogenes likewise produces ammonia and trimethylamine. That the ammonia must irritate the tissues is, of course, evident, and it is probable that in the nascent state it is still more irritating; while as regards trimethylamine, though it is not an alkaloid, it is in Brieger's opinion probably a descendant of, or very closely related to, the ptomaines, and, when present in considerable quantities in the body, is very hurtful to it. These organisms also produce a peptonising ferment, and can thus peptonise and dissolve coagulated albumen, and this property is of great importance in suppuration. When sown in milk they rapidly set up a pure lactic fermentation, leading to the production of large quantities of lactic acid, as the result of which the milk coagulates if kept for some days at the temperature of the human body. This production of lactic acid is an important fact, as it probably also takes place sometimes in wounds, causing acidity of the discharge, and in abscesses causing the well-known watery pus. Whether ptomaines will yet be found in the case of pyogenic cocci we cannot say; but the occurrence of fever in suppurative diseases may possibly, as Baumgarten suggests, be explained simply by the increased tissue change, as the result of their growth, the products thus formed requiring increased combustion, and perhaps also stimulating the thermic centres, and hence causing elevation of temperature; and in support of this view Baumgarten refers to the fever which occurs in trichinosis, where there is no idea of any action of ptomaines.

Seat of Inoculation and Anatomical Arrangement of the Part.—Much depends also, as regards the effect of these organisms, on the seat of inoculation and the anatomical arrangement of the part. These conditions are of importance in two ways. In the first place, certain organisms will not grow everywhere in the body, they will only grow in certain tissues; and in the second place, in some cases—especially in the case of the pyogenic organisms—the resulting disease varies chiefly according to the anat-

omical arrangement of the part in which the organisms are growing.

Some organisms, such as the higher fungi, seem only to be able to act if they are present within the capillary blood-vessels or large serous sacs; the bacillus of malignant œdema acts only in the cellular tissue; the micrococcus of erysipelas possibly only in the lymphatic vessels. As this is an important matter, I may refer in some detail to a few examples which show the great influence which these conditions exert on the development and the character of the resulting disease. In some experiments which I performed with Hauser's proteus vulgaris, I met at first with some very interesting difficulties. I injected the cultivations into the backs of rabbits, and I found that the results obtained varied in a manner very difficult to understand. After considerable investigation I found that the differences depended on the seat of inoculation; that, if the material was injected superficially to the muscles, a different result might be obtained to that which followed injection into the substance of the muscles. Thus quantities of a cultivation which, introduced into the subcutaneous tissue, would only have caused a large abscess, were followed, when injected into the muscles, by the death of the animal; and, further, a small dose, which would have been without apparent effect on the subcutaneous tissue, was sufficient to produce an abscess when injected into the muscles. What the explanation of this difference is I am unable to say. It is possible, however, that some chemical substance in the muscle is readily broken up, and readily gives rise to poisonous compounds; and that this substance does not exist, or is present in less amount, in the subcutaneous tissue. Similar differences, according as injections were made into the subcutaneous tissue or into the muscles, were noticed in the case of several other bacteria.

Perhaps the best example of the great influence exerted by the seat of inoculation and anatomical arrangement of the part is furnished by the disease known in this country as "black leg," in Germany as *Rauschbrand*, and in France as symptomatic anthrax. This disease has been investigated by a number of observers, chiefly by three French observers, who have worked together, namely, MM. Arloing, Cornevin, and Thomas. The disease affects chiefly cattle and sheep—more especially cattle—and is characterised by the rapid appearance of irregularly limited swellings of the skin and muscular tissues, these swellings being at first very painful and tense, but rapidly becoming painless and crepitating. The disease is accompanied by fever, which is often very high, and it is almost always fatal, usually after a duration of from thirty-six to forty hours. The cause of the disease has been demonstrated to be a bacillus which grows without oxygen, and thus belongs to Pasteur's class of anaerobes. These bacilli are remarkable in various ways, more especially in the conditions under which they exert their pathogenic action. In order to cause the death of the animals, the organisms must be introduced either into the subcutaneous tissue or into the muscles; if they are injected into the veins or into the bronchi they do not cause the death of the animal, but apparently after a time die out, leaving the animal, however, protected against the disease. And I have already mentioned that if, after the virus has been injected into the veins, a bruise is caused in some part of the body, the organisms reach that spot from the blood, grow there, and set up the disease. If inoculations are made quite at the tip of the tail in cattle, the result is only a moderate amount of reaction, even when large quantities of the material are introduced; the more proximal on the tail is the seat of inoculation, the more readily is a result obtained. The explanation of this fact is apparently partly the dense nature of the connective tissue at the tip of the tail, and partly also the low temperature of the part. That the density of the tissue in the tails of cattle interferes with the spread of the infection is evident, because sheep, at the tips of whose tails the cellular tissue is loose, react markedly on inoculation in that part. As regards the temperature of the part, it has been found that if, after inoculation, the tail is wrapped in bad conductors of heat, the local temperature can be so raised that considerable reaction occurs, and *vice versa* in the case of sheep. If, after inoculation, the part is kept cool by the application of ice-bags, the violence of the local reaction is much reduced.

As regards the pyogenic organisms, most of them act in the cellular tissue to which they gain access, as a rule, after the destruction of the epithelium. The gonococcus is, so far as we know, the only pyogenic organism in man which is able to penetrate uninjured epithelium; and with regard to the micrococcus, it is very striking that it only attacks certain mucous membranes,

and apparently cannot develop in any other tissue of the body, unless, perhaps, in the joints in which, according to Kammner, it is present in some cases of gonorrhœal rheumatism. (It must be said, however, that some investigators have failed to confirm this observation.) Bumm states that pure gonorrhœal pus may be injected into the subcutaneous cellular tissue without causing any reaction, and that if, after twenty-four hours, an incision is made, and some of the pus which was injected is removed, it will be found that the cells are still in good condition, but that the cocci have disappeared; this fact is of interest also as showing that pus, apart from the micro-organisms which it contains, does not exert any pyogenic action. Also, as I have previously said, when suppurative bubo occurs after gonorrhœa, the staphylococcus pyogenes aureus or albus is present in the pus from the gland, and not the gonococcus; suppurative bubo being therefore the result of a mixed infection, and not a necessary complication of gonorrhœa. The same is the case in abscesses outside the urethra in connection with gonorrhœa.

Kitt has found that, in the case of the coccus of mastitis in cows, the organisms only exert their pathogenic action when they are present in the ducts or acini of the mamma; if injected directly into the tissue of the mamma they cause no suppuration.

The anatomical arrangement of the part is probably a very important factor in the production of acute osteo-myelitis. This disease is, as we have seen, due to the action of the pyogenic cocci, and it not infrequently stands apparently in some relation to an injury. But the injury and the presence of the cocci do not explain the whole of the etiology of the disease, more especially they do not explain why it is that the disease is almost entirely limited to certain bones and to certain parts of bones. Not that most of the bones in the body may not, under certain circumstances, become the seat of this affection, but as a rule the disease has certain very favourite seats, such as the femur, especially its lower end, the upper and lower ends of the tibia, the upper end of the humerus, and the radius. Now these are the bones which grow most rapidly, and in them the disease commences during the period of growth, and most usually in the neighbourhood of the epiphysal line, where the growth is of course most active. Thus the fact that the bones are growing helps apparently to determine the seat of the disease, possibly because there is a large amount of young indefinite tissue at these parts, possibly also because there are plenty of blood-vessels, and also perhaps because the circulation in the ends of the bone is apparently less rapid than elsewhere (Neumann). It is interesting also to note, as showing probably the influence of similar conditions, that when this disease attacks infants, it is usually limited to the neighbourhood of the epiphysal line, giving rise to acute epiphysitis. At the same time, the anatomical peculiarities will not suffice to explain all the facts because in growing animals, belonging to species not insensitive to this poison, the disease is not produced by injection into the circulation, unless some other determining cause, such as injury, comes into play; and because also the disease not infrequently occurs after acute fevers, such as typhoid fever. As regards the anatomical arrangement of the part in its relation to acute osteo-myelitis, all that we can say therefore is that there is some peculiarity in growing bones, not necessarily limited to the growth at the epiphysis, which has an important influence on the production of the disease.

PLACENTA PRÆVIA.¹

By ROBERT BARNES, M.D., F.R.C.P.,

Honorary President of the British Gynecological Society; Honorary Fellow of the King and Queen's College of Physicians in Ireland.

THE theory and treatment of placenta prævia have been so frequently the subject of discussion, that it may seem to require an apology for bringing it before the Section. But it must, I think, be conceded that the conflicting ideas or dogmas urged as to the proper treatment prove that the true theory that can alone govern a rational scheme of treatment is not yet fairly recognised.

It will be my endeavour to put this fundamental point in a clearer light. I cannot better expose the unsettled and irrational practices that prevail than by briefly stating some of them.

¹ Read in the Section of Obstetrics at the Annual Meeting of the British Medical Association held in Dublin, August, 1887.

Some still advocate the old "*accouchement forcé*," pure and simple, or with slight mitigation, and these have the recent authority of Spiegelberg.

Schroeder, perhaps the greatest representative of modern German obstetric science, sums up the treatment thus: "Rupture the membranes, draw down a foot, and wait during extraction."

Some contend that the whole treatment consists in bimanual turning. This operation finds, as I long ago pointed out, useful application (*Lancet*, 1861); but it is really the "*accouchement forcé*," mitigated. Some think the whole treatment consists in plugging.

The following criticism by Ludwig Miller in his work on *Placenta Prævia* (1877) is, with few exceptions, singularly just: "Smellie did not follow any one method exclusively, but acted according to the indications of the case in hand. In this he made a step in advance, which places him higher than all his predecessors, and many of his successors."

It may be urged generally against the more rapid or forcible methods that they are fraught with danger to the child. Following the practice of the elder Simpson and of some of the older teachers, those who advocate these methods assume that the conditions are so perilous to the child that they are justified in leaving the child out of consideration, well satisfied if they can save the mother.

I cannot atop to discuss the fallacies which entangle this argument. I will simply state, as the result of extensive clinical experience and anxious casuistical analysis, that those methods which are the most successful in saving the mother are often exactly those which give the best chance to the child. Here, as in other of the great clinical problems in obstetrics, the guiding principle should be to seek for a solution which offers the greatest security for both mother and child, not condemning either.

It is no longer permitted to us, without ample proof of clear necessity, to sacrifice the child in order to save the mother. The cases in which the two lives are supposed to stand in antagonism are vanishing before the light of modern science and skill. And in no conjuncture is this more true than in the treatment of placenta prævia. Countless infants have been sacrificed on the altar of false theories. My own experience gives 33 per cent. of children born alive; and that, concurrently with a larger saving of mothers than has been secured by other methods.

A gross fallacy, which vitiates the teaching and practice of many men, is to regard the particular manipulation which they most affect as constituting the whole treatment of placenta prævia. If they had grasped the true theory, and had the faith that lends to action, they would have seen that there is no one method of treatment, but that several operations come into use in accordance with the stage of the labour, and the particular conditions of the case in hand.

Since I first sketched my theory of placenta prævia in the *Lancet* in 1847, and especially since the publication of my *Lectures on Placenta Prævia* in 1857, the leading idea of that theory has been largely recognised. Thus it is now admitted that there is a well-defined boundary between the lower zone of the uterus and the body of the uterus proper; and that the lower zone is distinguished from the upper zones of the uterus by peculiar attributes.

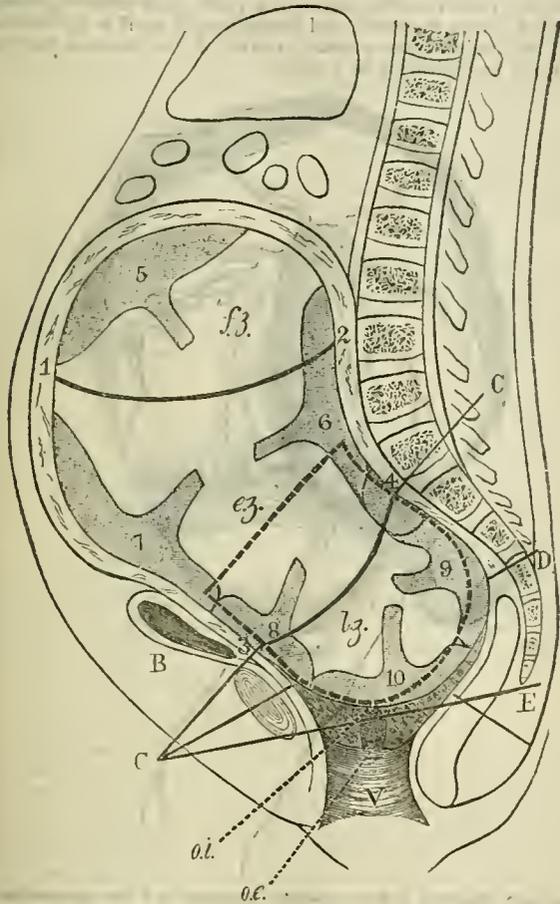

The theory of placenta prævia, developed from my original conception is depicted in the following diagram, (No. 1), and is summarised as follows:

The pregnant uterus is divided into three zones: the upper or fundal (*f.z.*, Diagram 1); the equatorial (*e.z.*) and the lower (*l.z.*). The fundal zone is divided from the equatorial by an imaginary line (1-2), the upper polar circle. This line has not been anatomically demonstrated, nor has it been recognised by anyone but myself; but it serves to mark a distinction, which I believe is real, between the properties of the upper and the equatorial zones in their relations to placental attachment and to hæmorrhage.

The equatorial zone is divided from the lower zone (commonly, of late, called the lower uterine segment), by the line 3-4. This is Barnes's boundary-line (1847-1857), since then sometimes called Braun's or internum, Band's ring, or Schroeder's contractions-ring.

The fundal zone (5) is the seat of fundal placenta, the region of safest and most typical normal attachment. The equatorial zone (7) is the seat of lateral or equatorial placenta. It disposes, I believe, to what is called accidental hæmorrhage, but may be fairly regarded as a comparatively safe normal attachment. This is still more true when the placenta is attached partly in the fundal zone and partly in the equatorial, as

seen (6). Danger especially begins when the placenta descends partly into the lower zone, as at 8-9. This constitutes partial placenta prævia. The part of placenta invading the lower zone is liable to premature separation. Complete placenta prævia, or placenta prævia centralis, occurs when all or the greater part of the placenta grows within the lower zone, and covers the os internum.

Explanation of Diagram 1.

1-2. Upper polar circle. 3-4. Lower polar circle. (This lower polar circle is Barnes's boundary line, 1847-1857; Branne's os internum, 1872; Bandl's ring, 1876, more lately Schroeder's contractions-ring), f.z. Fundal or upper zone. e.z. Equatorial or middle zone. l.z. Lower zone or lower uterine segment. n. Bladder. v. Vagina. o.i. Os internum uteri. o.e. Os externum. 5. Fundal or safe placenta. 6. Fundo-lateral placenta. 7. Lateral or equatorial placenta. 8. Partial placenta prævia. 9. Placenta prævia lateralis. 10. Placenta prævia centralis. c.c. Conjugate diameter of brim. c.d. Conjugate diameter of cavity. c.e. Conjugate diameter of outlet. The thick interrupted line represents the position occupied by the foetal head presenting.

In such cases as the last the gestation may not inaptly be called ectopic, inasmuch as the ovum, or an important part of it, is developed in the lower zone of the uterus, a region not adapted by Nature for the process.

The thick interrupted line in the lower zone marks the position occupied by the foetal head. The boundary line 3-4 nearly corresponds with the equator of the foetal head, and frequently nearly with the pelvic brim.

I think Bandl has exaggerated the anatomical differences between the middle and lower zones of the uterus. In specimens that have come under my observation [Drawings by Dr. Barnes were exhibited.] the course of the musculature is continuous, the wall not being materially thinner in the lower zone before labour. Of course, under the distension caused by the passage of the head, the lower zone and cervix may be thinned to the extent he depicts.

I will not in this place attempt a full discussion of the various theories emitted as to the cause of the hæmorrhage. I will only

state briefly some of the conclusions, more or less provisional, at which I have arrived. We may fairly start from two fundamental propositions: 1. The source of the hæmorrhage is the uterine vessels; 2. These vessels are torn across by the detachment of placenta from its uterine connection. The difficulty is to demonstrate what causes this premature detachment. Is it contraction of the uterus, causing such a diminution of its area that the placenta cannot follow? If this diminution of area of the uterine wall be the cause, we must postulate active uterine contraction. This is usually assumed to take place. No doubt sometimes it does. Possibly the frequent peristaltic movement of the uterine wall may occasionally pass the normal limit, and thus a degree of contraction may occur sufficient to throw off adhering placenta. Possibly uterine contraction more active, even spasmodic, may occur. But it is a matter of clinical observation that in many cases hæmorrhage sets in before there has been any obvious contraction of the uterus. It comes on when the subject is asleep; she is awakened, not by pain, but by the flooding. The most frequent time is at a menstrual epoch. One factor then presents itself: increased vascular tension. This tells upon the uterine vessels and upon the placental vascular system. This tension disposes to rupture of the vessels. This rupture takes place at the weakest part, that is, in the vessels running between the uterus and placenta.

Another factor cannot be overlooked. The spongy cellular structure of the placenta favours accumulation of blood in it. The uterine arteries continue to pump in blood, but the return by the venous sinuses does not keep pace with the inflow. Hence the rapidly distended placenta becomes larger in area than the corresponding area of uterus. Frequently the distension of the placenta is so great that its cavernous structure gives way, and there is hæmorrhage into the substance of the organ. Thus the placental bulk becoming suddenly too large detaches itself from the uterus. This process does not necessarily involve, in the first instance, contraction of the uterus. Contraction is, indeed, pretty likely to follow under the reflex irritation induced. But it does not always follow, at least not to any appreciable degree. Why does the flooding so often persist? Because contraction does not set in.

The form of contraction that prevails in the lower zone or segment is retraction. Longitudinal muscular fibres are continued from the middle zone along the walls of the lower zone, even into the cervix and vagina. Their action is to pull up or retract the lower zone, opening the cervix, thus aiding the driving power of the body of the uterus and the abdominal muscles in canalising the passage and forcing the fetus through it. When this retraction is retarded there is hæmorrhage; when retraction goes on well hæmorrhage ceases. An obstacle to efficient retraction is the partial adhesion of the placenta. Detach this, and frequently the vital power not being reduced too low, efficient retraction sets in. This is a matter of direct clinical observation, that is, to those who have the faith and courage to observe, not blindly thwarting Nature by rushing to the brutal expedient of "forced delivery." Those who intercept the natural order of a physiological process, are not entitled to give evidence in contradiction of those who have watched the process throughout. They are out of court.

There is still another condition of the placenta that disposes to self-detachment. This is alteration of its texture from fibrinous, indurations, fatty degeneration, or other condition impairing the natural homogeneity. Some such change is especially apt to occur in the praevial flap of placenta. In my *Obstetric Operations* and in the *System of Obstetric Medicine and Surgery*, written by myself and Dr. Fancourt Barnes, I started another theory of the cause of premature detachment and hæmorrhage; this is that the placenta, growing more rapidly than the corresponding uterine area, shoots out beyond this area, and so leads to detachment. It has been objected that there is no proof of this. It is true there is no direct proof; but, on the other hand, it is not disproved by simply denying it; and the argument from analogy with the history of tubal ectopic gestation is very strong. In cases of this kind the rupture of the sac and hæmorrhage take place mainly because the sac is not adapted to keep pace with the rapid growth of the ovum about the third month; the sac bursts, and there is effusion of blood. Now I have shown that placenta prævia is a form of ectopic gestation. It is a legitimate deduction that the processes of both are similar.

The case may be summed up in the following propositions:—
1. The hæmorrhage comes mainly from the bare uterine surface, and is arterial. (Simpson thought it was from placenta.)

2. In the progress of many labours, there is a stage when the flooding is spontaneously arrested. (The old dogma was, that the hæmorrhage was unavoidable, and must go on until delivery; and this dogma still governs the practice of many men, precipitating them into rash action.)

3. This spontaneous arrest does not depend upon total detachment of the placenta, nor upon death of the child, nor upon syncope of the mother, nor upon pressure upon the lower segment of the uterus bared of placenta, although one or more of these conditions may favour it.

4. The constant conditions of this physiological arrest are contraction of the uterus, active or tonic, thrombosis, or clotting at the orifices of the vessels, and

5. The physiological arrest of flooding is neither permanent nor secure until the whole of that portion of the placenta which had adhered within the lower zone is detached, this being the portion which is liable to be detached during the opening of the lower segment of the uterus to the extent necessary to give passage to the child. The limit of dangerous placental attachment corresponds to the equator of the child's head (*vide* Diagram 1, 3-4). Below it, the lower segment must dilate; above it the placental attachment is normal, and the uterine region need not and does not dilate. On the contrary, it contracts to force the child into the lower zone, which undergoes canalisation, continued by the cervix and vagina.

This boundary line, revealed to me by close clinical observation and physiological study, has since been demonstrated by anatomical research by others. The illustrations exhibited show this. My boundary line, described in 1847-1857, and many times since, became Braune's *os internum* in 1872, Bandl's ring in 1876, and more lately Spiegelberg's lower boundary of contracting part of uterus, and Schroeder's "contractions-ring." I think I am entitled to claim it as my discovery, if priority goes for anything. But I go further, and submit that these and other writers, although recognising this fundamental fact of a definite boundary line, and attaching their names to it, have failed to grasp its full significance. Had they formed a clear conception of its importance, they would have drawn the obvious therapeutical deductions, and would have made it the guiding principle of treatment. Instead of this, their treatment remains simply empirical. Imperfect in physiological conception, it is barren in therapeutical issue. Attempts have been made to define the extent of the lower zone by measuring the distance from the *os internum* to the boundary line. These are based upon the fallacy that all cases are alike. The uterus and the foetal-presenting part vary in absolute and relative proportions, according to the development of the uterus and the size of the child. It is idle to pretend to fix a constant boundary line, measured by tape or rule. My estimate is based on the observation of cases at term, and the measurement of foetal heads at the equator. The true limit is the height from the cervix to the equator of the foetal head.

6. When this stage of detachment has been reached, by Nature or by art, there is no physiological reason why any further detachment or flooding should take place until after the expulsion of the child, when, and not till then, the remainder of the placenta, which adheres to the middle and upper zones of the uterus, is cast off, as in normal labour. This preservation of the connection between placenta and the body of the uterus is commonly enough to preserve the child. It is chiefly in the extreme cases of central placenta prævia, in which the placenta is in greater part or wholly within the lower zone, or when as not seldom happens, labour sets in prematurely, that the child's life is compromised.

7. Adhesion of the placenta over the *os uteri internum* impedes the regular dilatation of the part; and, consequently, whilst such adhesion lasts, the ordinary course of labour is hindered or perverted.

8. Injury and inflammation of the uterine structures, particularly of the cervix, are especially likely to ensue upon delivery in placenta prævia. One of the purposes intended by Nature, in fixing the seat of the placenta in the fundal and equatorial zones, is the preservation of the parts, rendered highly vascular by connection with the placenta, from distension and contusion attending the passage of the child.

The treatment logically flowing from the foregoing physiological propositions is set forth in the following therapeutical propositions:—

1. The greatest amount of flooding frequently takes place at the commencement of labour, and frequently even before there is

any clear indication of labour; generally at what would have been a menstrual period. The cervix is always, from its being near the seat of placental attachment, highly vascular, and is frequently at this stage very rigid. Any attempt to force the hand through this structure at this stage, to detach the whole placenta or to deliver, must be made at the risk of injuring the womb. The dragging the child through the cervix, even when it has not been necessary to pass the hand into the uterus, is a proceeding affording slender chance of life to the child, and fraught with peril to the mother. Hence the indication to pursue a course of treatment as free from violence or precipitation as possible.

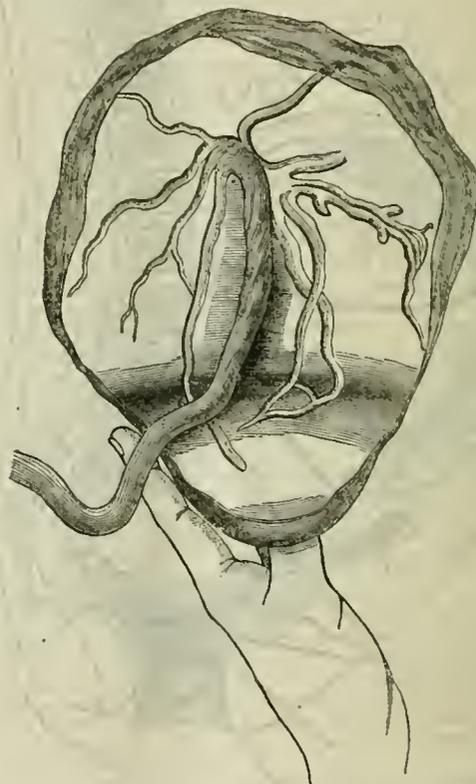

Diagram 2—Showing a flap of prævia placenta, and the demarcation between the prævia and equatorial portions of placenta, corresponding with the uterine boundary line. The finger shows how the prævia flap can be detached from the lower zone.

2. The entire detachment of the placenta is not necessary, and is not to be depended upon, to arrest the hæmorrhage. (Since my demonstration of this point, Simpson, I believe, abandoned the practice, and I do not think anyone now advocates it.)

3. Since the dilatation of the cervical portion must take place in order to give passage to the child, and since during the earlier stages of this necessary dilatation hæmorrhage is liable to occur, it is desirable to expedite this stage as much as possible, avoiding violence.

4. In cases where labour appears imminent, with considerable hæmorrhage, whilst the *os internum uteri* is still closed, the arrest of the flooding and the expansion of the *os* may be promoted by rupturing the membranes and the use of tents.

5. Since a cross-presentation or other unfavourable position of the child is apt to impede or destroy the regular contractions of the uterus, which are necessary to arrest the flooding, it is mostly desirable to deliver as soon as the condition of the *os uteri* will permit.

6. In some cases the simple use of means to excite contraction of the uterus, as rupturing the membranes or the employment of galvanism, may suffice to arrest the hæmorrhage.

7. In some cases in which it is observed that the *os uteri* has moderately expanded, or to a diameter of 1.25 inch or 4 centimètres, the placenta being felt to be detached from the lower zone, and the hæmorrhage having ceased, it is not necessary to interfere

with the course of labour, now become normal. Hæmorrhage rarely persists after full canalisation of the passage.

8. At the critical period, when the total detachment of the placenta or forcible delivery is dangerous or impracticable, the introduction of the index finger through the os, and the artificial separation of that portion of the placenta which adheres within the lower zone, is a practicable and safe operation. This proceeding is illustrated in Diagram 2, which represents the foetal surface of a placenta drawn from Nature. The flap at the lower part was prævial placenta. The shaded line exactly corresponds to the uterine boundary line. The flap itself corresponds to the lower zone of the uterus. It shows the compression of the foetal head. I have introduced the index finger to show how it is made to sweep behind the prævial flap to detach it as far as the boundary line.

9. The artificial detachment of that portion of the placenta which adheres within the lower zone will at once liberate the os internum from those attachments which impede its equal dilatation; and, by facilitating the regular contraction of this segment of the uterus, favour the arrest of hæmorrhage, and convert a labour complicated with placenta prævia into a natural labour.

10. The immature uterus, partly paralysed by loss of blood, cannot always be trusted to assume the vigorous action necessary to effect delivery; it is, therefore, necessary to aid canalisation by dilating the cervix artificially; this can be done safely and quickly by my caoutchouc water dilator. This has come into general use, and the testimony in its favour is conclusive. But one or two German teachers say it is not effective. The bags they have tried must be bad specimens, or skill in using them was wanting.

11. Sufficient dilatation being obtained, delivery may, if necessary, be accelerated by forceps, by turning, or by embryotomy, according to the special indications dictated by the condition of the child. If turning be resorted to, I insist strenuously upon the importance of delivering the after-coming head by the forceps, if there be any difficulty or delay in the passage of the head under manual traction. The forceps so applied takes off the constriction of the imperfectly dilated cervix from the child's neck; and traction bearing upon the head, facilitates moulding, and takes off all strain from the neck; axis-traction also is to be observed. In my hands, this proceeding has contributed materially to the saving of the child.

The measures that come into successive use are:—

1. Rupture of the membranes.
2. Apply a firm binder over the uterus.
3. A plug may be used to gain time, but it must not be trusted; watch closely.
4. Separate all the placenta that adheres within the lower zone, and observe closely. If no hæmorrhage, wait awhile. The uterus may do its own work; if not, dilate the cervix by the water bags. Again pause and observe. If Nature fail to deliver, we resort to the forceps, which gives the best chance to the child, or turn.

In following this order of procedure, we strictly follow the law of physiology. We do not force Nature, but obey her. Current medical literature is full of examples proving the value of these precepts, and not a few cases published as illustrations of the success of other methods, especially of turning, are more correctly explained by the fact, probable in many, certain in some, that in carrying out the operation of turning, the placenta had been detached from the lower zone. Where the principles enunciated by me have been thoroughly and intelligently observed, as has been done on a considerable scale, as by Dr. Murphy, the success has been unexampled.

An emphatic illustration of the treatment advocated by me is found in the following summary of the experience in placenta prævia in the practice of St. Thomas's Hospital for 1887 (*St. Thomas's Hospital Reports*) by Dr. Cory:—"Five cases occurred during the year. In one case there are no particulars; in two the placenta was partially separated, and delivery effected by forceps; both children were saved. In two the placenta was partially separated; version was performed, and the children were lost; all the mothers recovered." Dr. Cory adds:—"The lesson to be learned in these cases is well shown, namely, never attempt version if the head is presenting, and hæmorrhage has been stopped by the partial separation of the placenta."

LONGEVITY IN IRELAND.—Among the deaths registered in Ireland for the December quarter were the following:—Two at 100 years, two at 103, two at 104, one at 110, and one at 111 years respectively.

PATENCY OF THE UTERINE CANAL AS AFFECTED BY FLEXION OF THE UTERUS.

By GRAILY HEWITT, M.D., F.R.C.P.,

Emeritus Professor of Obstetric Medicine, University College; Consulting Obstetric Physician to University College Hospital.

THE effect of flexion of the uterus in interfering with the patency of the uterine canal is a subject on which a diversity of opinion exists. In the healthy normal uterus the tissues surrounding the uterine canal are of considerable strength and thickness, and under such circumstances a great degree of bending of the uterus does not occur; but when circumstances are otherwise, and the tissues are soft and non-resistant, possibility of severe bending is greater. When flexion is present, the thickness of the walls of the canal tend to preserve the patency of the canal, but it is evident that the calibre of the tube will be more likely to be diminished if at the same time the walls of the canal are relaxed, soft, and wanting in tonicity.

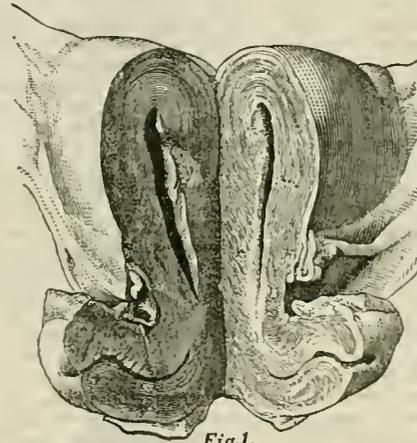

Fig. 1.

From the various conflicting descriptions of the state of the os uteri internum in cases of flexion, it is difficult to arrive at decisive conclusions, observations by means of the sound being difficult to make in a sufficiently uniform manner, and the sound itself being liable to alter the conditions actually present.

The following, as a piece of pathological evidence as to the condition in regard to patency of the canal in a case of ante flexion, may be considered worthy of attention.

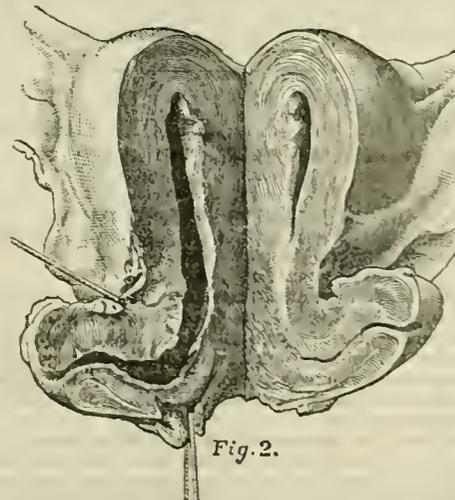

Fig. 2.

In the Museum of University College there is one of the few existing preserved specimens of acute ante flexion of the uterus. This specimen I had before described. Five years ago the speci-

men in question again attracted my attention, it having been meanwhile bisected antero-posteriorly so as to show the canal. Mr. Silcock kindly had photographs of the specimen taken for me so as to exhibit the condition of the canal more completely. The accompanying drawings are the result.

Fig. 1 exhibits the bisected ante-flexed uterus as it hangs suspended, the cavity of the uterine body being very evident, so, also, the cavity of the lower part of the cervix. But the upper part of the cervical canal for a length of three-quarters of an inch is hardly visible, and it looks as if obliterated at this situation. In Fig. 2 is shown the same specimen, but cords have been attached to the two sides of the apparently closed part of the cervical canal, and it is now seen that the cervical canal is only potentially, but not actually, closed. In point of fact the canal is really excessively compressed in the antero-posterior direction, the anterior closely in contact with the posterior wall (as shown in Fig. 1), and until opened out by the stretched cords, was virtually much blocked. It must further be noted that the section of the canal, which no doubt was intended to be made exactly in the middle line, was really made a little to the left of the middle line. The view of the interior of the canal of the cervix in Fig. 2, therefore, shows considerably more than half of the width of the canal. The shape of the canal at the virtually occluded part is not circular, but very much flattened from before backwards; in this case the shape of the canal, indeed, resembles very much the shape of a small, thin, india-rubber tube, compressed at a particular spot between the thumb and finger, and the result is that there is very great narrowing in one direction, but a widening in the opposite direction. Comparing, again, the uterine tube with one of india-rubber under compression, it is evident that the increased width of the tube is of no service so far as patency is concerned, so long as the compression in the opposite diameter continues to be exercised. It will be further obvious that, so long as the cervix continued flexed, as in Fig. 1, there would be an impairment of patency, which would be relieved or diminished by taking off the compression in the antero-posterior direction. This might be done in the way shown after death; during life the straightening of the canal by a sound, or a dilator or a tent, would be effectual in procuring a free passage out of the uterus. It is also evident from inspection of the drawings that a forcible expulsive force, that is, uterine contraction, acting on fluid contained in the uterine cavity, would or might be sufficient to open out the canal at the compression-narrowing spot, and thus to secure an outlet for the retained fluid. It is also evident that any increase in the degree of flexion present would tend to still further close the canal.

Nothing is known of the history of the above specimen, but it evidently belonged to a rather young woman. The slight indentations in the body of the uterus are accidental, and due to pressure of a piece of glass placed so as to expose the interior of the body of the uterus.

The specimen undoubtedly favours the opinion previously expressed on the subject, that the patency of the uterine canal is liable to be greatly affected by presence of marked flexion of the uterus.

ELECTRIC ILLUMINATION OF THE MALE URETHRA BY MEANS OF THE NEW INCANDESCENT-LAMP URETHROSCOPE.¹

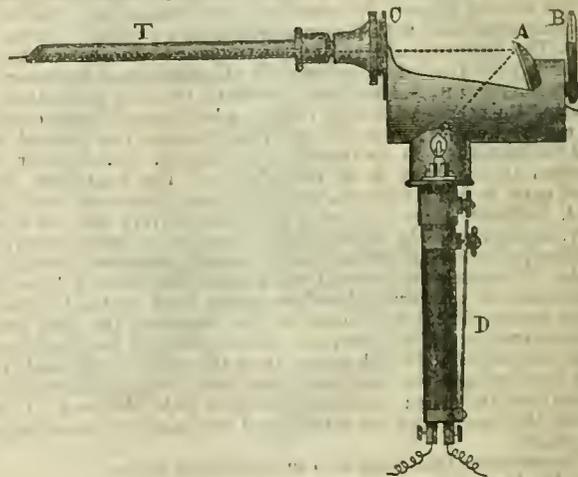

By E. HURRY FENWICK, F.R.C.S.

Assist.-Surgeon to the London Hospital and to St. Peter's Hospital for Stone and other Urinary Diseases.

SINCE April, 1887,² a simple, practical, and most efficient urethroscope has been placed in the hands of the profession, by means of which the entire urethra can be brilliantly illuminated; so that those diseases of that canal grouped for convenience under the term "gleet," which sometimes prove so rebellious, and are often obscure in their causes, can now be as scientifically studied as they can be effectively treated.

I have used the instrument in over fifty cases of gleet and stricture, and believe it to be the best and the most gene-

rally useful of any endoscope yet invented, for it can be adapted to every orifice of the body, even to the oesophagus. The instrument has been invented by Leiter, of Vienna, but it is only fair to explain that it combines, in reality, those various additions to Bozzini's "light conductor" of 1805, which mark the successive epochs in the development of urethral endoscopy. Thus its general construction is somewhat similar to the now twenty-five years old endoscope of Desormeaux-Cruise,³ but instead of the hot and cumbersome paraffin lamp of that period, or the still hotter and more complicated Nitze-Leiter urethroscope of 1879,⁴ Schall, of London, has substituted the incandescent lamp.⁵ Leiter has simplified the entire instrument, and has furthermore cleverly adapted a concave non-perforated reflector, which is the bone and marrow of the innovation. Although much good and sound work has been done by Oberländer by means of the Nitze-Leiter urethroscope, yet that instrument has never found favour or been in general use, because of its costliness, unwieldiness, and complication.

Leiter's Electric Endoscope for Urethral Examination.

Construction.—The incandescent-lamp urethroscope is made up of three pieces, D, B.C., and T. These pieces may be described as follows: 1. The handle D is made of caoutchouc, and carries on its upper end a small incandescent lamp, which is connected with the two binding screws which project from its lower end. A light steel spring forms the key. The handle fits into the bottom of the lantern B.C. 2. The lantern B.C. is a rootless gutter-shaped box, carrying at one end a fixed, obliquely-placed, concave mirror A for reflecting light along the urethral cannula T, and at the other the nozzle C for fitting on the urethral tubes. Two additional and important items of the lantern consist in small perforations around the lamp for ventilating off the heat, and a small movable lens B for myopic or hypermetropic observers. 3. A series of urethral cannulae T of various sizes and lengths. (Those supplied at present by Leiter are not long enough.)

A glance at the figure will show that the light from the lamp is cast directly along the tube, and that the observer's eye, which is placed at B, is shielded from the blinding light emitted by the lamp. It is worked by a small plunge battery of four cells.

Directions for Use.—Select a long cannula, and of a size suited to the mental calibre. Use glycerine as the lubricant. Pass the cannula up to the hilt after injecting a few drops of a 4 per cent. solution of cocaine. Every part of the urethra can now be examined as the cannula is withdrawn. If the cannulae are marked in inches, a note of the exact position of the diseased mucous membrane can be made for future reference. Frequently a drop of mucus, gleet, or the lubricant will obscure the surface of the mucous membrane; a pledget of cotton-wool on a stylet removes it, hence it is wise to use as little glycerine as possible. Should the wool slip off the end of the stylet it will be passed on urination, or may be removed by a hook-ended stylet applied through the cannula.

Capabilities.—The illuminating power is very considerable.

¹ Abstract of a demonstration of the instrument upon normal urethra as well as upon patients suffering from various urethral diseases—gleet of seven years' duration, etc.—at the Medical Society, January 27th, 1888.

² Dr. Brenner upon Leiter's Urethroscope, *Verhandl. der Deutschen Gesellschaft für Chirurgie*, xvi Congr., 1887, p. 92.

³ Desormeaux, *De l'Endoscope*, Paris, 1865. P. R. Cruise, *Die Endoscope*, *Deut. Quart. Jour.*, May, 1865.

⁴ Die Nitze-Leiterschen Urethroscope, *Berl. Klinisch. Woch.*, 1879, No. 48.

⁵ Leiter, *Neue Beleuchtungs-Apparate*, Wien, 1888.

Every section of the urethra can be thoroughly examined, and every detail of its surface can be as easily studied as if the canal were exposed to bright sunlight. Any change can, with practice, be detected immediately. But more than this; every diseased patch can be treated topically without withdrawing the cannula, for the reflector is so deeply placed in the lantern that bougies, or stylets armed with wool or medicaments, can be passed over its summit (Fig. 1 A, after twisting away the lens B), and down the cannula in the very axis of the light. Thus, as in the Desormeaux-Cruise instrument, the observer can govern the method and extent of his treatment, and watch the effect at the same time: The urethroscope has never been a popular instrument, and I believe it is due to this fact that so many of the long-standing, neglected gleet lapses into stricture. It is certain, however, that with a simple and practical urethroscope such as this is, and a greater visual knowledge of urethral disease, we shall have fewer false diagnoses of stricture; and, doubtless, fewer instances of normal urethra "worried into stricture" by unnecessary and harmful instrumentation.

ABSTRACTS OF THE MILROY LECTURES

OR

SOME GENERAL CONDITIONS WITH REGARD TO EPIDEMICS.

Delivered at the Royal College of Physicians of London, February and March, 1888.

By ROBERT LAWSON, L.R.C.S.E.D.,
Inspector-General (Retired) Army.

LECTURE I.—EPIDEMIC INFLUENCES.

AFTER thanking the President and Fellows for the honour done to him by selecting him to give the first series of lectures under the bequest of the late Dr. Milroy, the lecturer quoted two paragraphs from the testator's "suggestions for consideration by the Council of the Royal College of Physicians in relation to his bequest." In one the opinion was expressed that no question of medical doctrine stood "more in need of strict inductive examination than that of determining with accuracy the part which contagion—the communicability of disease from the sick to the healthy—plays in the development and spread of various maladies. . . . The correct solution of this problem thus becomes one of supreme importance in State medicine. This can only be effected by the patient investigation of numerous verified and authenticated facts in various localities and regions, and under different circumstances and conditions, apart from all previous speculation and any mere traditional or customary beliefs." In the other a strong desire was expressed "that more diligent and continued attention may be paid than has yet been attempted in this country to the study of the accurate geography of diseases, together with the exact chronology of the appearance and persistence of those diseases which are of only occasional and temporary occurrence; also the exact date of each epidemic prevalence or extra severity of the ordinary endemic maladies in different countries and localities, together with a brief notice of any exceptional feature or peculiarity characteristic of each aggravated manifestation of the malady in question, so that some record of its varying natural history may be preserved for the benefit of future times."

Passing then to the subject selected, the lecturer said that the terms "epidemic constitution," "epidemic influence," "pandemic influence," were merely conventional expressions embracing those factors which led to the diffusion and intensification of disease from time to time which were not referable to the individuals who suffered or the localities in which they resided. A study of the statistics provided by the Medical Department of the army showed that, though causes of insalubrity were more or less permanently present at various stations, severe epidemics of fever appeared at intervals only, leaving the respective stations comparatively healthy during the intermediate years, thus indicating the operation of factors during the epidemic years which were in abeyance during the intervening periods. From this it was concluded that the epidemic factor embraced large portions of the earth's surface at the same time, and that records of disease over an equally extended surface, and for many years in suc-

cession, were required to indicate the course these factors pursued.

A study of a large collection of notices of the occurrences of epidemics of fever and several other diseases led to the conclusion that in the case of fevers these outbreaks, besides embracing a considerable space in longitude, gave rise to epidemics in the respective localities they invaded, for the most part in a year with an even, or odd number. This conclusion was illustrated by quotations chiefly from the reports of the Army Medical Department. In Jamaica, for instance, the number of deaths from fever in the odd years (1817, 1819, etc.) was far greater than in the even years (1818, 1820, etc.), while the reverse held good in Ceylon.

An examination of the large body of evidence collected led to the further conclusion that epidemics of fever, which became developed at various points, from time to time, passed uniformly to the northward until they finally disappeared. The length of the course of individual epidemics varied much, but the disease generally appeared in each locality in the odd or even year which characterised it. From the combination of several details the period occupied in passing from the Cape of Good Hope to this country was found to be about six years.

A large mass of statistics was quoted in favour of the lecturer's views, and the general conclusion drawn was "that there is a factor concerned in the production of fever which determines its appearance at points more and more to the northward in successive years; that this factor revives periodically every second year, or at some multiple of two years, passing like a series of waves over a more or less extensive portion of the earth's surface. These waves can be traced from Buenos Ayres and Cape of Good Hope in 35° south, to northern Europe and Iceland, and in longitude from Ceylon and China to the west coast of America. To distinguish these I have named them pandemic waves. Of their intimate nature nothing is known at present, but as their position from year to year seems defined, approximately at least, by lines of equal magnetic dip, it is inferred they may be dependent in some way on that force."

THERAPEUTIC MEMORANDA.

SYRUP OF TAR IN WINTER COUGH.

TAR is undoubtedly one of the best remedies for chronic bronchitis and winter cough, but the difficulty is to know how to give it. In an article which appeared in the *JOURNAL* in 1875 I recommended that it should be given either in capsules or in pills made with lycopodium. Both these methods have their disadvantages, and I now use the syrupus picis liquidæ of the *United States Pharmacopæia* prepared as follows: "Tar, six parts; cold water, twelve parts; boiling distilled water, fifty parts; sugar in coarse powder, sixty parts, to make one hundred parts. Upon the tar contained in a suitable vessel pour the cold water, and stir the mixture frequently during twenty-four hours; then pour off the water and throw it away. Pour the boiling distilled water upon the residue, stir the mixture briskly for fifteen minutes, and set it aside for thirty-six hours, stirring occasionally. Decant the solution and filter. Lastly, in forty parts of the filtered solution dissolve the sugar by agitation without heat."

It is stated in most of the dispensatories that the syrup contains six grains in the drachm, but Mr. Tanner, of the Westminster Hospital, tells me that in reality it is not much stronger than the old-fashioned tar water. This, however, is a matter of little importance, for by the addition of a few drops of ammonia or other alkali it can be prepared of almost any desired strength. I usually give it in doses of from two to four drachms every three hours, or even oftener. It is by no means disagreeable to take, but should the taste be objected to it can be flavoured with syrup of Virginian prune made according to the following formula: "Wild cherry in No. 20 powder, twelve parts; sugar in coarse powder, sixty parts; water, a sufficient quantity to make one hundred parts. Moisten the wild cherry thoroughly with water, and macerate for twenty-four hours in a close vessel; then pack it firmly in a cylindrical glass percolator, and gradually pour water upon it until thirty-five parts of percolate are obtained. Dissolve the sugar in the liquid by agitation, without heat, add the glycerine and strain." The tar is an excellent stimulating expectorant, whilst the wild cherry is not without influence in allaying cough. The efficacy of the combination may be greatly increased by the addition of a little apomorphine. I use the 2 per cent. solution of the *British*

Pharmacopœia, and find that six minims may be given frequently without exciting nausea. Many patients take ten minims perfectly well; but in a few cases, in delicate women especially, it induces vomiting. During the last two years I have used this method of treatment in nearly a hundred cases of chronic bronchitis and winter cough, and have every reason to be satisfied with the result. The cough is relieved, expectoration is rendered easier, and the patient usually sleeps well the very first night. The syrup of tar alone without the apomorphine is admirably adapted for the treatment of the coughs and colds of children, and has none of the disadvantages of preparations containing opiates.

Weymouth Street, W.

WILLIAM MURRELL, M.D.

CLINICAL MEMORANDA.

OPHTHALMOPLÉGIA EXTERNA DUE TO ALCOHOL.

THE common causes of ophthalmoplegia externa are locomotor ataxy, syphilis, diphtheria, and exposure to cold. Though paralysis of the ocular muscles has been observed in chronic alcoholism, I am not aware that the condition to which the term ophthalmoplegia externa is applied has been met with, and its occurrence would seem to show that it may be produced by lesion of the nerves as well as by lesion of the nerve nuclei, alcoholic paralysis having been proved to depend upon peripheral neuritis.

The following case of chronic alcoholism, with ophthalmoplegia externa, is at present under my care.

J. B., a man, aged 50, was admitted into the workhouse infirmary on January 25th. His relatives stated that he had been drinking heavily for some years; and my friend, Mr. Newton, who attended him before his admission into the workhouse, tells me that he has been drinking for years, and that the drooping of the eyelids came on about a month ago, the patient having complained for some weeks previously of pains and cramps in his legs. The patient, on admission, was incoherent, constantly asking for drink, and unable to tell where he was or to give any account of himself. He was unable to raise his eyelids, there being drooping of both eyelids, the left being less affected than the right. There was slight external strabismus of the right eye. He was unable to rotate his eyeballs either upwards or downwards, but could move them readily from side to side. The pupils responded to light and accommodation, but sluggishly, and were small. The knee-jerk was lost on both sides, the plantar reflex increased. There was no paralysis of the legs or arms, but the calf muscles were exquisitely tender on being grasped, and pressure along the course of the posterior tibial nerves elicited great pain. He could point his toes, and there was no marked weakness of the extensors of the wrist or leg. The first metatarsal bone was fractured, and he said this was due to a chair falling on his foot. The muscles of the legs responded normally to faradism and galvanism. His memory was much affected, and he did not know where he was; he had no knowledge of time or place. When asked if he had been out he always responded in the affirmative, declaring that he had been several miles, and that he had had several glasses of whisky; in fact, he talked of nothing but drink. He took his medicine readily on being told it was whisky, though he thought the taste of it was very peculiar; in fact, he thoroughly illustrated the truth of the proverb, "In vino veritas," his speech betraying his previous habits.

Since his admission the patient has much improved, being now able to open his eyes, and the lids only drooping slightly. There is still considerable restriction of the movements of the eyeballs, but this is daily diminishing. The patient has had no alcohol since admission.

C. W. SUCKLING, M.D., M.R.C.P.

Birmingham.

SURGICAL MEMORANDA.

DISLOCATION OF THE RADIUS AND ULNA INWARDS.

AN example of this comparatively rare accident seems worthy of being recorded on account of the clearness of the signs and symptoms, and more particularly of the method of its production.

A young man, in driving a trap too sharply round a corner, capsized it, and was thrown out of it on the convex side of the curve. He alighted on the olecranon of the left side. The forearm being thus arrested by contact with the ground, while the rest of his body, including the left humerus, was still in projectile force, the humerus was carried beyond the forearm bones towards the outer

side, leaving the latter bones dislocated inwards. As usual, the dislocation was incomplete. The following signs were noted: The forearm was in a state midway between pronation and supination, and flexed at the elbow to an angle of 135°. There was marked bending of the forearm to the ulnar side, giving to the outer border a strongly convex outline, an appearance largely due to the prominence of the external condyle. This process, with the greater part of the capitellum, was easily felt from the surface, and so extensive was the laceration of the ligaments on the outer aspect of the joint, that the head of the radius could be separated from contact with the smooth ridge between the trochlea and capitellum to the extent of half an inch by forced ulnar flexion. The head of the radius had an inclination to displacement forwards, and the freedom of its movements was such as to suggest considerable yielding of the orbicular, as well as the external lateral, ligament. The greater sigmoid cavity of the ulna articulated with the under aspect of the internal condyle, which process was buried deeply. Very severe pain was complained of at this spot, intensified by pressure and movement, evidently due to the ulnar nerve being pressed. The olecranon, though prominent behind, was not raised above the inter-condylar line. There was no fracture of any of the bones, and passive movements were not so restricted as in some other elbow dislocations.

Reduction was easily effected by the usual method of placing the knee against the upper part of the forearm, and first extending, then flexing the joint, at the same time that the forearm was lifted outwards. When splinted it was thought desirable to place a pad on the front of the head of the radius to overcome the slight tendency to displacement forwards of this bone.

THOS. SINCLAIR, M.D., F.R.C.S.ENG.,
Professor of Surgery, Queen's College, Belfast.

REPORTS

OF

HOSPITAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN, IRELAND, AND THE COLONIES.

BRADFORD INFIRMARY.

A CASE OF HYDROPHOBIA TREATED BY THE BUISSON METHOD.
[Under the care of DAVID GOYDER, M.D.]

J. D., aged 49, farmer, a quiet, sober man, had always enjoyed good health. About the end of August, 1887, he was bitten by a strange dog on the outer angle of the left orbit, just under the end of the eyebrow. The dog was killed. Another dog, bitten by it just previously, was isolated, but had since shown no signs of rabies. The wound was not canterised, and healed readily in a few days. On October 30th the patient complained of a cold in the head and running from the eyes and nose, but did not complain of these symptoms afterwards. On this day he first noticed a slight pricking sensation in the seat of the bite, and complained of "neuralgic pain spreading from it, and also of headache on the left side, and spreading across the forehead." There was also some pain deep in the neck, immediately behind and below the left mastoid process, and a stiffness of the neck about this region and downwards from it. These sensations continued up to 4 P.M. of November 2nd, the pains and headache being almost constant, whilst the pricking sensation became less marked. On the morning of November 1st the patient felt "cold and starved," and in the evening his wife noticed a strange look in his eyes, which seemed "standing out," and also that he was continually "gasping" and drawing in his breath. He described his walk home that evening as terrible, having to "cover up his head and walk backwards" to avoid the effects of the wind, which "stopped his breath." He exhibited slight spasms on taking some brandy-and-water, and subsequently refused his tea, saying he could not swallow. In the night he once swallowed some brandy-and-water without difficulty. Shortly afterwards he started up, saying he felt "so low and queer," adding, "I believe I am going to leave you; I feel such a wanting here," pointing to his chest. Some warm milk was offered to him, when he got alarmed, and several times attempted to jump out of bed.

In the morning he procured some india-rubber tubing, and through this swallowed half a cup of milk in about half an hour. Dr. Hirst saw him at 11 A.M., and, recognising the nature of his case, advised his removal to the Bradford Infirmary, where he was

placed under the care of Dr. Goyder, and of the house-physician, Dr. Vaughan. Dr. Herbert Major and Dr. Hime kindly lent their valuable assistance. It was decided to give the sweating method of Buisson a thorough trial.

On the patient's admission into the ward at 6.30 P.M., on November 2nd, an attempt was made to sponge his face, but the pouring out of the water into the basin, as Dr. Hirst had already previously observed, brought on a spasm, and he begged so earnestly to have the jug and basin removed from the room, as he could not bear the sight or suggestion of water, that his request was acceded to. He complained of "catches" in his breath, and a feeling of suffocation from the slightest causes, either from a draught of air or the attempt to remove his clothes. Whilst being carried into the ward he exhibited this peculiarity, frequently giving vent to a high-pitched cry of a very suggestive character. Swallowing liquids, except in very small quantities, through his india-rubber tube, produced a sense of choking, and was dreaded by him. Solid food he masticated and swallowed without difficulty. He complained of throbbing in his chest, and of a sense of sinking in the præcordia. There was no priapism or salivation. His face and conversation were of a depressed character, his mind clear. Pulse 100, temperature 100.5°. Face anxious, pupils dilated, the right more than the left; skin moist and warm; general manner nervous. The application of a cold hand to the cicatrix on his forehead produced a sudden violent shrinking and a deep inspiration, almost spasmodic in character. A whiff of air blown on his face caused him to spring up from the lying to the sitting posture; then followed a prolonged, strong, and spasmodic inspiration, during which the jaws were set half open, the angles of the mouth drawn downwards and outwards, the eyes staring, the facial expression entirely changing to one of great distress and wildness: the hands were doubled and firmly clenched. This spasm lasted a few seconds, during which the pupils were extremely dilated, and assumed their more contracted condition after the spasms were over.

At 8 P.M. a combined steam and vapour bath was applied. On removal of the shirt a spasm was caused. During the bath two or three spasms were brought on by water dropping on to the body off the blankets. There was profuse perspiration during the one hour and a half the bath lasted. He was then rubbed dry with warm towels. He perspired gently for some time, expressing great satisfaction at the bath.

Between midnight and 2 A.M. one grain of morphine was given hypodermically to produce sleep and to allay the frequent spasms, but without effect. The pulse was then 120, temperature 98.5° F. Thirty-grain doses of chloral were then given every hour until 9 A.M. of November 3rd, but without any visible effect whatever, although 240 grains were administered.

At 10.45 A.M. half a pint of coffee was fairly well swallowed through the tube. The combined bath, aided by pilocarpine hypodermically, was then repeated, and also in the afternoon, producing as before profuse perspiration. About 3 P.M. the spasm appeared to be less frequent, and the restlessness not so great. The temperature was then 98°. Solid food was eaten, and enjoyed in the course of the day. During the night three-quarter-grain doses of morphine were twice given hypodermically, and seemed to produce a little sleep towards morning.

During the morning of November 4th the restlessness steadily increased. At 11 A.M. the temperature, which had risen to 100.2° in the night, measured 103°. The pupils were now equal, and measured one-eighth of an inch in diameter. Thick, ropy saliva appeared, at first excitedly rubbed off the tongue with a handkerchief, afterwards violently hawked up. The patient now got out of bed, put on his drawers and trousers. He said he felt stiff, and that he was going to die. When spoken to he answered rationally, but when left to himself he rambled and muttered. About 12.30 P.M. he became gay and shouted. Temperature 100.4°, pulse irregular in force and volume. Although but lightly clothed, he was bathed in profuse perspiration. At 12.45 P.M. he spoke rationally to the nurses, and for quite ten minutes did not have a spasm. At 1.0 P.M. he walked to a chair, talking pleasantly to the nurses. He tried to swallow some beef-tea, which brought on a deep spasmodic inspiration, accompanied by an expression of wild effort in face and manner; then suddenly he successfully gulped a mouthful down. This was repeated, the swallowing being accompanied by a kicking-out of the legs. At 1.30 he became violent, salivating freely, and excitedly rubbing away the saliva. Three-quarters of a grain of morphine were injected. At 2.50 the pulse was 150 and weaker, temperature 104.4°. Sixteen

ounces of clear urine were passed, specific gravity 1024, and pale yellow. Four minims of tinct. strophanthi were given. At 3.5 he was so excited that three-quarters of a grain of morphine were again given. At 3.18 and 3.40 there were outbursts of violence, but without spasms. At 4.10 a grain of morphine was injected. D. now became more and more violent, spitting in his attendants' faces, and at 4.40 he became so uncontrollable that chloroform was administered, under which he rapidly fell asleep. He died quietly at 6.55, having had one or two spasms at about 6.30, and one shortly before death. At 7.10 P.M. the temperature was 101.8°, and at 8.10, 103.8°.

In commenting upon this case, Dr. Goyder remarked that as Pasteur's method was here out of the question, the case had seemed to be a favourable opportunity for trying the so-called "eliminative" treatment of Buisson, although this treatment had already failed in the hands of some of the staff of Guy's Hospital. If the treatment consisted in producing diaphoresis, this had been essentially fulfilled, for from the commencement of the treatment until death the most profuse perspiration was present, not only during the baths, but also in the intervals between them. It had been objected that the Russian method advocated by Buisson had not been carried out, as the patient had not been sponged with cold water afterwards. Dr. Goyder submitted that this would have been impossible to carry out on account of the intense dread of water—"hydrophobia" in every sense of the word—exhibited by D., and he thought that no man who had seen a case of true hydrophobia would propose such a thing. He was reluctantly obliged to question the value of the Buisson method. The character of hydrophobia itself rendered it doubtful whether perspiration, however produced, could eliminate the poison, as it seemed to show an elective affinity for the nerves and brain, whilst zymotic poison generated and culminated in the blood. The outset of D.'s case illustrated this peculiarity. It began with pricking at the site of the bite; the irritation spread along the nerves, evidently towards the spine and brain, after which followed the spasms, directly proceeding from the medulla along the nerves of respiration and deglutition. The poison thereafter seemed to exhibit a stationary character, for a time at least, as the spasms were confined to the face, throat, and chest. During this interval the temperature sank to normal, then the patient began to be restless, the temperature gradually rose, the nervous system, though getting excited, was at first only pleasantly exalted, and at last, when it would appear as if the poison had spread to the universal cerebral structures, general, maniacal, and destructive excitement set in, rapidly speeding on to a fatal termination. This elective affinity for the nervous structures, in which the poison seemed primarily to generate, killing the patient by its excess of action, did not, it appeared to Dr. Goyder, offer a sufficient interval of time for its elimination by diaphoresis. The patient was practically beyond hope long before the first natural eliminative efforts—that is, the secretion of saliva—were established. Still, Dr. Goyder thought the Buisson method ought not to be decisively condemned before more exhaustive trials.

As to the *post-mortem* appearances, although it seemed so natural to assume that such violent spasms could not be produced without observable abnormality in the medulla, the most careful observation by Drs. Major, Vaughan, Hime, and Goyder had failed to detect the changes in the medulla recorded by Dr. Clifford Allbutt. The microscopical examination of portions of the brain and medulla, conducted by Dr. Major, whose large experience in this branch was a sufficient guarantee for its value, revealed no observable changes.

LONDON SANITARY PROTECTION ASSOCIATION.—The report of this Association, presented at its annual meeting held on February 25th at the Society of Arts, showed an increase of members over last year of 108. The number of inspections made during the year also showed an increase, the total being 1,488, including 451 first inspections and 602 annual. It is satisfactory to learn that the condition of the houses inspected for the first time showed a lower average than usual, the percentage of bad (rather bad and very bad) being 65, whereas on the average of the preceding six years that percentage was only 56. The treasurer's report showed a small balance of income over expenditure. Regret was expressed that charitable persons and public bodies had not made more use of the Association as a means to the improvement of the sanitary condition of working-class dwellings, a work in which the Association would be always willing to co-operate. It was remarked that large houses were often found to be more defective than small ones.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, FEBRUARY 28th, 1888.

G. D. POLLOCK, Esq., F.R.C.S., President, in the Chair.

Some Remarks on the Radical Cure of Hydrocele, with Notes of Two Cases of Excision of the Tunica Vaginalis, followed by Recurrence of the Hydrocele.—Mr. HENRY MORRIS read a paper on this subject. The history of hydrocele and its radical treatment were briefly referred to, as showing the frequent alternations between what might be called the "closed" and "open" methods of treatment, namely, injections on the one hand, and tents, setons, caustics, incision, and excision on the other. To be quite certain of a permanent cure the vaginal cavity must be entirely obliterated, either by firm universal adhesion of the two surfaces of the sac, or by the filling up of the sac by granulation tissue; but there was reason to believe that permanent cures had been effected by a simple change in the secreting capacity or character of the membrane. Although, on the whole, a more satisfactory mode of radical cure did not exist than the injection of small quantities of some irritating fluid, incision or excision was preferable under certain conditions. From a comparison of cases there did not seem to be much to choose, either as to duration of treatment or certainty of result, between injection on the one hand, and incision or excision on the other. The comparative values of injections, and of incision or excision, were alluded to. But it was pointed out that there was no method of radical cure yet devised which was not liable to occasional failure. The circumstances under which incision or excision was to be preferred to injections were the following: 1. When we were in doubt as to the precise nature or relations of the hydrocele sac, for example, whether the tumour was a congenital hydrocele, or a hydrocele of a hernial sac. 2. In some cases in which hernia complicated a hydrocele. 3. When a foreign body in the tunica vaginalis was the cause of the hydrocele. 4. When we had reason to think that the hydrocele was caused by, or associated with, a diseased condition of the testes, for which castration would be the right treatment. 5. When, as in a case lately under the author's care, a vaginal hydrocele was associated with an encysted hydrocele of the cord and a bubonocoele on the same side. The author's treatment of the cavity after incision was described. In conclusion two cases were related of recurrence of the hydrocele after excision of the sac.—The PRESIDENT observed that the behaviour of these cases of hydrocele was often capricious. In one case which he had long watched there had been no recurrence after one tapping. On the other hand, another had been twice tapped, and twice injected with iodine, with constant recurrence. A silver wire was then introduced for three weeks, with ample suppuration, but no permanent recovery; the sac was finally laid open, and lint put in day by day for a fortnight, and still, though it healed very well for the time, it recurred later on, until the patient finally declined any further treatment than simple tapping.—Sir JOSEPH FAYRE observed that during the years he had been in India hydroceles had come very frequently under his hands; they were not only much commoner than in England, but also much larger and with thicker walls. He had been inclined to consider them as part of a constitutional state, as being at least connected with, if not caused by, malarial fever. They were frequent precursors of elephantiasis. He had never removed a scrotal tumour without finding some hydrocele fluid. The sac was sometimes rigid, with cartilaginous plates, and bone was occasionally found in them. The fluid contained in such cases was full of plates of cholesterine. It was sometimes pale; sometimes granular and mixed with blood. For these no treatment availed to prevent recurrence except excision such as Mr. Morris had described. His master at Edinburgh, Professor Syme, had shown how necessary it was to use a strong injection of iodine, and to bring it in contact with all parts of the interior of the sac by manipulation. Some pain and thickening of the walls occurred, but cure at the time followed, and a recurrence was very rarely noticed. He was strongly of belief that the injection of two drachms of tinct. iodi, undiluted, would cure very nearly all simple hydroceles. That certainly should be first tried; and of other injections, of which he had tried many, none was nearly so good; for many cases one tapping was sufficient; and some Indian cases got well in England without any operation.—Mr. WILLETT had brought up a patient to show the Society in whom, as in Mr. Morris's case, operations had not led to cure.

He was a man aged 21, who had got hydrocele of the left side after a fracture of the thigh and a blow on the scrotum about two years ago. He was at first simply tapped and relieved for a time, then 2 drachms of tinct. iodi were injected undiluted into a sac containing a certain amount of fluid and well diffused. This was followed by a good deal of inflammation and by temporary relief, but subsequent return of the hydrocele, and this treatment was repeated three times at intervals of about six months. On his presenting himself for the fourth time it was determined to excise a portion of the tunica vaginalis; the tumour was grasped, an incision made, some 3 ounces or more of hydrocele fluid escaped, but it was found that the cavity was completely obliterated, and that the fluid had come from the meshes of a buboid growth. An attempt was made to peel off this buboid tissue, but its adhesion was too complete for that; it was broken down, and the wound closed.—Mr. BRYANT remarked that there could be no doubt there was not much unanimity in their treatment of hydrocele. It had been the universal custom in former days for all operators to inject iodine, and the questions then raised were chiefly as to the strength which it was best to employ. In his own practice he generally used 2 drachms of an equal mixture of the tinctura and liquor iodi undiluted. He advised that no fluid should be left in the sac before injection, for that was equivalent to dilution, and dilution to an unknown degree. Under these conditions he had had very few failures as far as he knew. He did not wish to be harsh on the plan of excision, which was becoming more popular with the growing confidence in the treatment of wounds. He described one case of incision and one of excision in which those operations had failed to bring about a radical cure, but injection with iodine subsequently had succeeded. Still excision was useful in some old cases of hydrocele with plates of cholesterine in the fluid. Next to iodine for injection he should choose hot water, which he had employed at someone else's suggestion, and had found to cause suppuration and radical cure by granulation tissue.—Mr. WILLETT asked to be allowed to observe that the fluid left in the sac in his case before injection of iodine was not left in accordance with his orders. He thoroughly agreed with Mr. Bryant in advising the injection of a strong solution of iodine into an empty sac. In reply to further questions he said that microscopical examination had done no more than show that the buboid tissue he had described was fibrous.—Sir J. FAYRE observed that he had several times found similar tissue, and had peeled it off if possible, or else excised it.—Mr. BRYANT thought it was probably organised lymph, such as he had found in some elderly subjects after operation.—Mr. CRIPPS said he was quite unfamiliar with the irritant action of hot water, and was inclined to attribute it to something other than the water.—Mr. TRAVES wished to express his opinion that Mr. Morris had been of considerable service to the profession in calling attention to the fact that there was no safe radical cure for hydrocele, which they were a little apt to fancy that there was, unless they took a good deal of trouble in following out the histories of their patients. He had been in the habit at the London Hospital of using for injection a solution of iodine known as Curling's, which was stronger than the tinct. iodi, B.P., and of leaving two drachms of that in the sac. He had followed out a great many of these cases, and found failure, that is, subsequent recurrence, in at least 25 per cent. Of cases of incision and excision which had been traced, he had found about the same percentage of failures, and he confessed that he thought that would be a not unusual percentage if the cases were thoroughly well followed up. He knew of no adequate explanation of the supposed curative virtue of incision or excision, if they were practised in a truly antiseptic manner, and little disturbance consequently involved. They could cure only by the accidents of wounds. His present practice in relapsing cases was to open the sac and have it all swabbed out with nearly pure carbolic acid. Even in these cases the part of the sac covering the epididymis and testis remained untreated.—Mr. WALSHAM had noticed failures after injection with undiluted tinct. iodi, and thought radical cure was only possible by granulation-tissue, and that any operation involving that was too serious to be risked in many cases, especially among the working classes, considering that they had the alternative of getting the tumour safely tapped every six months or so, and of suffering very little inconvenience meantime.—Mr. SNEED remarked, *à propos* of the yellow flaky tissue which Mr. Willett had described himself as finding, that he should expect it to be similar in origin and character to a substance

which he had sometimes found in other serous cavities, such as the pleura and peritoneum, and had taken to be an unusually good specimen of fibrin. If hydrocele fluid and serum were mixed in a glass, a similar specimen of fibrin would be obtained.—Mr. MORRIS was glad to think the subject had not been too commonplace for discussion. The capricious character of hydroceles, as the President had remarked, had been widely recognised, and had caused much oscillation in the methods of treatment even in one man's practice. He had himself seen one case in which no obvious change was produced immediately by an injection, and in which cure nevertheless resulted. Mr. Willett's case he took to be probably an exaggerated instance of trabecular adhesions rendered oedematous by hydrocele fluid. In using liquor iodi for injection, the increased strength in iodine was counterbalanced by the loss of the spirit as compared with the tincture. He had not any explanation to offer of the action of hot water. He had been much interested by Mr. Treves's experience, as he had not found a record of a case relapsing after treatment by excision.

CLINICAL SOCIETY OF LONDON.

FRIDAY, FEBRUARY 24TH, 1888.

W. H. BROADBENT, M.D., F.R.C.P., President, in the Chair.

Sequel of an Old Case of Ligature of the Carotid.—Mr. HOLMES furnished these notes. The case was published in the ninth and tenth volumes of the Society's *Transactions* as one of distal ligature of the left carotid for aortic aneurysm. The patient survived the operation for twelve years, and then died of phthisis. On *post-mortem* examination it proved that the thrill, bruit, and pulsation, which were thought to be caused by aneurysm of the aorta, depended on stenosis of the valves of the pulmonary artery, with dilatation of its left branch. There had been weakness and occasionally total absence of pulse in the left arm; but the cause of this was not explained by the *post-mortem* examination, which had been somewhat hurriedly made. The aorta and its branches were healthy as far as they were examined. The left carotid was obliterated in its whole extent. As the case had been used in discussing the propriety of distal ligature in aortic aneurysms, it was thought right to publish this correction.—Mr. CHRISTOPHER HEATH said that he took particular interest in this case because he had ligatured the carotid for the first time a year or two before. When he saw Mr. Holmes's case he certainly was doubtful as to its being an aortic aneurysm, though he was unable to suggest what else it might be. There was a distinct pulsating tumour after ligature. On the other hand, the age of the patient and the duration of the disease militated against the hypothesis of aneurysm, though the relief which followed operation might be thought to point the other way. He said there were no cases more difficult to diagnose than those of obscure tumours low down in the neck. He quoted a case which had been diagnosed as innominate aneurysm and turned out to be purely aortic. He hoped that a drawing would be made of the specimen, for insertion in the *Transactions*, before it was put in a bottle.

Laceration of Axillary Artery.—Mr. HOLMES described the case, which was that of a man, aged 54, in fair health, with no symptom of disease of the vessels. There was a systolic bruit. He had dislocated the left shoulder three weeks before. Attempts were made (January 24th, 1887) to reduce the dislocation by manipulation, by the knee in the axilla, and by extension vertically upwards. This was followed by the appearance of a large blood tumour. The progress of the case showed that this extravasation must have been caused by the rupture of some large vessel, though there was no loss of pulse at the wrist, no pulsation in the swelling, and no bruit. An operation was proposed, but the patient would not consent. Ultimately he began to sink rapidly, and died on April 23rd, apparently from septicæmia. *Post-mortem* examination showed no serious visceral disease, and only slight atheroma of the thoracic aorta. A small hole existed in the axillary artery. The vessel itself seemed healthy. The case was published as being probably the first in which the lesion had proved fatal from refusal of operation, and in which the parts had been obtained. It showed the great importance of timely operation in all cases where the extravasation went on extending, though there was no reason why so small a hole as existed in this instance might not close spontaneously, and similar symptoms had been present in cases which recovered without operation.—Mr. LUNN alluded to a case in which he had lacerated the axillary artery in an attempt at passive motion in an ankylosed arm. Soon after there was pain

and swelling in the axillary, with all the symptoms of ruptured vessel. Matters remained quiet for a day or two, when suddenly the arm swelled up, and the pulse on that side ceased to be perceptible. He then cut down directly on the tumour, but not being able to control the hæmorrhage he amputated at the shoulder-joint. The patient never rallied from the operation. At the *post-mortem* examination they found a great hole in the axillary artery. Although he had been blamed for doing so, he had published the case at the time, because he thought that they had often learned much from unsuccessful cases.—Mr. STEPHEN PAGET mentioned a case which had occurred in Sir James Paget's practice. The patient was a lady, who had a stiff arm, the result of rheumatism. For this, rubbing, galvanism, and passive movements were employed; after several applications movement was largely restored, when one day, to test the strength of the recovery, the patient rested her elbow on the mantelpiece, and threw the weight of her body upon it. She was soon after seized with pain in the axilla, with swelling. It soon became necessary to do something, and Sir James Paget cut down and found a rent, a quarter of an inch in diameter, in the long axis of the vessel. He ligatured the artery above and below the seat of injury, and the patient made a perfect and uninterrupted recovery.—Mr. HOLMES, in reply, said that Mr. Paget's case served to show how little violence sufficed to cause this grave injury when the parts had been matted together by past inflammatory changes. The noteworthy feature of his own case lay in that it was the only case on record in which the injury had been allowed to run its natural course in consequence of the refusal of the patient to be operated upon.

Ligature of Superficial Femoral Artery for Popliteal Aneurysm, without Rupture of the Coats of the Vessel.—Mr. J. R. LUNN gave particulars of this case. He said that the researches of Messrs. Ballance and Edmunds on the subject of the ligature of the arteries, which were published in Vol. 69 of the *Medico-Chirurgical Society's Transactions*, clearly demonstrated that it was unnecessary and inadvisable to rupture the coats of a large artery if it were desired to occlude it in its continuity. He determined, therefore, to adopt the method which was shown by the paper to be as efficient as, and apparently more safe than, the usual practice of dividing by the ligature the internal and middle coats. The question of the ligature of completely divided vessels, such as the main artery in an amputation stump, was quite another matter. He had usually employed catgut for large arteries, but in Messrs. Ballance and Edmunds's paper it was shown that even the best catgut might not hold for more than a few days when subjected to an environment of living tissue; and, on the other hand, that kangaroo tendon suitably prepared would resist the absorption process for two months, and also in other respects was admirably adapted for use in the operation of ligature in continuity. C. W., aged 45, widow, by occupation a needlewoman, was admitted in May, 1887, into St. Marylebone Infirmary, Notting Hill, with pulsating tumour in the right popliteal space. No history could be obtained of a blow, strain, or syphilis, etc. The urine contained no albumen. She noticed a pulsating swelling about the size of an egg behind the right leg, in the popliteal space, which gradually enlarged, and she was obliged to give up her work. The circumference of the pulsating tumour measured 16½ inches. After giving a fair trial to different methods of treatment, and having failed to make any impression upon the aneurysm, it remained only to advise the patient to submit to the usual operation of ligature of the superficial femoral artery, which she consented to. The usual antiseptic precautions were taken. When the sheath of the artery was opened, the vessel wall was noticed to be of a tallowy colour, and not the usual pinkish tinge of health. Wishing to try Mr. John Smith's suggestion, and ligate the vessel with a clove-hitch, and as Mr. Ballance had had some experience of the clove-hitch in his as yet unpublished experiments on the carotids of horses and asses, Mr. Lunn asked him to pass the kangaroo tendon, and occlude the vessel by means of a clove-hitch without rupturing the coats. This he did. The pulsation of the tumour was arrested immediately, and the woman made an uninterrupted and perfect recovery. The patient was kept in bed for seventy-two days after the operation. The case was offered to the Society as a contribution in aid of the advance of knowledge of the surgery of the arteries.—Mr. HEATH pointed out that they had two cases in which the clove-hitch with kangaroo tendon had been employed, which was a surgical novelty, involving as it did occlusion of the vessel without dividing the coats.—Mr. KEETLEY quoted the case of a man, aged 27, who came to the hospital with aneurysm of the femoral artery in the lower part of

Scarpa's triangle, about 4 inches long. He had only noticed it a fortnight before, and it rapidly increased in size. The upper limit of it came within 3 inches of Poupart's ligament. Not wishing to tie the external iliac, he ligatured the common femoral with kangaroo tendon, using a clove-hitch, with a reef-knot to fix it. The operation was performed on January 24th, and there had been no return of pulsation, and the man was doing well.—Mr. TURNER mentioned a case which occurred some three years since, in which he had ligatured the common femoral artery with common catgut, dividing the coats of the vessel. The artery had previously been ligatured with a silk ligature, which, in coming away on the sixteenth day, had given rise to profuse hæmorrhage. The man made a good recovery. The cases which had been brought before them showed that it was possible to deal with a vessel which they were formerly forbidden to touch.—Mr. HENRY MORRIS said the question would require some time before it could be authoritatively settled. It had yet to be proved that the method of ligaturing arteries without dividing the coats of the vessel presented any advantages. He thought that experience might show indeed that it was not as reliable. He mentioned the case of a man under his care who came to him in August with a tumour in the popliteal space of sudden onset, and rapidly increasing in size. There was pulsation in the arteries below. He cut down and turned out the clot. The artery was soft, and a good deal of arterial blood escaped from between the vessel and the bone. Ligatures of chromicised catgut were applied, and the man did well. Some days later pulsation returned at the upper part of the popliteal space, and that time he ligatured the femoral artery in two places with kangaroo tendon, dividing the artery between. He did well, but his leg became contracted, and he was subsequently anaesthetised to straighten the limb. No undue force was used, but within two or three days gangrene set in, and amputation was performed. Examination showed that the ligation was satisfactory in both cases. He called attention to the fact that pulsation was felt, although there was considerable extravasation. He approved of ligaturing the vessel above in some cases in preference to opening up at the site of extravasation.—Mr. TIMOTHY HOLMES said he always believed in ligaturing the common femoral instead of the external iliac artery, and he thought the prejudice against the course was based on a mistaken idea. He expressed himself in favour of the old-fashioned practice of tying a stout ligature tightly, so as to rupture the coats of the artery. The method of compressing the vessels was as old—at least—as John Hunter. In any case the advantage of such a modification was not obvious.

Amputation at the Hip-joint for Sarcoma of the Femur: Secondary Hæmorrhage: Ligature of the Common Femoral: Recovery.—Mr. BERNARD PITTS described the case. R. T., a draper, aged 30, came under Mr. Pitts's care in St. Thomas's Hospital on August 19th, 1887, with a hard tumour firmly attached to the left femur, at the junction of the middle and lower thirds. The tumour was first noticed four months before, and was then only as large as a pea; its measurement in August in the long diameter was between four and five inches. On August 24th, after an exploratory incision, a circular amputation was performed, and the limb removed just below the lesser trochanter, four inches clear of the periosteal growth. Whilst the vessels were being secured a longitudinal section was made through the removed bone, and the tumour showed the typical appearance of an osteoid sarcoma. The medullary cavity was involved as far upwards as within one inch of the lesser trochanter. An incision was then made on the outer side of the trochanter, and the remainder of the bone rapidly and easily disarticulated. The patient progressed well till the fifth day, when secondary hæmorrhage occurred from the stump. The bleeding into the dressings was considerable, and the patient was greatly exhausted. Finding that pressure on the common femoral controlled it, and since the patient would certainly have died if the flaps had been opened for a search for the bleeding vessel, a clove-hitch of kangaroo tendon was placed round the common femoral just below Poupart's ligament, and above the profunda. No return of hæmorrhage took place, and the patient made a good recovery, and left the hospital quite well early in November. Mr. Pitts, in his remarks, advocated the Furneaux-Jordan method of amputation, both on account of its safety, and also because it enabled the surgeon to stop short after the high amputation if the patient's condition, or the nature of the tumour, required it, and he proposed the following rule, namely, that in any periosteal sarcoma of the lower half of the femur, to amputate high in the thigh, and well clear of the disease; to have a longitudinal section of the femur made whilst

the vessels were being secured; and if it were found that the medullary cavity was infected, to remove the remaining portion; at the time, if the patient's state permitted, but, if not, at a subsequent operation. Mr. Pitts then stated the reasons why he had departed from the usual practice of opening the flaps when the secondary hæmorrhage occurred. He thought that ligature of the common femoral might now be safely tried, and the old fear of hæmorrhage at the seat of ligature was not felt by a surgeon who placed a flat tendon ligature on the vessel, and did not divide the coats, but merely closed the lumen of the vessel. Reference was made to the experiments by Messrs. Ballance and Edmunds, which so clearly proved that such a method of ligature was efficient. In conclusion, a case was referred to. A boy, aged 13, was brought last August to the hospital with a fracture of the thigh and a rupture of the popliteal artery. The effusion of blood had extended to Scarpa's triangle, and the boy was almost moribund. Mr. Pitts tied the common femoral with a flat ligature, without rupturing the coats. The boy died the next day, and at the *post-mortem* examination it was found that the artery was impervious to water, although the coats were entire. The ligature was placed on the vessel in order to give the boy a chance of recovering from his collapse, when an amputation was contemplated.—Mr. BRUCE CLARKE said that two years ago he amputated a child's femur for a sarcoma in the popliteal space. The mother refused to allow amputation to be performed higher than just above the seat of disease, and subsequently the disease recurred high up, where intervention was impossible. He advised removing the whole of the bone, but leaving the periosteum.—Mr. CHRISTOPHER HEATH recalled a case already published in the *Transactions*, in which he had tied the femoral artery in the early days of catgut ligatures, and in a few days pulsation returned. This was by no means the only case on record, and they tended to show that it was not safe to rely on anything less than the rupture of the coats. He suggested that it would not be safe to divide the artery between two ligatures in some situations, and mentioned a case where this had been done in respect of the subclavian, with death from the slipping of the knot. He expressed surprise that the question of the knot had not been discussed. Personally, he would prefer a reef-knot to a clove-hitch. He pointed out that Jordan's operation was not always applicable. He observed that present-day surgery was apt to be rather slow, surgeons not attributing sufficient importance to mere loss of blood.—Mr. HENRY MORRIS pointed out that his remarks as to dividing the artery between two ligatures only applied to the limbs.—Mr. LUNN, in reply, thought that in old people the employment of the broad ligature obviated the danger of tearing the coats of the artery.—Mr. BERNARD PITTS, in reply, asked Mr. Morris whether he would be inclined to divide the common iliac between two ligatures. He was satisfied that absolute security resulted from the changes which took place consequent on occluding the lumen of the vessel. The principle of surgery was that when the same result could be achieved with less damage, then it was to be preferred. He objected to leaving any periosteum when removing a bone for sarcoma as it would facilitate recurrence. He did not advocate Jordan's operation as such, but modified to suit the circumstances of the case.

Living Specimens.—The following were exhibited. By Dr. BARLOW: Case of Cured Subclavian Aneurysm.—Mr. SILCOCK: Case of Traumatic Meningocele.—Mr. FRED. TREVES: Patient upon whom Loreta's Operation on the Stomach was performed two months ago.—Mr. J. T. MORGAN: Case of Lymphangiectasis of Upper Lip.—Mr. MARSH: Case of Hairy Mole.—Dr. BROADBENT: Case of Subclavian Aneurysm cured by Pressure.

MEDICAL SOCIETY OF LONDON.

MONDAY, FEBRUARY 27TH, 1888.

J. HUGHLINGS JACKSON, M.D., F.R.S., President, in the Chair.
CLINICAL EVENING.

Case of Syphilis.—Mr. JAMES BLACK showed a woman who, after twelve miscarriages due to syphilis, bore a healthy child under mercurial treatment.

Bilharzial Epicystitis.—Mr. HURRY FENWICK showed a patient, aged 20, who had suffered from Cape hæmaturia for five years, and who had come under observation on September 23rd, 1887, with symptoms of extra-peritoneal perforation of the bladder of nine days' duration. Ten days previously, after severe exercise, the patient suddenly passed large quantities of blood, and was seized with extreme suprapubic pain. The abdomen was tympanitic in

its upper two-thirds, but absolutely dull in the suprapubic region. The dulness was not removed by catheterism of 8 ounces of clear urine. The entire recto-vesical pouch was found to be filled with a softish foetal-head-sized mass. He believed that pericystitis had been set up by incomplete perforation of, and leakage through, the posterior wall of the bladder, and that epicystitis and adherence of the intestines had resulted. A suprapubic incision was made for drainage purposes, but the prevesical space was found, on examination, to be free. The swelling in the recto-vesical pouch was gradually absorbed, and the patient recovered. He still passed bilharzial ova. Electric illumination of the bladder revealed multiple punctiform hæmorrhages of the base.—Mr. BERNARD PITTS asked whether any collection of blood was found on incision, and whether any oozing took place afterwards.—Mr. FENWICK, in reply, said the dulness he found was due to matting together of the intestines.

Two Cases of Friedreich's Disease.—Dr. ORMEROD showed a boy and a girl, the subjects of this peculiar form of hereditary ataxia. Both children walked imperfectly and awkwardly, and the patellar reflexes were wanting. Speech, vision, and hearing were apparently normal. A sister was quite healthy. Father asthmatic, and formerly a drunkard.—Dr. JACKSON asked whether any choroiditis was present. A patient of his own had nystagmus, and the pupils did not react to light.—Dr. ORMEROD, in reply, said he had not thoroughly examined the eyes. There was no history of syphilis or nervous affections in the parents.

Case of Ununited Fracture of Humerus.—Mr. MARMADUKE SHEILD showed a lad who had sustained a compound comminuted fracture of the right radius, from which pieces of bone had been at various times removed. No union had taken place, in spite of reiterated efforts with that object in view. The lad could use the hand fairly well, and Mr. Sheild insisted on the desirability of avoiding amputation in injuries of this sort in young people.—Mr. TURNER mentioned a case in which transplantation of medullary membrane was tried in a similar case, but without success. He mentioned that out of 48 specimens of false joints in the London museums, 16 were of the humerus, and 14 of the femur.—Sir Wm. MAC CORMAC thought, from the atrophied condition of the bone in this case, that efforts at inducing union would probably not be successful. He expressed a desire to see an attempt made with transplantation of bone, that being the only possible way of bringing about union.—Mr. SHEILD, in reply, asked Mr. BERRY, under whose care the patient passed immediately after the injury, whether the fragments had been wired.—[Mr. BERRY replied that he thought not]—because he thought that this ought to be done in such cases. He was afraid transplantation would be difficult to carry out successfully. He attributed the frequent occurrence of false joint after fracture of the humerus to the employment of four short splints, thus allowing considerable movement. He alluded to the danger of opening up the wound to secure union from the matting together of the nerves, vessels, etc.

Congenital Cysts in Mouth and on Chin.—Mr. BERNARD PITTS showed a boy, aged 14, with fluid swellings, one in the middle line of the chin, and the other in the floor of the mouth. The cysts had been tapped, but refilled, and he indicated the necessity for more radical measures of treatment.

Loose Bodies in the Knee-Joint.—Mr. SHEILD showed a man, with a history of syphilis two years previously, who had loose bodies in the knee-joint, one of which was the size of a filbert, causing continual irritation. It was suggested that the bodies might be ossified gummata, but he thought they were more probably synovial outgrowths, and advocated their removal.—Professor HUMPHRY agreed with the latter suggestion. He expressed himself sceptical with regard to the possibility of detachment of portions of the articular cartilages, and thought that the depressions found on the articular cartilages simulating the site from which such pieces had been detached were in reality due to absorption from pressure.—Mr. EDMUND OWEN asked whether there had been any synovial inflammation prior to the syphilis; also whether the patient was gouty. He mentioned two cases in which he had successfully effected the removal of similar bodies, without the spray, merely washing out the joint with sublimate solution.—Mr. SHEILD, in reply, said he regarded the spray as an additional safeguard. There had been no prior synovial inflammation, so far as he could ascertain.

Case of Limited Atrophy of the Face.—Dr. A. GARROD showed a girl, in whom, after a period of great anxiety, epileptic fits had supervened, with a curious atrophic condition of the forehead.

Spasmodic Twitching of the Ears.—Dr. BRAYOR showed a very

remarkable case of spasmodic twitching of the ears in a young girl, consecutive to general chorea. The twitching was rhythmical and persistent.—Dr. JACKSON said it was a most curious case, and he had never seen anything resembling it before.

Disease of the Nails.—Mr. SHEILD showed a case of disease of the nails, modified by treatment.

ROYAL ACADEMY OF MEDICINE IN IRELAND.
OBSTETRICAL SECTION.

FRIDAY, FEBRUARY 10TH, 1888.

JOHN RUTHERFORD KIRKPATRICK, F.K.Q.C.P., President, in the Chair.

Specimens.—Dr. COLCLOUGH HOBY exhibited specimens of mole pregnancy and *fetus compressus*. In the latter specimen the fœtus seemed to have reached about the fourth and a half month of utero-gestation. It was expelled a short time after the birth of a full-time child and before the expulsion of the placenta. The whole specimen seemed to be nothing more than a mass of adipocere. There was no trace of an umbilical cord, but the placenta was very large and apparently healthy.—Dr. S. M. THOMPSON exhibited two large calculi which he had removed by dilatation from the urethra of a woman 52 years of age.—Dr. MACAN said the stones were the most remarkable he had ever seen. Their extreme smoothness was most striking; they ought to be examined for the purpose of ascertaining of what they were composed. Professor Simon, of Heidelberg, had shown that, after the dilatation reached 2 centimètres the operator was on very dangerous ground. If he (Dr. Macan) had to deal with such a case, he would rather extract by means of an incision in the septum.—Dr. MACAN showed four specimens. The first was the head of a child born a few days before in the Rotunda Hospital. The woman had been undergoing a very protracted labour, and was brought into the hospital. On examination the head of the child was found to be encompassed with an elastic tumour filled with blood, and so disposed that it was difficult to detect the child's hair. Before delivery the child was known to be alive, although the fœtal heart could not be heard. The child was delivered with some difficulty with forceps, and was a very large one. The whole surface of the tumour was then of a bright crimson colour. Next morning it was incised, and the hair underneath was found to be cut off as sharply as if it had been shaved; he had never before seen anything exactly like it. The labour lasted twenty-four hours. While examining with his finger before delivery, the epithelium of the vagina came off under his finger, which he believed was due to an acrid secretion. The second specimen was an ovarian tumour, which was removed from a girl. When she first came she was in the seventh or eighth month of pregnancy, and had a very large abdomen. The tumour afterwards got smaller from day to day, and when he (Dr. Macan) first saw it, it was not the size of his hand. He thought this might have resulted from a rupture of a cyst, and the absorption of contained fluid. The next time he examined her, the tumour was almost as big as ever, and he diagnosed that another cyst had developed. When he operated he found an extremely short pedicle. The next specimen was a tumour removed from an unmarried woman, which had been eight or nine years growing. On the morning of the operation her temperature was 102.8°, and she had great pain in the abdomen. After making a large incision he first got hold of an enormous tube, from which a quantity of pus escaped, and then the opening was closed by a wisp of hair, which showed the tumour to be a dermoid cyst. She got on very well for some days, until suddenly one morning her temperature rose to 103°, her pulse being only 88, and a great swelling appeared in the right parotid region, from which it was obvious that she had parotitis on that side. This was an unknown complication to him until his attention was drawn to the JOURNAL of December 24th last, containing an account of seventeen cases, collected by Professor Bumm, of parotitis following ovariectomy. In nine out of thirteen of these cases suppuration followed, in two death resulted from inflammation, and in two others inflammation contributed to a fatal result. He (Dr. Macan) was unaware of the complication until Dr. Kidd told him that he saw the same thing after the operation of ovariectomy. The girl had since been going on extremely well, and that day she was up, but that evening her temperature was 101°, for which he failed to recognise any cause. The remaining specimen was an ovarian tumour, which he removed on the preceding day from a woman in the Rotunda Hospital. The diagnosis was very difficult, and

the operation was approached with great doubt. She was examined under ether, and the posterior wall of the uterus found to be very thin, but the tumour could be separated from the uterus with the sound. There was great difficulty in getting the tumour out through the pelvis, and there was an enormous pedicle, part of which was left behind. It was a ligamentous growth. There was a considerable quantity of pus in the tumour. Up to the present the woman was going on very well, the only danger being that some change might take place in the position of the pedicle that had been left behind.

Removal of Fibroid.—Dr. M'MORDIE read a paper on the successful removal of a large fibroid tumour.—Dr. ATTHILL, Dr. MACAN, and Dr. BARBOUR, of Edinburgh, took part in the discussion.

Report of the Rotunda Hospital.—Dr. SMITH read the report of the Rotunda Hospital for 1887. The gynaecological wards contain thirty beds. Four hundred and fifty patients were received during the year, being an increase of 106 over the previous twelve months. It was remarkable that retro-uterine hæmatocele occurred eight times, carcinoma thirty, and serious tubal disease only once. All the cases of carcinoma were too far advanced on admission into hospital to justify any radical operation. Nothing was left to be done except to palliate by thorough curetting and the application of Paquelin's cautery. The treatment in incomplete abortion and endometritis consisted of curetting down to the muscular coat of the uterus, and injecting equal parts of the liniment and tincture of iodine. Abdominal sections were performed eight times for the removal of ovarian tumours, once to remove the ovaries in a case of uterine fibromyoma, once to perform hysterotomy, twice for the radical cure of hernia, once for the removal of a double ovarian abscess, and once in a case of peritonitis, which proved carcinomatous, making in all 14, with 4 deaths. The uterus was curetted 105 times, including incomplete abortions 18, carcinoma 30, and endometritis 57, without any reaction following, showing that when properly performed this operation was entirely devoid of danger. The bimanual method of examination was practised and taught, with the patient in the dorsal position on a Schroeder chair. The uterine sound had been found most useful during the year as an aid in diagnosing many diseases of the endometrium. It detected with accuracy the patulous condition of the internal os, whether the mucous membrane were hypersensitive, thickened, or roughened, and it would demonstrate its tendency to hæmorrhage, if that condition were present. Schultz's pelvic diagrams were used to encourage accuracy of diagnosis, and Wyder's transparent plates as illustrations of pathological conditions. Antiseptic solutions were only employed where the hands or instruments had been engaged in septic cases. The stages of disinfection practised were, for the hands, 1st, thorough scrubbing for a couple of minutes with carbolic soap and a nail-brush in a 5 per cent. carbolic solution; 2nd, rinsing in fresh carbolic solution; 3rd, soaking for one minute in 1 in 500 corrosive sublimate solution. All instruments were disinfected by boiling in a 5 per cent. carbolic solution. For some time past irrigations of ordinary Vartry water had been employed in all ordinary operations about the uterus and vagina, such as curetting in the case of incomplete abortion, and as good results had been obtained as when solutions of carbolic acid or corrosive sublimate were used for this purpose.—Dr. ATTHILL said the proportion of cases of hæmatocele appeared to be unusually large. He was glad to find that cases of abdominal section were increasing in number. He would not say that in any of the 105 cases recorded the curette had been used injudiciously; but he thought there was a tendency to resort to it too often. He thought that in cases of uterine cancer it merely aggravated the symptoms, and in some cases accelerated death. For the purpose of washing out he thought that Vartry water was as good as the solution of carbolic acid.—Dr. MACAN said, as to curetting, he thought that, in cases of hæmorrhage with fetid contents of the uterus, the method, from its expedition, had a decided advantage over dilatation and removal by the finger. He only regretted that he had not been more energetic in the use of the curette in cases of cancer than he had been, because of the improved condition and ease it gave the patients before they died. The mortality in cases of hæmatocele had been increased by the inclusion under that head of cases of extra-uterine foætation.

GUY'S HOSPITAL.—The Treasurer of Guy's Hospital received last week an anonymous donation of £1,000 from H. A. N. towards the Guy's Hospital special appeal.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, JANUARY 20TH, 1888.

W. H. RANSOM, M.D., F.R.S., President, in the Chair.

Hydatid of Liver.—Mr. PRYCE showed a case of hydatid of the liver in a man aged 56, which was associated with a separate tumour of the abdomen due to the same disease.

Communications.—Dr. ELDER read notes on—(1) A Case of Missed Labour, and showed the patient; (2) Removal of the Breast for Intractable Eczema.—Mr. GIDDINGS read a paper on the Medicine of the Hippocratic Era.

Specimen.—Dr. Elder showed: (1) Ovarian Tumour; (2) Enchondroma; (3) Vesicular Mole.—Mr. KINGDON showed a microscopic specimen of the Bacillus Anthracis.

FRIDAY, FEBRUARY 3RD.

W. H. RANSOM, M.D., F.R.S., President, in the Chair.

Necrosis of Bone.—Mr. R. C. CHICKEN showed a young man on whom he had operated for diseased bone. From the humerus he had removed a sequestrum $4\frac{1}{2}$ inches long, involving in half its length the entire thickness of the upper third of the humerus. From the internal and external condyles, cuboid sequestra had been extracted. The elbow-joint was limited in motion owing to thickening, but a strong useful limb was left. From the right foot of the same patient the internal and middle cuneiform bones were excised, and two-thirds of the first metatarsal bone. The arch of the foot was supported by an accurately fitting cork. He had free movement of all his toes, and could walk long distances. The next case was a sequestrum from the middle and lower third of the femur, 5 inches long, involving the entire thickness of the shaft. The sinus occupied the line usually taken by Hunter's canal. The femoral artery could not be felt; it was probably enclosed in new bone. The case was of eight years' standing. The patient made a good recovery. In both of these cases amputation had been recommended. Mr. Chicken pointed out that in operations on large diaphysal necrosis of the femur there were three points which might prove sources of failure: 1. The method of operating. Two ways offered themselves; the removal of the sequestrum entire, or its division *in situ* by an oblique operation, and withdrawing in two parts. This might be called the "button-hole" operation. The first required the cutting away of a large portion of new bone and a very large incision through the soft parts. The second method required only a small incision, and the sequestrum could be removed through a very small opening in the new bone. 2. The drainage of the wound was often a source of great trouble. Sometimes the operation to establish drainage for a small exfoliation of the femur was more formidable than the removal of the bone. If the patient lay on the side opposite to that operated upon, and then flexed the hip- and knee-joints, causing the resected femur to cross the sound limb, the drainage was perfect and the position comfortable. 3. The button-hole operation could not be performed except with instruments which would divide the sequestrum as it lay imbedded in the new bone. The chisels of single bevel and the bone-forceps as supplied, were utterly inadequate. The great objection to the use of even the finest tempered double bevelled chisels was the injury caused by the hammering to the healthy bone. Mr. Sutton, of Nottingham, had made (from Mr. Chicken's design) a pair of cutting bone-forceps which divided a femur with ease, and were therefore capable of dividing any sequestrum. They were forged with care from the finest steel, and tempered most accurately, the parrot beak slipped easily around the dead bone, and held it whilst it bit. The screw gave any power required. The holes in the handles were roomy and smooth, to give play to the screw.

Malignant Disease of Larynx.—Mr. JOSEPH WHITE related two cases of carcinoma (one intrinsic, the other extrinsic in its origin) and drew attention to the influence of locality in its bearing upon the comparative malignancy of this disease as originating in the upper or lower part of the larynx; and pointed to the greater rapidity of growth, greater tendency to involve the neighbouring glands and other tissues, and more speedy termination in death, of extrinsic as compared with intrinsic carcinoma. He related other cases, showing the frequent obscurity of this disease in its earliest stages. He then discussed the question of operative treatment, and came to the conclusion that in cases of sarcoma, removal by operation was indicated; in intrinsic carcinoma this might also be tried, but not in the extrinsic form. Both in sarcoma and carcinoma, early tracheotomy might be very beneficial.

MIDLAND MEDICAL SOCIETY.

WEDNESDAY, FEBRUARY 8TH, 1888.

W. ROSS JORDAN, M.R.C.S., President, in the Chair.

Papilloma of Bladder.—Mr. JORDAN LLOYD showed a specimen of papilloma of the bladder removed from a man, aged 51, by suprapubic incision. The first symptom was slight hæmaturia with clots occurring during perfect health more than two years before. He remarked on the diagnosis of bladder tumours, and thought that spontaneous hæmaturia with clots in an apparently healthy man beyond 35 years of age, recurring from time to time without vesical symptoms of any kind, and without any objective evidence of other disease, ought to suggest to us the presence of vesical papilloma. Such growths could often only be discovered by suprapubic incision, which ought to be performed in preference to perineal incision.

Specimens.—Dr. HOGGEN showed some specimens of Cirrhosis of Liver in a Young Child, due to Alcohol.—Dr. SUCKLING specimens of *Trichocephalus Dispar*.

Communications.—Mr. BRACEY read a note on the Treatment of Tinea Tonsurans by Hot Oil.—Dr. HOLMES JOY read a paper entitled Notes on Puerperal Septicæmia.

Ataxia in a Brass-worker.—Dr. SUCKLING showed a case of ataxia in a brass-worker. The patient was a man, aged 54, who for many years had worked at bronzing. During the past eighteen months he had suffered from numbness of the feet and hands, and unsteadiness of gait. He had suffered also from attacks of vomiting, and shooting pains in his legs. He was very unsteady in walking, especially on turning round, and static ataxia was marked, for he could not stand with his eyes shut, swaying about and falling on closing his eyes. The pupils were unequal, but responded to light and accommodation; there were no changes in the fundus oculi. There was no decided anaesthesia or analgesia of the extremities, but he stated that he felt as though he was walking in wool. The knee-jerk was diminished, but could readily be elicited by Jendrassak's method. The man gave no history of syphilis, but there were pigmented scars on the legs. There was no green mark on the teeth, and he had not suffered from attacks of sweating or catarrh. Dr. Suckling pointed out that ataxia with numbness of extremities had been observed by Schloehow in workmen at zinc foundries, the ataxia being due to loss of muscular sense. The muscular sense in the above case was decidedly impaired, for he was unable to distinguish any weight less than four ounces suspended from the toes, and he could not distinguish between a four-ounce and an eight-ounce weight. He had decidedly improved under the administration of iodide of potassium.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

JANUARY MEETING.

Dr. T. W. HIME, B.A., M.B., President, in the Chair.

Retinoscopy.—Dr. J. JOHNSTON read a paper on retinoscopy, describing briefly the history of the test, the method of using it, and its advantages as a qualitative and quantitative test, especially in dealing with children, and in determination of astigmatism generally.—Remarks were made by Drs. GOYDER, HOBBOCKS, HIME, and BELL.

Destructive Diseases of the Eye.—Dr. BELL read a communication on some destructive diseases of the eye, with special reference to iritis. He stated that iritis was not common during the middle period of life, and that its causation was either traumatic or depended on some dyscrasia. He then showed how various classifications of iritis might be made, and mentioned several; at the same time, many of the different forms of iritis reacted on each other in such a way as to render the symptoms distinctive in only a few cases. In children under 6 months, and in certain rare cases where rusty spots appeared on the iris, the iritis was always due to syphilis, while serous iritis was always accompanied by white spots on the posterior layer of the cornea. The other symptoms of iritis which might or might not be developed, but which were common to all its forms, were a vascular zone on the sclerotic, change of colour and immobility of the iris, muddiness of the aqueous humour, pain and impairment of vision. With respect to treatment, special attention was drawn to the frequent use of atropine until the pupil was fully dilated, while mercury alone, or combined with iodide of potassium, was useful in all forms of iritis, with the exception of the traumatic.

Hydrophobia Treated by the Buisson Method.—Dr. GOYDER re-

ported a case which will be found in this day's JOURNAL at page 464.—Drs. HIME, BELL, WHALLEY, VAUGHAN, and others took part in the discussion.

MANCHESTER MEDICAL SOCIETY.

WEDNESDAY, FEBRUARY 15TH, 1888.

JULIUS DRESCHFELD, M.D., F.R.C.P., President, in the Chair.

Xanthelasma.—Dr. LEECH showed a case of xanthelasma.

Forcible Feeding.—Dr. BASIL described several methods of forcible feeding. He thought that if it were resorted to as intelligently in general practice as it was in the best asylums, many cases would be greatly benefited by it. Such conditions were typhoid states in many of the continued fevers, prolonged coma in diseases not necessarily fatal, after some operations, especially those about the mouth, in cases of delirium, severe chorea, etc. Many forms of insanity could be treated at home if the general practitioners were to resort more often to the use of the stomach-tube.

Treatment of Phthisis.—Dr. RANSOME presented some notes on the treatment of phthisis by pure oxygen and ozone. Pure oxygen prepared by Brin's process had been supplied by that company, and had been largely administered, but without very definite results until it was ozonised and administered under pressure by means of Waldenburg's apparatus. Beneficial results had then been obtained in three patients who carried on daily inhalations for from three to five weeks.

Sarcoma of Choroid.—Dr. HILL GRIFFITH showed a patient with intra-ocular sarcoma of the choroid, and read notes of a case of sarcoma of the choroid growing from and confined to the central region of the eye, and exhibited the specimen. Dr. Griffith also made some remarks on the diagnosis of the affection, and illustrated his remarks by preparations.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, FEBRUARY 17TH, 1888.

J. SPOTTISWOODE CAMERON, M.D., Vice-President, in the Chair.

Incision of the Cyst in Hydatid Disease of Liver.—Mr. MAYO ROBSON described the case of a patient admitted to the Leeds Infirmary under the care of Dr. Churton, with a history of a swelling in the abdomen of fourteen days' duration, with pain for the last five days. He was looking ill and anxious on admission, with a temperature of 101° F., and there was a tumour in the abdomen yielding an impulse on percussion. The cyst was exposed by an incision outside the rectus muscle, and a multitude of small cysts were withdrawn through a trocar, the whole contents amounting to 120 ounces. The edges of the sac were stitched to the abdominal wound, and the cyst was irrigated and drained. The patient made a good recovery. Mr. Robson referred to the various methods of treating this condition, namely, simple puncture, puncture with the injection of a solution of mercuric chloride (5ij of a ℥ in 5000 solution) as advocated by Dr. Sennett, incision *à deux temps*, and opening by means of caustic paste. He preferred in such a case as above, when the symptoms were urgent, to incise the cyst in one operation, and clear out the daughter cysts.—Dr. EDDISON thought it was very important to know whether secondary cysts existed, as, if not, recovery would follow tapping. Even if the daughter cysts were killed by puncture they would remain as foreign bodies.—Dr. MAJOR thought that "hydatid fremitus" was rare and fallacious.—Mr. MAYO thought there was danger of the escape of fluid after simple tapping.—Dr. GRIFFITH had seen many cysts aspirated, but even when the fluid was very thin there had been no extravasation. He had seen only two cases of suppuration after tapping.—Mr. MCGILL advocated tapping as easy and safe. He had tapped one cyst six times. The severer operation could be done afterwards if necessary. In doing the operation described by Mr. Robson, he would prefer stitching up the peritoneum before the cyst.—Mr. MAYO ROBSON, in reply, said he would always tap in non-urgent cases. He had seen serious symptoms from drawing off small quantities of fluid.

The Treatment of Empyema of the Maxillary Sinus.—Dr. ADOLF BRONNER described this condition as liable to be produced by disease either of the teeth or nose, but in most cases he thought it was secondary to a condition of hypertrophic rhinitis, the disease of the teeth being secondary to this. In all cases of unilateral recurrent chronic rhinitis, this condition should be suspected. He preferred the method of opening from the middle

meatus of the nose by means of instruments devised for the purpose by Dr. Hartmann, of Berlin, and by Dr. Krause, which he exhibited. The usual plan of perforating through the alveolar process had the advantage of allowing good drainage, but there was a constant dropping of pus into the mouth, and food penetrated from the mouth into the cavity. He described four cases in which the antrum was opened from the nose, and washed out with boric acid or mercuric chloride solution. In one case the sense of smell returned after being lost for sixteen years.—Mr. TEALE said he had been treating chronic diseases of the mucous membrane of the nose by more vigorous measures than he used to adopt, namely, forcible scraping.—Mr. JESSOP had been using the curette much of late, operating with the patient's head hanging down. He referred to a case of lupus in which he had scraped a large amount of periosteum from the hard palate, but a complete covering to the bone was reproduced. He said that a similar condition might arise in the nose after forcible abrasion.—Dr. JACON preferred the galvano-cautery to the curette in hypertrophic conditions of mucous membrane.

The Prevention of Ophthalmia Neonatorum.—Dr. BELL, after reminding the Society that 72 per cent. of the blind in England were so from this perfectly preventable condition, and that there were 10,000 blind in the country, urged the Society to make some organised attempt to stay the spread of this disease. The affection occurred mostly among the children of the poor, attended by ignorant midwives. Antiseptic midwifery had reduced the mortality in lying-in hospitals from 8 per cent. to 1 in 500, and a similar result might be obtained by applying the same principles to the prevention of ophthalmia. A petition from the Ophthalmological Society to the Government that the registrars of births might disseminate the information had been referred on the score of the expense which would be incurred; but this was much overrated. The Committee of the Bradford Eye and Ear Hospital supplied the registrar of births with slips of paper on which were printed plain directions, which he gave to each person registering a birth; and the total cost for the Bradford district did not exceed 25s., at this rate it would cost but £30 for the whole of England.—Mr. JESSOP, Mr. MAYO ROBSON, and Dr. PURDY made some remarks.

Pathological Specimens.—1. Kidneys; Suppurative Pyelitis with Dilated Ureters; Bladder with slight Enlargement of Middle Lobe of Prostate. 2. Double Ovarian Cysts removed from a Pregnant Woman. 3. Ovaries and Tubes showing early Broad Ligament and Parovarian Cysts.

Apparatus.—Dr. TEMPEST ANDERSON: 1. A Simple Eye Speculum; 2. A Bench for Operations on the Eyes of Children; 3. A varying Cylindrical Lens.

REVIEWS AND NOTICES.

THE DISEASES OF THE BREAST. By THOMAS BRYANT, F.R.C.S., M.Ch. (Hon.) Royal University of Ireland; Senior Surgeon to, and Lecturer on Surgery at, Guy's Hospital; Vice-President, Chairman of the Court of Examiners, and Hunterian Professor of Surgery, Royal College of Surgeons of England, etc. London: Cassell and Co., Limited.

A MANUAL written by an experienced hospital surgeon must necessarily be of high value and interest, more especially when, as in this case, the author has already shown literary capacity in the same department of medical education. A good surgeon and lecturer cannot always teach by his pen, but Mr. BRYANT is endowed with that talent. In this work, the author has epitomised his clinical and surgical knowledge, whilst he has been aided in preparing the scientific department by Dr. Goodhart and Mr. C. Symonds, likewise making full use of the researches of Creighton, Butlin, and many other British and foreign pathological authorities. At the same time it must be understood that *Diseases of the Breast* is essentially practical rather than scientific. The eight pages of chromo-lithographs show, by the excellence of their execution and the truthfulness of their colouring, how greatly this branch of art has improved in this country. Mr. Bryant's subject is not the most difficult to demonstrate by the resources of the pencil and paint-brush, but diseased breasts have often been very badly drawn, whilst in this work they are delineated and coloured with great care. There are but thirteen woodcuts, all either drawings of diseased breasts and nipples or of the microscopical appearances of tumours, with the solitary exception of Fig. 6,

which represents the operation of excision of the breast. Operations on the breast, it is true, are not readily explained by drawings, but a few sketches explaining the devices for retaining drainage-tubes and other technical details would have been advisable. No instruments are figured, but in the surgery of the breast special apparatus is hardly ever employed.

A manual on Mr. Bryant's subject must be chiefly devoted to tumours, for obvious reasons; still we are glad to find that nearly one-fifth of the 351 pages of *Diseases of the Breast* includes descriptions of the nature and treatment of other morbid conditions. The management of abscess, and the prevention of suppuration in the early stage of inflammation, are subjects of the highest importance to practitioners. Mr. Bryant has quite rightly allowed an entire chapter to supernumerary breasts and nipples, not omitting the remarkable milk-producing tracts of integument or axillary lumps described by Dr. Champneys. Any medical man may come across pathological curiosities, and therefore naturally expects to find some account of them in his manuals. He has not always the time or opportunities required for searching for desired information in archives of learned societies. Mr. Bryant has not overlooked this truth. The latest researches have been noted, as, for example, the facts brought to light during a discussion on galactorrhœa, at the Obstetrical Society, in February, 1887. Amongst rarities which are particularly instructive, we may quote the author's remarkable case of syphilitic disease of the breast, which was infiltrated with gummata and sloughed out entire within two years. Mr. Bryant has not overlooked the singular cases of inflammation of the breast which last for months without suppurating, and where the chief symptom is œdema.

The chapters on tumours, however, are the most important in this book. Clinical facts in relation to the subject, very abundant as we all know, are well condensed, and the cases which illustrate the history of special tumours and special symptoms are carefully selected, and reported in a readable and instructive form. Mr. Bryant directs, in his description of the operation for the removal of a benign tumour in a young woman, that the growth should be shelled out of its capsule after a free incision of the latter. He apparently does not believe in any attempt to remove the tumour elegantly, with capsule uncut. He notes that large benign tumours, even up to seven pounds, may be removed from a gland, the breast thus left intact being capable of performing its true functions, and, that, under these circumstances, it is the surgeon's duty to attempt to save the gland, even when it may appear hopeless, especially in the case of a patient still in the child-bearing period of life. Mr. Bryant publishes cases which illustrate the frequency of enlarged axillary glands in association with adenofibroma, the enlargement disappearing after the removal of the tumour.

Mr. Bryant writes, in his first chapter on carcinoma: "All evidence tends to show that carcinoma of the breast, as of other parts, is in its origin more a local than a constitutional disease, and that it becomes a general one in a secondary way by what has been described as 'local infection,' and 'vascular or secondary infection.'" The author finds that out of his own 360 cases of cancer in women who had borne children puerperal mastitis had occurred at some antecedent period in 80, but it was almost impossible to make out that the cancerous tumour originated at the seat of scar or induration. Mr. Bryant has much to say on the obstinate eczema of the nipple which Paget and others have described as the frequent precursor of cancer. In the 600 consecutive cases of cancer in the author's own practice (see table, page 149), he has only recorded 3 cases of this form of eczema; but he also published notes of 3 more which have occurred in his experience, 3 out of the entire 6 proving their malignancy by a fatal termination without any operation being performed.

In conclusion, we may note that some instructive observations on the curious pedunculated papilloma of the nipple are to be found towards the end of the volume; and in the same portion of the work are some valuable clinical reports in cases of galactocœle, and a useful "Summary of the Diagnosis of Tumours of the Breast."

TREATMENT OF HYDATID CYSTS.—Professor Baccelli, of Rome, recommends that a measured quantity (10 centigrammes) of fluid should be withdrawn with the aspirator, and a corresponding quantity of a 2 per 1,000 solution of corrosive sublimate at once injected into the cyst. In two cases in which this plan was adopted, the tumour gradually diminished till it almost entirely disappeared, and in ten days the patients were able to get up.

EUTHANASIA; OR MEDICAL TREATMENT IN AID OF AN EASY DEATH. By WILLIAM MUNK, M.D., F.S.A., Fellow and late Senior Censor of the Royal College of Physicians, etc. London: Longmans, Green and Co. 1887.

WHEN the medical art can do no more to arrest the progress of disease, and when medical science can but sorrowfully attempt to estimate the short span of days or hours yet remaining, it is too often assumed by the laity and accepted by the profession that the physician has no further duty towards the patient. How erroneous this opinion is it does not take much experience of medical practice to learn, and most physicians worthy of the name will have learnt for themselves the lessons which Dr. MUNK has to teach in this essay on the means for procuring an easy death. The term "euthanasia" has been somewhat narrowed in its meaning during a controversy which took place in the magazines a few years ago, and is often made to signify the procuring death by easy means, whereas it ought to be understood to mean easy or painless dying.

The means for procuring euthanasia are well worthy of study; but there is one objection which may fairly be urged against this volume, namely, that the subject is not one which permits of being treated in a detached essay. Dr. Munk himself observes that "the process by which death is brought about varies greatly in different instances, and this according to the disease or the organ of the body from which it essentially results;" and we confess to being of the opinion of Sir Henry Hallford—"a master," says Dr. Munk, "in all that concerns the management of the dying"—who by his example showed that the subject ought to be considered in relation with each type of disease, and consequently made his observations "incidentally in the course of his various essays."

Apart altogether from any objections which may be urged on general principles to the selection of the topic, the book is disappointing in its performance. A lively recollection of Dr. Munk as the reviser, annotator, and continuer of the *Gold-Headed Cane* led us to take up his new volume with expectations which have not been fulfilled. An unnecessary amount of space is given to the quotation of authorities to prove that the last few moments of the death struggle are not attended by pain; in a work addressed to physicians, as may be presumed from the author's official connection with the Royal College of Physicians this is, it was hardly necessary to discuss at such length a matter about which there is very little question, even in the minds of the laity. Chapter I, on the Phenomena of Dying, and Chapter II, on the Symptoms and Modes of Dying, consist of little more than a long string of quotations from the published works of Sir Henry Hallford, Sir Benjamin Brodie, Sir Thomas Watson, and other writers who have treated of the phenomena of death in its various forms. We observe incidentally, as an instance of the great advance which has been made in the education of the profession, that it is hardly possible to imagine any practitioner of medicine in this country at the present day falling into the mistake attributed to a colleague by Sir Henry Hallford in a passage quoted at page 38.

When at length we reach, on page 65, the real subject of the book, we find the author, when he has to put before us knowledge which he has really assimilated, capable of many judicious observations; he comments, for instance, on the mistaken kindness of administering food, except in small quantities, adapted to the diminished digestive powers of the stomach; on the value of alcohol, especially of madeira, tokay, and brandy when taken with food; of champagne as a rapidly diffusible stimulant; of opium for the relief of pain, or of the sinking feeling in the epigastrium; and of ether in dyspnoea.

In conclusion, we may quote with approval, if not the English, at least the opinion expressed in the following sentence: "The fewer the drugs and the less of medicine we can do with in the treatment of the dying the better."

The volume is well got up in the old-fashioned style dear to æsthetic postasters. As a matter which also concerns the publishers as well as the author, we may mention that the volume contains too many examples of bad reading, as, for instance, on page 92, lines 1 and 2.

CONSUMPTION OF AQUAVIT AND BEER IN ST. PETERSBURG.—In 1886 the inhabitants of St. Petersburg (about 930,000) have consumed 1,951,701 vedros (1 vedro = 2.7 gallons = 12.3 litres) of spirits (40°), or 2.1 vedros per person; and 3,236,305 vedros of beer, or 3.5 vedros per one inhabitant. (*Vratch*, No. 4, 1888, p. 77).

THE YEAR-BOOK OF TREATMENT FOR 1888. London: Cassell and Co.

THE contributors to this *Year-book of Treatment* undertake each a department, and as they are twenty in number, and each of them competent for critical discrimination of the materials of the year, the result is the production of a condensed and handy book of about 334 pages, which affords a very useful retrospect. As is convenient in a book of the kind intended for English readers, a good deal of attention is given to foreign periodicals; and as cuttings are more easily made from American papers than from those of which the extracts need to be translated, the American journals come in for a very full share of attention. It would be idle to attempt to review a book which is itself made up entirely of small abstracts, but after careful examination we can say that the work is very well done, and we would select for especial commendation the articles of Dr. Mitchell Bruce, Dr. Goodhart, Mr. Arthur Cooper, F.R.C.S., Dr. Berry Hart, and Dr. Charles Henry Ralfe. That of Mr. Edmund Owen is somewhat diffuse, imperfect, and not altogether free from egotism. The section contributed by Mr. Reginald Harrison shows indications of haste and is not very complete. There is a very useful index of subjects. It may be a matter of some interest to the readers of the *JOURNAL* to learn that, as might have been expected, the immense sources of information and mass of original matter contained in its volumes are laid heavily under contribution, and that the acknowledged extracts from our pages are more numerous than from any other periodical. Moreover, it is noticeable that a considerable number of the articles referring to papers read at the annual meetings of the Association and of the Societies are really quoted from our pages, though not so credited, and so with various articles from Swias, German, and Russian sources. It would be more judicious and more correct if in all cases the double reference were given.

As in most compilations of the sort, there is a notable deficiency of the sense of proportion; thus, while some subjects of little moment are treated at great length, especially in the department of surgery, it may be noted that in more than one instance the leading subjects of the year are either passed over almost unnoticed, or but slightly developed. This is especially notable in the surgical parts of the book. Thus, to the work of Lawson Tait there is only one reference, the name of Apostoli occurs only once in the index of authors quoted, the name of Spencer Wells only once, and the name of Victor Horsley not at all. To those who are competent to form an opinion of what have been the chief surgical work of the last twelve months, this speaks for itself. Georgi finds a place four times and Fränkel six times, Senator three times, Cohn three times.

It would be well if the editor of such a book were to make up his own mind what were the principal subjects of the year, and to give his departmental compilers instructions accordingly. It is one of the disadvantages of a book of this sort that in respect to really moving topics of the year, as to which, of course, it should be the most useful, it is out of date almost before it is published. Thus Apostoli's treatment, which receives such a meagre notice, is dealt with in a way which gives no idea of the present position of the question, which has been so much influenced by the experience of Keith and others. Little insight can be gathered from this year book into the achievements of gynaecological surgeons, or of the surgery of the nervous system. Still, taken as a whole, the book is interesting and instructive.

NOTES ON BOOKS.

Animal Magnetism. By ALFRED BINET and CHARLES FÉRÉ, Assistant Physician at the Salpêtrière. (London: Kegan Paul, Trench, and Co.) 1887.—This work is an addition to that valuable collection, the *International Scientific Series*, and deals in a popular and untechnical manner with the history, progress, and phenomena of the condition which, under various names, has been exploited by charlatans and, more recently, investigated by scientific men. The authors, in their descriptions, apply to facts observed in the Salpêtrière Hospital, in accordance with the method inaugurated by M. Charcot, to whom we are indebted for so much of what we now know of the recalcitrant phenomena of hypnotism and suggestion. The reader is warned at the outset that the work only aims at giving an account of special researches, which, notwithstanding their number and variety, will not justify general conclusions. The earlier history of mesmerism is toler-

ably well known, but the subject has not been seriously studied so far in this country, although one of the earliest adepts, Mr. James Braid, was a surgeon practising in Manchester. He it was who, at a time when the matter was practically given up to quacks and mountebanks, directed the question into its proper field—that of observation and experiment. With all his ardour and success, however, Braid left no successor worthy of the name, and it remained for Professor Charcot to take up the subject and investigate it on scientific principles. A chapter is devoted to the application of hypnotism to therapeutics, but it would not seem that any services are to be anticipated from it except in the treatment of symptoms which, for want of a better expression, it has been agreed to call "hysterical." There is much reason, indeed, to credit hypnotism or its collateral conditions with the curative results which follow pilgrimages and the operations of "faith-healers." A far more serious and thorny question is that which bears on the medico-legal aspect. The impairment of volition which results from repeated induction of this condition is a factor of which the law ought to take cognisance, though at present our knowledge is not such as to warrant a didactic treatise of jurisprudence based thereon. The book is well written and exceedingly interesting and instructive, but the subject is not altogether a desirable one for perusal by the general public.

Athothis; a Satire on Modern Medicine. By THOMAS C. MINOR. (Cincinnati: Robert Clarke and Co. 1887.)—This satire, conceived and executed in a style which is now fortunately out of date, introduces to the notice of the reader Doctor Paulus Androcydes and his pet cat Anubis, the latter being in reality a certain Egyptian, Athothis by name, who dated from forty-five hundred years before the dawn of Christianity. Out of gratitude to the doctor for having restored to him his human and corporeal being by the aid of divers incantations and uncanny gestures, after so many centuries of metempsychotic vicissitudes, the Egyptian *reluctantly* forthwith dislocated his benefactor's soul from his body, and took him (or, rather, that part of him) off on a jaunt round the city, peering on their way into the modern sickroom, in which they found much to excite their ethereal hilarity, or, as the author expresses it, they indulged in "ripples of spiritual laughter." We need not follow the unhallowed couple on their round, which comprised visits to the modern consulting-room, hospital, and pharmacy. Wherever they went and whatever they saw afforded them an apparently much-relished opportunity for saying disagreeable things about the present condition of the art and practice of medicine. Among many valuable discoveries, they found that the modern hospital was run in the interest of the doctor rather than that of the sick, and that the label on a bottle in a modern pharmacy was no sure guide to its contents. Notwithstanding the large demands which the author makes on our literary credulity, the book is uncommonly dull reading, and the author's friends should dissuade him from carrying his observations in this direction any further.

FORCEPS FOR POST-NASAL GROWTHS.

WHILST removing post-nasal growths with Löwenberg's forceps and the several modifications of it, I have found a certain defect in connection with all these instruments. This is that owing to the sharp edge only occupying a portion of the end of the instrument, it is frequently impossible entirely to cut off the piece of growth held between the blades, the portion not cut off having to be torn away, thus producing, in cases where the growth is thick and tough, more subsequent inflammation than would otherwise have resulted from the operation.

The reason given for the cutting edge being made only on the upper and posterior part of the instruments is that the growths are usually attached exclusively to the upper and posterior walls of the naso-pharynx, and that, therefore, a sharp edge is only required in those situations. Although what is thus stated with regard to the usual position of the growth is a fact, the deduction is erroneous, because the piece of growth grasped by the forceps

is frequently larger than the end of the instrument, and has an attachment greater than the length of its cutting edge, and a larger surface from before backwards than that covered by the blades. It is evident, therefore, that the instruments hitherto employed cannot remove such a piece entirely by cutting

In the instrument which has been made for me by Meyer and Meltzer, of 71, Great Portland Street, the defect mentioned above has been remedied by the entire circumference of the blades being made sharp, so that the piece of growth between them can be cut out completely. To further ensure the piece of growth which has been seized being thoroughly divided, one blade of the instrument has been made to pass inside the other, after the manner of punch forceps. The end of the instrument has also been fenestrated, to prevent a thick piece of growth interfering with the complete severing action of the blades.

The edge of the instrument has been made only moderately sharp because I have found that when the cutting edge of the forceps is very keen, the hæmorrhage which follows the operation is more profuse than when the blades are blunter.

The instrument was exhibited in the Annual Museum at the late meeting of the Association in Dublin.

3, Mansfield Street, W. T. MARK HOVELL, F.R.C.S.E.D.

AUTOMATIC APPARATUS FOR DISINFECTING AND DEODORISING SEWER-GAS AND SEWAGE (R. HARRIS REEVES'S PATENT).

THIS is an apparatus for the evolution of sulphurous acid gas and oxygen by means of an automatic mixture of strong sulphuric acid with a solution of permanganate of soda. The apparatus is placed in a chamber under the roadway, which is in communication below with the sewer by a ventilating shaft, and above with the external air by a grating. The sewer air, in its passage through the chamber, is deodorised by the sulphurous acid and oxygen before escaping into the outer atmosphere. The solution, formed by the mixing of the sulphuric acid and permanganate of soda, which contains a considerable percentage of permanganic acid, is allowed to overflow into the sewer below, where it becomes mixed with the sewage, and—if employed in sufficient quantity—deodorises it.

A very large number of processes for deodorising sewer air are now known to the sewage engineer, but very few have been found to be practically useful. Putrid sewage which gives off foul-smelling gases is undoubtedly a dangerous nuisance, but the proper remedy is to improve the construction of the sewers and form proper gradients, rather than to allow the nuisance to arise and then seek to remedy it by chemical disinfecting agents. Prevention is better than cure in sewerage as in other matters, and is also in the end a great deal cheaper. To deodorise putrid sewage or foul-smelling sewer air successfully, enormous quantities of chemicals must be used, at a proportional cost, or the result is not satisfactory. It is far better to replace the old sewers of "stagnation and deposit" by sewers constructed on modern principles, which convey everything away from the town in a fresh and undecomposed state. If this is done, sewer ventilation loses nearly all its difficulties. Mr. Harris Reeves also claims for his system that the solution containing permanganic acid, which overflows into the sewer, acts as a precipitant as well as a deodorant. It appears to us that it is not wise policy to add precipitating agents to sewage at a distance from the outfall and settling tanks. Such a proceeding, except in good sewers of rapid gradient, is likely to lead to deposit of sediment in the sewer, with consequent obstruction to the flow of sewage.

PRINCESS CHRISTIAN paid a visit to the London Hospital, Whitechapel, on Sunday afternoon, walking through several of the wards and to the nursing home.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1888.

SUBSCRIPTIONS to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the West Central District Office, High Holborn.

The British Medical Journal.

SATURDAY, MARCH 3RD, 1888.

ABERNETHY ON TUMOURS.

IT is a fault of the present age to ignore the work of preceding generations. We imagine that discoveries we have inherited from our fathers are really to be placed to our own credit. Thus a writer in a modern *System of Surgery* says of tumours: "Their anatomical classification was, a few years ago, little more than a suggestion."¹ Yet eighty years before this was written, John Abernethy had published in his monograph *On Tumours*² a new classification, which was a purely anatomical one, carried to as high a degree of perfection as was possible with the inferior histological knowledge and appliances at his command.

His system was eagerly adopted by his contemporaries as a great advance over all preceding ones. Even his initial definition of the word "tumour,"³ though by no means perfect, was a real improvement over that of any previous author. They understood the word in its widest meaning of "a swelling," and included in their descriptions diseases of arteries, veins, glands, tendons, joints, and bones, which had really nothing in common save the one feature, with what we understand to-day and what Abernethy understood by the word "tumour."

So widely was Abernethy's system accepted by his contemporaries, that it was not until many years after his death, and then only by a gradual process of replacement, that a clinical classification drove his anatomical one out of the field, to be in turn discarded in our own day in favour of an anatomical system not differing materially from his own.

Abernethy's theory of pathology was complete and attractive enough in itself; and it was perhaps the requirement of this theory which originally led him to attempt an anatomical classification of tumours. He began with an observation of John Hunter's,⁴ "that the cavity" (of a certain abdomen) "being opened, there appeared lying on the peritoneum a small portion of red blood recently coagulated. This, upon examination, was found connected to the surface upon which it had been deposited by an attachment half an inch long, and the neck had been formed

before the blood lost its red character." From this Abernethy concluded "that there can be little doubt but that tumours form everywhere in the same manner, the coagulated part of the blood being either accidentally effused or deposited in consequence of disease, become afterwards an organised and living part by the growth of the adjacent vessels and nerves into it. When the deposited substance has its attachments by a single thread, all its vascular supply must proceed from that part, but in other cases the vessels shoot into it irregularly at various points of its surface. Thus an unorganised concrete becomes a living tumour, which has at first no perceptible peculiarities as to its nature. Though it derives a supply of nourishment from the surrounding parts, it seems to live and grow by its own independent process. And the future structure which it may acquire seems to depend on the operation of its own vessels."⁵ Abernethy goes on to remark that the tumour is in structure sometimes like, but more frequently unlike, the part near which it grows; and on this ground he comes to the same conclusion as that set forth in the last paragraph, namely, "that in many cases the nature of the tumour depends on its own action and organisation; and that, like the embryo, it merely receives nourishment from the surrounding parts."

He explained malignancy by the following theory:—"The effused coagulable part of the blood," which on his hypothesis, was the origin of all tumours, might be deposited from the effects of accident, or from a common inflammatory process, or on the contrary it might be the result of some diseased action of the surrounding parts and vessels, which would influence the organisation and growth of the consequent tumour. In the former events he saw the origin of all innocent tumours, in the latter of malignant ones. Innocent tumours did not return after operation, because the parts surrounding, being merely the source whence the new growth procured its nourishment, had no power of reproducing it when once it had been removed. While malignant tumours, being originally produced by the diseased action of neighbouring vessels or tissues, was, upon removal, owing to a continuance of the same action, at once replaced by a second unhealthy effusion, which had in general the further development into a fungous growth.

Misled by the classificatory craze of his day, which saw no difficulty in arranging the morbid products of disease in as complete and interdependent a system as that introduced by Linnaeus into the kingdom of Nature, Abernethy classified tumours as follows:—

- Class:—Local diseases.
 - Order:—Tumours.
 - Genera:—I. Sarcomatous tumours. II. Encysted tumours. III. Osseous tumours. IV. Cartilaginous tumours.
- The first genus (sarcomatous tumours) he subdivided into eight species: 1. Common vascular, or organised sarcoma. 2. Adipose sarcoma. 3. Pancreatic sarcoma. 4. Cystic sarcoma. 5. Mastoid or mammary sarcoma. 6. Tuberculated sarcoma. 7. Medullary sarcoma. 8. Carcinomatous sarcoma.

⁵ Abernethy, *loc. cit.*, pp. 8, 9, 10.

² "An Attempt to form a Classification of Tumours according to their Anatomical Structure" (Abernethy's *Surgical Essays*, 1804, I, 1).

³ "Such swellings as arise from some new production which made no part of the original composition of the body." Abernethy, *loc. cit.*

⁴ Related by Sir Everard (then Mr.) Home (*Transactions of a Society for the Improvement of Medical and Surgical Knowledge*, I, 231).

By "sarcoma" and "sarcomatous," Abernethy of course only indicates tumours having a firm or fleshy feel, and these terms are most nearly represented in modern nomenclature by the expression "solid tumour."⁶ They bear the relation to modern sarcoma of an original term of widest signification narrowed down in course of time by a gradual process of elimination, to a special significance which etymologically the word was never intended to bear.

Of Abernethy's "sarcomatous tumours," the "common vascular or organised sarcoma is represented nowadays by the word "fibroma," and his clinical description of the kind is admirably true and graphic. He believed this to be the original form of tumour produced by the organisation of an effused clot, and was even inclined to think that all tumours are, in the first place, of this structure. His second species "adipose sarcoma," is of course the same as the modern "lipoma."

It shows how far Abernethy was in advance of his contemporaries and successors in close and accurate observation, that Chelius should write, so lately as 1847: "The pancreatic and mammary tissues are to be considered as accidental modifications of the medullary."⁷ This is no doubt true of Abernethy's mammary sarcoma, but in his pancreatic sarcoma he was evidently describing "adenoma," the following characteristics being decisive. It was, in the first place, like the pancreas in appearance of structure, generally occurred in young adults, and most frequently in the female breast; although it sometimes caused lancinating pain and enlargement of neighbouring glands,⁸ it was most amenable to treatment, did not recur when removed, was encapsuled; while any enlarged glands at once subsided after the tumour was operated on.

Abernethy draws a clear and just distinction between cysts and cystic degeneration, making of the former a distinct class, and placing the latter as one of the species of his solid tumours under the term "cystic sarcoma."

It is almost certain that, in his tuberculated sarcoma, he anticipated Wilks by nearly fifty years, and that this species is the same as Hodgkin's disease. But by Abernethy's immediate successors, it was compared with quite other and distinct pathological conditions; they were not sufficiently observant to accept at its full value his careful diagnosis.

His remark on medullary sarcoma could be inserted in the most modern work (but only in the most modern work) on tumours: "The term cancer is objectionable, because it conveys an erroneous idea of the nature of medullary sarcoma; for this disease, though perhaps equally destructive, will be shown to be unlike cancer in its nature and progress."

Abernethy, then, deserves credit for having worked out an anatomical classification of tumours, which was far better than any which had preceded it, or rather was the first intelligent step in such a direction; and it was also a giant step, for his system will bear a very favourable comparison when viewed by the light of modern research with that of his successor South, or of Liston,

and, indeed, comes newer to our present classification than any previous one we know. His clinical observation was most accurate, and, with one exception (that of mammary sarcoma), every one of his species is accepted as a distinct one, even in the present fierce light of new histological processes and modes of research. His opinion that malignant tumours were of local origin is also in advance of his age. Yet few among us recognise this of Abernethy; we know him as a distinguished surgeon in his day, celebrated for brusqueness and impatience of manner, but occupying a larger space in our jest book than our system of surgery.

And this is the one great loss we have sustained by modern methods of original observation and research. Up to the time of John Hunter, men were obliged to read and quote the works of deceased authors, back to the very earliest age, in order to procure acceptance for their own views and discoveries. This was destructive of all originality, but preserved from oblivion the name and fame of the mighty dead. To-day we neglect the works of our fathers in favour of those of our own contemporaries and immediate predecessors. Our students grow up with a pitying contempt for the benighted conviction of the elder writers on disease. They are accustomed to rely on original observations for knowledge and for success. And so science is the gainer, but the individual is the loser; our discoveries are either falsified or forgotten when we die, and our very name slips into the sea of forgetfulness.

Who will undertake the great task of research required to bring out the great successes of our forefathers, to write a history of medicine, if only in unfinished portions, and to replace such men as John Abernethy on the pedestal they ought to occupy in the Temple of Fame?

THE METROPOLITAN WATER SUPPLY.

THE somewhat unceremonious rejection by the House of Commons on Tuesday last of the Bill promoted by the Grand Junction Waterworks Company, is not a cause for unmixed satisfaction; but if, by the attention thus drawn to the matter, the settlement of the important question of the water supply of the metropolis generally can be brought a stage nearer solution, Londoners are to be congratulated. We have long insisted upon the increasing unsuitableness of the Thames as a source of domestic water supply. At present the supply for more than half the inhabitants of "Greater London," that is to say, some two and a half millions of souls, is drawn from the Thames after that river has received the crude sewage of Staines and other towns, as well as such polluted tributaries as the Wey. It has been estimated that the sewage of some 70,000 persons enters the Thames above the intakes of the Metropolitan Water Companies. We would have been glad, therefore, looking at the matter simply from the point of view of the sanitarian, if the first real indication of an effort to obtain a purer supply had been allowed to receive a fuller and more scientific consideration than could possibly be given to it on a motion for the second reading of the Bill.

The course of the discussion seemed to show that the House

⁶ Excluding cartilaginous and osseous growths.

⁷ South's Translation of Chelius's *Surgery*, 1847, II, p. 648.

⁸ When inflamed (?).

was not acquainted with all the circumstances. The Grand Junction Waterworks Company have at present power to draw 20,000,000 gallons of water daily from the Thames, and this limit has not yet been reached. For this privilege they pay an annual rent to the Thames Conservators. Formerly they took all their supply direct from the river, but in 1882 they obtained permission to construct works at Hampton, by which they were enabled to intercept the pure spring water to be found in the gravel beds in that neighbourhood before it reached the Thames, and also to utilise those beds as natural filters. The good results which followed this experiment led other companies to take a similar course; but recently the progress of building operations in the vicinity of the works, and the erection of houses draining into cesspools, have seriously endangered the purity of the subsoil water. Hence the proposal of the water company to obtain their supply farther up the river, and to adopt the plan, advocated in 1884 in an interesting but neglected report by Mr. J. Thornhill Harrison, C.E., one of the engineering staff of the Local Government Board, of tapping the chalk and gravel beds in the neighbourhood of Dorney and Windsor, where vast quantities of pure water are obtainable.

The opposition to the scheme is based on the assumption that, if adopted, the volume of water in the Thames would be seriously reduced, that the mud would silt up, that even the foundations of Windsor Castle would be affected, and that the trees in the Park would be injured. It is urged that the beauty of the river would be impaired, and that the pleasure of a number of people would be interfered with, whilst the river would become dangerous to health in its upper reaches. If these consequences were certain to follow, no arguments could justify sanction of the scheme; but they are disputed by the promoters of the Bill, and Mr. Ritchie, with his official knowledge as President of the Local Government Board, could not accept them as proved. As Lord Randolph Churchill observed, it is a scientific question, which could only be satisfactorily ventilated before a Select Committee.

It is unanimously admitted that at some time, which has already been too long delayed, and which at the present moment seems as remote as it has seemed at any period since Sir R. Cross's ill-fated scheme fell to the ground, the water monopolies must disappear, and the ratepayers must take the matter into their own hands. It is very necessary, therefore, that Parliament should continue to look jealously on any tendency on the part of the water companies to increase the value of their undertakings. But, although the companies deserve little sympathy, their powers of supplying wholesome water must be the first consideration for sanitarians. We hope that ere long the whole question of the London water supply may be fully investigated by a Special Commission.

Meanwhile, the legal proceedings instituted by the Thames Conservators with the view of putting a stop to the discharge of the unpurified sewage of Staines into the Thames have received a check. The Local Sanitary Authority contend that they do not own the sewers in question, and that they have no power to

prohibit the discharge of the sewage. The question is to be argued in the Queen's Bench Division on some more or less remote date, and, pending the legal decision, London must continue to wait and endure.

RECENT RULING AS TO EXPERT EVIDENCE.

A recent ruling by Mr. Justice Day, at assizes in the North-Eastern Circuit, will scarcely commend itself as a means best tending to the promotion of equitable verdicts in criminal cases, when the plea of insanity is raised on behalf of the prisoner. In the case referred to, a prisoner having been indicted for the murder of two individuals, a jury was empanelled in order that it should be ascertained, in the first place, whether he was or was not in a fit condition to plead. A medical witness being asked the question whether, in his opinion, the prisoner, when examined by him, was sane or insane, it is reported that the learned judge would not allow the opinion of the medical witnesses to be given upon that point, and restricted their evidence to matters of fact as to what they saw or heard, in their examination of the case, bearing upon the question of sanity, which the jury were sworn to try, and with regard to which counsel were not permitted to elicit the expression of medical opinion. Practically, this ruling reserved to the jury, and to the jury alone, the right to express any opinion in the court—any opinion, that is, having influence on the trial—as to the existence or non-existence of insanity, that is to say, of a form of disease. The importance of this ruling is magnified, and not lessened, by the fact that the judge is stated to have expressed his intention to deal in a similar manner with the evidence of scientific and expert witnesses in any and every kind of case, whether medical or other.

In the case affording the basis for these remarks, evidence was given as to the existence of numerous and extraordinary delusions; and, after an inquiry lasting more than three hours, the jury found that the prisoner was fit to plead, and he was put upon his trial accordingly. Eventually, the jury found the prisoner guilty, but also found that he was insane at the time he committed the acts, and he was ordered to be confined as a criminal lunatic during Her Majesty's pleasure.

The ruling above mentioned is all the more open to criticism, as regards what its effect might be in certain cases, inasmuch as it followed immediately after a trial elsewhere, in which, as reported, the expression of medical opinion as to the sanity or insanity of a prisoner was permitted by Mr. Justice Mathew, and acted upon by the jury, under circumstances apparently quite similar to those under which the expression of such opinion was prevented by Mr. Justice Day, as we have already briefly recounted.

Earnestly desirous as the members of a jury are to hold the balances evenly, it is quite impossible that they can form as accurately-grounded an opinion as a medical expert upon the frequently difficult and delicate question of the existence or non-existence of insanity. For a man to have close and intimate

practical knowledge of some part of the field of science is, in some quarters, apparently a reason why his deliberately-formed opinion on a subject within the sphere of his studies should be suppressed in a court of law, and the point at issue be decided by untrained minds. Carry this to its logical conclusion, and we must set up ignorance as a chief qualification of those fitted to decide scientific questions!

In cases of the kind referred to; it would be well if independent and expert medical evidence was secured by the initiative of some public authority.

THE honour of knighthood has been conferred upon Dr. J. W. Tyler, C.I.E., the well-known superintendent of Agra Gaol. Sir John Tyler's duties brought him at the time of the Indian Exhibition, and again last year during the Jubilee, under the personal notice of the Queen, and it is, the *Pioneer* believes, at Her Majesty's own wish and instance that the honour comes to him.

THE LUNACY LAWS.

THE Lord Chancellor's Lunacy Bill was issued on Wednesday last. In a memorandum it is stated to be substantially the same measure as that which passed the House of Lords last year.

RETREATS FOR DIPSOMANIACS.

In perpetuating the Habitual Drunkards' Act of 1879 (limited to expire next year) a Bill introduced by Dr. Cameron, M.P., would enable the licensee of a retreat to appoint from time to time a deputy to act for him during his temporary absence. Such an appointment, however, must be approved by the inspector of retreats. Another modification of the Act deals with the attestation of an habitual drunkard's signature on his applying to be admitted to a retreat. The attestation by one magistrate is substituted for that of two.

THE UNIVERSITY OF LONDON.

THE next meeting of Convocation of the University of London will take place on March 6th. Mr. James Anstie, Q.C., Mr. E. H. Busk, and Mr. H. A. Nesbitt have been nominated for election to the Senate on that occasion, but the contest lies between the two first named. Professor Silvanus Thompson has given notice of a motion requesting the Senate to consider whether it would not be desirable to confer *ad eundem* degrees upon those graduates of other universities who hold professorships in University and King's Colleges, so that they might be admitted members of Convocation. Several motions referring to the schemes for reforming the universities and asking for further information or suggesting amendments also appear on the agenda paper.

POST-GRADUATE LECTURES, CHARING CROSS HOSPITAL.

THE second course commenced on Friday last by a lecture on Dyspepsia, by Dr. Julius Pollock. At the conclusion the members held their business meeting, Dr. Walford in the chair. The Secretary's report showed that 140 practitioners had joined, and that, on an average, 75 had attended each lecture. The issue of coupons, which are available for twelve months, and give the members more than two opportunities of using them, had given great satisfaction to the members. The staff and governors had greatly assisted in promoting the success of the class. The Treasurer's report stated that, after paying all debts, there remained in hand sufficient money to cover all the coupons in the hands of the members. A proposal to publish the lectures had been warmly taken up by the class, and arrangements were being made for carrying it out. It was felt by all concerned that the provision of systematic post-graduate teaching was a great boon

to the practitioners of London and the surrounding district. Votes of thanks were passed to the governors and the staff for their assistance, and to the Secretary and Treasurer for originating and organising the courses.

ROYAL MEDICAL BENEVOLENT COLLEGE.

THE May elections of the Royal Medical Benevolent College at Epsom are once more at hand, and the governors and subscribers are being importuned to pledge their votes for particular candidates in whom the writers take a kindly and special interest, and for whom they solicit support from their personal friends. Circulars, moreover, are being distributed with influential names attached to them specially to solicit such votes from the governors. Without any reference to any particular case, it is our duty once more to express our regret at the disregard of the conclusions arrived at after thorough investigation and discussion at the meetings of the governors. At these meetings it was resolved that, in the best interests both of the candidates and of the institution, such canvassing should be discontinued, and that the selection of candidates should be entrusted to a committee, who could carefully and dispassionately weigh the special claims of one candidate against another. A system of canvassing by which the candidates whose friends have funds at their disposal, or who may have the advantage of the sympathies of a few influential persons, or of persons attached to some especially large hospital or school, or have in other directions a large connection, ought to be condemned; by virtue of these quite adventitious circumstances, such candidates acquire unjust advantage over others whose claims may be overwhelmingly greater, but whose very necessities and friendliness, which should constitute their best claim, are thus turned to their disadvantage. Everyone must desire that the election to the benefits of the College should fall to those persons who stand in most need of it, and not to those who are most influentially connected, or who have the largest command of funds for the costly process of sending out circulars and of organising a canvass for votes. We would earnestly recommend the governors to abstain from all promises, and to reserve all votes until they have the opportunity of seeing the full list of applicants and the report thereon by the Committee of the Governors of the College.

WALSALL COTTAGE HOSPITAL.

THE medical profession has ever recognised the great discretion which nurses as a body have brought to the discharge of the important duties confided to them, and it is comparatively seldom that any individual member oversteps the sphere of duty which properly belongs to a nurse. An instance has unfortunately recently been afforded by the "sisters" of the Walsall Cottage Hospital. The sisters, we are informed, do nearly all the work of the out-patient department, and a recent inquiry has shown that they treat fractures without surgical supervision, and it is reported that over a thousand fractures have been thus treated. A well-informed correspondent relates the following incident: "A lad with a fractured fibula was sent there by a medical man. Several days after he inquired of the mother how the lad was; her reply was: 'The sister says it is not broken; it is only a bad sprain.' He told her to bring the boy out again. He said at once it was broken, and ought to have been put up four or five days ago. These things are of daily occurrence. The sister in charge carries things with a very high hand, and gives the wretched patients herrings on Fridays throughout the year, even if the doctor orders meat for them." Such high-handed proceedings only need to be known to be condemned, and it is not surprising to be told that the people of Walsall, for whose benefit the Cottage Hospital exists, are losing confidence in the institution under its present management. It would also seem to be desirable that the funds of the Walsall Sea-side Home should be audited and published,

and that this institution—now, we are informed, managed by “Sister Ellen,” of Walsall—should be put under the control of a committee properly elected by the subscribers in the customary manner.

REFUSAL TO ADOPT PASTEUR'S METHOD IN NEW SOUTH WALES.

RECENTLY representations were made to the Minister for Mines, New South Wales, in favour of the introduction of disease amongst rabbits with a view to their extermination. The proposal was regarded by Mr. Abigail with disfavour, and a notification has been published to the effect that heavy penalties will be strictly enforced against persons who introduce diseased rabbits, and that the officers of the department have been instructed to guard against the introduction of such animals. The reception which awaits M. Pasteur's emissaries, who have just sailed for the colony in the Orient Line mail steamer *Cuzco*, is therefore somewhat doubtful. Most bacteriologists share to some extent the fears of the Minister of Mines; it is felt to be doubtful whether we yet know enough of the potentialities of this minute organism to render such an experiment justifiable. M. Pasteur himself has done more than any other investigator to teach us how profoundly their virulence may be modified by environing circumstances. It is impossible to foresee what may be the ultimate consequences of the experiment which it is proposed to make on so gigantic a scale. The mere fact that the microbe is capable of producing fatal disease in two animals so dissimilar as domestic poultry and rabbits ought to serve as a warning that it may possibly develop into a pestilence affecting other species of animals, and even man himself; for it ought to be remembered that, once the disease is introduced into the rabbit warrens, it has passed beyond human control.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE quarterly meeting of the Medico-Psychological Association was held at Bethlém Hospital on Friday, February 24th, at 4 P.M. The chair was occupied by the President, Dr. Needham, and there was a very full attendance. Dr. Hughlings Jackson read a paper “On Post-Epileptic States.” A special general meeting was subsequently held to consider the recent appointment at the Hayward's Heath Asylum. Letters expressing great indignation were read from Drs. Clouston, Yellowlees, Brushfield, and others; and a petition, numerously signed by assistant medical officers, was read, protesting against the circumstances of the appointment. Resolutions were passed, “That this Association is of opinion that it is highly desirable that medical superintendents of asylums should have spent, before their appointment, some time as resident medical officers in asylums, or in the study of mental diseases in these institutions;” and “That the qualifications in medicine and surgery required for the medical superintendent of an asylum should not be such as to preclude the application of a large proportion of suitable medical men engaged in the department of mental medicine.”

THE EDUCATION AND REGISTRATION OF PLUMBERS.

LARGE and representative meetings have been held recently at Edinburgh and Dundee in connection with the national movement for the education and registration of plumbers. This movement is now spreading extensively over the United Kingdom, and we are glad to learn that at both these meetings, at which the trade, the medical profession, and the public were well represented, resolutions were passed such as those which have been passed in so many other great cities of the kingdom, warmly approving of the scheme, and appointing representative persons identified with health and public interests as well as the plumbing trade, to form local councils. The Edinburgh meeting had the

great advantage of the presidency of Sir Douglas Maclagan, than whom no person is better qualified to form a judgment on the subject, or possesses more entirely the esteem and confidence of his own profession, and of the public generally. It is obvious that the system of examination must be arranged so as to secure an adequate minimum; and the advantage of having representative local councils in each of the great cities acting together, and in co-operation with a central body on which they are fully represented, is very considerable. This is, indeed, the only condition under which public confidence can be secured, and a downward competition prevented. The petty local movement which has been started in Edinburgh will not, we are convinced, receive serious consideration when the true bearings of the question are generally understood, and we are glad to see that Sir Douglas Maclagan, as well as the plumbing trade generally in Edinburgh, fully appreciate the importance of establishing the movement on a national basis, while leaving adequate local freedom to the local councils.

NEW WING OF THE HOSPITAL FOR SICK CHILDREN.

A SPECIAL court of the governors of the Hospital for Sick Children, Great Ormond Street, was held on Wednesday, February 29th, under the presidency of Lord Aberdare, for the purpose of sanctioning the commencement of the construction of a new wing when the building fund amounted to £15,000. It was pointed out that the fund had been found insufficient for completing the new hospital proposed in 1870, and that only a part of it was finished in 1874, since which every effort had been made to secure funds for carrying on the work. They were enabled to raise a fund of £6,000 last year, and £10,000 was now available for the building. The Council had fixed on £15,000 as the sum necessary to have in hand before proceeding to build further structures. The meeting was asked to sanction expenditure for constructing the foundation and drainage of the new wing, and to authorise the commencement of the new wing when the building fund amounted to £15,000.

HOW TO SPREAD SMALL-POX.

MR. HERRING, of Leeds, continues his efforts at Sheffield “for the special treatment of small-pox and the stamping out of the epidemic.” The “stamping out” process is illustrated in the contents of the advertisements calling his meetings. At one it is advertised that “several cured patients will give their experience,” and that at another “a number of persons benefited by their treatment will be present and testify.” An advertisement in the daily papers of February 25th appeals to the public for funds to “meet the necessary expenses of a treatment which has done and is doing so much to rid the town of the disease.” It states also that it is three weeks since the man Herring came to the town, so that the dangerous condition of at least some of the people advertised to attend and testify at his meetings on February 16th and the later one may be realised. Is it any wonder that infection spreads; especially when the character of the gatherings he calls together is considered?

ST. JOHN'S HOSPITAL.

THE Editor of *Truth*, in a characteristically bold and fearless maintenance of public rights, has taken up the case of the alleged mismanagement of St. John's Hospital, as to which statements of considerable public interest have recently been made. The Duke of Northumberland and other leading persons connected with the hospital having resigned in consequence of the refusal of the Board to permit a full inquiry into the management on behalf of the subscribers, the Editor of *Truth* has repeated and re-enforced a challenge, and applied for permission for an independent investigation in the public interest. This having also been refused, he

now summarises serious charges of mismanagement; and, after reaffirming them in a categorical and aggressive form, he challenges an issue at law, and invites those who have refused the inquiry to a legal investigation by the ordinary course of legal action. It remains to be seen whether the managers, after refusing investigation by a committee on behalf of their subscribers, will submit to the imputations of mismanagement thus publicly made, or whether they will take action for their self-vindication.

GALLANTRY REWARDED.

MR. HEADLEY HILL, student at the Bristol General Hospital, has been presented by the Mayor of that city with the Stanhope gold medal of the Royal Humane Society for having performed the most meritorious and gallant rescue during the year. The circumstances are worthy of record. Leaping into the Avon at Clifton Bridge Station on October 18th last, he, under most difficult circumstances, rescued a young girl from drowning, and, though greatly exhausted by his efforts, brought her ashore, and adopted prompt measures to restore animation. On being restored to consciousness he removed her to the Bristol General Hospital, where, under the care of Dr. Newnham, she was ultimately restored to her friends and family.

NEW MEDICAL CLUB.

A NEW club, entitled the "Galen Club," has been founded at 30, Sackville Street, Piccadilly, in convenient quarters and a central position, for the purpose of affording to members of the medical profession the conveniences of a club-house, having the same advantages of social intercourse as are attainable in clubs devoted to the political, literary, dramatic, sporting, and other classes. The Galen Club will be controlled by a committee of medical men of undoubted character, as is evidenced by the list of the first committee. The club will be provided with bedrooms, as well as the other usual features of a London clubhouse. There is at present no entrance fee, and the annual subscription for town members is four guineas, country members two guineas. While the club-rooms are being prepared, communications should be addressed to the secretary, Mr. Walter Paterson, 47, Albemarle Street, Piccadilly.

SEA-WATER FOR TOWNS.

AT a time when ominous reports as to the abnormally low condition of the water supply in many populous places are being published, it may be interesting to call attention to a proposal emanating from Mr. Ellis Lever, of Bowdun, near Manchester, who, looking to the fact that many of the busiest and most populous towns are within fifty miles of the sea, suggests that not only London, but other important towns, might have a plentiful and unfailing supply of sea-water brought in pipes from the coast, where it is clear and free from pollution. Mr. Lever recounts the many sanitary purposes for which sea-water can be used, and refers to its invigorating properties; its use for watering streets; for closets, flushing sewers, and extinguishing fires, for which purposes it is more effectual than the ordinary water supply.

COLOURED LIGHT IN THE TREATMENT OF INSANITY.

DR. PONZA, medical superintendent of the lunatic asylum at Alessandria (Italy), reports some experiments which he has made on the effect of coloured light on lunatics. The idea was suggested to him by the observations of Robert Hunt on the favourable effect which light transmitted through violet-tinted glass had on the development of animals and plants. Dr. Ponza selected rooms with as many windows as possible, and he had the walls painted of the same colour as the window-panes. A patient suffering from melancholia, who would not eat, was placed in a room with

bright red walls and windows; in three hours he became quite cheerful and asked for food. Another lunatic, who always kept his hands over his mouth to keep out air and nourishment, was placed in the same room, and the next day he was much better, and ate with a hearty appetite. A violent maniac was placed in a blue room, and became quiet in an hour. Another patient, after spending a whole day in a violet-coloured room, was completely cured. Theoretically this appears to be a very interesting experiment, but we have good reason to believe that in practice it is of little real service. It had one very good effect, which was that it induced the medical men who were making the experiment to spend a good deal of time and attention on the patients who were under treatment. One German medical man who visited Alessandria said it was "most excellent for the doctors." It is probable that in some future day electric light may be used for the darker parts of asylums, and then we shall be able to see whether electric light will serve to develop vitality in men as it has been proved to do in plants. In many persons of unsound mind the whole vital energy is defective, and the medical officers often feel a sad want of something which will produce energy. Stimulants of one kind and another are tried, and do some good; but we should welcome some more general natural means of improving the general health. The asylum physician looks to food, warmth, and exercise as his great assistants; and if electricity, or blue or yellow rays, can be added, so much the better.

THE ILLNESS OF THE CROWN PRINCE.

WE learn by special telegram from a most authoritative source at San Remo that the Crown Prince of Germany is slowly improving, though he has not made such good progress towards recovery from the immediate effects of the operation as it is considered he ought to have done. There is still great irritation in the trachea, which is probably attributable to ulceration of its inner surface caused by the tube, or to extension downwards of the laryngeal disease. We are deeply grieved to say that it appears to be only too probable that the case has now entered on a phase which, unfortunately, gives grounds for the most serious apprehensions. Sir Morell Mackenzie is no doubt technically justified in declining to accept the diagnosis of cancer as proved until it has been confirmed by a microscopic expert of unimpeachable authority, but the hope that the judgment of men of such high scientific position as Professors Von Bergmann and Kussmaul may be reversed on appeal is, it must be confessed, very slender. It cannot be too much deplored that, in a case of such importance to the world at large, national jealousies should have been allowed to interfere with the harmonious working together of the medical men in attendance, and we cannot help feeling that the publication of their mutual recriminations in the lay press is undignified and injurious, not only to themselves, but to their profession. We say this with the fullest appreciation of the difficult and even painful position in which they have throughout been placed, partly owing to the obscurity of the case itself, but mostly to the diplomatic reticence which has been imposed on them. We do not feel it necessary to discuss the relative advantages of English and German tracheotomy tubes, and we can only hope that the difficulty of finding an instrument to fit comfortably has by this time been happily surmounted. It is a curious commentary, by the way, on the "officious" denial which was given in the *Times* to the statement on this subject which was made in the *JOURNAL* last week, that Sir Morell Mackenzie, after having had two different tubes sent out from England, is said to have been obliged personally to superintend the construction of a new one at San Remo. In connection with this matter, we may mention that Sir Spencer Wells, on reading the paragraph referred to in the *JOURNAL* last Saturday, at once sent off to Sir Morell Mackenzie by post some simple contrivances which he had successfully used

as substitutes for tracheotomy tubes more than twenty years ago. These are small dilators, of a shape which may be described as something between an ordinary eye speculum and a *serre fine*; this is introduced into the tracheal wound, and keeps its edges apart. Mr. Gelding Bird, we believe, brought a somewhat similar instrument, designed for the same purpose, before the profession a few years ago. We are informed, however, that it has not been considered necessary to use these instruments in the case of the Crown Prince.

METHYLAL IN DELIRIUM TREMENS.

AN interesting note on the value of methylal, the new hypnotic described in these pages on October 22nd, 1887, in the treatment of delirium tremens, has been contributed to the *Therapeutische Monatshefte* (February) by Professor v. Krafft-Ebing, of Graz. Acting on the advice of Merck, the well-known pharmacist, he employed an aqueous solution of the strength of 1 in 10 as a hypodermic injection; each injection contained 0.1 gramme of methylal, and in this strength produced only slight and transient smarting. Thus administered it was found that the drug only produced its effect after an interval of about two hours; if sleep was not produced after between two and three hours, the injection was repeated. Twenty-one persons were thus treated, about half the number being slight cases; in 6 instances sleep was induced by 1 injection, in 10 by from 2 to 4, in 3 by from 5 to 8, and in 2 by from 10 to 20; deep, physiological, refreshing sleep, which sometimes lasted twenty hours, was then obtained; in other cases, the patient slept for two or three hours to wake again delirious, but the treatment being persevered with, the prolonged so-called critical sleep always ensued. Professor v. Krafft-Ebing considers methylal to be the best sedative and hypnotic in delirium tremens which he has ever used; it has no depressing action on the heart, but rather the contrary, and it is followed by no unpleasant after-effects. He considers that it is likely to be useful in insomnia and restlessness due to inanition or cerebral anæmia, but that it is contra-indicated in cases where there is cerebral hyperæmia. The very small doses which were found to be adequate give special importance to this communication.

LORETA'S OPERATION ON THE STOMACH.

DIGITAL dilatation for fibrous stricture of the pylorus, which was first practised by Professor P. Loreta, of Bologna, in 1882, has already in his hands given most satisfactory results in a large number of cases. The *Riforma Medica* of February 19th contains an account of a case in which the operation was recently performed by Dr. Loreta, which is of special interest owing to the detailed way in which it is reported. In January last a man, 54 years of age, but looking much older, owing to his wasted and careworn appearance, came under the professor's care with the following history:—He had been excessively intemperate both in eating and drinking, and had suffered from severe dyspepsia since 1872. In 1880 he began to be troubled with vomiting, which occurred regularly four or five hours after taking food. The stomach was visibly dilated, and a splashing sound could be heard on succussion. Microscopic examination of the vomited matters gave negative results; neither blood, starch-granules, nor sarcinæ could be detected. No tumour could be felt in the hypochondriac or epigastric regions; the abdomen yielded readily to pressure with the hand which, however, caused a slight amount of pain. At the place where this tenderness was most pronounced, a hard fibrous cord was felt at a point corresponding to the situation of the pylorus. On January 30th, after washing out the stomach with an alkaline solution, Professor Loreta made an incision along the linea alba from the xiphoid cartilage to the umbilicus, and exposed the stomach, which was drawn partly out of the wound and opened about midway between the greater and

lesser curvatures. The index finger was then passed into the viscera in the direction of the pylorus, through which, however, it could not be pushed. A large-sized urethral bougie and afterwards an œsophageal sound were then passed through into the duodenum. By this means the stricture was so far dilated that the operator was able to get his finger through the pylorus and draw it over almost to the abdominal wound. The index of the left hand was then also passed through on the right as a guide. The pyloric orifice was then dilated by forcible divulsion with the two fingers, a proceeding which the tightness of the stricture rendered very difficult. Finally, the wound in the stomach was closed by continuous, and that in the abdominal wall by interrupted, suture, and an antiseptic dressing was applied. On February 9th the wound was healed, and the patient had completely got rid of his troublesome symptoms. Digestion was perfect, vomiting had entirely ceased, and the man had lost the look of suffering which had been so marked before the operation. Dr. Maurizio Bufalini, who reports the case, says that not a single instance of relapse after Loreta's operation has yet been heard of.

A MEDICAL ACTS AMENDMENT BILL IN FRANCE.

THE practice of medicine is regulated in France by a law passed on the nineteenth of the month Ventôse, in the year IX, otherwise March 10th, 1803; during the past five years a series of proposals have been made by various individuals and societies for a new law. Two rival Bills, both having some sort of official sanction, are now before the Chamber of Deputies; one of these, drawn up by the Standing Committee on Public Hygiene, has been adopted by the Government; the other has been drafted with much care, and after very full consideration of all the interests involved, by a Parliamentary Commission nominated *ad hoc*, on the motion of Dr. Chevandier. Both measures maintain the distinction between the two classes of medical practitioners, the doctors of medicine and the *officiers de santé*, and the Government Bill would restrict the latter to practice in country districts and towns of less than 10,000 inhabitants. Dr. Chevandier's Bill contains no restriction of this kind, and further, has a clause giving *officiers de santé* of two years' standing the privilege of obtaining the degree of M.D. after undergoing two examinations and presenting a thesis. Dr. Chevandier's Bill is framed in a much more liberal spirit, also, towards foreigners practising in France; it accepts the principle of reciprocity, and enacts that qualified foreign physicians, of whatever nationality, possessing diplomas which have been recognised to be equivalent to the French diploma, shall be authorised to practise in France and her colonies. Where reciprocity does not exist the candidate would be subjected to two examinations—would have to sustain a thesis, and to obtain a special dispensation. The Government Bill does not recognise the principle of reciprocity, and would require every foreign M.D. to submit to one or more examinations; Dr. Chevandier's Bill, moreover, would empower the Minister of Commerce to grant special licences permitting a person possessing a recognised foreign degree of M.D., who is in attendance on a patient to practise in a French watering-place or winter resort. The regulations with regard to the illegal practice of medicine, of pharmacy by a M.D., or of midwifery by an uncertificated midwife, would be very stringent under either Bill; the chief difference is that the Government Bill would attempt to regulate the practice of dentistry, while the Parliamentary Commission thinks such provisions premature. A medical practitioner, whether M.D. or *officier de santé*, is under the existing law forbidden to dispense his own drugs, and this regulation would be fully maintained by both Bills, the only exception permitted being where there is no pharmacy within four kilomètres. Dr. Chevandier's Bill is framed in a wise and liberal spirit, and under it the position of English practitioners desiring to practise in France would be greatly improved, since the Medical

Act (1886) recognises the principle of reciprocity, and contains elaborate provisions for its application.

SCOTLAND.

EXTENSION OF ABERDEEN UNIVERSITY BUILDINGS.
INTIMATION has been given to the Senatus Academicus of Aberdeen University of the intention of the Government to offer a grant of £5,400 (subject to certain conditions) towards the carrying out of the proposed extension of the University Buildings. At a meeting of the Plans Committee of Aberdeen Town Council last week a plan of the proposed extension was submitted, but decision in the matter was deferred until a more detailed scheme has been formulated.

THE GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

THE fifth meeting of the present Session was held in the Faculty Hall on the evening of February 22nd, Dr. Abraham Wallace, President, in the chair. Dr. Nigel Stark presented his report on the dysmenorrhœal cast shown by Dr. Park at the meeting of December 28th. He found it did not yield under the microscope any of the classical features of such membranes; it gave, for example, no evidence of utricular glands. Dr. Park then read a clinical history of the case, which exhibited the combined phenomena of dysmenorrhœa, metrorrhagia, and hydrorrhœa, extending over a prolonged period. The patient was a lady, aged 36. Dr. Park also showed a number of specimens from cases of mucous disease of the colon.

ROYAL EDINBURGH ASYLUM, MORNINGSIDE.

As usual, Dr. Clouston, Medical Superintendent, Morningside Asylum, Edinburgh, made some interesting observations in his annual report submitted to a meeting of the corporation of the institution held on Monday, and presided over by Lord Provost Sir Thomas Clark, Bart. One observation showed that, allowing for increase of population in Midlothian during the last ten years, there was only 1 per cent. addition to the insane admitted into the asylum from the county during that period. The death-rate was only 6 per cent. during last year in the asylum, and a large number of the deaths was of patients who had only been in the asylum for from three to six months. The general health of the inmates was shown by the fact that the mean age of death had risen during the last fifteen years; in the five years 1873-77 inclusive, the mean age at death was 49.4; in the next five years it rose to 51, and during the last five years it had risen to 52.4, and last year it was 53. Dr. Clouston mentioned these facts specially in connection with the recent structural alterations, improved dietary, larger nursing staff, and new hospital arrangements, to which the results were undoubtedly largely attributable. Of 282 patients discharged during the year, 192 were recovered, 24 relieved, and 26 not improved. There had been an unusual number of cases treated where the mental condition was coincident with advanced cardiac disease. The number of cases of general paralysis of the insane kept low, and Dr. Clouston said there was some connection between this and the enforced sobriety and better living of these unprosperous years, as compared with the years of plenty and of inflated wages, 1873-77. With regard to the total returns for the year, it was stated that in the beginning of the year there were 793 patients, and on December 31st, 1887, there were 806, including 14 absent on probation; there were 365 patients admitted during the year, of whom 185 were men and 180 women; altogether there were 1,158 patients under treatment. During the year 282 had been discharged, 194 men and 148 women. The deaths numbered 70, and were those of 47 men and 23 women. The average number of patients resident was 803.

The number of admissions was 31 over the average for the previous years, and had only once (in 1878) been equalled in the history of the institution. As to private patients, 104 had been admitted; this was 15 over the average, and the rate-paid class 231, or 16 over the average. More patients from the higher classes had to be refused admission than in any previous year owing to want of accommodation. Dr. Clouston's report was favourably received, the Chairman speaking of him as undoubtedly the right man in the right place.

IRELAND.

DEATH OF DR. CHARLES CROKER KING.

THE illness of Dr. Croker King, Medical Local Government Commissioner, terminated fatally on Tuesday, February 28th. He had been suffering for some weeks from gangrene of the foot, which followed the cutting of a corn. The appointment thus left vacant is worth £1,200 a year. There are already several candidates, amongst whom are mentioned Dr. O'Farrell and Dr. Hamilton Burke, Local Government Board Inspectors, Dr. Archibald Jacob, and Dr. Henry Fitzgibbon.

DEATH FROM HYDROPHOBIA.

A DEATH, reported to be due to hydrophobia, has occurred this week at the Mater Misericordiæ Hospital, Dublin. The patient, a woman named Mary Curtin, was bitten by a greyhound on the hip about a month ago. On February 22nd she had a shivering fit, and was removed to the hospital, where she died on February 26th. The greyhound, it is said, did not exhibit any signs of rabies, but had strayed from its owner, and received no food. At the inquest the jury found a verdict that death was caused by hydrophobia.

THE IRISH CONJOINT BOARD.

ON Wednesday, February 29th, in the Chancery Division, before the Vice-Chancellor, Mr. Serjeant Hemphill applied, on behalf of the Attorney General, acting at the instance of the President and Fellows of the King and Queen's College of Physicians, for an injunction directed against the Governor and Company of the Apothecaries' Hall, the College of Surgeons, and against Dr. Robert L. Heard, Registrar of the Irish Branch of the General Medical Council, declaring that the Governor and Company of the Apothecaries' Hall were not entitled to hold a qualifying examination under the Medical Act, 1886, or to grant a diploma in respect of medicine within the meaning of that Act, and also that the Apothecaries' Hall and the College of Surgeons were not entitled to enter into a combination for the purpose of holding a qualifying examination under the Act. The case is proceeding.

MERCER'S HOSPITAL, DUBLIN.

THE case of Mr. O'Grady v. Dr. Knight and other Governors of Mercer's Hospital was again before the Vice-Chancellor on Monday, on a motion to have the action dismissed for want of prosecution. It was brought by the plaintiff for an injunction to restrain the defendants from removing him from his office of surgeon. The Vice-Chancellor decided that there was a *forum domesticum*, and the inquiry was then held, the result of which has been already reported in our columns. Mr. O'Grady now submitted to the application of the general body of Governors that his action should be dismissed with costs, but resisted the application for costs on the part of Dr. Knight. The Vice-Chancellor dismissed the action in both cases, with costs. With regard to the case of Dr. Knight, it was admitted that the plaintiff had no intention of proceeding with the action, and therefore, of course, an order to dismiss it for want of prosecution must be made. He regretted that he was obliged by the practice of the court

to award costs against the party whose suit was dismissed for want of prosecution. He expressed that regret because he thought it only just to the plaintiff to state that he considered that great public good had resulted from the action he had taken, although it appeared to have been in point of form, and in point of form only, a mistaken proceeding. He trusted that what had occurred in the case would make a change in the way in which this Board of Governors had been acting in reference to the institution, a great part of them entirely neglecting duties which, by the fact of their being Governors, they must be deemed to have undertaken, and others allowing matters to go on in connection with that hospital which came out on the former motion. The result had been practically to acquit Mr. O'Grady of the charges brought against him. In dismissing the action against Dr. Knight, therefore, he dismissed it with £10 costs, to be paid by Mr. O'Grady in connection with the injunction motion, and six guineas costs of the present application.

WESTPORT UNION: PUERPERAL FEVER.

In the Achill district about a dozen deaths have recently taken place from puerperal fever—a large number considering the scanty population. The guardians consequently have requested the Local Government Board to send down Dr. Todd, their medical inspector, to investigate the matter.

NAVAN UNION: SLANE WATER SUPPLY.

DR. RICHARD CRONIN, medical officer of health, states, in a communication to the Local Government Board, that the water which is about to be supplied to the inhabitants of Slane for domestic purposes is quite unfit for use, and dangerous to health. The supply is from a disused quarry where cats and dogs are frequently drowned, and where liquid manure is drawn in from a large dung heap above the level of the quarry. Dr. Cronin, although the medical officer of health, very properly complains that he was not consulted directly or indirectly in a matter of such importance. The only excuse the guardians have given is that they intend to filter the water.

SCHOOL OF PHARMACY.

THE directors of the Apothecaries' Hall, Dublin, announce the opening of a School of Pharmacy in which teaching will be provided for students proceeding for licence under the conjoint scheme. The following is the course. I. *Preliminary*.—Pharmaceutical nomenclature and abbreviations; the weights and measures of the *British Pharmacopœia*, and how to use them; the processes and apparatus of the *British Pharmacopœia*, namely, filtration, maceration, percolation, trituration, pill-making, plaster-spreading, etc. II. *Official Pharmacy*.—Systematic exercises in the preparation of official compounds, and the application of the *Pharmacopœia* tests for purity. III. *Extemporaneous Pharmacy*.—The reading in full Latin, compounding and dispensing of prescriptions, and the study of incompatibles. The fee for a three months' course will be £3 3s.

BRAIN SURGERY IN DUBLIN.

At a meeting of the Surgical Section of the Royal Academy of Medicine on Friday last three successful cases of trephining were reported, and the discussion upon the papers was adjourned to a future night. These cases were all remarkable. Professor Thornley Stoker read particulars of a case in which a man fell from a cart while drunk. He came to the Richmond Hospital some days later, rather stupid, and with some lightly-marked paralytic symptoms. It was not easy to determine whether he had not had an attack of apoplexy. The paralysis becoming more marked, Mr. Stoker trephined in the region of the fissure of

Rolando—there was no fracture—and struck the margin of a blood clot. He again trephined and more fully exposed the clot, which was washed out. The area so compressed was about three inches, and the clot measured nearly an inch in depth. The patient recovered and was exhibited. Sir W. Stokes read a paper on a case of successful trephining for cerebral abscess, and exhibited his patient. The man had been struck with a poker on the left side of the mesial line of the head, and about an inch anterior to the coronal suture. He was treated as an out-patient at another hospital, but ultimately applied at the Richmond, when he was admitted, several weeks having elapsed from the date of the injury. He soon presented brain symptoms, became convulsed and comatose, and it was determined to trephine. A small fracture was found under the scar; the dura mater bulging into the wound, an exploring needle was introduced to the depth of an inch and a-half, and pus was at last found. The dura-mater was then incised, and one ounce and a-half of pus was evacuated. The patient completely recovered, and is now attending to his ordinary work. The paper noted eleven other cases of abscess which had been operated upon by various surgeons, and discussed the questions involved. The third case was brought forward by Dr. C. B. Ball, of Sir Patrick Dun's Hospital, and the patient was also produced. The lad had been struck with a small knife over the squamous portion of the left temporal bone ten days before admission. The wound was healed, but he had some aphasia. Pain in the head and ear supervened, and the aphasia increased. It was determined to explore. He was trephined some weeks after the original injury. A wound was found in the dura mater corresponding to the puncture of the bone. A sinus forceps was passed in, the wound opened up, and some blood clot escaped. The patient was decidedly better but next morning he was again aphasic. The wound was washed out, and more blood clot escaped. The aphasia almost disappeared, but two days later it returned, and the wound was again washed. After this the patient progressed favourably, and is now well. Dr. Ball pointed out the rôle of the brain lesion, as indicated by the various symptoms of aphasia. The group of cases was a very remarkable one, and the record of them cannot fail to influence the views of surgeons on the subject of brain surgery.

THE SIR GEORGE BURROWS MEMORIAL PORTRAIT.

President: Sir WILLIAM JENNER, Bart., K.C.B.

Committee:

- | | |
|----------------------------|----------------------------|
| Sir Henry A. Pitman, M.D. | Sir Alfred B. Garrod, M.D. |
| Henry Monro, M.D. | Robert Martin, M.D. |
| Richard Quain, M.D. | James Andrew, M.D. |
| William Munk, M.D. | William Selby Church, M.D. |
| John Wm. Ogle, M.D. | J. Matthews Duncan, M.D. |
| George David Pollock, Esq. | Robert L. Bowles, M.D. |

Treasurer: Sir Dyce Duckworth, M.D., 11, Grafton Street, Piccadilly, W.

Secretary: Edward Liveing, M.D., 52, Queen Anne Street, W.

The above Committee has been formed for the purpose of obtaining a replica or copy of the portrait of the late Sir George Burrows, Bart., painted by G. Richmond, R.A., for presentation to the College of Physicians, London.

Subscriptions, not exceeding one guinea each, may be sent to the Treasurer, Secretary, or any member of the Committee, who will also be happy to receive the names of gentlemen wishing to join the Committee.

THE "Queen's Register" is the title of the superbly bound manuscript volume containing the names of all donors and collectors of cards received by the Central Committee of the Countess of Dufferin's Fund in honour of Her Majesty's jubilee year, which, together with an address, has been transmitted to the Queen-Empress.

REFORM OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Rejoinder of the Association of Fellows to the Reply of the Council of the College to the Statement presented to the Lord President on behalf of the same Association.

To the Right Honourable the Lord President of the Privy Council, —The Committee of the Association of Fellows of the Royal College of Surgeons have seen in the medical journals of February 4th the "reply" of the Council of the College to the "statement" presented by the Association to the Lord President. This "reply" is in so many respects misleading that they are reluctantly compelled to ask your lordship's attention to the ensuing rejoinder.

The first clause of the "reply" deals with the number of Members and Fellows. Without criticising the accuracy of these statistics, we would call your lordship's attention to the fact that the number of Fellows, who are the elective body, has been for some time steadily diminishing. In the year 1874, 1,295 Fellows appeared in the College Calendar, and this number has diminished slightly but almost uniformly every year, till in 1887 it was only 1,116. The number of Fellows by examination in the year 1887 was 645. It should be remembered that the chief means by which the Fellowship examination is maintained is the requirement now general at all large London and many provincial hospitals, that their surgeons must be Fellows of the College. There have, however, recently arisen many other surgical qualifications of rival importance, such as the Mastership in Surgery at some universities. If these were admitted by the hospitals as qualifying for their appointments (which is highly probable), the supply of Fellows by examination of the College of Surgeons would probably decline rapidly; and then the privileges which the Council are so anxious to confine to the Fellows would be in the hands of a body evidently too small to administer so important an institution. Nor would the defect be remedied by the proposal of the Council of the College to make large annual elections to the Fellowship, inasmuch as, even if the selections were always judicious, such elected Fellows could scarcely be recognised as representatives of the highest surgical culture.

We are unable to agree with the second and third clauses in the "reply" dealing with the objects of the Fellowship, and stating that all Members of two years' standing can obtain it by examination.

Though it is true that the Fellows constitute the electoral body, the following extract from the *Autobiography* of Sir B. Brodie, to whose initiative the Fellowship owed its origin, will show that this was not its sole object:—

"The object of this institution is to ensure the introduction into the profession of a certain number of young men who may be qualified to maintain its scientific character, and will be fully equal to its higher duties as hospital surgeons, teachers and improvers of physiological, pathological, and surgical science afterwards. With this view, if they have not university degrees, they are required to undergo a preliminary examination in classics and mathematics, while their professional education having been continued for a longer period of time, they are expected to show that they have a more perfect acquaintance with those sciences which are the foundation of medical and surgical knowledge than can be expected of the great majority of those who are candidates for practice. If this system be properly and honestly carried out, I apprehend that the result will be that the Fellowship of the College of Surgeons will be the most honourable distinction that is offered to the junior members of the medical profession." (Sir B. Brodie's *Works*, vol. i, p. 108).

This shows beyond question that the Fellowship was never intended for the same class of men as the ordinary Membership, which is, as Sir B. Brodie says, a minimum qualifying examination. It was intended as a professional distinction—a mark of honour, and it is a creditable feature in the management of the College that the character of the Fellowship examination has been upheld. But it is a mockery to say that any Member of two years' standing may present himself for the examination, when it is perfectly well known that only the very small proportion who have had the time, money, and talent necessary to prepare themselves have any chance of passing. The "reply" says the Fellowship can be obtained without additional expense. Few, indeed, of the candidates do not find it necessary to spend

money on tuition. All must spend their time, which is money to a young surgeon or his friends. As evidence of this, we may say that last year of 142 candidates who presented themselves for the first examination for the Fellowship, 67, or 47 per cent., were rejected; and of 58 who presented themselves for the final examination, 27, or 46.5 per cent., were rejected. All these candidates had gone through the special training required by the College regulations.

The "reply" then details the so-called privileges of Members. Most of these are merely the ordinary rights which no member of any society can be denied, of entrance into the common rooms; and some of them (for example, admittance to the Museum) rest not on the pleasure of the Council, but on Act of Parliament. But as to the eligibility of Members, who are not Fellows, for the Examinerships, the "reply" is most misleading, to use no stronger term. It is true that certain of the Junior Examinerships have lately (and since the beginning of the agitation carried on by this Association) been thrown open to Members; but it is distinctly the reverse of the fact to say that the Members are allowed admissions to all Examinerships except those for the Fellowship. They are not eligible on the Court of Examiners, the only body which admits to the Diploma of Member.

The authors of the "statement" to the Lord President made no complaint of the original creation of the order of Fellows by election. On the contrary, we would remind your lordship that we merely gave a critical explanation of the transaction, and expressed the opinion that no such order should be perpetuated now, but that the only entrance to the ordinary Fellowship should be by examination.

The next clause, which relates to the proposal that a Member should be qualified by a certain seniority before he can vote and before he can become a candidate for a seat in the Council, seems strange to us. Such seniority qualifications exist in the present constitution of the College, and will continue to exist even if the modifications proposed by the Council are introduced into the charter. But the weakness of the argument of the "reply" on this particular is so obvious that we need not labour the point.

Still stranger is the clause about by-laws. The "reply" states that "delay and difficulty" would be caused in the passing of a by-law by an appeal to the Fellows and Members. We say, on the contrary, that such an appeal need not involve one day's delay. In the very "elaborate" process of making a by-law there are intervals between one act of Council and another amply sufficient for calling a general meeting, so that no delay would occur if the Council chose to call this meeting in the interval (at least a month) between the first vote at which the by-law is accepted and the next meeting of the Council to confirm this vote. That the proposal would entail "difficulty" in passing by-laws condemned by the general opinion of the profession, such as that relating to the Fellowship examination, referred to in our "statement," we cordially admit, and for that reason we press it on your lordship's consideration. Even, however, if the progress of new by-laws were to be somewhat slower, where would be the harm? The Council has had a working experience of 87 years, and it is scarcely conceivable that any occasion should arise for the urgent and hasty alteration of a by-law. And we cannot forbear again to remind your lordship that the Fellows and Members are bound to observe the by-laws without at present the power of opposing any addition or alteration made in them.

With regard to the election of President, we may say, without fear of contradiction, that the routine method uniformly followed up to the time of the first re-election of the present President in July, 1886, is generally disapproved, and that the fact that the President has now been twice re-elected does not afford any guarantee that the former custom will not be resumed as soon as it is thought that public interest in the matter has subsided. With regard to the objections to our proposal stated in the "reply," we answer (a) that while the great body of the Fellows may never have been specifically consulted in the matter, the general principle was adopted at the meeting of Fellows and Members held in 1884, and by every member of this Association; (b) that the proposed arrangement is exactly that which prevails for Members of Council, and which has not proved an insurmountable obstacle to the present councillors coming forward as candidates, nor has the fact that the President of the College of Physicians is elected by a general meeting of the Fellows prevented the most eminent men in the profession from coming forward for the presidency of that body; (c) that if the Council are the best judges of the qualifications of their own Members for the presidency,

they have never exercised any such judgment, but have, up to eighteen months ago, passed the office round in rotation; (d), (e), and (f) that these supposed objections apply equally to the present mode of election to the Council, and from their not producing any of the supposed results, may be inferred to be imaginary.

We cannot but most earnestly protest against the assertion in the "reply" that the College is not a "political" institution. A body having functions and privileges derived from the State, and having such important duties and responsibilities both to the public and to individuals, cannot be called private, and its well-being and good government are matters of general concern.

As to the results of the inquiries made by the Council, they are perfectly worthless for the present purpose, since the opinion of the Fellows was not asked as to the actual proposals of either the Association of Fellows or that of Members. Still, as we have shown to your lordship, the result was clearly to prove that the majority of the Fellows have expressed no objection to the principal claims of the Members. The number of the Members who have signed the petition presented to your lordship (4,665) is, if not a majority, we believe, nearly half of those in the United Kingdom who can be reached through the agency of the Post Office.

With regard to what in the "reply" is brought forward as an instance of the inaccuracy of our "statement," we are justified in retorting that the inaccuracy is not ours. We never said that the principle of a union between the College of Surgeons and that of Physicians had not been sanctioned by a resolution passed at a general meeting. What we complained of was that the completed scheme had not been submitted to the whole body of the College, as it was to the Fellows of the College of Physicians; and that a portion of it so vitally important as the exclusion of the Society of Apothecaries had been insisted on, in spite of the protest, not only of the Fellows and Members (also assembled in general meeting), but of the General Medical Council. It is, however, surprising to find the Council of the College now sheltering themselves under the authority of the resolution passed at the meeting in 1884, which was proposed without notice, and was carried by twelve votes against six, at the end of a long meeting, when the room was nearly empty, while they treat with entire indifference the resolutions lately passed with only either one or two dissentients, at one of the fullest meetings that ever assembled in the Theatre of the College.

With regard to the proposal in the Council for admitting fifty Members a year to the Fellowship, it was no doubt never brought on for discussion—a result which we have reason to believe was largely due to the opposition of this Association. But the fact that such a proposal was made, and (as we have also reason to believe) that it was suggested to elect even 100 Members annually to the Fellowship, shows how strong the temptation may be for the Council to resort to measures of this kind, by which the order of Fellows can be recruited without any regard to the "professional merit" of the persons elected. The present proposal of the Council is only somewhat less objectionable; and the "reply" of the Council itself tacitly admits that it has been emphatically condemned, by the voice of their own Members, as inconsistent with the high objects for which, according to Sir B. Brodie, the Fellowship was instituted.

On all which grounds we submit to your lordship that the "reply" of the College leaves our "statement" entirely unrefuted, and confirms our contention that the petition of the Council for a modified charter should be referred back to them for reconsideration and discussion with the general body of their constituents.

(Signed) G. D. POLLOCK.

POSTSCRIPT.—In order to prove to your lordship that our sentiments are not unrepresented on the Council of the College, we beg to call your attention to the following amendment, which was moved and seconded at the meeting of the Council at which their "reply" was settled.

(This amendment was published in the JOURNAL of February 25th.)

DR. H. C. REID, of Coatbridge, was recently presented by the Coatbridge Foresters with an excellent life-size portrait of himself in oils.

Of the 10,679 students of the University of Paris, 3,696 are studying medicine, and 1,767 pharmacy. There are 167 female students—108 of medicine, 7 of science, and 1 of law. There are 593 foreign students of medicine, 58 of science, and 21 of pharmacy.

THE DUTIES AND PAY OF THE MEDICAL STAFF.

A CORRESPONDENT, writing on this subject, has sent us some detailed remarks, of which we can only give a summary. His observations are, however, of special value just at present, because they bear directly on the line of attack which in all probability will soon be made on the medical vote by certain economists. He, in truth, but makes a little plainer what everyone who cares to look below the surface already well knows, that the life of the army medical officer is anything but the one of ease and idle swagger which the enemies of the Department would fain have the unthinking public believe. Neither are his functions merely those of the "good doctor," which even some who must know a great deal better are too fond of reiterating; but rather, and far more, those of the good all-round officer, whose well-performed duties are not only essential to the discipline, but to the very fitness of the army as a military machine. His duties, in fact, are essentially those of the thoroughly trained life-worker, and cannot be suddenly, much less systematically, assumed by any medical volunteer or tyro, however willing; still less successfully farmed out haphazard in casual medical "contract."

When the fit of economy (which seems to recur regularly at intervals of years) recently set in, the medical vote, as on former occasions, was about the first attacked; not, indeed, in the "service" papers, which are posted up in the real facts, but in so-called "Society" journals, hitherto, at all events, not distinguished for accuracy in military matters. Now, the medical vote may be a very bloated one; or, as we believe, only sufficient for the wants of a great and important army department; but, whether or not, we would not seek to defend it on narrow professional, but on broad public, grounds. We do protest, however, that, in discussing it, fairplay should at least be shown to the officers and men of the Medical Staff, and all unworthy and scurrilous detraction avoided.

The cry "Ye are idle" is as old as the Pharaohs; and it is not the first time it has been most unjustly resuscitated against medical officers; but now it is combined with another clamour, that these officers are overpaid both on pay and pension for the little they do! Let us remind virtuous economists why the present scales of pay and pension were granted; simply in strict obedience to the inexorable law of supply and demand, which, whether they like it or not, governs the value even of medical as it does of all other work in a free country. It is quite useless for them to draw comparisons between, say, the British and German rates of army pay; it will be time enough to do that when the conditions of service in the two armies have any similarity; when, for instance, we adopt compulsory service, and the Germans, having acquired a great foreign empire, exact military service from their soldiers all over the world and in all climates.

It should be particularly noted that whenever an economical clamour has been got up against the Medical Department, it has always had reference to its peace duties, never to its functions in war; indeed, this is very necessary to make the outcry any way effective in the all too forgetful public ear. Every reminder of war has to be avoided; the ugly word might recall Crimean horrors, the result of attenuated and unorganised departments; it might even straightway raise the question, how, from an attenuated medical list, Lord Wolseley's "two army corps, always ready for mobilisation," are so suddenly provided with 400 trained medical officers fit to take the field. These are awkward questions, but we are not without indications of the sort of answer with which the shifty economists would try to meet them. They would, in effect, say: "Are there not plenty of medical rolling stones, chronic students, and women nurses to form a scratch medical service for the two army corps when wanted? Can we not, when in difficulty, play off (financially) the needy civilian against the greedy, haughty army doctor? Can we not leave things to chance, or boldly put up the lives and limbs of our soldiers, both in peace and war, to civil medical 'contract'?" Fortunately, there are arguments probably sufficient to nip such happy-go-lucky proposals in the bud. Would the humanity and common sense of the country consent that the health and wounds of our soldiers be left to such chance medical and surgical aid as can be best picked up by civil "contract"? Would our responsible military authorities accept for field service, without protest, a scratch medical service got together anyhow at the beginning of a great war? What if the soldier himself should resent a purely heart-

less economy which seeks to place his life on the battlefield in the hands of undisciplined and irresponsible strangers?

We think, therefore, that when the country is duly informed on this subject, it will not for a moment permit the Army Medical Department to be crippled or starved to meet the exigencies of party politics. It is much more likely to insist that a well-manned and thoroughly organised medical service be maintained, even although it does cost money.

Our correspondent's remarks are almost wholly confined to the medical duties during peace. Even these can be shown to be anything but unimportant, and just as exacting and never-ceasing as professional practice in civil life. It is well that those who are ill informed, or perhaps altogether ignorant of their nature, should know what they are. His observations are limited to the medical care of the army at home and in the colonies, altogether excluding the great interest of India, which absorbs one-third of the entire Medical Staff. He classifies the peace duties as follows:—

- A. With regular troops.
- B. With militia.
- C. As officers of the Medical Staff Corps.
- D. Miscellaneous.

Under A he mentions:—

1. *Attendance on Sick in Hospital.*—He states that in 1885 the sick (exclusive of India) admitted into military hospitals numbered 114,295, and the average duration of the cases was 18½ days. He points out that these sick are visited by the medical officers twice daily, or oftener, if necessary; that prescriptions, diets, and records of cases, with the entry of every little "extra" and "medical comfort," have to be in the officer's own handwriting; that he is responsible for check and countercheck of all expenditure. Is this necessary? Most assuredly, if the sick, on the one hand, are to have proper treatment, and the public, on the other, are to be safeguarded against inordinate hospital expenditure. The smallest reflection will show that unchecked and unauthorised hospital expenditure would speedily run up totals sterling which would make the economist stare, and beside which the mere salaries of the medical service, at which he grumbles, would look small indeed!

2. *Daily Sick.*—Besides sick admitted, there are naturally and inevitably a large number of men who receive slight treatment while remaining at their duty, but nevertheless involving considerable medical labour. For, let it be noted, the medical officer has not only to be careful that none really sick are refused admission, but he has to discriminate and checkmate schemers wishing, perhaps, to escape some unpleasant duty. Let those who grudge the medical officer his pay, and sneer at or minimise the value of his services, consider what would be the state of the daily sick lists, what the hospital expenditure, if there were no trained, expert, and responsible medical officers keeping watch, as it were, at the entrance to the wards:

Not only are the medical officers constantly on duty in relation to the patients under their immediate care, but in all the larger hospitals they have besides to take their turn, every third or fourth day, on "orderly duty" for twenty-four hours at a time, during which they must not leave the precincts of the hospital. It is well known that medical officers prematurely break down and die in a much greater proportion than any other class of army officers, and we cannot help thinking the perpetual grind of ordinary duty every day in the week has more to do with undermined health than even trying foreign service.

3. *Recruiting.*—Our correspondent states that 72,249 recruits were examined by army medical officers in 1885. There are few more fatiguing and responsible medical duties than the thorough examination of a recruit; it is truly the work of an expert, and should only be entrusted to officers of wide experience. It is the medical officer, and he almost alone, who guards the portals of entrance into the service, and stands between the State and numberless methods of chicanery and fraud; all who have a money interest in the recruit are against him; the admission of unsuitable men and fraudulent re-enlistment, if not checked by the fitness and skill of the medical officer, would cause enormous loss to the public. Besides recruits, all men re-engaging or passing into the Reserve have to undergo medical examination.

4. *Vaccination.*—In 1885, we are told, 39,433 men, women, and children were vaccinated or revaccinated in the army.

5. *Inspection of Prisoners.*—154,026 minor punishments were inflicted, and 7,790 men were tried by courts martial, during 1885.

Now no soldier can be awarded or undergo any punishment without being previously medically examined and certified fit; and no court martial can proceed without a medical certificate as to the prisoner's fitness or otherwise to undergo imprisonment, with or without hard labour. Every prisoner in confinement must also be daily visited by a medical officer. Are these unimportant duties? It simply comes to this, that the medical officer plays a most important part in maintaining the discipline of the army. Without his discrimination, skill, and firmness, the best commanding officer would be powerless; the prisoners would laugh at his awards, and find means of avoiding punishment.

6. *Attendance on Officers, their Wives and Families, Servants, and on Soldiers' Wives and Children.*—This forms no inconsiderable part of a medical officer's duty.

7. *Boards.*—These may be strictly professional, or mixed with other branches of the service, on sanitary deliberations, stores, etc., all requiring technical knowledge and training. How, we should like to know, are such duties to be carried out by civilians on "contract"?

8. *Sanitary Duties.*—No duties of the medical officer are of more vital importance to the army than these; thorough and incessant sanitary supervision of barracks, quarters, camps, and their surroundings has to be kept up. Through unceasing watchfulness of this kind at home and abroad, the Medical Department has been instrumental in enormously reducing the sick- and death-rate of the army during the past thirty years at a saving to the State many hundredfold more than any increase of medical pay and pensions. Such services may be conveniently forgotten when suitable, but they stand recorded and cannot be ignored.

9. *Correspondence and Returns.*—In a widespread army, and with a public demanding statistics and information of every kind, the returns are naturally of a complex and voluminous kind, requiring much special knowledge of the regulations. Would this work be successfully handled by "contract"?

10. *Responsibility for Public Property.*—This is an important medical duty, that might touch the heart of the virtuous economist, if nothing else would. The unthinking and uninformed may ask, "Why saddle the medical officer with this?" Well, somebody must be responsible for hospital property, and if not the medical officer, then there must be some other well-paid official, introducing an additional and fresh element of expense. But the proper man is the medical officer, who must be master in his own hospital, and in the interest alike of the patient and the public, unsheltered behind conflicting and divided responsibility. Will it be proposed to put up the care of much valuable hospital bedding, furniture, equipment, and stores of all kind to "contract"? Or do the War Office authorities expect civilian practitioners, or any others, will accept "financial responsibility" for nothing?

B. *Duties with Militia.*—As the old militia surgeons have disappeared, their duties for years past have been assumed by the army medical officer without additional emolument, with a consequent considerable saving to the State. The permanent staff of the militia are now attached to the various regimental districts, as well as recruiting and training.

C. *Duties as Officers of the Medical Staff Corps.*—These are of the first importance, and involve command, discipline, interior economy and payment, and the training of 2,000 men. They necessitate, also, a certain knowledge of drill and military law. Certain innocent civilians may ask, as certain jealous soldiers who would like to deprive medical officers of all army rank and status do, with a sneer, "Is this 'doctors' work?" The answer is, it is without doubt one of a military medical officer's proper duties, essential to his training for peace and war, as well as for the due performance of his daily work. Divided authority in a military hospital as in any institution, is wholly fatal to efficiency; and it is just as essential that the hospital servant and subordinate should look upon the medical officer as his real master, as the soldier in barracks on the colonel as his commander. The function of command of the Medical Staff Corps was at one time delegated to another set of officers, with the result that there was much confusion and bad work.

D. *Miscellaneous Duties.*—Under this head our correspondent mentions charge of such institutions as the Royal Military Academy, Woolwich; Military College, Sandhurst; military schools, Chelsea and Dublin; military prisons; Royal Arsenal, etc. He asks, what would civilians expect for medical work of such an onerous and responsible nature as charge of these institutions? Could they be safely handed over to the nearest general practitioner by "con-

Table showing the Daily Rates of Pay of different Branches of the Army taken from the Royal Warrant on Pay and Promotion of 1884.

No. of years' Service Required.	Medical Staff.		Commissariat Department.		Chaplain Department.		Ordnance Store Department.		Pay Department.		Royal Engineers.		Foot Guards.	
	Rank.	Daily Pay.	Rank.	Daily Pay.	Rank.	Daily Pay.	Rank.	Daily Pay.	Rank.	Daily Pay.	Rank.	Daily Pay with higher near a Pay.	Rank.	Daily Pay.
On appointment	Surgeon	£ s. d. 0 10 10	D. A. C. G.	£ s. d. 0 12 6	Chaplain 4th class	£ s. d. 0 10 0	D. A. C. G.	£ s. d. 0 12 6	Paymaster	£ s. d. 0 15 0	Lieut. under 3 years	£ s. d. 0 9 7	Lieut.	£ s. d. 0 9 1
After 5 years' service	"	0 13 9	Do. from 3 to 5 years	0 15 0	"	0 12 6	Do. 5 years	0 15 0	Do. 5 years	0 17 6	Do. after 3 years	0 10 10	Do. after 3 years.	0 10 4
After 10 years' service.	"	0 15 0	Do. 10 years	1 0 0	3rd class	0 15 0	Do. 10 years	1 0 0	Do. 10 years	1 0 0	Do. after 10 years	0 11 10	Do. after 10 years	0 11 4
After 15 years' service.	Surg.-Major.	1 2 6	A. C. Genl.	1 5 0	2nd class	0 17 6	A. C. Genl.	1 5 0	Staff Paymaster	1 2 6	Captain Do. higher (brevet rank)	0 17 7	Captain Do. higher (brevet rank)	0 19 2
After 20 years' service	"	1 5 0	Do. after 5 yrs in the rank	1 10 0	1st class	1 0 0	Do. 5 to 10 yrs	1 10 0	Do. after 5 years	1 5 0	Major	1 5 0	Major	1 2 10½
After 25 years' service	Surg.-Maj. Brig.-Surgeon	1 7 6	Do. after 10 years.	1 10 0	"	1 2 6	—	1 10 0	Chief Paymaster	1 10 0	Lt.-Colonel	1 13 0	Lt.-Colonel	1 3 11½
Uncertain		2 0 0												
"	General.	2 15 0	Com. Genl.	3 0 0	Chap.-Genl.	£800 yearly	—	—	—	—	Generals	4 5 0 to 9 17 9	Generals	4 5 0 to 9 17 9

From this Table it will be seen that medical officers (who are professional men) are paid very much at the same rates as the officers of other departments for which very little special training is required. It will also be seen that the Guards and Engineers are paid very nearly, if not quite, as well as the medical officers, and have other advantages, such as mess allowances, etc., besides. The only real advantage medical officers have is the higher rate of pension. Against this must be placed the foreign service and the mortality, which exceeds greatly that of any other branch of the army.

tract"? He should have included also among miscellaneous duties attendance on inspections, parades, field-days, etc. We would ask, who but a commissioned, uniformed medical officer should or could perform such duties?

Having thus sketched out the multifarious duties of the army medical officer, which go far beyond those merely of the "good doctor" kind, our correspondent proceeds to estimate the money value of these duties as measured by what civilian medical men would expect to get for their performance, supposing they could or would undertake them. We fear our correspondent here enters on a somewhat futile and unprofitable task. After what we have said, surely no reasonable man will affirm that the army medical officer's special training and skill can be bought ready-made in the civilian market, whatever the price offered? It is no doubt true that the sick soldier might, in certain places, be duly "physicked" in a civil hospital by "contract." But at what cost? The surroundings of such an establishment would speedily unsoldier him; unless the military discipline of the barrack and the parade follows the sick soldier to hospital, he would very soon become no soldier at all. That would be one fatal result of a "contract" system.

But our correspondent—taking no account of such trifles as command of the Medical Staff Corps, responsibility for equipment and stores, and the many miscellaneous duties daily performed by the medical officer—proceeds to work out the value of the merely professional treatment of the soldier at home and in the colonies. At the shabbiest rates of "contract," what would be the cost? He assumes as data 2s. for each day of each man sick; a lump sum for care of daily casual sick; a lump sum for militia, chiefly for recruiting; 5s. for each army recruit passed; 2s. 6d. for each vaccination; and arrives at the following totals:—

Attendance on sick in hospitals ...	£211,445
Treatment of daily casual sick ...	8,572
Militia ...	10,000
Recruiting of Regulars ...	10,000
Vaccination ...	5,000

Total ... 245,017

We will not attempt to criticise, much less verify or vouch for, these figures. They may be too little or too much, but as they stand are, at all events, no improvement, from an economical point of view, on the medical vote of £246,000, which includes provision for all the duties.

But even supposing they represented a large peace saving, do they furnish the smallest provision for war? An army is no army if unfit to take the field, and in these days no army dare take the

field, with any chance of success, unless thoroughly organised during peace. The truth is, the efforts to get rid of the medical officer by substituting civil "contract," show the most lamentable ignorance of, or indifference to, the perfecting of military organisation, and a most misguided statesmanship.

Our correspondent concludes by offering some remarks on the pay of medical officers, and by way of comparison with those of other officers, furnishes a table, which we here reproduce.

From this it appears the mere pay of the medical officer is not much superior to those of other officers who bring with them into the service no expensive special education acquired at private cost. Then, again, medical officers have few or no staff and other appointments giving additions to pay, such as the combatant officer can look to. We should like to know, what with frequent moves and the thousand and one expenses consequent on a nomadic sort of existence, how much a medical officer is expected to save from his pay for himself or family—if he has one? He, in truth, has nothing to look to but his pension, or more properly, deferred pay, an annuity which dies with him. Consider, also, the risks he has to run before he can get a pension. We hear rumours and threatenings, that in future a longer period of full-pay service will be exacted before he can claim pension; this, according to well understood actuarial calculations, would have the effect of increasing the risks, and lessening the value of the pension when obtained. A pension only held out to a man when years are on him and health has gone is but a lure and a snare; the odds against him rapidly increase, and become more and more in favour of those offering the pension. If too vigorous conditions of full-pay service are exacted, this ultimately may become so apparent, that double or treble pay will be demanded, and pensions allowed to go by the board.

In conclusion, we regret we cannot help thinking, that not zeal for public economy alone has prompted late unfair attacks on the medical vote, but there has been mixed with it not a little hostility to the medical profession at large.

HEALTH OF ITALIAN TROOPS AT MASSOWAH.—A correspondent of *La Semaine Médicale* states that typhoid fever and acute rheumatism are very prevalent among the Italian troops at Massowah; the number of sick is between twelve and thirteen hundred, and two or three deaths occur daily.

THE MOSCOW MEDICAL FACULTY IN 1887-88.—According to the *Vratch*, No. 4, 1888, p. 75, on January 1st, 1888, the Moscow University numbered 3,259 students, 1,218 of whom belonged to the medical faculty. During 1887, 231 obtained the diploma of medical practitioner (*lekar*).

GREAT NORTHERN CENTRAL HOSPITAL.

On Saturday, February 25th, the new buildings of this institution were shown to visitors by the architects, Mr. Keith Young and Mr. Henry Hall. So far as at present constructed the hospital consists of three rectangular wards (twenty beds in each), one above another in a building of three stories, with a block for administrative purposes, and separate buildings for the out-patient department and mortuary chambers. It is also in contemplation to erect a block containing three circular wards (twenty beds in each), so that when the hospital is finally completed, it will be capable of making up 120 beds, besides the accommodation of the special wards (one bed in each), and provision is also to be made for the reception of 24 paying patients. As at present arranged, each bed in the rectangular wards will have 127.5 square feet of floor space and 1,650 cubic feet of air space, each ward having a length of 88 feet, a breadth of 29 feet, and a height of 13 feet. The circular wards will have a diameter of 57.5 feet and a height of 13 feet, which will give practically an identical amount of floor space and air space to each one of the twenty beds which they are to contain. It will thus be seen that when finally completed an interesting experiment will be carried on within the walls of this institution, which should go far to settle the claims made as to the rival merits of the oblong and circular ward systems.

It is, perhaps, needless to say that, in the general design, the best approved and most modern principles of hospital construction, ventilation, warming, drainage, and general convenience have been everywhere applied by the architects. The lowest ward is raised some feet from the ground by vaults open on each side for their whole length for thorough ventilation; there is, thus, no possibility of ground air gaining admission into the wards. The arrangements made for the ventilation of the wards are most complete. In winter fresh air is admitted warmed by passing through one of two stoves (Boyd's Hygiastic Hospital Grates) placed in the centre of the ward; whilst in summer the outer air can enter in an upward slanting direction by revolving on its lower border the upper portion of each one of the windows, and special fresh air wall inlets are also provided near the floor at the heads of the beds. For the escape of vitiated air there are four extraction shafts for each ward, which are kept warm by the flues of the stoves in winter and by Bunsen gas burners in summer. The wards can be heated as well by hot water pipes leading from a boiler house. Each ward is paved with solid wood-block flooring, and the beds are fitted with spring wire mattresses and movable fracture boards. At the further end of each ward are the water closets, bath room, and slop sinks in a turret block separated from the ward by a cross ventilated lobby. The roof of the building is flat, and is to be used as an exercise ground for the patients; there is besides a covered balcony attached to each ward for the use of patients. The kitchens and sculleries are placed at the top of the building; all the cooking is to be done by gas and steam. A very commodious operating theatre lighted from the roof is in connection with the first floor, and a hydraulic lift large enough to carry a hospital bed runs the whole height of the building from roof to basement. Attached to the boiler house is a small destructor furnace for burning dirty dressings, poultices, bandages, etc., which are usually relegated to the dusthole. The water supply and drainage appliances are the best of their kind. Great care has been bestowed on the ventilation of drains, soil pipes, and waste pipes, and we were glad to see that siphonage of water closet traps—a possibility often overlooked by architects—is rendered well nigh impossible by the system of ventilation pursued. The main drain is a 9-inch pipe which is laid outside the building, and is disconnected from the sewer in the usual manner.

The out-patient department has been designed to secure at once the greatest amount of comfort to the patients during their long hours of waiting, as well as the requisite facilities for the out-patient surgeons and physicians in their examination and treatment.

It is only to be regretted that to such a hospital there is no medical school attached, but it is intended that the institution shall be open to medical practitioners in the neighbourhood, and it may possibly add to its usefulness by becoming an important post-graduate teaching centre for the north of London.

ASSOCIATION INTELLIGENCE.

NOTICE OF QUARTERLY MEETINGS FOR 1888.

Meetings of the Council will be held on April 18th, July 18th, and October 17th, 1888. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before each meeting, namely, March 28th, June 27th, September 26th, and December 28th, 1888.

ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No member can be elected by a Branch Council unless his name has been inserted in the circular summoning the meeting at which he seeks election.

FRANCIS FOWKE, *General Secretary.*

COLLECTIVE INVESTIGATION OF DISEASE.

THE Report upon the CONNECTION OF DISEASE WITH HABITS OF INTEMPERANCE, which was presented to the Section of Medicine in the Annual Meeting of 1887, and a further portion of the Report upon OLD AGE have been completed, and will shortly be published in the JOURNAL.

Reports upon the two remaining inquiries, namely, that into DIPHTHERIA, and that into the GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES, are in preparation, and will be published as soon as ready.

The following inquiry only of the first series remains open, namely, that on THE ETIOLOGY OF PHTHISIS.

A fresh inquiry into the ORIGIN AND MODE OF PROPAGATION OF EPIDEMICS OF DIPHTHERIA has just been issued.

Memoranda upon these subjects, and forms for recording observations, may be had on application to the Secretary of the Collective Investigation Committee, 429, Strand, W.C.

BRANCH MEETINGS TO BE HELD.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT.—The next meeting of the above District will be held at Ashford, on Thursday, March 15th. Dr. Wilks in the chair. Anyone wishing to send communications should inform the Honorary Secretary at once.—W. J. TYSON, 10, Langhorne Gardens, Folkestone.

EAST SURREY DISTRICT: SOUTH-EASTERN BRANCH.—The spring meeting of this District will be held at the Queen's Hotel, Upper Norwood, on Thursday, March 8th, at 4 P.M.—W. F. R. BURGESS, M.D., of Streatham, in the chair. Dinner at 6 P.M.; charge, 7s., exclusive of wine. The following papers have been promised: Mr. Noble Smith: On Hip-joint Disease, with diagrams. Dr. P. T. DUNCAN: On Simple Catarrhal Fever. Members desirous of exhibiting or reading notes of cases are invited to communicate at once with the Honorary Secretary, P. T. DUNCAN, M.D., Croydon.

METROPOLITAN COUNTIES BRANCH: EAST LONDON AND SOUTH ESSEX DISTRICT.—The next meeting will be held in the Hackney Town Hall, on Thursday, March 15th, at 8.30 P.M. A paper will be read by A. J. PEPPER, Esq., on Medical Evidence in Courts of Law. Visitors will be welcomed.—J. W. HUNT, Honorary Secretary, 101, Queen's Road, Dalston.

SOUTH-EASTERN BRANCH: EAST AND WEST SUSSEX DISTRICTS.—A conjoint meeting of the above districts will be held at the Grand Hotel, Brighton, on Thursday, March 22nd. F. W. SALZMANN, M.R.C.S., will preside. Meeting at 8.30 P.M.; dinner at 5.30 P.M.; charge 6s., exclusive of wine. The following papers will be read: Dr. Starling: A case of Fibroid Induration of the Stomach (with specimens). Dr. Howard Marsh: Recovery after Laparotomy for Intestinal Obstruction; with Remarks. Gentlemen desirous of making any communication to the meeting should write to the undersigned or to Dr. Gostling, West Worthing.—T. JENNER VERRALL, Honorary Secretary, 97, Montpelier Road, Brighton.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH.—The sixth general meeting of this Branch will be held in the Medical Institute, Edmund Street, on Thursday, March 8th, 1888. The chair will be taken by the President, Mr. Lawson Tait, at 3 P.M. Business: The following member of the Association will be proposed as a member of the Branch: E. R. WOODHOUSE, M.B., C.M. Edin., West Bromwich Hospital. The officers of the Branch to be elected at the annual meeting will be nominated. Papers: Dr. Suckling: Alcoholic Paralysis. Mr. J. W. Taylor and Dr. Stacey Wilson: Treatment after Perforation from Ulcer of Stomach. At the Council meeting to be held after the Branch, the following gentlemen will be proposed as members of the Association: James A. B. Thompson, M.D. Glasgow, Bradles, Warwickshire; Frank J. Allen, M.A., M.B. Cantab., Mason College, Birmingham; Joseph Henry Patrick, M.R.C.S., 212, Balsall Heath Road; John Angell James, M.R.C.S., L.R.C.P., Queen's Hospital. Mem.

bers are invited to exhibit patients, pathological specimens, new drugs, instruments, and appliances at the commencement of the meeting.—ROBERT SAUNDY, M.D., 83A, Edmund Street; JORDAN LLOYD, F.R.C.S., 22, Broad Street, Birmingham, Honorary Secretaries.

SOUTHERN BRANCH: ISLE OF WIGHT DISTRICT.

An ordinary meeting of this District was held at Daish's Hotel, Shanklin, on January 26th, 1888. The chair was taken by Mr. CHARLES MEERES.

New Members.—The following new members were admitted: G. Bernard Hoffmeister, M.D., Cowes; Henry Harland, M.D., Ryde.

The Heart in Phthisis.—Dr. ROBERTSON gave notes as to the results of a careful physical and sphygmographic examination of the heart and pulse in fifty cases of phthisis.

Demonstration.—Mr. ELLIS exhibited sections of a Carious Tooth under the microscope, showing the manner in which, after erosion of the enamel, the leptothrix buccalis inserted itself, wedgeshape, and split up the tooth, allowing decay to progress rapidly.—Mr. GREEN exhibited Tinea Trichophyton, and also photographs of the diseased and natural hairs as seen under the microscope; also Microsporon Fur-fur, Gregarines, the Bacillus of Anthrax, and Diplococcus of Pneumonia.

Antifebrin in Phthisical Pyrexia.—Dr. SINCLAIR COGHILL read a paper on this subject. He began by reference to his previous paper on the Action of Kairin, Thallin, and Antipyrin. He had entirely given up the two former, but had continued to employ antipyrin, but in cases in which that drug had failed to reduce temperature he had latterly employed antifebrin with much success; indeed, he thought it preferable to antipyrin. It produced no unpleasant effects, and seemed to be tolerated for indefinite periods. In commencing its administration it was as well to test the tolerance of the patient by giving a dose of 5 grains, but usually 10 grains would be found the best initial dose. The temperature should be taken every three hours, and a dose of from 5 to 7½ grains given each time it registered above 99°. He had found the control of the pyrexial state, when treated by antifebrin or antipyrin, much aided by giving tincture of strophanthus in doses of from 3 to 5 drops three or four times a-day, to sustain the action of the heart, and reduce the vascular tension, which was certainly increased by the action of these drugs. From 5 to 10 grains of quinine should also be given as often as the temperature was found under 98°. He also showed a chart of a case of enteric fever in which antifebrin had kept the temperature steadily under control.

Dinner.—The members afterwards dined together, and a pleasant evening was spent.

NOVA SCOTIA BRANCH.

THE third ordinary meeting of this Branch was held at the Hon. Dr. Parker's office, Halifax, on February 16th, 1888. Present: Deputy Surgeon-General MACDOWELL, C.B., President of the Branch, in the chair; Hon. Dr. Parker, Dr. Farrell, Surgeon-Major Bolster, A.M.S.; Dr. de Witt, Dr. Wickwire, Surgeon Deeble, A.M.S.; Dr. Trenaman, City Medical Officer of Health; Drs. Black, Campbell, Curry, Surgeon Fowler, A.M.S.; Surgeon Grier, A.M.S.; Drs. Cameron, Godwin and Chisholm; and Dr. Tobin, Honorary Secretary.

Injuries to the Eye.—Dr. TOBIN read notes of three cases of injury to the eye, involving the cornea and iris and the lens; in two instances producing traumatic cataract. In all, the wound was in the ciliary region or dangerous zone. In one the sclerotic had been freely opened, and required a suture to retain the contents of the globe; yet this case had recovered with a fair amount of vision. In all an indelible cicatrix occupied the area of the pupil, extending across the cornea, but leaving the rest of that membrane transparent. The eye, in all three cases, had been saved, and no sympathetic trouble had, so far, arisen though several months (in two of the cases) had elapsed since the receipt of the injury. The patients were brought in and examined by the members present.

Proposed Public Health Act.—A letter was then handed in from Mr. Bulmer, barrister-at-law, asking the help of the Branch towards procuring from the local Legislature a Public Health Act, the same being much needed in this province. The letter was discussed, and a Committee appointed consisting of three civilian (Drs. Trenaman, city medical officer; Drs. Campbell and Curry) and two military members (Surgeons Deeble and

Grier), to report upon the matter to the Branch at an extraordinary meeting to be held a fortnight hence.

Appointment of Treasurer.—Dr. TOBIN then proposed that a treasurer be appointed to collect subscriptions from members for the BRITISH MEDICAL JOURNAL, and to forward the same to the General Secretary in England; also to collect the local subscription for the Branch. A motion to that effect was moved and seconded, and carried, and Dr. Tobin was himself desired to act as treasurer as well as secretary to the Branch. The meeting then adjourned.

JAMAICA BRANCH.

THE annual meeting of this Branch was held at the Public Library, Kingston, on January 27th.

Office-bearers.—The following are the office-bearers for the present year:—*President:* Hon. J. C. Phillippo. *President-Elect:* Dr. F. H. Saunders. *Honorary Secretary and Treasurer:* Dr. G. F. Da Costa. *Members of Council:* Dr. A. L. Saunders; Dr. J. L. Cox; Dr. C. Gayleard; Dr. Plaxton; Dr. G. C. Henderson; Hon. C. B. Morse; H. Strachan; Dr. J. Scott.

Dinner.—The annual dinner was held in the evening at Park Lodge, at which eleven members were present.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.

THE February meeting of the Branch was held at 198, Union Street, Aberdeen, on Wednesday, February 15th, at 8 P.M., Dr. URQUHART, in the chair.

Minutes and Nomination of New Members.—The minutes of the last meeting were read and approved, and seven new members were nominated for ballot at next meeting.

New Member.—Dr. J. Marshall Lamb, Borneo, was admitted a member of the Branch.

Medical Officer of Health for Aberdeen.—Dr. WIGHT proposed a motion that the Branch memorialise the Town Council of Aberdeen that the appointment of medical officer of health, at present vacant, be filled up by a qualified medical practitioner, who shall be precluded from private practice, and whose whole time shall be devoted to the duties of the office, in terms of the duties of the medical officer of health of the city of Aberdeen, of date March 15th, 1886.—Dr. URQUHART seconded the motion.—Dr. ANGUS FRASER moved as an amendment that the Branch do not memorialise the Town Council, on account of being beyond its province.—Professor STEPHENSON seconded.—The amendment being lost, Professor OGSTON proposed that the words following "private practice" in Dr. Wight's motion be altered to read "and who shall devote himself to sanitary and medico-legal work."—Professor STEPHENSON seconded this amendment, which was lost on being pitted against Dr. Wight's motion. The latter accordingly became the ruling of the meeting, and the secretaries were instructed to have the memorial prepared and submitted to the Town Council of the city.

METROPOLITAN COUNTIES BRANCH: EAST LONDON AND SOUTH ESSEX DISTRICT.

A MEETING was held at the Town Hall, Walthamstow, on Thursday, February 15th, at 8.30 P.M. Present, 21 members and visitors. Dr. ADAMS, Vice-President of the District, was in the chair.

Pernicious Anæmia with Jaundice.—Dr. BRISTOWE read a most interesting paper on Pernicious Anæmia with Jaundice, and Cases illustrating it, and he compared those cases with others of jaundice which were not due to pernicious anæmia. A discussion followed.

Specimen.—Mr. G. WELLER showed a specimen of typhlitis due to perforation of the vermiform appendix, and read notes of the case.

Votes of Thanks.—Hearty votes of thanks brought the meeting to a close.

SALOL IN CYSTITIS.—Professor Demme, of Berne, has recorded (*Therap. Monatshefte*) a case of cantharidin poisoning following the application of an enormous blister over the sacrum. The patient was a boy, aged 5, and the blister was recommended by a "friend" as a cure for nocturnal incontinence of urine. The general symptoms were very severe for two days, and subsequently the boy suffered from cystitis, which, however, yielded to salol. The quantity given daily was gradually increased from twenty-three grains to thirty-eight grains; improvement commenced on the second day, and the cure was complete on the fourteenth day of the treatment. In another case of cystitis, which had been caused by measles, salol was also given with benefit.

SPECIAL CORRESPONDENCE.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

Transmission of Human Tuberculosis to a Cat.—Eye Lesions in Leprosy.—Pathogeny of Bright's Disease.—Treatment of Diphtheria.—Local Anæsthesia.—Enlargement of Supra-clavicular Glands in Uterine Cancer.—Salicylic Acid in Phthisis.—Pyridin Inhalations in Dyspnoea.—Preparations of Catgut.—Intramuscular Injections of Quinine in Malaria.—Heart Disease and Marriage.—Case of Narcolepsy.—Naphthol as an Antiseptic.

DR. LÉON PETIT, at the Société de Médecine Pratique (*Journal de Médecine*, January 1st, 1888), lately described a curious case of pulmonary tuberculosis transmitted to a cat by human sputa. M. Petit has already observed two cases of tuberculosis transmitted to dogs by human beings. The cat was in the habit of devouring the sputa of consumptive patients. This taste had become a passion; the animal followed the patients about, waiting for them to expectorate; it used to devour the tuberculous sputa which had served for microscopical examination in M. Petit's laboratory. After a time the following symptoms were observed: the animal grew thin, its hair stood erect, the eyes were blind, a mucous secretion escaped from the nostrils; there were attacks of sneezing and coughing, followed by vomiting. Koch's bacillus was detected in the secretion from the nose, which apparently proceeded from the bronchial tubes. At the end of two months and a half a complete change took place; the morbid phenomena became modified, and the animal appeared as if she were about to recover. She had seven kittens, one of which she nursed for five months, during which time she presented no symptoms of cachexia. A slight dry cough however persisted. Six months after the kittens were born the cat was killed. At the necropsy, the lower parts of both lungs showed signs of congestion. On cutting into the lung a small quantity of light, muco-sanguinolent fluid escaped. There was a collection of small, hard, cretaceous lumps in the lower part of the lower lobe, which gave a rough surface to this region. These little islets, which were of a grayish hue, were surrounded by a dense pale tissue. There were no lesions in the apex nor in the pleura. The peritoneum, intestine, mesenteric glands, kidneys, and liver were normal. Microscopical examination revealed alveoli in the indurations above described. These alveoli were filled with filaments which contained swollen and deformed epithelial cells. Ehrlich's process revealed the presence of a number of large bacilli collected in the periphery near to the hepatised spot. A few tuberculous bacilli were found in the muco-sanguinolent fluid which exuded from the small bronchial tubes. The tuberculous nature of the affection was unmistakable. Pregnancy had caused the appetite to return, and a consequent improvement in the animal's condition. M. Petit believes that had the cat lived, the improvement would have continued, and recovery would have ensued. It is admitted that the organisms of dogs and cats resist the introduction of tuberculosis; it is therefore probable that they are equally refractory to the evolution of the disease.

Professor Poncet, of the Val-de-Grace, has lately studied the lesions produced in the eye by tubercular leprosy. He examined in Mexico, a number of cases of leprosy, which he divides into three forms: the leonine, or tuberculous; the antonine, nervous or mutilating; and the macular, lazarine or ulcerated form. He has received from Dr. Lambucco some water-colour drawings of leprosy ocular lesions, and also two entire eyes of lepers. Dr. Poncet says, that in the eyelids the bacilli of leprosy soon leave the epidermis to attack the deeper parts. It is the same on the mucous surface; the epithelium is respected. The cornea is invaded from periphery to centre, and the accumulation of microbes may cause abscesses. The microbes penetrate the back of the eye through the zone of the pericorneal circle; from this point the parasite reaches the iris and the ciliary processes, becoming more and more rare towards the optic nerve. It seems, therefore, that the microbe of tuberculous leprosy seats itself in the conjunctival tissue, in the cells and sacs, after passing through the cutaneous epithelium, and penetrates but slowly into the special tissues, sparing the glandular epithelial elements, without taking the vascular or nervous road. It forms at first a limited superficial

lesion, and the tubercle may not be the sign of an affection already generalised. This view may be of capital importance in therapeutics.

At a recent meeting of the Société Médicale des Hôpitaux, M. Gaucher read a paper on Bright's disease, in which he maintained that the ordinary pathogenic conditions which caused parenchymatous epithelial nephritis were due to an excessive proportion of extractive principles in the organism. The epithelial form of Bright's disease might be caused by these conditions alone. If chronic nephritis resulting from some other anterior cause existed, the renal mischief would be aggravated by defective elimination of the extractive matter. From these facts M. Gaucher deduced valuable therapeutical indications; for instance, the danger of administering meat broth to patients suffering from Bright's disease. He considers that extracts of meat in different forms, besides containing toxic mineral salts, such as salts of potassium, contain organic poisons highly injurious to sick and even to healthy persons.

M. Gaucher also read a paper on the treatment of diphtheria by removing the false membranes, and cauterising the places from which they were taken with a concentrated solution of carbolic acid. He dissolves 5 to 10 grammes of carbolic acid in 10 grammes of alcohol, and adds to this mixture 15 to 20 grammes of camphor with a small quantity of oil. M. Gaucher obtained excellent results with this treatment in two cases. M. Joffroy stated that he employed chloral as a local application in diphtheria. This substance had more powerful parasiticide properties than carbolic acid. M. Joffroy washed the throat with a 2 per cent. solution of chloral; he then applied a one-fifth solution to the false membranes, which disappeared; the throat remained ulcerated; the application of the solution was continued. By this means diphtheritic angina was transformed into erythematous angina. This treatment could not be applied to children. M. Gaucher stated that he had tried chloral, but had found carbolic acid more efficacious. M. Blachez believed that false membranes might be destroyed in a less painful manner with petroleum oil. M. Gaucher remarked that the special object of his treatment was to destroy the false membranes in order to prevent secondary infection. M. Richard stated that the addition of one half per cent. of tartaric acid rendered carbolic acid much more powerfully antiseptic.

The *Gazette des Hôpitaux* of February 2nd publishes a summary of a report made by M. Vidal at the meeting of the Académie de Médecine, on January 31st, on a note by Dr. Bailly concerning a new method of local refrigeration by chloride of methyl. M. Bailly concludes, from numerous experiments, that plugs of which the centre is formed of dry cotton-wool and the periphery of floss silk, the whole surrounded by gauze, constitutes the best agent for imbibing and preserving the refrigerant liquid; two-thirds of cotton-wool to one-third of floss silk are employed. By a prolonged application of these plugs, saturated with chloride of methyl, M. Bailly has soothed the pain in 26 cases of toothache, and in 9 cases of facial neuralgia. Out of 10 cases of sciatica, he obtained successful results in 8. In 62 cases of different forms of neuralgia, recovery was almost invariably the result of this treatment. Of 16 cases of lumbago, 14 were rapidly cured. MM. Dieulafoy, Buequoy, Féréol, Lailler, and Pozzi have employed this method to soothe the internal pains. M. Bouchard has found it efficacious in intercostal neuralgia, torticollis, muscular pains, lumbago, toothache, and in one case of lead colic and one of gastric attacks of tabetic origin. M. Bouchard found that, at certain times it relieved dyspnoea in an emphysematous, asthmatic patient. M. Bailly has employed this method to obtain local anæsthesia before opening abscesses, incising whitlows, removing growths, and in anal fistula. M. Vidal stated that he had performed over 120 operations of different kinds during anæsthesia induced by M. Bailly's method, which was applied about 300 times in these cases in which the operation could only be completed in several sittings. M. Bouchard remarked that M. Bailly had preferred M. Debove's method. M. Bouchard has substituted the reflected action produced by refrigeration for the actual cautery with advantage, especially in the treatment of uterine affections. M. Besnier believed that M. Bailly's method might prove of great service when applied to the mucous membranes, but added that it would be advisable to interpose a piece of plaster. A vote of thanks to M. Bailly for having perfected a valuable method of local refrigeration was proposed by Dr. Vidal, and was unanimously adopted.

The *Gazette des Hôpitaux* of January 21st publishes a report presented by M. Troisier to the Société Médicale des Hôpitaux, at the

meeting of January 13th, on M. André Petit's observations on the existence of enlarged supra-clavicular glands in cases of cancer of the uterus. M. Troisier stated that he had met with several cases of uterine and ovarian cancer, accompanied by enlarged glands, in the supra-clavicular region in which no intermediary glands could be detected elsewhere. This symptom may also be met with in cancer of the abdomen as well as in cancer of the stomach or of the thorax. It should be looked upon as contra-indicating surgical interference in such cases.

The *Revue de Thérapeutique* of February 1st contains a note on pulmonary tuberculosis by Professor Jaccoud. He regards it as an acute infectious disease. The only effectual method of treatment is to substitute the form which develops slowly, and may, therefore, be arrested, for the form which develops rapidly and quickly proves fatal. It is generally admitted that salicylic acid is the best agent for reducing the fever, which is the chief factor in producing the pulmonary lesions. This substance should be given in doses of 2 grammes daily for three days, and in doses of $\frac{1}{2}$ gramme the three following days. The doses are then suspended for two days, after which they are resumed as before. If the fever diminishes, 1 gramme of salicylic acid is then administered daily.

Dr. W. Relemen has observed the following results in the course of his experiments with inhalations of pyridin. In nineteen cases of dyspnoea caused by different lesions of the heart and lungs this remedy invariably produced beneficial results. Pyridin is an energetic anti-asthmatic agent, and is principally efficacious in asthma of nervous and cardiac origin. In emphysema it acts merely as a palliative, its beneficial effects lasting from eight to twelve hours.

At a recent meeting of the Surgical Society, M. Lucas-Championnière showed different samples of catgut, prepared in various ways, some by the ordinary method, and others by a special process which renders it very resisting, even when dry. This catgut is made from three different kinds of sheep's intestine twisted together, and is far superior for ligatures to the *mî* fiddle string which is usually employed. M. Pozzi highly extolled the method of preparing catgut with oil of juniper wood, which renders it supple without making it less resisting.

The *Journal de Médecine* states that hypodermic and intra-muscular injections of hydrochlorate of quinine are most effectual in obstinate cases of malaria, when internal treatment has proved inefficacious. One-third of hydrochlorate of quinine is mixed with two-thirds of water. The alkaloid is dissolved by the action of heat. A Pravaz's syringe is introduced perpendicularly in the gluteal region, and fifteen centigrammes of the salt are injected. This method is not painful, and neither irritates nor hardens the tissues.

With regard to the question whether young girls affected with an organic lesion of the heart should be allowed to marry, Professor Jaccoud, in opposition to the views expressed by Professor Peter, believes that no absolute rule can be laid down. If the valvular lesion has never produced disturbance, then marriage is permissible. If symptoms of asystolia (especially in lesions of the mitral valve) have been observed, then there is considerable risk in marrying. Pregnancy would be very dangerous, on account of the pulmonary congestion which it would cause.

A case of narcolepsy was recently treated at the Hôpital St. Antoine, by Dr. Dieulafoy. The patient, aged 16, a waiter in a wineshop, complained of attacks of irresistible drowsiness, recurring at short intervals. His grandfather was asthmatic, and his father died of diabetes, but there was nothing otherwise worthy of note in the family history. The patient was not a drinker, and had never had syphilis or malaria. He had a sister, aged 17, who was decidedly hysterical. From the age of 7 up to the present year he had always suffered from a slight tic of the head and neck, causing him every now and then to raise the head suddenly and turn it to the right, the mouth being at the same time drawn the same side. A short time ago he contracted itch, for which he was treated at the Hôpital St. Louis, where he underwent the usual "scrubbing." Three days afterwards the sudden attacks of sleep commenced. At any moment, while he was standing walking, even at meals, his eyes would suddenly close, his head droop, and he would fall sound asleep for twenty, forty, or sixty seconds, sometimes longer; he would then as suddenly awake and instantly recover consciousness. These attacks were more frequent in the afternoon and after meals; they amounted to seven or eight in the course of an hour, and to upwards of 200 during the day, there being sometimes as many as three or four in fifteen

minutes. The attacks could always be brought on voluntarily by inclining the head forward, and the patient could not pick up anything from the floor without instantly falling asleep and falling violently forward on his face. His sleep at night was natural and quiet, but on awaking he felt fatigued, and his limbs were heavy. His health was otherwise good. The sight was good, the hearing normal. Careful examination revealed a slight degree of anaesthesia on the arm and chest on the left side; on auscultation a slight systolic *souffle* of the heart, more distinct towards the base, could be heard. The urine showed no trace of sugar or albumen. Dr. Dieulafoy prescribed 2 grammes of bromide of potassium daily, and cold shower-baths every morning. There was rapid improvement; the attacks diminished in number, and the patient was soon able to resume his occupation, which was very fatiguing, as he never got to bed till 2 o'clock in the morning, and had to get up again between 6 and 7. The treatment was continued for three months, when the bromide causing nausea, he ceased taking it, but went on with the douches three times a week. The attacks ceased almost entirely, except in the evening between 6 and 7 o'clock, before supper, when he still fell asleep suddenly, in whatever position he happened to be, remaining unconscious for about half an hour. On the days he had the douche this attack often did not occur. In March, eight months after the first attack, he was almost cured; he seldom fell asleep, and could even stoop and pick up things from the floor without inconvenience. A year after the onset of the symptoms the cure seemed to be complete. There was still slight anaesthesia of the left arm and on the left side, between the third intercostal space and a transverse line crossing the umbilicus. The cardiac *souffle* was no longer perceptible. Dr. Dieulafoy believes that the case was one of hysteria, probably brought on by the "scrubbing" to which the patient was subjected for itch, and that it was a degeneration in the neuropathological sense.

M. J. Maximovitch has determined the antiseptic properties of naphthol by comparing fourteen different microbes in nutritive solutions, containing different proportions of naphthol-x, thus ascertaining the proportion of naphthol which retards or prevents the development of each microbe. In ordinary cultivation broth, 0.10 gramme of naphthol per 1,000 entirely prevents the development of the microbes of glanders, mammitis of sheep, chicken cholera, bacteridian ulcer, micrococcus of pneumonia, the two organisms of suppuration—staphylococcus albus and staphylococcus aureus—the microbe of Biskra pustule, tetragenes, the bacilli of typhoid fever, and pigeons' diphtheria. Naphthol-x, in the proportion of from 0.06 to 0.08 gramme per 1,000, retards (from three to eight days) the development of the same microbes, and prevented it entirely in the cases of bacteridian ulcer, typhoid fever, and the two staphylococci of suppuration. Though the same doses of naphthol-x in gelatine, as in broth, suffice to prevent the development of microbes, in gelose 0.12 gramme to 0.15 per 1,000 are necessary to prevent the development of those of mammitis of sheep and Biskra pustule. For the destruction of the other microbes the doses are the same as those indicated for cultivation broth. In the proportions of 0.20 to 0.25 gramme per 1,000 naphthol-x entirely prevents the germination of the tubercle bacillus; in the proportion of 0.10 gramme it retards it. In doses of 0.20 gramme and of 0.35 to 0.40 gramme in solids, naphthol-x completely destroys the multiplying power of the bacillus pyocyanus and bacillus chromogenes of MM. Charrin and Roger. Urine does not ferment when shaken up with naphthol-x, either in solution or in powder. Human faeces cause only a slight cloud in cultivation broth containing naphthol-x in the proportion of 0.10 to 0.12 gramme per 1,000. Naphthol-x is nearly three times less poisonous than naphthol-b, and nearly seven hundred times less poisonous than bi-odurate of mercury. It would take a dose of 585 grammes of naphthol-x to kill a man. Albuminuria is produced by subcutaneous injection of 2 grammes in a saturated alcoholic solution; the injection of 3.5 to 4 grammes per lb. causes death. When injected into the portal system, naphthol-x is not poisonous in different degrees, as is the case with naphthol-b. These results, when compared with those obtained by M. Bouchard with naphthol-b, prove the inferiority of the latter, which is more poisonous and less valuable as an antiseptic.

THERMAL SPRINGS OF NEW ZEALAND.—The sum expended by the Government of New Zealand for improvement of the thermal springs was £7,814 in 1886, and £3,200 in 1887; £300 will this year be expended, principally on the completion of the water-supply at Rotorua, and in the planting and improvements of the baths and grounds.

SAN REMO.

[FROM OUR OWN CORRESPONDENT.]

SINCE writing to you last the Crown Prince has made a slight improvement. The mucus is still tinged with blood, however, more so, I believe, than the physicians care to admit. At the time when the slough separated the expectoration was, as might have been expected, discoloured to a certain extent, but this tinging had ceased altogether for a week or two before the operation. Two days after tracheotomy had been performed great quantities of mucus began to be discharged, tinged freely with blood. A number of tubes of different angles, curves, and lengths, have been tried, but slight hæmorrhage still continues. It is stated that Professor Bergmann believed that a secondary deposit had taken place in the lungs; and, although Sir Morell Mackenzie would not agree to this view, he raised no objection to Professor Kussmaul being called to determine the matter. The eminent professor of Strasburg University arrived here on Saturday evening, and a consultation was held on Sunday morning. No disease of the lungs could be detected. I hear that Professor Kussmaul takes an unfavourable view of the case entirely, from the microscopic examinations made at San Remo. Sir Morell Mackenzie, however, without wishing to discredit these investigations made by the German surgeons, naturally attaches more importance to the examinations made by Virchow, and is not prepared to assume a different attitude in the case, unless a microscopist of equal standing to Professor Virchow (who is now gone to Egypt) states that he has found nest-cells in the deep tissues or an alveolar structure.

The last few nights have been decidedly better—less coughing and more sleep—and the patient has been able to take some walking exercise on the balcony in front of the house. This he does with apparent strength and vigour, and as I saw him to-day (February 27th) one would little think what he has undergone.

VIENNA.

[FROM OUR OWN CORRESPONDENT.]

Gaseous Treatment of Lung Disease.—Hygiene in Austria.—Legacy to the Imperial Royal Society of Physicians.

IN a recent number of the *Wiener Medizinische Presse* Dr. Anton Karika gives some important details as to the treatment of pulmonary affections by inhalations of sulphuretted hydrogen and carbonic acid. He had used these inhalations in the case of pulmonary tuberculosis during several years. He had already, in 1887, reported the case of a girl affected with tuberculosis, whom he had treated with inhalations of carbonic acid without having obtained the results desired. As to the results which he had obtained with inhalations of sulphuretted hydrogen, he could give the following particulars, basing himself on observations made on more than fifty patients: 1. In several cases the very first inhalations with sulphuretted hydrogen gave a certain amount of relief. The cough and dyspnoea diminished, the expectoration became easier, and the patients felt refreshed and invigorated. In some this improvement took place very rapidly, so that after three or four inhalations they declared themselves to be cured. In other cases this result was obtained much later, and in others not at all. 2. A special advantage of the inhalations with sulphuretted hydrogen consisted in the fact that the vital powers of the patients were not impaired, as was the case after the use of antiepileptic narcotics. 3. No radical cure with these inhalations was observed in any case. Among the tuberculous patients treated with sulphuretted hydrogen inhalations six years ago, three were still living, who were said to be healthy; among these was the girl referred to above. They were, however, also treated with other medicaments, and especially with antiphlogistic remedies. 4. Only the first inhalations produced any appreciable good effect; after the eighth or tenth inhalation the condition of the patients underwent no change, so that it seemed to be useless to continue the inhalations. 5. In cases of relapse—namely, when the cough, etc., came on again, the inhalations generally did no good. 6. The best effect with the inhalations was obtained in (a) rapid breaking down and suppuration of large tubercular foci in the lungs, (b) inflammatory irritation of the walls of the pulmonary cavities, (c) acute or chronic irritation of the bronchial mucous membranes, (d) paroxysmal cough. 7. The sulphuretted hydrogen inhalations did good in about 60 per cent. of the patients thus treated. It must, however, be added that the author had used this course of treatment

most frequently in severe and advanced cases of pulmonary tuberculosis. 8. The inhalations caused patients no discomfort, and were well tolerated by feeble and sensitive women and children. These observations, in Dr. Karika's opinion, proved that sulphuretted hydrogen was not a specific remedy against tuberculosis; it was, however, an agent which sometimes produced excellent results in tuberculous persons, which we were quite incapable of obtaining by any other means. The observations showed, moreover, that (1) by means of sulphuretted hydrogen alone, without being mixed with carbonic acid, the same results could be obtained as those produced by the intestinal injections recommended by Dr. Bergeon; (2) this effect could also be obtained by inhalations. The use of this treatment would thus be more general and could be used without expensive apparatus, and without causing disgust to patients.

The establishment of an Austrian Sanitary Board ("Gesundheitsamt") on the model of the German one, was, as is well known, proposed long ago. The committee to whom the preparation of the scheme was entrusted recently recommended to the Austrian Parliament the adoption of the following resolutions: The Imperial and Royal Government is requested to: 1. (a) Create in each medical faculty special chairs for the teaching of hygiene and bacteriology, and to supply them with the necessary means; (b) to issue a decree making the study of hygiene compulsory in future for ordinary students in the Austrian medical faculties. 2. To improve the organisation of the public sanitary service by increasing the number of State medical officers, and nominating sanitary inspectors. 3. To increase the influence of the *landes-sanitätsräthe* (country sanitary councillors) and the *oberster-sanitätsrath* (superior sanitary council) by the appointment of well-known specialists in hygiene, architecture, statistics, etc. 4. To give the public sanitary officers greater independence in their relations with the political authorities. 5. To make adequate provision for the creation and endowment of laboratories for chemical and microscopical examinations. 6. To take care that the druggists should have a more thorough practical education at the beginning of their career.

At the last meeting of the Imperial Royal Society of Physicians, the President, Hofrath Bamberger, informed the members that, under the will of a Portuguese physician, the late Dr. Da Costa, the Society had received a legacy of 12,000 florins.

SWITZERLAND.

[FROM OUR OWN CORRESPONDENT.]

Petition of the Engadine Hotel-keepers; Decision of the Federal Council.

THE question relative to English practitioners in the Grisons (*vide* JOURNAL, February 18th, p. 374) has entered upon a new and more important stage. The Engadine hotel-keepers addressed a petition to the Grisons Kleiner Rath, requesting that English medical practitioners settled in the Engadine who wished to obtain a Swiss diploma should be permitted to be examined in their native tongue. This petition was immediately referred by the Kleiner Rath to the Bundesrath. We learn from an official report in the *Bund* (February 25th, 1888) that the Federal Council, having duly considered the petition at their meeting on February 24th, flatly refused to comply with the request, for the following reasons: First, because such a permission would be a privilege granted to English practitioners which is denied to the Swiss medical man in Great Britain; and secondly, because, if such a favour were granted to English practitioners, the Bundesrath would be logically bound to extend the same facilities to medical men of any other nationality or language, which would lead to obvious practical inconveniences. In coming to this decision, the "Federal fathers (*Bundesvaeter*)" have not, perhaps, displayed their usual sagacity. The decision cannot possibly satisfy either their petitioners and the important section of the Swiss population connected with the "hotel industry," or, indeed, anyone of ordinary common sense outside official circles. Of course, it is a great pity that there does not yet exist anything like an international right of medical practice, and that, amongst other things, the Swiss medical man, on his coming to England, is not even allowed to pass his examinations in his native (German, French, or Italian) tongue. The Swiss Federal Council might find many less important matters to occupy itself with than, for instance, the initiation of a reform in this direction, as it has already more than once tried to do, with regard to the

international regulation of factory labour, and the establishment of an international standard of working hours, etc. Its present line of policy in relation to English practitioners appears to be purely vindictive. The attention of the Bundesrath ought to be drawn to the following simple facts: Their singularly beautiful and attractive little county, with its industrious and kindly population, is a convenient and excellent health resort. (see the *Journal*, June 18th, 1887, p. 1359), which does an immense amount of good to mankind, by giving year opportunities to legions on legions of people to restore their shattered physical and mental health, or to recruit their strength, exhausted by overwork. A very large proportion of the foreign visitors are English or English-speaking. The Bundesrath will probably admit that a well-organised medical service at every health resort is as essential and reasonable a condition as good sanitary surroundings. Patients, rightly or wrongly, prefer to be treated by their own fellow-countrymen, who know more of what may be termed their national constitution, and are, therefore, more likely to select remedies suited to each individual case than a foreigner, however learned and skilful in his profession.

In conclusion, we cannot help thinking that the fears of the Federal Council as to other nationalities claiming to be examined in their native tongues are quite groundless. A couple of years ago English medical students in Switzerland could claim to be examined in English, and even published their inaugural dissertations in that language. In spite of this "privilege" nobody—no Russian, Servian, Spaniard, or Chinese—ever came forward to claim similar rights. We may assure the Bundesrath that if they had granted the prayer of the Engadine petitioners nothing of a revolutionary nature would have taken place in respect of medical examinations. The matter really concerns one of the three principal languages of this curious world, because everyone might naturally expect that such a highly educated person as a professor would know English as well as German and French. On the other hand, there does not yet exist any other human speech (except, perhaps, Volapük) which can claim to be regarded in the same light as the three named above.

CORRESPONDENCE.

THE ELECTRICAL TREATMENT OF UTERINE TUMOURS.

SIR.—Dr. Apostoli's wrath carries him far beyond the point up to which it is necessary for me to follow him after I have said that you have granted him most unusual grace in taking up a dispute from the columns of another journal; I, therefore, shall be brief.

I spent last Easter week in Paris as the guest of one of its most distinguished gynaecologists, and during that time I met nearly all the gynaecologists of that city whose names were known to me. My astonishment was not small, therefore, when a few weeks afterwards I read in your columns such glowing accounts of Dr. Apostoli and his electrolysis, that I had never heard his name nor anything of his treatment from friends in Paris, who, one and all, evinced the utmost anxiety to show me everything worthy of notice.

On my return to England I wrote asking several of them if it were worth my while to return to Paris to see about this new method of treatment. They all replied that it was not, and within a month I had letters indicating deaths traceable to Dr. Apostoli's treatment in six instances. I am not in a position to publish these letters, but that they exist is easily proved. You, Sir, have had at least two of them in your hands and have read them.

I said (December 17th) that the treatment must be tried. It has been, and I have heard nothing yet that will induce me to give it any countenance. It is a significant commentary on Dr. Apostoli's letter that by this morning's post I have been summoned to Paris to a patient "atteinte d'une tumeur fibreuse que la fait garder le lit depuis dix mois et la met dans l'impossibilité de la rendre chez vous. Elle est abandonnée de tous les médecins." Are Dr. Apostoli and his electrolysis still unknown in Paris, or what other explanation is there of this curious fact?—I am, etc.,

LAWSON TAIT.

SIR.—As one of the English surgeons who have profited by M. Apostoli's teaching, and as I have put the teaching into practice, I may be considered to be in a position to say something on the question. In the first place, I have seen no appearances threaten-

ing danger to life from the use of electricity, and I have now used it sixty-two times. Secondly, I have used it in seven cases of uterine myoma, and of this number three are already practically cured, the tumours being so much reduced in size as to have become insignificant. As I only began the electrical treatment in December, I claim that three recoveries out of seven cases in the short space of about two months quite equals the success obtained by castration operations. Indeed, I look upon the latter as regards the treatment of the tumours under discussion as dead as amputation of the finger for whitlow. Wiseman was a good surgeon, no doubt, in Charles II.'s time, and when he advocated amputation for whitlow, the treatment he recommended was right and proper, and remained so until a better became known. So castration for myoma was right and proper in its day, before the safer, quicker, and surer method introduced by Dr. Apostoli became known; but the former treatment by castration is now, as I said before, as much a thing of the past as amputation for whitlow.—I am, etc.,

J. E. BURTON,

Liverpool, February 27th.

L.M. COOMBE HOSPITAL, DUBLIN.

SIR.—It is interesting to read together your leading article in the *JOURNAL* of February 11th on the "Dublin Schools and their Teaching," and the paragraph in the *JOURNAL* of February 18th, on the prosecution for illegal practice of the man Middlebrook, who sheltered himself under the Coombe Hospital, Dublin. But it is still more interesting to inquire about this hospital, which, according to the "master," gives a "qualification" of "L.M." to anyone "who attends thirty cases of labour in the hospital in a period of six months," and of course pays a fee and passes an examination in "midwifery and diseases of women and children."

The candidate need have no other qualification; more than that, he need have had no other hospital training, need not know anything of anatomy, physiology, or pathology, and need never have dissected! What a farce this is!

It is all very well for the authorities of the Coombe Hospital to say, "the L.M. does not license a man to practise, as it cannot be registered," but they know that men do practise on it alone, and represent themselves to be qualified in virtue of the "L.M.," and why do they not interfere to stop it? Is it because they are willing for a fee to act as cloak to unqualified practice?

In my own neighbourhood is a man, imperfectly educated and without any hospital training, who, having acted for years as dispenser and assistant, and having been summarily dismissed by his employer, goes over to Dublin for six weeks (or less), takes his "L.M.C.H.," returns brandishing his "diploma," calls himself qualified, sets up for himself, is appointed "surgeon" to various friendly societies, vaccinates, signs death certificates, and even gives evidence at an inquest! Is not this a case for the Medical Council?

If the Coombe Hospital would confine itself to relieving humanity and imparting special instruction to those qualified to learn, well and good; that is what the special women's hospitals and chest hospitals of London do, and do well, but they do not pretend to give "qualifications" (L.M.'s or L.Chests) to men without any training. That the Coombe Hospital should do this appears to me to be a great scandal, and one that calls for exposure and discussion in the *JOURNAL*.—I am, etc.,

MAURICE PARRY JONES, M.D.Lond.

Pinxton, Alfreton, Derbyshire.

February 23rd.

PROTECTION IN THE STATES.

SIR.—A paragraph appeared in the *JOURNAL* of January 21st, headed "Protection in the States," in which it was stated that there was a probability of Dr. Heneage Gibbs being prevented from taking up the engagement at the University of Michigan which he had accepted. I am happy to say that I have received a letter from Dr. Gibbs, informing me of his safe arrival at the university, and of the kind reception he received. From this I conclude that no difficulty was raised against his entering on the duties of Professor of Pathology—the chair to which he has been appointed.—I am, etc.,

F. DE HAVILLAND HALL.

47, Wimpole Street, W., February 20th.

ACCIDENT TO A MEDICAL PRACTITIONER.—Dr. Nelson, of Belfast, by a fall from his horse while out hunting on Saturday, February 25th, sustained a fracture of the right arm.

MEDICO-LEGAL AND MEDICO-ETHICAL.

CHARGES TO PATIENTS.

T. P. S.—A rector in the position to maintain an establishment consisting of a cook, housemaid, nurse, groom, and pony carriage, cannot be regarded (his own statement to the contrary notwithstanding) as a "poor" clergyman, and as such, under the "true Samaritan" rule of the profession, entitled to a greater or less reduction of the usual medical fees, much less to gratuitous medical attendance, as would seem to have been the case in one or more instances. Be that as it may, an independent examination of the respective items specified in our correspondent's statement of account, and a subsequent comparison with the fees suggested in the Medico-Chirurgical Tariffs, leave no doubt upon our mind that the charges made in the cases in question are very moderate.

T. P. S. may, we think, consult with advantage the new edition of the Medico-Chirurgical Tariffs, in which the question of charges to the clergy is reviewed.

ASSISTANTS AND PARTNERS.

R. L. D. writes: I came here as temporary assistant, and in doing so signed the usual bond not to practise within a certain distance for five years unless under written authority. I am now to be adapted as partner (paying for my share). If we separate by the present principal's desire, say, after five or six years, does the bond still hold good for a further period, or does the partnership deed absolutely set it aside?

"* Without seeing the exact words used in the bond, it is impossible to say what it does or does not prohibit. The safe course is to have words inserted in the partnership deed putting an end to the previous agreement, and providing for what is to happen at the termination of the partnership.

LEASES FOR LIVES.

AN OLD SUBSCRIBER writes: Is there any law to prevent one's life being put on property against his consent? In addition to taking such a liberty some time ago, as mine is now the last life on very considerable and valuable property, I was asked to submit to an examination by an insurance agent and medical man in order that my life might be insured to compensate for the loss of property at my death. This I very promptly declined, but my death would mean the falling to the lord of the manor (not too rich a man) of the valuable property above named.

"* We presume the question refers to a lease for lives. We know of no law to prevent the life of a stranger being inserted in such a lease; and the names of people of public position have often been selected. The person whose name is inserted is, of course, under no obligation to submit to a medical examination for the purpose of insurance. It has been proposed to forbid leases for lives altogether.

GRATUITOUS ATTENDANCE ON MILITARY MEDICAL OFFICERS' WIVES.

AN EX-BRANCH-PRESIDENT writes: I am in consulting and general practice. Plenty to do. Have a good reputation as a skilful and successful accoucheur. In consequence, I am called upon to attend the wives of naval and military hospital medical officers here. I have spent a whole night in a house, and concluded labour by a very difficult forceps operation above the brim, successfully all round. Paid cab-hire, bridge-tolls, etc., throughout five weeks, more than once. Get verbal thanks. One case is coming off again I am told, and I am asked to attend. Ought I not clearly to have a fee? The husbands, though medical men, are not civil practitioners, and therefore not obstetricians. It is a very serious matter to be detained from one's patients, and have to render skilled aid at such a cost to one's self. If in civil life or circles recommendation might result, but as it is, such runs on the same lines.

"* In response to our correspondent's request, we would remark that, although it has always been (so far as our personal knowledge extends) the rule and custom, as laid down in the Code of Medical Ethics, that "all legitimate practitioners (naval, military, and civil alike) of medicine, their wives, and children while under the paternal care, are entitled (not as a matter of right, but) by professional courtesy to the reasonable and gratuitous services of the faculty resident in their immediate or near neighbourhood whose assistance may be desired," it is as distinctly emphasised therein that "railway and like expenses are excepted;" our correspondent, therefore, is clearly and justly entitled to all expenses out of pocket, such as the cab-hire, bridge-tolls, and the like.

It may be well to add that it is not of infrequent occurrence, especially in cases which give rise to unusual fatigue, anxious responsibility, and prolonged attendance, that an honorarium, in some form or other, is presented (and rightly so, we think) to the attendant practitioner by a grateful patient or family.

ANNÓYED.—If the facts of the case be as related by "Annoyed," the conduct of Dr. A. in officiously obtruding himself on the patient, and subsequently repeating the visit, and proceeding to examine him, regardless of the fact previously made known to him (Dr. A.) that Mr. B. was in professional attendance, clearly constituted a gross breach of medical etiquette, which, if renewed, can scarcely fail to evoke severe professional censure.

LUNATIC IN SINGLE CHARGE.

R. W. D. asks: Is it legal for a qualified medical man or a layman to have supervision over a patient who has been under charge of a private lunatic asylum without being certified?

"* No, not legal, without compliance with statutory requirements as to order and certificates of insanity, transmission of copies, and visitation by lunacy authorities, etc.

NAVAL AND MILITARY MEDICAL SERVICES.

THE ARMY ESTIMATES.

In anticipation of the discussion on the Army Estimates, which is put down for Monday next, the Secretary of State for War has, in accordance with the precedent of last year, issued a memorandum which replaces the verbal statement formerly made by the Minister in the House of Commons.

The memorandum states that there has been a decrease of 200 in the Medical Staff Corps, and that it had been decided during the year to enlist men for the Royal Engineers, the Commissariat and Transport Corps, and the Medical Staff Corps, for three years' service only with the colours. "This is an important step, which will, as time goes on, materially increase the reserve of these valuable corps."

The Secretary of State makes the following reference to the question of finance:

"The cost of the Army Medical Department (Vote 4) has undergone careful examination; the rapid growth of the charge for non-effective services having called special attention to the present system. The scale of remuneration now in force was adopted on the report of a committee, which sat in 1878, to consider the grievances of the department, and the disinclination of the profession to enter its ranks. But it is obvious that a system which offers inducements to officers to retire upon a pension after only twenty years' service is expensive to the State; and not even acceptable to that large section of the profession who, while feeling themselves unfitted for further service abroad, are ready and anxious to continue their duties at home stations. It is proposed to utilise in this manner the services of a large number of retired officers, and, further, not to allow any medical officer to retire on the pension attached to his rank until he has served in it for a reasonable period. By these means a large reduction will be effected in the pension list; while, by extending the term of foreign service by one year, and by other steps now under consideration, we hope to make a considerable reduction in the establishment. For the present, therefore, all admissions to the Service are suspended, and it is probable that by the end of the financial year twenty-eight officers will have been absorbed. The net result this year is a saving of £19,100; but the effect of these changes, especially upon the non-effective votes, will be more marked in future years."

It is added that it has been found possible to dispense with a deputy surgeon-general at headquarters.

THE INDIAN MEDICAL SERVICE.

The following is a list of the candidates for Her Majesty's Indian Medical Service who were successful at the competitive examination recently held at Burlington House. Seventy-three candidates competed for fourteen appointments. All were reported qualified:—

	Marks.		Marks.
Marshall, D. G.	3,410	Gray, W. H.	3,110
Moir, D. H.	3,355	Gee, F. W.	3,100
Roberts, J. B.	3,350	O'Gorman, B. W.	3,100
Whitechurch, H. F.	3,275	Pereira, F. C.	3,080
Arnin, H. C. L.	3,250	Prasad, K.	3,080
Grant, A. E.	3,160	Mould, G. T.	3,070
Hejel, J. G.	3,145	Thomson, G. S.	3,070

THE NAVY.

STAFF-SURGEON G. H. MADELEY has been promoted to the rank of Fleet-Surgeon. He was appointed Surgeon, July 5th, 1867, and Staff-Surgeon December 29th, 1878.

THE MEDICAL STAFF.

SURGEON G. S. ROBINSON, of the Scots Guards, is promoted to be Surgeon-Major, in succession to Brigade-Surgeon W. H. Lane, retired. He entered the service March 6th, 1880, when he was sent to Bombay. In the early part of 1881, however, he was appointed to the 2nd Scots Guards, and has remained with that corps ever since. He served with his battalion in the Soudan campaign in 1885, and was present in the engagement at Hasheen and at the destruction of Tamal (medal with clasp and Egyptian bronze star).

THE VOLUNTEERS.

SURGEON W. O. BLACKETT, 4th Volunteer Battalion, Durham Light Infantry (late the 4th Durham), is granted the honorary rank of Surgeon-Major.

Honorary Assistant Surgeon W. F. M. JACKSON, 1st Volunteer Battalion South Staffordshire Regiment (late the 2nd Staffordshire), is appointed Acting Surgeon.

Acting Surgeon W. E. GASCOIGNE, 1st Volunteer Battalion West Riding Regiment (late the 4th West Riding), has resigned his appointment, which was dated December 7th, 1881.

PUBLIC HEALTH

AND

POOR-LAW MEDICAL SERVICES.

ENGLISH URBAN MORTALITY IN 1887.

In the accompanying table will be found summarised the vital and mortal statistics issued by the Registrar-General in his weekly returns relating to the twenty-eight large English towns. Weekly summaries of these statistics have already been published in these columns.

During the year 1887 the births of 296,951 children were registered in the twenty-eight large English towns, equal to an annual rate of 32.2 per 1,000 of their aggregate population in the middle of that year, estimated at 9,250,000 persons. This birth-rate showed a further decline from that recorded in recent years; indeed, since 1876, when the birth-rate was as high as 38.1 per 1,000, it has year by year steadily declined. In London the birth-rate last year was equal to 31.7 per 1,000, while in the twenty-seven provincial towns it averaged 32.7, and ranged from 25.8 in Brighton and 27.7 in Bradford and in Huddersfield to 38.5 in Preston, 39.1 in Newcastle-upon-Tyne, and 41.1 in Cardiff.

The 191,887 deaths registered last year in the twenty-eight towns were equal to an annual rate of 20.8 per 1,000 of their estimated population, which, with the exception of the rate in 1885, which was only 20.6, was lower than in any year on record. During the ten years 1871-80 the rate of mortality in the large towns dealt with by the Registrar-General averaged 24.0 per 1,000. During the first seven years of the current decade, 1881-87, the death-rate in these towns has not exceeded 21.4 per 1,000. This reduction in the death-rate implies that nearly 162,000 persons in these twenty-eight towns were alive at the end of last year whose deaths would have been recorded therein had the mean rate of mortality equalled that which prevailed during the ten years 1871-80. It may be noted here that the estimated saving of life in England and Wales during the same period of seven years, 1881-87, as the result of the marked decline of the general death-rate of the country, is no less than 400,000. The rate of mortality in London during last year was only 19.6 per 1,000, while it averaged 21.9 in the twenty-seven provincial towns, among which

it ranged from 16.9 in Brighton, 17.1 in Derby, and 18.7 in Nottingham to 25.3 in Newcastle-upon-Tyne, 25.5 in Blackburn, 27.0 in Preston, and 28.7 in Manchester.

During the year under notice, 29,615 deaths were referred to the principal zymotic diseases in the twenty-eight large towns, equal to a rate of 3.21 per 1,000, which, though slightly exceeding the low zymotic death-rates recorded in either of the two preceding years, was below the average rate in the ten previous years, 1877-86. The lowest zymotic rates last year were 1.3 in Halifax, 2.2 in Brighton, and 2.3 in Plymouth; while the highest were 4.4 in Blackburn and in Salford, 4.5 in Preston, and 4.9 in Manchester. The 29,615 deaths referred to these zymotic diseases included 9,151 which resulted from diarrhoea, 7,248 from measles, 5,675 from whooping-cough, 3,609 from scarlet fever, 1,983 from fever (including typhus, enteric, and simple or ill-defined fever), 1,617 from diphtheria, and 332 from small-pox. The rate of mortality from diarrhoea was equal to 0.97 per 1,000, which almost corresponded with the average rate in the preceding ten years, 1877-86. This disease showed the largest proportional fatality in Wolverhampton, Bolton, Salford, Leicester, and Preston. The death-rate from measles was equal to 0.79 per 1,000, and exceeded the rate in any year on record. In London the rate of mortality from measles was 0.69 per 1,000, while in the twenty-seven provincial towns it averaged 0.87, and was proportionally highest in Huddersfield, Salford, Norwich, and Manchester. The death-rate from whooping-cough was equal to 0.62 per 1,000, and although exceeding the rate in either of the two preceding years was below the average; this disease was much more prevalent in London than in the aggregate of the provincial towns, among which, however, it caused high rates in Liverpool, Oldham, Blackburn, and Birmingham. The rate of mortality from scarlet fever was equal to 0.39 per 1,000, and although considerably below the average rate in the ten preceding years, 1877-86, showed a marked increase upon the low rates in the two previous years; the highest death-rates from this disease were recorded in Salford, Oldham, Birkenhead, Bristol, and Blackburn. The rate of mortality from "fever" (principally enteric), which had been 0.20 to 0.23 per 1,000 in the two preceding years, was again 0.22 during the year under notice; against an average rate of 0.32 in the ten preceding years, 1877-86. The death-rate from fever in London last year was only 0.16 per 1,000, and was lower than in any

year on record; in the twenty-seven provincial towns it averaged 0.26 per 1,000, and was highest in Blackburn, Newcastle-upon-Tyne, Salford, Portsmouth, and Preston. The rate of mortality from diphtheria was 0.18 per 1,000, and exceeded that recorded in any preceding year; in London the diphtheria death-rate was 0.23 per 1,000, while it did not average more than 0.13 in the provincial towns, among which, however, this disease was fatally prevalent in Portsmouth, Oldham, and Huddersfield. During the year under notice 332 fatal cases of small-pox were recorded in the twenty-eight towns; only 9 occurred in London, and 323 in the twenty-seven provincial towns, including 278 in Sheffield, 13 in Bristol, 11 in Cardiff, 6 in Manchester, 4 in Blackburn, 3 in Portsmouth, 2 in Hull, 2 in Birmingham, and 1 each in Liverpool, Preston, Leeds, and Newcastle-upon-Tyne. The highest number of small-pox patients under treatment in the Metropolitan Asylums Hospitals at any time during last year was 15, and only 7 remained at the end of December; 63 cases were admitted during the year, of which 30 were admitted during the last quarter.

Infant mortality, measured by the proportion of deaths under one year of age to registered births, averaged 168 per 1,000 in the twenty-eight towns during the year under notice. In London the rate did not exceed 158 per 1,000, whereas in the twenty-seven provincial towns it averaged 176, and ranged from 142 in Derby, 143 in Portsmouth, and 149 in Bristol to 195 in Salford, 201 in Blackburn, 209 in Leicester, and 214 in Preston.

SANITATION OF DWELLINGS.

A BILL having an important sanitary object has been introduced by Lord Henry Bruce. On a representation to the Local Government Board, signed by at least six ratepayers of a district, to the effect that the local authority of a district has failed to put in force, as occasion required, its powers for securing the proper sanitary condition of the premises within its district, the Board will, according to his scheme, proceed to hold a local inquiry as to the truth of the representation. If on the report of the inspector the Board are of opinion that the representation is well founded, they will dissolve the defaulting local authority, and direct a fresh election of members. The obligation is also imposed by the Bill on local authorities of making by-laws respecting lodging-houses. The penalty is increased to which the owner of a dwelling is liable for disobeying an order as to the abatement of a nuisance. Provision is also made for the inspection of cellars or underground rooms occupied as dwellings in London.

THE POST OF PUBLIC VACCINATOR AT WALSALL.

THE action taken by the Walsall Board of Guardians in calling upon Mr. Willmore to resign his appointment of public vaccinator at the end of the year, and in announcing their intention of appointing someone else in his place, has caused some feeling of dissatisfaction. A circular has been issued signed by two medical men, expressing the opinion that Mr. Willmore has been the victim of a series of attacks from the guardians, and protesting against the arbitrary conduct of the guardians. It is stated that the guardians are unable to bring any sufficiently grave charge against Mr. Willmore to make the Local Government Board dismiss him from the post of medical officer for the No. 1 District; that he has been public vaccinator for years, and has received the Government grant as often as it is possible to receive it. The circular calls upon the medical men of Walsall "to stand together as a body and pledge themselves that they will not offer themselves as candidates for the vacant post," as a protest against the arbitrary conduct of the guardians.

HEALTH OF ENGLISH TOWNS.—In the twenty-eight large English towns, including London, which have an estimated population of 9,338,273 persons, 8,478 births and 3,888 deaths were registered during the week ending Saturday, February 25th. The annual rate of mortality per 1,000 persons living in these towns, which had been 22.2 and 20.9 in the two preceding weeks, rose again during the week under notice to 21.6. The rates in the several towns ranged from 13.0 in Cardiff, 15.7 in Derby, 16.7 in Norwich, and 16.8 in Hull to 25.4 in Manchester, 26.5 in Salford, 28.5 in Blackburn, and 32.2 in Plymouth. In the twenty-seven provincial towns the mean death-rate was 21.6 per 1,000, and corresponded with the rate recorded in London. The 3,888 deaths registered during the week under notice in the twenty-eight towns included 173 which were referred to whooping-cough, 70 to scarlet fever,

46 to measles, 43 to "fever" (principally enteric), 40 to diphtheria, 29 to small-pox, and 28 to diarrhoea; in all, 429 deaths resulted from these principal zymotic diseases, against 491 and 403 in the two preceding weeks. These 429 deaths were equal to an annual rate of 2.4 per 1,000; in London the zymotic death-rate was 2.8, while in the twenty-seven provincial towns it averaged only 2.0 per 1,000, and ranged from 0.3 and 0.4 in Newcastle-upon-Tyne and Brighton to 3.4 in Plymouth and in Manchester, 4.4 in Blackburn, and 5.5 in Sheffield. Measles caused the highest proportional fatality in Blackburn and Plymouth; scarlet fever in Blackburn, Cardiff, and Birkenhead; whooping-cough in Derby, Manchester, Leicester, and London; and "fever" in Derby. Of the 40 deaths from diphtheria recorded during the week in the twenty-eight towns, 30 occurred in London, 3 in Liverpool, 2 in Salford, and 2 in Preston. The 29 fatal cases of small-pox included 20 in Sheffield, 5 in Manchester, 1 in Leeds, 1 in Oldham, and 1 in Blackburn. The number of small-pox patients in the Metropolitan Asylums Hospitals was 6 on Saturday, the 25th ult. of which 4 had been admitted during the week. These hospitals also contained 1,308 scarlet fever patients on the same date, against numbers steadily declining from 2,600 to 1,395 in the twelve preceding weeks; there were 93 admissions during the week, against 146 and 104 in the two previous weeks. The death-rate from diseases of the respiratory organs in London was equal to 5.8 per 1,000, and was slightly below the average.

HEALTH OF SCOTCH TOWNS.—During the week ending Saturday, February 25th, 835 births and 571 deaths were registered in the eight principal Scotch towns. The annual rate of mortality, which had been 22.5 per 1,000 in each of the two preceding weeks, was 22.6 during the week under notice, and exceeded by 1.0 the mean rate during the same period in the twenty-eight large English towns. Among these Scotch towns, the lowest rates were recorded in Greenock and Aberdeen, and the highest in Glasgow and Paisley. The 571 deaths in these towns during last week included 61 which were referred to the principal zymotic diseases, equal to an annual rate of 2.4 per 1,000, which corresponded with the mean zymotic death-rate during the same period in the large English towns. The highest zymotic rates were recorded in Perth and Paisley. The highest proportional fatality of measles occurred in Edinburgh and Leith, and from whooping-cough in Glasgow and Paisley. Three deaths from diphtheria were recorded in Glasgow, and 2 in Edinburgh. The mortality from diseases of the respiratory organs in these Scotch towns during the week under notice was equal to 5.6 per 1,000, against 5.8 in London.

HEALTH OF IRISH TOWNS.—In the sixteen principal town districts of Ireland, the deaths registered during the week ending Saturday, February 25th, were equal to an annual rate of 31.2 per 1,000. The lowest rates were recorded in Armagh and Kilkenny, and the highest in Limerick and Dundalk. The death-rate from the principal zymotic diseases in these towns averaged 2.9 per 1,000, and was highest in Belfast and Lurgan. Measles showed fatal prevalence in Belfast. The 192 deaths registered last week in Dublin were equal to an annual rate of 28.4 per 1,000, against 29.9 and 25.9 in the two preceding weeks, the rate during the same period being only 21.6 in London, and 21.0 in Edinburgh. The 192 deaths included 17 from the principal zymotic diseases (equal to an annual rate of 2.5 per 1,000), of which 8 resulted from scarlet fever, 4 from whooping-cough, 3 from "fever," and 2 from measles.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

WALSALL (Population, 65,220).—It must always be a matter for congratulation when a low death-rate can be recorded, and as this was Dr. John Wood's experience of the year 1886, he has every reason to look upon his report as satisfactory. A severe epidemic of measles visited the borough and caused 90 deaths, for the most part the result of bad nursing. There were 37 cases of small-pox, of which 3 terminated fatally. Nearly all the cases were treated in the hospital, which, as Dr. Woods observes, is growing in popularity. Scarlet fever appeared to have died out entirely, and only one death was recorded. There was the usual prevalence of autumnal diarrhoea destructive to infant life. Typhoid fever caused 14 deaths in widely separated localities. No special insanitary conditions are recorded in connection with these cases, except that in some instances vaulted privies existed

and suspicious well water was being made use of. The general death-rate was 18.2 per 1,000, of which the zymotic proportion was 3.25.

LAMBETH (Population 274,196).—Diphtheria in St. Thomas's Hospital.—Dr. Verdon's report for the year 1886 is in reality a very able and comprehensive essay on the agencies which have had an effect in ameliorating the condition of the poor and the relationship which the mortality in a district bears to the degree of the poverty of its inhabitants. He views with special satisfaction the progress made of late years by the temperance movement in all classes of society, and points out that pauperism has been attacked and partially overcome by the advance of education. The death-rate for the year was 19.2 per 1,000, and the zymotic death-rate 2.5, the metropolitan rates being 19.9 and 2.6 respectively. He mentions the following peculiar circumstance. A child that had been under treatment for an injury for several weeks in St. Thomas's Hospital had recovered from the worst effects of its accident when it was suddenly attacked by diphtheria and died. No other person in the ward was suffering from diphtheria, and no one could throw any light upon the manner in which the child had been infected. A month later a little boy was taken to the hospital on account of a rupture, and an operation was successfully performed. The mother had already made arrangements to remove him from the hospital, when he was taken ill with diphtheria and died. Within a period of eight months seven cases of a like nature, received into the hospital for operation or from accident, died of diphtheria. The origin of that complaint remains a mystery, but Dr. Verdon is under the impression that the precipitated filth exposed at low water in the Thames at the base of the hospital may have had something to do with it.

STAMFORD (Population, 9,263).—Epidemic of Scarlet Fever associated with Cases of Renal Disease.—The statistics compiled by Dr. T. E. Carter for 1886 were remarkably favourable, the general death-rate of 15.5 per 1,000 being much below the average, and the lowest on record in Stamford. Scarlet fever was the chief infectious disease which had to be dealt with. The epidemic broke out in November, 1885, and lasted more or less through the following year, causing 6 deaths, and terminating at last because there was hardly any more material for it to feed upon. In connection with this epidemic, Dr. Carter states that he has since met with a larger number of cases of renal diseases. His belief is that the inflammation of the kidney is of scarlatinal origin. Of the other zymotic diseases, diarrhoea caused 5 deaths, typhoid fever 1, and diphtheria 1.

TAUNTON URBAN AND RURAL (Population, 17,437 and 19,367).—Increasing Appreciation of Infectious Hospital.—Of both these districts Dr. Alford had a very favourable report to make for 1886 in respect of vital statistics. Not only were the death-rates materially diminished, but there was an almost complete absence of any epidemic. The Sanitary Hospital did good service in preventing the spread of infectious sickness. Dr. Alford states that it is more freely used than formerly, and that the prejudice against it is fast passing away. The good nursing, well-ventilated wards, and general comforts are, moreover, of great benefit to the patients. A case of small-pox was brought into the borough, and a second occurred in the rural district; both were removed into hospital, and the disease did not spread. Cases of scarlet-fever of a mild type cropped up at intervals. Where possible isolation was ensured, disinfection of houses and bedding, etc., was carried out, and in no case did the disease spread. The early part of the year was remarkable for the inclemency of the weather, easterly winds and low temperature prevailing. Hence diseases of the pulmonary organs were common, and caused an unusually heavy mortality. Two cases of diphtheria were reported in the rural district, one of which appeared to be attributable to the cleansing of a pond, which for years had been a receptacle for manure.

MEDICO-PARLIAMENTARY.

HOUSE OF LORDS.—Friday, February 24th.

Pharmacy Acts Amendment Bill.—The Earl of MILLTOWN moved the second reading of this Bill, which had, he said, the full approbation of the Council of the Pharmaceutical Society. The Bill, which made certain changes in the procedure of qualification

under the Pharmacy Acts, would not come into operation until more than three years had elapsed from the present time, the object of the postponement being to safeguard the interests of those who were now going through an apprenticeship. The motion was agreed to.

Tuesday, February 28th.

Fires in Theatres.—The Earl of MILLTOWN moved that a humble address be presented to Her Majesty praying for the reply of the local magistrates to the report of Captain Shaw on the late fire at Exeter. The motion was agreed to.

The Sweating System.—Lord DUNRAVEN, in calling attention to the report to the Board of Trade on the sweating system in the East-end of London by the labour correspondent of the Board, read numerous extracts from the report to prove the severity of the work done by the poor people of both sexes. He showed that not only is their remuneration on a scale that scarcely affords them the means of bare existence, but that the number of hours worked by them is dangerously excessive, and that in very many cases they perform their task in miserable rooms, which they are obliged to overcrowd, and in which the most ordinary sanitary laws are entirely disregarded. He moved for inquiry into the question by a Commission or Committee empowered to examine witnesses on oath, and he concluded by moving for a Select Committee.—Lord ONSLOW accepted the motion, which was agreed to. He stated that nineteen-twentieths of the persons who did tailoring under sweaters in the East-end were German and Polish Jews and Jewesses, and the habits of these persons, even in their own countries, were very different from those of the English working-classes. They threw obstacles in the way of workshop inspectors.

HOUSE OF COMMONS.—Thursday, February 23rd.

Hydrophobia.—On the motion of Viscount CURZON, a return was ordered, showing the number of deaths from hydrophobia during the ten years ending in 1886 in the United Kingdom.

Monday, February 27th.

Rating of Lunatic Asylums.—Mr. W. H. SMITH, in reply to Mr. KIMBER, said: The Government do not propose to bring in a Bill dealing with the assessment of rates on lunatic asylums, but an opportunity will arise for raising the question when the Lunacy Acts Amendment Bill is before the House.

Compulsory Notification of Disease.—In answer to Mr. HOWARD VINCENT, Mr. RITCHIE said the system of compulsory notification of infectious diseases was in force in England and Wales in forty-three boroughs and four local board districts. He had no precise information at the present moment with regard to Scotland and Ireland, but, if wished, he would procure it. The question as to the introduction of a Bill to extend the system of compulsory notification was, he said, under consideration.

Tuesday, February 28th.

Flogging.—Mr. MATTHEWS, in reply to Mr. POWELL WILLIAMS, said the Lord Chancellor and the Lord Chief Justice concurred with him in the opinion that Act 7 and 8, George IV, cap. 28, should be repealed (thus reserving the punishment of flogging for offences attended by violence). Steps would be taken by the Government to effect its repeal.

London Water Supply.—The second reading of the Grand Junction Water Bill was under discussion for some time, and, on a division, the Bill was thrown out by 188 to 104.

OBITUARY.

CHARLES CROKER KING, M.D., D.Sc., F.R.C.S.I.,

Commissioner, Local Government Board, Ireland.

WE regret to announce the death of this most highly esteemed member of the profession. He descended from a very distinguished family, his grandfather, Samuel Croker King, having been the first president of the Royal College of Surgeons as nominated in the charter of 1784. A fine portrait of him now reverts to his College. He was almost exclusively the attendant of the numerous noblemen who had residences in Dublin towards the end of the last century, and his most famous case was that of an infant, who in time became the illustrious Duke of Wellington.

The subject of our notice became a Licentiate of the College of Surgeons in 1837 and a Fellow in 1844. While acting as Demon-

strator in Trinity College, he gave valuable aid to Professor Harrison in the preparation of that popular textbook *The Dublin Dissector* as acknowledged in the preface, and he delivered several courses of delightful lectures on artistic anatomy at the Royal Dublin Society. These services and the publication of several scientific papers ensured his election to the Chair of Anatomy and Physiology in Queen's College, Galway, on its foundation in 1849. This post he filled with striking ability until 1863, when he accepted an inspectorship under the Local Government Board. His skill in carrying out the sanitary Acts and controlling the epidemics of cholera in 1866 and of small-pox in 1871-2 induced the Government to select him for the Commissioner-ship which became vacant in 1876.

Dr. King while in practice was a very excellent operator, and he helped in no small degree to the success of the Medical School at Galway. He contributed several papers on surgical subjects to the journals. He was an excellent lecturer. In the position of Medical Commissioner he was regarded as a most fair-minded and kindly superior, and his death will be much regretted by the members of the department which he so long controlled.

This office is somewhat analogous to that held with such renown by Sir John Simon (who had before been medical officer of health for London City), and at present by Dr. Buchanan. In Ireland, however, the holder of this position is not merely an advisor, but a Commissioner for directing the medical charities, vaccination and sanitary Acts, and framing by-laws and statistics under them. Questions touching water supply, sewerage, dwellings for the working classes, closure of burial grounds, and adulteration of food are those which are mainly presented to him for consideration and decision. The honorary doctorates in Medicine and in Science of the Queen's University were amongst the distinctions conferred on the late Commissioner. Dr. Croker King was in good health until December last, when a slough was caused by rasping a corn on the little toe of the left foot. The severe pain felt when the limb was dependent, and the feeble pulsation of the arteries, at once gave a grave aspect to the case. Senile gangrene supervened and proceeded to the tarsus, where a good line of demarcation formed. All hope of recovery was, however, abandoned last week, when septicæmia was developed, and he sank on Tuesday morning. He was attended throughout by Dr. Mapother and Sir George Porter, and other senior surgeons as consultants. His genial and benevolent character had so much endeared him that the widest sympathy is felt for his widow and their only child, Colonel King, now of Cheltenham.

FRANCIS HIRD, F.R.C.S.

Consulting Surgeon to Charing Cross Hospital.

On Friday, February 24th, Mr. Francis Hird died at Brighton, at the age of 74. He was born at Darlington in 1813, and received his medical education at the Westminster Hospital and in Dublin. When Charing Cross Hospital was founded he joined its teaching staff, and for forty-three years after that date he remained an active officer in the school and wards. Amongst his pupils, when he was Lecturer on Anatomy, were Dr. Livingstone, Professor Huxley, Sir Joseph Fayrer, and Sir Guyer Hunter. In 1843 he became Honorary Fellow of the College, having taken the Membership in 1836. He was appointed assistant-surgeon in 1855, and remained surgeon to the out-patient department for fifteen years. In 1870 he was elected full surgeon, resigning in February, 1881, when he was made consulting surgeon. On the occasion of his retirement, a service of plate and a testimonial engrossed on vellum was presented to him by the Governors and staff.

Mr. Hird wrote but little. He was orator at the Medical Society in 1848 and in 1850. In 1855 he delivered the Lettsomian Lectures; the subject was "Some Special Points in the Anatomy of the Uterus and its Structural Lesions the Result of Inflammation." He was a gentleman of commanding presence, handsome features, and conciliatory manners, thoroughly suited for a medical school.

Mr. Hird was one of the warmest supporters of the late Mr. Probert in the foundation of the Royal Medical Benevolent College at Epsom, of which he was a Member of Council for more than thirty years. He succeeded his old friend Mr. Hancock as treasurer of the College, on the resignation of the latter in 1876, and it was only in May last year that he resigned the treasurership, having retired from practice and gone to live at Brighton. Mr. Hird leaves a son, who is a clergyman of the

Church of England, and three daughters. He was buried on February 28th, at Kensal Green, several members of the staff of his hospital being in attendance.

The following resolution was passed at a meeting of the School Committee on Wednesday:—"The School Committee of Charing Cross Hospital have learnt with the deepest regret that Mr. Hird, late Dean of the school, died suddenly on Friday last, and beg to express their warmest sympathy with his family in the loss that they have sustained, a loss which is especially felt by the officers of this School, with which he was for many years so closely connected."

FRANCIS BOASE, M.R.C.S.

MR. BOASE, whose death at the age of 69 occurred on February 7th, was an old and highly esteemed inhabitant of Penzance. He was born in 1819, in the room in which he died; he studied at University College, and became a member of the Royal College of Surgeons in 1841. For a period of thirty-five years, Mr. Boase filled many important local offices, and identified himself with every laudable and progressive movement. He became a member of the Town Council in 1833, he was elected alderman in 1861, and became a justice of the peace for the borough in 1869. No better instance of his well-deserved popularity could be given than the fact that he filled the office of mayor no less than eight times.

Mr. Boase was an ardent volunteer, having connected himself with the movement at its very commencement, and attained, after successive steps, the rank of captain, ultimately retiring with the rank of honorary major. At the time of his death he was vice-president of the Penzance Board of Guardians. He has been a warm supporter of the West Cornwall Infirmary and Dispensary.

ALEXANDER McBEAN, M.R.C.S.

We have to announce the death of this gentleman, at the age of 78. He was a native of Aberdeen, and for a period of forty years he practised at Hanley, where he made many friends, and was highly esteemed. He was of quiet and unassuming manners. He, retired from practice about seventeen years ago, being succeeded by his former partner, Mr. W. D. Spanton. For many years past the deceased gentleman had been in the habit of spending his winters in Italy, but this year was prevented by his growing infirmities. He was unmarried.

M. LÉON (BASSEREAU).

M. LÉON BASSEREAU, whose name was so familiar throughout Europe in connection with the theory of dualism, died lately in Paris at the age of 77.

From a memoir in the *Annales de Dermatologie et de Syphiligraphie* it appears that M. Bassereau, who was born in the year 1810, was a cousin of the beautiful and celebrated Madame Récamier, and at first studied for the law, which, however, he soon abandoned for medicine. He became an *interne* of the Paris hospitals in the year 1835, and took his doctor's degree in 1840. Under the guidance of Brett and Ricord he devoted special attention to venereal diseases, and in 1852 published his well-known *Traité des Affections de la Peau, Symptomatiques de la Syphilis*. This book was the chief means by which the confusion which then reigned between syphilitic and non-syphilitic primary sores was brought to an end. By a large number of careful observations, including the confrontation of syphilitic persons with those from whom their disease had been contracted, it was shown that when the former developed constitutional symptoms, the latter were also syphilitic. M. Bassereau was also the author of an essay on the influence of iodide of potassium in syphilis, which gained him the silver medal of the Paris Society of Medicine in 1845.

Though he continued throughout his life to take great interest in the subject of venereal diseases, Bassereau was not a specialist, but practised as a general physician. He was made a Chevalier of the Legion of Honour in 1861.

LALOO, THE CASE OF PARASITIC FŒTUS.—Mr. M. D. Francis, who is at present exhibiting Laloo, writes to state that the statement that Laloo was prevented from appearing at the Indian Exhibition owing to a legal question is incorrect. Mr. Francis brought him to England and exhibited him at that exhibition until its close. Mr. Francis also states that he has never been forbidden to exhibit Laloo on the score that such an exhibition would be indecent. Laloo has been exhibited without any interference in the principal towns of England, Scotland, and Ireland.

MEDICAL NEWS.

SOCIETY OF APOTHECARIES OF LONDON.—The following gentlemen having passed the Qualifying Examination in Medicine, Surgery, and Midwifery have received certificates entitling them to practise in the same, and have been admitted as Licentiates of the Society.

Carter, Ernest, 4, Beaconsfield Villas, Brighton.
 Crofton, Edward Regan, Cleheen House, Carrick-on-Shannon.
 Duckett, Charles Alexander, Great Yarmouth.
 Fletcher, Frederick James, 13, St. John's Road, Dudley.
 Fox, Hugh Clayton, Caddenham, Needham Market, Suffolk.
 Haynes, Edmund Lyall, 1, Lahsdowne Villa, Scarborough.
 Howard, Arthur Bertram MacLagan, 42, Orchard Road, Kingston-on-Thames.
 Moss, Arthur James, 11, Royal Crescent, Whitby.
 Sugden, Henry Clapham, Broad Oak Park, Worsley.
 Thomas, Charles Ernest, 126, Leadenhall Street, E.C.

The following gentlemen passed the Surgical portion of the examination.

J. O. W. Barratt, of University College Hospital; G. A. Gunton, of St. George's Hospital; S. H. Hughes, of St. Bartholomew's Hospital; W. J. Middleton, of St. Bartholomew's Hospital; H. H. Phipps, of University College Hospital; F. H. Roberts, of King's College Hospital; T. H. A. Valentine, of St. Bartholomew's Hospital; L. L. Verano, of St. Bartholomew's Hospital; J. S. Walton, of the Newcastle School of Medicine; R. E. Weigall, of the University of Melbourne; G. H. Whitaker, of St. Bartholomew's Hospital.

The following gentleman passed the Medical portion of the examination.

A. E. Read, of Thomas's Hospital.

ERRATUM.—In the pass list for the final examination of the Royal College of Physicians of Edinburgh, published in the JOURNAL of February 4th, Mr. J. Hoy, Ashby-de-la-Zouch, should have been Mr. J. Hoyle.

MEDICAL VACANCIES.

The following Vacancies are announced:

- BRISTOL DISPENSARY.**—Surgeon. Applications by March 8th to E. Stock, Esq., 57, Queen Square, Bristol.
- BRITISH SEAMAN'S HOSPITAL,** Cronstadt, St. Petersburg.—Resident Medical Officer. Salary, £180 per annum, with furnished apartments, etc. Applications to H. Bell, Esq., H. M. Consul, St. Petersburg.
- CANCER HOSPITAL,** Brompton.—Registrar. Salary, £50 per annum, with board and residence. Applications by March 6th to the Secretary.
- CENTRAL LONDON OPHTHALMIC HOSPITAL,** Gray's Inn Road, W.C.—Two Assistant Surgeons. Applications by March 6th to the Secretary.
- CITY OF ABERDEEN.**—Medical Officer of Health. Salary, £300 per annum. Applications by March 14th to W. Gordon, Esq., Town Clerk, Aberdeen.
- CITY OF ST. ALBANS.**—Medical Officer of Health and Analyst. Salary, £65 per annum. Applications by March 7th to I. N. Edwards, Esq., Town Clerk, St. Albans.
- CLOGHER UNION.**—Medical Officer, Aughnacloy Dispensary. Salary, £115 per annum, and fees. Applications to Honorary Secretary of Committee. Election on March 14th.
- COTON HILL LUNATIC HOSPITAL.**—Assistant Medical Officer. Salary, £100 per annum, with board, etc. Applications by March 10th to the Medical Superintendent.
- DEWSBURY AND DISTRICT GENERAL INFIRMARY.**—House-Surgeon. Salary, £80, with board, etc. Applications by March 6th to the Chairman of the House Committee.
- EAST LONDON HOSPITAL FOR CHILDREN,** Shadwell, E.—Resident Clinical Assistant. Board and lodging. Applications by March 22nd to the Secretary.
- LEICESTER INFIRMARY AND FEVER HOUSE.**—Assistant House-Surgeon. Salary, £50, with board, etc. Applications by March 10th to the Secretary, 24, Friar Lane, Leicester.
- LUDLOW UNION.**—Medical Officer, Munslow District. Salary, £70 per annum, and fees. Applications by March 10th to W. J. Holyoake, Esq., Clerk, Poor-Law Office, Ludlow.

- OUGHTERAD UNION.**—Medical Officer, Oughterard Dispensary. Salary, £112 per annum and fees. Applications to Mr. Robert Mous, Honorary Secretary, Drumnakill Lodge. Election on March 7th.
- OUGHTERAD UNION.**—Medical Officer to the Workhouse, Infirmary, and Fever Hospital. Salary, £70 per annum. Applications to Mr. J. Gillmore, Clerk of Union. Election on March 7th.
- OWENS COLLEGE,** Manchester.—Professor of Obstetrics. Applications by March 20th to the Registrar.
- ST. HELEN'S FRIENDLY SOCIETIES' MEDICAL AID ASSOCIATION.**—Resident Medical Officer. Applications by March 20th to Mr. H. Whittle, Secretary, 85, Argyll Street, St. Helen's, Lancashire.
- UNIVERSITY OF GLASGOW.**—Four Examiners in Medicine. Annual fee, £30 or £40. Applications by March 5th to the Secretary of the University Court, G. D. McLellan, Esq., 145, West George Street, Glasgow.

MEDICAL APPOINTMENTS.

- AOKLAND,** W. R., M.R.C.S., L.D.S., appointed Dental Surgeon to the Royal Infirmary, Bristol.
- CALVERT,** James, M.D.Lond., B.A., B.Sc., appointed Assistant-Physician to the Royal Hospital for Diseases of the Chest, City Road, vice J. J. Pringle, M.B., C.M.Edin., resigned.
- CLARK,** A. F. C., M.B., C.M., appointed Assistant Medical Officer to the District Asylum, Roxburgh.
- HARDWICK,** F. S., M.D., C.M., appointed Medical Officer to the West Ashford Union, Second District.
- JONES,** F. W., Brandram, M.B., C.M., appointed Medical Officer to the Monmouth District of the Monmouth Union.
- MACKINNON,** Charles, M.B., C.M.Glas., appointed Medical Officer to the Cirencester Union, vice C. P. Hooker, L.R.C.P., L.R.C.S.Edin., resigned.
- MITCHELL,** Gerald, M.D., appointed Medical Officer to the Templemore Dispensary District, vice Wm. Fennelly, L.R.C.P., deceased.
- RUSSELL,** W., M.D., appointed Pathologist to the Royal Infirmary, Edinburgh.

PRIZE ESSAY.—Prizes of the value of 1,500 pesetas (£60) and 750 pesetas (£30) respectively, are offered by the Royal Academy of Medicine and Surgery of Barcelona under the will of the late Dr. Francisco Garé y Boix, for the two best essays on the following subject: Pathogeny of Gonorrhœa (with illustrative preparations); its Clinical Features, with Special Reference to the Chronic Forms of the Disease, and to Recurrence; the various Morbid Processes accompanying and following it; its Prophylaxis and Treatment. In addition to the money prize, the title of Corresponding Fellow of the Academy will be conferred on each of the successful candidates. Essays, which must be written very legibly either in Spanish, French, or Italian, must be sent to the Perpetual Secretary of the Academy, Dr. Luis Suñé y Molist, Baños Nuevos No. 9, Barcelona, before midday of June 30th, 1889. No essay must bear the name or address of the author, which must be sent separately in a sealed envelope, bearing a motto corresponding to one on the essay. The successful essays are to be the property of the authors, who will be at liberty to publish them, but without any correction, addition, or suppression.

INTERHOSPITAL FOOTBALL MATCHES.—In the penultimaet round (Association), the match St. Bartholomew's v. St. Mary's was decided on February 22nd. These clubs had previously played a draw, but St. Bartholomew's got together their best team and gained a decisive victory by five goals to one. In the penultimate round (Rugby), St. Thomas's v. St. Bartholomew's was postponed until Monday last on account of the frost. It was expected that the St. Thomas's forwards would effectually prevent their opponents backs being dangerous, and the result was a victory for St. Thomas's by one goal, five tries, and four minors to *nil*. Up to half-time only a try had been scored, but towards the end the game was one-sided. St. Mary's v. Middlesex (Holders): Unfortunately for the holders, they lost both their half backs about half-time—one with fractured clavicle, and the other with a crushed malar bone. The game was fairly even, but the St. Mary's men held the scrimmage. The result was one goal, four tries and four minors to *nil*.

In connection with the Royal visit which the Queen paid to the Royal National Hospital for Consumption, Ventnor, on February 11th, Her Majesty has been graciously pleased to forward eight engravings of herself and other members of the Royal Family, including one of the late Duke of Albany, who was President of the hospital at the time of his death. The Board of Management have received a communication from the Home Secretary stating that Her Majesty has been graciously pleased to command that the block of houses which was inspected by the Queen shall be known hereafter by the title of "The Victoria Block" of the Royal National Hospital for Consumption.

SEAMEN'S HOSPITAL, GREENWICH.—The report presented at the annual court of governors of the Seamen's Hospital, Greenwich, stated that the institution had extended its operations to Gravesend, for the benefit of the sick sailors arriving there, and that, during the last year, 2,382 patients had been treated in the wards at Greenwich, in addition to the treatment of out-patients. There was a lessened income, owing to the falling in of annuities.

PAISLEY INFIRMARY AND CONVALESCENT HOME.—During 1887, there were treated in Paisley Infirmary 1,207 patients, of whom 114 had died. It is satisfactory to observe that there has been an increase in all items of income, and a previously existing deficiency on revenue account had been reduced from £630 to £356.

GREENOCK INFIRMARY.—The report of this infirmary for 1887 shows the total number of cases treated during the year to be 924, an increase of 61 on 1886. Of these, 575 were admitted to the medical and surgical wards, 19 fewer than during the preceding year. A very large proportion of the cases consisted of accidents and other urgent cases. The mortality was 8.8 per cent. To the fever hospital 349 had been admitted, an increase of 80, and the mortality in this department was less by 2 per cent. than in 1886. Scarlet fever had prevailed during the whole year, and had been epidemic in September, October, and November. No less than 208 children of 10 years of age and under had been admitted, of whom 7 died. The calls at the dispensary numbered 10,750.

THE METROPOLITAN ASYLUMS BOARD.—The returns presented at the meeting of the Metropolitan Asylums Board, held on Saturday last, stated that during the fortnight up to midnight on February 23rd, 239 patients were received into the fever asylums, as against 260 in the previous fortnight; 33 died and 384 were discharged, leaving 1,507 cases under treatment, including 1,358 of scarlet fever. The number under treatment on Friday morning, February 24th, was 178 fewer than a fortnight before.

INSPECTION OF THEATRES.—The Bill for a reform of the present system of licensing and inspecting of metropolitan theatres and music halls, which bears the name of Mr. Dixon-Hartland, Mr. Woodhall, Mr. Lawson, and Sir Albert Rollit, proposes to place these places of entertainment under the Home Secretary, who will have the power of appointing inspectors, whose duty it will be to make an annual inspection of the arrangements, and to report thereon. No licence will be granted until the Home Secretary's certificate is obtained. This is a step in the right direction.

THE POLLUTION OF THE THAMES.—In the Queen's Bench the case of the Queen v. the Staines Local Board recently came before the Court in the form of an indictment against the Local Board under the Public Health Act to recover penalties for the pollution of the Thames by the influx of sewage. The Thames Conservancy were the prosecutors. The Staines Local Board agreed to a verdict against them on the facts, with the view of having the points of law involved discussed on a future day.

DEATH FROM A FOOTBALL ACCIDENT.—A man named Murphy has recently died in Bootle Hospital from injuries sustained at a football match. In the course of the game in which he was engaged Murphy received his opponent's elbow in his throat with such force as to burst the trachea. A tube was inserted, but the deceased never rallied.

A STOMATOLOGICAL SOCIETY.—"Stomatology" appears to be the latest development of specialism. It has not yet spread to this country, so far as we are aware, but a Society has, it is said, been founded in Paris which is to devote itself exclusively to the study of diseases of the mouth and its "annexes."

DR. T. LAUDER BRUNTON, F.R.S., has been elected a member of the Athenæum Club by the Committee under Rule 2, which empowers them to elect nine persons annually "of distinguished eminence in science, literature, or the arts, or for public services."

THE PARKES MUSEUM (Margaret Street, W.)—The following donations to the funds of the museum have just been received: The Right Hon. Earl of Derby, £25; the Leathersellers' Company, £21; Mr. Robert Pullar, £10 10s.; and also a donation from the officers of the Army Medical Staff, Netley.

WEST LONDON HOSPITAL.—The Duke of Cambridge has signified his intention to preside at the festival dinner in aid of the funds of the West London Hospital, Hammersmith Road, on Tuesday, May 1st, at the Hôtel Métropole.

FAILURE OF ANTIFEBRIN IN EPILEPSY.—Antifebrin has been tried in epilepsy by Dr. Borosnyoe, of the Hermannstadt Asylum. He found (*Therap. Monatshefte*) that it had no effect on the fits.

ARDEE UNION.—The Local Government Board have sanctioned the appointment of Dr. Bradley as medical officer to St. Mary's Dispensary.

LIMERICK WORKHOUSE.—It appears that the hospital part of the workhouse is greatly overcrowded; and a committee of the guardians has been appointed to consider the matter.

SUCCESSFUL VACCINATION.—Dr. Charles J. Jones, Justice of the Peace of Rhondda Valley, South Wales, has for the third time received the Government grant for efficient vaccination.

MR. ERNEST SHEAF, F.R.C.S. Ed., M.R.C.P., of Toowoomba, has been appointed Justice of the Peace in the Colony of Queensland.

The next meeting of the American Medical Association will be held in Cincinnati in May.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 P.M.—Professor Charles Barrett Lockwood, F.R.C.S.: Lecture I. On the Development of the Organs of Circulation and Respiration, including the Pericardium, Diaphragm, and Great Veins.

MEDICAL SOCIETY OF LONDON—General meeting at 8 P.M. Ballot. Ordinary meeting at 8.30: Dr. Ferrier and Mr. Victor Horsley: A Case of Successful Treatment of a Cerebral Abscess in connection with Otitis Media. Dr. Ord: A Paper on Some Curious Relations of Gastric Ulcer. Dr. Broadbent: A Paper on the Prognostic Significance of the Blood Pressure in Acute Renal Disease.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—Casual communications by Mr. David Hepburn and Mr. Boyd Wallis. Mr. Frederick Eve: Communication on Actino-Mycosis and some Micro-parasitic Affections of the Jaws and Mouth. Inaugural Address by the President, Daniel Corbett, M.R.C.S.

TUESDAY.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, 5 P.M.—Dr. W. J. Mickle: The Goulstonian Lectures: Lecture I. Insanity in Relation to Cardiac Disease and Phthisis.

PATHOLOGICAL SOCIETY OF LONDON, 8.30 P.M.—Specimens.—Sir W. Mac Cormac: Epithelioma of Kidney associated with Calculus. Mr. B. Pile: Villous Carcinoma of Breast. Mr. H. Fenwick: Villous Papillomata and "Contact" Carcinoma of Bladder. Dr. N. Moore: Two Cases of Renal Disease. Mr. Silcock: Acute Necrosis. Mr. Clutton: Osteitis Deformans. Mr. Treves: Horny Tumour on Neck of Mouse. Card Specimens.—Mr. Shattock: 1. Osseous Ankylosis after Gouty Disease. 2. Gouty Deposit in Bone. Mr. Treves: Tumour of Spermatie Cord. Mr. Mansell-Moullin: Syphilitic Crania.

WEDNESDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 P.M.—Professor Charles Barrett Lockwood, F.R.C.S.: Lecture II. On the Development of the Organs of Circulation and Respiration, including the Pericardium, Diaphragm, and Great Veins.

OBSTETRICAL SOCIETY OF LONDON, 8 P.M.—Specimens will be shown. Dr. Boxall: Scarlatina during Pregnancy and the Puerperal State. Dr. Champneys: Description of a New Operation for Vesico-urinary Fistula.

HOSPITAL FOR CONSUMPTION, Brompton, 4 P.M.—Dr. Theodore Williams: Pathology and Modern Treatment of Bronchial Asthma.

THURSDAY.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, 5 P.M.—Dr. W. J. Mickle: The Goulstonian Lectures: Lecture II. Insanity in Relation to Cardiac Disease and Phthisis.

FRIDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 P.M.—Professor Charles Barrett Lockwood, F.R.C.S.: Lecture III. On the Development of the Organs of Circulation and Respiration, including the Pericardium, Diaphragm, and Great Veins.

CLINICAL SOCIETY OF LONDON, 8.30 P.M.—Mr. Croft: Case of Dislocation of Semilunar Cartilage of Knee-joint: Excision; Cure. Mr. C. Symonds: Two Cases of Dislocation of Index Finger; Reducing by Opening the Joint and Division of a Retaining Band after Failure of Other Methods. Mr. G. R. Turner: Case of Dislocation Backwards of the Metacarpophalangeal Joint of the Thumb in which Resection of the Head of the Metacarpal Bone was practised. Mr. Bland Sutton: Case of Adenoma of the Pinna. Dr. Hadden: Case of Dry Mouth or Suppression of Salivary and Buccal Secretions.

BIRTHS, MARRIAGES, AND DEATHS.

The *charoe* for inserting announcements of Births, Marriages, and Deaths is 5s. 6d., which should be forwarded in stamps with the announcement.

MARRIAGE.

BEALES—BARNDY.—On February 25th, at the Parish Church, Great Yarmouth, by the Vicar, Thomas Wm. Lewis Beales, M.R.C.S. Eng., L.R.C.P. Lond., to Clara Barnby, youngest daughter of the late J. E. Barnby, Esq., of Great Yarmouth.

DEATHS.

DOWNES.—On Wednesday, February 29th, 1888, at Mellerstein, Bolton Road, Eastbourne, Ellen Mary (May), the only daughter of Dr. and Mrs. Downes, aged two years and seven months.

MERRIMAN.—On February 25th, at 42, Kensington Square, John William Conyers Merriman, L.R.C.P. and M.R.C.S.E., in the 34th year of his age, eldest son of John J. Merriman, of Kensington.

SANKEY.—February 28th, at the Elms, Sutton Valence, Kent, William Sankey, M.D. St. And., M.R.C.S., and L.S.A., aged 72.

TERRY.—On February 23rd, at Mells, Frome, George Terry, M.R.C.S., aged 60.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY.....10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's (Ophthalmic Department); and Royal Westminster Ophthalmic.—2 P.M.: Metropolitan Free; St. Mark's; Central London Ophthalmic; Royal Orthopædic; and Hospital for Women.—2.30 P.M.: Chelsea Hospital for Women.

TUESDAY.....9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's; St. Bartholomew's (Ophthalmic Department); St. Mary's; Royal Westminster Ophthalmic.—2 P.M.: Westminster; St. Mark's; Central London Ophthalmic.—2.30 P.M.: West London; Cancer Hospital, Brompton.—4 P.M.: St. Thomas's (Ophthalmic Department); Guy's; National Orthopædic.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: Middlesex.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: London; University College; Westminster; Great Northern Central; Central London Ophthalmic.—2.30 P.M.: Samaritan Free Hospital for Women and Children; St. Peter's.—3 to 4 P.M.: King's College.

THURSDAY.....10.30 A.M.: Royal London Ophthalmic.—1 P.M.: St. George's.—1.30 P.M.: St. Bartholomew's (Ophthalmic Department); Guy's (Ophthalmic Department); Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Central London Ophthalmic; Hospital for Diseases of the Throat; Hospital for Women.—2.30 P.M.: North-West London; Chelsea Hospital for Women.

FRIDAY.....9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.15 P.M.: St. George's (Ophthalmic Department).—1.30 P.M.: Guy's; Royal Westminster Ophthalmic.—2 P.M.: King's College; St. Thomas's (Ophthalmic Department); Central London Ophthalmic; Royal South London Ophthalmic; East London Hospital for Children.—2.30 P.M.; West London.

SATURDAY.....9 A.M.: Royal Free.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: King's College.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Middlesex; Royal Free; Central London Ophthalmic.—2.30 P.M.: Cancer Hospital, Brompton.

HOURS OF ATTENDANCE AT THE LONDON HOSPITALS.

CHARING CROSS.—Medical and Surgical, daily, 1; Obstetric, Tu. F. 1.30; Skin, M. Th. 1.30; Dental, M. W. F., 9.

GUY'S.—Medical and Surgical, daily, 1.30; Obstetric, M. Tu. F. 1.30; Eye, M. Tu. Th. F. 1.30; Ear, Tu. F. 12.30; Skin, Tu. 12.30; Dental, Tu. Th. F. 12.

KING'S COLLEGE.—Medical, daily, 2; Surgical, daily, 1.30; Obstetric, Tu. Th. S., 2; o.p., M. W. F., 12.30; Eye, M. Th. 1; Ophthalmic Department, W., 1; Ear, Th. 2; Skin, Th.; Throat, Th., 3; Dental, Tu. F. 10.

LONDON.—Medical, daily, exc. S., 2; Surgical, daily, 1.30 and 2; Obstetric, M. Th., 1.30; o.p. W. S., 1.30; Eye, W. S., 9; Ear, S., 9.30; Skin, Th., 9; Dental, Tu. S., 9.

MIDDLESEX.—Medical and Surgical, daily, 1; Obstetric, Tu. F. 1.30; o.p. W. S., 1.30; Eye, W. S., 8.30; Ear and Throat, Tu., 9; Skin, Tu., 4; Dental, daily, 9.

ST. BARTHOLOMEW'S.—Medical and Surgical daily, 1.30; Obstetric, Tu. Th. S., 2; o.p. W. S., 9; Eye, Tu. Th. S., 2.30; Ear, Tu. F., 2; Skin, F., 1.30; Larynx, F., 2.30; Orthopædic, M., 2.30; Dental, Tu. F., 9.

ST. GEORGE'S.—Medical and Surgical, M. T. F. S., 1; Obstetric, Tu. S., 1; o.p. Tu., 2; Eye, W. S., 2; Ear, Tu., 2; Skin, W., 2; Throat, Th., 2; Orthopædic, W., 2; Dental, Tu., S., 9, Th., 1.

ST. MARY'S.—Medical and Surgical, daily, 1.45; Obstetric, Tu. F., 1.45; o.p., M. Th., 1.30; Eye, Tu. F. S., 9; Ear, M. Th., 3; Throat, Tu. F., 1.30; Skin, M. Th., 9.30; Electrician, Tu. F., 2; Dental, W. S., 9.30; Consultations, M., 2.30; Operations, Tu., 1.30; Ophthalmic Operations, F., 9.

ST. THOMAS'S.—Medical and Surgical, daily, except Sat., 2; Obstetric, M. Th., 2; o.p. W., 1.30; Eye, M. Th., 2; o.p., daily, except Sat., 1.30; Ear, M., 12.30; Skin, W., 12.30; Throat, Tu. F., 1.30; Children, S., 12.30; Dental, Tu. F., 10.

UNIVERSITY COLLEGE.—Medical and Surgical, daily, 1 to 2; Obstetrics, M. Tu. Th. F., 1.30; Eye, M. Tu. Th. F., 2; Ear, S., 1.30; Skin, W., 1.45, S. 9.15; Throat, Th., 2.30; Dental, W., 10.30.

WESTMINSTER.—Medical and Surgical, daily, 1.30; Obstetric, Tu. F., 3; Eye, M. Th., 2.30; Ear, M., 9; Skin, Th., 1; Dental, W. S., 9.15.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS respecting editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

In order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the office of the JOURNAL, and not to his private house.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate beforehand with the Manager, 429, Strand, W.C., London.

CORRESPONDENTS who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication. CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

QUERIES.

A CASE OF "QUINTAN" AGUE.
T. E. L. writes: In the JOURNAL of February 18th Dr. J. P. Henry describes a case of "quintan" ague. It would be interesting to know if the patient's blood was ever examined for *flavaria sanguinis hominis*, as the febrile attacks occasionally occurring in persons who have flavaria in their blood somewhat resemble ague with a long interval.

SEA-SICKNESS.
M.R.C.S. would be glad to have the practical experiences of any member as to the value of antipyrin as a cure for sea-sickness.

PODOPHYLLIN.
M.D. writes: Will any of your readers who are in the habit of using resina podophylli kindly answer the following question: Is podophyllin in solution as effectual as a purgative or cholagogue as the same dose given in the solid form to the same patient? I say the same patient because this drug varies in its effect in different cases.

OILY DIARRHŒA.
DEPUTY SURGEON-GENERAL writes: A healthy-looking lad, aged 10½ years, has suffered for the last five years from discharge of oil from the bowels; the discharge is most frequently at night, and involuntary—occurs during sleep; the discharge is not constant, nor is it of the same amount always; usual quantity about one drachm and a half when most severe. Ordinarily it is sufficient to stain his clothes or sheets: He is bright, intelligent, and very active, except when the discharge is greatest, when he is dull and looks depressed. His motions are very offensive, never natural in colour or consistence, whitish and clay- or chalk-like. He does not suffer apparently from disease of liver, spleen, or pancreas, except so far as the oily discharge points to disease of the latter. He has had iron and bismuth, Parrish's chemical food, and attention to diet; but, although with benefit, not with such marked improvement as to encourage a continuance of the treatment. Any indigestible food increases the disorder. Appetite is very good, often too much. The lad had cholera in India about eight years ago, but this complaint did not show itself until some three years afterwards. Suggestions regarding this case are requested.

ANSWERS.

B.—The publication of the addresses of medical officers on the Illustrated advertisement of the Chelsea Hospital for Women is not in accordance with professional rule.

DR. JOHN WIGHT.—Yes.

IDIOSYNCRASY TO QUININE.
D. L. R. writes: In reply to "H. G. H.," I may state that I know of two cases in which quinine produced exactly the symptoms mentioned. One was a lady I attended for malarial symptoms during a voyage from India, in whom it produced redness of all the skin and intense itching. The other is in myself. Ever since taking an overdose some years ago I cannot take even a small dose without its producing redness and great itching of all the body, accompanied by diarrhœa. Arsenic did not prevent the symptoms in either case.

NOTES, LETTERS, ETC.

METROPOLITAN PROVIDENT DISPENSARIES.
DR. RICHARD PARAMORE (2, Gordon Square, W.C.) writes: Your correspondent Dr. Rentoul says: "It is well known that a club doctor's life is a broken-hearted life, full of worries and insults." The provident dispensary is an extension of the club system. Yet Dr. Rentoul hopes that the provident system will be given a trial in London. It has been tried, and it has been found defective. Its warmest advocates admit that it is merely a tentative measure. There never has been before the profession a more absurd and mischievous attempt to improve medical matters than the establishment of provident dispensaries. In endeavouring to relieve the congested state of the out-patient department of hospitals, the interests of the great mass of the profession have been jeopardised, and all that makes life worth having, namely, happiness, in danger of being sacrificed.

I challenge anyone to show any difference between the club system, which Dr. Rentoul holds up to contempt, and the provident dispensary, for which he has an affection. Surely love is blind! When the controversy was raging on the Metropolitan Provident Medical Association in 1881, Mr. Timothy Holmes said he was proud of his connection with the movement, and extolled the Leicester Provident Dispensary, which, according to the *Leicester Journal* of January 15th, 1888, has exemplified its inferiority to ordinary club practice by giving quassia in a decomposed state, methylated spirits to make the tinctures, and the price of one hundred bottles of medicine being the same as one bottle!

I ventured to write a letter, which was published in the *Lancet*, in answer to Mr. Timothy Holmes, in which I said: "Contract work is notoriously bad, especially when the greatest amount has to be done for the least remuneration. Club practice is degrading and is a loophole for dishonesty, and it is rare for a club patient to receive the same amount of attention and quality of medicine that ordinary private patients obtain, and yet this dispensary scheme is merely an amplification of the club system—with this important difference, that in clubs and friendly societies none but candidates of a certain age and in good health can be admitted."

It is sad to see men of intelligence lending themselves to bolster up a system which has nothing to recommend it beyond pandering to those mean, paltry, niggardly, and contemptible persons who gladly avail themselves of cheap doctoring, especially when they read, in one of the handbills extensively circulated by the Metropolitan Provident Medical Association: "Families may join and insure against the risk of heavy doctors' bills, often difficult to pay."

The stamp of respectability has been endeavoured to be put on that touting which has hitherto been looked upon as disreputable. What may be forgiven under extenuating circumstances in a young, needy, and struggling practitioner is unpardonable in a company of medical men who are firmly seated on the saddle of successful pursuit.

The following are some of the objections to the scheme of the Metropolitan Provident Medical Association: 1. That it is destructive to the interests and welfare of the members of the medical profession, whose peace of mind is

essential to the proper discharge of their duties. 2. That it sails under false colours by offering independence, no charity, self-support, self-management, choice of a doctor to those who will join it, and by saying every medical man of respectability may be on the staff of the dispensary. 3. That it is injurious to the public by creating distrust and want of confidence in the medical profession, and encouraging medical men to scamp their work by underpaying them. 4. That it fosters meanness, trickery, lying, and deception on the part of the members who join it who are well able to pay ordinary medical charges. 5. That it condones and encourages fraud by obtaining for an unlimited time what ought to be valuable services under the pretence of payment which amounts to next to nothing, so that each member can get "on demand" and as "a matter of right" "the sort of treatment that the family doctor gives to the rich men." 6. That it is founded on the club system, which has continued to exist through greed on the one hand and impecuniosity on the other to degrade the medical profession and to demoralise the public.

I repeat what I wrote seven years ago: "Wherever the provident dispensary movement has been tried, it has done more harm than good. Evidence is not wanting to prove that its introduction has harassed and undermined the profession." The happiness of the many is sacrificed by the more than doubtful benefit of the few. We have already too many medical monopolies, and quite enough to contend against, without the manoeuvres of provident dispensaries or any great wholesale plan of treating disease. If there were a scarcity of medical men and a dearth of medical relief there would be some excuse for the cruel, wanton, and needless experiment on the lives of suffering humanity in the form of provident dispensaries. I know it has some upholders; so has every wrong that has disgraced the world!

VENTRAL NEPHRECTOMY FOR HYDRONEPHROSIS.

MR. R. H. A. HUNTER (Battersea) writes: In reply to the letter of Mr. Clement Lucas, I can only repeat what I stated in my last communication that as in my opinion each case of hydronephrosis requires to be treated on its own merits, it is a waste of time to continue this controversy. As Mr. Lucas did not see the case, I maintain he is not in a position to judge as to whether the treatment adopted by me was right or wrong. My own impression, as well as those who were with me, regarding the case is that I acted rightly, so much so that should a similar case fall into my hands I would treat it in the same manner, with the addition of the drainage-tube, when I would have but little fear as to the result. Such operations I am confident do not depend so much upon their magnitude as the manner in which they are performed.

INVERSION OF THE UTERUS.

DR. MARK SHARMAN (Leicester) writes: Shortly after 12 A.M. on February 16th I was called to the assistance of a midwife. On arriving, I found the patient, aged 40, pulseless, collapsed, and dying. I gave two hypodermic injections of ether, and raised the foot of the bed. There had been considerable hæmorrhage, but not sufficient to account for her condition. On examination, the uterus was found completely inverted, protruding beyond the external genitals as far as it was possible to do, the placenta being firmly adherent over the fundus. I replaced the organ and removed the placenta. The patient died within five minutes of my arrival. The midwife said: "The child was delivered alive without difficulty, and"—pointing to the uterus and placenta—"this came ten minutes afterwards." Of course I was unable to verify my suspicion that the cord had been pulled upon and undue pressure applied to the fundus uteri.

I may add that the woman had been in a very destitute state during this winter, probably causing a relaxed state of her system. There was no history of any appreciable difficulty in her former labours.

BRITISH QUALIFICATIONS.

MR. G. H. PINDER (Manchester) writes: I was asked the other day to sign a certificate for a patient who is a member of the Railway Guards' Universal Friendly Society. As I am only a College and Hall man, having been unfortunately enough to be an English student, I was unable to do so. Rule 34 of this society states: "In all cases this certificate must be signed by an M.D." And attention is specially called to the letters M.D., which in the certificate are underlined. Thus, a man with the qualification of F.R.C.S. Eng. and M.R.C.P. Lond. would be unable to sign this certificate, whereas one holding that of one of the numerous Scotch universities could settle the matter at once.

If Scotch degrees were thrown open to English students as English qualifications are to Scotch, we Englishmen should not have so much reason for complaint. For many years the passport to Manchester appointments has been "Scotch M.D.," and, as a rule, to have been a Manchester student was quite enough to damn any chance which a candidate might have, if a Scotch qualification was in the way. We have been inundated for years with Scotch qualifications, from the M.D. Edin. to the Licentiate of the refuge for the destitute. Many a man, after having been plucked in England, has wended his way North, and, to the surprise of his fellow-students, has reappeared as "Dr. Smith," or "John Jones, Physician and Surgeon."

Everything English now seems under a cloud, and until we get a good sound British qualification, which every man practising in Great Britain ought to be compelled to possess, the only consolation which most of us College of Surgeons men have is the satisfaction of knowing that "Mr. So-and-So, Surgeon," practically means "English student, London qualification; get your bread and cheese as best you can."

A POST-GRADUATE COURSE IN SKIN DISEASES.

MR. W. STUART LOW, 309, Waterloo Road, S.E., writes: For two or three weeks past an advertisement has been inserted in the JOURNAL stating the desire of a number of medical men to get up a course of post-graduate lectures on skin diseases. As we have not yet got a sufficiently large number of names to form a good class, and as we know that this is a course that is much wanted by practitioners, perhaps you would be kind enough to give all an opportunity of joining by giving a prominent notice in the JOURNAL of our desire and intention.

COMMUNICATIONS, LETTERS, etc., have been received from:

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE "BRITISH MEDICAL JOURNAL."

Seven lines and under	£0 3 6
Each additional line	0 0 4
A whole column	1 15 0
A page	5 0 0

An average line contains seven words.

When a series of insertions of the same advertisement is ordered, a discount is made on the above scale in the following proportions, beyond which no reduction can be allowed.

For 6 insertions, a deduction of	...	10 per cent.
" 12 or 13	20 ..
" 26	25 ..
" 52	30 ..

Special terms for occasional change of copy during series: 20 per cent. if not less than 26 pages be taken (or their equivalent 25 52 in half or 30 104 } quarter pages.

For these terms the series must, in each case, be completed within twelve months from the date of first insertion.

Advertisements should be delivered, addressed to the Manager, not later than noon on the Wednesday preceding publication, at the Office, at the time, should be accompanied by a reference to the JOURNAL; and, if not paid

Post-Office Orders should be made payable to the British Medical Association, at the West Central Post-Office, High Holborn, London, W.C. Small amounts may be paid in postage-stamps.

THE GOULSTONIAN LECTURES

OR

INSANITY IN RELATION TO CARDIAC AND AORTIC DISEASE AND PHTHISIS.

Delivered before the Royal College of Physicians of London.

By WM. JULIUS MICKLE, M.D., F.R.C.P.LOND.,
Medical Superintendent, Grove Hall Asylum.

LECTURE I.

WHEN deeply but unexpectedly honoured by the invitation to deliver the Goulstonian Lectures at the Royal College of Physicians, and the choice of a subject became necessary, my mind turned, in the first place, to the therapeutics of insanity. Ascertaining, through the courtesy of Sir H. Pitman, that it was neither usual nor deemed to be desirable that therapeutics should occupy the Goulstonian lecturer, I next turned to the pathology of insanity. Having recently written on the pathology of general paralysis, the most interesting, and a very frequent form of mental disease, I could not well deal with the pathology of insanity, except in its general aspects. This course seemed to be undesirable, unless in conjunction with the exposition of a new and more scientific classification of insanity, an ambitious task to which I did not feel adequate, and for the successful accomplishment of which, indeed, the time is not yet ripe. Therefore the subject selected was one of more common medical interest. In general terms, these lectures constitute an attempt to assist, however slightly, in the work of bridging over the chasm which unhappily has separated, more than is necessary, the study of mental disease from that of the general body of medical science, and the treatment of insanity from that of other forms of disease; and, in particular terms, they constitute an attempt to clear up the existing obscurity on some important relations of mental disease, to more accurately and definitely subdivide and arrange the phenomena concerned, and in accordance with the teaching of my clinical and pathological studies.

In the relations of insanity to visceral affections one is dealing with a subject which should interest other medical men as much as mental specialists; a subject which lies in the "border-land," which blends mental with general medicine, which at least, in some of its phases, may be equally studied by the family or consulting practitioner, and by the one engaged in the care of the insane, which, in other of its phases, can scarcely be studied adequately by either alone.

Intending to deal in a general way with the subject of visceral affections in the insane, I analysed the clinical and necroscopic records relating to all the viscera in nearly 250 cases, constituting slightly more than half of my necropsies at disposal, but found that persistence in that intention and work would reduce these lectures to a dry statistical record; and, in the event, it was found impossible to do more than deal—and even that inadequately—with some of the forms of heart disease, aortic disease, and pulmonary phthisis, in certain of their relations to insanity. Yet, over those of most others, my cases possess the advantage that the clinical and pathological material come from the very same cases, the clinical phenomena being noted and the necropsies made by the same observer.

General considerations, as to visceral affections producing or modifying insanity.

Our emotions are closely bound up with our systemic conditions, and there was some degree of truth in Bichat's¹ notion that in the organic processes are located the emotions and passions; but upon this general aspect of the subject—upon the broad question of visceral states affecting mental—I need not dilate, and the less so as it has been eloquently set forth by Dr. Maudsley² in his Goulstonian lectures some years ago. His argument I need not reproduce; but let me, at a stroke, place the matter before you by

a citation or two. "The internal organs are plainly not the agents of their special functions only, but by reason of the intimate consent or sympathy of functions, they are essential constituents of our mental life." Again, "mind.....sums up and comprehends the bodily life." Now, if this be so, "the question arises whether each of the internal organs has not also a special effect, giving rise to particular feelings with their sympathetic ideas." Comparatively slender has been the clinical and pathological evidence hitherto brought forward in support of that thesis, and for decision of the questions involved. To add to that evidence will be one of the endeavours in what I subsequently place before you.

INSANITY IN RELATION TO DISEASE OF THE HEART AND AORTA; THE CEREBRAL CIRCULATION.

Before turning to the special groups of cases, let us glance at some general aspects of the subject.

That so little is known of the influence of heart affections on insanity or its production, so little of the influence of insanity upon the heart, so little, in a word, of the play of mutual action and reaction between the heart and the cerebral (psychic) processes and their results, is surprising when we consider how easily and obviously the heart is affected by every emotion, and how dissimilar upon the heart and circulation are the effects of each.

Moreover, in reference to some of the factors yet to be named—the factors of insanity in heart disease—it has been denied that any marked changes of repletion or depletion can take place in the state of the cerebral circulation; it has been denied that active hyperemia or anemia of the brain can occur; or that, if it occurs, congestion of the brain can produce any decided cerebral symptom, or even any noteworthy influence on the tone or activity of the mental operations. Thus we know how vigorously the theory of cerebral congestion as the alleged basis of several forms of brain symptoms was attacked by the late Dr. Moxon³ in his Croonian lectures before this College, and how he attempted to show that the symptoms, so-called, of cerebral congestion came neither from visibly forcible arterial action, nor from visibly great venous congestion of the vessels of the head.

Obviously, with questions at once springing up as to the relation of cardiac disease to the nutrition of the brain, through the cerebral circulation, it will save much repetition and reference, later on, if at the very outset the salient conditions of the intra-cranial circulation are brought under view.

In proceeding to examine the conditions of the intra-cranial circulation, one meets the gravest discrepancies as to the most elementary facts. For example, while Haller⁴ alleged that one-fifth of the whole mass of blood in healthy man constitutes the supply to the encephalon, and while Spehl⁵ found in the rabbit in the waking state one-eighth to be the amount of blood contained in the head at a given moment relatively to the total bulk of blood in the system, yet we find it stated in Foster's *Physiology*⁶ that in the rabbit only about one per cent. of the total blood is at any one time in the brain, and that the blood supply to the human brain must be small. Making some allowance for the difference between the amount of blood in the rabbit's head at a given moment, and that in its brain only, there is still an enormous discrepancy between the estimate of 1 per cent. in the rabbit's brain, and the estimate of 12½ per cent. in its head, which latter share indeed, for the rabbit, does not offer any incongruity with the Hallerian estimate of one-fifth of the total blood as the supply for the relatively more developed, more preponderant, and more active human encephalon.

Leaving this subject of the share of the total blood contained in the cranium, we pass to the question whether, so long as the brain remains the same in size, the amount of blood within the cranium is, or is not, a fixed and definite quantity, an invariable amount. That, under all circumstances, it is an unchanging amount appeared to be evident from the theoretical considerations that the skull is a closed cavity, a complete sphere, the total bulk of whose contents, removed from the more usual conditions as to atmospheric pressure, must at all times be the same, and loss of the fluid portion of these be prevented, and therefore that, so long as the brain is neither shrunken, nor compressed, nor enlarged, the amount of intra-cranial blood must remain the same. Experiments by Kellie appeared to give reinforcement to this view, experiments widely accepted, and of which the reported

³ *Lancet*, April 18th, 1887, p. 689.

² *Body and Mind*. By Henry Maudsley, M.D.

results were that, on bleeding animals to death (their skull intact), the usual amount of blood was found, *post mortem*, in the cranium, and in strong contrast with the exsanguine state of the rest of the frame.

It is unnecessary here to refer in detail to the numerous experiments and observations which, since then, have clearly shown that physiological changes occur in the brain circulation, and that the amount of blood in the visible parts of its meninges, or making exit from its sinuses, varies constantly, and in a very considerable measure; of these observations I need only mention that on the vastly different states of the circulation of the brain, and the amount of its arterial supply, in the waking as compared with the sleeping state.

But still the skull has remained to some extent, a closed cavity, and there still existed a necessity for an unchanging amount of its total contents, and still has there been a disinclination to admit the existence of quantitative pathological changes in the circulation, that is to say, of amounts of blood not within the limits of physiological fluctuation, but springing wide therefrom on the line either of deficiency or of excess.

In this relation much has been made of the peculiarities of the intra-cranial circulation, and of the provisions for placing checks on excess, or grave deficiency, in the amount of blood supplied to the brain; and much has been made, also, of any great change in the blood-pressure on the walls of its vessels, and of the impossibility of any change whatever in these, except through the medium of the blood-vessels entering or leaving the skull, or through the medium of the cerebro-spinal fluid. These same checks, also, are concerned in the mechanism preventive of ill result from alteration in the pressure in the brain, whether from changes in atmospheric pressure, or in posture of the body, or in the force and activity of the blood circulation. So, also, are they intimately connected with the structural arrangements whereby the erect posture of man is made possible, and whereby the blood supply is kept up, and kept up so richly, too, at the lofty elevation of the brain.

The checks on over-active entrance of blood to the cranium, and on too great a blood-pressure in the vessels of the brain, are, chiefly, that the cardio-inhibitory centre in the medulla oblongata is stimulated, that the heart in this way is slowed, and thus the incoming overflow of blood is automatically stayed, and the balance of local circulation maintained. Moreover, that an increased supply of blood is stimulating to the brain is shown by experiments, for example, those of Lépine,⁷ in which stimulation of the anterior part of the cerebrum (of dogs) influences the heart-beats, and in so doing operates through the vagus, for on dividing one vagus no change followed stimulation of the opposite side of the brain, whereas stimulation of the same side of it lessened the frequency of heart and pulse. And, as Dr. Moxon pointed out, in man there is a supplemental contrivance whereby, when blood is streaming too freely, and under too severe pressure, into the brain, the finger-like vascular process, the cornu of the choroid plexus of the fourth ventricle, composed of thick tufts of blood-vessels, lodged in the lateral offset of the ventricle, and swollen by the incoming tide of blood, promptly presses on the adjoining and tense nerve-roots of the vagus, retarding the action of the heart, and thus shutting off the overplus of blood which would otherwise continue to arrive within the cranium. That these plexuses are so promptly swollen by the extra-inrush of blood is due to the fact that they receive their arteries directly from the great vessels immediately the latter enter the skull; hence they swell up, and promptly press on the pneumogastric nerve roots.

Another way in which a check is placed upon too great an influx of blood is connected with the fact that a change of pressure in or on the brain is necessitated by every change in the intra-cranial circulation. When, in active states of molecular movement and function on the part of the brain, there is more rapid blood-movement and increased intra-capillary pressure, the swelling of the brain in volume is checked, not merely by the unyielding walls of the cranial vault, but also by compression of the pial veins. Associated, as shown by Dr. Cappie⁸ with increased tension in the brain itself, with increased tension to which all the cranial contents are subjected, this compression of the veins places a brake on the over-activity of circulation, and tends to bring it to a stop. Placed between the onward driving forces of the heart, arteries, and capillaries, on the one hand; and, on the other, the locking or backward driving force of atmospheric pressure on the

blood in the sinuses, and thence on their tributary veins; and subjected with every expansion of the brain to pressure on the side of their walls, lessening and tending to obliterate their lumen, the veins of the brain-meninges occupy a position exposed to stress. If the forces on one side sink, those on the other rise; for example, (taking an illustration converse of the preceding) if influx of blood fails, the forces preventing efflux are enhanced, and of these the chief has now become the atmospheric pressure, the suction action of the sinking brain on the blood in veins and sinuses tending to fill them, and thus to bring about a venous fulness compressive of the brain surface.

By experiment, Grassley⁹ also showed that, under certain circumstances, an increase of the arterial blood-pressure retards the circulation in the skull; that, inasmuch as the blood-pressure in the brain-capillaries is greater than in the large cerebral veins, with increase of the brain pressure comes compression of the large cerebral veins rather than of the capillaries, as also a clogging and retardation of the blood stream. Another provision for relief of disorder of the cerebral blood movement is the so-called "derivative" circulation of the head, a side channel, so to speak, whereby some relief is afforded when the intra-cranial circulation is embarrassed and sore pressed.

On the other hand, the automatic mechanisms for checking the exit of blood from the brain are chiefly the arrangement of the cerebral and meningeal veins, which never accompany their arteries, ascend against the force of gravitation to the summit of the brain, pass forward; many of them, and enter the superior longitudinal sinus against the backward flowing stream, this opposition of currents in the sinuses and in the veins tending strongly to retard the venous flow, and make the venous side of the intra-cranial circulation leisurely, or even stagnant; and, in fact, the blood appears to issue from the sinuses only under pressure in the veins; while, if in active and strong states of the circulation the lock becomes too stringent here, relief is afforded by escape of blood through the inferior longitudinal and straight sinuses at the base of the brain, and out of the way of the lock just-mentioned (Moxon). Of atmospheric pressure we have already spoken.

Moreover, the choroid plexuses soak up, as it were, and account for, much of the incoming blood for the time, thus assisting in another way in giving easement. And in doing this they displace portions of the cerebro-spinal fluid, forcing it down from the ventricles of the brain to the subarachnoid space of the spinal cord; this upward and downward flow of the cerebro-spinal fluid, according to some, playing an important part in making changes possible in the blood supply to the brain. For a discussion of the automatic checks on great changes of the intra-cranial circulation involves a consideration of the mechanisms whereby variation of the blood-supply is permitted in health. Some hold that this is chiefly effected by the upward and downward play of the cerebro-spinal fluid, and by the changes of high and low tide in the lymph channels and lymph spaces of the brain, especially those that are subdural and those that are perivascular. When the brain is active, when the incoming tide of blood attracted to it swells it up and it expands, the hypothesis has been that room is made for the dilating vessels and for the larger amount of arterial blood they contain (and contain under increased pressure, perhaps), by the absorption of the lymph circulating in the finer passages, and pericellular, perivascular, and subdural lymph spaces, in proportion as the blood-vessels bathed in it dilate; and that the choroid plexuses press the cerebro-spinal fluid out of the ventricular spaces of the brain into the subarachnoid of the cord.

Nevertheless, it is not altogether clear to my mind why the spinal cord should be deemed to be prepared to receive without embarrassment or disorder two or three or more ounces of cerebro-spinal fluid over and above the usual quantity, and at a moment's notice, on the behest of the brain; those who tell us all about the backward and forward flow of the cerebro-spinal fluid have not provided for this exigency, or explained how the spinal cord adapts itself, without more ado, to the altered circumstances; they have not pointed to any mechanism in the cord whereby, in a moment, it may rid itself of the inundation. Perhaps the large and soft-walled veins of the meninges of the cord and of the bodies of the vertebrae easily permit outflow of blood under the pressure of cerebro-spinal fluid; or it may be that when the brain circulation is extremely active, that of the cord is less so; for when the amount of blood sent to the brain is increased during intellectual activity, the amount going to the arm is lessened, as tested by the plethysmograph; for, during intellectual activity,

⁷ Gazette des Hôpitaux, No. 90, 1875.

⁸ Brain; a Journal of Neurology, vol. II, p. 373.

⁹ Allgemeine Zeitschrift für Psychiatrie, Band XII, 1885, p. 707.

whilst the volume of the brain increased, Mosso¹⁰ found diminished calibre of the arteries to the forearm, together with a more frequent, smaller, pulse in them, and now catacrotic instead of anaerotic, as it had been; a change not due to respiratory influences. During mental attention and activity E. Gley¹¹ found the number of heart-beats increased, and the carotid artery and its pulse becoming dirotic, whilst a contrary state of the radial pulse existed; effects attributed to vasomotor influence. Thus it may be that if the cerebro-spinal fluid is forced from brain to cord, the concomitant conditions of lessened blood-supply to the cord enable the vertebral canal to accommodate the increased amount of cerebro-spinal fluid by an automatic arrangement. But be this as it may, there are two lines of discrepant view on the subject: the importance of the cerebro-spinal fluid, or its operation as above described in providing for easement and for considerable variations of the cerebral circulation, having been upheld by Majendie, Burrows, Carpenter, Hilton, Moxon and others; whilst, on the other hand, this importance and operation of the cerebro-spinal fluid have been called in question (amongst others) by Prof. Foster, Dr. Cappie, and M. Franck. Some of these affirm that changes of the brain circulation are provided for by the venous sinuses of the skull; that these form reservoirs of the blood—temporary reservoirs for extra blood in times of emergency—and that when the blood-pressure is increased in the brain the blood flows with greater freedom away from the sinuses and out of the skull; so that when the brain is anæmic, as in sleep, the sinuses become correspondingly and compensatorily fuller of blood; thus the amount within the bony cranium remaining the same, a much larger share of it than in the waking state is now external to the brain, a smaller share within the brain itself.

In the young and healthy, rapid and extreme changes in the position of the head may take place without any evil or inconvenient result; but in old age, when the vessels become altered and their elasticity is impaired, when their vasomotor apparatus is worn out or deranged, when the meninges become thick and tough, the choroid plexuses sodden, or stony, and the brain is less elastic, similarly sudden and marked changes in the posture and relation of the head occasion giddiness or syncope.

That marked changes are constantly occurring in the brain and in its circulation appears to be shown also by the fact that, if the brain is exposed, it and the quantity of blood in it rise and fall with the respiratory movements—the brain rising in expiration, falling in inspiration; and also rise and fall with each beat of the heart and the interval before the next; as well as rise and fall in a slower manner than with respiration, doing so in response to various influences, such as changes in mental activity, in relative position of head, movements of limbs, respiratory modifications.

Inspiration also assists to unload the sinuses, promoting a rush thence to the thoracic vessels and heart. Without entering upon the complex causation of the respiratory undulations just mentioned, we may notice M. François Franck's¹² observation, that when the heart is arrested the pressure on the sinus remains equal to the general encephalic pressure, the veins swell, especially in the deep parts, and particularly in the cranial cavity, so that the arterial anæmia is replaced or counterbalanced by venous congestion. Yet against this view is the result of Spehl's¹³ experiments on rabbits, in which the blood in the head during the chloral sleep was diminished, being now only 8.7 per cent., instead of 12.5 per cent., as in the waking state.

All the above facts, including those concerning the existence of checks on wide variations of blood-supply and blood-pressure in, and tension of, the brain surrounded by various structures, go to show that considerable variations may exist in the supply, in the distribution of that supply, and in the pressure under which it circulates. And pathologic states show this increase or diminution, as the case may be. Observe not merely the exudation but hyperæmia of inflammation within the cranium; observe the intensely gorged, congested—passively, if you like, but gorged—blood-vessels in cases dying in epileptiform seizures; observe the blanched brain of the lunatic dying of purpura hæmorrhagica, or of other maladies attended with rapid or severe loss of blood—and you will admit pathologic hyperæmias and anæmias of the cerebrum.

In reference to this subject of the relative amounts of arterial and venous blood in the cranium, and the alternate ebb and flow

of the amount of each, are experiments showing the relation of active cerebral hyperæmia or anæmia—of changes in the blood-pressure within the skull—to degrees of free outflow of venous blood from the cranial sinuses, and its return to the heart. Thus Gärtner and Wagner¹⁴ found that, whilst the calibre of vessels remains the same, the higher the pressure under which it circulates the more blood must stream through them; and thus, without any change in the calibre of the vessels, a larger amount, per unit of time, may circulate under a higher pressure, and a correspondingly larger amount keep outflowing from the sinuses of the skull. Compress the aorta above the diaphragm, thus raise the blood-pressure, and in a parallel way the quantity of blood issuing from the cerebral veins and the sinuses is augmented. On the other hand, compress the ascending vena cava, and with the lowered blood-pressure the outflow from the veins and sinuses immediately sinks; and, indeed, when the blood-pressure sinks to 30 to 40 millimetres of Hg., "the efflux of blood from the brain quite ceases." Now, under irritation of sensory nerves, strychnine poisoning, asphyxia, etc., contraction of blood-vessels of various organs occurs, together with rise of blood-pressure; but that the cerebral vessels do not thus contract, under similar circumstances, appears from the fact that the outflowing amount of blood from the brain sinuses, instead of lessening, actually increases then, and in direct proportion to the increase of blood-pressure induced by the experiment. Whereas, on the contrary, the outflow from the sinuses would be lessened if the brain vessels contracted, or at least their contraction would proportionately subtract from the effect of the increased blood-pressure. And direct electrical stimulation of the often so-called "motor area" of brain cortex ("kinæsthetic centres" of Dr. Bastian¹⁵) appears to cause, not brain anæmia by contraction of vessels, as usually supposed, and hence convulsions, but, active hyperæmia of the brain, and this sometimes independently of an increase of the blood-pressure, although the latter usually assists in the result. Intimately bound together in this relation are the local vasomotor changes affecting branches of the circle of Willis, and the local molecular activity of portions of brain tissue. Let definite parts or centres be roused by any unusually active incitations of psychic or of somatic origin, and instantly the circulation thereto becomes, at a leap, more active and the blood-supply richer.

INFLUENCE OF CARDIAC DISEASE ON MENTAL STATE AND PRODUCTION OF MENTAL SYMPTOMS.

The chief factors of the brain circulation being the heart's action, the vasomotor apparatus of brain, the molecular functional activity of brain, and the atmospheric pressure (opposing return from skull, whose contents are partially withdrawn from its influence), it is evident that cardiac disease may play an important part in modifying that blood-supply and the cerebral functions. And the shrewd forecast of the late Sir G. Burrows,¹⁶ as to its frequent connection with insanity, has been justified by actual observation.

Speaking of the mental disease with which so frequently an accentuation of the aortic sound is allied, Professor Rudolf Arndt¹⁷ said that it often takes origin when degeneration of the heart has followed its overstrain, and here the mental disorder, grounded in a disposition of the affected individual, is to be taken as an expression of general disease rather than as a brain disease, strictly speaking.

The influence of heart diseases in the production of brain affections is chiefly to bring about functional disorders of the brain, including insanity. Although Dr. R. Law and Dr. Wm. Stokes¹⁸ held that, independently of arterial disease, which Rostan connected with white softening of the brain, the latter might be brought about by heart disease, yet I have never seen a case of such "exsanguineous softening" fairly attributable to cerebral anæmia the effect of cardiac disease; for in all cases where disease of the vessels locally was insufficient to account for the circumscribed softening, I have found embolism, or hæmorrhage, exudation, or new growth. But whatever their connection with cardiac or other disease, these several forms of local gross cerebral lesion may originate mental derangement, chiefly with dementia. An examination of this department of the relations of cardiac to mental disease would occupy too much time, does not fall within the scope of these lectures, and will now be dismissed for good.

How, then, may cardiac disease either modify the symptoms of pre-existent insanity, or of that which appears about simultaneously with itself; or give origin to the mental disease; play the part of a chief factor of the psychological malady? A question of difficulty and complexity. Combined as they usually are in operation, the several elements may be disentangled in some examples. They are as follows: 1. The heart disease may act by disturbing the balance of the general circulation in various ways and degrees. 2. Similarly, it may act by disordering the intracranial circulation (this includes its effect on the local vasomotor mechanisms). 3. It may operate by leading to a change in the composition of the blood within the cranium; or 4, of the blood generally. 5. It may act by the pulmonary disorder it induces, and the morbid impressions and sensations resulting therefrom, so that eventually some of the effects arising are of pulmonary origin, or partly so. 6. Through the nerves it may become a source of peripheral irritation, and influence cerebral functions reflexly, by sympathy, inhibiting some forms of activity, deranging others.

Lest the above statements should bear a dogmatic impress, I must add that as yet they are not actually demonstrated and generally accepted facts. Some, indeed, while admitting a change of balance of general or of local circulation in heart disease, changed blood-pressure within the vessels, and altered quality of the blood therein, yet deny any effect, worth mention, of these on the production of mental symptoms, and hold that the original endowment of the nervous system, and the previous mental qualities, govern the state of psychic functions during the existence of heart or renal disease, of changes of pressure and circulation. Nevertheless, as regards the first two of the above-mentioned results of cardiac disease, and factors of mental, the preceding discussion shows their importance in determining the state of the brain, and therefore in producing disorders of it. In relation to this come cases¹⁹ with feeble circulation and with cerebral vessels imperfectly filled, in which the mental state or the sensory brain functions varied with the oscillations of arterial anæmia of the brain, according as the subject was in the erect or in the horizontal position; as where one, feeble-minded, apathetic, and peevish whilst in the erect position, became intelligent, lively, and conversational in the recumbent; or the student, mentioned by Burrows, who, owing to defective bulk of blood in the cerebral vessels when sitting up, could study only in the recumbent position; and Witkowski²⁰ found two patients with aortic stenosis lie' abed with head low: whereas other persons with congested head held it stiff and high erect, as in a case of mitral insufficiency with swollen red head, most carefully balanced. Then from the asylum ward come cases in which maniacal excitement is often cleared up, and disquieting delusions abated or dispersed, by moderate doses of digitalis, as shown in my paper²¹ on the subject; and I need only mention vertigo and syncope as active cerebral symptoms often connected with defective or disordered encephalic arterial supply.

Then, as regards the third of the factors enumerated, what has gone before demonstrates that in disordered conditions of its circulation parts of the brain may be poisoned by venous blood, relatively too venous, and relatively too long stagnating in the veins and sinuses, and dammed backward upon the capillaries. As regards the fourth and fifth of the factors, also, we need only draw attention to the frequent disorder and imperfection of respiration, or even pulmonary disease, secondary to cardiac disease, and the interference with normal hæmatosis thereby engendered, and therefore defective nutrition of the brain, as well as the mental effects of morbid impressions coming from such pulmonary disorder or disease.

The sixth manner in which heart disease may occasion or modify mental symptoms is one which has been almost entirely ignored, but which I deem to be of great efficacy. When we consider the painful impressions, the distress, the physical anguish, the extraordinary variety of abnormal sensations, that may arise in cardiac disease, the closely, urgently pressing nature of many of these, the vague discomforts, the oozing away of strength and courage and nerve, the easy access to the brink or depth of syncope; we shall see in all these a fertile field for the growth of depressed or hypochondriacal feeling and ideas of a delusive character. That peripheral local morbid states often directly occasion definite mental symptoms, and even particular

delusions, I have had many necroscopic proofs; and, had I space, might relate many cases in illustration of that thesis, and might select abdominal and other cases, in order that what I shall say hereafter about the heart might exhibit conspicuously a parallelism with these other pathological facts; but space fails me. Moreover, this doctrine is not a new one. Thus, the wide employment of "sympathetic insanity" as a general etiological term, was largely built upon occurrences similar to those long ago spoken of by Brown-Séquard,²² and others, as insanity by reflex effect of irritation of centripetal nerves.

One may describe the above methods of action of the graver maladies of the heart; more difficult, may often be impossible, is it to apportion to each one its place and rôle in particular cases, or in the several forms, of cardiac disease.

With disabling heart disease, and especially if thereupon pulmonary disease supervenes as a secondary result, or even independently, come a general disturbance of the balance of the circulation, and impeded return of blood to the right side of the heart, including impeded return of blood from the cranial cavity, and all the more so as here comes into play the closed nature of the skull. And not only is the venous blood in the sinuses and large cerebral and meningeal veins brought to a state tending to stagnation, but it also acts backward towards, and upon, the arteries, in this course giving rise to irregular circulation, local retention and blood-stasis, poisoning of the parts with retained effete products of tissue-metabolism, and to changes in the pressure of the blood upon the vascular walls, and in the tension of the brain. Lung disease greatly enhances this condition of the intracranial circulation, a condition which also is accompanied with arterial cerebral anæmia, which we have seen the above-mentioned changes tend to produce. And this being the state of affairs, should there now be also histological changes in the walls of the cerebral blood-vessels, their partial occlusion starves the brain substance, their diminished elasticity further aggravates the stasis and promotes gravitation of blood. Of the evil effects of persistent passive congestion of the membranes and brain substance I need not tarry to speak. Yet the heart disease, in some forms particularly, and eventually in all, of itself directly, often mechanically, occasions a defective arterial supply to the brain, with or without venous congestion, and in the train of this arterial anæmia (and venous congestion) follow all the changes in the circulation and nutrition of the brain to which I have referred, but which I need not recapitulate. And utterly mistaken are those who in the diseased or healthy state of the brain vessels, respectively, would seek the complete solution of the seeming mystery that one case of heart disease is attended by mental symptoms, and one, apparently similar, is free therefrom.

Notwithstanding the effect of emotions on the heart, and the frequent effect of heart disease on the spirits of the sufferer, and that some have attributed mental symptoms, and even the production of insanity, to chronic heart disease, yet others have denied the existence of any such influence by cardiac affections, or, if not denying it, have minimised its importance and effect, holding, rather, that when they co-exist, the heart disease is secondary to the mental. And of those who do admit that influence, nearly all have described the clinical results in brief and general terms, as applying to chronic heart disease, in a wide sense, have failed therefore to distinguish the mental effects flowing from its different forms. Thus, Solfanelli²³ opined that while hypertrophy affecting the left side of the heart is connected with more active, and valvular disease with more passive, hyperæmia, and its results; and while cerebral anæmia will arise from aortic-valve stenosis, and cerebral venous congestion, and œdema will follow upon mitral regurgitation, yet a correspondence fails to be observed between the variety of heart disease and the form of insanity found accompanying it.

Those who have brought forward large statistics on heart disease in the insane have drawn the clinical facts from one set of cases, the necroscopical from another set, and the latter from records entirely or largely made by others. Not only are there discrepancies between the facts adduced by the several observers; and not only do the conclusions drawn from the living fail to harmonise with those drawn from the dead, in the statistics of each observer; and not only have some pathologic rela-

tions and factors been lost sight of, in their figures, but also when these observers turn to the clinical features of the insanity produced by heart disease, or the modifications wrought thereby, their statements are not drawn from the cases and statistics preceding, which, indeed, so far as they go, would lead us to very different conclusions.

Of insanity where heart disease is the chief factor it has been said that hypertrophy of heart goes with exalted conditions, dilatation with depression; or, again, that aortic-valve affections mostly occasion excitement, whereas, on the contrary, mitral affections lead to melancholia chiefly; while states of excitement are often attended by temporary murmurs originating at the aortic valve. Yet most or all of the existing statements on this particular relation of heart disease to insanity are vague, general, indiscriminate, insecurely based.

The clinical and pathological sketches to follow are entirely from cases under my care, and many of them so far years, and of which I made both notes and necropsies. A few other cases are utilised, of persons who are living, or did not die under my care, or on whom a necropsy was not made. Thus the clinical and the pathological facts are drawn from the same cases and by the same observer, and, it is believed, are sufficient in numbers to elucidate the different relations to insanity of the several forms of cardiac and aortic lesion; and, moreover, are reported without bias, prejudice, or preconception.

Acute affections of the heart may be the source of mental disorder, as the insanity observed in some cases of rheumatic endocarditis by Burrows and others, or as in cases of ulcerative endocarditis in the childbed state, causing derangement taking the form of puerperal mania.²⁴ But I am about to speak of something other than the delirium or other mental symptoms occasionally observed in the acute and febrile affections of the heart—of something other than its functional affections, or even than its milder organic changes; for not only is it more difficult to trace the effects (if any) of functional disorder or mild organic disease on the mental state, and not only are these producible by many causes, and easily engendered by the mental disturbance itself, and by states such as lithæmia and renal inadequacy—thus rendering them less suitable for our purpose—but also in omitting them there are two further advantages; the one an avoidance of being overloaded by a throng of cases of little use for our present purpose; the other, that by selecting only the severe cases of organic disease the necropsy is conclusive as to the cardiac condition, and therefore we can be spared that recital of the physical signs and somatic symptoms of the heart affections which would become almost necessary in dealing with functional cases and mild organic ones. And still another reason is that it is not part of my scheme to furnish a new and ostensibly complete set of statistics as to the proportions, per cent., of the several forms of insanity affected with this or that cardiac condition or lesion—a matter of secondary interest from our point of view.

Continually do we find mental symptoms cropping up in heart cases. For example, in Dr. Bristow's²⁵ article on "Recurrent Palpitation of Extreme Rapidity in Persons otherwise Apparently Healthy" we find that even in some of these cases of purely functional affection with only incidentally present cardiac disease, or slight dilatation and hypertrophy secondary to the palpitation, he noticed an irritable, fidgety condition, and sense of being always in a hurry, or a feeling of being ill, faint, and weary, coincidently with the paroxysm of palpitation.

To illustrate the effect of heart disease on the mental state I need not confine attention to the insane. Their attendants and others occasionally furnish me with effective examples. One such will be mentioned under aortic regurgitation. A second case was that of one disabled elsewhere for attendant's work by a heart crippled by rheumatic fever, and to whom I gave the situation of porter. In his chest was always to be heard a loud churning of rumbling murmurs, which sometimes became worse, the pulse, ordinarily above 100, running to a great frequency then; asthma-like attacks of dyspnoea being severe, the congestion and œdema of lungs adding to the distress; the face becoming blue and livid, and the lips more everted. Now at these times I noted a concomitant mental change imprinting itself on the man's visage, and chiefly manifesting itself by suspiciousness and a substitution of the usual cheerful, lively buoyancy by moroseness, withdrawal of self, and a mental attitude as of one standing on defence against unjust reflections upon, unjust feeling toward, himself—

an incipient morbid idea of the hostility of those around him, and the misinterpretation of their actions and motives, ending occasionally in his bringing to me some suspicious suggestion rather than definite accusation—suggestion which I was wont to ignore. Finally, the kidney becoming affected, he died albuminuric, but a few days before death confessed to me that, when in his "bad turns," he for years had had visual hallucinations or illusions, and that, as in dyspnoea lividity he spoke to me, he could see a man and dog at the foot of his bed (hallucination).

Still another attendant became changed in disposition and feeling, but was unaware of his heart disease until, on examination, I found left hypertrophy and double aortic bruit.

Nor can I forget the case of a medical friend with heart disease, chiefly of the aortic valve, so far as valvular, and a bruit in the aortic arch; whose life became overcast by restless anxiety. Oppressed by apprehensions and vague disquietude, and with his thoughts ever returning to revolve around his morbid sensations and vague mental and physical discomforts, his conversation kept recurring to his sensations, his disease, and his impending death, the constant themes with which by day and night he worried those around him. Mirth or pleasantry grated upon his feelings, circling around their sombre centre. Fidgety, restless, perturbed, anxious—a hundred times a day he would beg of me to feel his pulse, or seek the expression of my opinion on his state; and in the night, when sleep failed, he would rouse one up in order to seek suggestion of some new soporific plan, to be relieved of his dread, and to have his pulse again felt.

And here I may mention the case of a deteriorated imbecile monomaniac, not in the following statistics, who, after several rheumatic attacks leaving damage of the mitral valve and of the lunate cusps of the pulmonary artery, had vast increase of what had previously been only a slight tendency to occasional, sudden, quasi-impulsive, transitory outbursts of excitement, violence, and destructiveness.

INSANITY IN RELATION TO FORMS OF CARDIAC DISEASE.

Passing to *Heart Disease and Insanity*, and the groups I have formed: all the cases were males. Once for all, it must be stated that under each of the following heads I have two objects in view, the one being to trace the clinical aspects of the insanity produced, or the modification of pre-existent insanity wrought, by the particular variety of heart disease; the other, conversely, being to indicate the several forms of insanity in the course of which each cardiac affection is most liable to appear; for both the cardiac and the mental may be deeply rooted in one and the same diathesis or diathetic tendency.

Mitral Valve Disease.—Three sub-groups. In the first and second sub-groups, mitral valve disease was the chief or predominant somatic condition, both clinically and pathologically; in all the sub-groups it was the chief or only cardiac abnormality. The twenty-nine mitral cases I bring forward are grouped as (1) marked regurgitation; (2) marked obstruction; and (3) comparatively slight or moderate mitral valvular disease. Of those in which mitral disease was severe, the sole or predominant cardiac condition, and of considerable influence on the fortunes of the case, six were examples of mitral regurgitation, seven of mitral obstruction. One might well anticipate that disease of the bicuspidates, whether giving rise to obstruction or to regurgitation of the blood stream, would practically be of the same effect on the nervous system, and therefore on the mental state; or if the bicuspidate disease is later in time than the mental, that there would be no special difference in the liability of the subjects of the several forms of mental disease to one or the other lesion—to stenosis, or incompetency, as the case might be; and that the modifying effect (if any) of either upon the pre-existent mental state would be the same: but the facts I have observed, and will mention, point to a different conclusion.

First Sub-group: Mitral Regurgitation.—Let me give a summary of the cases of regurgitation due to incompetency of mitral cusps. The patients were aged from 37 to 59, and on the average 47. At death, the insanity had lasted from a few weeks or months to twenty years. In some the cardiac affection supervened on mental disease, in some it preceded the latter. For reasons already specified I need not give the physical signs of the cardiac disease, so well marked in these cases, or the other somatic symptoms, although noting incidentally the comparative frequency of Cheyne-Stokes's respiration in this sub-group. The heart was enlarged in these cases, weighing on the average 17½ ozs. Av., the left ventricle be-

²⁴ Arch. für Path. Anat. und Phys., Band xx, p. 542.

²⁵ Brain, July, 1887, p. 164.

ing hypertrophied and dilated, the left auricle somewhat so, as also the right ventricle; the heart muscle was in some cases pale and slightly granulo-fatty, and its coronary arteries atheromatous. Even when least affected in structure the incompetent mitral cusps were also more or less thickened and unduly opaque. The other valves may be so also, the tricuspid, however, often escaping. We may find in the lungs congestion, pneumonia, hemorrhage; the kidneys smallish (4 to 4½ ozs.), and slightly or moderately granular.

The heart disease in some of these cases preceded either melancholia or suspicious delusional insanity. In others the heart disease was subsequent to religious or to persecutory monomania, or to expansive, maniacal, hostile, irritable general paralysis, running an aberrant course in one with hereditary psychic degeneration. Of the two sets of cases, the more interesting is that of mitral disease preceding mental disorder and influencing its production and aspect.

When rheumatic fever has founded the chronic heart disease, and mental symptoms have been noticed for six months, one is emotionally depressed, melancholic, acknowledges morbid feeling in the head for a long while, as if the vertex was cut off and lifted up. To him it seems as if something "wrong inside him" says he is to be shot or hung; he believes it, and wishes to be opened at once for the benefit of medical science, by the discovery of the internal pathologic state. He fancies that imaginary voices address him; people turn round and speak to him; the Lord talks to him, and says he is to be shot; he feels wicked, and as if cast out by the Lord. At times his description is that he had felt as if the calvaria was off and the heart down. From the cardiac region he hears voices say, "It's a shame to keep him here;" but this he explains, in a sense unusual for asylum inmates, as meaning that he has become too wicked to be here, and therefore ought to be shot or killed. At one time the hallucinatory voices had suggested his sexual mutilation, and he confesses to past onanism; falling on his knees he tells of youthful sexual excitement, aroused by his presence in the bedroom to which his widowed mother often brought home a paramour. At times he had felt increased in height, lifted up, and as if he was not a natural being. Something seemed to be blowing on the top of his head; he felt as if a snake worked from right thigh to shoulder. Sometimes he perceived strange smells without external cause. These were auditory, tactile, olfactory, and visceral hallucinations and illusions.

In the next case the coming on of mitral regurgitation was probably subsequent to the insanity. A religious monomaniac, who had settled down as a quiet, respectful, pleasant, industrious inmate, fell at last into physical and graver mental difficulties. With his cardiac and renal disease came, first, pulmonary engorgement, muco-aqueous expectoration, œdema of lower limbs; and, later on, marked albuminuria, defective vision, mental dullness, drowsiness; from congestion of lungs, at times dyspnoea or orthopnoea and cyanotic livid hue of face and hands, but the dyspnoea was in part renal. And so the case progressed, with recurring dyspnoeal attacks, a lessened amount of the now highly albuminous urine, mental heaviness and drowsiness. And during these latter and evil days, when the cardiac and renal diseases were telling upon him, the state of mind was modified; for, in contrast with his former mental characteristics, he had become depressed, very quiet, somewhat sombre, and showed a marked inclination to taciturnity and silence, as if the mental sky had become dull, leaden, oppressive.

Another monomaniac had had delusions as to poisoned food and persecution; hallucinations of sight and hearing, and a variable emotional state—now amiable and industrious, now sullen, moody, and menacing. That he was persecuted by men who annoyed him by blasphemy and by tramping about so as to get him to commit himself, that he was kept to be tortured, were some of the various delusions under the influence of which at times he became noisy, excited, threatening, or violent. Later on, he destroyed his bedding, declared he was tormented at night, especially by women and the Queen; therefore he threatened and planned to assault the officers of the asylum, or to smash windows, if not shifted away. Subsequently, becoming more quiet and sullen, he said he had no flesh on his bones, or those about him were "against" him, or that he was persecuted. The marked heart disease had now become manifest, and now, neither excited nor noisy, he was sullen, reserved, taciturn, of forbidding look, and the delusions were somewhat in abeyance. Later on he said the patients were "all against him; his testicles were eaten away, he was tormented;" everything not agreeable to him he looked on

as an injustice, an act of hostility to him, a punishment. Subsequently deaf and phthisical. Here the mitral disease appears to have modified the mental state; changing it from a chronic, paroxysmally excited, violent, destructive, and "threatening" state, to a more depressed, morose, sullen, taciturn one, yet combined with a quiet, tractable docility, in strong contrast with the former aggressiveness.

Another, a protracted erratic case of general paralysis, at first was extremely maniacal, irritable, full of hallucinations and delusions of exalted type. "Is Jesus Christ, has millions of money, is an Adonis, is all-powerful to strike or heal." Subsequently, with big ideas, he still at times was irritable, angry, quarrelsome, disdainful. Latterly, with marked mitral, also with aortic-valve, lesion, and in contrast with his previous state, he gradually became quiet, reticent, depressed, incoherent, childish, somewhat demented; but impatient, irritably waving his hands, and offering a ready resistance to management or manipulation.

Finally, the order of incidence of the two affections was not absolutely clear, although the total stated duration of the insanity was under ten months, but the heart disease obviously of some years' standing, in one who died after being only four weeks under care. The clinical aspects were: very fidgety and restless movements, muttering, incoherence, repetition of the same words, rambling statements, loss of mental perception and of memory, extreme dementia—a condition as of premature and intense senile decay of mind. Less marked examples of mitral regurgitation occur in the third sub-group.

Thus, where mitral regurgitation most evidently influences the production of insanity, or the modification of the clinical aspect of pre-existent insanity, the state is usually a sombre emotional depression, or melancholic dread, with hallucinations or illusions and hypochondriacal symptoms; or else morose, sullen, taciturn states, with a marked attitude as of one subjected to annoyance or persecution.

Second Sub-group: Mitral Stenosis.—Varying from 30 to 79, the age at death, on the average, was about 47½, and the insanity had existed from two months to twenty-four years. The cardiac disease, in some preceding, in others supervening on, insanity, had in some an order of incidence not absolutely known with certainty. On the whole, pleuritic and pulmonary conditions had as much (or more) to do with determining the site of the apex beat as had the intrinsic cardiac lesions. Bronchitis, emphysema, pulmonary congestion, pneumonia, pleuritic effusion, hydrothorax, œdema of feet and legs, more generalised dropsy, albuminuria, subcutaneous œdema over base of a pleura; these conditions were apt to be found singly, or variously combined, or succeeding.

The average weight of the heart was 13.188 ozs. In all were degrees of constriction at the left ostium atrio-ventriculare, and of thickening, rigidity, deformity, or cohesion of mitral cusps. Part of the cases were of the "button-hole," and part of the "funnel-shaped," variety of mitral constriction.²⁰ Less change usually affected the other, and chiefly the pulmonary and tricuspid, valves. The left auricle was more or less hypertrophied and dilated; the left ventricle not markedly or not noticeably hypertrophied as a rule. In most the right chambers were hypertrophied, or hypertrophied and dilated. The heart muscle was usually flabby and friable. The coronary arteries atheromatous in several. Pericardial fluid often increased. Spleen, on the average, 7.375 ozs., usually of undue firmness, the capsule more or less irregularly thickened and opaque, occasionally scarred, pigmented, brownish. Liver, average 47.25 ozs.; "hepatic venous congestion" usual; often some "nutmeg-like" appearance; parenchyma firm, or even hard; capsule partially thickened or adherent to surrounding parts. The kidneys presented one or more of the following changes: granular surface, adherent capsules, cystic change; average weight, 4.85 ozs. apiece. In the lungs were one or several of these conditions, namely: bronchitis, emphysema, pleuritic effusion or old adhesions, apical cirrhosis, or even traces of former cured phthisis, bronchiectasis, carcinification, or brown induration of lung at base, occasionally cheesy nodules or cheesy bronchial glands, calvaria dense in some, brain usually somewhat wasted, and meninges slightly thickened; fissures and gyri occasionally abnormal.

With regard to the mental state and its modification by mitral stenosis; the cardiac disease distinctly preceded the mental and influenced its production in one who had thrice attempted suicide before admission. His memory was impaired, and he had no

recollection of his mental attack in India; but he was not merely stupid, simple, unable to take proper care of himself, and ignorant of the value of money; he was also irritable, suddenly, as if impulsively, violent and destructive when displeased; jealous of others getting better things or larger shares than he; made grievances of nothing; frequently transferred from ward to ward at his own wish, he was not contented in any; was excitable, quarrelsome, resentful, readily and impetuously made sudden attacks if he thought (delusion) that he was insulted or called names; excited about grievances, he imagined injustice; would not occupy or amuse himself, demanded his release; later, he made assaults under the influence of hallucinations of hearing. In anger he hurled his dinner away, smashed plates, threatened to and did commit sudden quasi-impulsive acts of violence. For a time he continued to attack others under the delusion that they annoy, push against, talk about, or even look at him. Finally, he became quiet, depressed, reserved, subdued, answering in monosyllables.

Another case, in which the cardiac affection long preceded the mental, comes here in order, but was aged and less characteristic. He had some active symptoms, being noisy, shouting "murder," and delusionally asserting that people came and assaulted him, that there was some criminal charge against him, that he had been out and robbed on his way to a bank, or had lost a cheque belonging to his employers. Moreover, he became suicidal, tried to get out of and smashed a window to go and throw himself over a bridge. Later he was petulant, irritable, struck at an attendant about to feed him, confused persons and places, was rambling and incoherent in conversation, imagined he had to pay for his maintenance, had just left his business situation which still depended on him, and was the subject of a criminal charge. Better for a time, but latterly worse, with vague depression, discontent, dissatisfied with his food and his position, occasionally rambling and odd in conversation; he talked of having been overdosed with chloroform. Subsequently, says he "is dying fast," his "brain is going," or he is "disturbed," has not slept for weeks or months, will soon be dead, and was troubled by the delusive notion that he must go to see a "dying sister and nephew." Latterly were delusions about his dying or being dead, dreams in which he saw corpses laid out, desire for death.

The order of incidence of the two affections was somewhat doubtful in a case of religious monomania with excitement, becoming querulous, and finally deteriorating, and the querulous maniacal elements continuing. At times, restless and excited, he asserted that he was St. Patrick and suffered on the cross, that voices from the other world spoke to him. Declaring his independence, and not brooking the slightest interference, he was quarrelsome and assaulted his companions. Later were notions that true angels tell him what to do; his fixation on a bed at Malta he took as comparable with the Crucifixion. Excessively querulous, he complained of his treatment and diet, and was inclined to fight. A marked stenotic mitral *bruit* was heard, and now came frequent pulmonary complications and dyspneal attacks. After the heart condition became worse he was querulous, morose, discontented, was growling, grumbling, making absurd complaints of being injured and treated in a hostile way by everyone, and absurd statements as to the imaginary bodily injuries inflicted upon him.

As in the last, so in another case, the funnel-shaped mitral constriction may have been congenital; otherwise, knowing them only in the later years, one would have said their heart disease probably appeared later than the querulous persecutory monomania. This one had delusions as to men being murdered and boiled to lard, and their skins tanned to leather; as to the army officers being against him; delusions of being annoyed, ill-treated, of everything being wrong, of the food being deleterious or stinking, or poisonous. But with these were occasional delusions as to his valuable clothing or wealth, as to his being proof against snares, sword, or gunpowder. Yet usually he was suspicious, querulous, discontented. Latterly, when more in trouble with heart and lungs, he said the food was dead men's lard, or made of dead men's yeast, that "bad stuff" was intentionally put in it, that voices told him he annoyed his comrades, that American interference compelled him to stop work, but that he had "raised £500." In low spirits, he yet became excited, noisy, and abusive if questioned, and had delusions of persecution. Latterly he declared he was poisoned, often refused food, and the delusions on this subject became predominant. Peevish and irritable, he insisted that the milk was poisoned, that his medicine burnt him

up, that the attendants smelt offensively. Even at the last, under delusions of persecution, he shouted about "blood-sucking" and about his being "tormented." Besides the heart disease there were caseous bronchial lymphatic glands, and some cheesy nodules in the lungs.

In a case in which insanity probably preceded the heart affection there were early despondency and desire to be killed, then usually querulous, but sometimes expansive, symptoms—sullenness, restlessness, irritability, mental confusion. Later he was noisy, quarrelsome, dissatisfied, querulous, and by his own wish transferred successively from ward to ward; at times were expansive ideas, such as that he was "next to God." Later, impaired in memory, he was confused, incoherent, now and then excited, threatening, and on those occasions refusing food and resisting interference. Subsequently hypochondriacal, baselessly asserting that he was ill, that his tongue hung loose, that his left eye was blind; and now, strange to say, came recollection and mention by him of his early long-past despondency and desire to be killed. Still later, absent in mind, confused, of defective memory, and repeating words and sentences with an odd smiling look, as of a chronic maniac. He died of an acute inflammation.

Of the above cases, the first, third, fourth, and in less degree the fifth, show this association of obstructive mitral disease with chronic insanity characterised by delusions of persecution, annoyance, injury, or hypochondriacal ones; and often hallucinations, at first with, and then superseding, expansive ideas, chiefly of the religious order; also with another group of symptoms—querulousness, irritability, ill-temper, discontent, grumbling moroseness, and peevish cross-grained cantankerousness. It is partly the symptoms of this latter group which grow worse in proportion as disabling mitral stenotic disease tells on the vital forces and the functions of the brain. And in some of these the cardiac, in others the mental, is the earlier malady; if preceding, the mitral stenosis appears to foster the production of symptoms of the kind described; if, on the contrary, apparently supervening, it seems to intensify the similar symptoms, and to assist in the supersession and gradual extinction, by them, of formerly existent symptoms of the expansive order.

In two less marked cases the order of incidence was unknown, and the mitral affection probably not of very much influence. One was mixed monomania, persecutory, expansive, hypochondriacal. Patient says he "is tried, accused of crimes, is annoyed, apparatus is applied to him, is the object of conspiracy; is persecuted by Orangemen's secret, or by a 'piercing wind with a voice,' which once he saw; it pains him all over; this is done to prevent proof of his grievances. To him the power of Orangeism, Freemasonry, and Devil are applied; he can be pained by others at their will; is worked on at night; Freemasonry is dragged from him, so is his nature, and the flesh is dragged through his body." Later, refused food, declared he would starve himself if not discharged, and should he starve the world would be destroyed; "Is Saviour of the World, has spoken to God;" becomes excited about his imagined persecutions. Here, there were also some cheesy and calcareous nodules in the lungs.

The other had been grotesquely irrational in demeanour and language, alternating between melancholic depression and agitation, with monotonous repetition of ejaculations on religious subjects. There were also delusions of conspiracy, and that his soul was lost, and that his food was poisoned, with obstinate refusal of it. Subsequently, *melancholia agitata*; still noisily repeating some words or phrases, and refusing food. Later, silent, reticent, depressed, unsocial, and refusing to be examined.

Comparing the most characteristic, respectively, of mitral regurgitant with mitral stenotic cases, broadly speaking the former show more tendency to melancholy, the latter to intense querulousness, and delusions of persecution, annoyance, injury.

The third sub-group of morbid mitral orifice or valve consists of those in which there was slighter mitral change and effect. For, in sixteen mitral cases the valve disease was comparatively slight, or somewhat overshadowed by important changes of other organs, or the valve change, although the chief cardiac abnormality found was not of grave import, and probably did not exercise any markedly noxious influence on the course or symptoms of the case in reality. However important these may be as showing the tendency and line along which disease works in some groups of persons, they are of comparatively little usefulness for our particular present purpose, inasmuch as their influence upon, or their relation to, the mental state of the patient, or to the con-

stitutional state or circulatory condition which favours the production of that mental state, was not very clear and distinct. Therefore, although they were analysed, I shall exclude the sixteen from further consideration, except to add that most of these cases of lighter mitral disease, although many of them were general paralytics, exhibited an inclination to depression, irritability, delusions of annoyance, danger, ill-treatment, persecution, or showed inclination to dementia. Emotional facility was marked in some. Only a few had occasional expansive delusions or exaltation.

ABSTRACTS OF THE MILROY LECTURES ON SOME GENERAL CONDITIONS WITH REGARD TO EPIDEMICS.

Delivered at the Royal College of Physicians of London,
February and March, 1888.

By ROBERT LAWSON, L.R.C.S.Ed.,
Inspector-General (Retired) Army.

LECTURE II.—EPIDEMIC INFLUENCES (*continued*).

Small-pox.—The early part of this lecture was devoted to proving that small-pox, like fever, was under the influence of a pandemic factor which determined its development as an epidemic at some point in the first instance, and its subsequent extension to the northward in successive years. The illustrations given were mostly taken from the Indian returns, and such notices of its occurrence in Europe and America as gave specific information as to dates of commencement and decline of the disease, or statements of the deaths in particular years. Small-pox generally appeared in the southern part of Hindustan between the isoclines 0° and 30° north in the first instance, and extended to the portion beyond the isocline 30° subsequently, varying in force in different parts of the country invaded in different epidemics, but still presenting a wave-like mode of progression in the same direction. Thus the epidemics reached a maximum in the Madras Presidency in 1868, 1872, 1877, and 1882; in the North-West Provinces and Bengal in 1869, 1873, 1878, and 1883; and in Punjab in 1870, 1874, 1879, and 1884. The want of information regarding Central Asia prevented the wave being traced further north; but in 1869 small-pox commenced at Marseilles, became epidemic in the north of France in 1870, in Holland and London in 1871, and in the north of England, Scotland, and Ireland in 1872; on the other side of the hemisphere, it could be traced in Teneriffe in 1870, and in the United States in 1871. The Madras epidemic of 1872, it was suggested, was part of the same wave which reached Western Europe and the United States in 1875.

Pandemic Waves.—Nothing, it was said, is known of the intimate nature of these pandemic waves, nor had any explanation been given as to why they should proceed from south to north. Further, the kind of fever developed, as it was assumed, under their influence varied very much at different periods, and this was enough to show that the pandemic wave of itself was insufficient to account for such varied results, and that recourse must be had to other factors connected with each locality for the time. With regard to intermittent and remittent fevers, the endemic sources of malaria must be all that was requisite in most cases; but with yellow fever and plague and some other fevers something else was necessary.

Yellow Fever.—An examination of the epidemics of yellow fever observed at Sierra Leone, where the ordinary fever is the remittent, led to the inference that the immediate exciting cause of the disease is generated by a special factor acting on a suitable locality in a place where the disease appears, and which is either absent or in abeyance during the intervening periods. And a more extended series of statistics showed that from time to time there is, over a varying extent of the earth's surface, an increased activity of the factors which lead to yellow fever, under the influence of which that disease becomes developed when local circumstances are suitable. Of these the most important were the state of the weather and the presence of a certain amount of moisture in the soil. Too much water or too little stopped the disease; thus at Sierra Leone, where the rainfall was heavy, the epidemics came in dry seasons; while at Goree and Senegal, where the climate was dry, the epidemics fell on years more than usually wet.

Plague.—A study of the reappearance of plague at various points where it had formerly been epidemic afforded some evidence as to the factors concerned in the production of the disease. Special reference was made to the cases of benign plague, described by Tholozan as preceding severe outbreaks of the disease. Though this sequence had not been proved to be invariable, it indicated the operation of a separate factor, concurring with the pandemic wave in those localities where that form of disease presented itself. It did not appear that plague was communicated from the sick to the healthy by contact, but that the danger really arose from remaining in an apartment occupied by the sick. Several authors who had personal experience of plague had described it as "a poor man's disease that never went upstairs," and the sufferers, in addition to delicate food, had inhabited apartments badly ventilated, and often in the most insanitary condition. Whether there were a specific factor required to excite the fully-developed disease; or whether that causing the benign form merely became intensified in certain localities, from circumstances existing temporarily, were points which must be left for future investigation, which the progress of bacteriology might hereafter facilitate.

ON A NEW METHOD OF STAINING SECTIONS OF THE CENTRAL NERVOUS SYSTEM.

By FRANK J. WETHERED, M.B. (LOND.), M.R.C.P.

I AM indebted to Dr. J. Pal, of the Pathological Institute in Vienna, for permission to publish a new method, recently introduced by him, for staining sections of the brain and spinal cord.

It is in reality a modification of the method first introduced by Professor Weigert, but differs from it in many particulars. Dr. Pal claims the following advantages for this modification: The picture produced is sharper in outline; the nuclei and nerve-cells can be separately stained, and the process is a more speedy one. Not the least advantage is that the treatment of the sections by a solution of the acetate of copper is entirely done away with. Having worked with both processes myself, I can fully confirm all that Dr. Pal states. Dr. Pal's method is as follows:—

The spinal cord or brain is hardened in Müller's fluid in the ordinary manner, and when ready is embedded in paraffin, and the sections cut into absolute alcohol. An aqueous solution of hæmatoxylin of the strength $\frac{1}{2}$ per cent. is then made by dissolving the hæmatoxylin by means of heat, and, after cooling, some alcohol is added. This solution must not be kept very long, or allowed to stand in the sunlight. Immediately before using, a few drops of a solution of carbonate of lithium are added; on the addition of this salt the solution assumes a violet red colour. Dr. Pal uses three or four drops of the lithium carbonate solution to 10 cubic centimètres of the hæmatoxylin. The sections are allowed to remain in this stain for about five or six hours, at the end of which time they should be of a bluish black colour; they are then thoroughly washed in water until no more colour comes out; if they do not appear to be deeply enough stained, a few drops of the solution of lithium carbonate may be added to the water in which they are washed.

The sections are next to be "differentiated;" for this purpose they are first placed in a $\frac{1}{2}$ per cent. solution of permanganate of potash for 15-20 seconds, and then for a short time into "Pal's solution," until the white and grey matters are plainly defined; this is generally completed in one or two minutes. If black specks are seen on the sections, or if the white and grey matters are not quite distinctly defined, the process is to be repeated. "Pal's solution" has the following composition: Oxalic acid, 1 part, sulphide of potassium (K_2SO_3) 1 part, distilled water, 200 parts.

After having been taken out of this solution, the sections are thoroughly washed in water, and the nuclei may then be stained in eosin or carmine, the stain which acts best being alum-carmine. After another washing the sections are dehydrated by absolute alcohol, cleared in oil of cloves or crocote, and mounted in balsam.

Stained in this manner, the medullated nerve-fibres are coloured blue, and stand out sharply on a white background, presenting a strong contrast to the red nuclei.

In order to bring out the nerve-cells prominently, after the specimens have been "differentiated" they are placed for a short time in picro-carmine, which should be only slightly alkaline, and, after being washed in water, the nuclei may be stained as before in alum-carmine.

REPORTS
OF THE
COLLECTIVE INVESTIGATION
COMMITTEE
OF THE
BRITISH MEDICAL ASSOCIATION.

REPORT ON INQUIRY No. IV.

AGED PERSONS.

PREPARED BY PROFESSOR HUMPHRY, F.R.S.

REPORT ON THE PRESENT CONDITION, HABITS, CIRCUMSTANCES,
ETC., OF AGED PERSONS.

THE following report, which relates to the present condition of the aged (that is, their condition at the time when the several reports were made), is, like the report on the *Maladies of Old People*, which appeared in the *JOURNAL* of July 30th, 1887, founded upon the analyses printed at page 515 *et seq.* These analyses, as there stated, were derived from the returns respecting 824 persons, made for the most part by medical men, in reply to the inquiries of, and upon the forms issued by, the Collective Investigation Committee of this Association.¹

Of these 824 persons, 340 were males (and 282 were females between the ages of 80 and 90, and 92 were males and 110 were females between the ages of 90 and 100. Of the whole number, 89 per cent. were, or had been, married; 48 per cent. were poor, 42 per cent. were in comfortable circumstances, and 10 per cent. only were described as being in affluent circumstances. This must not be regarded as representing the relations of poverty and affluence to longevity, because, in the first place, the poor at all ages and in all districts bear a large proportion to the affluent; and, secondly, our returns are largely made from the lower and middle classes, and, in many instances, from the inmates of union-workhouses, where a good number of aged people are found, and where information respecting them is most easily obtained.

The important questions of the relative longevity in different classes and among those following different occupations scarcely comes within the range of our inquiry. Indeed, they require carefully collected statistics of varying kinds, and much labour for their solution.²

It does not appear that the Shakespearian sequence of the "lean and slippered pantaloon" to that "fair round judge" is by any means the ordinary one, for the 'spare' condition and the 'average' condition between 'spare' and 'fat' greatly predominates in our old people at all ages between 80 and 100. The 'average' condition is noted in 47 per cent. of the whole number, the 'spare' in 41 per cent., and the 'fat' only in 11 per cent.,³ and the accounts of their condition at earlier periods of life indicate the same, by the far larger proportion having throughout life come under the denomination of 'spare' or 'average.'

The average height of the men (67 inches), and the women (62 inches), if we take into account the lowering of stature attendant upon age, which may be estimated at not less than 2 inches, gives a high standard, the average height of Englishmen at 25 being 67½ inches, and of Englishwomen 62 inches. This, as in the case of the centenarians (*JOURNAL*, December 11th, 1887), corroborates the observations of Mr. Roberts (*JOURNAL*, January 1st, 1887), who found, "on grouping the measurements of a large number of individuals together, that the curve of stature continued to increase up to the age of 70, which was the limit of the statistics;" and he expresses the opinion that "this increasing stature of the population throughout life was due to the greater viability of persons whose stature was up to or above the average; or, in other words, to the weeding out by disease of the [smaller and worst developed members of the community."

The lowering of stature attendant upon age is due partly to the loss of elasticity of the intervertebral substances and other

parts of the frame, but chiefly to the inability to attain and maintain the fully erect attitude, which requires a certain effort on the part of the extensors, especially of the knees and hips, fatiguing at all periods of life, and often impossible in the aged. A lowering of the heads of the thighbones, owing to an alteration in the angles of their neck, is, according to my observations, of less and less common occurrence than is generally supposed. The fair maintenance of elasticity and erectness shown in the tables to be one of the attributes of great age may lead us to infer that the lessening of stature in our old people was less than is usual; and I have accordingly estimated it at not more than two inches.

The importance of this relation between physical development and longevity acquires increasing force in proportion to the value of the evidence which is being adduced as to the diminishing physique of our people, ascribed to their transfer from rural districts to large towns. In reference to this point I may allude to the words of Sir Thomas Crawford in his recent address at Dublin (*JOURNAL*, August 13th, 1887): "A careful examination," he says of these tables (tables of the causes of rejection of recruits for the army), "leads to the inference that the lower classes, from whom recruits for the army are chiefly taken, are of inferior physique now to what they were twenty-five years ago." If the physique is becoming less good, must we not expect to find a proportionate diminution of the instances of great longevity? Sir Thomas Crawford's statistics have not passed without criticism; but, at any rate, it is a matter deserving serious attention.⁴

The average weight of 227 men in whom it is given under 11 stone, and of 114 women about 9 stone, is, especially in the women, small in proportion to the height and well-developed forms of these old people, and corresponds with the 'spare' condition noticed in so many, and shows that people usually become of less bodily weight as they grow older. These well-developed, and for the most part slender, figures maintain gallantly that erect attitude, which is the special feature of the human form, forasmuch as we find 62 per cent. are stated to be 'erect,' and 28 per cent. only to be 'bent.'

The 'anæmic' and 'pale' condition of a large proportion (respectively 58 per cent. and 30 per cent.) accords with the fact noted in my account of the *post-mortem* examinations of centenarians (*JOURNAL*, March 12th, 1887) that the spleen, lymphatic glands, and other blood-making organs are in a comparatively atrophic state in the aged. Nevertheless, it is to be remarked that a good proportion (28 per cent. and 35 per cent., making together 63 per cent.) are noted to be 'strong' or of average strength, as against 36 per cent., who are described as 'feeble.'

Among these old people, as in the case of the centenarians, a large number (80 per cent.) retained good sight; and the evidence is confirmatory of the view, derived from the records of the centenarians, that the occurrence, even the early occurrence, of presbyopia (83 per cent. used glasses) does not militate against the continuance of good sight to a very late period of life.

Hearing failed in a larger proportion than sight, being reported as 'indifferent' or 'bad' in nearly half the number of returns under that head. The failure of this sense in a greater number than that of vision is probably due in great measure, as I have before said (*JOURNAL*, July 30th, 1887), to the liability of the delicate mechanism of the middle part of the ear—the tympanum, with its bones, joints, membranes, muscles, and lining membrane—to impairment from colds, shocks, and a variety of other causes.

The good general condition, the good performance, that is, of the various functions, in a large number of these old people, is, as in the case of the centenarians, a noteworthy fact, and contributes, it need scarcely be said, in very large measure to the comfort and happiness of old age. In 71 per cent. the digestion, and in 62 per cent. the appetite, is stated to be 'good.' In only 4 per cent. is the former, and in only 5.4 per cent. is the latter, said to be 'bad.' In

¹ Mr. Charles Roberts, for instance (The Physical Condition of the Masses, in the *Fortnightly Review*, October, 1887), has been led by a careful examination of the same statistics to conclusions quite opposite to these at which Sir Thomas Crawford has arrived. He finds that improvement in sanitation has not only made the population more healthy, but has materially lengthened the term of life. "Stature and weight of body," he says, "are very much matters of race, and vary in different parts of the country according to the racial origin of the inhabitants. In Scotland and the North of England the men are tall and heavy (from 5 feet 8 to 10 inches, and from 11 to 13 stone), while in the East of England they are tall but less bulky. In the southern parts of England men are much shorter and lighter of weight than in the north and east (5 feet 6 to 7 inches, and 9½ to 10½ stone), while in Wales they are also short, but very heavy in proportion to their stature. The adult inhabitants of towns do not fall much below that of the adjoining districts in either stature or weight. The average stature of the much-abused cockney is 5 feet 7 inches, only half an inch short of that of the whole kingdom, and higher than that of all the home counties."

² The Report on Centenarians, with table, appeared in the *JOURNAL* of December 11th, 1887.

³ See Class-Mortality Statistics, by Dr. Grimshaw, *JOURNAL*, August 13th, 1887; and Influence of Easy Circumstances on Longevity, by Dr. Drysdale, *Ibid.*, August 20th.

⁴ The round numbers only in the percentages and not the decimals are given, in most instances, which will account for the slight discrepancies occasionally observable, such as above, where 47+41+11= only 99, instead of 100.

60 per cent. the bowels acted daily, and in few do they appear to have given trouble. Very few resort to aperients; and it could be wished that a greater number of the young and middle-aged persons in the upper ranks of life would follow the example of the old people in this respect.

The process of micturition is found to be natural in 83 per cent. of the women and in 53 per cent. of the men. In 20 per cent. of the men and in less than 3 per cent. of the women it is noted as being slow; whereas incontinence is said to exist in about 5 per cent. of the women and in only 3 per cent. of the men. Frequency of micturition appears to be a source of annoyance in not more than 3 per cent. or 4 per cent. in either sex.

The evidence of sound brain-condition is furnished by the report of an 'average' amount of intelligence in 74 per cent.; in 15 per cent. it is stated to be 'high,' and in 11 per cent. only to be 'low.' The memory also is in most instances reported to be 'good,' especially (in 78 per cent.) for past events. The recent impressions, as is the case with most of us after youth, are less durable; still as many as 59 per cent. of these old people are noted to have good memory for recent events. A further evidence of good brain-condition is furnished by the observation that only 9 per cent. are bad sleepers, whereas 64 per cent. are said to be good sleepers, and 27 per cent. to be moderately good sleepers. This does not quite accord with what seems to be a generally received impression that the sleeping faculty of the aged is indifferent. It may be, and it probably is the case, that the work which should go on in sleeping, that is the repair of the ordinary wear and tear associated with the exercise of the various functions, and more particularly of the brain functions, proceeds slowly, and that a proportionately long period is required for it; so that, although the 'sleeping faculty' may be good, the 'sleeping power' may be less than in earlier life. This sluggishness of the nutritive processes in carrying on renewal after the wear attendant upon functional exercise, and which is an appropriate associate with the sluggishness or diminution of functional activity in the aged, seems at first thought to be scarcely compatible with that good performance, in these same persons, of repair after the greater lesions by wounds and ulcers to which I have called attention in former reports. The apparent paradox, however, is probably explained, as mentioned in the report on the maladies of old people, by the lower sensitiveness, excitability, and activity of the tissues in the aged, and by the better opportunity thus afforded for the quiet operation of the healing processes.

It does not appear that much is to be inferred from the presence or absence of the arcus senilis, forasmuch as it is noted to exist in 'considerable' degree in 25 per cent. in 'slight' degree in 37 per cent., and to be 'absent' in 37 per cent.

The disappearance of the teeth also, as remarked in former reports, does not portend so much as is commonly supposed. In 41 per cent they were all gone, and in some this had been the case for many years. We find, moreover, in these analyses (JOURNAL, July 9th, 1885) confirmation of the observations before made as a result of this investigation, that the teeth disappear at an earlier period and more commonly in women than in men, though the former are the more long-lived, the proportion in which they were absent being 52 per cent. in the women and 30 per cent. in the men, also that they disappear in the upper jaw earlier than in the lower jaw. Our reports are drawn chiefly from the class of persons who are not able to make amends for natural deficiencies by artificial aids. Thus thirty-seven only out of the whole number had artificial teeth; some of these had used them for many years. We can scarcely, therefore, from our tables draw inferences respecting the advantage to health and the prolongation of life which may be afforded by the dentist's skill; although it can scarcely be doubted that benefit in these respects, as well as in comfort and other ways, will be found to result from the science and art of dentistry, which is making such great advances.

The hair seems to have held its ground well in these old people, for we find that baldness took place late in life, or not at all, in 73 per cent., and that 26 per cent. only are said to have been bald early; also that greyness occurred early in 24 per cent. and late in 76 per cent.

It is interesting to note that the pulse-rate between the ages of 80 and 100, which in the whole number of the cases observed averages 77, is about the same as that of middle-life. The slight excess above the average of middle-life may be accounted for by the presence of a certain amount of chest-affection in some of these old people. In the women the average (79) somewhat ex-

ceeds that of the men, which is 75. In 80 per cent. it is said to be regular, and in 20 per cent. to be irregular. In the greater number (60 per cent.) the pulse is described as small, and in by far the greater number (81 per cent.) as compressible. Hence the ordinary pulse of the old person may be said to be 77, regular, small, and compressible; and this may be called the 'pulse of endurance.' It indicates that the heart beats quietly and steadily, and that the arterial system is sound. In confirmation of the latter point, we find an absence of evidence of arterial disease noted in 72 per cent.; in 21 per cent. they are described as being 'tortuous,' and in 12 per cent. only as being 'knotty.' I am rather surprised that the men and women are about equal in this respect, for I had supposed calcareous and other like degenerative changes in the tissues to be more common in men than in women.

The respiration, averaging about 21, is rather less frequent than might have been expected, considering the liability to bronchitis, and the diminishing elasticity of the pulmonary tissues and of the chest walls, which must, to a greater or less extent, form one of the senile changes; but it accords with the observations that a comparatively good maintenance of elasticity is one of the features associated with longevity; our tables indicate that the elasticity of the chest wall was fairly distinguishable in about one-half of those in whom a return on this point was made. Moreover, the chest measurement, averaging about 36 inches in inspiration, and 35 in expiration, in the men, and 31 in inspiration and 30 in expiration in the women, is a fair medium, and shows that, considering the time of life, the range of respiratory movement is well maintained. It is also to be noted that, in a large proportion, the voice is stated to be clear, loud, and full, evidencing a sound condition, as well probably as a good development, of the vocal apparatus, a point upon which Sir Duncan Gibb is known to have laid much stress.

It is very satisfactory to find that nearly a half are reported to be of 'placid' disposition, and 45 per cent. to be still 'energetic' and brisk, whereas 17 per cent. only are said to be rather 'irritable.' With regard to several it is noted that these qualities are combined. Thus, some are stated to be 'placid' and 'energetic,' and some to be 'irritable' and 'energetic;' but, on the whole, the placid and energetic dispositions much predominate.

With regard to habits, 54 per cent. are stated to be 'active,' and taking more or less out-of-door exercise; 31 per cent. to be 'sedentary,' and 14 per cent. to be 'confined to bed.' Though the last is rather a large number, it must be remembered that many solaces attend upon this condition, not the least being the enjoyment of rest, which to the weary body is a real luxury. The need for it is usually, in the first instance, caused by weakness, perhaps rheumatic, in the lower limbs. These parts of the frame, which are the latest to be developed in size and strength, are the most prone to defect, disease, and debility. There is no doubt that in many cases confinement to bed leads to prolongation of life by the immunity it affords from exposures, and by its reservation to the organs essential to life of so much nerve force and nutritive energy as is economised by the diminution of bodily activity.

The greater number (60 per cent.) are 'moderate' eaters, 30 per cent. are 'small' eaters, and 9 per cent. only are 'large' eaters. A fair proportion (40 per cent.) are in the habit of taking a little alcohol, which, in the form of beer, whisky, or brandy, they feel to be a comfort and support, alleviating the sense of sinking which many feel; and perhaps this small quantity, especially if taken in the latter part of the day, does some real good. A smaller proportion take rather more, and are classed as 'moderate' drinkers. A considerable number, however, 36 per cent., take none at all, and very few, (2.5 per cent.) are described as taking much. It is also observed that a large number (62 per cent.) take but little animal food; 32 per cent. partake of it moderately; 3 per cent. take none at all; and 1.1 per cent. only take it in considerable quantity. It may commonly be observed that as persons advance in years and lessen in activity, the inclination for animal food diminishes. Most of our old people are content with about three meals a day. We now and then meet with old persons who eat rather ravenously and frequently, thinking perhaps that it is necessary to do so in order to maintain their strength, and that the need for so doing is indicated by the sense of sinking at the stomach which they experience. These instances however are very exceptional; and it is probable that a small quantity of cod-liver oil, taken once or twice daily in a little wine or spirit, would relieve the sense of sinking, and would promote digestion and nutrition, and so maintain strength in a safer and better manner than an extra and quickly swallowed amount of food.

REPORT ON THE PAST LIFE HISTORY OF AGED PERSONS.

THE following account of the past life history of aged persons is a sequel to the account of their present condition (see p. 511), and, like it, is taken from the analyses of the returns respecting 824 persons (432 men and 392 women) between the ages of 80 and 100 made upon the inquiry papers issued by the Collective Investigation Committee of the Association.⁵

It is worthy of remark that, of the 824 persons, nearly a fourth (24 per cent.) were 'first children,' and at least 17 of the number were 'only children,' though the greater number were about the third or fourth in the family. In 196 instances, in which the ages of the fathers and mothers at the time of the birth of the children were included in the returns, the average age of the fathers was 34, and that of the mothers 32. This would indicate the age of about 30 to be, as we might expect, so far as the offspring are concerned, the most favourable for child-producing. Five are stated to have been 'twins.' A gentleman of my acquaintance, himself a twin, married a twin, and has a large family of very healthy children and several grandchildren, thus proving that the reproductive as well as the enduring qualities may be fully possessed by twins.

Of the 335 who are stated to have been married, the average age at which they married was 29, the average duration of their married life was forty-five years, and the average number of their children was six.

Of the 292 women who are stated to have been married, the average age at which they married was 26, the average duration of their married life was forty years, and the average number of their children was six. The shorter term of married life of the women as compared with that of the men is explained by the fact that men are, on the whole, somewhat shorter-lived than women, and also that they marry at a rather later age, the term of the married life of the woman being, therefore, curtailed by the earlier deaths of the men. Not much information has been given respecting the labours of the women; and it may, therefore, be probably inferred that they did not in most instances present any very remarkable features. One woman is stated to have had severe flooding after a confinement at the age of 42, and to have rallied with difficulty. Two had many miscarriages. In the case of one, each of her fourteen labours was by the aid of instruments, and most of the children were born dead. One had twin daughters, both of whom were alive at the age of 56, and had large families. Fifty-seven of the married women were childless. It appears, therefore, that longevity was about equally shared by the single and the married, by those who had borne children and those who had not. At the same time, among those who had children, fertility, which means soundness and activity of the generative organs, is indicated to have been an associate of longevity.

The greater proportion (55 per cent.) of these old people had lived in comfortable circumstances, 35 per cent. had been 'poor,' and 10 per cent. had been 'affluent.' The greater number had been of average stoutness or of spare habit. Eight per cent. are said to have been 'delicate,' whereas 54 per cent. are reported to have been 'robust' throughout life, and 37 per cent. to have been about 'average' in this respect. Ninety per cent. had always enjoyed good health. In the category of 'good health' are comprised good digestion, which is reported with regard to 92 per cent., good appetite, which is noted in 88 per cent., and good, regular action of the bowels, which had taken place, and in most instances daily, in 85 per cent., costiveness being noted as habitual or frequent in only 10 per cent.

With regard to diet we find that the smallest proportion (15 per cent.) had been habitually 'large' eaters, 20 per cent. had been 'small' eaters, and the largest proportion (61 per cent.) had been 'average' in this respect. Five per cent. only had been in the habit of taking 'much' animal food—that is, more than a pound of meat daily; 38 per cent. took 'little'—that is, less than half a pound; and 53 per cent. had been accustomed to partake of it 'moderately'—that is, from half a pound to a pound in the day. Fifteen per cent. had taken no alcoholic drink at all throughout the whole or great part of their lives, 40 per cent. had been in the habit of taking a 'little'—that is, less than a pint of beer or two glasses of wine; 33 per cent. had been accustomed to take it in

'moderation'—that is, one or two pints of beer daily; and less than 9 per cent. had taken more than this. The last number is composed chiefly of men who lived to between 80 and 90; with respect to the men between these ages, of whom there were 298 returns under this head, it is to be observed that 15 per cent. appear to have drunk rather freely—2 or more pints of beer daily—and 10 or 12 had drunk rather heavily for a portion or throughout the greater part of their lives. These exceptional cases scarcely detract from the value of the important confirmation which our tables afford of that which good sense suggests and which ordinary observation tells—namely, that abstinence from, or a spare or moderate partaking of alcoholic drinks, as well as spare or moderate eating, and spare or moderate meat-eating are most compatible with health and most conducive to the prolongation of life. In this respect the poor are at some advantage as compared with the rich, for it is quite possible—indeed, very easy, to have too much of good things in the way of food, especially when they are made agreeable to the palate; and out of the abundance of what is good much that is evil is likely to ensue. Persons are apt to forget that limitation in quantity in any article of food is one of the requisites for its wholesomeness and good nutritious effect, that what is wholesome in moderation becomes unwholesome when the bounds of moderation are exceeded, those bounds being set by the real requirements of the system, and the brisk, complete appropriative powers of the stomach and nutritive organs; and they need the caution, as I have elsewhere expressed, that "the body quickly finds for idle food some mischief sure to do."

A greater number and a wider range of statistics would be needed to give trustworthy information respecting the influence of different occupations, modes of life, and places of dwelling upon the duration of life; but we find that by far the greater number (94 per cent.) of those included in our tables had been 'active' persons, and had led active lives, only 6 per cent. being described as 'sedentary.' The greater proportion (77 per cent.) of the men had been occupied much out of doors; this being the case, as might be expected, to less extent (33 per cent.) with the women. Of several it is remarked that they were good walkers, athletes, sportsmen, etc. Nothing, perhaps, more surely than good enduring power in walking, running, or similar exercise, indicates that soundness of frame and nutritive energy and good balance of organs which lead to longevity. Moreover, the opportunity for nutrition to do its restorative work was in nearly all provided by the faculty of 'good sleeping,' to which was commonly added its appropriate attendant, the habit of 'early rising.' I say 'appropriate attendant' for 'good' sleeping is, for the most part 'quick' sleeping, that is, the reparative work which has to be done in sleep is done briskly and well. Good sleepers, in the prime of life, do not usually sleep very long, especially when they are well and actively and happily employed during the day; and we are sometimes surprised at the small amount of sleep which those who are actively employed seem to require, the fact being that activity and energy of the will and the volitional system induce activity and energy in the sleeping or restorative operations, and, conversely, a dawdling day is commonly followed by dawdling sleep or drowsiness at night. When we speak of early rising, it must be observed that the word 'early' has a relative significance with reference to the time of going to bed. A person who retires to rest four hours after midnight and gets up at 10 A.M., may be strictly regarded as an 'early riser.'

As we found in the case of centenarians with regard to the hair, so in the old people we are considering it held its ground and its colour well, the proportion of those who were bald 'early' being about 26 per cent., whereas those in whom it was noted that this had not taken place amounted to 72 per cent. Those who were grey 'early' are 24 per cent., whereas in 75 per cent. this change is said to have been 'late.'

Sixty-nine per cent. had been of 'energetic' temperament, giving us the satisfaction of finding energy thus associated with the qualities that promote longevity, and that good working and good wearing qualities are commonly linked together. Thirty-six per cent. are reported to have been of 'placid' temperament, and 13 per cent. to have come under the designation of 'irritable.' In a few (5 per cent.) only is the intellect described as having been 'low'; in 21 per cent. it is said to have been 'high'; and 75 per cent. are said to have possessed an 'average' amount of intelligence.

It may seem somewhat remarkable that nearly one-half had suffered illnesses, more or less severe, at some period or periods of

⁵ These analyses are to be found at p. 515 *et seq.* of the JOURNAL, and the Report on Centenarians (those who had attained and passed their hundredth year) is in the JOURNAL for December 11th, 1886.

⁶ See remarks on this point in "Centenarians," *loc. cit.*

life. Of these illnesses many were caused by some external influences or poisons, such as those of fever, small-pox, or scarlatina, and they therefore had no special relation to weakness, disorder, or defect in the body. Though often directly destructive of life and seriously damaging to organs, they do not infrequently, even when severe, pass away like a cloud and leave the body quite unscathed, the only remaining vestige of incomplete recovery, that is, of incomplete restoration to the previous condition, being perhaps the change, whatever it be, which renders the system insensible to the influence of the poison, and so confers an immunity from the recurrence of the particular disease. Moreover, certain local inflammatory affections, those of the lungs, for instance, and some other parts, erysipelas, and a variety of affections, are in like manner engendered by, or attributable to, poisonous or malarial agencies introduced from without, while some, of which gout may be taken as a type, are the result of noxious materials engendered within the body. Whatever view may be taken of the causes and nature of the illnesses which had been undergone by these old people—and they were of various kinds—it is interesting to learn that in so many instances illness, though severe, did not prevent the sufferer from reaching old age. Doubtless the qualities which lead to old age are those which best promote complete recovery from illness as well as complete nutritive reparation under other circumstances; and, in relation to this subject, I may refer, especially with regard to affections of the nervous system, to the remarks on the *Maladies of Old People*, in the *JOURNAL* of July 30th, 1887.

The minor ailments with which a small proportion had been troubled at various periods in their lives may not have been altogether without their compensating advantages, forasmuch as these disorders not infrequently clear away slight accumulations of evil which would otherwise have increased and festered into graver maladies. These ailments, moreover, often serve as kindly warnings against indiscretions and exposures which, if continued, might prove disastrous. Though it is better not to err at all, it is a saving thing to be stopped or recalled in time. Thirty-nine of the whole number (824) had suffered occasional attacks of bronchitis; 41 had been troubled with dyspepsia; and 30 with rheumatism. A few gave accounts of skin-eruptions—eczema or psoriasis—more or less troublesome; others of gout, varix, or sore leg; but 72 per cent. appear to have passed their lives in freedom from these and other maladies. Our statistics, therefore, are confirmatory of the view that the qualities which lead to old age are those which for the most part give immunity from ailment and disease, and also promote recovery from them when they occur.

With regard to family history, this subject has been so much dwelt upon and so worked out in connection with life-insurance that little remains to be said. In many of our cases no sufficient information respecting it could be obtained. Still, 406 are reported to have belonged to long-lived families, those only being included in this number in the case of whom four of the immediate relatives (grandparents, parents, brothers, or sisters) had attained to the age of 70, or three to the age of 80. In six instances the families are stated to have been "short-lived."

In 367 instances, in which returns on blood-relationship are given, it is stated that none such existed between the grandparents or between the parents in 357. In four instances the grandparents were said to have been cousins; and in six instances the parents are said to have been cousins; and it is probable that in all these the relationship was that of first cousin. I do not know the proportion which the marriages of cousins bear to those in which no such relationship exists, or what is the numerical proportion of the children of cousins to the population generally; but the fact that 10 out of 367, with respect to whom a return on this point was made, or rather more than 2.7 per cent., were the children of cousins, seems to place the offspring of cousins in a very fair position with regard to the prospects of longevity.

The results of this collective investigation respecting aged people have not been to evolve anything very novel or startling, or to give rise to any fresh theories with regard to longevity and the means of attaining it, but rather to dissipate certain ideas which are more or less current though founded upon too limited observation, and to show that the maxims and laws which common sense and sound reason would dictate hold good, and that, as a general rule, those persons live the longest who might be expected to do so. Thus:—

1. The prime requisite is the faculty of age in the blood by inheritance; in other words, that the body has been wound up, as it were, and sent into the world with the initial force necessary

to carry on the living processes through a long period, that this is the case with every organ, and that the several organs are so adjusted to one another as to form a well-balanced whole. The various functions will then be equally and harmoniously performed, and there will, consequently, throughout life, be little cognisance of imperfection or ailment of any kind.

2. The body is usually well developed, and though there are many exceptions to this, rather exceeds the average standard of height. It is capable of much endurance and of quick and complete restoration after fatigue, this latter faculty giving the habit of, and probably the desire for, early rising; and with it also is associated a good power of recovery from the disturbances caused by accident or disease. The cerebral or intellectual powers accord with the general good quality, and the whole nervous system is active and energetic without being irritable.

3. Owing to the inherent good quality of the nutritive processes, those degenerative changes which, in advancing years, always more or less diminish the elasticity of the arterial coats and of other parts, are slow to occur, so that the pulse retains, in great measure, its softness and the thorax its vital capacity; while stiffness of limb and general feebleness are late in their manifestation. The decadence of the teeth, which in the animal world generally sounds a death-knell, inasmuch as it deprives the body of the means of obtaining its subsistence, does not seem to augur much in the case of civilised man, to whom the teeth are less directly needed for his maintenance, while another cuticular appendage, the hair, seems to share, to some extent, the enduring quality of the rest of the system.

4. To this natural long-livedness must be added the fair opportunities for the career of the body through the ascending and descending stages of the course assigned to it; that course will not be exceeded, but it may be, and usually is, curtailed. Indeed, as we know, even in those endowed with the greatest perfection of physique, the natural life-period is, owing to a variety of circumstances more or less unfavourable and often unavoidable, rarely completed, and the normal processes of decay and dissolution are seldom allowed to have their regular course. In the domain of Nature, as I have said on a former occasion, these processes are not suffered to advance very far, for the simple reason that the weakness associated with them causes the animal to fall a victim to some one of the various methods of killing which may hence be said to constitute the natural manner of death. Under the saving influence of civilisation, by which the rough and ready law of killing is modified, that which most contributes to the prolongation of life and the consummation of the inherited period, is "temperance in all things," especially in eating and drinking, and above all in alcoholic drinking, and to a large extent also in meat-eating. If the world did but realise, and would have the good sense and self-restraint to act upon the knowledge, how large a proportion of the ills to which man is regarded as the heir to, and which are therefore looked upon as inevitable, are simply the result of excess in eating and drinking, a large addition would be made to the average term of human life and health, as well as a large economy in the consumption of the materials—the food-stuffs—by which life is sustained. This saving would probably more than compensate for the additional requirement made by the addition to life. Under the term "excesses" must especially be included those small day-by-day superfluities which attract little attention and are thought little of, but the insinuating evil of which accumulates surely, inducing often, in the first instance, a sense of weakness which is thought to imply a need for more of that food or stimulus which is the cause of the weakness, and which gradually sows the seeds of disease that is attributed probably to some other cause. "Temperance" is the great lesson under this head which our tables teach; and its importance overshadowing all others is a reason for not diverting attention from it by mentioning them.

5. To the recovering power—the good and often the quick recovering power—of the aged after operations, fractures and other accidents, ulcers, inflammatory and other affections, manifested in many of the returns, I have already, and perhaps sufficiently, directed attention (see the *JOURNAL*, July 12th, 1884, December 11th, 1886, and July 30th, 1887). In confirmation of these observations, many cases have been published in the *JOURNAL* and elsewhere, and others have been privately communicated to me by medical men living in various parts of the kingdom.

6. Our returns give general evidence of the comfort and happiness of old age. Indeed, when the body remains sound, and when the aspirations are, as commonly is the case, toned into re-

ation with its diminishing capabilities, when the surroundings are favourable, and the mind, freed from the struggle of the world, can enjoy calm reflection on the past and the future, and by a genial sympathy with others can fulfil the mission which remains to it here of promoting peace on earth and good will among men, the declining days are often the happiest ones of the long life. Finally, when the developmental processes have carried the body through the stages of its allotted span, the gradually thinning thread of life yields without a snap, and the aged one passes contentedly and gently away.

I cannot close this report without hearing testimony to the comfort and kindness which the old people receive in the various union houses that I have visited. They are well fed, kept warm and free from exposures, walk out when they can, and lie in bed when it suits them to do so, and great attention is paid to their cleanliness. It was obvious that mutual attachment had grown up, in most instances, between them and the master and mistress of the house and the medical and other attendants. It would, I think, tend to soothe the feelings of the unwilling ratepayer if he occasionally visited the poor-house and witnessed the comfort which the aged and infirm are deriving from that largest charity ever known—the English poor-law system—to which he contributes.

ANALYSES OF RETURNS RESPECTING THE PRESENT CONDITION AND PAST HISTORY OF PERSONS BETWEEN EIGHTY AND A HUNDRED YEARS OLD.

For the following analyses of the returns respecting the present condition, including the habits and circumstances, and the past history, including the family history, of 824 persons between the ages of 80 and 100, we are indebted to A. Francis, M.R.C.S., who also assisted me in collecting the tables from which the analyses were made. I do not publish the tables, because they are long, the printing would be costly, and the analyses are sufficient.

Of these persons, 340 were males and 282 were females, between the ages of 80 and 90; and 92 were males and 110 were females between the ages of 90 and 100.

No. 1.

ANALYSIS OF RETURNS RELATING TO PRESENT CONDITION, HABITS, CIRCUMSTANCES, ETC. (MALES, 80 to 90. 340 RETURNS.)

SINGLE: MARRIED: WIDOWED.—335 returns; S. 36, M. 80, W. 219.

AFFLUENT: COMFORTABLE: POOR.—337 returns; A. 40, C. 138, P. 159.

FAT: SPARE: AVERAGE.—333 returns; F. 37, S. 114, A. 182.

FULL-BLOODED: PALE: AVERAGE.—321 returns; F. 54, P. 57, A. 210.

STRONG: FEEBLE: AVERAGE.—329 returns; S. 106, F. 100, A. 123.

HEIGHT.—313 returns; average, a little over 5 feet 7 inches.

WEIGHT.—188 returns; average, a little over 11 stone.

FIGURE.—299 returns; erect 198, bent 101.

VOICE.—325 returns. Weak, 31; loud, 57; clear, 81; full, 16; loud and clear, 77; clear and full, 44; clear and weak, 11; loud and full, 7; loud, clear, and full, 1.

SIGHT.—267 returns; good, 224; cataracts (both sides), 19; cataract (one side), 3; failure of sight, apparently independent of presbyopia, 21; one of them had been "blind for ten years," and one had had "opaque cornea for twenty years."

GLASSES.—259 returns; none, 42; one of these used them formerly; 217 used glasses. In some of them the number of years during which glasses had been used was given: "All life," 3; "many years," 17; "occasionally," 1; "for small print," 1; "not long," 1; "none till 80," 1; 1 year or less, 3; 2 to 3 years, 11; 4 to 5 years, 3; 6 to 7 years, 10; 8 to 10 years, 20; 12 to 15 years, 20; 16 to 20 years, 39; 21 to 25 years, 6; 26 to 30 years, 23; 31 to 35 years, 36; 36 to 40 years, 19; 41 to 45 years, 4; 46 to 50 years, 7; 62 years, 1; 65 years, 1.

HEARING.—329 returns; good, 188; indifferent, 98; bad, 43.

JOINTS.—330 returns; natural, 287; stiff, 17; deformed, 15; stiff and deformed, 9; Dupuytren's contraction, 2.

DIGESTION.—337 returns; good, 253; moderate, 72; bad, 12.

APPETITE.—335 returns; good, 224; moderate, 95; bad, 16.

EATER.—320 returns; large, 24; moderate, 211; small, 85.

NUMBER OF MEALS.—275 returns; average rather over three daily.

ALCOHOL.—320 returns; none, 120; little, 120; moderate, 67;

much, 13; one of these took three glasses of wine and half an ounce of spirits.

ANIMAL FOOD.—304 returns; none, 9; little, 182; moderate, 109; much, 4.

BOWELS.—313 returns; daily, 219; alternately, 23; irregular, 68; relaxed, 1; costive, 1; 3 to 4 times daily, 1.

APERIENTS.—294 returns; never, 85; occasionally, 1; rarely, 149; frequently, 59.

DISPOSITION.—328 returns; placid, 140; irritable, 33; lethargic, 7; energetic, 100; placid and lethargic, 6; placid and energetic, 25; irritable and energetic, 17.

INTELLECT.—322 returns; high, 55; average, 242; low, 25.

MEMORY.—*Past Events*.—307 returns; good, 253; moderate, 34; bad, 20. *Recent Events*.—260 returns; good, 166; moderate, 56; bad, 38.

HABITS.—327 returns; active, 202; sedentary, 93; one of these "could work, but for deafness;" bedridden, 32; of these, one for 5 weeks, two for 6 months, one for 5 years.

OUT-OF-DOOR EXERCISE.—306 returns; none, 45 (including 32 who were bedridden); little, 81; moderate, 65; of these one works still; short walks, 44; much, 71; of these one "in river daily," "two still work," one "worked until stopped by an accident 4 months ago," one "gardens," one "walks much," three "walk 3 miles," one "walks for 2 hours," one "walks and rides," two "walk 8 to 10 miles," one "walks 12 miles a day," two "hunt," one of them twice a week.

SLEEP.—326 returns; good, 230; moderate, 78; bad, 18. *Number of Hours*.—213 returns; average, 7½ hours. *Hour of Going to Bed*.—275 returns; average, about 9 o'clock. *Hour of Rising*.—271 returns; average, about 7.10 A.M.

CHEST-GIRTH IN INSPIRATION.—167 returns; average, little over 36 inches.

CHEST-GIRTH IN EXPIRATION.—167 returns; average, little over 35 inches. Only those cases are here included in which the chest-girth both in expiration and in inspiration were returned.

ELASTICITY OF RIB CARTILAGES.—209 returns; distinct, 106; indistinct, 103.

PULSE.—280 returns; average, about 74 per minute. This average is rather high, owing to the frequent occurrence of chest-affections; a large number had pulse-rate below 70 per minute. *Regular, Irregular*.—262 returns; R. 201, I. 61. *Large, Small*.—237 returns; L. 111, S. 126. *Compressible, Incompressible*.—261 returns; C. 208, I. 53.

ARTERIES.—252 returns; even, 144; visible, 7; tortuous, 19; tortuous and even, 9; tortuous and visible, 20; visible and even, 22; tortuous, visible, and even, 2; knotty, 12; visible and knotty, 6; tortuous and knotty, 7; tortuous, visible, and knotty, 4. So that they were even in 177 cases, *knotty* in 29 cases, *visible* in 61 cases, *tortuous* in 61 cases.

RESPIRATION.—Number, 237 returns. Average, 20 to 21 per minute. The average is high, owing to the frequent occurrence of chest affections. *Regular, Irregular*.—252 returns. R. 242, I. 10.

ARCUS SENILIS.—266 returns. Absent, 94; little, 98; much, 74; one of these had had arcus senilis since 44 years of age.

TEETH.—300 returns; average about 6 each; but 87 had no teeth, and one of these not for 20 years. In 282 cases the teeth were specified. Upper incisors, 235; canines, 147; molars, 249; lower incisors, 438; canines, 221; molars, 330.

ARTIFICIAL TEETH.—195 returns. 158 did not use them, and of these 46 had not any teeth, and one had not had any teeth for 20 years, another not for 30 years; besides these 46 cases, many others had very few teeth. 37 used artificial teeth; for many years, 3; 35 years, 1; 32 years, 1; 30 years, 2; 28 years, 1; 20 years, 10; 17 years, 14; 15 years, 4; 12 years, 1; 10 years, 5; 9 years, 1; 6 years, 2; 4 years, 2; "yes," 8.

EVIDENCES OF FAILURE.—235 returns. None, 102; heart, 16; heart and lungs, 5; heart, lungs and brain, 1; heart, lungs, and urinary organs, 4; heart, brain, and urinary organs, 1; heart and urinary organs, 12; heart, lungs, brain, and urinary organs, 3; lungs, 29; lungs and brain, 2; lungs and urinary organs, 18; brain, 11; brain and urinary organs, 7; urinary organs, 74. In 22 cases the heart-sounds are returned as "normal."

So that the *heart* was affected in 42 cases, the *lungs* in 62 cases, the *brain* in 25 cases, the *urinary organs* in 119 cases. In the case of the urinary organs the failure was in many cases very slight, not affecting the general health (*vide* Micturition).

MICTURITION.—267 returns. Natural, 157; frequent, 14; one occasionally; slow, 56; incontinence, 7; one of these "for years," one for 3 months, and one "nocturnal;" quick, 1; difficult, 2.

slow and difficult, 11, one of them "for 30 years," another used a catheter twice daily; difficult and painful, 1; frequent and painful, 2; slow and frequent, 6; frequent and incontinence, 1; slow and painful, 2; slow, difficult, and painful, 2; catheterised, 6, of these, one twice daily, one 4 times daily, one 6 times daily, one for 3 years, one daily for 40 years (*vide Present Maladies*).

PRESENT MALADIES.—The returns are very incomplete; in many cases only symptoms have been returned, in others failure of some organ was returned, but the nature of the failure was not stated; in hardly any cases have details of the malady been given; the maladies have therefore been grouped in relation to the organ which appeared most affected.

278 returns; none, 89.

Bronchitis.—43 cases; 1 frequently, 1 occasionally; 9 chronic, and one of these for 2 years. **Asthma.**—3 cases; 1 chronic. **Cough.**—5 cases. **Dyspnoea.**—4 cases. **Emphysema.**—8 cases; one for 2 years. **Congestion of Lungs.**—3 cases; 1 died. **Pneumonia.**—1 case; died. **Chronic Naso-pharyngeal Catarrh.**—1 case.

Debility.—24 cases; one for 6 months. **Weak Heart.**—12 cases, 1 with giddiness and fainting. **Syncope.**—1 case, occasionally. **Vertigo.**—1 case. **Palpitations.**—2 cases; one occasional and severe for 20 years. **Dilated R. Heart.**—1 case. **Murmurs.**—7 cases; one for 2 years; systolic at base in 2, mitral in 2 (in one of these for 10 years), mitral systolic in 1, aortic in 1. **Intermittent Heart.**—2 cases; in 1 every fourth beat, in the other occasionally. **Anæmia.**—1 case, for a year.

Dyspepsia.—5 cases. **Diarrhoea.**—6 cases; two occasionally, one for 3 months, one for 16 years, one for 4 days, with death. **Piles.**—2 cases. **Fistula.**—one case for 30 years. **Prolapsus Ani.**—2 cases; one for 15 years. **Enlarged Liver.**—1 case. **Hernia.**—8 cases; 1 double, one for 10 years, one for 55 years. **Inguinal Hernia.**—15 cases; 1 double, 1 large, one large for 12 years, one large for 30 years, one for 50 years, one for 60 years. **Umbilical Hernia.**—1 case. **Headaches.**—1 case.

Enlarged Prostate.—11 cases; 1 for several years, three for 2, 3, and 4 years respectively, and one gives less trouble now than formerly. **Cystitis.**—2 cases; 1 died. **Pus in Urine.**—1 case. **Irritable Bladder.**—4 cases; one for 18 months, 1 for a few years. **Atony of Bladder.**—2 cases. **Gravel.**—1 case. **Hæmaturia.**—3 cases; 1 occasionally prostatic, 1 three attacks in last 6 months. **Retention.**—2 cases; 1 occasionally, 1 with death.

Rheumatism.—19 cases; one for 12 months, one of hip for 4 years. **Sciatica.**—4 cases. **Lumbago.**—1 case. **Gout.**—7 cases; 1 of them in foot. **Pains in Bones.**—1 case. **Lame.**—1 case.

Paralysis Agitans.—3 cases. **Delusions.**—1 case. **Mental Depression.**—1 case. **Insane.**—1 case for 60 years. **Epileptic Fits.**—1 case recently, 1 fit every 2 months. **Occasional Fits.**—1 case from "brain congestion." **Cerebral Hemorrhage.**—4 cases, all died; one was the "third attack at 86." **Partial Hemiplegia.**—2 cases, one for 13 months, one for 4 years. **Paralysis of Face and Voice.**—1 case for 6 months.

Epithelioma.—5 cases; three of lip; in one of these removed at 84, wound healed by first intention; one of finger, removed; one of penis and prepuce, operated on two months ago. **Rodent Cancer.**—1 case, of ear. **Nasal Polypi.**—1 case. **Fibrous Tumour.**—1 case, size of hen's egg, over orbit, removed at 81 after 3 years' duration. **Sarcoma.**—1 case of shoulder, 15 months' duration, increasing rapidly, with little effect on general health.

Œdema of Legs.—5 cases, one for 14 weeks. **Enlarged Legs.**—1 case, hard and brawny. **Inflamed Legs.**—1 case. **Sore Leg.**—1 case. **Varicose Ulcers.**—4 cases; one for 6 months, one for 2 years, one for 20 years, now healing; one for 6 years. **Eczema.**—4 cases; one of ankle, one for 5 years. **Psoriasis.**—1 case. **Lupus.**—1 case, from stroke of whip. **Bedsores.**—1 case. **Senile Gangrene.**—4 cases, one of these of toe. **Ophthalmia.**—2 cases.

Erysipelas.—1 case with death. One died after "4 days feverish illness."

Fracture of Femur.—2 cases, one "impacted, one month ago."

NO. 11.

ANALYSIS OF RETURNS RELATING TO PAST HISTORY INCLUDING FAMILY HISTORY.

(MALES, 80 to 90.)

Age when Married.—273 returns. Average a little over 28 years of age.

Duration of Married Life.—260 returns. Average about 43½ years.

Number of Children.—269 returns; average about 6 each, but 34 had no children.

Affluent, Comfortable, Poor.—326 returns; A. 33, C. 190, P. 103. **First or — Child of Parents.**—303 returns; average 3rd to 4th child. Fat, Spare, Average.—317 returns; F. 69, S. 100; average, 148. **Delicate, Robust, Average.**—311 returns; D. 12, R. 189, A. 110.

Health, Good, Moderate.—315 returns; G. 304, M. 11. **Often, Rarely, Ailing.**—14 returns; O. 7, R. 7.

Digestion.—325 returns; good, 307; indifferent, 17; bad, 1.

Bowels.—307 returns; good (daily) 266; irregular, 12; costive, 25; relaxed, 4.

Baldness.—191 returns; early, 55; late, 135; not bald, 1.

Greyness.—248 returns; early, 58; late, 189; not grey, 1.

Disposition.—308 returns; placid, 98; irritable, 19; lethargic, 2; energetic, 133; placid and energetic, 35; placid and lethargic, 2; irritable and energetic, 19.

Intellect.—308 returns; high, 68; low, 16; average, 224.

Habits.—308 returns; active, 293; sedentary, 15.

Out-of-Door Exercise.—298 returns; little, 31; of these one "could walk 50 miles," and one "always worked indoors;" moderate, 39; one of these travelled much in Germany and America; much, 228; of these 13 were great walkers, 1 walked 20 to 30 miles a day, one "30 miles on 4 days a week," one 5 to 20 miles daily, one "50 miles, many a day;" two 10 miles daily. Besides these, six had much walking, riding, or driving, or worked hard; one was an "athlete, walked 20 miles;" one "great athlete, runner, and jumper;" two were pugilists; one "active in boyish and manly exercises;" one "much hunting;" one "hunting since 8 years old;" one "hunting and shooting all his life;" one "hunting, drinking, shooting, fishing;" one "in saddle as doctor for 50 years;" one "led an irregular gipsy life;" one was at sea; one "much exposed in India for over 25 years;" one was "engaged in whaling, and in India, leading an adventurous life."

HOURS IN BED.—243 returns. **Average.**—Nearly 8 hours.

HOUR OF RISING.—253 returns. **Average.**—A little before 6 A.M.

SLEEPER.—311 returns. Good, 278; average, 26; bad, 7.

APPETITE.—295 returns. Good, 289; indifferent, 6.

EATER.—305 returns. Large, 52; average, 194; small, 59.

ALCOHOL.—298 returns. **None.**—28; besides these, one "never till 30," and another "none after 60." **Little.**—(under 1 pint) 95; of these, one took a quarter and one half a pint of beer daily. **Moderate** (1 to 2 pints).—112; of these, six took 1 to 2 pints of beer or porter daily, one 4 glasses of wine, one half a pint of claret, one was an abstainer till 40, one "little in early life," one "much in early life," one took a little rum, one had "tendency to drink," one "much at times," one "did not take alcohol daily, but occasionally to excess; 4 pints of beer made him tipsy." **Much** (more than 2 pints).—45; of these, two were "free livers," two "much beer, free livers," one "very much beer," one "much beer regularly," two 2 to 3 pints of beer, one "2 to 4 pints of beer all his life," one 4 pints of beer daily, one 6 pints of beer often, three 3 to 5 pints of beer, one "in early life, never intemperate," one "drank heavily in early life," one "heavy drinker, able to stand large quantities," one "much of all kinds," one "much port," one "three-fourths of a bottle of Marsala for years," one "often drunk," one "freely never too much," one took 5 ounces of rum daily, one "a pint and a half of wine and spirits daily for years," one "three glasses of whisky and wine," one "6 ounces of whisky," one "drank all he could get," three "much when they could get it," one was a publican, one "drank freely of rum (1 pint daily) till 46, none since," one "took 6 pints of beer and much spirits, was a great drinker till 6 years ago, never went to bed sober if he could get beer," one "often drank a bottle of rum before breakfast when in Australia."

ANIMAL FOOD.—272 returns. **None.**—1. **Little** (under half a pound).—107; one of these was "almost a vegetarian." **Moderate** (half a pound to a pound).—143. **Much** (more than 1 pound).—21.

ILLNESSES UNDERGONE.—**Fever.**—16 cases; one "young," one "40 years ago, severe," one "a year ago," and nine at 16, 20, 25, 34, 35, 40, 40, 50, and 74 respectively. **Typhus Fever.**—16 cases; one severe, one in childhood, and eight at 14, 20, 24, 25, 37, 40, 45, and 46 respectively, one in 1827, one at 40, severe, two 40 and 50 years ago respectively. **Typhoid Fever.**—8 cases; two severe at 27 and 67 respectively, five at 15, 40, 50, 55, and 60 respectively. **Yellow Fever.**—1 case, twice. **Scarlet Fever.**—3 cases; one "young,"

four at 18, 40, and 40, severe, and 65, severe. *Influenza*.—1 case, at 50. *Whooping-cough*.—1 case, at 56. *Small-pox*.—9 cases; one in childhood, one slightly, one at 16, severe, one at 74, one "confluent at 19," one 77 years ago, one twice, one "in 1825 after vaccination." *African Fever*.—1 case.

Ague.—5 cases; one "prolonged at 20," in three at 40, 44, and 68. *Intermittent Fever*.—1 case. *Erysipelas*.—5 cases; one "of leg often," one at 81 recovered, one severe 50 years ago. *Cellulitis*.—2 cases; one at 82 with incisions, one three times at 65, 75, and 80.

Cholera.—3 cases, one at 30. *Dysentery*.—2 cases, one at 82, one in 1883. *Syphilis*.—1 case. *Carbuncle*.—5 cases, one had two, one 20 years ago, three at 60, 74, and 75, the last with incisions and quick recovery.

Brain Fever.—2 cases at 30 and 46. *Sunstroke*.—1 case at 50. *Adder Bite*.—1 case.

"*Cerebral Affection*."—1 case, 30 years ago. *Rheumatic Fever*.—14 cases, two "young," two 30 and 40 years ago, nine at 20, 34, 40, severe; 42, severe, with complete recovery; 45, 53, 60, 63, and 65. *Chorea*.—1 case. *Rheumatism*.—6 cases, one twice, one 12 years ago, one for 12 years. *Rheumatic Gout*.—1 case at 37. *Gout*.—10 cases, one occasionally, one frequently, one frequently for 10 years, one for 17 years, one since 21 years old, chalk stones in fingers. *Sciatica*.—3 cases, one at 69. *Lumbago*.—1 case. *Neuralgia*.—3 cases; one at 55, one in legs with insomnia at 55, with issues for 8 years. *Rheumatic Iritis*.—1 case, 25 years ago. *Lithotomy*.—1 case, 15 years ago, removal of large uric acid calculus. *Lithotripsy*, 1 case, 24 years ago. *Lithuria*.—1 case. *Renal Colic*.—1 case, 50 years ago.

Hæmatemesis.—1 case. *Jaundice*.—3 cases; one at 84 severe, one at 81 recovered. *Gall-stones*.—4 cases; one for 34 years. *Hepatic Abscess*.—1 case bursting into colon at 43. *Hepatitis*.—2 cases, in one two attacks at 30 and 35. *Bilious Attacks*.—1 case occasionally. *Hepatic Congestion*.—1 case occasionally. *Colic*.—2 cases; one severe a year ago. *Dropsy*.—1 case, 5 years ago, tapped 6 quarts, recovered. *Diarrhoea*.—1 case at 85. *Typhlitis*.—1 case at 40. *Inflammation of Bowels*.—2 cases, one at 21.

Hæmaturia.—1 case, 3 attacks in 6 months. *Albuminuria*.—2 cases; one 4 years ago, one 1 year ago for a few days. *Irritable Bladder*.—2 cases; one a few years ago, one from 50 to 60. *Retention*.—1 case, catheterised twice daily for one month, with recovery. *Difficult Micturition*.—1 case at 68, catheterised then and occasionally since. *Disease of Bladder and Prostate*.—1 case, severe, from 72 to 78, now quite well. *Stricture*.—1 case when young.

Diseased Hip.—1 case in infancy, lame. *Syncope*.—1 case at 74. *Bled*.—2 cases; one for illness at 40, one for transfusion. *Epistaxis*.—2 cases; severe at 30 and 73; one was thought to be dying 15 years ago. *Fistula*.—1 case 50 years ago. *Sarcoma of Eye*.—1 case. *Abscess*.—4 cases; one of thigh 50 years ago, one "strumous when young;" one of "shoulder at 76, recovery;" one in "side, at 30 in bed 8 weeks."

Bronchitis.—23 cases; one "severe," three severe at 47, 60, and 84; two at 65 and 68; four 6 months, 6 months, 10 years, and 17 years ago; one "several attacks since 80;" one "3 attacks severe, with recovery at 50, 83, and 84;" one "5 acute attacks in successive winters from 77 to 82 years;" one "two attacks at 50 and 75;" one "several severe attacks;" one "severe 2 years ago, recovery." *Broncho-pneumonia*.—1 case at 82, recovery. *Edema of Lungs*.—1 case. *Asthma*.—1 case for 10 years. *Pulmonary Congestion*.—2 cases, at 30 and in 1875 respectively. *Bronchitis and Pleuro-pneumonia*.—1 case, three times in last 7 years, last at 84, good recovery. *Pneumonia*.—4 cases, one "two attacks at 45 and 50," one severe 10 years ago, two at 66 and 79. *Pneumonia and Pleurisy*.—1 case at 78. *Pleurisy*.—6 cases; five at 16, severe, 28, 60, 72, 82 respectively. *Phthisis*.—3 cases; two had "slight symptoms when young;" a third had "hemoptysis at 40, in bed 8 weeks;" one was "delicate in early life;" one had "breakdown from anxiety, with diplopia and intermittent pulse at 64, with recovery;" one had "irregular heart 10 years ago, from study; recovering with change."

Epilepsy.—2 cases; one 20 to 30, fits in last two years, failure of memory. *Insane*.—1 case. *Apoplexy and Paralysis*.—16 cases; one "20 years ago, partial paralysis of right arm for 5 years, recovery;" one "in 1850, with right hemiplegia;" one "convulsions on right side with unconsciousness, a year ago with recovery;" one "fit at 79, with hemiplegia, complete recovery except of voice;" one "hemiplegia a year ago," one "left hemiplegia at 76," one "3 attacks at 82, 85, and 86;" one "paralysis at 65;" one "slight stroke at 85, slight paralysis after;" one "slight stroke

lately, weak after;" one "paralysis of both legs and left arm, not unconscious, quite recovered;" one "paralysis at 84, partial recovery, died of apoplexy;" one "hemiplegia at 45, recovery;" one "hemiplegia at 84, nearly recovered;" one "right hemiplegia and aphonia at 84, recovered." *Congestion of Brain*.—1 case at 62.

Slight Ailments.—256 returns; none, 156. *Bronchitis*.—16 cases; one "several times," four chronic. *Cough*.—2 cases; one frequently. *Catarrh*.—1 case. *Asthma*.—1 case, 28 years.

Dyspepsia.—16 cases; one lately, one at 70, recovery. *Bilious Attacks*.—3 cases. *Giddiness*.—2 cases; one occasionally, one "after meals." *Flatulence*.—1 case. *Gall-stones*.—1 case. *Palpitations*.—3 cases; one occasionally, one "for 20 years."

Headaches.—3 cases; of these one "sick headaches every 3 months," one "sick headaches frequently." *Constipation*.—4 cases.

Diarrhoea.—8 cases; one "in summer," two occasionally, one has "tendency to diarrhoea," one "for 15 years, since injury to abdomen." *Piles*.—3 cases. *Epistaxis*.—1 case.

Rheumatism.—16 cases; one at 68, one "lately, in bed 3 months." *Gout*.—7 cases; one slight, one annually for 30 years, two occasionally. *Sciatica*.—2 cases. *Neuralgia*.—1 case. *Angina*.—1 case rarely.

Ague.—1 case. *Orchitis*.—1 case occasionally. *Hernia*.—6 cases; one double, one "from infancy," one for 30 years, one "inguinal," one "right inguinal," and one "inguinal for 30 years."

Difficult Micturition.—1 case, few years ago, from stricture. *Eczema*.—7 cases; one "of legs," one at 46, one "30 years of leg," two for 2 and 4 years, one "grocer's eczema all his life till lately." *Psoriasis*.—1 case, alternating with asthma. *Variol*.—1 case, many years. *Ulcer of Leg*.—4 cases; one "20 years, now healed," one "for 30 years," one "from 60 to 80, now healed," one was "ailing till 50," one had "feeble childhood and youth, health and appetite better after 80."

ACCIDENTS.—175 returns. None, 128.

Concussion of Brain.—3 cases; two at 62 and 70; the third "four times, was bled each time." *Spinal Concussion*.—1 case at 34. *Severe Railway Accident*.—one case at 56. *Knocked Down*.—1 case at 76. *Severe Fall*.—1 case, three weeks ago, scalp wound healed rapidly. *Run Over*.—1 case, by a cab at 80. *Severe Bruising*.—1 case at 64. *Kick on Head*.—1 case when young, large depression of right frontal bone. *Fracture of Skull*.—1 case at 49. *Injury to Chest*.—1 case at 16, with repeated hæmoptysis and venesection. *Injured Abdomen*.—15 years ago, diarrhoea since.

Dislocation: Shoulder.—6 cases; two at 65 and 79; three 1, 8, and 40 years ago. *Ankle*.—2 cases; one at 50, one 30 years ago. *Hip*.—1 case, 20 years ago. *Injured Hip*.—1 case at 71, lame since.

Fracture: Patella.—2 cases; one 8 months ago, one "muscular at 78, with bony union." *Arm and Leg*.—1 case at 45. *Arm*.—1 case at 83. *Leg and Thigh*.—1 case at 86. *Right Humerus*.—1 case at 85. *Ribs*.—5 cases; three at 64, 70 and 70, one a year ago with recovery in 3 weeks, one "3 ribs at 58." *Sternum*.—1 case at 30. *Shoulder*.—1 case, "compound, after 70." *Leg*.—2 cases; one at 45. *Thigh*.—6 cases; one 5 years ago, one "in 1880, close to knee," one "left, at 66," one "at 83, in bed nine weeks with perfect union," two of neck of thighbone, one of them in January, 1883, the other "at 79, recovered after being in bed nine weeks."

Amputation: Arm.—1 case at 47. *Leg*.—2 cases; one for "diseased ankle at 25," one from "accident at 46."

LONGEVITY.—Taking as a standard of a long-lived family one in which of the near relations (grandparents, parents, brothers, sisters, and subject of inquiry) 4 attained the age of 70, or 3 the age of 80, we have at least 182 cases; two of them were on mother's side only; one was returned as short-lived family.

BLOOD-RELATIONSHIP BETWEEN PARENTS OR GRANDPARENTS.—163 returns. None, 157. In two cases "grandparents were cousins," in one "maternal grandparents were first cousins," in one "paternal grandparents were cousins," in one "parents were cousins," in one "parents were first cousins."

AGE OF FATHER AT BIRTH OF SUBJECT OF INQUIRY.—96 returns. Average, about 36 years of age.

AGE OF MOTHER AT BIRTH OF SUBJECT OF INQUIRY.—96 returns. Average, about 31 years of age.

Only those cases are included in which both age of father and mother are given.

DISEASES IN FAMILY (in relations and subject of inquiry):

Cancer (malignant growths).—44 families.
Consumption.—65 families.
Scrofula.—1 family.
Gout.—30 families.
Apoplexy and Paralysis after 40.—42 families.
Rheumatism.—59 families.
Epilepsy.—5 families.
Insanity.—13 families.
None.—40 families.

No. III.

ANALYSIS OF RETURNS RELATING TO PRESENT CONDITION,
HABITS, CIRCUMSTANCES, ETC.
(MALES, 90 to 100. 92 Returns.)

Single, Married, Widowed.—76 returns; S. 4, M. 18, W. 54.
Affluent, Comfortable, Poor.—77 returns; A. 6, C. 42, P. 29.
Fat, Spare, Average.—78 returns; F. 8, S. 35, A. 35.
Full-Blooded, Pale, Average.—73 returns; F. 12, P. 16, A. 45.
Strong, Feeble, Average.—76 returns; S. 31, F. 31, A. 14.
Height.—70 returns; average, 5 feet 6½ inches; one, now 5 feet 6 inches, was 5 feet 9 inches; another, now, 5 feet 6 inches, was 5 feet 7½ inches.
Weight.—39 returns; average, 10 stone 9 pounds.
Figure.—70 returns; erect, 40; bent, 30.
Voice.—76 returns; loud, 10; clear, 10; loud and clear, 33; clear and full, 7; full, 3; loud and full, 2; weak, 5; clear and weak, 6.
Sight.—61 returns; good, 50; *Cataract* (both eyes), 4, in one case at 88 years. *Cataract* (one eye), 1. Failure, apparently independent of presbyopia, 6; in one case "blind for 20 years."
Glasses.—49 returns; none, 10; 39 wore them; of those in which period was given, many years, 3; 2 to 3 years, 1; 8 to 10 years, 5; 12 to 15 years, 4; 16 to 20 years, 6; 26 to 30 years, 5; 40 years, 3; 50 years, 2. In two cases "can read for five minutes without spectacles, and then 'goes all of a piece.'"
Hearing.—77 returns; good, 38; indifferent, 20; bad, 19.
Joints.—77 returns; natural, 64; deformed, 7; stiff, 4; stiff and flexed, 1; stiff and deformed, 1.
Digestion.—74 returns; good, 57; moderate, 14; bad, 3.
Appetite.—74 returns; good, 52; moderate, 17; bad, 5.
Eater.—71 returns; large, 12; moderate, 46; small, 13.
Number of Meals.—55 returns; average rather over 3 each daily.
Alcohol.—73 returns; none, 21; little, 26; moderate, 26; 1 "takes occasionally a little too much."
Animal Food.—69 returns; none, 1; little, 41; moderate, 26; much, 1.
Bowels.—74 returns; daily, 49; three times daily, 1; alternately, 8; every third day, 1; irregular, 13; costive, 2.
Aperients.—72 returns; never, 24; occasionally, 1; frequently, 10; rarely, 37.
Disposition.—76 returns; lethargic, 1; energetic, 28; placid, 28; irritable, 12; placid and energetic, 3; irritable and energetic, 4.
Intellect.—72 returns; high, 12; average, 51; low, 9.
Memory, Past Events.—70 returns; good, 58; moderate, 5; bad, 7.
Memory, Recent Events.—60 returns; good, 34; moderate, 14; bad, 12.
Habits.—75 returns; active, 46; sedentary, 21; bedridden, 8, one for 1 year, one for 2 years.
Out-of-Door Exercise.—68 returns; none, 17, of which 8 were bedridden, 1 not out for years, 1 not for 9 years; little, 7; moderate, 2, one travels by train alone; much, 3, one of these attended Norwich market as a cattle dealer a few days before death, another works in garden 3 hours daily; short walks, 23; walk and drive, 2; walks 1 hour, 1; walks 2 to 3 hours, 1; walk 1 mile, 3, one of these could do so "easily at 94;" walk 2 miles, 2; walk 3 miles, 3; rides on horseback, 1; "work as labourers," 2; "works on farm," 1; one "at work in hayfield 3 days before death."
Sleep.—70 returns; good, 47; moderate, 16; bad, 7.
Sleep, Number of Hours.—39 returns; average 8½ hours.
Hour of Going to Bed.—54 returns; average, 8.30 P.M.
Hour of Rising.—56 returns; average, 8 A.M.
Chest Girth in Inspiration.—30 returns; average, 35½ inches.
Chest Girth in Expiration.—30 returns; average, 35 inches. Only those cases are included in which chest girth in both inspiration and expiration are given.
Elasticity of Rib Cartilages.—41 returns; distinct, 16; indistinct, 25.

Pulse.—57 returns; average, little over 75 per minute. *Regular, Irregular*.—51 returns; R. 38, L. 13. *Large, Small*.—49 returns; L. 20, S. 29. *Compressible, Incompressible*.—51 returns; C. 42; I. 9.
Arteries.—55 returns; even, 38; visible, 1; visible and even, 2; tortuous, 1; tortuous and even, 2; tortuous and visible, 5; knotty, 3; visible and knotty, 2; tortuous and knotty, 1. So they were visible in 10 cases, even in 42 cases, tortuous in 9 cases, knotty in 6 cases.

Respiration Number.—48 returns; average, about 23 per minute. *Regular, Irregular*.—48 returns; R. 43, I. 5.

Arcus Senilis.—55 returns; much, 13; little, 22; absent, 20.
Teeth.—69 returns; average, 4 to 5; but 27 had none, and two had "several," one had a "third set of bicuspids at 89 years of age;" in 62 cases the teeth are specified. *Upper incisors*, 44; *canines*, 23; *molars*, 57. *Lower incisors*, 60; *canines*, 40; *molars*, 58.

Artificial Teeth.—71 returns; 66 did not use them, and of these 26 had no teeth, and several others very few; 5 used them; one for 3 years, one for 10 years, one for 20 years.

Evidences of Failure.—58 returns; none, 18; heart, 1; heart and brain, 1; heart and urinary organs, 2; lungs, 9; lungs and urinary organs, 2; lungs, brain, and urinary organs, 1; brain, 4; brain and urinary organs, 1; urinary organs, 19; so the heart was affected in 4 cases, the lungs in 12 cases, the brain in 7 cases, the urinary organs in 25 cases. Heart sounds returned as "normal" in 7 cases.

Micturition.—58 returns; natural, 32; slow, 8; frequent, 5; incontinence, 4, one partial for 18 years; difficult, 3, in one case catheter used occasionally, in one from contraction of urethra after amputation of penis. Slow and difficult, 4; slow and frequent, 1; slow, difficult, frequent, and painful, 1; in this case "micturition has been frequent for several years, sometimes a quarter of an hour before he can make water."

Present Maladies.—63 returns; none, 25.
Debility.—10 cases. *Weak Heart*.—1. *Mitral Bruit*.—1. *Senile Decay*.—1; died. *Cardiac Dropsy*.—1.

Bronchitis.—8 cases; three slight, one for 18 years, one with death. *Cough*.—2 cases, one chronic. *Emphysema*.—1. *Congestion of Lungs*.—1 case for 2 weeks.

Indigestion.—1. *Ulcer*.—1 from injury. "Gouty erysipelas and eczema."—1 case. *Hernia*.—1 case. *Dementia*.—2 cases; one for a few years, one since 1847 in St. Luke's.

Hemiplegia.—1 case. *Brain impaired*—recently in 1, from anxiety.

Senile Gangrene.—2 cases; 1 of foot, 1 of toe; both died. *Rheumatism*.—4 cases; 1 often, 1 of hip.

Enlarged Prostate.—1 case. *Albuminuria*.—One case for 6 months. *Atony of Bladder*.—One case for 14 years, with occasional retention. *Uræmia* and death, 1 case, difficult micturition from contraction of urethral orifice after amputation of penis for epithelioma 24 years previously.

Temperature.—3 returns; one of 95.0°, two of 96.0°; one of these "under the tongue." In one case, aged 99, some head measurements were given: circumference around temples, 21 inches; coronal from ear to ear, 14½ inches.

No. IV.

ANALYSIS RELATING TO PAST HISTORY, INCLUDING FAMILY HISTORY.

(MALES, 90 to 100.)

Age when Married.—62 returns; average, 30 to 31 years of age.
Duration of Married Life.—54 returns; average, little over 47 years.

Number of Children.—68 returns; average, little over 7 each.
Affluent, Comfortable, Poor.—72 returns; A. 6, C. 42, P. 24.
First or — Child of Parents.—64 returns; average, about third, but 18 were "first child," and of these one at least was "only child." In 19 cases the number in the family was also returned; of these, the average position was about third, and the average number in the family was 7 to 8 children. One was a twin, second born, the other being a girl.

Delicate, Robust, Average.—69 returns; D. 2, R. 47, A. 20.
Health: Good, Moderate.—70 returns; G. 70, M. 9. *Often Rarely Ailing*.—1 return; O. 1, R. 0.

Digestion.—74 returns; good, 72; indifferent, 2.
Bowels.—68 returns; good (daily), 58; irregular, 3; costive, 6 loose, 1.

Baldness.—38 returns; early, 12; late, 26.
Greyiness.—50 returns; early, 13; late, 37.

Disposition.—68 returns; placid, 18; irritable, 5; lethargic, 1; energetic, 32; irritable and energetic, 6; placid and energetic, 6.

Intellect.—59 returns; high, 13; average, 44; low, 2.

Habits.—72 returns; active, 70; sedentary, 2.

Out-of-Door Exercise.—68 returns; little, 5; moderate, 6. One "worked hard, often late at night;" one was a "good walker." Much, 57; of these, six were great walkers, one "walking four to five miles daily till 87;" one "ten to twenty miles daily, at 80 could run two miles without stopping;" one "on horseback till 85;" one a "sportsman," one had "laborious occupation as a stevedore;" one "worked hard, often late at night;" one "had a good deal of night-work;" one "often had night-work as a coastguard;" one, "a cattle-dealer, often twelve hours without food."

Hours in Bed.—44 returns; average, 8½ hours.

Hour of Rising.—53 returns; average, 6 A.M.

Sleeper.—67 returns; good, 61; average, 4; bad, 2.

Appetite.—67 returns; good, 65; indifferent, 2.

Eater.—66 returns; large, 13; average, 48; small, 5.

Alcohol.—67 returns; none, 1; little, 27; moderate, 32; one of these "took much when he had the chance;" much, 7; of these, two were "free eaters and drinkers," one "took two glasses of beer and four glasses of wine daily," one "took three glasses of whisky a day," one was "often drunk and in gaol," one was "drunk about once a week," one "boasted that he smoked and drank more than any man in the town, and was most irregular in every way."

Animal Food.—58 returns; none, 1; little, 14; one of them "once a week;" moderate, 41; much, 2.

Illnesses Undergone.—69 returns; none, 32.

"Fever."—6 cases; at 18, 21, 33 severe, 40, 65, and 76. *Yellow Fever.*—1 in West Indies. *Typhus Fever.*—4 cases; one at 15, one at 45, one when young in the Peninsular war, one at 65. *Typhoid Fever.*—4 cases; one young, three at 45, 50, and 67. *Ague.*—1. *Erysipelas.*—4 cases; one at 60, one severe at 80, one severe, with recovery at 89. *Brain Fever.*—1 with much venesection.

Bronchitis.—8 cases; three at 80, 88, and 96, one had two attacks in last four years, one severe at 94 with ultimate recovery, one at 98 severe with recovery. *Pneumonia.*—2 cases; one at 75, one within last 4 years.

Phthisis.—1 had symptoms, when 15 was at Brompton Hospital. *Abscess.*—1 in back at 45.

Jaundice.—2 cases; one at 60, one when young. *Fistula.*—1 at 48.

Epithelioma of Penis.—1 with amputation at 70.

Rheumatism.—2 cases, one as a boy. *Glaucoma.*—1 case, in left eye.

Strangulated Hernia.—1, with operation at 84. *Gangrene.*—1 of left foot at 77. *Venesection.*—1, several times when young.

Exema.—2 cases; one acute at 90, with complete recovery.

Dementia.—1 case since 1847, in St. Luke's.

One had slight paralysis at 72, one slight apoplexy and hemiplegia at 89, one 3 "strokes" with temporary paralysis, one during last 15 years had occasional loss of consciousness and use of left side, with quick recovery.

Retention.—One 4 years ago. *Atony of Bladder.*—One for 14 years from over-distension, occasionally catheterised; one for several years has had frequent micturition, sometimes a quarter of an hour before he can make water.

Slight Ailments.—63 returns; none, 38.

Bronchitis.—3 cases; one slight, one chronic for 8 years. *Asthma.*—1 case.

Rheumatism.—5 cases; one slight, one at 80, unable to walk since. *Gout.*—4; one for 20 years.

Diarrhoea.—1 lately. *Piles.*—1 for 70 years. *Bilious.*—1.

Ague.—1. *Gravel.*—1. *Renal Hemorrhage.*—one case, copious 4 times in last 20 years.

Dizziness.—2 cases; one occasionally for 10 years.

Hernia.—3 cases; one "all life," two for 20 and 50 years.

Ulcer of Leg.—1 case, healed at 98. *Eruption on Legs.*—1. *Exema.*—1. *Ailing in Youth.*—1.

Accidents.—49 returns; none, 35.

Concussion.—1 at 84 from fall of 10 feet. *Dislocated Thumb.*—1 from fall from scaffold at 81, recovered. *Sprained Ankle.*—1 at 93, quick recovery. *Scalp Wound.*—2 cases; one severe lately with quick recovery, one from fall at 89, healed quickly.

Fracture: Ribs.—3 cases; one at 84 with speedy recovery, one at 93 healed well. *Clavicle.*—Spontaneous at 90 in raising himself from chair, united. *Thigh.*—1 at 82. *Humerus.*—1 at 92, perfect union. *Neck of Thighbone.*—2 cases; one 87 not united, one at 20 at

Quatre Bras. *Leg.*—4 cases; one at 85, one compound, one both bones at 80 with recovery, one at 80 in middle, "leg slipped off fender as he sat, he did not fall, not united, quite flexible, in bed 7 weeks."

Longevity.—Taking as a standard of a long-lived family, one in which of the near relations (grandparents, parents, brothers, sisters, and subject of inquiry), 4 attained the age of 70, or 3 the age of 80, we have at least 40 cases; one was returned as "short-lived."

Blood Relationship between Parents or Grandparents.—29 returns; none, 29.

Age of Father at Birth of Subject of Inquiry.—11 returns; average, 35 years of age.

Age of Mother at Birth of Subject of Inquiry.—11 returns; average, nearly 32 years of age. Only those cases are included in which the ages of both father and mother are returned.

Diseases in Family.—(in relations and subject of inquiry).—*Cancer* (malignant growths).—8 families. *Consumption.*—13 families. *Scrofula.*—0 families. *Gout.*—8 families. *Apoplexy and Paralysis after 40.*—9 families. *Rheumatism.*—10 families. *Epilepsy.*—0 families. *Insanity.*—5 families. *None.*—5 families.

In one case almost every member of family except the subject terribly addicted to drink; in another case his son, daughter, and 4 nephews and nieces were deaf mutes.

NO. V.

ANALYSIS OF RETURNS RELATING TO PRESENT CONDITION, HABITS, CIRCUMSTANCES, ETC.

(FEMALES, 80 to 90. 282 Returns.)

Single, Married, Widowed.—280 returns; S. 32, M. 26, W. 222.

Affluent, Comfortable, Poor.—280 returns; A. 23, C. 112, P. 145.

Fat, Spare, Average.—277 returns; F. 36, S. 119, A. 122.

Full-blooded, Pale, Average.—275 returns; F. 18, P. 104, A. 153.

Strong, Feeble, Average.—274 returns; S. 58, F. 110, A. 106.

Height.—218 returns; average, a little over 5 feet 2 inches.

Weight.—86 returns, average, about 8 stone 10½ pounds.

Figure.—242 returns; erect, 146; bent, 96.

Voice.—268 returns; clear, 103; loud, 40; weak, 32; full, 11; clear and weak, 9; clear and full, 23; loud and clear, 49; loud and full, 1.

Sight.—220 returns; good, 184; cataracts, 15; failure apparently independent of presbyopia, 21.

Glasses.—227 returns; none, 32; 195 wore them. In some the number of years during which they were worn was given; many years, 19; 2 to 3 years, 2; 4 to 5 years, 6; 6 to 7 years, 4; 8 to 10 years, 14; 12 to 15 years, 10; 16 to 20 years, 31; 21 to 25 years, 10; 26 to 30 years, 34; 31 to 35 years, 6; 36 to 40 years, 28; 41 to 45 years, 3; 46 to 50 years, 10; 54 years, 1; 58 years, 1; 60 years, 1; 65 years, 1.

Hearing.—279 returns; good, 175; indifferent, 77; bad, 27.

Joints.—278 returns; natural, 243; stiff, 12; deformed, 13; stiff and deformed, 10.

Digestion.—280 returns; good, 169; moderate, 94; bad, 17.

Appetite.—278 returns; good, 144; moderate, 115; bad, 19.

Eater.—275 returns; large, 22; small, 105; moderate, 148.

Number of Meals.—225 returns; average, 3 to 4 daily.

Alcohol.—270 returns; none, 105; little, 117; moderate, 44; much, 4.

Animal Food.—249 returns; none, 10; little, 164; moderate, 72; much, 3.

Bovels.—266 returns; daily, 183; irregular, 51; alternately, 30; costive, 1; once a week, 1.

Aperients.—265 returns; never, 58; rarely, 150; frequently, 52; daily, 3; occasionally, 2.

Disposition.—267 returns; placid, 119; irritable, 28; lethargic, 4; energetic, 93; placid and energetic, 14; irritable and energetic, 9.

Intellect.—266 returns; high, 33; low, 36; average, 197.

Memory, Past Events.—258 returns; good, 186; moderate, 41; bad, 31. *Recent Events.*—221 returns; good, 120; moderate, 58; bad, 43.

Habits.—275 returns; active, 128; sedentary, 100; bedridden, 47; of these five for 2, 3, 4, 4, 15 years respectively, and two for 3 weeks and 3 months respectively.

Out-of-Door Exercise.—259 returns; none, 88 (of these 47 were bedridden); little, 102; moderate, 34; much, 14; short walks, 18 (of these one walks 2 miles). Besides these, three walk 3, 4 and 6 miles respectively.

Sleep.—267 returns; good, 146; moderate, 89; bad, 32. *Number of Hours.*—147 returns; average, a little over 7 hours.

Hours of Going to Bed.—204 returns; average, a little past 9 o'clock P.M.

Hour of Rising.—202 returns; average, 7.45 A.M.

Chest Girth in Inspiration.—73 returns; average about 31½ inches. *Expiration.*—73 returns; average, about 30½ inches. Only those are included where both inspiration and expiration are given.

Elasticity of Rib Cartilages.—139 returns; distinct, 65; indistinct, 74.

Pulse.—228 returns; average, nearly 70 per minute; high, owing to chest affections in many cases. *Regular, Irregular.*—201 returns; R. 164, I. 37. *Large, Small.*—194 returns; L. 60, S. 134. *Compressible, Incompressible.*—221 returns; C. 181, I. 40.

Arteries.—211 returns; even, 138; visible, 13; tortuous and even, 8; visible and even, 11; tortuous, 13; tortuous and visible, 6; knotty, 6; visible and knotty, 2; tortuous and knotty, 12; tortuous, visible, and knotty, 1; tortuous, visible, and even, 1; so that they were even in 158 cases, tortuous in 41 cases, visible in 34 cases, knotty in 21 cases.

Respiration.—Number, 204 returns; average, nearly 22 per minute; rather high, owing to chest complaints in many cases. *Regular, Irregular.*—212 returns; R. 198, I. 14.

Arcus Senilis.—224 returns; much, 48; little, 80; absent, 96.

Teeth.—253 returns; average, little over 3 each; but 122 had no teeth; of these, two had not had any for 40 and 55 years respectively. In 241 cases the teeth were specified. *Upper incisors, 103; canines, 75; molars, 96. Lower incisors, 201; canines, 112; molars, 121.*

Artificial Teeth.—208 returns; none, 176; of these, 89 had not any teeth, and 4 had not had any for 4, 30, 40, and 40 years respectively, and 3 had not had any "for years," and many others had very few teeth; 32 used artificial teeth, in some cases the number of years during which they had been worn was given. Many years, 5; 5 years, 1; 7 years, 1; 10 years, 2; 12 years, 1; 15 years, 1; 20 years, 4; 21 years, 1; 25 years, 3; 30 years, 4; 36 years, 1; 40 years, 1; 55 years (full set), 1.

Evidences of Failure.—228 returns; none, 117; heart, 11; heart and lungs, 6; heart and brain, 5; heart and urinary organs, 5; heart, lungs, and urinary organs, 2; heart, brain, and urinary organs, 2; heart, lungs, brain, and urinary organs, 5; in 14 cases heart-sounds returned as normal; lungs, 21; lungs and brain, 3; lungs and urinary organs, 7; brain, 18; brain and urinary organs, 3; urinary organs, 23; so that the heart was affected in 36 cases, the lungs in 44 cases, the brain in 36 cases, the urinary organs in 47 cases; in the case of the urinary organs, the failure was often slight (*vide Micturition*).

Micturition.—207 returns; natural, 166; incontinence, 13; slow, 11; slow and difficult, 3; frequent, 8; painful, 1; difficult, 1; hæmaturia, 1; difficult and painful, 1; slow, difficult, and painful, 2.

Present Maladies.—248 returns; none 91. *Debility.*—34 cases. *Weak Heart.*—5. *Syncope.*—2. *Palpitations.*—3. *Vertigo.*—3. *Angina.*—1, occasionally. "Aortic Disease."—1. *Murmur at Base.*—2 cases, one of them systolic. *Senile Edema.*—1. *Swelled Feet and Legs.*—1.

Dyspepsia.—9. *Diarrhœa.*—5, one slight, one occasionally. *Piles.*—3. *Flatulence.*—2. *Constipation.*—1. *Hernia.*—5, one for 40 years, one strangulated, with death three days after herniotomy, one umbilical.

Bronchitis.—32 cases, 6 of them chronic. *Cough.*—2. *Emphysema.*—2. *Pneumonia.*—1. *Rheumatism, Rheumatic Gout.*—26 cases. *Gout.*—6. *Swelled Knee.*—1.

Uterine Hæmorrhage.—1. *Polypus Uteri.*—1. *Prolapsus Uteri.*—4, one for 30 years. *Irritable Bladder.*—2. *Retention of Urine.*—1. *Intermittent Hæmaturia.*—1, for 20 years.

Caries of Rib.—1. *Lame (Hip).*—1. *Dislocated Ankle.*—1, for many years. *Fracture of Neck of Femur.*—2.

Cancer of Breast.—5. *Epithelioma of Face.*—1. *Rodent Cancer.*—1. *Carbuncle.*—1, large. *Periostitis.*—1.

Eczema.—3. *Erythema of Leg.*—1. *Sore Eyes.*—3. *Sore Mouth.*—1. *Eczema of Nipple.*—1 (no cancer). *Ulcer of Leg.*—1. *Inflamed Legs.*—1.

Neuralgia (Face).—3. *Sciatica.*—2. *Lumbago.*—1. *Hysteria.*—1. *Paralysis Agitans.*—2. "Lunatic."—1. *Dementia.*—13 cases. Besides these, one with epileptic attacks, and occasional delusions and excitement, and one "light-headed for one year." *Epilepsy.*—1, occasionally. *Maia.*—1, chronic; well for 17 years, recurring at 57.

Hemiplegia.—6. *Paraplegia.*—1. *Paralysis of Left Arm.*—1. *Senile Fits.*—1.

Temperature.—6 returns; in two cases "normal," in three, 98.0°; in one, 98.2°.

NO. VI.

ANALYSIS OF RETURNS RELATING TO PAST HISTORY, INCLUDING FAMILY HISTORY. (FEMALES, 80 to 90.)

Age when Married.—220 returns; average, about 26 years of age.

Duration of Married Life.—199 returns; average, nearly 39½ years.

Number of Children.—228 returns; average, 5 to 6 each, but 43 had no children; one had "prostration at 41, from child-bearing," one "often ailing since a bad labour 46 years ago," one "had severe flooding at 42, with difficulty rallying," one "nursed 8 children for a year each," two "many miscarriages," one "7 miscarriages out of 10 conceptions," one had "only one child, still-born," one "early profuse catamenia, menopause at 48," one "catamenia commencing at 16, moderate," one "catamenia from 17 to 40, moderate."

Affluent, Comfortable, Poor.—263 returns; A. 23, C. 138, P. 102.

First or — Child of Parents.—249 returns; average about 4th child. In 70 cases the number in the family was returned; in these the average position was 3rd to 4th, and the average number in the family 7 to 8 children; 58 were "first child," and of these 4 at least were "only child;" three were twins, and two twin brothers of one of the subjects both died over 80 years old; the mother of one not included in above had 22 children, and the maternal grandmother of one included above had 22 children, of which 20 grew up.

Delicate, Robust, Average.—240 returns; D. 37, R. 100, A. 103.

Health.—232 returns; good, 207; moderate, 25.

Often Ailing, Rarely Ailing.—26 returns; O. 25, R. 1.

Digestion.—248 returns; good, 211; indifferent, 37.

Bowels.—226 returns; regular, 184; irregular, 9; costive, 29; relaxed, 3; twice daily, 1.

Baldness.—80 returns; early, 17; late, 61; none, 2.

Greyness.—210 returns; early, 53; late, 155; none, 2.

Disposition.—242 returns; placid, 74; irritable, 20; lethargic, 2; energetic, 128; irritable and energetic, 13; placid and energetic, 5.

Intellect.—238 returns; high, 43; average, 180; low, 15.

Habits.—234 returns; active 215; sedentary, 19.

Out-of-Door Exercise.—206 returns; little, 64; moderate, 72, one a moderate walker; much, 59, one hard working. Besides these, eleven others: one worked hard, one walked daily, one "good walker," one "walked 3 hours," five "took walks," one "could walk 30 to 40 miles when young," one was "never very active."

Hours in Bed.—171 returns; average a little over 8 hours.

Hour of Rising.—196 returns; average a little past 6 A.M.

Sleeper.—232 returns; good, 188; average, 33; bad, 11.

Appetite.—233 returns; good, 209; indifferent, 21.

Eater.—230 returns; large, 29; small, 63; average, 138.

Alcohol.—232 returns; none, 54; very little, 2; little, 109, one of these "none till 35;" moderate, 60, one of these "none till 40;" much 7, one of these was a "notorious drinker, locked up 200 times for being drunk, father died aged 90, and brother died aged 70, both heavy drinkers.

Illnesses Undergone.—231 returns; none, 111.

"Fever."—19 cases; three "young," two severe at 20 and 60, eight at 28, 30, 50, 60, 40, 60, 63, and 70 respectively. *Measles.*—1 case. *Tonsillitis.*—1 case. *Typhus Fever.*—10 cases; 1 "young," five at 15, 20, 28, 30, and 46 respectively. *Scarlet Fever.*—5 cases; two severe at 40 and 42; one at 72. *Typhoid Fever.*—6 cases; one at two severe, five at 12, 19, 30, 47, and 70 respectively. *Influenza.*—1 case at 68. *Croup.*—1 case at 16, was bled excessively. *Whooping-cough.*—1 case. *Erysipelas.*—5 cases; 1 "frequently," one severe at 57, three of face at 20, 57, and 62 respectively. *Diphtheria.*—1 case at 68. *Rheumatic Fever.*—14 cases; one twice, one prolonged at 74, one at 26, deaf since; five at 21, 24, 26, 30, and 72 respectively. *Rheumatism.*—3 cases. *Gout.*—3 cases; at 31, 73, and 81. *Stroke.*—1 case at 52. *Cholera.*—1 case at 30. *Dysentery.*—1 case, severe, at 50.

Jaundice.—4 cases; three at 12, 81, and 83; all recovering. *Enteritis.*—4 cases; two at 44 and 80, one severe at 34. *Hæmatemesis.*—1 case at 60. *Diarrhœa.*—2 cases; one at 88, severe, recovered.

Bilious Attacks.—2 cases; one at 60, with gall-stones; one "severe to point of sinking." **Gall-stones.**—2 cases; one "badly when young." **Gall-stones and Jaundice.**—1 case at 66. **Inflammation of Liver.**—1 case at 73. **Strangulated Hernia.**—2 cases, at 50 and 85, with death in latter. **Intestinal Obstruction.** 1 case at 76.

Pneumonia.—7 cases; one at 82, recovered; one at 72, with pleurisy; one severe at 69, and four at 57, 67, 79, and 80 respectively. **Congestion of Lungs.**—1 case at 83. **Pleurisy.**—6 cases; five at 20, 40, 50, 60, and 72 respectively. **Bronchitis.**—26 cases; five at 25, 81, 86, "86 for four months," and "after 80" respectively; four severe at 62, 74, 80, and 88 respectively; two died; one 6 months ago; three "winter bronchitis" one of them for 5 years; one 15 years ago, one at "80 with complete recovery," one 3 severe attacks at 76, 77, 78; one with pneumonia at 86 recovering; one had "two attacks in last 2 years."

Uterine Fibroid.—1 case. **Nephritis.**—1 case at 77. **Phlebitis.**—case at 75 recovering. **Gangrene.**—1 case at 75 recovering. **Herpes.**—1 case at 77 never completely recovering. **Glaucoma,** with removal of eye.—1 case. **Feeble Heart and Anasarca.**—1 case for several years. **Poisoned Hand.**—1 case, 12 years ago; laid up several months. **"Inflammation."**—1 case at 30. **Abscess.**—1 case of thigh at 57. **Eczema.**—1 case for 2 years at 78; "ill three years at 50;" 1 case with recovery.

Insanity.—1 case. **Paralysis Agitans.**—1 case at 66. **Paralysis.**—2 cases at 79 recovering, and 82. **Hemiplegia.**—8 cases; one 2 years ago, one 3 years ago for a week, two at 81 and 82, both recovering; two at 77 and 78, with "partial recovery;" and two at 72 and 81.

Cancer of Breast.—3 cases; two doubtful and removed, one of them at 50, the third, "from injury 16 years before death, did not trouble her until ulcer of leg healed one year before her death."

Slight Ailments.—218 returns. None, 119. **Dyspepsia.**—21 cases; one for 5 years, 1 "all her life." **Bilious Attacks.**—3 cases. **Piles.**—4 cases. **"Spasms."**—1 case. **Congestion of Liver.**—2 cases. **Costive.**—1 case, since typhoid fever at 47. **Diarrhœa.**—2 cases; one occasionally.

Headaches.—7 cases; one "all her life," one "terrible from 20 to 50 years of age." **Pruritus.**—1 case for 40 years. **Neuralgia.**—1 case.

Palpitations.—4 cases; 1 "all her life," 1 for many years. **Menorrhagia.**—1 case. **Amenorrhœa.**—1 case. **Hysteria.**—1 case. **Prolapsus Uteri.**—2 cases. **Hernia.**—5 cases; three for many, 20, and 40 years; one "femoral" for 15 years; one large umbilical.

Gout.—5 cases; one frequently, one "for 15 years." **Rheumatism.**—16 cases; one for 20 years, one since 76 years of age.

Bronchitis.—14 cases; one "slight, occasionally," one "not for 10 years," one "for 10 years." **Coughs.**—2 cases; one for many years. **Catarrhs.**—1 case.

Eczema.—1 case. **Sore Leg.**—1 case. **Edema of Legs.**—1 case, recently. **Ulcer of Leg.**—4 cases; one for 8 years.

Hæmaturia.—2 cases; one in "3 successive springs," one "intermittent for 20 years." **Lame.**—1 case, "from birth." **Melancholy.**—1 case. **Debility.**—1 case. **Delicate.**—2 cases; one "throughout life," one "in early life." **Lateral Curvature.**—1 case. One took $\frac{3}{4}$ grain of morphine daily for many years.

Accidents.—188 returns. None, 150. **Burn.**—1 case, "when a child." **Concussion of brain.**—1 case at 36. **Head injury.**—1 case at 79. **Jarred by railway accident.**—1 case, 30 years ago. **Injury to Back.**—2 cases; one at 35; one from fall, bedridden since. **Fall Downstairs.**—3 cases; one at 88, one 2 years ago; her pulse, previously 60, has been 120 per minute since.

Amputation: Leg.—1 case at 50, for accident. **Breast.**—2 cases; for doubtful cancer, one at 50; one recovered in 14 days (*Lancet*, June, 1885). **"Operation for Tumour of Womb."**—1 case at 53. **Hermiotomy.**—1 case; death, 3 days later. **Dislocation of Shoulder.**—3 cases, two at 70 and 79.

Fracture: Neck of Femur.—6 cases; one 4 years ago, one "3 years ago, bedridden since;" four at 70, 81, 81, and "77 with recovery." **Thigh.**—3 cases; two at 40 and 74, one 9 months ago (*Lancet*, April, 1884). **Arm.**—5 cases, at 6, 60, 78, 80 "70, with quick recovery." **Forearm.**—2 cases; at 84, and "82, with firm union in 25 days." **Wrist.**—1 case; both wrists at 60 and 78 respectively. **Ribs.**—5 cases: three at 25, 60 and 81. **Patella.**—1 case at 25. **Hip.**—1 case at 57, on crutches since. **Both Legs.**—1 case at 78. **Compound Fracture of Leg.**—1 case 10 years ago, no lameness.

Longevity.—Taking as a standard of a long-lived family one in which of the near relations (grandparents, parents, brothers, sisters, and subject of inquiry), 4 attained the age of 70, or 3 the age of 80, we have at least 135 cases. Five families were returned as "short-lived."

Relationship between Parents or Grandparents.—134 returns. None, 132. Parents, first cousins, 1. Parents, second cousins, 1.

Age of Father at Birth of Subject of Inquiry.—70 returns; average, rather over 33 $\frac{1}{2}$ years of age.

Age of Mother at Birth of Subject of Inquiry.—70 returns; average, about 29 $\frac{1}{2}$ years. Only those cases are included in which the ages of both the father and mother are returned.

Diseases in Family (in relations and subject of inquiry.)—**Cancer** (malignant growths).—30 families. **Consumption.**—75 families. **Serofula,** 1 family. **Gout.**—24 families. **Apoplexy and Paralysis after 40.**—45 families. **Rheumatism,** 53 families. **Epilepsy.**—3 families. **Insanity.**—28 families. **None.**—21 families.

NO. VII.

ANALYSIS OF RETURNS RELATING TO PRESENT CONDITION, HABITS, CIRCUMSTANCES, ETC. (FEMALES, 90 to 100. 110 Returns.)

Single, Married, Widowed.—108 returns; S. 15, M. 10, W. 83. **Affluent, Comfortable, Poor.**—110 returns; A. 12, C. 46, P. 52. **Fat, Spare, Average.**—109 returns; F. 10, S. 62, A. 37. **Full-blooded, Pale, Average.**—104 returns; F. 7, P. 56, A. 41. **Strong, Feeble, Average.**—106 returns; S. 28, F. 45, A. 33. **Height.**—92 returns; average, 5 feet 2 $\frac{1}{4}$ inches. **Weight.**—28 returns; average, 8 stone 7 $\frac{1}{2}$ pounds nearly. **Figure.**—93 returns; erect, 54; bent, 39. **Voice.**—105 returns; clear, 25; full, 5; loud and clear, 33; weak, 11; clear and full, 14; loud, 11; clear and weak, 6. **Sight.**—93 returns; good, 58. Cataracts, 12; one at 85, and two for 1 and 4 years respectively. Failure apparently independent of presbyopia, 23; one blind for 2 years.

Glasses.—77 returns; none, 16; 61 wore them. In many cases the number of years during which they were worn was given. Few years, 1; many years, 9; 4 to 5 years, 2; 8 to 10 years, 2; 12 to 15 years, 1; 16 to 20 years, 6; 21 to 25 years, 2; 26 to 30 years, 6; 31 to 35 years, 3; 36 to 40 years, 10; 41 to 45 years, 3; 46 to 50 years, 6; 60 years, 2; 57 years, 1; 63 years, 1; 75 years, 1; 83 years, 1. Of those who use no glasses, two can thread a needle without, one used them from 40 to 80, but reads well without them now, one used them from 40 to 60, but reads well without them now.

Hearing.—110 returns; good, 48; indifferent, 34; bad, 28. **Joints.**—107 returns; natural, 90; deformed 7; stiff, 5; stiff and deformed, 4; slight Dupuytren's contraction, 1.

Digestion.—107 returns; good, 84; moderate, 21; bad, 2; one can "live on anything, and eat anything."

Appetite.—108 returns; good, 71; moderate, 34; bad, 3. **Eater.**—101 returns; large, 10; moderate, 62; small, 29.

Number of Meals.—77 returns; average, 3 to 4 daily. **Alcohol.**—105 returns; none, 32; moderate, 24; little, 48; much, 1.

Animal Food.—98 returns; none, 4; moderate, 38; little, 56. **Bowels.**—103 returns; once a week, 1; twice daily, 1; alternately, 8; irregular, 22; daily, 71.

Aperients.—97 returns; daily, 2; frequently, 20, in one case the "bowels never acted without;" rarely, 48; never, 27.

Disposition.—105 returns; placid, 37; irritable, 13; lethargic, 2; energetic, 32; irritable and energetic, 14; placid and energetic, 7.

Intellect.—102 returns; high, 18; average, 71; low, 13. **Memory, Past Events.**—105 returns; good, 80; moderate, 11; bad, 14.

Memory, Recent Events.—93 returns; good, 55; moderate, 17; bad, 21.

Habits.—108 returns; active, 48; sedentary, 33; bedridden, 27; 2 for a year, 1 for 6 months.

Out-of-Door Exercise.—104 returns; none, 50, of which 27 were bedridden; little, 25; moderate, 2; short walks, 21; one of these "walked 4 miles last week;" walks much, 1; much, 4; of these, one "able to walk some miles," one "walked 3 miles within a month of her death, and walked a third of a mile to morning service and back on the day before death, died from a cold." Drives out, 1.

Sleep.—103 returns; good, 69; moderate, 24; bad, 10, one of these kept awake by rheumatic pain.

Sleep, Number of Hours.—59 returns; average, about 7½ hours.

Hour of Going to Bed.—71 returns; average, little past 8.30 p.m.

Hour of Rising.—70 returns; average, about 8.45 a.m.

Chest-girth, in Inspiration.—27 returns; average 31½ (about).
Expiration.—27 returns; average, 30½ (about). Only those cases are included in which chest-girth in both inspiration and expiration are returned.

Elasticity of Rib-cartilages.—53 returns; distinct, 28; indistinct, 25.

Pulse Number.—78 returns; average, nearly 80 per minute; high from chest affections in many cases. *Regular, Irregular.*—70 returns; R. 60, I. 10. *Large, Small.*—72 returns; L. 20, S. 52. *Compressible, Incompressible.*—75 returns; C. 63, I. 12.

Arteries.—71 returns; even, 54; tortuous, 1; visible, 1; visible and even, 6; tortuous and visible, 4; tortuous and even, 2; knotty, 1; tortuous and knotty, 1; visible and knotty, 1. So they were even in 62 cases, *tortuous* in 8 cases, *visible* in 12 cases, *knotty* in 3 cases.

Respiration Number.—62 returns; average, 21 to 22 per minute; higher from chest affections in many cases. *Regular, Irregular.*—67 returns; R. 65, I. 2.

Arcus Senilis.—77 returns; much, 23; little, 25; absent, 29.

Teeth.—95 returns; average, a little over 2 each, but 58 had no teeth, one "none for 20 years," one "lost teeth when young, but can eat a beefsteak as well as anyone." In 92 cases the teeth are specified. *Upper incisors,* 26; *canines,* 23; *molars,* 25. *Lower incisors,* 49; *canines,* 26; *molars,* 41.

Artificial Teeth.—96 returns; none, 85, but one of these "used them formerly;" of these, 47 had no teeth, and one had not had any for 20 years, and another lost her teeth when young, and many others had very few teeth; 11 used artificial teeth, and another did so formerly. Many years, 4; "from early life," 1; 10 years, 1; 30 years, 1; 45 years, 1; 50 years, 2.

Evidences of Failure.—83 returns; none, 43; heart, 4; heart and lungs, 1; heart and brain, 1; heart and urinary organs, 2; heart, lungs, and urinary organs, 1; lungs, 3; lungs and urinary organs, 2; brain, 15; urinary organs, 11; so that the heart was affected in 9 cases, the lungs in 7 cases, the brain in 16 cases, the urinary organs in 16 cases.

Micturition.—79 returns; natural, 63; slow, 6; frequent, 3; difficult, 2; incontinence, 1; slow and difficult, 1; slow, difficult, and painful, 1; difficult and painful, 1; difficult and frequent, 1. In one case the urine was pale, clear, 1010; no albumen, 1.

Heart Sounds returned as "normal" in 13 cases.

Present Maladies.—86 returns; none, 39.

Bronchitis.—6 cases; 3 slight. *Chronic Cough.*—1. *Weak Heart.*—1. *Syncope.*—1, slight. *Anasarca.*—1, few months. *Edema.*—3 cases, of legs, ankles, and feet respectively. *Valvular Disease.*—1, long-standing disease; carried up and down stairs for years; breath short. *Murmurs.*—4 cases, 2 "systolic," 1 "basic," 1 "basic systolic."

Debility.—13. *General Decay and Death.*—2 cases.

Rheumatism.—5. *Backache.*—1.

Abdominal Tumour.—1 case, dying semicomatose soon after.

Tumour of Right Hypochondrium.—1 case, for many years.

Diabetes.—1. *Bilious.*—1. *Constipation.*—1.

Neuralgia.—2 cases after herpes, 1 of arm after herpes a year ago, 1 for 9 months.

Gastralgia.—1. *Blepharitis.*—1. *Varix of Leg.*—1. *Ulcer of Leg,* 1, for 2 years.

Premors.—1. "Wanders."—1. "Eremitism and Illusions."—1. "Childish."—2. *Senile Dementia.*—1. *Imbecile.*—1. *Slight Paralysis.*—1. *Senile Paralysis.*—1, for 5 years. *Epileptic Convulsions.*—1. *Partial Left Hemiplegia.*—1. *Apoplexy and Left Hemiplegia,* 1.

No. VIII.

ANALYSIS OF RETURNS RELATING TO PAST HISTORY, INCLUDING FAMILY HISTORY.

(FEMALES, 90 to 100.)

Age when Married.—72 returns; average, 26 to 27 years of age, and 1 married again at 81 years of age.

Duration of Married Life.—61 returns; average, 42 to 43 years.

Number of Children.—83 returns; average, nearly 6 each, but 14 had no children, 1 of these having been married 3 times; in 1 case all labours (14) instrumental, killing most of children; 1 had 7 children, and of these 2 were twin daughters, both alive at 57 both had large families, and 1 had twin boys.

Affluent, Comfortable, Poor.—102 returns; A. 14, C. 50, P. 38.

First or—Child of Parents.—80 returns; average, fourth child; 20 were "first child," and of these at least 1 was an "only child." In 24 cases the number in the family was also given; of these the average position was third to fourth, and the average number in the family 7 to 8.

Delicate, Robust; Average.—95 returns; D. 10, R. 48, A. 37.

Health: Good, Moderate.—95 returns; G. 90, M. 5.

Often, Rarely Ailing.—12 returns; O. 10, R. 2.

Digestion.—99 returns; good, 94, indifferent, 5.

Bowels.—88 returns; good, 77; costive, 9; irregular, 2. One "took much aperient medicine till 70; another "all her life."
Baldness.—27 returns; early, 5, 1 "from eczema"; late, 22. One had much hair on chin.

Greyness.—71 returns; early, 18; late, 53.

Dyspepsia.—97 returns; placid, 26, irritable, 9; energetic, 41; irritable and energetic, 12; placid and energetic, 8; placid and lethargic, 1.

Intellect.—92 returns; high, 23; low, 3; average, 66.

Habits.—140 returns; active, 132; sedentary, 8.

Out-of-Door Exercise.—87 returns; little, 19, one a laundress till 92; moderate, 28, one a bad walker; great walkers, 2; much, 38, of these 2 were good walkers and 1 a great walker; 1 "walked barefoot all her life, and does so all the year round"; 1 a "noted tobacco smuggler, many hardships, slept in chair 50 years without undressing."

Hours in Bed.—60 returns; average about 8½ hours.

Hour of Rising.—74 returns; average, about 6.15 a.m.

Sleeper.—83 returns; good, 75; average, 11; bad, 3.

Appetite.—89 returns; good, 85; indifferent, 4.

Eater.—87 returns; large, 10; average, 56; small 21.

Alcohol.—92 returns; none, 22; very little, 1; little, 43; moderate, 24; rather free, 1; much, 1.

Animal Food.—82 returns; little, 38; moderate, 43; much, 1.

Illnesses Undergone.—93 returns; none, 42.

"Fever."—2 cases: one severe at 30, one "many years ago."

Scarlet Fever.—1 case, severe at 19. *Typhus Fever.*—2 cases at 27 and 42. *Typhoid Fever.*—1 case at 27. *Croup.*—1 case at 50.

English Cholera.—1 case at 80. *Small-pox.*—1 case. *Erysipelas.*—3 cases; one severe, one of head.

Chorea.—1 case twice, at 7 and 10. *Rheumatic Fever.*—6 cases; three at 18, 40, 40, two at 50, severe. *Rheumatism.*—3 cases; one at 82 for six months. *Gout.*—2 cases; one occasionally for 16 years.

Diarrhoea.—1 case. *Enteritis.*—2 cases; one at 76, one at 71, with complete recovery. *Hæmatemesis.*—1 at 78; no return.

Jaundice.—3 cases; one at 60, one severe at 40. *Congested Liver.*—1 at 88.

Poisoned Hand.—1 at 95. *Sloughing Ulcer of Foot.*—6 months ago, quite healed. *Inflammation in Side.*—1 case, twice. *Pelvic Abscess.*—1 case at 45. *Herpes.*—2 cases; one at 92, one of right side of head and neck at 95.

Bronchitis.—13 cases; three at 75, 78, and 96 respectively, one "several times," one "lately, severe, with recovery," one "3 times in 20 years," one "severe at 67," one "3 times, at 75, 76, and 89, with recovery from each in 3 months," one "severe at 95, with complete recovery."

Pneumonia.—5 cases; two at 60 and 78, one "double, severe, at 94, with recovery in 6 weeks." *Congestion of Lungs.*—1 at 93. *Spasmodic Asthma.*—1 case, severe from 50 to 70, circumstances then suddenly reduced her from affluence to penury, and the asthma then ceased.

Valvular Disease of Heart.—1 case, long standing, short breath, carried up and down stairs for years.

Paralysis.—2 cases; 1 at 60, complete recovery, one twice, at 85 and 90, with partial recovery. *Apoplexy.*—2 cases; in one 3 attacks, two at 83, the third at 90 with death.

Paraplegia.—1, two years ago. *Hemiplegia.*—3 cases; one right, at 89, recovered use of leg, not of arm; one had several attacks and recoveries, namely, left hemiplegia and convulsions at 78, with good recovery; paralysis of left hand at 82, severe apoplexy at 89; got about again, but mind weakened and with occasional epileptic attacks. One was "out of her mind" for a few days a short time ago, slept 14 hours, and awoke well.

Slight Ailments.—79 returns; none, 52.

Bronchitis.—3 cases. *Coughs.*—2 cases; one slight, one for 20 years. *Winter Cough.*—1 case.

Indigestion.—1 case, "all her life." *Gastralgia.*—1 case.

Bilious Attacks.—2 cases. *Bilious Headaches.*—2 cases; one

when young. Headaches.—6 cases; one of "sick headaches," one "severe every month," one "till 60 years old," one "severe till 50 years old."

Diarrhoea.—1 case occasionally. Gravel.—1 case, slight, lately. Eczema.—1 case, slight. Delicate.—2 cases; one when young. Neuralgia.—1 case. Rheumatism.—2 cases. Syncope.—2 cases; one occasionally. Conjunctivitis.—2 cases. Varix of Leg.—1 case. Prolapsus Uteri.—2 cases. Polypus Uteri.—1 case.

Irritability of several Mucous Membranes.—1 case, from 40 till death. Issue for 60 Years.—1 case, closed 3 years ago, with gain in weight after.

Frequently in Bed, and Bled because Full-blooded.—1 case. Accidents.—71 returns; none, 57.

Falls.—3; one "downstairs at 94, sedentary since," and two at 87 and 90 respectively.

Burn.—1 at 92, perfect healing. Contusion.—1 severe at 34. Fracture: Ribs.—1 at 84. Arm.—1, 6 years ago, rapid recovery. Thigh.—1 at 90. Coller's.—1 at 89, rapid union. Neck of Femur.—4 cases; one at 93, one died in 3 months, one "10 years ago," one "at 80, not united." Injury to Hip.—2 cases, one at 88 with lameness since, one 6 months before death.

Blood-Relationship between Parents or Grandparents.—41 returns; none, 38. Parents, distant relations, 1; cousins, 1; first cousins, 1.

Age of Father at Birth of Subject of Inquiry.—19 returns; average, 32½ years old.

Age of Mother at Birth of Subject of Inquiry.—19 returns; average, nearly 29 years old. Only those cases are included in which the ages of both father and mother are returned.

Diseases in Family (in relations and subject of inquiry).—Cancer (malignant growths).—15 families. Consumption.—16 families. Serofula.—1 family. Gout.—9 families. Apoplexy and Paralysis after 40.—16 families. Rheumatism.—18 families. Epilepsy.—2 families. Insanity.—8 families. None.—11 families.

Longevity.—Taking as a standard of a long-lived family one in which of the near relations (grandparents, parents, brothers, sisters, and subject of inquiry) ¼ attained the age of 70, or 3 the age of 80, we have at least 49 cases.

The Medical Men who were good enough to make the Returns, and the Number of Returns made by each, are as follows:

Table listing medical men and their return counts, categorized by letter (A, B, C, D, E, F, G, H, I, J, K, L, M, N, O, P, Q, R, S, T, V, W, X, Y, Z).

Table listing medical men and their return counts, categorized by letter (G, H, I, J, K, L, M, N, O, P, Q, R, S, T, V, W, X, Y, Z).

Table listing medical men and their return counts, categorized by letter (O, P, Q, R, S, T, V, W, X, Y, Z).

LECTURES ON SUPPURATION AND SEPTIC DISEASES.

Delivered at the Royal College of Surgeons, February, 1888.

BY W. WATSON CHEYNE, F.R.C.S.

Hunterian Professor; Surgeon to King's College Hospital, and to the Paddington Green Children's Hospital; Examiner in Surgery at the University of Edinburgh.

LECTURE III.

I MENTIONED in the last lecture that, as the result of differences in the seat of inoculation, and the anatomical arrangement of the part, there may be differences in the character of the disease produced. Virchow has long ago pointed out that the cause of a disease does not by any means determine the product of the disease, for that depends chiefly on the internal predisposition; thus the same agent acting on the cellular tissue may cause thickening of it, and, acting on the periosteum, may lead to ossification. This is probably in part the explanation of the different types of disease produced by these pyogenic organisms according as they act in the skin or in the connective tissue. I have previously mentioned the result of Boeckhardt's investigations on impetigo and boil, from which it is evident that the character of the inflammation depends greatly on the point of entrance, and the seat of development of the organisms, and Garré has also come to the same conclusion.—It seems that in the case of multiple abscesses of the skin in infants, the cocci spread into the hair follicles, and sebaceous and sweat glands, and, growing there, set up inflammation and abscess, the process being similar to that which occurs in the formation of boils in adults, but being clinically distinguished from that by the tendency to form true abscesses, and by the absence of necrosis. Escherich believes that these differences depend on differences in the degree of tension of the skin in adults and infants, and more especially in atrophic infants, in which these abscesses are especially apt to occur. It is possible however that, as Baumgarten points out, the greater softness and irritability of the tissues of the child, as compared with those of the adult, play an important part.

The different course which is run by acute osteomyelitis, when it occurs spontaneously, and when it follows operations on bones, is also probably due, in the main, to the seat of inoculation. In the latter case we never see the scattered patches of necrosis which so frequently occur in the former, and this may be explained by the fact that, in the latter, the infective agents spread continuously in the tissue from the point of inoculation, whereas, in the former, they are carried by the blood, and may be deposited at various parts, thus giving rise to various foci of disease.

Another example of the influence of the seat of inoculation is the difference in the behaviour of the peritoneum as compared with the cellular tissue in regard to the pyogenic organisms. In former times the peritoneal cavity was looked on as one especially liable to inflame, and it was thought to be one of the chief triumphs of antiseptic surgery that operations could be performed on the peritoneum without bad result. The experience of a number of surgeons has, however, now shown that it is not absolutely necessary for success in operations on the peritoneum that all bacteria should be excluded from the cavity; in fact, this seems to be much less necessary than where operations are performed on other serous cavities, such as joints, or on the subcutaneous or muscular tissues.

The explanation of this surprising result is found in the nature of the lining wall of the cavity, and in the conditions under which pyogenic organisms find themselves there. The peritoneum has marvellous powers of absorbing fluids, and thus effusions into it are very rapidly removed, and in this way micro-organisms are deprived of the necessary nutrient material, while they are also, in all probability, absorbed along with the fluid and destroyed in the blood, or excreted. Wegner, who performed a number of experiments on this subject some years ago, has shown, in a very striking manner, the great absorptive power of the peritoneum.

I may mention one of his experiments. Two hundred cubic centimetres of warm serum were injected into the peritoneal cavity of a rabbit. An hour later the animal was bled to death, and the amount of fluid then present in the peritoneal cavity was only 66 cubic centimetres, no less than 134 cubic centimetres having been absorbed in one hour. Apparently the rapidity of absorption of fluid depends, in the first place, to a great extent, on the tension under which the fluid is, fluid under low tension, as when the walls of the abdomen are lax or when the fluid itself is small in amount, being absorbed comparatively slowly; and, in the second place, on the nature of the fluid, fluid of lower specific gravity than blood serum, leading, in the first instance, to transudation from the blood. If we contrast the condition of a wound in the cellular or muscular tissues in respect of its absorptive power, we find that we have not here an actively absorbing surface; in fact, the whole surface is for a few hours in the early stage of inflammation as the result of the injury done by the knife, and is not only not an absorbing surface, but is not even a healthy surface.

Wegner has also shown that a great variety of fluids free from bacteria, such as water, bile, urine, blood, etc., may be injected into the peritoneal cavity of rabbits without causing any bad results, and even large quantities of unfiltered air may be similarly introduced without setting up peritonitis, the air being soon absorbed, though by no means so rapidly as fluids. If putrescible fluids are injected into the peritoneal cavity at the same time that air is introduced, they rapidly undergo decomposition; but this is only the case if the quantity of fluid is too great to be quickly absorbed. Thus 15 cubic centimetres of putrescible fluid injected into the peritoneal cavity of a rabbit will usually be absorbed before decomposition has had time to occur; but if as much as 50 cubic centimetres are employed, then only a part is taken up during the first hour, and the rest furnishes a substratum for the growth of the organisms present in the injected air, and these organisms develop with extraordinary rapidity, and may cause the death of the animal from septic intoxication.

In none of Wegner's experiments with the injection of putrefying or putrescible fluids and air did peritonitis occur, and Grawitz, who has since investigated the matter, has directed special attention to the conditions under which peritonitis is produced. Apparently the explanation why Wegner did not obtain peritonitis, but only septic intoxication, is that pyogenic organisms are not frequently present in the air, and were, therefore, not injected along with it, and also that they only act under certain special conditions.

As the result of Grawitz's experiments, the following seem to be the facts of the case; in the first place, saprophytic bacteria are absorbed or destroyed by the peritoneum in relatively enormous numbers; where, however, the peritoneum is abnormal, or where the quantity of fluid is too great to be rapidly absorbed, and where the bacteria are able to set up putrefaction, the symptoms of septic intoxication, as described by Wegner, result, but these symptoms are unaccompanied by suppurative peritonitis. In the second place, pyogenic organisms, when injected in small numbers into the normal peritoneal cavity, and when suspended in such an amount of indifferent fluid as can be readily absorbed, cause no peritonitis. On the other hand, peritonitis occurs as the result of the injection of these organisms if the peritoneum is abnormal; or if, with a normal peritoneum, large numbers of pyogenic cocci are introduced, or if the cocci are suspended in too large an amount of fluid to be quickly absorbed. The necessary abnormal conditions of the peritoneum may be set up if, at the same time that the pyogenic organisms are introduced, substances act which weaken or kill the tissue of the peritoneum, and thus provide a suitable soil for the penetration of the cocci; and above all, if there is a wound of the peritoneal wall in which the infective organisms can develop.

The factors, then, which are required to produce suppurative peritonitis are the presence of the pyogenic cocci—usually the streptococcus pyogenes—along with too large an amount of fluid to be rapidly absorbed, or along with disease of the peritoneum, or themselves in too large numbers, or acting in too great concentration. In other words, in order to develop peritonitis, the cocci must either be introduced in such numbers, along with their products, that a part of the peritoneum is at once injured, and thus ceases to exercise its normal functions; or they must be introduced into an unhealthy peritoneum, or they must be able to grow in the peritoneal cavity, either because fluid is present in too large a

quantity to be quickly absorbed, or because the absorptive power of the peritoneum has been diminished, or because some material, such as a piece of blood-clot or a piece of injured or dead tissue, is present, in which they can develop.

It is evident, therefore, that when authors draw conclusions to the effect that aseptic treatment is unnecessary in surgical practice, because they obtain good results in operations on the peritoneum when they take care to introduce as few of these organisms as possible (in many cases probably none at all are allowed to enter), to introduce them in as dilute a state as possible, to remove all the fluid and other materials, such as blood-clot, in which they can grow, and to avoid injury to the peritoneum as far as they can, they make an assumption which is not at all in accord with other clinical and experimental observations. The points which I have mentioned amply explain the results, and bring them into unison with those of experiments and of clinical experience with regard to other tissues of the body.

Indefinite Conditions on the part of the Body.—Further, we have conditions of a more indefinite character on the part of the body. Thus age, as we have seen, is an important factor in the production of acute osteo-myelitis. This is a disease of youth, and occurs most frequently between the ages of 7 and 20, and I have mentioned the different situations which are attacked in infants and in youths. Other diseases also vary in frequency at different ages; thus spontaneous erysipelas is apparently most frequent in persons between 35 and 45 years of age, and next most frequent between 45 and 55. Diphtheria most commonly occurs below 5 years of age, and steadily decreases in frequency as the age increases.

As regards sex also we find in some of these diseases a marked difference in the frequency of occurrence in the two sexes; thus spontaneous erysipelas is apparently much more frequent in women than in men. Eschbaum found, in 181 cases, that 122 of those attacked were females and only 59 were males. Osteo-myelitis, as we have seen, is most common in males.

It is possible that the state of the digestive organs may have an important influence on the occurrence of these suppurative diseases, as shown by Kocher's experiments and views on the production of acute osteo-myelitis. Kocher came to the conclusion, in the case of dogs, that after injury to bone this disease could be induced by feeding the animals with large quantities of putrid materials, and he thinks that in many cases of acute osteo-myelitis the starting-point is a disturbance of the digestive organs, permitting excessive multiplication of bacteria in the intestinal canal and their entrance into the blood. In fact, Kocher holds that an individual in whose intestinal canal fermentative changes of an intense character are going on is practically in the incubation stage of acute inflammation, which will develop if an injury or some other local depressing cause comes into play. In this way Kocher explains the occurrence of acute osteo-myelitis after typhoid fever, and he relates a case as bearing on this view, in which a girl, shortly after recovery from an attack of epidemic cholera, knelt for a long time in church, and was immediately attacked by acute osteo-myelitis of the tibia. Kraske, however, who has paid great attention to this matter in *post-mortem* examinations of cases of acute osteo-myelitis, and has carefully examined the wall of the intestine and the mesenteric glands, both microscopically and by cultivation, states that he has never been able to obtain any evidence that the infective material had entered the body by these channels. Whether Kocher's view is correct or not, the possibility that, during the progress of some wound or inflammatory disease, if the digestive organs are very much out of order, organisms may multiply to a great extent in the intestinal canal, and may enter the blood and thus reach the seat of the local disease or injury, is worth bearing in mind.

It is possible, also, that the nature of the diet may affect the occurrence of these diseases. It has been observed, for instance, in the case of symptomatic anthrax, that calves are more or less immune against this disease so long as they are fed on milk, but that, after this period has passed, and when their diet becomes exclusively vegetable, they lose their immunity. Arloing, Cornevin, and Thomas explain this by supposing that the milk diet induces a particular constitution of the body which is unfavourable to the development of this disease, but, on the other hand, this may be a mere coincidence, and the cause may be some peculiarity in the youthful connective tissue.

The state of the blood is also of importance; for example, the frequency of carbuncle and furuncle and of ulcerative and suppurative affections and their stubborn course in cases of diabetes

is well known. It is very probable that part of the explanation of this fact is the presence of the sugar or its chemical progenitors in the juices of the part, leading to the formation of a better pabulum for the development of the micro-organisms, though no doubt much depends on what we must more vaguely term the general depression of vitality of the tissues caused by the disease.—Dilution of the blood also apparently interferes to some extent, though only slightly, with the rapidity with which bacteria are killed in it. Thus Von Fodor found that if, at the same time that non-pathogenic bacteria were injected, a quantity of water was introduced into the blood, the bacteria did not disappear so quickly as in undiluted blood. Pettenkofer, in fact, has come to the conclusion that everything which increases the amount of water in the body increases the predisposition of the individual to infective diseases. There is no doubt, also, that other chronic affections, such as albuminuria, predispose to septic diseases.

Acute diseases, such as acute fevers, also predispose to these affections, as in the case of the occurrence of acute osteo-myelitis after acute fevers, of pneumonia after typhoid fever, etc., probably in part because, as in the case of scarlet fever, the pyogenic cocci are able to enter and live in the blood.

Tension apparently has a considerable influence in causing inflammation and in predisposing to suppuration. The spread of an abscess after it has once completely formed is, no doubt, largely due to the tension of its contents; for the microscopical examination of the wall shows that the increase is not due to the spread of the micro-organisms, and, further, if an abscess is opened aseptically and well drained, the secretion of pus ceases. The same is seen in the case of wounds, where, if micro-organisms are present, the occurrence of tension from accumulation of discharge is apt to be followed by suppuration, and where, on relief of the tension, the suppuration ceases.

In some cases, however, the predisposition is apparently lessened as the result of the action of various indeterminate causes, and apparently, also, this lessening of the predisposition may be due to a previous attack of the same disease, though, as regards the organisms under consideration, erysipelas seems to be the only case where a temporary and partial protection is attained in this way.

We now come to the consideration of the conditions which more especially affect the bacteria, and which are not, perhaps, of less importance than those to which we have been alluding; these are chiefly the species, the dose and concentration of the organisms, the virulence, and the concurrent growth with other bacteria.

Influence of Species.—As regards the species, while, as we have said before, the nature of a disease does not by any means altogether depend on the cause, it does so to a large extent; and all writers are now agreed as to differences in the pathogenic action of the pyogenic streptococci and staphylococci. These differences have been previously referred to, and it has been seen that the streptococci are generally associated with erysipelatoid processes, while the staphylococci tend to cause more circumscribed suppurations. The streptococcus is by far the most dangerous organism, and apparently has the property of creeping in the living tissue, spreading in it for a time without being noticed, and then setting up violent reaction. Fränkel has found streptococcus pyogenes in a great variety of puerperal diseases, especially in the so-called lymphangioitic forms. It gains entrance to the cellular tissue of the pelvis from ulcers in the vagina, spreads in the pelvic cellular tissue, reaches the ligamenta lata and the peritoneum, and, spreading along the lymphatic channels, ultimately attacks the diaphragm and pleura; finally it reaches the blood, and causes septicæmia, pyæmia, suppuration in joints, etc.

As regards the other pyogenic cocci, I have already referred to the differences in their effects on animals, some of them not being pathogenic in rabbits, and some, such as micrococcus pyogenes tenuis, being especially associated in man with mild inflammations.

Dose and Concentration of the Organisms.—Perhaps the most important factor with regard to micro-organisms is the dose or numbers, and the concentration in which they enter the body. Ogston has already laid stress on the dose as explaining the different diseases which result from the introduction of these organisms, and he looks on the difference between acute abscess and pyæmia as in the main a quantitative one. This, however, is only partially correct, as must now be evident.

Various authors have, from time to time, mentioned with regard to bacteria, that some act best, or only, when present in

large numbers, but the matter has not till recently been thoroughly worked out. I was led to investigate this matter in connection with some interesting experiments made by Sir Joseph Lister, which appeared to show that one or a few putrefactive bacteria could not set up putrefaction in blood taken with various antiseptic precautions, while that result was obtained if a mass of putrefying material was added to it. At first sight I did not think that it could matter much, except as regards the rapidity of the result, whether to begin with, one or a million bacteria were employed, but nevertheless I determined to put the matter to the proof, and to my surprise I found that difference in dose was a most important factor in the production and the type of many diseases. The experiments were made in such a manner that I was able to ascertain exactly the number of bacteria introduced, the material being in the first place diluted to such an extent that, on rough estimation with the microscope I obtained a general idea as to the number of bacteria present in a given quantity of the fluid; a certain amount of this fluid was then injected into the animals, and at the same time a measured quantity was thoroughly mixed with liquefied nutrient jelly which was then poured out on glass plates and allowed to solidify. By counting the number of colonies of bacteria which developed on these plates, each colony probably originating from a single bacterium, I ascertained exactly how many organisms were present in the amount of fluid injected.

Without going into further details, the following are the most important results that I obtained. In the case of Hauser's proteus vulgaris, I found that a definite and large dose of the cultivation in nutrient jelly was necessary to kill rabbits, and in comparing these doses, I took care that they were always injected into the same tissue, for example, the muscles, in accordance with the facts previously mentioned with regard to the importance of the seat of inoculation. I found that about $\frac{1}{10}$ cubic centimetre of an undiluted cultivation was a rapidly fatal dose when injected into the muscles, and I ascertained that this quantity contained about 225,000,000 of bacteria; $\frac{1}{20}$ cubic centimetre containing therefore about 56,000,000 bacteria, always caused an extensive abscess, of which the animals usually died in six to eight weeks. Doses of less than $\frac{1}{30}$ cubic centimetre produced no effect; in fact, doses of less than $\frac{1}{40}$ cubic centimetre, or, in other words, fewer than about 18,000,000 bacteria, seldom caused any result. From $\frac{1}{50}$ to $\frac{1}{60}$ cubic centimetre caused abscesses; above $\frac{1}{60}$ cubic centimetre caused death in twenty-four to thirty-six hours.—Further, the size of the abscess apparently depended on the initial dose. If $\frac{1}{50}$ cubic centimetre caused any effect at all, it was only a very slight trace of opacity which soon disappeared, while $\frac{1}{60}$ cubic centimetre caused a large and spreading abscess, ultimately resulting in the death of the animal, and intermediate doses produced abscesses intermediate in size.—Further, the concentration of the bacteric material is also of great importance, as shown by the fact that the dose must act at the same place, at the same time. It apparently will not do to split up the dose and inject various portions of it into different parts of the same animal at successive periods of time, or even at the same time. In both cases the effect of the smaller dose is produced.

I have tested this matter in the case of a number of other infective diseases, and have found that the result depended mainly on what we may, for want of better knowledge, term the predisposition of the animal to the disease. Thus in the case of mouse septicæmia, mice, which are extremely susceptible to this disease, die as the result of the injection of a single bacillus, while the only result of the injection of 4 cubic centimetres of a jelly cultivation, containing myriads of bacilli, into the base of the ear of rabbits, is to cause illness for a few days, along with slight swelling and redness of the part. In like manner, in the case of chicken cholera, rabbits die apparently as the result of the introduction of a single microbe, but a considerable number—some where between 150,000 and 300,000—are required to cause the death of a guinea-pig; and here again we meet with the fact that where the animal is less predisposed to the disease, we have different effects, according to differences in the dose. As I have said, 300,000 bacilli are apparently able to kill guinea-pigs; as the result of a smaller dose, down to 10,000 bacilli, suppuration follows their injection; below 10,000 bacilli apparently no effect is produced. In the case of staphylococcus pyogenes aureus, I have found that it was necessary to inject something like 1,000,000 cocci into the muscles of rabbits, in order to cause a rapidly fatal result, while 250,000,000 produced a small circumscribed abscess. The same result was obtained with staphylo-

coccus pyogenes albus, only apparently fewer cocci were required. In the case of the tetanus bacillus, death did not occur in rabbits when fewer than 1,000 bacilli were introduced.

I think that in these experiments a good deal depends on the simultaneous action of the products of the bacteria, and I would suggest the following explanation of the facts. When the animals are not very susceptible to the action of a bacterium, the cells and tissues soon gain the victory in the struggle for existence; but where a large number of bacteria are introduced at one place they grow for a time before they are attacked by the cells, and, growing there, each produces a small quantity of poisonous material. The products thus formed must interfere with the action of the cells, and thus enable the bacteria to gain a foothold. The more bacteria are introduced at one time the more of these products will be formed, the more extensive will be the foothold, and the more marked will be the result. Where only one or a few bacteria are introduced into a slightly susceptible animal, they are overpowered by the cells and quickly destroyed. When the number of bacteria is greater, these poisonous products destroy the tissues in their vicinity, and enable the bacteria to spread over a large area before the cells collecting around them are able to form an efficient barrier against their progress; and where the dose is very large no efficient barrier can be set up in time, and the death of the animal is the result. Thus the extent to which the organisms spread, and the violence of their action in animals not very susceptible to the disease, depend, first, on the number of bacteria and the quantity of products introduced in the first instance; and secondly, on the vitality of the animal and the rapidity with which a granulation wall is formed.

The facts made out in this research enabled me to lay down the following laws. In the first place, the pathogenic dose of a virus varies inversely with the predisposition of the animal to the disease in question; the greater the predisposition to the disease, the less is the quantity required, and conversely the less the predisposition the greater is the number of bacteria that must be introduced to produce the same effect. Of course the term "predisposition" is an absolutely indefinite one, but I have already discussed a number of conditions which go together to make up predisposition, and it is a convenient term, as expressing a complex set of conditions which undoubtedly exist, but about which we do not know very much.—A second law is that, in animals which are not very susceptible to a disease, the severity of the affection varies directly, within certain limits, with the amount of virus introduced. In all the affections of this class which I investigated, I found three stages, according to the dose injected: first, a stage where, with a small dose, no apparent effect was produced; secondly, an intermediate stage where a local affection resulted, the extent of the local affection depending to a great degree on the dose of the virus; and thirdly, a stage where, after a very large dose, death occurred. Of course, as predisposition varies in the same species of animal—for example, in man—we cannot measure out the dose nor calculate the effects of a given dose in each instance.

The importance of these facts as regards dose is very great in connection with our subject, for man is not very susceptible to the action of pyogenic organisms, and the results produced by them vary to a great degree in accordance with the second law. In the case of wounds, it is important to know that apparently in man a single pyogenic coccus might possibly do no harm, unless indeed it met with conditions, such as retention of fluid, under which it could grow. At the same time, I doubt if a single coccus ever enters a wound; as a rule they occur in masses containing many individuals, and then, of course, we have the effects of a large instead of a small dose. And there is no doubt that man is very much more susceptible to the action of these organisms than rabbits, and, therefore, a very much smaller dose will probably produce the same effect. These facts as regards dose probably explain to some extent the fairly good results obtained where, by imperfect attempts at antiseptic work, the introduction of gross particles of dirt, that is to say, of large numbers of bacteria, is avoided, and where, consequently, the effect of the injection of a small instead of a large dose of the virus is obtained.

The importance of dose has, as I have said before, been mentioned by various observers. Thus Ribbert, in his research on experimental myo- and endocarditis, already referred to, found that in order to obtain the desired result it was necessary to inject a considerable quantity of the cultivations. Thus a Pravaz syringe-ful of the emulsion killed the animals in from twenty to twenty-four hours; if the dose was somewhat less, the animals might live

even for five days; if only one-sixth of a syringe-ful was injected, the animals lived still longer, and endocarditis was not produced. —In the case of symptomatic anthrax, the relation of dose to the production of disease is extremely marked, a small dose either producing no effect at all, or only local reaction, which, however, may suffice to render the animal immune, while a larger dose causes the death of the animal.

Virulence.—It is also important to remember that organisms may vary in virulence at different times, and that the greater the virulence of the organisms the less are other conditions necessary to enable them to gain a foothold. A virus, or, at any rate, most viruses, is, as regards virulence, not a fixed quantity; it is, in fact, in a constant state of variation under the influence of the external conditions under which it finds itself. I need not refer to the well-known facts with regard to variations in virulence in the case of anthrax, chicken cholera, swine erysipelas, etc., as the result of the mode of cultivation employed outside the body; but I may mention some of the points which seem to bear especially on the pyogenic organisms. In many cases it is found that as the cultivations carried on outside the body become older, so the virulence of the organisms is apt to decrease. This is very well seen in the case of Fränkel's pneumonia coccus, which loses its virulence within two or three days, when grown in the same medium outside the body, and which, if its virulence is to be maintained, must be reinoculated frequently, and passed from time to time through the animal body. It can be readily seen, also, that staphylococcus pyogenes aureus grows most luxuriantly in the early cultivations from the body; but after it has been artificially cultivated for some time, its growth is by no means so rapid. Emmerich states with regard to cultivations of erysipelas cocci that they vary much in virulence, and that the longer the time between each fresh inoculation, the less is the virulence of the culture; in fact, the erysipelas cocci can be readily attenuated to such a degree that they can no longer kill mice.

It is important also to remember that where the virulence of an organism is diminished, its effects on animals vary in accordance with the second law; thus if a considerable number of attenuated anthrax bacilli are injected into rabbits the result will be, not a general fatal disease, but a local inflammatory affection, with possibly the production of abscess, varying in degree to a certain extent with the amount injected. In fact, the effect of the attenuated organisms on animals highly susceptible to the virulent virus is the same as if virulent organisms were injected into less susceptible animals, and consequently, in order to produce the same effect as the virulent organism, correspondingly large doses of the attenuated organisms are required. Thus Kitt and Hueppe have found that they could obtain the same result by injection of the organisms of an infective disease of deer into animals if, as the organisms lost their virulence, the number of microbes injected was increased. These facts are also important as showing how, even in a mild epidemic of a disease, where the virulence of the virus is not very great, bad cases may occur where extra large doses of the virus have been taken in, and this is probably in part the explanation of the occurrence of isolated severe cases in the course of a mild epidemic.

It is further important to remember that loss of virulence may not only be due to the ordinary conditions of growth, but may result from the action of various chemical substances. Thus carbolic acid and other antiseptics apparently diminish the virulence of anthrax bacilli, and it is possible that something of the same kind occurs with regard to the pyogenic cocci in wounds; and this may to some extent explain why, at the present day, although pyogenic cocci occasionally enter wounds treated aseptically, they sometimes do but little harm, less harm, in fact, than when they enter wounds in the treatment of which these antiseptics are not employed. It is quite possible that in growing in fluids containing a minute amount of an antiseptic, they are deprived, at any rate to some extent, of their virulence.

As regards increase of virulence, a very curious observation has been made in reference to the bacilli of symptomatic anthrax. It has been found that the addition of a minute quantity of lactic acid to a fluid containing these bacilli increases the virulence of a very attenuated virus within a very short time. Thus Arloing, Cornevin, and Thomas found that if to a fluid containing these bacilli $\frac{1}{100}$ part of lactic acid is added, and the mixture allowed to stand for twenty-four hours, the pathogenic power is increased twofold; if then a little water, containing a very easily fermentable sugar, is added to the mixture, and another twenty-four hours allowed to elapse, the virulence has attained its maximum,

and frogs inoculated with this virus die in from twelve to fifteen hours, whereas when inoculated with ordinary virus they live forty to fifty hours. Kitt has repeated and confirmed these experiments, and he mentions the following. A small quantity of the vaccine material—that is to say, the attenuated virus of symptomatic anthrax—was divided into two parts, of which one was mixed with water, and injected into two guinea-pigs, while the other was mixed with the same quantity of water, to which three drops of lactic acid had been added; this mixture, after standing for six hours, was injected into the other two guinea-pigs. The result was that the first two guinea-pigs remained well, the virus being very attenuated, while the last two guinea-pigs died of typical symptomatic anthrax within twenty-four hours. With regard to this point, it is worthy of note that the pyogenic cocci, when grown in milk, for example, produced lactic acid, but, so far as I am aware, there is no evidence that, under these circumstances, their virulence is altered. Something of this kind may, however, be the explanation of Ogston's results; he found that if pyogenic cocci were grown in eggs, their virulence was increased, and he attributed this result to the absence of oxygen. I tested this matter with regard to the possible alteration in virulence when grown in various gases without being able to make out any noticeable difference; but it may be that, in Ogston's experiments, some chemical substance was present in the egg, or was produced by the organisms when growing in that material, which led to the increase in virulence. The fact with regard to lactic acid does not apply to the coccus of pneumonia, which, according to A. Fränkel, loses its virulence most quickly when grown in milk, and, in his opinion, this is due to the presence of lactic acid produced by them. Whether or not this fact has any bearing on our subject, it is worth remembering as showing what slight and unexpected causes may alter the virulence, and thus cause a difference in the result of the action of these organisms.

Concurrent Growth with other Bacteria.—We have also to consider the effect of the concurrent growth with other bacteria, and we shall find that the result may be either to increase or diminish the pathogenic action; in man, in all probability, the pathogenic action of the pyogenic organisms is generally increased. When two organisms grow together in the same medium outside the body, they either do not interfere with each other, or, what perhaps most frequently happens, one of them gains the upper hand in the struggle for existence, and, if a number of bacteria gain access to a wound, a struggle for the mastery at once commences between the different kinds. In wounds, this struggle in most cases probably ends in favour of the pyogenic cocci, and as the result of the concurrent growth other factors come into play which still further aid their action. Thus, although the pyogenic cocci gain the upper hand, the putrefactive bacteria may aid their action very much, for the products of putrefaction, when absorbed, act in an extremely poisonous manner, depress the vitality of the patient, and may thus enable the cocci to live in the body; and locally these products injure the young granulation tissue of the wound, and may thus open up an entrance for the pyogenic organisms. I have already referred to the experiments made by Grawitz and Scheuerlen on cadaverine and putrescine, products of putrefaction, and it will be remembered that the experiments showed that these substances, when present along with the pyogenic cocci, enabled the latter to obtain a foothold in the body.—The bad effects resulting from the concurrent growth of different kinds of bacteria is also very evident in tubercular cases. If a sinus leading to carious bone, the wall of which is lined with tubercles containing tubercle bacilli, becomes the seat of development of these pyogenic cocci, the result may be—in fact, generally is—a more rapid growth of the tubercle bacilli; and it seems that it is just in these septic cases, especially where irritating injections are also employed, that the danger of further and general tubercular infection is greatest, the local depression of vitality produced by the septic organisms enabling the tubercle bacilli to grow more luxuriantly.

Then also in some instances it appears that a mixed infection is more dangerous than a pure infection. Thus, in some cases the presence of more than one kind of pyogenic organism apparently increases the severity of the suppurative process. Kraske, for example, has observed in acute osteo-myelitis that the cases were most severe when the infection was a mixed one, that is to say, when the disease was caused not only by the staphylococcus pyogenes aureus, but where in addition "albus," and in some cases the streptococcus pyogenes, were also present; and, as a result, of his observations, he thinks that the discovery of mixed infection

in acute osteo-mycelitis ought to lead to a bad prognosis. Probably, also, one reason why we so seldom at the present day see the extremely bad septic cases formerly described is that, even where the treatment is not thoroughly aseptic, such precautions are taken as to exclude not only gross masses of dirt—in other words, large numbers of the organisms—but also a great mixture of them. And this is possibly also in part the reason why, in my first work on this subject, I was led to think that bacilli were of more importance in wounds than micrococci, for I observed that the wounds in which both organisms were present did not pursue so favourable a course as where the cocci alone were found.

Apparently, however, in some cases the presence of two species of pathogenic organisms is better for the animal than if only one species were present; and, although the facts as yet made out have no direct bearing on the production of suppuration, yet, as they are of great interest, and as something similar may occur in the case of the pyogenic cocci, I shall mention some of the experiments. A number of observers have attempted to utilise the antagonism which exists between certain species of bacteria in cultivations outside the body as a means of cure when the body is attacked by organisms, but till quite recently these attempts have not been followed by success. Emmerich, however, has lately performed some very remarkable experiments on rabbits, showing the value of the erysipelas cocci as a protective and curative agent against anthrax in these animals. For example, in one set of experiments rabbits were first inoculated with large numbers of the cocci of erysipelas, and then two to fourteen days later anthrax bacilli were introduced. Of fifteen animals treated in this way, seven recovered, while all the control animals inoculated with anthrax alone died; of the seven animals which died after inoculation of both organisms, some succumbed to the anthrax bacillus and some to the erysipelas organisms. The results were not so successful when, after anthrax had been set up and after symptoms of disease had appeared, erysipelas cocci were injected subcutaneously; but they were somewhat better where the erysipelas cocci were injected into the blood stream.—In a later paper Emmerich and Mattei communicated results obtained by injecting erysipelas cocci into the circulation and subcutaneously in rabbits about twenty-four hours before infection with anthrax. They found that in rabbits in whose bodies large numbers of erysipelas cocci were present, anthrax bacilli, though injected in enormous numbers, were destroyed in from twelve to seventeen hours, and could not be found either at the seat of injection or in the blood and internal organs, whether by microscopical examination or by cultivation. The bacilli were evidently unable to penetrate into the blood or internal organs, nor could they cause any local reaction or œdema; in fact they very quickly died out.—Perhaps still more remarkable are the experiments performed by Pawlowski. He found that, after injection of a mixture of erysipelas cocci and anthrax bacilli under the skin of seven rabbits, only two died. Pawlowski has also made the important discovery that the erysipelas coccus is not the only organism which interferes with the growth of anthrax in the body. Thus, ten rabbits were first inoculated with anthrax bacilli and then cultivations of micrococcus prodigiosus were injected subcutaneously into each animal on two occasions two and twenty-four hours after infection; of these ten animals, eight recovered. He also found that subcutaneous injection of anthrax bacilli and cultivations of the pneumonia cocci were not fatal to rabbits, and that subcutaneous injection of cultivations of anthrax bacilli and staphylococcus pyogenes aureus was not followed by the death of the animal; four rabbits treated with "aureus" recovered.

As to the explanation of these facts, Emmerich and Pawlowski come to very much the same conclusion. Apparently, with the exception of the pneumonia coccus, anthrax bacilli grow readily outside the body in cultivations containing also the other organisms mentioned, such as the erysipelas coccus. Hence the explanation cannot be that the erysipelas cocci *per se* prevented the growth of the anthrax bacilli in the body. It seems to be rather that these cocci irritate the cells of the body, the phagocytes, and increase their destructive power; it may be, as Emmerich suggests, that this irritation leads to a slight alteration in their physiological functions, so that they excrete some chemical substance which is very injurious to the anthrax bacilli.

How far these facts may be applied to the treatment of anthrax pustules in man, where either from the situation or the size of the pustule excision or cauterisation is impracticable, is a question very difficult to answer, but it seems to me that we must await

the results of further investigations before any attempt to apply them practically in man would be justifiable. In any case, the facts are well worthy of note as affording another example of what unexpected factors may come into play if we once admit organisms to wounds.

Local and Seasonal Conditions.—Lastly, we have certain local and seasonal conditions which appear, in some way or other, to influence the occurrence of some of these diseases. For example, Eschbaum, who has gone into this matter very carefully, finds that spontaneous erysipelas occurs most often apparently in February, then next most frequently in November, and least frequently in July. Apparently the cold months, and those where there is most moisture and greatest variations in temperature, show the largest number of cases, and Eschbaum summarises the facts by saying that the cases are most numerous when we have marked variations of temperature, with a medium height of the barometer and a high degree of moisture. In the case of diphtheria also, cold and moisture seem to be a great predisposing cause, most cases occurring about the months of November and December. Kocher and Lücke have found that acute osteo-mycelitis also is most frequent in winter. Probably besides the seasonal conditions, the confinement in badly-ventilated rooms, foul air, and want of exercise which come into play more frequently in cold and wet weather than in summer, have an important influence on the result. In the case of diseases of animals, more especially in the case of anthrax, there is a very marked relation between the season and the outbreaks of the epidemic, the disease apparently occurring where there is great moisture and high temperature. As regards anthrax, Chauveau has shown that increased atmospheric pressure tends to cause a loss of virulence.

As an example of the influence of locality on these suppurative diseases, we have the greater frequency of acute osteo-mycelitis in certain parts; for example, this disease seems to be more frequent in Berne than anywhere else, and, according to Volkmann, it occurs next most frequently in Halle, and then in Marburg; these, however, are rather impressions than actual statistical facts.

SUMMARY.

We thus come to the end of our considerations with regard to the factors involved in the production of suppuration and septic diseases. It must be admitted that our knowledge still shows many blanks, but nevertheless, enough has been gained to enable us to judge what are the most essential factors which come into play. That the pyogenic organisms are essential for the production of these diseases as they occur naturally there can no longer be any doubt; but in many cases much depends on other conditions, of which the chief probably are the dose or number of the organisms and their concentration, general and local depression of vitality, and the seat of inoculation. If the organisms enter in large numbers, sufficient to overcome the resistance of the body, they alone may cause the disease; frequently, however, they enter in smaller numbers, and then other conditions become necessary to enable them to act. Of these conditions the chief are, as I have said, depressed vitality—either local or general—combined with the possibility of their remaining in the weakened tissue. This depression of vitality may be brought about by conditions acting on the body generally, such as acute fevers; or by local conditions, more especially those which induce the early stage of inflammation, such as cold, injury, chemical substances, the products of the bacteria themselves, or the products of other kinds of bacteria which may happen to be growing along with them. Or again, the favourable condition may be some peculiarity in the soil, as shown by variations in the character of the disease in accordance with the seat of inoculation and the anatomical arrangement of the part. The only factor, however, as I have said before, with which we can reckon with certainty, is the cocci themselves.—I need not enter into details as to the pathology of all the various suppurative and septic diseases, it will be easy for anyone to apply the facts which have been stated to each case; but in conclusion, I should like to make one or two remarks with regard to the mode of entrance of these organisms into wounds.

OCCURRENCE OUTSIDE THE BODY.

These organisms are fairly widely distributed outside the body. In the air they have only been found on a very few occasions, and in very small numbers. Staphylococcus pyogenes aureus has been found on one or two occasions in the air of surgical wards, as has also the streptococcus of erysipelas. Experiments have been made as to the presence of the latter organism in the air of

wards in which erysipelas patients were present, and they have in one or two instances been found in small numbers; as a rule, however, they are apparently present only when the patients are in a state of convalescence and when desquamation of the skin is occurring, and it seems highly probable, from the observations that have been made, that they are carried in the cutaneous scales thrown off during desquamation. Erysipelas cocci have also been found in a *post-mortem* room where cases of erysipelatos infection had occurred, and in this case the infection was supposed to have come from the floor. The pyogenic organisms are very rarely present in putrefying fluids, but they have been found on decomposing beef, and in the water employed in kitchens for rinsing dishes; they are also sometimes present in the superficial layers of the soil. One of their most common seats outside the body is the surface of the skin, and they especially occur in parts where the skin is moist, for example, in the axilla, between the nates, between the toes, etc.; they are also frequently present in connection with the hair, and in the dirt beneath the nails. Fränkel has found them in the secretions of the healthy pharynx, and Bockhardt found "aureus" and "albus" in large numbers in the nasal mucus of a patient suffering from chronic catarrh of the nose, and, at the same time, affected with syccosis of the upper lip.

MODE OF ENTRANCE INTO WOUNDS.

As regards the entrance of these organisms into wounds, they may get in during an operation from the air, from the instruments and hands of the operator or his assistants, from surrounding objects, or from the skin in the neighbourhood of the wound. We are now, however, sufficiently acquainted with the various precautions necessary to prevent the entrance of these organisms, and it is a comparatively easy matter to leave a wound made through a previously unbroken skin without any pyogenic organisms in it.

In the after-treatment of wounds there are two situations where the battle with these parasites may take place; it may either occur outside the wound, the organisms never being allowed to enter it, or it may take place inside the wound after their entrance has been permitted. It is hardly necessary to remark that in case of war we try, if possible, to carry the war into the enemy's country, at all events, we do all we can, by guarding the passes and borders, to prevent the enemy from entering our own country; and in like manner, in the case of wounds, it seems to me that it is much better to keep these pyogenic organisms out of the wound and to do battle with them outside the body, than to let them enter and trust to the efficacy of the tissues to repel their attacks. For once they have entered the wound, it is but little that we can do to aid the action of the body, and what little we do do has to be done with extreme caution, for not uncommonly our efforts, instead of being of service, do a great deal of harm. As I have said, it is comparatively easy now to keep these pyogenic organisms out of a wound while it is being made, and to leave the wound without any of these microbes in it; the problem is to prevent their entrance afterwards. In this case, however, we have at any rate succeeded in transferring the field of battle from the interior of the wound to the surface of the body, and we have no longer to trust to the imperfect and but little understood action of the tissues; we can step in with vigorous action without any fear of doing harm. For it cannot be too much insisted on that antiseptic dressings are not, in their essence, applications to wounds; they are applications to the discharge which has come from the wound and to the skin around it.

As to the mode of entrance of these pyogenic organisms after the operation, they may get in while the dressing is being changed, either by falling in from the air, though this must be of rare occurrence seeing that they are so rarely present in the air, or by contamination by the surgeon's hands, instruments, etc.; but this is also very easily avoided, and ought not to occur. Usually they spread in either through the dressing or beneath it during the interval between the change of dressings. In my opinion they most commonly spread in by growing in the discharge which is lying between the dressing and the skin, and in the superficial layers of the epidermis, more especially in the latter; for as the result of the irritation of the antiseptic employed there is hypertrophy of the epithelium, and thus a large number of dead epithelial cells are present, which, being soaked with the discharge, form a good nidus for the development of the bacteria, unless, indeed, enough of the antiseptic has been communicated to the discharge and the epithelium from the dressing to render it an unsuitable soil for the growth of organisms. If this is not the case, the organisms

will go on growing in the substance of this dead epithelium, protected by the superficial layers from the action of the dressing; and thus they may, if a dressing is left on for too long a time, ultimately reach the wound. This is not a mere theoretical speculation, for I have been able to trace the development of the organisms beneath the dressings, from their margin towards the wound, the extent to which they spread varying with the length of time that the dressing has been applied.

If these views as to the mode of entrance of bacteria into wounds are correct, it follows that it is very important when a dressing is changed to wash and thoroughly disinfect the skin around the wound as far as the dressing extended, and beyond it, with an antiseptic lotion, care being of course taken by covering up the wound not to infect it while so doing. If this is done, then at each change of dressing the field of battle is transferred from the neighbourhood of the wound to the margin of the dressing, and in accordance with the size of the dressing, this battlefield will be at a greater or less distance from the wound.

I shall not enter any further into the subject of the treatment of wounds. We have now at our command a large number of antiseptics which more or less answer the purposes required, and it is only by careful attention to the exclusion of these organisms that we can obtain the best results. That we can completely exclude these bacteria from wounds—both at the operation and afterwards—I have been able to ascertain by numerous experiments; and that, just in proportion as we are successful in so doing, we are to a like degree freed from the occurrence of suppuration and septic diseases, and can to a like degree reckon with confidence on rapid and painless healing of wounds with the least disturbance to the patient, is a matter now of everyday observation.

CASE OF CEREBRAL ABSCESS IN CONNECTION WITH OTITIS MEDIA, SUCCESSFULLY DIAGNOSED AND EVACUATED.

By DAVID FERRIER, M.D., F.R.S.,

Physician to the National Hospital for the Paralysed and Epileptic.

THE case which I have the honour to bring before you this evening is one of the few cases of cerebral abscess in connection with disease of the middle ear which have been accurately diagnosed during life, and successfully treated by operation. For though abscess of the brain is a very common occurrence, in connection with inflammation of the ear, and perhaps more frequently in chronic affections of this kind, it is generally the subject of post-mortem record, rarely accurately localised during life, and still more rarely treated successfully.

I have only been able to find two cases of a similar nature. One of these has been recorded by Gowers and Barker (*JOURNAL*, December 11th, 1886). This was a case of abscess in the right temporo-sphenoidal lobe, diagnosed without external indication, beyond the fact of inflammation of the ear, and successfully evacuated. The second has been recorded by Greenfield (*JOURNAL*, February 12th, 1887). This was a case of abscess situated in the anterior part of the left temporo-sphenoidal lobe, in which, in addition to the general indications of abscess, there were symptoms of pressure on the third nerve, a fact which prohibited the localisation of the seat of the abscess.

Two others have been referred to by Greenfield, namely, a case reported by Schondorff (*Monatsschrift für Ohrenheilkunde*, 1885, No. 2); and a second by Truckenbrod (translated in *Archives of Otolology*, June to September, 1886). In both these cases, however, there were, in addition to the general symptoms, external indications of the seat of the abscess in the form of localised pain and œdema of the skull; and a fistula leading from the primary seat of disease.

The fistula in Truckenbrod's case led only under the pericranium to a rough place on the outside of the bone, while in Schondorff's case it led directly into the brain, and indicated the way by which the pus had penetrated. These two cases therefore are to be placed in a different category from those of Gowers and Barker and Greenfield; but a successful result was obtained in all.

Of the successful result in the case I bring before you this evening you will all be able to convince yourselves, as the quondam patient is here, and apparently as well as he has ever been.

On the evening of December 8th, 1887, I was asked by Mr. T. W. Coffin to see with him a case under his care, the history of which he related to me, and subsequently gave me the following detailed notes.

T. H., aged 47, a skilled artisan, was first seen by Mr. Coffin on November 25th. He had been ill since November 10th. On the 15th a discharge, somewhat offensive, had come from the left ear, which continued for about eight or ten days. When first seen he

was in a drowsy condition, but was capable of being roused, and replying to questions put to him. He complained of pain over the left side of the head, forehead, and back of the eyes, with a considerable degree of photophobia. The pain on the left side of the head was interrupted by pressure and percussion. There was slight discharge from the left ear, but the ear could not be thoroughly examined on account of the tenderness. The pupils acted normally, and vision appeared unaffected. There was no motor or sensory paralysis. The pulse was 52, weak and intermittent; respirations 14, laboured and sighing. The temperature was normal.

Mr. Coffin ordered the ear to be syringed with weak Condy's fluid, and prescribed a stimulant.

Next day the patient was brighter. He had less pain in the head. He was able to sit up in bed and smoke a cigarette, but he continued very drowsy and slept much.

On the 27th, 28th, and 29th he was still improving. The temperature was normal, the pulse regular, and the tongue cleaner under the influence of a saline mixture and small doses of mercury. The discharge from the ear was more copious than it had been. There was very little tenderness on percussion of the left side of the head. The patient was generally asleep, but would rouse up for an hour or so, and occasionally smoke a cigarette.

On the 30th he was more drowsy, and apparently unwilling to be disturbed. At times it was very difficult to rouse him at all. He complained of more pain at the back of the eyes and general headache. His pulse was 60, respirations 16, and temperature absolutely normal.

On December 1st and 2nd the condition was essentially the same. There was no increase in the headache, but the drowsiness was greater.

Early on the 3rd he had become temporarily delirious, and had fallen back exhausted, but during the rest of this day and next there was no noteworthy change in the symptoms.

On the 5th, Mr. Coffin thought there was slight weakness in the right angle of the mouth, but so slight that it was considered somewhat doubtful by those who were acquainted with the usual expression of face.

On the 6th, for the first time there were indications of affection of speech. He used wrong words, and seemed angry at not being understood when he asked for what he wanted.

It was on the evening of the 8th that I saw the patient. He was at that time less drowsy and much clearer in his intellect than he had been for some time previously. He was able to sit up in bed, and talk, but his words were incoherent and for the most part unintelligible. He appeared to understand simple questions; but at other times appeared confused and unable to understand. He called things by wrong names. When asked to read a few sentences from a journal placed before him, the words he uttered had little or no resemblance to those before him.

There was no appreciable defect in the mobility or sensibility of his limbs, but the right angle of the mouth acted less energetically than the left. Examination of the eyes, carried out with some difficulty, revealed signs of optic neuritis, but a more thorough investigation of this and other conditions was reserved till the following day. From the facts, however, related to me by Mr. Coffin, and the patient's condition as seen by myself, I confirmed the opinion passed by Mr. Coffin that it was a case of abscess of the brain, in connection with disease of the middle ear, and I considered that the position of the abscess was fairly indicated by the symptoms.

The case seemed to me to be one which ought to be dealt with speedily, and I advised immediate removal to the hospital, with a view to further careful investigation and operative measures. The patient was removed the next morning to the National Hospital for the Paralysed and Epileptic, under my care. At this time he was conscious, and complained of no pain anywhere. He replied to questions, but frequently used wrong words without seeming to be aware of the fact. He occasionally hesitated to do what he was told, appearing as if he had some difficulty in understanding what was said to him. There was perceptible weakness of the right angle of the mouth, and though he could make every movement with his right hand, it was found that the grasp of the right hand was only 80 lbs., whereas that of the left was 100 lbs., the patient being a right-handed man. The tendon reactions were active on both sides, and there was no appreciable difference between those of the left and right. There was no affection of sensation. Ocular movements were normal, and the pupils equal and contractile. Ophthalmological examination

(verified by Mr. Brudenell Carter) showed the existence of well-marked optic neuritis, with a small hemorrhage over the right disc, and a whitish band below that of the left. The senses of taste and smell were normal. The patient could hear a watch 15 inches from the right ear, but only on contact on the left side. The left auditory meatus was filled with a purulent secretion, which prevented a view being obtained of the condition of the membrana tympani, and it was considered not advisable to attempt to remove this at the time.

Though the patient complained of no pain in his head, I found on careful examination that there was a spot tender to pressure and percussion situated two inches above and just anterior to a line drawn upwards from the external auditory meatus.

From the results of my examination on this and the previous day, I had no doubt that the patient was suffering from a cerebral abscess. The comparatively rapid onset of symptoms indicative of cerebral mischief in a man previously in good health, coincidently with signs of inflammation and purulent discharge from the left ear, were in favour of abscess rather than tumour. There had been no vomiting, convulsions, or febrile disturbance or other indications of meningeal inflammation.

The fact that there had been no rise of temperature did not exclude the idea of encephalitis resulting in abscess, for many cases of cerebral abscess appear to run their course without causing febrile disturbance, the temperature being in some rather subnormal than the reverse. The position of the abscess, verified by the operation, was determined both from the symptomatology and the position of the pain experienced on percussion. The relative weakness of the right angle of the mouth, the ataxic speech, and slight degree of word-deafness, indicated that the disease was situated in close proximity to the speech and auditory centres of the left hemisphere, but not actually destroying them; and the conditions of such a lesion would be supplied by an abscess situated in the anterior third of the temporo-sphenoidal lobe and abutting or pressing on the fissure of Sylvius.

This localisation from symptomatology I considered confirmed by the discovery of a spot, tender on pressure and percussion, coinciding in position with that part of the superior, or superior and middle, temporal convolution which lies immediately posterior to the ascending limb to the fissure of Sylvius, and below the inferior extremity of the ascending frontal convolution. I would not consider the position of the tender spot as by itself a safe guide to the localisation of abscess or other cerebral disease, for the pain may be referred to a region at a considerable distance from the disease. Thus Mr. Hulke (BRIT. MED. JOURNAL, July 3rd, 1886) records a case in which there was a tender spot above the ear, whereas the abscess was in the cerebellum; and in a second pain was felt acutely in the occiput, whilst the abscess was in the temporo-sphenoidal lobe.

But when, as I pointed out many years ago, there is pain on percussion not spontaneously complained of over a region indicated by the symptoms as probably the seat of disease, the localisation is rendered all the more certain. I was therefore confident that an abscess would be found in the position indicated, and was of opinion that no time should be lost in resorting to trephining with a view to its evacuation.

My colleague, Professor Victor Horsley, after consultation on the case, concurred in my views, and operated accordingly on the following day. I need only remark that when the dura mater was removed over the region indicated, the brain, which had a normal appearance on the surface, was seen to bulge forward into the opening in the skull, a sure indication of pressure underneath; and on puncturing with a trocar, a considerable quantity of inodorous pus—about five drachms—welled out through the cannula. The subsequent history is one of uninterrupted recovery. The optic neuritis gradually subsided. Already, on the fourth day after the operation, the optic discs were clearing, the margins were becoming defined, and the extravasation of the edge of the right disc had disappeared.

On December 23rd the left disc was apparently quite normal; the right was still a little veiled, but the effused blood was no longer visible.

On January 3rd no difference could be perceived in the action of the twosides of the face. At this time the wound had become quite cicatrised. The removal of the surgical dressings allowed of a more careful examination of the condition of the left ear than had been previously considered advisable. After examination of the ears on January 18th Mr. Cumberbatch reported that the discharge from the left ear had entirely ceased, and there was no abnormal

condition of the external auditory meatus. Hearing, right $\frac{1}{10}$, left $\frac{1}{20}$.

Process conduction was normal, indicating mischief confined to the middle ear. No perforation could be detected in the membrana tympani, but it was thickened, cuticular in appearance, and purely granular. There was a slight opacity—probably cicatricial—behind the handle of the malleus, and rather above the centre of the membrane.

Before leaving the hospital the patient gave me the following personal details of his case. He first complained of pain in the left ear on Tuesday, November 8th. For this he inserted some cotton wadding in the ear. Next day this appeared tinged with blood. For about five days a clear discharge occurred, soaking through the wadding, and staining the pillow on which he lay. At this time, also, he had some pain in his throat and chest, which, together with the condition of his ear, he attributed to chill. The discharge from the ear changed to a thick, gummy, slightly yellow flow. He then took to his bed, as he did not feel able to stand up.

From November 20th his memory became an entire blank. "The next thing I recollect," said he, "was you standing by my bedside."

CLINICAL MEMORANDA.

HEMOPHILIA.

M. A. P., a countrywoman, primipara, aged 30, was on January 26th last delivered by me of a male child. The labour was normal, but somewhat prolonged from feeble uterine action. The child was of average size and apparently healthy. On the fifth day the funis separated, leaving the umbilicus perfectly sound and healthy-looking. On the fourteenth day the nurse called my attention to a dark livid swelling which extended over the region of the left scapula, evidently extravasated blood. The child was jaundiced, but otherwise seemed happy and comfortable. Next day there came on a rather copious exudation of darkish blood from a crevice in the umbilicus, while the swelling on the back had increased and extended to the opposite side. I found a considerable difficulty in arresting the hemorrhage; but it ceased after about two hours' pressure and the use of styptics. I put a pad over the part, strapped it tightly, and bound it up, and had no reason to apprehend any further difficulty. However, in about an hour the bleeding returned. We kept up pressure for about seven hours with more or less success. We found tannin the best styptic, and this at length stopped it. Then a fresh symptom arose: there then appeared an oozing of blood from the month, but this almost stopped when the flow from the umbilicus returned, which it did subsequently in spite of all treatment. Finally the child was taken to the London Hospital, where, as I am told, similar treatment was pursued with similar unsatisfactory results, the child ultimately dying from loss of blood about six hours afterwards. There is no history of such a diathesis in the family of either parent, and the child received no injury at any time.

H. F. C. EAGLE, M.R.C.S., L.S.A.

Bethnal Green Road, E.

OBSTETRIC MEMORANDA.

TRANSVERSE RUPTURE OF UTERUS.

THE following are a few particulars of the first case of rupture of the womb which has occurred in my practice of forty years, with more than 4,000 labours.

E. H., aged 29 years, married, of short stature and phlegmatic temperament, was taken in labour on the night of October 19th, 1887, with her fifth child; her previous labours had all been protracted and her last child stillborn. I was called to her at 8 A.M. of the 20th, when the os was well dilated, the pains frequent and severe, but without the usual explosive character of the third stage. I had been with her five hours when the pains ceased, the patient crying suddenly with a new agony; there were the usual symptoms of "shock." I then sent to my friend, Mr. G. Fraser, who assisted in the delivery by forceps, which was effected at 4 P.M. Death ensued on the morning of the 25th. At the necropsy, performed by my son, John S. Prowse, twenty-four hours after a

very extensive transverse rupture was revealed at the anterior part, almost severing the neck from the body of the uterus; the parietes were abnormally thin.
Bleaden. WILLIAM PROWSE, M.R.C.S. etc.

REPORTS

HOSPITAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN, IRELAND, AND THE COLONIES

CHILDREN'S HOSPITAL, NOTTINGHAM.

LITHOLAPAXY & SUPRAPUBIC LITHOTOMY.

By LEWIS W. MARSHALL, M.D., Surgeon, Children's Hospital, Nottingham.

I HAVE adopted the heading which my friend Mr. Walsham used to his paper, which was published in the JOURNAL of October 15th, because the case which I am about to refer to was by his kindness done by him for my benefit on October 23rd. I therefore wish to add another success to those previously recorded by himself. Having a case under my care at the time of reading Mr. Walsham's paper which was eminently suitable for testing the value of the method of crushing and rapid removal of the stone, and wishing to contrast it with my own lithotomies, I appealed to him to give me that opportunity. The report of the case will speak for itself.

J. R., aged 6 years, was admitted with symptoms of stone, October 12th. Straining and pain in passing water were severe. The presence of a small stone was verified by me the following day by sound and palpation under chloroform.

October 23rd. The boy being well under chloroform, Mr. Walsham proceeded to crush. A sound was first passed, and the presence and size of the stone were made out. No. 9 evacuating catheter was inserted after slitting up the urethra, and about two ounces of weak boracic solution were injected. On removal of the catheter, No. 6 lithotrite (Weiss) was easily passed and the stone seized, showing a measurement of five-eighths of an inch. The second time the stone was caught three-quarters of an inch was read. Crushing was easy; the first time ten minutes were thus occupied. No. 5 lithotrite was introduced the second time. The evacuating catheter was used three times in all. The boy slept on being put to bed, and passed his water unconsciously shortly afterwards.

Two pieces were passed in the first twelve hours after the operation. There was no rise in temperature; no pain; and on the second day he sat up in bed to play with his toys.

On the third day he was riding a rocking horse in the ward.

October 28th. He left the hospital.

Since my appointment to the Children's Hospital I find that I have done about twenty lithotomies—nineteen lateral, one suprapubic. All the "lateral" cases recovered, but the "suprapubic" died on the fourth day from cellulitis. This case was done by Annandale's method, which reads so well, but is neither so easy to perform nor so free from complication as would at first appear. The stone being grasped by the lithotrite and pressed against the bladder wall, it was thrown out from the instrument when cutting into the bladder, with the result that the points of the lithotrite minus the stone protruded. The bladder dropping back into the pelvis, some difficulty was found in removing the calculus by dressing forceps. After this experience I am not disposed to adopt this method again. Mr. Annandale recommends his plan for use where the stone is small; in fact, in those cases which are so suitable for litholapaxy.

My success in the lateral operation is not of course exceptional—no death in nineteen cases—but it is too good to allow me to set the operation aside for a more novel procedure without due consideration. The case reported by me for Mr. Walsham does, however, afford a good reason for declaiming in favour of litholapaxy in the majority of cases, because I find on examining my calculi that there are at least thirteen that might very fairly have been dealt with in this way.

Speaking from memory, an average of three weeks for convalescence from lateral lithotomy may be given in my cases. When risk from hæmorrhage—pain suffered—risk from possible incontinence of urine for some years, and the asserted danger of emascu-

lation are placed in the scale with the relatively long confinement to bed, it seems to be a clear duty to practise the more simple plan of litholapaxy.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

ANNUAL MEETING

THE annual meeting was held on the evening of March 1st, the retiring President, Mr. GEORGE DAVID POLLOCK, F.R.C.S., President, in the Chair.

Annual Report.—The annual report announced the continued prosperity of the Society, and a further increase in the number of Fellows. This now stands at the highest point yet reached since the foundation of the Society. Thirty-three new Fellows have been elected. Of these, nineteen are resident, eight non-resident, three English honorary Fellows, and three foreign honorary Fellows. The Society has lost fifteen Fellows by death. Of these, nine were resident, including Sir George Burrows, a former President of the Society, Dr. Wilson Fox, the late honorary librarian, and Mr. Quain; five non-resident, and one foreign honorary Fellow, Professor Von Langenbeck. The number of papers read, and the attendance of Fellows and visitors during the past seven years, are given in the following table:

Year.	No. of Meetings.	Papers.		Present.		Joined in Discussion
		Medical.	Surgical.	Fellows.	Visitors.	
1881	15	5	21	540	70	94
1882	15	12	14	517	117	102
1883	15	14	17	607	119	113
1884	15	18	13	632	118	145
1885	17	10	18	759	201	171
1886	16	15	18	558	111	169
1887	16	10	18	559	88	173

The report of the honorary librarians states that the additions to the library during the year 1887 consist of 460 works, including pamphlets, but not including transactions, journals, and other periodical publications; 165 of these additions have been obtained by purchase, and 295 by donation. The latter include 53 volumes presented by Dr. Wickham Legg. The total number of works in the library, December, 1887, was 30,742. During the past year 3,694 books have been borrowed from the library. The number of visits of Fellows has been 4,574. The collection of portraits of members of the medical profession has been enriched by the addition of sixteen new ones, and two oil paintings have been presented to the Society by Dr. R. J. Lee.

The PRESIDENT then delivered the annual address, dwelling specially, in his obituary notices, on the life and works of Dr. Wilson Fox, Mr. Richard Quain, Dr. Arthur Farre, and Sir George Burrows. Mr. Edmund Owen, seconded by Dr. Day, proposed a vote of thanks for the address; Mr. Butlin, seconded by Mr. Parker, for the services of the President, which was carried by acclamation; Dr. Sansom proposed a vote of thanks to Mr. Holmes, who is retiring from the office of Treasurer; Dr. Buzzard, seconded by Dr. S. Coupland and supported by the President, proposed a vote of thanks to the retiring Vice-Presidents and other officers; Mr. T. Holmes, seconded by Dr. Myers, to Mr. Howard Marsh, the retiring Secretary, who, in reply, spoke warmly of the services of the Resident Librarian.

The list of officers for the current year is as follows:—*President*: *Sir Edward Henry Sieveking, M.D. *Vice-Presidents*: *Sir Andrew Clark, Bart., M.D., F.R.S.; *James Andrew, M.D.; *Sir Henry Thompson; Thomas Smith. *Treasurers*: Charles John Hare, M.D.; *John Ashton Bostock, C.B. *Secretaries*: Walter Butler Cheadle, M.D.; *J. Warrington Haward. *Librarians*: *Samuel Jones Gee, M.D.; John Whittaker Hulke, F.R.S. *Other Members of Council*: *William Cayley, M.D.; *Sir Joseph Fayrer, K.C.S.I., M.D., F.R.S.; *Thomas Lauder Brunton, M.D., F.R.S.; Richard Douglas Powell, M.D.; Arthur Ernest Sansom, M.D.; *Robert William Parker; *William Johnson Walsham; Henry Trontham Butlin; *Edward Morris; *Edward Tegart. Those gentlemen to whose names an asterisk is prefixed were not on the Council or did not fill the same office last year.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, MARCH 6TH, 1888.

Sir JAMES PAGET, Bart., F.R.S., F.R.C.S., President, in the Chair.

Epithelioma of Kidney associated with Calculus.—Mr. SHATTOCK showed for Sir WILLIAM MAC CORMAC a specimen of epithelioma of the kidney associated with pelvic calculus. There was a history of long-standing calculous pyelitis. It seemed probable that the cancer was produced by the chronic irritation of the calculus. The specimen had a bearing on the contention of Mr. HURRY FENWICK, who at the last meeting had advanced the theory that cancer of the bladder might be produced by chronic irritation produced by a calculus. Dr. SÄNGER had recently communicated to the Berlin Medical Society the negative results of bacteriological investigations of cancerous growths. Mr. Shattock pointed out that this confirmed the results reached by himself and Mr. Ballance, and led him to believe that Scheuerlen's bacillus was not the pathogenic organism of cancer. It was, however, not possible to prove a negative, as Dr. SÄNGER had supposed; for in actinomycosis, though the parasite was so large, nobody had succeeded in cultivating it.—Mr. WALSHAM mentioned a specimen in which the whole cortex of the kidney, where a pelvic calculus had long existed, was converted into epitheliomatous tissue. The clinical history rendered it probable that in this case the calculus was the primary disease. In another specimen of calculous pyelitis, also in the Museum of St. Bartholomew's Hospital, the kidney was carcinomatous.—Dr. NORMAN MOORE had shown a case of pelvic calculus and renal cancer. He referred to the association between gall stones and cancer of the gall bladder.—Dr. WILKS had always regarded the calculus as the primary disease, from the clinical history of cases of pelvic calculus followed by cancer, and of gall stones followed by cancer. Professor Frerichs had expressed a similar opinion to him on one occasion when going over the museum of Guy's Hospital, and had stated that the association of pelvic calculus and renal cancer was familiar to him.

Villous Carcinoma of the Right Breast.—A specimen of this disease, removed from an unmarried lady, aged 53, was exhibited by Mr. BERNARD PITTS. The patient had been conscious of its existence for three months. The axillary glands were not enlarged, and the skin was not adherent. It was removed, and was found to be an oval mass, surrounded by an imperfect capsule, from which branching processes, thickly invested with actively growing epithelium, extended. He referred to three similar tumours in the Society's *Transactions*. They all had a more or less perfect capsule, and a foliaceous included growth.—Dr. WILKS asked how the tumours had been described by early writers; it appeared to be what would have been called a cystic sarcoma. The clinical history did not seem to be that of carcinoma.—Mr. A. A. BOWLBY thought that it was the kind of growth described by Cornil and Ranvier under the term villous carcinoma. The clinical history was not well known. It had perhaps been included under the name melanotic sarcoma, as in the three cases he had seen the villous growth was dark-coloured, and the fluid blood-stained. In none were the glands enlarged, and it seemed possible that the tumours ran a more benign course than scirrhous carcinoma.

Contact Carcinoma of the Bladder.—Mr. HURRY FENWICK brought forward statistics of 60 cases from various museums as regards the varying conditions which might be encountered by the surgeon in dealing with such growths. The male was affected thrice as often as the female, a proportion which was found to hold good in a series of 634 cases, embracing all varieties of vesical growth; 60 per cent. of the specimens were single and 40 per cent. multiple; of the single, 43 per cent. were at the right ureteral orifice and 26 per cent. at the left; 86 per cent. of the single growths were at the inferior zone, originating at the margin of the trigone, pedunculated, or tending to become so, in the proportion of 2 to 1. In 80 per cent. of the multiple growths there were 3 to 22 in the same bladder. They were rare in diverticula. Specimens were brought forward proving that carcinoma might coexist with benign growth (10 per cent.), and that vesical carcinoma might propagate itself by contact.—The PRESIDENT said that the cases of communication of cancer by contact were so few that they might be accidental coincidences; moreover, if we assumed that there was a tendency to the symmetrical occurrence of disease, it was easy to understand their occurrence on corresponding parts of the same viscus. Cancer of the side of the tongue and cancer of the contiguous part of the lining membrane of the cheek had never been recorded, although these two surfaces were continually in contact, and the former

malady was common; nor had anyone seen cancer of the lower lip with cancer of the upper lip, nor of cancer of the lower lid with cancer of the upper lid, except where there had been extension round the corner of the mouth or round the canthus.—Dr. GOODHART had seen many instances where the circumstances suggested transmission by contact. He had seen it in the stomach. He also referred to cases where cancer appeared to be conveyed by particles dropping down from the upper part of the abdomen into the pelvis.—The PRESIDENT thought that a distinction ought to be drawn between cancer transmitted by contact and cancer produced by transmission of elements.—Dr. GOODHART, continuing, said that the distinction drawn by Sir James Paget would materially limit the number of instances which he could cite. He thought, however, that the apparent spread of warts by contact might be quoted in this connection, and referred to certain specimens illustrating the dissemination of warts in the lower animals preserved in the Museum of the Royal College of Surgeons. While admitting the comparative rarity of cases in which cancer appeared to be transmitted by contact, he thought the instances which were occasionally observed were strikingly confirmatory of the theory.—Mr. BRUCE CLARKE thought that in a certain number of cases of vesical cancer the theory of transmission by contact afforded a better explanation of the appearances than any other. The exceptional frequency with which such an occurrence appeared to take place in the bladder might be accounted for by the force with which the walls of the bladder were squeezed together.—Mr. BOWLBY mentioned the case of a woman with epithelioma of the left labium. While under observation, the right labium became affected.—Mr. WALSHAM, who had operated on this case, had seen another precisely similar.—Dr. COUPLAND thought that it was not uncommon to observe carcinoma communicated between the peritoneal coats of adjacent coils of intestine.—Mr. BERNARD PITTS mentioned a case of pedunculated tumour of the bladder in which a growth recurred eighteen months after the pedunculated tumour had been removed. The recurrent tumour was malignant, whereas the pedunculated growth appeared to be innocent.—Mr. SHATTOCK said that it had to be shown that dissemination was not in a radial manner from the primary tumour; on the other hand, he mentioned a case in which Sir William Mac Cormac had excised half the larynx, which was affected by extensive cancerous disease; on the vocal cord on the opposite side was a small discrete growth which had exactly the same microscopic structure as the ulcerating carcinoma of the other side of the larynx; this case seemed almost to prove that transmission by contact could occur.—Mr. FENWICK, in reply, said that seven cases of simultaneous affection of the tongue and the side of the cheek had been recorded, and mentioned several cases in which the opposing walls of the vagina had been affected by the same growth.

Renal Disease.—Dr. NORMAN MOORE exhibited the following specimens of renal disease: (1) Congenital narrowing of both ureters, with dilatation of the kidneys and perinephritic inflammation, due to injury. The patient was a man aged 20, under his care in St. Bartholomew's Hospital. He had received a severe kick in his left inguinal region, and six weeks after noticed a large tumour in the left hypochondrium. This tumour projected close to the left lobe of the liver, and on aspiration three pints of blood-stained urine were drawn off. A fortnight later, the patient one night passed a greatly increased quantity of urine, and the tumour became much smaller, but soon regained its former size, and was tapped three times, about three pints being let out on each occasion. Mr. Walsham then tied a drainage-tube into an opening made by him in the left loin. A few days later suppression of urine took place, and the patient sank. *Post mortem* the cyst, which had been tapped, occupied the whole left side of the abdomen, was adherent to the diaphragm, and most parts of its wall showed very great thickening of the perinephritic tissue. It contained no pus, but about four pints of urine slightly blood-stained. The right kidney was also cystic: the urethra and bladder were natural. Both ureters became narrow just before entering the pelvis of the kidney, and the opening was valvular. There was no hypertrophy of the heart. Microscopic sections of both kidneys showed parenchymatous inflammation, without connective tissue increase, or increase of thickness of arterioles. The dilatation was probably gradual, and due to congenital smallness of the orifice of the ureter. The enormous thickening of the capsule of the right kidney was no doubt due to inflammation caused by the kick on the abdomen. (2) Kidneys, with microscopic sections showing advanced chronic interstitial nephritis, from a man aged 39, who was under Dr.

Moore's case in St. Bartholomew's Hospital. The left ventricle was hypertrophied, the heart weighing 20 ounces. In the right kidney were three rounded calculi. Twenty-three years before his death the patient had retention of urine for three days, relieved by the removal of a calculus from his urethra in St. Bartholomew's Hospital. His health was afterwards weak, and twelve years later he was treated at the Royal Free Hospital for dropsy, due to chronic interstitial nephritis. Eight years later he was treated for the same disease at St. Bartholomew's, and was there under observation for the remaining three years of his life. It was thus certain that he had had interstitial nephritis for eleven years, and probably for twenty-three years, as it seemed in all probability due to the prolonged retention by the calculus in the urethra. Oppolzer records one case of the same duration. —Mr. LENN mentioned the case of a man aged 27, who, when 10 years old, attended University College Hospital for hæmaturia; after death one ureter was found to be blocked, and there was hypertrophy of the heart. —Dr. NORMAN MOORE said that hypertrophy of the heart had never in his experience occurred when one kidney only was damaged.

Acute Necrosis.—Mr. A. Q. SILCOCK showed bones removed from a case of osteo-myelitis; the patient was also present. The disease had apparently started in isolated inflammatory foci situated at the line of junction of the epiphysal cartilages with the diaphyses of the tibia, and terminating in acute necrosis. The patient was a girl, aged 11. Tenderness at the head of the left tibia and tumefaction of the soft part were first noticed; no pus was found on incision, but some appeared on the following day. A few days afterwards pain and tenderness were observed over the right tibia; in both cases a small quantity of pus was evacuated by free incision of the periosteum in the neighbourhood of the epiphysal line. Next the inner malleolus on the right side was affected; here it was subsequently ascertained a small focal abscess, just above the epiphysal line, existed; then the inner malleolus on the left side became affected. Both knee-joints became full of fluid; the right knee-joint had to be laid open, and eventually the right thigh was amputated. Subsequently the whole of the diaphysis of the left tibia was removed piece by piece, but the amount of new bone thrown out, as was anticipated, looking to the severe damage which must have been done to the osteogenetic layer of the periosteum by inflammation so acute, intense, and widespread, was very small. The patient ultimately made a fairly good recovery so far as her general health was concerned. A longitudinal section of the right tibia showed that the inflammatory process was focussed at the upper and lower ends of the diaphysis in the regions which French authors had called juxta-epiphysal, or as Mr. Silcock proposed to term it, para-epiphysal. The symmetry of the bony lesions implied a morbid condition of the blood; a deterioration of quality associated perhaps with a micrococci accompanied by a lowered vitality of the patient. The para-epiphysal regions in long bones, and the sutural edges of the flat bones of the face and skull were peculiarly liable to become affected, probably because the physiological balance was here easily upset by injury or exposure, circulation being slow, and the vitality of the cells of the part easily exhausted. —Mr. SHATTOCK suggested that the disease was due to some accidental circumstance lighting into activity latent pathogenic organisms in the medulla of the bones.

Osteitis Deformans.—Mr. CLITTON described a case which he considered to be an example of osteitis deformans in a woman. At the age of 50, a slight prominence was noticed at the lower end of the right ulna; the right radius, the left humerus, and finally the lower limbs became bent and her head became larger. She had been reduced in height from 5 feet 1 inch to 4 feet 6 inches; the spine was also curved, as well as the femora and tibia.

Card Specimens.—Mr. SHATTOCK: 1. Osseous Ankylosis after Gouty Disease. 2. Gouty Deposit in Bone. —Mr. TRÉVES: 1. Fibro-cellular Tumour of Spermatic Cord. 2. Horny Tumour of Mouse developed from a Dermoid Cyst. —Mr. MANSFELD MOUTLINS: Syphilitic Crania. —Mr. W. S. COLMAN: Diphtheria of Pharynx and Larynx with Acute Inflammation of Peyer's Patches. —Mr. HURPSON: Tubercular Ulceration of Intestine associated with the presence of foreign bodies.

Living Specimens.—Mr. CLITTON: Long-standing New Growth of Skin probably Sarcoma.

A CORRECTION.—In a review of the *Year Book of Treatment for 1888*, published on page 473 in the *JOURNAL* for March 3rd, the name of the author was incorrectly given as Mr. Arthur Cooper. It ought to have been given as Mr. Alfred Cooper.

MEDICAL SOCIETY OF LONDON.

ANNUAL MEETING.

MONDAY, MARCH 5TH, 1888.

J. HUGHLINGS JACKSON, M.D., F.R.S., President, in the Chair.

Election of Officers.—The list of officers and council prepared by the Council for election was unanimously adopted. *President:* Sir William MacCormac, F.R.C.S. *Vice-Presidents:* Thomas Henry Green, M.D.; John Knowsley Thornton, M.D., F.R.C.S.; William Richard Gowers, M.D., F.R.S.; Edmund Owen, M.B., F.R.C.S. *Treasurer:* Arthur Edward Durham. *Librarian:* William Henry Alchin, M.B. *Honorary Secretaries:* Bernard Pitts, F.R.C.S.; Charles Edward Beevor, M.D. *Secretary for Foreign Correspondence:* Felix Semon, M.D. *Council:* Thomas Lauder Brunton, M.D., F.R.S.; J. N. C. Davies-Colley; Clinton Thomas Dent; John Henry Drew; Sir Joseph Fayrer, M.D., F.R.S.; David W. Finlay, M.D.; Francis Fox; William Adams Frost; Walter Baugh Hadden, M.D.; Reginald Harrison; J. Hughlings Jackson, M.D., F.R.S.; Thomas John MacLagan, M.D.; Robert Percy Middlemist; Angel Money, M.D.; Charles D. F. Phillips, M.D.; A. J. MacConnell Routh, M.D.; Seymour Taylor, M.D.; Samuel West, M.D.; John Williams, M.D.; T. Outterson Wood.

Fothergillian Prize.—It was announced that the Fothergillian prize had been awarded to Dr. Haro, of Philadelphia.

Cerebral Abscess in Connection with Otitis Media.—Dr. FERRIER, and Mr. VICTOR HORSLEY read the notes of a case, which is published at page 530. —Dr. HUGHLINGS JACKSON said the result obtained was simply magnificent. —Sir WM. DALBY expressed the satisfaction he felt at the progress which had been effected in the treatment of what were formerly considered to be hopeless cases. He quoted from a previous paper of his own to the effect that an experience of ten years had given a mortality in cases of antral disease of 8 per cent, not all, however, from cerebral abscess. He classified these cases according as the patients developed cerebral symptoms and died, or only showed symptoms after many years. He further subdivided the cases with respect to the presence or absence of diseased bone. The proportion of cases of cerebral abscess was much greater where dead bone was diagnosed. He thought patients ought to be warned to look out for the occurrence of certain threatening symptoms, so that intervention might be in time. —Dr. BRISTOWE called attention to the absence of pyrexia, and observed that this was often the case in cerebral abscess, but that fever was generally present in inflammation of the lateral sinus. He mentioned three cases of patients with old ear disease who had attacks of high temperature and rigors. Nothing was done, but in each case there was no abscess, but inflammation of the lateral sinus. —Mr. JAMES BLACK mentioned several cases of a similar kind. —Dr. KINGSTON FLOWER observed that in several cases at Middlesex Hospital the site of pain had not proved a reliable guide to the seat of the abscess. It was remarkable that no inflammation was found along the line of injury in cases where unsuccessful punctures had been made, and he inferred that exploratory operations were by no means necessarily dangerous. —Dr. FERRIER, in reply, said that the risks of trephining were so small when properly carried out that he would not hesitate to resort to it, even if the diagnosis were not absolutely sure. —Mr. VICTOR HORSLEY, in reply, said he would like to ask whether optic neuritis was to be considered a reliable symptom of threatened abscess? He mentioned a case in which symptoms were present, pointing to cerebellar disease, but in which the disease proved to be in the lateral sinus. He suggested, therefore, that should puncture of the cerebellum prove futile, the lateral sinus should be examined.

On Some Curious Relations of Gastric Ulcer.—Dr. ORD read the notes of the case of an unmarried woman, who was admitted into St. Thomas's Hospital in December, 1887, with symptoms of gastric ulcer and extreme anæmia. After her admission, certain heart symptoms which were noticed on her admission underwent further development. Dr. Ord gave the grounds of his diagnosis of peri- and endocarditis. There was no pyrexia, nor any history of rheumatic fever. The coexistence of symptoms of gastric ulcer with those of peri- and endocarditis had already been noted by Dr. Ord in three cases, and a remark by Dr. Buzzard elsewhere, to the effect that acute rheumatism might be the result of irritation

of the medulla, had deeply impressed him. When, therefore, the coincidence of the signs of gastric ulcer with those of cardiac inflammation had been observed in at least four cases, the occurrence appeared to be worthy of serious thought. Several explanations were forthcoming: 1. Was it possible that in an anæmic person with oversensitive pneumogastric centres, that gastric irritation, well known to be capable of producing cardiac disturbance, could be capable of producing cardiac lesion? 2. Could pneumogastric irritation be the common cause of gastric ulcer and cardiac inflammation, the pneumogastric irritation being determined by excitation proceeding from the uterine organs, in a person already anæmic and prone to active reflex disturbance? 3. Was it possible that both sets of symptoms might be disorders of nutrition arising out of anæmia? Anæmia was known to have as an association optic neuritis; might both the ulcer and the cardiac inflammation be disturbances of nutrition similar to optic neuritis? Dr. Ord quoted a case at present under his care, in which the signs of gastric ulcer, of cardiac inflammation; and of optic neuritis were present in conjunction with extreme anæmia. He also quoted a case recently under his care, in which myocarditis had been observed *post mortem* as one of the associations of pernicious anæmia. On the whole, Dr. Ord was inclined to regard the curious combinations of lesions noticed as disturbances of nutrition consequent on anæmia, and appealed to the Fellows for information on this point.—Dr. MACLAGAN quoted the case of a woman who had a violent attack of hæmatemesis after a dispute, and this was followed by symptoms of endocarditis. In reference to one of the cases alluded to by Dr. Ord, he pointed out that there had been no attack of hæmatemesis prior to the first sign of heart mischief. He suggested that they had yet much to learn on the effect of nervous influence on the venous circulation. He preferred the hypothesis of their being of central origin.—Dr. SIDNEY COUPLAND expressed a doubt of the possibility of making a certain diagnosis of heart mischief in anæmia, and quoted a case in which the error was demonstrated at the necropsy.—Dr. KINGSTON FOWLER alluded to the great difficulty of diagnosing gastric ulcer, and quoted several cases where the *post-mortem* examination had shown the diagnosis to be wrong, even where the symptoms had pointed clearly to ulcer. He doubted also the reliability of the diagnosis of heart disease in anæmia.—Dr. ORD, in reply, acknowledged the difficulties of diagnosis, and discussed the objections thereto. He requested Fellows merely to keep the possible relationship before their eyes.

On a Case Illustrative of the Prognostic Significance of Blood-Pressure on Renal Disease.—Dr. BROADBENT read a paper on this subject.

BRITISH GYNÆCOLOGICAL SOCIETY.

FEBRUARY 8TH AND 22ND, 1888.

ARTHUR W. EDIS, M.D., F.R.C.P., President, in the Chair.

The Diagnosis and Electrical Treatment of Early Extra-uterine Gestation.—Dr. JAMES AVELING read this paper. He said that to the Americans was due the credit of having established the efficacy of the electrical treatment of extra-uterine gestation. Although electricity had been employed as a feticide more than thirty years ago, it received little attention until Dr. J. G. Allen brought a case before the Philadelphia Obstetrical Society in 1872. Numerous cases had since then been published by American gynæcologists. More recently it had been employed in this country; but the method of using it had been erroneous. In one case, three needles of improper metal were inserted, and used with the positive pole of a thirty-celled constant-current battery. The result was that the mother died. Experience proved that a moderate faradic current was sufficient to kill the foetus in early gestation, and the employment of such strong means was quite unnecessary. The brilliant results of the operation for dealing with these cases when death from laceration and hæmorrhage was imminent had blinded some gynæcologists to the necessity of adopting a plan of treatment which would prevent these fatal ruptures. Objections had been raised on the ground that a diagnosis in tubal pregnancy was never called for before the rupture of the tube; that there were no symptoms before rupture was established; that to apply the electric current to every kind of pelvic lump, under the suspicion that it was an extra-uterine pregnancy, would be a most haphazard and dangerous proceeding; that the destruction and death of the child was of no consequence

at all; the organ which could not be destroyed by the electric current, but which would go on growing and would go on bleeding when it was torn, was the placenta: finally, that supposing the foetus had passed through the stage of tubal rupture and remained alive, one had no right to murder the child. All these objections could be easily answered. Any practitioner who met with a case presenting the history and subjective symptoms of ectopic gestation should endeavour to clear up his doubts by making a physical exploration of the pelvic organs. The history of a case of misplaced gestation was of great importance, and should never be overlooked. As a rule, erratic pregnancy was found to occur most frequently during a prolonged sterile period following a first confinement. The patient generally believed herself to be pregnant, and that there was something unusual about her condition. Pain of a peculiar paroxysmal and agonising character was a most reliable guide. The ordinary supervening signs of conception would be noticed. Metrorrhagia also was an important symptom. If in addition to the foregoing symptoms a rounded, elastic, tender tumour was discovered behind or to one side of the uterus, rapidly increasing in size and vascularity, there was no other pelvic tumour with which it could be confounded. The condition and situation of the uterus also gave valuable diagnostic information. As regards treatment, laparotomy after rupture was a necessary and life-saving operation, but the object of all treatment should be to prevent rupture, and thus render the more dangerous operation unnecessary. No one would wait until an aneurysmal sac had burst before using means to arrest its progress. Electricity might be employed with every chance of success during the first four months. No doubt the earlier it was had recourse to the better, a satisfactory diagnosis having been arrived at. There were two theories as to the way in which electricity caused the death of the foetus: one that it was brought about by electrolysis, the other that death was due to nervous shock. He believed that death was due to the tetanic contractions of the foetal mass, resulting from the repeatedly broken current of an induction machine. To be effective the current should be as strong as the patient could bear, not turned on all at once, but gradually increased to that point. It should be continued for at least ten minutes, and repeated every day until the effects upon the tumour became evident. These effects, which confirmed the accuracy of the diagnosis, were cessation of pulsation, diminution of resistance, and reduction in the size of the tumour; and besides these, retrograde changes in the breasts, and retiring of the cervix uteri from the pubes. In a case he had treated a short time since, he had used Gaiffi's induction machine, and employed only half its power. The negative electrode was applied to the most prominent part of the oyst through the vagina (it might be found convenient to pass this through the rectum in some cases). The positive electrode was placed on the abdominal wall opposite the tumour. No pain or inconvenience was felt after the applications. They were only four in number, for, on the fifth day, when about to repeat the faradisation, such marked change in the cyst was apparent that he was convinced gestation had been arrested. This proved to be true, and the patient was now in health, and no trace of the tumour could be felt.—Mr. LAWSON TAIT said that in the single case of tubal pregnancy he had met with before the date of rupture the symptoms had been obscure pelvic pain of several months' standing, in fact the usual symptoms of salpingitis. He saw her again three days subsequently, and her symptoms had become most acute; she was bent double and could hardly walk. Finding the whole floor of the pelvis was fixed in one mass, she was admitted into the hospital, and the next morning he opened the abdomen and found a ruptured tubal pregnancy. He denied it was possible to have diagnosed such a case beforehand, for the woman had not even missed a period. No diagnosis could be depended upon before the date of rupture; one might guess, but it was impossible to affirm. Speaking of the growth of the placenta, he had found instances of a macerated foetus not more than ten or twelve weeks old, while the placenta was the size of a four months' pregnancy. Dr. BERRY HART and Mr. KNOWSLEY THORNTON had confirmed his observations. He could not accept the twenty cases alluded to by Dr. Aveling which "disappeared" after treatment as cases of tubal pregnancy, and disbelieved his own observations, which were supported also by others. Speaking of cases allowed to go on towards term, he believed that all the children and most of the mothers might be saved by proper surgical intervention at the opportune moment.—Dr. INGLIS PARSONS said there was no evidence to show that the placenta would continue to grow when the child

had been killed by electricity. The force that could produce the death of the foetus was not likely to leave the placenta untouched. No subsequent trouble had resulted in the twelve cases mentioned by Dr. Garrigues.—Dr. RUTHERFORD said that before the third month they could not be sure they had to deal with a case of extra-uterine gestation. He thought the faradic current distinctly dangerous, as the muscular coat of the tube was greatly hypertrophied, and therefore the risk of rupture would be increased by the strong contraction. If the current were employed at the fourth or fifth month, when the sounds of the foetal heart could be heard, and if after treatment they ceased, then they would be entitled to claim that the treatment had been so far successful, but Dr. Aveling had spoken of a case at two months, when of course no such proof was available.—Dr. ISLACH said that opinions had advanced much since the year 1872, when he had seen a case at full time allowed to perish for want of surgical interference. He maintained that the same thing happened in a tubal pregnancy as did inside the uterus when the foetus died. As soon as the child died or was killed, the tube endeavoured to discharge its contents, and, as it could not possibly pass into the uterus, the tube was ruptured. If they killed the foetus they were doing the best they could to bring about the very thing they wished to avoid. Let it go on to full term, or until rupture, and then operate at once. Laparotomy could always be performed almost without danger, so that there was really no excuse for killing the foetus. He considered it to be an absurd piece of meddling gynæcology.—Dr. JAPP SINCLAIR said that in three cases, with the details of which he was familiar, there were absolutely no symptoms before rupture; and in two of the cases even after rupture the symptoms were most misleading. He had met with many cases which simulated tubal pregnancy.—Dr. BARNES maintained that the diagnosis of tubal gestation might be made with reasonable certainty even at the seventh or eighth week. The ordinary signs of pregnancy being present, there were two signs that called for special examination. These were, first, pain more or less acute in the pelvic region, of a spasmodic character; secondly, more or less hæmorrhagic discharge from the uterus and vagina. There were signs of abortion—it might be of uterine gestation; but they called for local exploration. The uterus would be found not in the normal median position, but pushed across the pelvic brim to one side; on the opposite would be found an extra-uterine swelling of an ovoid shape. The size of the uterus itself might or might not, most probably did not, equal that of the estimated stage of gestation. If all these conditions had developed in a short period in a subject hitherto free from symptoms of pelvic distress, the case for tubal gestation rose to more than suspicion. If the symptoms were not urgent enough to call for active intervention, an opportunity occurred for making comparative observations. If in a week or two the extra-uterine tumour had increased considerably, and shreds of decidua membrane had been cast with the uterine hæmorrhage, the case for tubal gestation was all but complete. The process of abortion had fairly set in. In the case of uterine abortion we might safely wait, aiding Nature according to her indications. But Nature's course in the case of tubal gestation was to burst the sac, and that might be fatal. At this point rupture might be averted by puncturing the sac, thus relieving tension by drawing off the liquor amnii and any blood that might have been effused into it. This almost certainly involved the death of the foetus, and this treatment with rest was often enough. But it was also the opportunity for galvanism. He had no personal experience of this proceeding, but with the present state of knowledge should prefer simply to tap the sac, and proceed to ulterior measures according to circumstances. Dr. Barnes summed up the question of treatment in the following propositions: 1. The treatment to be adopted must be governed by the nature of the case, by the urgency of the symptoms, and especially by the stage of development of the gestation. 2. In the early stage, before bursting of the sac, electricity to kill the foetus might be applicable; but simple puncture of the sac was better. 3. When signs of rupture of the sac, with manifest signs of hæmorrhagic effusion, shock, and collapse, had set in, no time should be lost before opening the abdomen and tying the pedicle, and, if possible, removing the pregnant tube. If the primary effects of rupture had been tided over, and a fair degree of tolerance had been gained, it might be enough to treat the case as one of simple retro-uterine hæmatocele, by puncturing more or less freely the sac behind the uterus, and leaving in a drainage-tube. This plan had been adopted with success. 4. When the stage of

danger of cataclysmic rupture had passed, laparotomy should be performed as soon as the condition was recognised, not waiting for the maturity of the foetus. 5. Lastly, when in the presence of urgent or threatening symptoms a doubt arose as to the course to pursue, the decision should be, as a rule, in favour of opening the abdomen and going straight to the seat of mischief. It mattered little to the patient, if her life were imperilled by the bursting of an ectopic gestation sac, or by some other condition causing rapid hæmorrhage into the abdomen or pelvis. The same remedy was indicated in different diseases. Precise diagnosis was not necessary to justify laparotomy.—Dr. ROUTH said the uterine *souffle* could be heard as early as the sixth week by means of the vaginoscope. A similar sound was heard in certain cases of fibroid tumour; but it was easy to distinguish the two. A fibroid giving rise to a *souffle* must be much larger than an extra-uterine pregnancy of three months. He approved of puncture of the sac, provided the aspirator was used. In any case, he thought electrolysis unnecessary and most dangerous. It was quite sufficient if the electrodes were placed one within the uterus and the other on the abdomen at the point nearest to the foetal sac. He did not believe in the growth of the placenta after the death of the child. Speaking of ventral pregnancy, if seen at a late period, and viable, no doubt he should operate. But if not viable he would not think it right to wait until it became so, and allow the mother to be sacrificed for the sake of the child. He should think it his duty to destroy the foetus, whether by electricity or puncture, up to three months; after that, remove it by abdominal section.—The PRESIDENT thought the facts before them were not sufficient to warrant a clear expression of opinion. He would not recommend anyone for whom he had a regard, and who was suffering from an ectopic gestation, to be electrified, but would prefer opening the abdomen and removing the mass at once. The cases in which dead foetuses had been left for long periods of time inside the body without giving rise to symptoms were very exceptional, and the electrical treatment might be the means of causing the very mischief they were endeavouring to avoid.—Dr. HENWOOD SMITH remarked that it would be helpful to divide the consideration of treatment into three stages: (1) the pre-rupture stage; (2) the stage of immediate post-rupture; and (3) that which might be called paulo-post-rupture. Inasmuch as hitherto the second stage (that of primary rupture) had usually proved fatal, and would in severe cases continue to do so unless the abdomen were opened and the seat of lesion removed, it stood to reason that whenever the first stage was diagnosed the pregnant tube should be removed, so that the woman should not be exposed to the risk of rupture.—Mr. LAWSON TAIT exhibited a large collection of specimens, illustrating every variety of ectopic gestation, from the museums of St. Thomas's, Guy's, Queen's College, and the Royal College of Surgeons. In the event of meeting a case of ectopic pregnancy, before rupture had taken place he would prefer to remove it, for several reasons. First of all he would not have been called in if the patient were not ill, and the urgency of the symptoms would justify the treatment. For one case they could diagnose, fifty would escape recognition. Further, if electrolysis were successful a useless organ was left with the risk of subsequent pyosalpinx. The growth of the placenta after the death of the foetus was evidenced by his specimens. In the later stages of the ventral pregnancy he would leave the foetus as long as he could, so as to give it the best chance of living, the more so as the mother's life was not thereby imperilled. His opinions regarding the removal of the placenta had been gradually changing, because experience had taught him that its removal was easier than he had once thought.—Dr. FANCOURT BARNES, Dr. BEDFORD FENWICK, and others, took part in the discussion.—Dr. AVELING replied.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

WEDNESDAY, FEBRUARY 28th.

R. THORNE THORNE, M.B., F.R.C.P., President, in the Chair.

Yellow Fever.—Dr. DONOVAN, of Malta, read a paper, giving a summary of Professor Freire's work on the microbial doctrine of yellow fever and its preventive inoculations. In this work the isolation and growth of a particulate germ, called by the discoverer the "cryptococcus xanthogenicus," was described at some length. The mode of its attenuation was also fully given, as well as an account of its inoculation into human beings at Rio Janeiro, with a view to prevention of yellow fever. Some statistics were given on the latter point. A detailed account was also given of

the examination of the earth of cemeteries containing yellow fever corpses, and the discovery of the same microbe as was found in the fluids and tissues of yellow fever patients. Cremation of the dead was strongly advocated.

Some Specific Febrile Diseases of Malarious Origin, and on the Necessity of the Existence of Germs for their Production.—Inspector-General DONNET treated of the specific nature of the various malarious diseases, and gave a full description of the etiology, behaviour, and geographical distribution of yellow fever. Malarious diseases were spoken of as choosing the deltas of large rivers as their especial *habitat*. Thus, the plague was generated in the delta of the Nile, cholera in the sunderbunds of the Ganges, and yellow fever in the deltas of the Mississippi and the Orinoco. Yellow fever was not known in Europe before the discovery of America by Christopher Columbus, no well-authenticated instance of its invasion having occurred prior to the Lisbon epidemic in 1723, which was imported there from the marshy shores of the American continent. The zone of yellow fever commenced at Georgetown in South Carolina, swept round the southern shores of North America and the eastern shores of Mexico and Central America, and terminated at Georgetown in Demerara, being contained between latitudes 33° and 6° north. The factors necessary for the development of yellow fever were: (1) importation; (2) a temperature above 70° F.; (3) a suitable soil; and (4) an appropriate pabulum. Cold had a remarkable power of arresting it; thus ships from the West Indies were ordered to Halifax. Reference was made to the preference of yellow fever for white races and for newcomers, and also its greater proneness to attack the young and vigorous. The latter peculiarity was so marked that physicians in former days used to recommend people visiting the tropics to adopt such a regimen as would ensure a lowered vitality of their system. A useful table, embodying the characteristic distinctions between yellow and remittent fever, was appended to the paper.—In the discussion which ensued, the PRESIDENT, Inspector-General LAWSON, Deputy Inspector-General LLOYD, Dr. WILLOUGHBY, Surgeon-Major PRINGLE, and Surgeon-General MANIFOLD took part.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

FRIDAY, FEBRUARY 17TH, 1888.

Mr. WILLIAM FRAZER, and subsequently Dr. C. B. BALL, the President, in the Chair.

Hydatid Cyst of the Deltoid Muscle.—The PRESIDENT (Dr. C. B. Ball) communicated a case. The patient, a housemaid, sought advice for a tumour on the outer side of the right arm. It had commenced three years previously as a small nodule, which afterwards gradually enlarged. There was fluctuation, but it was not distinct. The nature of the tumour was not diagnosed previous to the operation, and it was determined to explore it by an incision. On opening it six ounces of thin pus escaped, and a cyst was found about the size of a large grape. It was enucleated and the capsule removed, and the wound healed under a single anti-septic dressing. At the commencement of the process of removing the capsule the impression was that it was a parent cyst, and that the other was a daughter cyst; but after dissection it became manifest that this was not the case, and that the capsule enclosed a worm. The extirpation of the capsule was completed, and the cavity closed by deep sutures. No further suppuration took place. No traces of hooklets or smaller cysts were found. Projecting into the interior of the sac was what might have been either a brood capsule or the retracted head of a cystoid worm. The whole tumour, when recent, was about the size of a small orange.—The case was discussed by Mr. SCOTT, the CHAIRMAN, and Dr. FINNY.—The PRESIDENT, in reply, said two forms of bladder worm were tolerably frequent in the human subject. One was the cystic form of the *tænia echinococcus*, and the other was the *cysticercus cellulosus*, which was the first stage in the development of the *tænia solium*. In Germany, where the *tænia solium* was of frequent occurrence in the human subject, the *cysticercus cellulosus* was also considerably frequent. In this country the *tænia solium* was almost unknown. Dr. FOOT and Dr. LITTLE had been unable to find a single specimen of it in the museum. What was the nature of the cystic worm now before the Section? Now from the existence of one retracted head, the absence of daughter cysts, and the fact that the retracted head had four suckers and a number of hooklets, they could not but conclude that it was *cysticercus cellulosus*.

Rupture of the Trachea, with Fracture of the Sternum and Rib.—Dr. E. H. BENNETT exhibited an example of complete transverse rupture of the trachea, and of fracture of the sternum, taken from the body of a man who had been killed by being crushed between a hoist, used in raising coal, and a wall. There was no external wound, but blood had poured from the mouth. The trachea was found ruptured transversely, and the fragments were separated by an interval of one inch. The œsophagus was bruised, but not torn; much blood was shed in the tissues around the trachea and œsophagus, but none of the great arteries or veins were torn. The fracture of the sternum was very oblique from above, and in front downwards and backwards; its upper border passed between the cartilages of the second ribs, while its mediastinal margin was placed below the level of the third pair of ribs. The second and third ribs on both borders were also broken, and on the right the fourth and fifth also.—The PRESIDENT said the principal feature in this fracture was its extreme obliquity. The only fracture of the sternum he ever saw was a directly transverse one.

Ulcerative Endocarditis.—Dr. JAMES LITTLE submitted the following case of ulcerative endocarditis. The specimen was from a silk weaver, aged 32, who had recently returned to this country after having spent a year in New York. Upon his admission it was evident that he was suffering from aortic valve disease. His mental state was rather peculiar. When he came in he was in such a state that he was barely able to leave his bed, yet he spoke of getting up and going back to America; and during the whole period of his illness it was impossible to get him to explain much about his symptoms, or what it was that distressed him. When asked whether he suffered pain or felt ill, he drifted off into growling complaints of the food that he got, or of his treatment in other respects. His pulse at his admission was about 100, but during the two months that he survived it increased, and a few days before his death had reached 130. His temperature fluctuated a good deal, but was always above the normal, varying from 101° to 103°. His urine was very highly coloured, turbid from urates, and of a high specific gravity—1030. At first it did not contain any albumen, but during the last three or four weeks of his life was highly albuminous. On *post-mortem* examination the spleen was found to be very much enlarged, and in its centre was a considerable-sized abscess, from which, when opened, two or three ounces of chocolate-coloured fluid flowed. There was also a small abscess in the upper end of it. The right cavities of the heart were empty. The whole heart was rather bigger than it should be—the enlargement being due to thickening of the walls, and some increase in the size of the cavity of the left ventricle. The aortic valve, on being tested, was found to be quite incompetent; a stream of water flowed through it. On opening it all the valvules were found to be more or less puckered and thickened. The first portion of the aorta did not present, on the surface, any distinct indication of change; on cutting it across, the coats were found to be much thickened. The most characteristic appearance was on the anterior curtain of the mitral valve—a patch nearly as large as a florin, distinctly ulcerated, and covered with luxuriant vegetation. Some of this vegetation, and also vegetation from the kidneys and spleen, had been microscopically examined by Dr. BEWLEY. It left no doubt that the disease was, as he had guessed during the patient's life, ulcerative endocarditis. Though this was a rare affection, it was not so rare as was generally supposed. He could recollect several cases which went to a fatal termination, uninfluenced by care or drugs, and which were not understood at the time, and which he now believed were cases of this septic malignant ulcerative endocarditis.—Dr. BEWLEY said the vegetation was composed partly of fibrin. The portions which appeared blue under the microscope disclosed an enormous number of micrococci. On the anterior wall of the left ventricle, below the aortic valve, there was a small amount of vegetation, in which also there were micro-organisms. There was a considerable number of micro-organisms in the small infarcts of the spleen, and there were also thrombi in some of the splenic arteries.—The PRESIDENT and Dr. WRIGHT made some remarks, and Dr. LITTLE replied.

Intra-uterine Amputations.—Dr. E. H. BENNETT read an account of a dissection of the stumps obtained in a case of intra-uterine amputations of the fingers and toes. The point of chief interest seen in contrasting the specimen with an ordinary surgical stump of finger amputation was the absence of neuromata on the ends of the nerves in the intra-uterine as compared with large and well-defined tumours in the surgical stump. All the intra-uterine amputations had been disarticulations, and each preserved

almost a complete joint between the extremities of the bones and the soft structures of the ends of the stumps. The anatomical changes in the circular grooves of the digits where amputations had not been completed, and the condition of the several muscles, etc., of the limbs involved, was described.—The President asked were the nerves of the extremity of normal size up to the amputation, or did they exhibit signs of atrophy?—Mr. FRAZER remarked that in all cases of this sort there was generally a history from the mother of some fright or start.—Dr. BENNETT, in reply, said there was no sign of arrested development in the specimens now before the Section. It was simply a case of removal by something twisted round the part, the nerve-cords being perfect down to the line of amputation without any defect of structure. The muscles of the forearm, though small, were perfectly normal both at the back and front; and the nerve fibres maintained their character as such up to the scar tissue, where they ceased to be nerve fibres at all.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, MARCH 2ND, 1888.

C. B. KEETLEY, F.R.C.S., President, in the Chair.

AFTER the minutes were read, the PRESIDENT announced that Sir William Stokes, Professor of Surgery, Royal College of Surgeons, Dublin, would deliver the "Cavendish" Lecture in June.

[[The formation of a library was announced, and members were invited to contribute.

Massage.—Dr. ECCLES gave a demonstration of the various manipulations in massage.

Sarcoma of Vertebra.—Mr. J. ROCHE LYNCH exhibited a specimen of alveolar sarcoma of the vertebra, taken from a lady, one of three sisters, who all died within twelve months of malignant disease. In two the growths commenced in the mamma. In this case the symptoms were persistent lumbago, followed by rigidity of the spine, and a week previous to death right unilateral convulsions. The duration of the disease was eight months. On post-mortem examination the vertebral bodies, from the sixth dorsal to the sacral, were impregnated with the growth—only a thin shell of compact bone remaining at the margin. There was a considerable amount of fluid, but no secondary deposit in the brain. The liver showed numerous patches. The microscopic examination of the growth indicated alveolar sarcoma.

Oophorectomy for Uterine Fibroid.—Mr. JOHN R. LUNN read a paper on a successful case of oophorectomy for a bleeding fibroid of the uterus. On opening the peritoneum the left ovary and uterus presented. Several small fibroids were seen springing from the fundus. The left ovary was cystic, and as large as an orange. It was pulled out of the abdomen and ligatured, with the fimbriated extremity of the tube, with carbolised China silk (previously boiled for twenty-four hours). The abdominal opening was then enlarged, and the right ovary searched for. It was behind the uterus, and very adherent to the surrounding tissues. It was carefully torn away, ligatured, and removed, the uterus being previously pulled out of the abdomen. The uterus was well washed with carbolic lotion, and returned; the pelvic cavity was well irrigated, and slightly sponged. The abdominal incision was then closed with carbolised silk, and dressed with iodoform and dry iod. lint. Recovery was complete, and five months and a half after operation the uterus only reached midway between the pubis and umbilicus, and the patient had gained 20 lbs. in weight.

Electricity in the Treatment of Uterine Fibroids.—Dr. INGLIS PARSONS read a paper on the Application of Electricity to Uterine Fibromata. He did not find it necessary to use clay for the external electrode; a large concave metal plate, lead or copper, placed on a damp linen pad so as to cover the abdomen was sufficient. Currents up to 300 milliampères could be passed in this way. It was necessary to see that the pad was smooth and in contact all over with the skin. A new electrode for intra-uterine use was also described. A case was related in which, after two applications of the current, all hæmorrhage ceased. Six applications were made in all; from 100 to 300 milliampères. She was quite free from symptoms for three months, until February 20th, 1888, when slight hæmorrhage again came on.—The President congratulated Mr. Lunn upon his skilful operation, and referred to the warmth of feeling often exhibited in discussions upon the therapeutic uses of electricity.—Mr. ALBAN DORAN considered that almost any treatment would decrease a fibroid. Formerly the action of ergotin, subcutaneously administered or otherwise,

had been much lauded, and similarly with other methods. He doubted whether the diminution of the growth by means of electrolysis would be permanent. Most of the cases thus treated had not yet been sufficiently long under observation.—Mr. KNOWSLEY THORNTON thought we should wait before accepting Mr. Keith's views on the matter. There were rumours of some cases having ended fatally—he himself knew of one. Certain uterine growths disappeared after oophorectomy; he considered, however, that it should not be practised when the uterine fibromata were larger than a coconut. The rapidity of disappearance of small or soft myomata after removal of the ovaries was extraordinary. He had operated on twenty-eight cases and lost two. Of the others all but one had been completely successful, the uteri being left in the senile condition.—Dr. GRAILY HEWITT agreed with Mr. Thornton in his remarks regarding electrolysis: we really knew as yet very little about it. He could conceive danger when the tumour was punctured in the process, otherwise he thought the method would be harmless, and that it might be tried in certain cases.—Dr. LEWERS considered that if electrolysis were a remedy of such power in interstitial fibroids, it should be efficacious in the removal of polypi. The value of the method could thus be tested by direct evidence, for there was often doubt as to the presence of an interstitial fibroid.—Dr. ALDERSON believed in spontaneous cure. He asked whether some of the cases did not die of exhaustive diseases such as pernicious anemia.—Dr. TRAVERS thought that electrolysis should be given a fair trial. If there really had been fatal cases it was likely that we should have heard more about them than mere rumours.—Mr. LUNN, in replying, said he considered that unsuccessful cases should be more frequently published.—Dr. PARSONS also replied.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.

WEDNESDAY, FEBRUARY 15TH, 1888.

JOHN URQUHART, M.D., in the Chair.

Cerebral Lesion in a Child.—Dr. MACGREGOR showed a girl, aged 8 years, with paralysis of the left side of the face and the left upper extremity. There was optic neuritis in both eyes, most marked in the right, where also there were several retinal hæmorrhages. The heart seemed normal; the liver and spleen were both enlarged, and, with the exception of a small quantity of pus, the urine was normal.

Congenital Heart-disease in Children.—Dr. EDMOND showed two cases of this condition, occurring in children of 12 and 4 years of age respectively. In both there was well-marked cyanosis. In one case a systolic bruit was heard over the pulmonary area, in the other a systolic bruit over the apex. In the elder child there had been frequent attacks of hæmoptysis. Dyspnoea was marked in both cases.

Case of Pyloric Stenosis, with Hypertrophy of the Walls of the Stomach.—Dr. BLAIKIE SMITH read notes of an interesting case of this nature. The patient was a man, aged 57, who for eleven months previous to his coming under observation had suffered from dyspeptic symptoms with vomiting, coming on at irregular intervals after taking food. When first examined the epigastrium was a little tender and slightly prominent, and the spleen was enlarged, but latterly there was distinct evidence of bulging, pulsation, and dullness on percussion over a small area just below the left costal margin, in the mammary line. Obstructive jaundice soon made its appearance, and about this time the vomiting became more periodical, resulting in the evacuation of a pint or two of grumous-looking material, presenting no obvious signs of fermentation. The ordinary signs of pyloric stenosis were absent, the stomach did not become dilated, and hæmatemesis never occurred. Death resulted from the persistent vomiting, and from the unrelieved jaundice. The diagnosis arrived at was malignant disease of the pylorus, with secondary invasion of the liver, and at the post-mortem examination the pyloric orifice was found constricted by cancer, and the gastric walls were much thickened by muscular hypertrophy. The liver was the seat of a small cancerous nodule, which completely obstructed the common bile-duct. Dr. Blaikie Smith considered that the thickening of the walls of the stomach had given rise to the epigastric fulness, and the physical signs in the left hypochondrium noted during life, but he was of opinion that the hypertrophy was not analogous to that seen in the urinary bladder in cases of urethral stricture, ascribing it rather to the existence of chronic gastritis, a condition so frequently present in cancerous degenerations of the stomach wherever they were situated.

SOUTH INDIAN BRANCH (MADRAS).

FRIDAY, OCTOBER 7TH, 1887.

Surgeon-General BIDIE, C.I.E., President, in the Chair.

Varicose Veins of Scalp and Eyelid.—Surgeon-Major E. F. DRAKE-BROCKMAN described a case of a Hindu, aged 25, who presented a puffy swelling occupying the whole of the right upper eyelid, except a small portion near the inner canthus; it was said to be of three years standing; it could be emptied by pressure, and was apparently continuous above with a sacculated and greatly enlarged vein, which coursed over the forehead and head in an upward direction between the parietal eminence and the sagittal suture on the right side. The margin of the lid at the most dependent part of the tumour presented a purplish coloured excrescence consisting of congeries of blood-vessels, and the same condition, in a most exaggerated degree, was to be noticed in the inner surface of the eyelid when everted, bearing a strong resemblance to the choroidal plexuses in the ventricles of the brain. The weight of the tumour, which was of the size of a gooseberry, caused the lid to droop, giving rise to a certain amount of ptosis. Vision was unimpaired, and an ophthalmic examination showed that there was no abnormal distribution of the blood-vessels in the fundus. When in the recumbent position, with the head turned to the right side, the diseased vessels became enormously distended; no *bruit* nor pulsation could be heard or felt. The bone beneath the dilated vessels appeared to have been extensively eroded. The veins of the neck did not exhibit any enlargement, and the arteries were free from any visible pulsation. No abnormal sounds attended or replaced those of the heart. Soon after assuming the erect position the swelling diminished materially, and the upper lid could be partially elevated by the patient. Pressure brought to bear upon the external and internal jugular veins, in the erect position, did not materially influence the size of the blood-vessels. The large superficial blood-vessels were in connection with the great venous sinuses within the cranium, into which the blood could be emptied without causing any unpleasant symptoms in the brain. Interrupted pressure by means of a series of pads along the course of the chief venous channel, fixed in position by means of strapping, was employed for some days, and had the effect of keeping the varicosities from filling, but produced no permanent improvement. Mr. Drake-Brockman thought the case was unique, and referred among the points to the disproportion between the actual œvoid growth of the upper lid and the size of the venous blood channels which were in connection with it; the important anastomosis which seemed to have been established between the venous distribution within and on the outer surface of the skull; the entire absence of all symptoms when the blood, which distended the superficial vessels, was forced by manipulation within the cranial cavities at the situation of the posterior fontanelle; the erosive action which had been exerted on the calvaria by the distended soft blood-vessels.—Brigade-Surgeon SIBTHORPE mentioned a case of a European who had a large nevus occupying the greater portion of one side of the face; several abscesses formed in this, and a cure (spontaneous) was to a certain extent effected as the nevus decreased in size with hardening of the surrounding tissues.

Cystic Orbital Tumour.—Surgeon-Major DRAKE-BROCKMAN also read the notes of a case of cystic tumour of the orbit observed in a Hindu woman, aged 30. The tumour was only noticed for six months before she came under treatment; it had then attained the size of a large orange; the skin of the eyelid and of the side of the face was thickened, and the glands at the angle of the jaw were enlarged, probably owing to irritative treatment by native practitioners. About two ounces of clear, alkaline fluid, of specific gravity 1006 was drawn off by a grooved needle, permitted of the elevation of the upper lid by means of a speculum, and the eyeball was discovered lying to the lower and deeper part of the orbital cavity. The patient was able to see with the organ, but had no power to move the eyeball in any desired direction; pressure was applied, and the tumour refilled in three days. A week later it was tapped again; pressure was applied, and produced an ulcer which gave way under manipulation; about two ounces of sero-purulent fluid were evacuated, and the cyst was exposed entire. The cavity thus left extended far back into the orbital cavity. The case eventually did well, and regained to a considerable extent the movements of the eyeball, but there was complete ptosis, which it was feared would be permanent, owing to atrophy of the levator palpebræ.

Radical Cure of Hydrocele.—A paper on the radical cure of

hydrocele by the injection of carbolic acid was contributed by Surgeon W. B. BROWNING. He had used castor oil for protecting the skin of the perineum and serotum. The fluid used for injection was pure carbolic acid, as in India a sufficient quantity could always be found fluid in the bottle; he had found that as much as two drachms was generally necessary; in the cases he had treated the hydroceles were old and large, and in one case he had used three drachms. No symptoms of carbolic acid poisoning had ever been noticed, and the local pain was less than when iodine was used. Reaccumulation was noticed in several cases shortly after the operation, but disappeared in all the cases but one. In this, on the twenty-eighth day, four ounces of dark coloured fluid were drawn off, and when seen three months later the fluid had not again accumulated.

Pseudo-hypertrophic Paralysis.—Brigade-Surgeon A. PORTER exhibited an East Indian lad suffering from well-marked pseudo-hypertrophic paralysis. The patient was a Eurasian, aged 14. He had had dengue fever when four months old, did not begin to crawl till after two years old, did not walk till over three years old, could never run, pick up anything off the ground, or go up steps. His calves had been noticed to grow large, and after the age of 12 he had been unable to attend school, owing to difficulty in walking. There was no history of any neuroses in the family: the three elder children of the family were all healthy; one younger child died in infancy. His condition when he came under treatment was fully described, and was quite typical of the disease.

False Joint of Humerus treated by Wiring.—Brigade-Surgeon C. SIBTHORPE related the case of a strong, muscular Tamil coolie, aged 28, who sustained a compound comminuted fracture of the upper third of the left humerus. The protruding portions of bone were sawn off, the fracture was then set, and the arm placed on a Stromeyer's cushion; the wound was treated by the Listerian method. No union took place, owing to the bones being too far apart; the two ends of the bone were exposed and wired together; the wires were removed two months later. The patient was shown to the meeting. The bone was strong, but there was some atrophy of the muscles from disuse, and the hand and fingers were stiff; these, however, were improving under the use of electricity and shampooing. The left arm was only one inch shorter than the right.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, MARCH 2ND, 1888.

Dr. BELL in the Chair.

Simple Perforating Ulcer of Septum Nasi.—Mr. JESSOP described four cases. The first, a lady aged 44, applied on account of a whistling sound produced in her nose on breathing, and slight itching. There was some ulceration round the perforation, with dried blood on the surface. The sore healed under the use of strong nitric acid, followed by scraping, leaving an aperture which would admit a cedar pencil. The second case occurred in a married woman aged 30. The aperture was at the anterior edge of the septum, of a year's quiet growth, and the edge was ulcerated only posteriorly. The third was in a man aged 30. The aperture was of the size of a threepenny piece, and the edges were covered with crusts, which he used to remove with his finger. The sore improved under the use of nitric acid. The fourth case occurred in a lady aged 34, who applied to him in March, 1865. She had been married ten years without family, and her uterus was ante-flexed, with a copious discharge. In September, 1866, the sight of one eye (the other having been previously lost) began to fail, for which spectacles were given; and in April, 1887, she complained of redness of the ala nasi. In August an examination in consequence of nasal irritation revealed a perforation of the septum, which improved under local treatment. Her husband thought he had had syphilis three years before marriage, but had had no secondary symptoms. This was the only case in which there could be the faintest suspicion of a syphilitic history. Mr. Jessop referred to Mr. Jonathan Hutchinson's paper describing this condition, with its description of a number of cases; and he commented on the slow course of the ulcer, its uniform character, and the absence of fœtor or discharge. It seemed to be a condition affecting middle life, and answered well to local treatment, anti-syphilitic remedies being useless.—Mr. LODGE showed a patient suffering from a perforation of the septum nasi extending some distance back towards the posterior nares, which he thought was

probably congenital.—Dr. CHURTON referred to Mr. Hutchinson's cases of a peculiar ulceration of the tongue curable by opium, and suggested a trial of that drug for non-syphilitic nasal ulcers. He mentioned a case under his own care of lingual ulcer in a gentleman aged 72, cured by opium after Hutchinson's method.—Dr. JACOB referred to lupus and certain acute diseases, as typhoid, rheumatism, as recorded causes of perforation of the septum other than syphilitic.—Dr. BARRS described a case which had been under his care with anomalous nervous symptoms, in which there eventually supervened a condition of progressive ulceration of the nose, with atrophy and disappearance of the bones, but without discharge or fœtor. He thought it was neither lupus, rodent ulcer, nor syphilis.—Dr. A. BROSMER referred to the researches of Zuckerkandl, who found, out of 180 necropsies, the septum perforated in eight. Three of these had the aperture covered by a thin skin. He thought perforation might be the result of nasal catarrh, with scabbing so common in children.

The Treatment of Urethral Stricture by Rapid Dilatation.—Mr. MAYO ROBSON remarked that the rapid dilatation of stricture by means of Lister's graduated metal bougies—either used immediately, dilating at once up to No. 13 or 14, or, if the smallest metal instrument could not be passed, employing the same method after a fine filiform bougie had been left in for forty-eight hours—was in his experience a safe and efficient method of treatment. In some cases he had injected a solution of cocaine into the urethra before dilating, but in only one instance had he employed a general anæsthetic. In two cases of extreme distension of the bladder, where no instrument could be passed, the bladder had been aspirated several times, and then it had been possible to pass a fine bougie and to dilate. Mr. Robson related selections from fifty difficult cases thus treated, and remarked that if this method were adopted, cutting operations would be required but very occasionally—that is, internal urethrotomy in very resistant strictures, and external in cases of extensive fistulæ or abscess or extravasation. He always advised his patients to pass a No. 9 or 10 elastic bougie once a week. He had treated many other cases than those related, but had never seen any serious symptoms to follow.—Mr. R. ATKINSON, Dr. SWANN, Mr. LITTLEWOOD, Mr. JESSOP, Mr. MAYO, and Dr. ALLAN made some remarks.

Nitrate of Silver in Erysipelas.—Dr. ALLAN recommended a saturated solution of silver nitrate in spirit of nitrous ether as an application. He had found this use also in cases of threatened bedsores.—Mr. LITTLEWOOD thought cases of erysipelas required merely to be kept warm.—Mr. JESSOP referred to the use of iodine, and of iron as external applications. The latter use he thought originated in the Leeds Infirmary, where many years ago a thoracic aneurysm, under the care of Dr. Hardwick, was treated by the external application of perchloride of iron. At the necropsy the solution was found to have penetrated the tissues very deeply, and where it had penetrated through the wall of the aneurysm there was a clot formed, and there only.

Case of Variola coincident (?) with Typhoid.—Dr. PURYX was called to a case which, with a history of three weeks' ailing, had all the characters of enteric fever, with rose spots on the abdomen, increased splenic dulness, temperature 102°, and characteristic "pea-soup" stools. The temperature rose, and was 104° on the fourth day afterwards. On the fifth day a copious confluent small-pox rash appeared. The patient was removed to the hospital, where he died. There was absolutely no preliminary symptom of small-pox.—Mr. GODFREY CARTER related a case of small-pox where the patient had worked up to the eighth day. Though there were only two or three pustules and neither pulse nor temperature exceeded 100. On recovery the patient was extremely weak.—Dr. CHADWICK had seen the case of a child who had the typical appearance of typhoid fever, but three days later three pustules appeared, and the case turned out to be small-pox. In another case the symptoms and rash were those of scarlet fever, and the child was taken to the Fever Hospital, but the next day had to be removed to the small-pox ward.

A NEW journal, entitled the *Revue Illustré de Polytechnique Médicale et de Chirurgie Orthopédique* has just appeared. This journal, edited by M. Albert Leblond, physician to St. Lazare, and editor of the *Annales de Gynécologie*, and by M. R. Chenet, will give descriptions, with plates, of all the newest instruments and scientific inventions. A German edition will be published in Switzerland, simultaneously with the French edition in Paris.

REVIEWS AND NOTICES.

PRACTICAL MANUAL OF DISEASES OF WOMEN AND UTERINE THERAPEUTICS. By H. MACNAUGHTON JONES, M.D., M.Ch., etc., Examiner in Midwifery and Diseases of Women and Children in the Royal University, etc. Third Edition. London: Baillière, Tindall, and Cox. 1888.

THE vacillations which are continually manifesting themselves in the science and practice of gynecology—sometimes merely changes, at other times real advances—render it necessary for writers on this subject to keep well up to date. This work is intended more particularly for the use of students, and therefore purely controversial matter is intentionally excluded as far as possible; but, as examiners sometimes require their victims to be posted in the most recent methods of treatment, the author has had to embody a few of these in his work, even though their value has still to be demonstrated.

The manual is essentially practical; it is profusely illustrated with woodcuts of instruments and appliances, together with others showing the various positions for examination. There are some excellent coloured plates of the retina, to aid in the differential diagnosis of Bright's disease in women, and of microscopical sections to assist in the identification of cancerous growths of the uterus, etc. Except perhaps in his abuse of pessaries, the author has sought to avoid too didactic a tone, especially in the matter of treatment. The information given is in many cases evidently designed to satisfy examination requirements rather than those of practice. We refer, *inter alia*, to the treatment of uterine fibroids by iodide of potassium, mercury, etc. It may be remarked that Dr. JONES uses the word *spaying*, notwithstanding the strongly expressed objections of certain of his fellow gynecologists; but students would do wisely to have a care in their use of it in the examination room elsewhere than at the Royal University of Ireland. We are unable, even after a diligent search, to find any mention of the etiology, description, and treatment of extra-uterine pregnancy. Surely this should be comprised in a treatise on the diseases of women, which is made to include such a disease as nephritis. The author, as a matter of fact, gives a large amount of information about subjects not usually found in textbooks on the diseases of women. He speaks highly of the value of massage in gynecological practice, and gives the necessary indications as to when and how to *massé* (?). The book is certainly a valuable one, and fulfils the purpose for which it was written. The style is clear and unembarrassed.

VACCINATION VINDICATED. By JOHN C. McVAIL, M.D. Cassell and Co.

THE author tells us in the preface that this book was "begun merely as a reply to Mr. Alfred Russell Wallace's monograph on *Small-pox Statistics and Vaccination*, and has developed into a commentary, more or less complete, on much of the anti-vaccination literature of the day; and we have no hesitation in saying that it is the most masterly exposure of the method of argument used by the anti-vaccinationists which has appeared since the Royal Commission of 1871.

At the commencement of the volume Dr. McVAIL shows how the statistics of the four years 1843-46 are made use of by the anti-vaccinationists by first admitting an epidemic of small-pox in 1844, and then denying it, just as it happens to suit them; and he also shows how Mr. Wallace sometimes places unlimited faith in the statistics of the last century, and at other times denies their trustworthiness altogether. Further on Dr. McVAIL quotes Mr. Wallace, that the Registrar-General's statistics are "imperfect and unreliable," and then shows how he uses these very statistics to try and prove his first, second, and fourth propositions. He also explains how Mr. Wallace has manipulated a chart illustrating the amount of small-pox mortality at different periods, by compressing it from above downwards, and thereby concealing the decrease in the small-pox mortality since vaccination has been practised. Comparing the mortality from small-pox at different age-periods (which by the bye Mr. Wallace absolutely ignores), the author proves how, coincidentally with the extension of vaccination, there has been a gradual decline in the mortality at all ages; and that this decline, as shown by a table, is most marked among children under 5 years of age, in which class the small-pox death-rate has fallen no less than 80 per cent. (per million living) between the

years 1847 and 1880, while after the age of 10 years the mortality increases as age advances.

This alteration in the mortality at different age-periods does not hold good for other diseases, and can only be explained by vaccination, and not, as the anti-vaccinationists maintain, by improved sanitary conditions; for we are told that "while the small-pox death-rate fell 80 per cent. in children under 5 years, other diseases fell only 6 per cent.; and while the small-pox mortality in persons over 45 years increased 164 per cent., the mortality from other diseases fell 3 per cent. He then quotes from his well-known Kilmarnock statistics to show how, in the prevaccination periods, small-pox was accountable for 91 out of every 100 deaths under 5 years of age. When dealing with the diminution of typhus and enteric fevers as compared with small-pox, he very pertinently asks why, if sanitary agencies reduced other diseases, they did not reduce small-pox.

In dealing with Marson's celebrated tables relating to the ratio of protection afforded by the number and quality of the vaccine cicatrices, he shows that during the years 1871-7 the better vaccinated parts of the community supplied less than one-thirteenth part of the cases to the Homerton Hospital, while the worse vaccinated and unvaccinated minority supplied twelve times as many.

As regards the question of the increase in the fatality of unmodified small-pox, Dr. McVail compares the hospital mortality at different periods, beginning with 1746, and shows how it has increased in that year from 25 per cent. of those attacked to 43.2 per cent. in our own time. In exceptional cases such as Dublin, in 1876-81, it reached 64 per cent.; in Montreal, 54 per cent.; and in Boston, 50 per cent. At the same time, a slight rise in mortality has also taken place among the vaccinated, showing either that the disease has increased in virulence, or that the present generation is more susceptible.

The chapter on the mitigation of small-pox by vaccination will give the reader a partial insight into the laborious work of attempting to verify the statements of anti-vaccinationists, and in tracing their statistics through the hands of various manipulators to their original sources.

As a fair example of such manipulations, we quote a paragraph from the author: "We thus see that just as Mr. Wallace's 18 per cent. rate for last century was obtained by lumping together hospital and non-hospital mortalities, so his 18 per cent. rate for the present century is got by lumping together the vaccinated and unvaccinated mortalities."

Referring to the vaccination of the criminal and nomad class, Dr. McVail quotes from Dr. Buchanan's 14th annual report to the Local Government Board, showing that the poorer classes, from which criminals and nomads are mainly recruited, are, owing to the superiority of public over private vaccination, more perfectly protected from small-pox than their betters in social position.

The whole volume is replete with such trenchant arguments, and is so ably written, that it cannot fail to find a place in the library of everyone interested in the vaccination question. Moreover, it is not a book to be read once and then laid aside, but from its very character it must rank as a classical essay on the subject.

Dr. McVail clearly proves the necessity for his rule of procedure, which is to believe no single word that an anti-vaccinator, as such, says, without obtaining independent evidence of its truth.

TRANSACTIONS OF THE AMERICAN GYNECOLOGICAL SOCIETY.

Vol. XII. For the year 1887. New York: D. Appleton and Company.

This volume commences with the annual address, delivered by the President, Dr. Skene, of Brooklyn. He concludes by observing: "Should fate determine that this board of medicine shall have its rise, decline, and fall, like many of the nations and their works in the past, I predict that when the men of the future come to explore the ruins of the once mighty Gotham, while they may find in the débris modifications of Sims's speculum, and quaint and curious uterine supporters, and many musty jars with human ovaries and tubes, they will find also the works of great masters and their monuments in perfect preservation, including the *Transactions of the American Gynecological Society*, and especially the volume of 1887."

Dr. Emmet in a contribution on the Treatment of Uterine Displacements, discusses his theory that pessaries give relief chiefly by counteracting the impediments to the blood-supply of the uterus which occur in prolapse and other abnormal alterations in

the position of that organ. We may note two interesting memoirs on the serious questions relating to chronic disease of the appendages by Drs. Polk and Battey. The latter insists that the aim of his operation is to produce an artificial "change of life." It is not his purpose to remove diseased ovaries; the fact that the ovaries are diseased in the cases where his operation is performed is merely accidental. Nevertheless, he strongly objects to the synonym "normal ovariectomy."

Dr. Mundé's Drainage after Laparotomy, and Dr. Bantock's Treatment of the Pedicle in Hysterectomy are valuable papers, with instructive discussions. Dr. Engelmann contributes a monograph, over one hundred and fifty pages in length, on the Hystero-neuroses; it includes a long series of clinical reports. Dr. Johnstone, of Danville, writes on the Infantile Uterus, and believes that the arrested growth of the body tends to interfere with the proper development of the endometrium, and that structure being imperfect it is unfitted to form the placenta in conjunction with the chorion, so that sterility is unavoidable. Dr. Chadwick's Ventral Hernia after Laparotomy and its Surgical Treatment is another memoir which deserves special notice.

REPORTS AND ANALYSES

AND

DESCRIPTIONS OF NEW INVENTIONS, IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

BARRETT'S PERFECT INDICATOR BOLT.

This simple and useful appliance, of which the inventor and patentee is Mr. Barrett, M.R.C.S., 25, Clarendon Road, Holland Park, W., is designed to afford a ready means of enabling the occupant of an apartment to indicate by a sliding bolt that he is engaged, and therefore does not wish to be disturbed, or that the intending interviewer should "knock," "wait," or "enter:" the notice displayed on the outside of the apartment by means of a handle moved on the inside, admits, of course, of any modification to suit particular needs. The absence of some such announcement is often the cause of unpleasant interruptions, for even if the door be locked on the inside, the newcomer often tries the handle several times, and sometimes uses force, before he has fully satisfied himself that the door is really locked against intrusion. When the slide is shot the door is fastened, and at the same time the word "engaged," or any modification, is displayed in letters on a white ground on the outside. This invention is recommended for consulting rooms, bath rooms, and lavatories.

VIKING ESSENCE OF BEEF AND CONCENTRATED BEEF TEA.

(The Viking Food and Essence Company, Hearn Street, Curtain Road, E.C.)

We have examined samples of the above meat extracts, and have found them strictly what they profess to be, namely, the essence the pure juice of meat, without addition of water; the concentrated beef tea is an evaporated decoction of meat of very good colour and flavour. The samples are thoroughly well preserved, and put up in attractive-looking glass bottles with ingenious anti-bacterial lids. The preparations of this Company are pure and of very high quality.

TELEPHONES IN HOSPITAL WARDS.

TELEPHONIC communication between the ten separate blocks into which the National Hospital for Consumption, Ventnor, Isle of Wight, is divided has now been completed. The Equitable Telephone Association, Limited, 75, Queen Victoria Street, E.C., who have been entrusted with the installation, have fixed one of their Swinton patent telephones in each block, and one in the porter's lodge, making eleven in all. These instruments are all connected to a central exchange switch board in the head nurse's room, whereby any one block can be put into communication with any other in a few seconds. Arrangements have been made to admit of the system being extended to the private residences of some of the medical officers who live in Ventnor, should this be considered advisable at some future time.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1888.

SUBSCRIPTIONS to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the West Central District Office, High Holborn.

 The British Medical Journal.

SATURDAY, MARCH 10TH, 1888.

SIR JAMES PAGET ON SCIENTIFIC STUDY.

IN addition to his claims on our attention and respect as a great scientific surgeon, Sir James Paget has two qualities which make any of his speeches worthy of careful study and consideration. First, he is a master of English, clothing all his thoughts in the purest and most elegant language; secondly, he has the power of cheering and heartening the humble labourer on the borderland of science, not only by showing that his work may be of real value, but also by pointing out the direction where success may be most probably sought, and by indicating the means most likely to attain it. In his last Saturday's address to the students of the London Society for the Extension of University Teaching, these characteristics were well shown.

In a speech of much eloquence he first of all defended the Society, whose students he addressed, from the old proverb launched at all such bodies, "that a little knowledge is a dangerous thing," declaring, with Charles Lamb, that like nearly all such popular proverbs, the very reverse of this one was the truth. He insisted that it was the quality not the quantity of knowledge possessed which made it dangerous, and that nothing was really to be so much dreaded as absolute ignorance. But he said that the Society really imparted much more than a little knowledge, and that its teaching was of great value.

The main part of Sir James Paget's address, however, was occupied with a consideration of the things learnt in a scientific education. They were four: first, the power of observation; secondly, accuracy; thirdly, the difficulty of attaining a real knowledge of the truth; fourthly, the methods by which they could pass from that which was proved to the thinking of what was probable. He pointed out to the students he addressed that even though they lived in London there was much they could study—the wild birds of the parks, for instance, or the wild flowers and weeds that grow on every piece of waste ground.

In speaking of accuracy he drew a portrait, which we shall most of us recognise, of that considerable body of men "who would not for their lives tell a lie, but who nevertheless seemed as if for their lives they could not tell the exact truth."

Perhaps the most valuable part of the address was the one in

which the speaker dealt with the place and method of theoretical thought in science; inductive reasoning being probably not the strong point of the class of students he addressed. He gave the example of Darwin to show that theories should not be arrived at by vainly and vaguely guessing at possibilities, but by the slow and laborious collection and consideration of facts, and then by working out the probable truth from such material, or, as the great John Hunter said, "Don't think; try."

In his concluding sentence, Sir James dealt with a subject which Carlyle has also treated in his *Sartor Resartus*, the proneness of man to wonder and to take pleasure in wonderment—the quickness with which familiarity makes the subjects of wonder commonplace and ordinary. Perhaps it is not without interest to compare the different modes of thought exhibited by these two men. The scientific surgeon accustomed to deal with facts, to accept them and make the best of them, speaks calmly of these peculiarities of man; they are there, and must be taken into consideration in any dealings we have with our fellows. The philosopher, who believes he has a mission to regenerate the world, rages at the same peculiarities, and by excess of praise and blame seeks to alter those things which the surgeon treats as inherent and unalterable.

"There is another faculty in the human race," says Sir James, "another desire—the love of wonders. Everyone admires them, and nearly all have an insatiable appetite for the knowledge of wonders." And then he goes on to remark: "It is singular to notice how the love of wonders passes from scientific men in their every-day occupation. You look at a machine, so perfect in construction, so exact for the purpose for which it is built, made with such foresight and such precision that the mind of the inventor really seems to be in it; it seems to be working by mind; and there stands the workman by the side of that machine, but his sense of wonder has long since passed away. He knows what is going on; he knows how all is come to pass, and to him that which you think to be a wonder is a common experience of every-day life."

How different Carlyle! "The man who cannot wonder, who does not habitually wonder, were he President of innumerable Royal Societies and carried the whole of the *Mécanique Céleste* and Hegel's Philosophy and the epitome of all laboratories and observatories, with their results, in his single head, is but a pair of spectacles, behind which there is no eye." And, again: "Strange enough how creatures of the human kind shut their eyes to plainest facts, and by the mere inertia of oblivion and stupidity live at ease in the midst of wonders and terrors. But indeed man is and always was a blockhead and a dullard, much readier to feel and digest than to think and consider. Prejudice, which he pretends to hate, is his absolute lawgiver; mere use-and-wont everywhere leads him by the nose. Thus, let but a rising of the sun, let but a creation of the world, happen *twice*, and it ceases to be marvellous, to be noteworthy or noticeable."

Sir James Paget's address ought to be of real use both to the students he addressed and to others who read it.

PROGRESS IN MORALS.

It is a question of much interest and importance whether the great material progress of the present century has been accompanied by any corresponding moral advance. That we have made immense strides in wealth and luxury, in scientific and industrial development, in all the arts and inventions that contribute to ease and comfort, is a commonplace and unquestionable statement. It is more open to debate whether the tone of public morality has risen, and whether vice and crime have undergone any notable diminution. There are not wanting those who regard the growth of great cities—that striking and essential feature of modern civilisation—as conducive to moral degeneracy, and preach a reversion to simple modes of life as a necessary condition of the preservation of a high tone of national character. Much of the argument on this subject is conducted by those who prefer vague declamation to scientific induction, and hence the question has been obscured by rhetorical exaggeration, and often argued with a notable disregard of fact. Let us briefly consider the subject, and, shunning hypotheses however attractive, look strictly to evidence that is incontrovertible.

In proof that the material progress of the century has had a correlative moral advance, we can point to a diminished and steadily declining consumption of intoxicants, and to a notable improvement in the views generally held upon the liquor question. In the last century drunkenness was not regarded as a degrading vice, and hardly constituted a defraction from the character of the fine gentleman. Now the drunkard is held to be scarcely fit for decent society, and even the tippler is rightly viewed as one to be sedulously shunned. Not less encouraging is the altered tone of public opinion regarding such cruel and demoralising pastimes as pugilism and cock-fighting. These are still, no doubt, practised, but scarcely a voice is now raised in their defence.

A welcome addition to the statistics of public morals is afforded by Sir Edmund Du Cane in an article upon Crime and Criminals published some time ago in *Murray's Magazine*. Taking the year of the Queen's accession and that of her Jubilee as a basis for comparison, he is able to point to a highly satisfactory, and, indeed, surprising, diminution in crime. In spite of the fact that the population has almost doubled during this period, we find that the convicts of all classes in the year 1837 were only about one-fifth of their number in 1887. If we compare the sentences to transportation in 1837 with those to penal servitude in 1887, the contrast is only a little less encouraging, the figures being for the former year 3,785, and for the latter 910. The number of executions in 1837 (including those carried out in the colonies) Sir E. Du Cane puts at 46, while for the five years ending 1886 the average was only 14. In addition to these statistical facts, he points out that highway robbery, once very common, is now practically unknown, and that smuggling, from being one of the most frequent, has become one of the rarest of offences. Surely the most confirmed pessimist or the most persistent *laudator teporis acti* can hardly study such facts and continue to deny to this age the credit of growth in morals.

While facts such as the above are beyond dispute, their explanation is more open to casuistry. Sir Edmund assigns the chief credit to the efforts made by benevolent societies to aid discharged prisoners in obtaining honest work, to the beneficial influence of reformatories and industrial schools, and to the gradual spread of education. We have no doubt all these causes, and others, have been in operation. In spite of occasional discouraging signs, we believe that this age has been one of great moral and religious progress all along the line, and that a great advance is constantly being made towards those

Sweeter manners, purer laws,

of which the Laureate sings. How far the work of the churches and of benevolent societies has co-operated with wise legislation and private philanthropic efforts it is not our province to seek to determine, but the general conclusion remains certain.

As regards the most efficient means of dealing with crime *per se*, two points require to be kept in view, namely, that the natural tendency of blind social forces, unless wisely counteracted, is to keep criminal the man who has once fallen into crime, and to cause the offspring of criminals themselves to drift into a criminal life. Of the two problems, the preservation of the young from their threatened evil destiny is undoubtedly much the easier of solution. Hence, the great importance of reformatories and industrial schools, which tend to divert the current of crime at its very source. Heredity is, doubtless, strong, and the children of thieves and vagabonds come into the world heavily handicapped; but there is no reason to doubt that due restraint timely employed, proper education, and the opening up of honourable careers, have been, and are, most efficient means for cutting off the supplies from the criminal market.

The reform of the hardened criminal is a more difficult matter, but without going into other matters, it is certainly essential that we should not regard the man who has once fallen into crime as hopelessly depraved, and that we should afford him the chance of reformation. Such is the aim of the various charitable organisations, which recognise that society has not done its duty to the criminal when it has merely punished him, however deservedly, and that after punishment comes the not less imperative duty of opening up the way to a return to honesty and purity of life.

THE Albert Medal of the Society of Arts for 1887 was presented to the Queen by a deputation from the Council of the Society on Thursday afternoon.

THE Council of Charing Cross Hospital, on Wednesday last, March 7th, unanimously elected Mr. John H. Morgan to the post of Surgeon to the hospital, vacant by the retirement of Mr. Barwell.

WE much regret to have to report that Sir Henry Acland has undergone the operation of removal of the eyeball, due to an attack of hemorrhagic glaucoma of the left eye. He is going on well. The operation was performed by Mr. Henry Power.

THE HOSPITALS ASSOCIATION.

THE next meeting will be held in the Board Room of St. Mary's Hospital, Paddington, on Wednesday, March 14th, at 8 P.M., to hear and discuss a paper by Mr. Thomas Ryan, Secretary of St. Mary's Hospital (late of Queen Charlotte's) on "The Origin, History, Work, and Present State of Metropolitan Lying-in Hospitals." The chair will be taken by W. S. Playfair, Esq., M.D., LL.D. Cards of admission can be obtained on application from Mr. Howard J. Collins, Secretary, The Hospitals Association, Norfolk House, Norfolk Street, W.C.

PHYSICAL TRAINING IN THE ARMY.

A NEW system of drill, combining with it physical training, is being tried at Aldershot, where a number of men were put through the exercise on Monday last, in the presence of the Duke of Cambridge. Major-General P. Smith, from whom the idea emanated, maintains that the physical training of a soldier is entirely neglected in the routine of regimental drill, and, with others of high military standing, realises the want of a minor drill, which combines with it physical training.

LECTURES ON DOMESTIC HYGIENE.

A COURSE of five lectures, on "Domestic Hygiene" (jointly arranged by the Councils of the Parkes Museum and the National Health Society), will be delivered in the Parkes Museum, 74A, Margaret Street, at 3 P.M., on March 14th, 16th, 21st, 23rd, and 28th, by Dr. A. T. Schofield. The subject of the last lecture (March 28th) is "Home Nursing," when clinical demonstrations will be given by trained hospital nurses. After the completion of the course an examination will be held (after Easter), and the Duchess of Albany has consented to present the certificates to the successful candidates.

INFECTIOUS HOSPITAL PROVISION AT THE SEASIDE.

THE local sanitary authorities of those seaside places that at present have no proper means of isolating cases of infectious disease, or of disinfecting infected articles and clothing, would do well to adopt the reiterated advice of the Local Government Board, and make the requisite provision without delay. Such provision need not be on an extensive scale, but it should be in readiness for the reception of earliest cases. The prompt isolation of such cases, and the systematic disinfection of infected houses and articles are the most effectual method of preventing epidemics. Independently of the advantages thus actually derived by the resident population of health resorts, the additional sense of security afforded to the visiting public would, in the long run, fully compensate the local ratepayers for their trivial initial expenditure.

ST. JOHN'S HOSPITAL.

IN view of the grave charges made against the board of management of maladministration of the funds of the hospital, and of the fact that the court of inquiry which the Duke of Northumberland (President of the hospital), Lord Aberdare, and other influential governors have declared to be necessary, has been refused (a refusal which has led to the resignation of the President and many influential governors), we cannot, while the challenge of the editor of *Truth* remains unanswered in the only way in which it is possible to answer it—namely, by an action at law—advise the public to respond to the appeal for funds which the officials of this hospital are now issuing. It should be remembered that the medical management of this hospital has been shown to be unsatisfactory, while its financial management is thus openly challenged, so that in two most essential particulars it is not in a position to claim public confidence until further and ample inquiry has been conceded and has resulted satisfactorily.

THE LATE EMPEROR OF GERMANY.

WE understand that the malady from which the Emperor of Germany has been suffering, and which has now terminated fatally, was renal colic. His Majesty had for several years been subject to sharp attacks of this affection, bearing the pain with great fortitude, but being much weakened on each occasion by the sleeplessness to which it gave rise.

VACANT CHAIR OF OBSTETRICS IN OWENS COLLEGE.

As will be seen from our advertising columns, the Council of Owens College are prepared to receive applications for the vacant Chair of Obstetrics. So far, three local candidates are in the field, namely, Drs. Lloyd Roberts, Sinclair, and Walter. The election will probably take place at the end of this month, and the new professor will be expected to begin his duties in May. All three local candidates hold hospital appointments. What is wanted is a man who has shown himself to be energetic and thoroughly abreast of the latest advances in his own department, and who is thoroughly conversant with medical Continental literature. If to this be added aptitude as a teacher, these are the requirements to be sought for by the Council.

SACCHARITE OF COCAINE.

DR. ANDREW H. SMITH writes to the *New York Medical Record*, "Observing the strong acid property of saccharin, it occurred to me that it could be made to take the place of an acid in combination with the alkaloid cocaine, and thus avoid the extremely bitter and disagreeable taste of the muriate, the salt usually employed. With the aid of Mr. B. Frank Hays, the well-known pharmacist of New York, a salt was obtained which is freely soluble in water, and has an agreeable, sweet, fruity taste—a valuable property when the drug is to be employed in the throat, especially in the case of children. The molecular number of saccharin (a better name would be saccharinic acid) is 183, that of cocaine 303; combined in these proportions a neutral salt is formed having about 80 per cent. of the alkaloidal strength of the muriate, a 5 per cent. solution of the first being equal to a 4 per cent. solution of the second."

THE INFLUENCE OF NASAL DISEASE ON THE THYROID GLAND.

At the meeting of the Berlin Medical Society on January 20th, Professor Fränkel mentioned an interesting case showing the influence of nasal irritation upon thyroid enlargement. The patient, a young man, aged 17, had an enlarged thyroid, with murmur on auscultation, and a pulse of 120, but no exophthalmos. During treatment (with the constant current) the lad complained of nasal obstruction; accordingly, without reference to the other symptoms, the left inferior turbinated bone was removed by the galvano-cautery. Within a few days the thyroid gland rapidly diminished, and the pulse became slower. After waiting three weeks, during which time the symptoms were stationary in spite of the constant current, the right side of the nose was operated on as above four days before the case was reported to the meeting. During these four days the enlargement had again undergone a rapid diminution, and the pulse had become normal. The thyroid had diminished by certainly a fifth of its bulk. Haack, in 1886, had reported a complete cure of Basedow's disease by treatment directed to the nose. Although this case could not fairly be termed Basedow's disease, because both exophthalmos and v. Graefe's symptom (defective movement of the upper lid with the globe) were absent, it certainly showed, Professor Fränkel argued, the influence of nasal irritation upon thyroid enlargement.

THE LATE MR. CURLING.

WE are much grieved to have to announce the loss of one of the veteran masters of English surgery, Mr. T. B. Curling. We are informed by Dr. Brandt, that on Friday morning, March 2nd, Mr. Curling drove out at Cannes, where he was residing for the winter. The day was bright, but owing to the snow on the Alps, the weather was very cold. He was already suffering from a slight cold. During the night he became restless, and shortly afterwards symptoms of pulmonary congestion set in. He was carefully attended by Dr. Brandt and Dr. Frank, but in spite of their united efforts, the symptoms rapidly increased, cerebral effusion supervened, and he breathed his last peacefully at 8.30 on the morning of March 4th. Mr. Curling had a large circle of attached friends, to whom he was endeared by his sterling uprightness of character, tenderness of heart, and the affectionate constancy which underlay his reserved manner. He was an old and valued friend of the JOURNAL, in the progress of which he took a great interest. In making this announcement we have to mourn a personal as well as a public loss. In another column will be found a brief obituary notice of this able and distinguished man.

INFLAMMATION MASKING CANCER.

DR. ORECCHIA has recently called attention (*Gazzetta degli Ospitali*, March 4th, 1888), to the frequent combination of inflammation with cancer in the same part, the graver disease being sometimes so obscured in this way as to be overlooked for a considerable time. He reports six cases in which this occurred. In one of these cancer of the larynx was supposed to be nothing more than perichondritis; in two malignant disease of the jaw was mistaken for osteitis; in another periproctitis for some time masked a rectal cancer; parotitis concealed cancer or sarcoma of the parotid; and simple inflammation of the lip, an epithelioma. The possibility of malignant disease underlying what appears to be a simple inflammatory process should never be forgotten when the age and appearance of the patient, and the part affected, are such as to make the existence of carcinoma probable. Dr. Orecchia believes that in these cases the cancer is the primary disease, which, owing to the slightness of the symptoms, remains unnoticed till the supervention of inflammation calls attention to the part. In the stroma of all the tumours referred to, Dr. Orecchia found much extravasated blood, with abundance of leucocytes, of which there were also a great number in the neighbouring tissues.

ERYTHROPHLEIN.

THIS African product has been the subject of a lively debate in the Berliner Medicinische Gesellschaft (*Berliner Klin. Wochenschrift*, 1888, March 5th, also February 27th). Dr. Lewin asserted that it possessed a local anæsthetic action far stronger than that of cocaine. Professor Liebreich replied that the sample examined by Dr. Lewin was in reality a snake poison, and that the rosy red coloration produced by evaporation with sulphuric acid is shown also by snake poison, and even by dried egg or serum-albumen. Dr. Schöler read a paper at the last meeting of the above Society, in which he confirms Lewin's results. An erythrophlein solution of 1-5 per cent. strength, when dropped into the eye gave rise to a good deal of irritation at first, but perfect insensibility of the cornea ensued in about twenty minutes (or half an hour). The pupil was not affected and intra-ocular pressure was lowered, but a slight degree of hyperæmia of the conjunctiva persisted for a long time, and the subject of experiment complained of a feeling of weight in the upper lid, a sensation as of a veil before the eyes, and of interference phenomena—for example, coloured rings. On the other hand, Dr. Loewenhardt, of Breslau, writes in the *Berliner Klin. Wochenschrift* (March 5th) to the effect that he obtained no

anæsthesia, but a considerable degree of hyperæsthesia, after subcutaneous injection in animals, and found that he could easily produce sloughing. Dr. Epstein, of Nürnberg, in an original communication to the *Centralbl. f. Klin. Med.* (March 3rd), finds that erythrophlein has only a slight local anæsthetic action when subcutaneously injected, and that a good deal of pain is caused by it. So far then this last observer is opposed to Dr. Lewin, who said in his communications to the Berliner Med. Gesellschaft that erythrophlein had a marvellous power of producing anæsthesia. The difference of opinion evolved by this statement has had the effect of bringing a number of experimenters upon the field of action and no doubt precise results will soon be afforded from uniform samples of erythrophlein.

THERAPEUTICS WITHOUT ALCOHOL.

THE Temperance Hospital has been in existence now about twelve years, and the annual report for 1886-7 may be studied with advantage in order to compare the results with those of other hospitals. It must not be supposed that the hospital only receives abstainers, though these are in the majority, probably due to the large proportion of infants and children. In the surgical department the results have been very satisfactory, so far as one is enabled to judge from mere figures, but turning to the medical cases, we may restrict examinations to one or two groups of disease, with advantage. Out of thirteen cases of acute pneumonia, four (abstainers) died, one of them on the fifty-fourth day from exhaustion. Only four cases of typhoid fever were admitted in all, and although the cases were of young people—15, 7, 14, and 35 respectively—and comprised three abstainers, they all proved fatal. The treatment was the same as elsewhere, and the only difference consisted in the non-exhibition of alcohol. Then again, simple exhaustion, eighty-seven days after the onset of the disease, proved fatal in one instance. The average stay of patients in the hospital would seem to show that convalescence is unduly prolonged, and this, notwithstanding the fact that the list of cases comprises several of "nasal catarrh" and other trivial complaints. The only occasion on which alcohol was administered was in a case of operation for strangulated hernia, in which death resulted from an unreduced constriction. Every credit is due to the registrar, Mr. Leopold Hudson, for the clear and practical manner in which he has tabulated and arranged his figures. We shall look forward with interest to future reports drawn up on the same excellent plan, as it is only by comparing results that medical men will be enabled to judge the merits of treatment without alcohol. Thanks to the impartial summary with which the report opens, it is easy to grasp its general tenour. It constitutes an innovation which other hospitals would do well to copy.

PRIMARY MELANOSIS OF THE VULVA.

DR. TERRILLON has recently described a remarkable case of this kind which he observed at the Salpêtrière in 1885. The patient was an insane woman, aged 62, with anæsthesia on the right side. She complained of pain in the vulva, and on the inner side of the right labium minus was a small tubercle the size of a nut, hard, smooth-surfaced, and very black; outrunning rays of tumour-substance proceeded from its periphery. The labium around the tubercle was deep black, but patches of healthy integument still remained. This discoloration extended to the vaginal mucous membrane, the cervix, and the opposite labium. No other tumour could be found, nor was there any glandular infection. Two months later the pigmentation had made no further progress, but the tumour had grown larger; it was removed by the thermo-cautery. The epidermis and corium were both found to have undergone alteration; in the corium were collections of round cells bearing pigment: and altogether the tumour appears to have

been a melanotic sarcoma. Four months after the operation there was no recurrence, but a month later the right inguinal glands began to enlarge, and soon multiple tumours developed. At the eighth month after operation melanotic tumours were found on the left labium minus, the posterior vaginal wall, and the meatus. The vagina and cervix were jet black. In the right groin was a large hard mass; its black coloration showed through the tense integument as yet unpigmented; a black tumour was found on the back, and indurated glands were discovered in the left groin and the right subclavian fossa. There was general cedema. Pigment granules were found in the blood, which contained an undue proportion of white corpuscles. The urine on standing for some time exposed to the air became almost like ink. A month later the patient died after severe dyspnoea and abdominal pain. All the pelvic, abdominal, and thoracic glands were melanotic, some being reduced to a black semi-fluid mass; the liver and the spleen were riddled with little black masses. M. Cornil found that all the infected parts presented the microscopic appearances of diffuse melanotic sarcoma.

MALFORMED VAGINA COMPLICATING LABOUR.

DR. FLEISCHMANN has described, in the *Prager Medicinische Wochenschrift*, amongst a series of contributions based upon material gathered in Professor Breisky's wards, the case of a primipara who had, during labour, very strong and unusually painful uterine contractions. When these had continued for two hours, a transverse line could be seen under the integuments, about the level of the umbilicus, indicating the limits of the body of the uterus and its thin-walled lower segment. During each pain it was found that the foetal head, evidently retained at the outlet, pushed forwards a very tough septum, as thick as the finger, and lying in an almost median position; this septum was inserted into the edge of the hymen and of the vagina, just above that membrane. It was ligatured in two places, and cut through. Convalescence was rapid. The local appearances, when the patient was discharged, were as follows. Tracing upwards from the remains of the septum in front and behind, a comb-like crest was found to run along the vaginal wall of the cervix. These crests were continued to the cervix, where they ended in a septum which ran right up the cervical canal and the uterine cavity, as far as the fundus. That cavity was thus divided into a large and a small lateral compartment; the larger, which appeared to have contained the placenta, was on the left side. The malformation was of that kind known as vagina subsepta and uterus bilocularis. The case is of considerable practical interest; anything like a double vagina is very puzzling to the obstetrician if unrecognised till the beginning of labour, or, later still, in the stages of parturition.

MULTIPLE SALIVARY CALCULI.

DR. NIKOLAI J. MOISEFF, of Shtchizry, reports (*Proceedings of the Shtchizry Medical Society*, vol. i, 1887, p. 68) the case of a retired major-general, aged 70, who sought his advice on account of incessant profuse salivation, pain on deglutition, and sublingual swelling of several years' standing. An oblong, hard elevation was found along the course of Bartholin's duct, which, even on slight pressure, gave the finger a distinct grating sensation. The duct was considerably distended along its whole course, and contained three salivary calculi lying in close contact. The nearest and smallest concretion, of the size of a big pea, was easily removed with forceps, but the other two could be extracted only after slitting up the duct, since they were considerably larger, especially the deepest one, which measured two centimètres in length and one in breadth, and, in addition, was intimately adherent to the gland substance; it resembled a bird's bill in shape. When dry it weighed 2.2 grammes, and consisted of a compara-

tively hard and compact nucleus, with a spongy, friable outer capsule. The smallest calculus was of pyramidal form, of spongy consistence, and greyish-yellow colour; while the middle one was quadrangular, with rounded angles, and of a distinctly laminated structure. The total weight of the dried calculi was thirty-eight grains. The wound healed well in a week. Dr. Moiseff has been unable to find another recorded instance of multiple calculi simultaneously present in the same salivary duct.

LAPAROTOMY FOR DILATATION OF THE COLON.

A REMARKABLE case of fecal accumulation is reported by Dr. Worrall in the *Australasian Medical Gazette* in a girl, aged 14. She was brought to the hospital suffering from an enlargement of the abdomen, which had been gradually increasing for two months. The patient had not had any previous illness, and her mother "thought" her bowels were not regular. On examination a solid tumour, neither painful nor tender, was found to fill the whole abdomen except portions of the left hypochondriac and left lumbar regions, having its greatest prominence to the left of the umbilicus. The tumour was hard, nodulated, and irregular. It seemed to touch the liver above and dip into the pelvis below, being bounded laterally to all appearances by the colon. The tumour could be moved slightly in every direction. A day or two after admission, although the bowels were moved several times daily, a laxative powder and an enema were given prior to examination under chloroform. As the rectum was found to be still blocked with feces more aperients were ordered, and for the next ten days there was diarrhoea with numerous horribly offensive stools. The temperature averaged 101° F. It was decided to perform an exploratory laparotomy. On opening the abdomen what looked like an enormous cyst, fluid above and solid below, was seen, which on being opened was discovered to be the ascending colon enormously hypertrophied and dilated. The wound in the colon was sutured, and the abdominal incision closed. Not the least remarkable feature of the case is the fact that the youthful patient was discharged quite well on the fourteenth day after the operation.

CASTRATION AND THE DEVELOPMENT OF THE GENITAL TRACT.

DR. KEHRER, in 1879-80, made a series of experiments to ascertain the effect of castration on the development of the genitals in young animals; the results were published in his *Beiträge zur Klinischen und Experimentellen Geburtshunde und Gynäkologie*. He castrated rabbits between two and three months of age, and killed them one year later. He found that unilateral castration or spaying caused no arrest of development; on the other hand when the operation was performed on both sides, the genitals and mammary glands remained stationary, never developing beyond the stage which they had attained when the essential organs were removed. Dr. Kehrer attempted to prove which theory was true—Pflüger's, according to which there existed in the uncastrated female a stimulus to growth through periodical irritation of the ovarian nerves set up by the ripening of follicles which goes on long before puberty; or, on the other hand, the theory that spaying caused a disturbance of the blood supply of the remaining genital organs, through the occlusion of the ovarian arteries. For this purpose he ligatured the ovary and ovarian artery in two series of experiments. He found that neither in unilateral nor in bilateral ligature of the tubes or extremities of the uterine cornu, with separation of the ovarian arteries, was the normal development of the genitals in any way affected. He concluded that the ovarian nerves, or some other and unknown influence in connection with the ovaries, played the most prominent part in stimulating the development of the genital tract.

THE ILLNESS OF THE CROWN PRINCE.

It is with the greatest satisfaction that we learn by special telegram from San Remo that the general condition of the Crown Prince is now very good. The irritation of the windpipe that was so troublesome for some time has almost entirely disappeared, but there is some increase in the swelling within the larynx. We may add that we are able to confirm this comparatively favourable account by independent information which we have received from a perfectly trustworthy source. We are in a position to state that neither Sir Morell Mackenzie nor Mr. Hovell is inclined to share the pessimistic views recently made public, though they do not of course deny the possibility of the disease proving to be cancer. With regard to a rumour which has been largely current in society, and which lately found most unseemly expression in a French contemporary, we have the fullest authority to deny, in the most emphatic manner, that there is any ground for such a suspicion. We may repeat that the recent sufferings of the illustrious patient have been almost wholly due to the irritation caused by an ill-fitting tracheotomy tube. The operator, as was perhaps natural under the circumstances, appears to have been rather nervous, and the windpipe was opened some way to the right of the middle line; hence the difficulty of finding a suitable tube. Sir Morell Mackenzie, assisted by Mr. Hovell and Dr. Evans, the well-known dentist of Paris, spent the greater part of one day in constructing a tube of a shape specially adapted to the requirements of the case. Since this has been worn the Crown Prince has been more comfortable in every way; he has been able to sleep, the cough has diminished, and the expectoration has almost lost the blood-stained character which excited so much alarm. It is satisfactory to see from the official bulletin lately published in the *Reichsanzeiger* that the medical men are now in substantial agreement as to the nature of the disease. We do not think, however, that the inference which has been drawn from this in certain quarters, that Sir Morell Mackenzie has abandoned his recently published opinion on the subject, and adopted the less favourable view of some of his colleagues, is altogether warranted. Although the result of Professor Waldeyer's microscopical examination has not been published, we have reason to believe that it is such as to admit of a favourable interpretation.

THE TREATMENT OF UTERINE FIBROIDS.

THE theories and practice of Apostoli have led to much discussion on the treatment of fibro-myomatous tumours of the uterus, more conveniently termed uterine fibroid disease. This method, like everything else in the universe, is the effect of a cause. In this case, the cause is the danger of amputation of the uterus, balanced by the uncertainty of palliative measures. Electricity is a fascinating middle course between physic, often so impotent, and the knife, often so fatal. A fibroid uterine tumour may assume gigantic proportions, and cause serious trouble; but its increase in bulk is never rapid, in the same sense that the growth of a cyst or a sarcoma is rapid, and the menopause is often its limit. Yet it may be the source of pain, menorrhagia, and often troublesome and dangerous symptoms. Then operative measures are suggested. In the case of hysterectomy or oöphorectomy, the operation is always perilous, and depends, perhaps more than any other surgical operation, on the experience as well as the mere skill of the operator. Hence gynaecologists turn to palliatives or electrolysis. With respect to palliatives, it is certain that almost any rational treatment tends to reduce the size of a large fibroid tumour. Rest, moderate purgation, and the administration of ergot without any of those incompatibles with which it is often given, all appreciably affect tumours of this kind for a time. Authorities of the negative or expectant school believe in Woodhall Spa. The amount of benefit derived from palliative treatment is ever uncertain.

though permanent arrest of the tumour is occasionally effected. When an operation is contemplated, the choice lies between oöphorectomy and hysterectomy. Surgeons without special experience too often look on oöphorectomy as an easy and safe operation; but facts have shown that, in the case of fibroids, it is often difficult or impossible, and that when possible it is perilous, owing to the difficulties experienced in securing the pedicle. Enucleation during abdominal section is not justifiable. Hysterectomy may be performed as an intraperitoneal or an extraperitoneal operation. The intraperitoneal variety is logically the better, but it is extremely dangerous. No surgeon can calculate how to tie each suture firmly enough to check hæmorrhage, yet not so tightly as to cause sloughing or tearing of the thread through its track; still less can he guard against contraction or relaxation of the uterine tissues around the uterus after the return of the stump into the abdominal cavity. The extraperitoneal operation is less dangerous; but it requires nerve, dexterity, and experience at least of other surgeons' practice. Statistics are absolutely worse than useless as guides to surgeons devoid of special experience; and decision, sad to say, is too frequently qualified by personal predilection for some operation, or by dislike for another. Unconscious hypocrisy often influences inexperienced operators. Apostoli's electrolysis is fascinating, because, unlike palliative treatment, it means "doing something;" whilst many believe that it involves neither the difficulties nor the risks of operation. Experience is proving, however, that Apostoli's method requires great skill and demands many precautions, and that it is not altogether free from danger. As to permanent results, even so respected an authority as Dr. Keith depends upon the words of another, and that other is Apostoli himself (*JOURNAL*, December 10th, page 1258). The conclusions to which we are led by the above facts are that palliative treatment is the only course which a practitioner without special experience can justifiably pursue in the case of uterine fibroids; and that the relative merits of oöphorectomy, hysterectomy, and electrolysis can only be decided by experts.

AN ERGOT-MILL FOR OBSTETRIC BAGS.

DR. LOVIOT, in describing Professor Pajot's obstetric bag in the *Annales de Gynécologie*, notes that it contains an ergot-mill. This instrument resembles a small coffee-mill, bearing, like that familiar domestic instrument, a handle, but in size it is not larger than a pepper-mill, and might work by the same simple mechanism. It may readily be packed in the bag, as it takes up very little room. The practitioner can only rely on freshly pulverised ergot of rye. This mill enables him to powder the ergot on the spot, so that in the hour of need a strong preparation of the drug may be made in the patient's chamber, even in the most remote country districts. In this manner perilous delays caused either by inert liquid preparations of ergot, or by waiting till some fresh tincture or fluid extract is brought to the lying-in room from some distant druggist's shop, are avoided, to the great advantage of the patient and the practitioner.

COMPARATIVE STUDY OF THE ACTION OF VARIOUS DRUGS ON THE HEART.

AT the Italian Medical Congress, held at Pavia, Professor Rummo and Dr. Ferranini read a paper on this subject. They have made experiments in the laboratory attached to Professor Cantani's *clinique* on frogs, toads, crustacea, guinea-pigs, rabbits, and dogs, with the view of determining the precise mode of action of those drugs which have a definite effect on the heart. They used the graphic method throughout, and the drugs which they experimented upon were: digitalis and digitalin, strophanthus and strophanthin, upas antiar, helleborin, erythrophlecin, oleander, spartein, caffeine, adonidin, and convallamarin. They observed that these drugs

first diminished the frequency of the pulsations and augmented the blood-pressure in all animals (homothermic and heterothermic), whereas in a second stage, especially when the doses were toxic, they disordered the rhythm of the heart, and diminished the blood-pressure. In a third stage, a diastolic pause of the cardiac action, after the use of all the drugs, supervened in heterothermic animals, whereas in the homothermic ones, the heart stopped in the systolic phase only after certain drugs, such as digitalin, strophanthus and strophanthin, helleborin, erythrophloëin, upas antiar, oleander; adonidin and convallamarin, however, produced in these animals, even in small doses, a diastolic pause of the cardiac action. Spartein and caffein, on the other hand, had no great influence on the blood-pressure. As regards the mode of action of the drugs used, it must be remarked that strophanthus and strophanthin, helleborin, digitalis, erythrophloëin, upas antiar and oleander, chiefly influenced the heart-muscle, and in the second place, the cardiac nerves. Adonidin and convallamarin simultaneously influenced the cardiac muscle and the cardiac nerves, whereas spartein, and particularly caffein, chiefly affected the cardiac nerves, and the heart-muscle little, or not at all. All those drugs which augmented the blood-pressure, did this by means of a combined mechanism, as they simultaneously increased the systolic energy of the heart, and produced narrowing of the peripheral blood-vessels by irritation of the vasomotor centres. The experimenters, furthermore, tried to answer the question whether those drugs which had a particular influence on the cardiac muscle had also an effect on the striped muscles in general, and whether those which influenced the cardiac nerves could also produce a similar effect on the whole nervous system. They found that only those drugs which chiefly influenced the cardiac nerves produced also, to a certain extent, disturbances in the nervous system in general.

CREASOTE IN PULMONARY PHTHISIS.

In the *Meditzinskoë Obozrenië*, No. 23, 1887, p. 1024, Dr. P. Bogdanovitch, of Yalva, publishes very interesting personal observations on the therapeutic value of creasote in phthisis. The writer, who has been suffering from pulmonary and laryngeal tuberculosis for about two years, had tried the drug on himself in small doses (half a grain four or five times a day) some time ago, but without appreciable benefit. After perusal of the observations of Professors Sommerbrodt (*Berlin. Klin. Wochenschrift*, No. 15, 1887) and Guttman (*Deutsche Med. Zeit.*, No. 42, 1887), however, he again began to take creasote in gradually increasing large doses, beginning with four grains a day, and reaching, in about two months, a daily dose of forty-four grains. There took place, fairly rapidly, an unmistakable and permanent improvement in his symptoms. Fever disappeared in a week; expectoration, cough, and dyspnoea steadily decreased to a considerable degree; laryngeal spasm, which had formerly occurred once or twice every month, ceased altogether. As regards the objective signs, however, there was only some diminution of dulness over a certain area, with complete disappearance of fine crepitant râles. As to tubercle bacilli in the sputum, they remained just as numerous as before the creasote treatment. The latter has lasted in all four months, during which period not less than four ounces and two drachms of pure creasote have been ingested. The drug must be taken in doses of about five grains four times daily, in the form of capsules (filled up *ex tempore*), after meals. With regard to disagreeable after-effects Dr. Bogdanovitch observed in himself, when, by way of experiment, he took as much as twelve grains, at a time, or twenty grains in the course of an hour, only giddiness, cardiac palpitation, small and accelerated pulse, general weakness, pallor, and anxiety; but all these toxic phenomena disappeared spontaneously and com-

pletely in about half an hour or an hour. On an empty stomach, however, he experienced epigastric uneasiness and pain even from small doses. Dr. Bogdanovitch resumed of late the use of creasote in order to study the effect of a six months' course. Dr. Hermann Sahli's paper on Guaiacol as a Substitute for Creasote (*see the JOURNAL*, vol. ii, 1887, p. 1237) seems to be unknown to him.

ACUTE INFECTIOUS PHARYNGITIS.

THE above term, which should be supplemented by the word "primary," is used by Professor Senator (*Berliner Klin. Wochenschrift*, 1888, Nos. 5 and 6) to indicate a rare and "perhaps always fatal" form of pharyngitis, not hitherto described in textbooks of medicine. Two examples had occurred within the last few months, and a study of similar cases had revealed three more as having occurred within the last twelve years. In all these cases, reported at a meeting of the Berlin Medical Society on January 4th, and discussed on January 18th, the disease affected previously healthy persons, without any apparent cause, and ran an acute course, ending in death in a few days. It began with cervical pains and dysphagia, accompanied by fever, often moderate; then followed hoarseness, or loss of voice, and dyspnoea; finally, the sensorium was affected, and death quickly ensued. The chief anatomical sign found *post mortem* was diffuse purulent infiltration of the deeper tissues of the pharyngeal mucous membrane, the inflammation extending to the trachea and glands of the neck and secondarily to other parts, especially the gastric mucous membrane. Senator is of opinion that many cases hitherto regarded as examples of acute oedema of the larynx are in reality cases of the above disease. Notably in a case of Cruveilhier's the pharynx was affected for a day or two before the larynx. The very rare "typical oedematous laryngitis," mentioned by Sir Morell Mackenzie as of septic origin, is also claimed as in all probability affording an example of the above disease. The spleen was generally enlarged in Senator's cases, and the kidneys, as a rule, showed parenchymatous inflammation. A peculiar exanthem appeared in one case. The blood removed both before and after death had been carefully examined, but no specific microorganisms had revealed themselves in attempted cultivations, injections of which, as also of fresh blood, had been harmless in rabbits. The streptococcus of Friedländer (*erysipelas coccus*) was certainly absent. In the discussion which followed, Dr. Guttman argued that the cases were probably erysipelatous in spite of the above fact, and referred to Ziemssen's *Special Pathology*, an *Eichhorst's Pathology*. Virchow leaned to Guttman's opinion, but also described other pharyngeal diseases which might mislead especially metastatic abscesses in puerperal fever, suppurative pharyngitis accompanying acute gastritis and, in one case, mediastinitis. But Senator urged in his reply that there was no abscess in any of his cases, but a diffuse purulent infiltration always beginning in the pharynx. The cause was absolutely unknown to him at present, but the system was very rapidly affected in a characteristic manner, and tracheotomy was of no avail. He had no doubt that a study of the subject as revealed in hospital records would reveal numerous examples of this disease overlooked under the title of "acute oedema of the larynx."

ETIOLOGY OF CROUPOUS PNEUMONIA.

At the meeting of the Italian Medical Congress at Pavia, Professor Bozzolo communicated the results of investigation on the etiology of croupous pneumonia, which he had carried out together with his assistant, Dr. Tassinari. In their experiments they used flu which had been obtained from hepatised lungs during life puncture, on the fifth or seventh day of disease, before crisis had yet supervened. They prepared cultures on bouillon or agar-agar, and, in order that the virulency of the cultures should be

be weakened, the animals on which it was used were first inoculated with the impure culture of the sterilised nutrient fluid. In eight out of fifteen fresh cases, the development in the cultures of Fränkel's diplococcus was observed; it killed rabbits, but had no effect on guinea-pigs. The rabbits died in the course of twenty-four hours, and their blood was full of diplococci. Professor Bozzolo had observed similar facts in 1882, when he reported them to the Academy of Medicine of Turin. The same micro-organism had also been detected by him in a recent epidemic at Cuneo, in which, besides pneumonia, several cases of pronounced meningitis, had also occurred. In five cases the staphylococcus aureus and albus, the staphylococcus pyogenes albus, citreus and aureus, either alone or together with the diplococcus, could be proved to be present. In one case, which proved fatal owing to œdema of the glottis, numerous diplococci had been found in the subcutaneous cellular tissue of the larynx. In no single case had the coccus pneumoniæ of Friedländer been found. Professor Bozzolo deduces from these facts the conclusion that the coccus pneumoniæ played no important part in the development of this disease, and that the epidemic which had been observed by him was to be looked upon as having been produced by the diplococcus. He maintains that until the contrary has been proved, we are not justified in considering idiopathic croupous pneumonia as being caused by different micro-organisms.

THE DISCOVERY OF CONCEALED INSANITY.

IN a recent number of the *New York Medical Journal* a rather startling and novel suggestion is made for the use of nitrous oxide for the detection of concealed insanity. Dr. A. M. Hamilton is the author of this suggestion. He points out that anaesthetics are often of great service in detecting shamming, and that as an extension of this, the use of some of these may be of service in unmasking symptoms which may be concealed from one cause or another. We shall not spend much time in discussing the moral side of the question, though it strikes us that there would be many in England who would object strongly to the production of this temporary loss of control only to see what was to be found in the lower stratum of mind. We are all familiar with the effects of alcohol, and we know how many friendships are cemented and how many are broken by the glimpses given into the hidden world of character by the effects of wine. Truth is revealed by this we know, but as a medical means of investigation we are behind our cousins in its use. Our author has been trying its effects for ten years; we, therefore, must not pass over his remarks without some consideration. He finds that, in some cases, nitrous oxide gives sleep where it is much wanted from temporary causes. We fancy that this gas is hardly likely to become dangerous in the way that chloroform has to the medical man who cannot sleep, and so we welcome the suggestion as one more means to produce what becomes daily more needed and daily more difficult to obtain—sleep for the brain-disordered man who must work or starve, and who cannot work without sleep. We have tried all the known anaesthetics in cases of insanity, and cannot speak with any praise of the results. In melancholia the sleep produced does no real good, and in mania we have not had the least improvement following sleep so produced and kept up or hours together. Chloroform, amyl nitrite, and even duboisin have been given with the idea of changing the current of thought but in vain, save that with amyl we have seen some passive cases become hysterical, and with duboisin some cases of depression have become for a short time maniacal. Alcohol has saved many lives in acute insanity, but we have not found that it assisted to the real understanding of any case; that is, that drink loosened the tongue and dispelled the delusion. It is a very plausible thing to say that certain delusions which are hidden and are really the ground for the acts of certain patients can be discovered by means

of nitrous oxide, but we fancy no medical man would be prepared to sign a certificate on the evidence obtained while a person was under its influence. We have also to assume a good deal when we say that the true nature of a person is revealed by the removal of the control. We might come to many strange revelations not conducive to domestic happiness if this treatment were pursued far. Besides this, it seems that if there is any truth in the observation made by Dr. Savage on the effects of anaesthetics in producing insanity, that occasionally harm might result in an unexpected way. Our author admits there is a great possibility of "suggesting" ideas to the person as he passes into the stage of unconsciousness: this should make us hesitate before making use of a weapon so dangerous and easily perverted. He says hypnosis is unreliable and not always justifiable. We should be inclined to say the same of the use of nitrous oxide for the detection of concealed delusions.

THE TREATMENT OF SNAKE-BITE BY AMMONIA.

WELL authenticated cases of recovery from the bite of a cobra are sufficiently rare to lend special interest to a report published by Dr. Percy Rigby, in the *Indian Medical Gazette*. The patient, a Hindu, aged 30, was bitten, in the presence of a hospital assistant, by a young cobra two feet long, the wounds of both fangs being visible; four hours later he was brought to the dispensary, unable to stand or raise his head, gasping for breath, with copious salivation and bronchorrhœa, and full soft pulse; the bite had been inflicted on the back of the hand, and the hand and forearm were much swollen. A solution of permanganate of potash (5 per cent.) was injected in the situation of the bite, the salt in powder was rubbed into the wound, and a draught containing liq. ammoniæ π xx was given; the patient grew worse, and was seized with convulsions. The draught was repeated in half an hour, but when two hours had passed, the patient appeared to be sinking fast; an hypodermic injection of liq. ammoniæ π xv with an equal quantity of water was given, and repeated in half an hour; finally several convulsive seizures occurred, the respirations sank to 6, and the patient seemed *in articulo mortis*; he was however given another draught containing ammonia, and in ten minutes began to rally, and in about three hours more was out of danger. The next day the temperature was 101.2° F., and the arm was much swollen; no ulceration was produced by the hypodermic injections. A second case was mentioned in which the injection of strong ammonia and tight bandaging of the leg was effectual against the bite of *Dabria Elegans*.

AMYLENE HYDRATE AS A HYPNOTIC.

DR. GEORG AVILLES has made a number of new experiments in the clinic of Professor Riegel at Giessen with "amylene hydrate." The following is a summary of his results:—1. Amylene hydrate is a hypnotic, the effect of which is certain if it is given in sufficient doses. Control experiments have shown that amylene hydrate has a less powerful effect than chloral, and a more powerful one than paraldehyde. 2. Amylene hydrate had also an influence on people who were accustomed to the use of narcotics, these, however, required a larger dose (4 grammes). 3. Sleep came on very quickly without a stage of excitement. The intensity of the sleep varied according to the quantity of the dose, but the patients could always be easily aroused. When awakened, they at once became fully conscious, and, if undisturbed, they immediately fell asleep again. 4. The sleep lasted, after very small doses, from two to three hours; after large doses (from 2.0 to 3.2 grammes) from six to eight hours. 5. The awakening resembled that after natural sleep; the patients felt refreshed, and there was neither headache nor lassitude. 6. Respiration was not affected. 7. There was no change in the pulse or the blood-pressure, except

the retardation of the pulse, which was also observed in the normal sleep. This was shown by sphygmographic tracings of different patients made by Professor Riegel. 8. There was no bad taste in the mouth nor disagreeable smell of the breath on awakening, such as was noticed after paraldehyde. 9. As to whether patients were liable to become habituated to the drug no decision could yet be arrived at. In no case had they been obliged to increase the dose, even after repeated use. Disagreeable after-effects of a somewhat dangerous character were observed only in two cases; in three cases it had no effect at all. The drug was tried in various internal diseases; the effect was particularly good in jaundice and icteric itching of the skin. Chloral hydrate had been recommended by Eichhorst, but amylene hydrate would be better as it had no weakening influence on the heart. In all cases of disordered circulation, the amylene hydrate was preferable to chloral, as the latter considerably diminished the pressure in the vascular system. No counter indications could be found. In severe disorders of the stomach it was to be administered by clysters, according to the following formulae:—R Amylene hydrate, 3.0 grammes; aq. destill., gumm. arab., aa 25.0; m. ft. clyster.

SCOTLAND.

HONORARY DEGREES, ABERDEEN UNIVERSITY.

AMONG the honorary degrees conferred by Aberdeen University last week on those considered worthy of the honour was that of LL.D., which was conferred upon Charles Douglas Ferguson Phillips, M.D., London, who is a graduate of Aberdeen University and a Fellow of the Royal Colleges of Physicians and Surgeons.

LADY STUDENTS AT LEITH HOSPITAL.

THE lady students of medicine who are doing their clinical work in Leith Hospital, are so well pleased with the treatment by the staff of the hospital, that at the annual meeting of the supporters of the institution, held last week, Dr. Sophia Jex Blake, in moving the usual vote of thanks to the staff, also thanked them for their kindness and care bestowed upon the lady students in every part of the hospital.

GLASGOW ROYAL INFIRMARY.

DR. NEWMAN's class of laryngology for students and practitioners has just been brought to a close after a most successful session. No less than 105 students joined, and maintained throughout a very good attendance. After the distribution of class honours the students presented Dr. Newman with a pair of study lamps, and his assistant, Dr. Dewar, with a case of surgical instruments.

THE POLLUTION OF THE CLYDE LOCHS.

MR. A. E. FLETCHER, inspector under the Rivers Pollution Act, has recently made a report to the Government on his examination of the waters of Loch Goll and Loch Long in reference to their alleged pollution. The dredgings from the Glasgow and Greenock harbours, and from the Clyde, are deposited at the entrance to Loch Long to the extent of one and a quarter million tons per annum. Besides this, Loch Long receives a weekly deposit of 150 tons of alkali waste from a chemical work, discharged directly into the loch, and indirectly the waters are polluted by the sewage from Glasgow discharged into the Clyde. Mr. Fletcher submitted specimens of the water and of the bottom of the lochs to analysis, and also of the floating scum. Mr. Fletcher finds that the complaints of pollution are well founded, and that the material yielded by the alkali waste is poisonous to fish. While much of the pollution is of local origin, Mr. Fletcher thinks the

making of Loch Long a receptacle for the refuse of Glasgow and neighbourhood is a gross evil, which should now be stopped.

PROPOSED FRIENDLY SOCIETIES' MEDICAL ASSOCIATION.

A JOINT meeting of friendly societies was held in Glasgow last week for the purpose of hearing reports from various representatives as to the feasibility of establishing among them a medical association for Glasgow and district. There were 150 delegates at the meeting, and they represented 13,500 members of various friendly societies. The reports submitted showed that 29 lodges, courts, and tents, with membership of 5,356, were favourable to the establishment of such an association, while 42 were doubtful and desired more information. It was resolved to afford the desired information, and to hold another meeting for further consideration of the subject and arrangement to be held in April.

THE PHYSICAL CIRCUMSTANCES OF GLASGOW POOR.

IN a recent public lecture on "The City in which we Live," Dr J. B. Russell, the medical officer of health, exhibited with great clearness the conditions under which the poor of large towns such as Glasgow live. He succeeded in making statistics pathetic, and in forcibly bringing before the public mind the enormous hindrances to the preservation of health and purity of life which these conditions involve. Contrasting Glasgow with other large towns, he found only one—Liverpool—exceeding it in density of population, and only another approaching to it, namely, Manchester; the density being for Glasgow, Liverpool, and Manchester, 84, 106, and 80 respectively. While 84 was the average for the whole city, it rose to as high a figure as 348 in some of the sanitary districts into which the city is divided, falling to 25 in others. Of Glasgow houses, 30 per cent. consisted of only one apartment, 44 of only two, 14 of three, and only 5 per cent. were of five apartments and upwards. Of the population, 25 per cent. lived in one-apartment houses, 45 in two-apartment houses, 16 per cent. in three-apartment houses, 6 per cent. in houses of four apartments, and only 8 per cent. in houses of five apartments and upwards. In no other town in Scotland is so large a proportion of the population confined to one-apartment houses, and no other town in Scotland has so small a proportion living in the larger houses. One of the worst features of the small houses was that 14 per cent. of them contained lodgers. It was these small houses that gave to the death-rate the striking characteristics of an enormous proportion of deaths in childhood, and of deaths from diseases of the lungs at all ages. In such districts the annual death-rate was 48 per 1,000. "Of all the children," Dr. Russell went on to say, "who died in Glasgow before they completed their fifth year, 32½ per cent. died in houses of one apartment and not 2 per cent. in houses of five apartments and upwards. There they died, and their little bodies were laid on a table or on the dresser, so as to be somewhat out of the way of their brothers and sisters, who played, and slept, and ate in their ghastly company." Dr. Russell concluded a very striking lecture by showing how much improvement had been effected in Glasgow since 1861, and how much might yet be done by providing air spaces and play spaces, and means of recreation, culture, and instruction for the people.

AYRSHIRE MEDICAL CLUB.—Dr. Dobie, Ayr, has been elected President of the Ayrshire Medical Club, in succession to Dr. Beedie Robertson, Ardrossan, and Dr. Alexander Dundonald, vice-president. Dr. Moore, Ayr, was re-elected honorary secretary. The membership of the Club now amounts to 48. These appointments were made at a meeting held last week, at which about 30 members of the medical profession were present.

IRELAND.

THE MEDICAL COMMISSIONERSHIP OF THE LOCAL GOVERNMENT BOARD.

As we go to press we learn by telegram from Dublin that Dr. Henry Fitzgibbon, Vice-President of the Royal College of Surgeons in Ireland, and brother of Lord Justice Fitzgibbon, has been appointed to this office in succession to the late Dr. Croker King. The salary is £1,250 a year. There were many candidates for the post.

THE COLLEGE OF PHYSICIANS AND THE APOTHECARIES' HALL.

The proceedings at law between these bodies having, as will be seen from the report published at page 559, been so far unfavourable to the College of Physicians, the President and Fellows have had under consideration the present position of affairs. They are not satisfied with the Vice-Chancellor's judgment, and the case will therefore come before another court on appeal. It is stated by some, moreover, that should the ultimate decision be hostile to the College of Physicians, that body will retire from the alliance with the College of Surgeons, and apply to the Medical Council for additional examiners. It is not quite certain, however, that the Council would accede to this arrangement. There is not any strong feeling in Ireland in favour of the Apothecaries, either among physicians or surgeons. It is probable that if a poll were taken in Dublin, the vast majority would be in favour of their extinction as a body having any function outside the compounding of medicines. But, whether it was right or wrong to recognise them originally as able to give a diploma to practise, is now beside the question. They have been recognised; and they have a representative on the Medical Council. Many think that the only solution of the difficulty is to absorb the Hall in a Conjoint Board, in which it would be allowed to take part in the pharmaceutical portion of the examination. Such an arrangement has been proposed, but has fallen through; and it is not unlikely that it may again be brought forward. The solution of the difficulty apparently lies in this direction. Meantime, the lawyers are the gainers, the "little bill" thus far amounting to something like £800.

CORK MEDICAL PROTECTIVE ASSOCIATION.

At a general meeting held some time since, Professor Stephen Sullivan in the chair, and at which Drs. E. R. Townsend, Power, Magner, Cooper, Golding, Fitzmaurice, Cremin, Jennings, A.M.D., Burke, Cotter, Donovan, Corby, H. R. Townsend, O'Connor, jun., Daly, Riordan, Twomey, Ryan, Hayes, T. Riordan, Guisani, Riordan (Cloyne), Johnstone, Pearson, Crowley, Harvey, W. J. Cummins, Hobart, Sandford, Evans, Moriarty, Crowley, Ryan, Loinihan, Daly, and others were also present. The case of Dr. Magner's dismissal from his dispensary, under sealed order of the Local Government Board, was brought before the meeting. It was pointed out that, as a medical man, Dr. Magner's punishment was far in excess of that received by others guilty of similar offences, inasmuch as he not only suffered the full legal penalty of imprisonment, but was, in addition, dismissed from his post, and, moreover, disqualified from ever again, under any circumstances, obtaining any appointment under the Medical Charities Act. The following resolution was proposed and carried, and directed to be forwarded to the Local Government Board. Resolved: "That we, the members of the County and City of Cork Medical Protective Association, although differing, as many of us do, from Dr. Magner's political views, nevertheless are of opinion that he has been treated with exceptional severity in being deprived not only of his present position

and means of livelihood, but in addition rendered ineligible for an appointment under the Medical Charities Act. We arrived at this conclusion from the fact that previous instructions had been issued by the Local Government Board (as in the case of civil servants and others) prohibiting medical officers of dispensaries from taking part in politics; and moreover Dr. Magner has been punished by imprisonment for any offence committed by him. Under these circumstances, we would respectfully ask the Local Government Board, to re-consider their decision, and withdraw the sealed order dismissing Dr. Magner from the post as dispensary officer of the Courcies District, Kinsale Union." The following is the answer received from the Local Government Board, under date of February 27th:—

Sir,—I am directed by the Local Government Board for Ireland to acknowledge the receipt of your letter of the 10th instant, forwarding a copy of the resolution passed by the Cork Medical Protective Association at a general meeting held on the 7th instant, requesting the Board to withdraw the sealed order issued by them removing Dr. Magner from his position as medical officer of the Courcies Dispensary District, Kinsale Union; and, in reply, I am to state that the Board have given Dr. Magner's case very careful consideration, and are not prepared to withdraw the order removing him from the office in question.—I am, sir, your obedient servant,

THOMAS A. MOONEY, Secretary.

Honorary Secretary Cork Medical Protective Association.

A general meeting will be held on Saturday, March 10th, to consider the correspondence.

INTERHOSPITAL FOOTBALL MATCHES.—The final round of the (Rugby) Cup Tie, St. Thomas's v. St. Mary's, was played at the Richmond Athletic Association's Ground, on Wednesday, March 7th. St. Thomas's, the favourites, kicked off shortly after 3 o'clock, with the wind in their favour. Toller secured a try, but Lambert failed at the place. After half-time St. Mary's played up with great determination, and had two free kicks about their own quarterway flag. The last was a failure, and soon after Senior secured a try, but the place again failed. Subsequently a touch in goal was obtained, and, soon after, time was called, leaving St. Thomas's victors by two tries, one minor—twenty-one points—to nil. St. Thomas's: Back, A. Gedge; three-quarter, H. A. Julius, W. Senior, P. M. Toller; half, R. Hatherall, P. Northcott; forwards, H. J. Cooper, J. H. Dewhurst, T. A. M. Forde (captain), J. Harper, T. Lambert, C. Moxon, W. Milton, F. Pitts Tucker, G. Stillwell. St. Mary's: Back, W. T. Daniel; three-quarter, A. N. Harrison, F. P. Hill (captain), C. A. Balderson; half, S. B. Williams, A. B. Franey; forwards, F. Lewis, G. T. K. Maurice, F. C. Martley, J. A. Aikinson, C. F. Warren, J. O. Summerhays, H. Legge-Willis, H. F. Ealand, C. D. Leyden. The final round of the Interhospital (Association) Cup, St. Bartholomew's v. Guy's (Holders), was played at Upton on March 1st. The holders managed to secure the cup for the third successive year. The game was well contested; the winners only managed to score one goal.

COCAINE AS AN AID TO DIAGNOSIS IN LARYNGEAL DISEASE.—Dr. Baumgarten not long ago called attention in the *Wiener Medicinische Wochenschrift* to the value of cocaine in enabling true thickening of the vocal cords to be distinguished from the swelling of simple catarrhal inflammation. Even the most experienced laryngoscopists often find it very difficult to come to a definite conclusion on this point. If Dr. Baumgarten is right, however, nothing is more easy. As cocaine causes spasm of the capillaries, local depletion, with more or less transient blanching of the mucous surface, will follow its application to cords that are tumid and red from congestion. No such effect, on the other hand, will be produced when the substance of the cord is infiltrated with tubercular, syphilitic, or carcinomatous material. When, therefore, brushing with a 10 per cent. solution of cocaine fails to make the redness disappear, it may be taken as a proof that one has to deal with a serious disease.

UNIVERSITY OF LONDON.

A MEETING of Convocation was held at the University Buildings on March 6th. It was announced that Mr. Anstie had received 436 votes, Mr. Busk 367, and Mr. Nesbitt 35 votes. Mr. Anstie will, therefore, probably be nominated by the Crown to the vacancy in the Senate.

Dr. S. P. THOMSON proposed that Convocation should invite the Senate to grant *ad eundem* degrees to graduates of other universities who hold professorships in University and King's Colleges, thus enabling Convocation to admit them to its membership. The proposition was rejected by a large majority.

Dr. M. BAINES moved the following resolution:

"That Convocation disapproves the course pursued by the Senate with reference to a petition to the Crown of the Royal College of Physicians of London and the Royal College of Surgeons of England for a charter enabling them to confer degrees in medicine."

He narrated the history of the action of the Senate in connection with the two Colleges, and considered their action in the matter inconsistent. He read the minutes of the Senate, in which they resolved (by a majority of one) not to oppose the scheme on three conditions, namely: 1. That the degree proposed should not be confounded with the London University degree. 2. That the preliminary education of those who received the degree should not be inferior to that required of those who receive university degrees. 3. That the proposal to confer degrees on those already passed be not approved. The College of Surgeons had given up its Arts examination, and had delegated all such requirements to the Society of Apothecaries and the College of Preceptors; that showed how little that body cared for polite culture. The governing body would be elected from the two Councils, and would be self-elective, so that they would be masters of the entire situation. The teachers could never advise or direct the Senate, except such as might by chance be on that body, the bulk of the teachers being completely shut out. Hence, in want of any external influence, all regulations would be framed and all action taken in the interests of the Colleges themselves, and not for the good of the profession. This was the case with the College of Surgeons, whose present action in obtaining a new charter was sufficient evidence of what might be expected if any such power were given to the corporations named. A one-sided faculty was objectionable and unprecedented, and tended to the depreciation of a degree which should represent culture and learning. To separate medicine in this way from arts and kindred sciences would be prejudicial to all kinds of liberal education. The absence of representation of the proposed graduates was condemned. A great blot on the scheme was the fact that it was proposed to give the degree only to those who passed the examination of the two Colleges; and so those bodies, without any reason, usurped the position of a university, which was preposterous. Other London students, who did not enter the two Colleges, were excluded.

Mr. B. WHITEHEAD, B.A., seconded the resolution, and enlarged upon the impolitic action of the Senate.

Mr. T. B. NAPIER, LL.D., wished the proposal to be modified, so that it might read thus:—"That Convocation desires respectfully to express regret that the Senate has not seen fit to take action against the petition to the Crown of the Royal College of Physicians and the Royal College of Surgeons for a charter enabling them to confer degrees in medicine." He said this was not a medical question alone. The scheme, if adopted, would inaugurate quite a novel method of granting degrees, namely, by professional bodies alone.

Mr. M. F. O'REILLY, D.Sc., seconded the amendment, which Dr. Baines accepted, so that the amendment became the substantive motion.

Mr. OSLER defended the action of the majority in the Senate and said that the following arguments had weighed with him when he had given his vote in the Senate: 1. That there was a certain practical grievance, in the fact that there was no accessible degree in London for the bulk of London students. The picked men of the schools would still come to the University of London. 2. The two Colleges he was assured would give a good

degree. How far it would involve general culture was perhaps uncertain; but he doubted whether any universities required general culture for the degrees of other faculties than that of arts.

Dr. W. J. COLLINS said that so far as the Members of the Royal College of Surgeons had been consulted, they were adverse to the scheme.

Dr. SIDNEY COUPLAND said that the scheme did not originate with either of the Colleges, but was pressed upon them from without by other medical bodies. The degrees of the University of London were too severe for the usual run of students, who now went to Scotland and elsewhere in large numbers. At Edinburgh English students outnumbered those of all other nationalities.

Dr. P. H. PYE-SMITH said that the degree of M.D. did not represent academic culture or any other attainment than that of merely professional education. The Licentiates of the College of Physicians and Members of the College of Surgeons who were now passing were generally as highly cultured as the men who held the M.D. of many universities other than that of London. The resolution was carried by a large majority.

After disposing of some other business, the House adjourned.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An ordinary meeting of the Council was held on Thursday, March 8th, 1888.

The minutes of the Ordinary Council on the 9th ultimo were confirmed.

A unanimous resolution of condolence with the family of the late Mr. T. B. Curling, past President, past member of the Council, and Court of Examiners, was passed.

The seventh report, dated March 2nd, 1888, on the extension of the College premises was approved, adopted, and entered on the minutes. This report read as follows:—"The Committee recommend to the Council that, in addition to the works in connection with the extension of the College premises already sanctioned by the Council, a further sum of £692 11s. be expended in building, in accordance with the plan submitted by Mr. Salter, a corridor and lavatories behind the theatre, and a staircase communicating with the new portion of the Library and the proposed corridor, in lieu of the iron staircase already sanctioned by the Council, and in providing a hot-water supply for the lavatories."

The Council approved of the proposed conditions relating to the uses to which the new workrooms at the College may be devoted, as proposed by the Museum Committee.

The Finance Committee was then elected. It consisted of the President, Vice-President, Chairman of the Museum, Library and General Purposes Committees, and Messrs. B. Hill, Sibley, and Willett.

The Council voted a sum of £50 towards the expense of building a mission church in the Seven Dials.

A letter of February 16th from the legal adviser of the College was read, stating that the authorities at Somerset House have decided that the College diplomas are not liable to stamp duty.

A letter of February 13th from the Clerk to the Privy Council was read, forwarding, by direction of the Lord President, for the information of the College, a copy of a letter from the French Ambassador at this Court, announcing that a Congress of Surgeons will take place at Paris from the 12th to the 17th of March next.

A letter of February 29th from Mr. Peel was read, transmitting, by direction of the Lord President of the Council, to be laid before the Council of the College, a copy of a "rejoinder" which the Committee of the Association of Fellows have forwarded to his Lordship.

The Council resolved that a reply to the letter be sent, to the effect that the Council request his lordship to grant them an interview for the purpose of giving him any further information he may require in respect to the said rejoinder.

Mr. WILLETT's motion that a committee be appointed to consider and report to the Council on the form of the Report of the Council to the annual meeting of the Fellows and Members, was seconded by Mr. CADGE, and carried. Messrs. Marshall, Cadge, and Willett were appointed to form that committee.

Mr. SIBLEY's motion, that in view of the appointment by the Council of a professional auditor to annually audit the accounts of the College, a committee of auditors is no longer necessary, and that Section 21 of the standing Rules be accordingly abrogated and annulled, was seconded by Mr. T. SMITH, and carried *nem. con.*

ASSOCIATION INTELLIGENCE.

NOTICE OF QUARTERLY MEETINGS FOR 1888.

Meetings of the Council will be held on April 18th, July 18th, and October 17th, 1888. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before each meeting, namely, March 28th, June 27th, September 26th, and December 28th, 1888.

ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No member can be elected by a Branch Council unless his name has been inserted in the circular summoning the meeting at which he seeks election.

FRANCIS FOWKE, *General Secretary.*

COLLECTIVE INVESTIGATION OF DISEASE.

THE Report upon the CONNECTION OF DISEASE WITH HABITS OF INTEMPERANCE, which was presented to the Section of Medicine in the Annual Meeting of 1887, and a further portion of the Report upon OLD AGE have been completed, and will shortly be published in the JOURNAL.

Reports upon the two remaining inquiries, namely, that into DIPHTHERIA, and that into the GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES, are in preparation, and will be published as soon as ready.

The following inquiry only of the first series remains open, namely, that on THE ETIOLOGY OF PHTHISIS.

A fresh inquiry into the ORIGIN AND MODE OF PROPAGATION OF EPIDEMICS OF DIPHTHERIA has been issued.

Memoranda upon these subjects, and forms for recording observations, may be had on application to the Secretary of the Collective Investigation Committee, 429, Strand, W.C.

BRANCH MEETINGS TO BE HELD.

SOUTH-EASTERN BRANCH: EAST AND WEST SUSSEX DISTRICTS.—A conjoint meeting of the above districts will be held at the Grand Hotel, Brighton, on Thursday, March 22nd. F. W. SALZMANN, M.R.C.S., will preside. Meeting at 3.30 P.M.; dinner at 5.30 P.M.; charge 6s., exclusive of wine. The following communications are promised: Dr. Starling: A case of Fibroid Induration of the Stomach (with specimens). Mr. Howard Marsh: Recovery after Laparotomy for Intestinal Obstruction; with Remarks. Dr. Mackey will show: Cases of Lupus Erythematosus, etc. Gentlemen desirous of contributing short papers or cases, should write at once to the undersigned or to Dr. Gostling, West Worthing.—T. JENNER VERRALL, Honorary Secretary, 97, Montpellier Road, Brighton.

SHROPSHIRE AND MID-WALES BRANCH.—The next meeting of the Branch will be held at the Salop Infirmary, on Tuesday, March 27th, at 3 P.M. Mr. W. Eddowes in the chair. Gentlemen wishing to exhibit or read notes of cases, or to bring forward subjects for discussion, are requested to communicate with the honorary secretary, EDWARD CURETON, Shrewsbury.

NORTH WALES BRANCH.—The intermediate meeting of this Branch will be held at Colwyn Bay on Tuesday, March 20th, at 2 P.M. Members who wish to read papers, etc., or nominate candidates for membership, are requested to communicate at once with W. JONES-MORRIS, Honorary Secretary, Portmadoc.

EAST ANGLIAN BRANCH: ESSEX DISTRICT.—The next meeting will be held at the Saracen's Head Hotel, Dunmow, on Friday, March 23rd, 1888, at 2.30 P.M. R. B. MARRIOTT, Esq., Swaffham, President of the Branch, in the chair. Notices of papers, etc., should be sent as soon as possible to C. E. ABBOTT, Braintree, Honorary Secretary.

METROPOLITAN COUNTIES BRANCH: EAST LONDON AND SOUTH ESSEX DISTRICT.—The next meeting will be held in the Hackney Town Hall, on Thursday, March 15th, at 8.30 P.M. A paper will be read by A. J. PEPPER, Esq., on Medical Evidence in Courts of Law. Visitors will be welcomed.—J. W. HUNT, Honorary Secretary, 101, Queen's Road, Dalston.

SOUTHERN BRANCH: SOUTH WILTS DISTRICT.—The next meeting of this Branch will be held at the Bath Arms, Warminster, on Wednesday, March 21st, at 4 o'clock. Dinner at 6 o'clock. Tickets 5s., not to include wine. Members intending to be present, to communicate with the honorary secretary, H. J. MANNING, Laverstock, near Salisbury.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT.—The next meeting of the above District will be held at the Cottage Hospital, Ashford, on Thursday, March 15th, at 3 P.M. Dr. Wilks in the chair. The President kindly invites members to luncheon, between 1 and 2.30, at his house, 22, North Street. The dinner will take place at 5 P.M., at the Saracen's Head, price 6s. (exclusive of wine). All members of the South Eastern Branch are entitled to attend these meetings, and to introduce professional friends. N.B. All gentlemen purposing to dine are particularly requested to inform the chairman by Tuesday the 13th, that proper arrangements may be made.—W. J. TYSON, Honorary District Secretary, 10, Langherne Gardens, Folkestone.

CEYLON BRANCH.

THE inauguration of the Ceylon Branch took place on December 17th, 1887, when a large and representative gathering of the members of the profession met in the Hall of the Colonial Medical Library. The following gentlemen were present: W. R. KYNSEY, F.R.C.S.P., Colombo; S. ARCHER, M.D., Brigade-Surgeon, Medical Staff, Colombo; J. L. VANDERSTRAATEN, M.D., M.R.C.P.L., Colombo; W. G. VAN DORT, M.D., C.M., Colombo; J. LOOS, M.D., M.R.C.P.E., Kandy; The Hon. P. D. ANTHONISZ, M.D., F.R.C.S.E., Colombo; W. DIAS, M.D., M.R.C.S.E., Galle; C. W. VAN GEYZEL, M.B., C.M., Colombo; H. THORNHILL, M.B., Kandy; W. G. ROCKWOOD, M.D., M.R.C.S.E., Colombo; J. ATTYGALLE, M.D., M.R.C.S.E., Colombo; T. F. GARVIN, M.B., C.M., Colombo; J. D. MACDONALD, M.D., Colombo; S. FERNANDO, M.B., C.M., Colombo; H. A. KEEGEL, L.R.C.P.E., Colombo; M. ELEYATAMBY, M.R.C.S.E., Colombo; H. HUYBERTSZ, L.R.C.P. and S.E., Kalatura; E. N. SCHOKMAN, L.C.M.C., Colombo; S. de M. ASSERAPPA, M.D., Colombo.

Specimens.—The Hall of the Library was tastefully arranged, a number of side tables having been set apart for specimens of considerable interest. Table I contained a large and varied collection of Plaster-of-Paris Casts executed by a local artist under the direction of the late Dr. Koch. The specimens included the following: Casts of Talipes, of Pott's Fracture, of Stumps after Pirogoff's, Syme's, and Chopart's Operations; Subglenoid Dislocation of the Humerus, Fractures at the Wrist, Fractures of the Clavicle, of Cases of Elephantiasis Græcorum, Bronchocele, and various other conditions.—Table II contained Eight Ovarian Tumours from cases operated upon by the Hon. Dr. Anthonisz, Dr. Rockwood, of Colombo, Dr. Schokman, of Galle, and the late Dr. Koch.—Table III contained a large collection of Urinary and Biliary Calculi, Concretions round Foreign Bodies, and Salivary Calculi presented to the De Soyza Museum by Drs. Koch, Rockwood, Anthonisz, Vandersmagt, Garvin, and others.—On Table IV Dr. MACDONALD exhibited microscopic slides showing the Bacilli of Splenic Fever, Cholera, Lepa, Erysipelas, Tubercle, Typhoid Fever, Pyæmia, Gonorrhœa, and Actinomyces, the Streptococcus of Pus, the Ova of the Round Worm, and the Cocci of Pneumonia. Several very good specimens of the Ova of the Anchylostoma Duodenale in different stages of development were shown taken from the fæces of patients at present under treatment from anchylostomiasis in the General Hospital at Colombo. The Embryo of the Worm was also shown.—On Table V Mr. BRITO exhibited a collection of microscopic slides, showing Epithelioma, Fibroid Tumour, Lupus, Anchylostoma Duodenale (female and male), Parasites in Beef, Tricocephalus Dispar, besides preparations of various normal tissues.—Table VI contained a collection of Entozoa in spirits very neatly mounted for examination by Mr. BRITO: 1, Oxyurus Vermicularis; 2, Amphistoma Explanatum (Buffalo?); 3, Tenia Solium (Human); 4, Tricocephalus Dispar (Human); 5, Lumbricoides (Human); 6, Tricocephalus (Horse); 7, Anchylostoma Duodenale.—Mr. BRITO also exhibited well-executed Dissections of the Human Brain hardened in spirits.—On Table VII Dr. MACDONALD exhibited a set of Esbach's Albuminometers, and a Portable Spirometer which attracted much attention.—Table VIII had the following preparations, exhibited by Mr. BRITO: 1, Human Fœtus and Membranes, about three or four weeks old; 2, Uterus and its Appendages, Fœtal Membranes and Cotyledonary Placenta; 3, Encephaloid Cancer of the Liver; 4, Heart of Frog showing Aortic Arches; 5, Blood-clot expelled Ten Days after Parturition (case of Puerperal Septicæmia); 6, Kidneys, Bladder, and Ureters of a Man—right kidney hypertrophied, left containing a calculus of the size of a small lemon; right pelvis and ureter distended; bladder carcinomatous.—The Museum of the Ceylon Medical College was also thrown open to the members.

Preliminary Proceedings.—At 12.30 P.M., in pursuance of notice, Dr. LOOS moved that Mr. KYNSEY, P.C.M.O., do take the chair. Brigade-Surgeon Dr. ARCHER seconded the motion.—Mr. KYNSEY, having taken the chair, addressed the meeting and expressed his satisfaction at seeing such a representative gathering assembled to inaugurate the Ceylon Branch of the British Medical Association.

tion. The first thing to do would be to complete the constitution of the Council by electing three members not resident in Colombo to the vacant seats in the Council.—Dr. ATTYGALLE proposed, and Dr. ASSERAPPA seconded: That Mr. Renny, M.B., C.M., Hatton; Surgeon Wallis, M.R.C.S., Army Medical Staff, of Galle; and Dr. James Loos, of Kandy, be elected members of Council under Section 7, By-law 4. Carried unanimously. From the Council thus constituted the election of the office-bearers for the year 1888 took place.

Election of President.—Brigade-Surgeon Dr. ARCHER then proposed, that from the Council thus constituted, the meeting do elect Mr. W. R. Kynsey to be the first President of the Ceylon Branch.—Dr. VANDORT having seconded the motion, Mr. KYNSEY thanked the meeting for this expression of its confidence. He felt that his approaching departure from the island on leave would interfere with the proper discharge of those duties which would devolve upon him as President in the organisation and working of the Branch at its first start. He felt sure that the meeting would cordially join him in the nomination of the gentleman whose name he would submit to them in his stead, a gentleman whose reputation in the medical profession had been established both here and in Great Britain, and who was his oldest friend in the island. He begged to propose the Hon. Dr. P. D. Anthonisz as the first President of the Ceylon Branch.—Mr. VANGYZEL seconded. The Hon. Dr. P. D. Anthonisz was declared duly elected President of the Ceylon Branch. Mr. KYNSEY then vacated the chair to the PRESIDENT, who returned thanks for his election. He felt that by reason of his years his term of usefulness in the profession would necessarily be limited, but under the circumstances of the case he gladly accepted the responsibility of occupying the chair he had just assumed, and which he trusted Mr. Kynsey would, on a future occasion, occupy.

Officers.—On the proposal of Mr. KYNSEY, seconded by Dr. VANDERSTRAATEN, Brigade-Surgeon Dr. Archer, M.S., and Dr. W. G. Vandort were unanimously elected Vice-Presidents of the Branch.—Mr. THORNHILL proposed, and Dr. MACDONALD seconded, the election of Mr. Henry Keegel as Honorary Secretary of the Branch. Carried unanimously.—Mr. VANGYZEL proposed the election of Dr. Vanderstraaten as Honorary Treasurer. Mr. HUYBERTSZ seconded the motion, which was carried unanimously.

Representative on the Council of Association.—On the proposal of the PRESIDENT, seconded by Mr. THORNHILL, Mr. Kynsey was nominated Representative from the Ceylon Branch to the Council of the parent Association.—Mr. KYNSEY, in returning thanks, hoped that during his stay in Europe, he would be able personally, if necessary, to further the interests of the Branch there.

New Members.—The HONORARY SECRETARY then proposed the election of the following gentlemen, Dr. VANDORT seconding each proposal. *To the Parent Branch.*—W. Dias, M.F., St. And., M.R.C.S. Eng., L.S.A.; S. de M. Asserappa, M.D. Edin.; A. Nell, L.C.M.C.; M. Candyah, L.C.M.C. *To the Local Branch.*—W. Dias, M.D. St. And., M.R.C.S. Eng., L.S.A.; S. de M. Asserappa, M.D. Edin.; A. Nell, L.C.M.C.; M. Candyah, L.C.M.C.; S. B. Perera, L.C.M.C.

Vote of Thanks.—Dr. MACDONALD proposed, and Dr. ASSERAPPA seconded, that a vote of thanks be accorded to the Chair. The resolution was carried unanimously, and the meeting ended.

Luncheon.—All the members of the Association who were present at the meeting, and Surgeon-Major Stokes, M.S., Surgeon Birch, Mr. Spence, Mr. Cochran, Lecturer on Chemistry, and Mr. Meier, the medical superintendent of the Leper Asylum, assembled at 1.30 P.M., by the invitation of the Principal Civil Medical Officer, at Guyscliff, where they were entertained at luncheon. The only toasts were the "Health of Mr. Kynsey," which was proposed by Dr. Loos, and drunk with acclamation and hearty wishes of a pleasant voyage and safe return; and the "Health of the first President of the Ceylon Branch of the British Medical Association," proposed by Mr. KYNSEY, to which the Hon. Dr. ANTHONISZ replied.

GLOUCESTERSHIRE BRANCH.

An ordinary meeting was held on Tuesday, February 21st, 1888, at 7.30 P.M., at the Gloucester Infirmary, under the presidency of Dr. CURRIE.

Suppuration of Vitreous.—Mr. BOWER showed a patient suffering from suppuration of the vitreous humour of the eye due to the presence of a steel chip. He had failed to see the fragment by the ophthalmoscope, and also to remove it by the electro-magnet. He pointed out the total absence of injury to the lens and cornea, or of inflammation.

Homœopathy.—Dr. CURRIE opened a discussion on the present position of Homœopathy in relation to regular Medicine, in which he propounded the question whether the hand of brotherhood should not be held out to the homœopaths, and concluded that it should.—Dr. BOND answered in the negative.—Mr. WADDY urged that all distinctions should be dropped.—Dr. NEEDHAM argued that no conciliation could be effected until the distinctive name be dropped.—Dr. BATTEN spoke strongly in favour of Dr. Currie's proposition.—Mr. ELLIS said there was much to learn from the homœopaths.—Dr. SOUTER said that, considering the great changes of opinion with regard to therapeutics, there was no reason for ostracising homœopaths.—Dr. CLARKE and Messrs. BOWER, CUTHBERT, and CARDEW also took part, and Dr. CURRIE replied. The meeting closed at 10 P.M.

The result of this meeting was most important, showing the great feeling in favour of admitting homœopaths to equal fellowship, and, as far as the county of Gloucester is concerned, having settled the question as to the right of holding consultations with them.

BORDER COUNTIES BRANCH.

A MEETING was held at the County Hotel, Carlisle, on Friday, February 24th, 1888. The chair was taken by Dr. McLEOD, Hawick, President, at 6 P.M. Twenty-four members and five visitors were present.

New Members.—The following were elected members of the Branch: William Blair, M.D. Glasg., Jedburgh; William Henry St. Leger Carter, L.R.C.P. and S. Ed., Conishead Priory; Donald Macgregor, M.D. Ed., Denholm, Hawick; Charles John Tifen, M.D. Ed., Wigton.

Process of Compensation.—Dr. BYROM BRAMWELL, of Edinburgh, read a paper on the process of compensation and its bearing on prognosis and treatment, which was illustrated with specimens and drawings.—In the discussion which followed, the PRESIDENT and Drs. J. ANSON, HADDON, BARNES, MACLAREN, GREEN, MACDOUGALL, LOCKIE, ALTHAM, and CAMPBELL took part.—Dr. BRAMWELL replied.

Vote of Thanks.—A vote of thanks was accorded to Dr. Bramwell, on the motion of Dr. HADDON.

Hypertrophy of Breasts.—Dr. MUIR, Selkirk, read notes of a case of hypertrophy of the mammae, and showed photographs.

Operation for Rectal Hemorrhage.—Dr. ALTHAM (Penrith) read notes of a case. A woman, aged 34, had had bleeding from the bowel for fourteen years, with much suffering. As none of the ordinary causes of hæmorrhage were found, the redundant skin round the anus was cut away, with the object of leaving a considerable surface to granulate and contract. The operation was completely successful.

Case of Herniotomy with Omental Cysts.—Dr. ALTHAM read notes of a case in which a woman, aged 70, was operated on for strangulated hernia. On cutting down it was found that what seemed like a knuckle of strangulated bowel was really a cyst in the omentum, which had been bruised during taxis. After making sure that no portion of bowel was contained in this sac, the omentum was ligatured and cut off. The patient did well, but it would no doubt be better in such cases to open the cysts and explore the cavity with the finger, so as to make sure that none of the bowel was included.

Intracranial Hemorrhage in a Boy.—Mr. T. P. DEVLIN (Carlisle) read notes of a case of cerebral hæmorrhage in a boy aged 11, who till three hours before his death had enjoyed good health. *Post-mortem* examination did not reveal disease in either thoracic or abdominal organs; but there was a large cavity filled with recent clot situated in the right hemisphere of the brain.

Supper.—Twenty-one gentlemen sat down to supper.

Next Meeting.—The next meeting of the Branch will be held in spring, at Cockermouth.

THE Duke of Bedford, as Lord-Lieutenant of the County, and the Lord Bishop of the diocese have become patrons of the Huntingdon County Hospital, and the Earl of Sandwich has been elected President, vice Baron de Ramsey, deceased.

JOHNSTONE COMBINATION HOSPITAL.—The Combination Hospital, which has been built at Johnstone to meet the requirements of five parishes, at the cost of £2,200, has been inspected by a Government officer, and pronounced thoroughly satisfactory, and is to be opened at the end of the month.

SPECIAL CORRESPONDENCE.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

Cold Bathing in Typhoid.—Lead Poisoning.—Photoxyline as a Surgical Dressing.—Toxic Effects of Antipyrin.—Carbolic Acid in Pulmonary Phthisis.—Effects of Boric Acid.

M. JUHEL-RÉNOY recently read a paper before the Société Médicale des Hôpitaux on cold bathing in typhoid. He had treated forty-three cases in this way, with only three deaths. Sixty-five baths were given in each case. The nature of the disease was established beyond a doubt in every instance. M. Juhel-Rénoy considers that cold baths prevent hæmorrhage, pulmonary complications and syncope, modify the diarrhoea, and clear the urine, which is secreted in great abundance. Among his patients there were pregnant women, hysterical, alcoholic, and tuberculous patients. In cases of perforation of the intestine and peritonitis, cold bathing should never be employed. M. Dujardin-Beaumetz remarked that M. Quinquand had proved that cold baths increase organic combustion, and consequently the production of heat. He admitted that cold baths may act as a tonic, but the same result was obtained with tepid baths, which were not so dangerous. The increased arterial tension produced by cold baths might cause sudden death in cases of cardiac weakness.

At the meeting of the Surgical Society on February 9th, M. Duguet described a case of lead poisoning. The patient, a woman aged 38, was employed in a factory where coloured cardboard boxes are made by machinery. Her business was to gum small bands of paper 0.15 centimètre long on these boxes, which were intended to hold reels of cotton. These paper bands are coloured red and orange on one side, being grey on the other side, which is covered with gum. In taking up these bands, which are packed in layers, the patient was obliged to wet her finger with her tongue each time, and slip off each band, of which the red and orange side is placed uppermost, with her finger. The grey side of the band had then to be licked, and the band gummed on the box. The patient had frequently gummed as many as 5,000 of these bands in one day. She stated that her companions (eight or ten) who did the same work, all became pale and thin, and suffered from colic. Those who were employed in pasting on blue-coloured bands of paper were not affected with any morbid symptoms. The red and orange bands of paper were analysed by M. Gur. The residue of the paper, when burnt, gave all the reactions of salts of lead. Each band contained about 12 milligrammes of metallic lead. This form of lead poisoning has not been described before. M. Monod suggested that the case should be reported to the Préfet de Police.

M. von Wahl has lately tried substituting photoxyline, which is used in photography, for collodion in surgical operations. He employs a 5 per cent. solution mixed with equal portions of alcohol and ether. His experiments showed that photoxyline has the following advantages: It adheres more closely to the skin than collodion; it is absolutely impermeable, and is not deteriorated by washing or by prolonged contact with other fluids; it exercises a uniform compression on the tissues. It can, therefore, be strongly recommended in the case of slight surgical operations, when the patient is not obliged to lie up and a voluminous antiseptic dressing is most inconvenient; as in plastic operations on the face, and in those performed in the region of the genital organs in male patients (radical operations for hernia, hydrocele, castration, etc.). In these cases a thin layer of cotton-wool, free from all greasy principles and saturated with photoxyline, is applied to the wound and fixed by means of sutures and court plaster after bleeding has stopped. This layer will resist the dissolving action of any foreign fluids for eight or ten days. The uniform pressure it exercises renders drainage superfluous. In the case of children, where it is almost impossible to prevent the contact of the dressings with the urine, photoxyline will be found especially valuable. In laparotomy this form of dressing will suffice by itself, and will protect the abdominal wound in the most efficient manner.

At a recent meeting of the Académie de Médecine Dr. Ball read a paper by Dr. Oscar Jennings on a case of poisoning by antipyrin. The patient suffered from nodular rheumatism, for which 2.50 grammes of antipyrin were given daily for a week. On the eighth day erythematous spots were observed on the arms, and

the patient had an uncomfortable sensation in the eyes. On the following day the face was red, the eyelids swollen. The day after a rash came out all over the body; there was catarrhal conjunctivitis, loss of appetite, and a sensation of internal cold. The pulse was 78. There was singing in the ears. The patient was very weak. A few drops of tincture of belladonna caused these symptoms rapidly to disappear. Dr. Jennings considers that antipyrin should be given with great caution to old people and persons of an impressionable temperament. The symptoms of poisoning can, however, be easily subdued by administering a few drops of tincture of belladonna, or by subcutaneous injections of atropine. M. Germain Sée observed that he had met with many similar cases. The symptoms of poisoning which he had observed were usually due to doses of three or four grammes of antipyrin, given for several consecutive days. Such symptoms were most commonly met with in female patients. Antipyrin should never be given a second time to patients in whom they had been observed. In such cases antifebrin (acetanilide) should be substituted for antipyrin. M. Sée strongly condemned the practice of giving belladonna or injections of atropine to combat the symptoms of poisoning, which will spontaneously disappear in from twenty-four to forty-eight hours if the drug is discontinued, and which cannot be regarded as of a serious nature. M. Dujardin-Beaumetz, who shares this opinion, remarked that, after a prolonged use, antipyrin caused pain in the stomach and dyspeptic symptoms. The adulteration of antipyrin with benzine or other substances was possibly the cause of these symptoms, which had been more frequently observed of late. M. Dujardin-Beaumetz further remarked that subcutaneous injections of antipyrin were painful. Acetanilide caused cyanosis in certain cases. A dose of two grammes a day should never be exceeded. M. Germain Sée had observed the gastric symptoms described by M. Dujardin-Beaumetz, and believed them to be due to the manner in which the antipyrin was prepared. In order to prevent these symptoms, M. Sée employed carbonate of soda or seltzer water. For subcutaneous injections he gave one gramme in four injections. In this way the injections were not painful. M. Ollivier stated that he did not share the belief held by many authors concerning the good effects of antipyrin. He had employed it in the treatment of chorea, and found that, although it modified the affection in certain cases, in others it did no good.

M. Dujardin-Beaumetz, in a lecture which he recently delivered on carbolic acid in the treatment of phthisis, expressed himself to the following effect: "The absorption of the acid by the air-passages being out of the question, the only means of administering it is by hypodermic injections and by the alimentary canal (stomach or rectum). As the digestive organs of phthisical patients are usually out of order, any irritation of the stomach should be avoided in their case. The skin and the rectum are therefore the only means by which the acid can be safely introduced. It has been used by many medical men in cases of pulmonary tuberculosis. The injection may be hypodermic or into the deeper parts; by this means the antiseptic liquid may be conveyed to the very spot in which the lesion exists. Professor Lépine and his pupil Truc tried intra-pulmonary injections of a 2 per cent. alcoholic solution of creasote in tuberculosis. A weak solution of morphine had been previously injected to prevent pain. These authors recommended iodoform, with which excellent results were obtained in the treatment of tuberculous abscess. For the carbolic acid injections a syringe large enough to hold 5 grammes of the liquid should be employed. A 2 per cent. solution of carbolic acid, perfectly pure, and previously dissolved in glycerine (alcohol is irritating) should be used. The spots at which the injections are made should be chosen in the anterior portion of the chest, below the clavicle. The number of punctures to be made must be determined by the special character of the affection, but an excessive number may cause symptoms of carbolic acid poisoning. Under this treatment it will be found that in a large proportion of cases the appetite returns; the patients can leave their beds and walk out; the coughing and expectoration are diminished, and the night sweats frequently cease.

At a recent meeting of the Société Médicale des Hôpitaux, M. Gaucher described the results of his experiments with boric acid, administered internally. He has discovered that, in doses which produce the required effects, this substance is not toxic. When applied to the bare skin only it is not caustic, and only a slight amount of absorption takes place; for this reason it is of great service in skin diseases. In infectious and contagious impetigo it

has the same effect as oil of cade, without its drawbacks. M. Gaucher used it successfully in a case of cutaneous tuberculosis. He raised the question whether there may not be some analogy between this affection and impetigo. M. Grancher, on the other hand, stated that he had made numerous inoculations with the virus of impetigo, but in only one case had he produced tuberculosis. He believed that the micro-organism of impetigo and that of tuberculosis were quite distinct. M. Gaucher administered internally from 50 centigrammes to 1 gramme of boric acid to a series of consumptive patients with the following results:—The general condition improved, the local condition remained stationary. The acid was eliminated by the urine in the form of boric ether. He considers that internal doses of boric acid might be substituted with advantage for injections of this substance in the treatment of cystitis. He gave one gramme of the acid daily to several aged patients with hypertrophy of the prostate, accompanied by cystitis; the urine, which was thick and contained muco-pus, quickly became clear. Boric acid is not astringent like borate of sodium, which is used by some surgeons.

SAN REMO.

[FROM OUR OWN CORRESPONDENT.]

By the time this letter reaches you I trust some of the tension on the public mind in connection with affairs at the Villa Zirio may be relieved. I can at any rate report (March 5th) some progress within the last few days, the Crown Prince having now had three comparatively good nights, with less cough and expectoration, and having been out on the piazza upon which the windows of his room open for several hours each day. This he has been able to do thanks to the ingenuity of Sir Morell Mackenzie, who extemporised a screen which shelters the patient from any wind, and gives some amount of privacy from the gaze of the crowds which congregate in the road below the villa.

The embargo laid by the Emperor on the physicians as to giving any information beyond that conveyed by the official bulletins, which are probably submitted to the august patient before being published, has struck terror into the heart of the host of special correspondents now here, and renders it extremely difficult to obtain reliable information. It has also had the worst possible effect in causing information of a pessimist nature to be invented.

The suggestion made by Sir Morell Mackenzie alluded to in my last has been carried out, and on Saturday evening Professor Waldeyer, now holding the Chair of Anatomy at the University of Berlin, and formerly Professor of Pathology, arrived here. This eminent microscopist, who has written important works on the origin of cancer, I have reason to know spent the whole of Sunday in making examinations of the expectorated matter, and the greater part of the morning Sir Morell Mackenzie was with him. The doctors, however, have been requested not to make known his views, whether favourable or not, so that whatever conclusions he may arrive at will be forwarded to Berlin, and are not likely to be known here. A new cannula was made here last week under the superintendence of Sir Morell Mackenzie, who spent nearly a day and a half in the workshop of the local silversmith, exciting much interest in the Italian artisan mind. In this work he was assisted by Dr. T. Evans, of Paris, the American dentist of European fame, who is staying here. Since this tube was taken to the Villa Zirio, I hear that the cough and expectoration have materially diminished, and that the latter is much less blood-tinged than it was; whether this is due to the new tube or not I cannot say.

The Crown Princess continues to display the admirable fortitude and bravery that have distinguished her all along, at a time when one knows her heart is wrung with the bitterest anxiety. Her kindness and consideration for others are perpetually shown, an example of which has just been brought to my notice. An English nurse, trained at the Liverpool Hospital, who has nursed here with great success for several years, was recommended by Dr. Freeman to assist in the nursing, preparing food, etc., after the operation. A hospital orderly has now arrived from Berlin, and on the nurse's departure the Crown Princess personally presented her with a pretty and valuable brooch, thanking her warmly.

There is still a good deal of international feeling and jealousy, and though natural to a certain extent, it is, I fear, carried much too far. Sir M. Mackenzie has now resumed charge of the illustrious patient, being supreme in the case. Prince William arrived

last week, and Professor von Bergmann has remained by command of the Emperor. I understand that either Sir M. Mackenzie or Mr. Mark Howell is always on duty at the Villa. It is hoped that this anxious state of matters will not last much longer. The Bishop of Gibraltar is here, and preached at All Saints' Church on Sunday. He was received by the Crown Princess on Monday afternoon at the Villa Zirio. The weather has quite changed, and is very fine.

MANCHESTER.

[FROM OUR OWN CORRESPONDENT.]

Hospital Funds.—*Small-pox.*—*Owens College.*—*British Association Local Committees Accounts.*

THE collections on Sunday amounted to £4,285, and on Hospital Saturday to £1,494, but to the latter sum an addition may still be made.

Additional cases of small-pox continue to crop up in various towns near Manchester. In Stockport alone twenty-one cases with four deaths have been notified since the disease broke out again.

The principal and treasurer of Owens College have issued a circular setting forth the needs of the College, and soliciting subscriptions to clear off the debts on the new laboratories and museums which have recently been erected and equipped. We feel certain that the public of Manchester—so justly proud of its College, entirely endowed and supported by the contributions of its citizens apart from State aid—will respond liberally to the appeal. The sum required to pay off the debt on the buildings is about £45,000.

The Local Executive Committee of the British Association has reported on the expenditure incurred at the recent meeting of this Association, held in Manchester in September last. Altogether the amount received was £4,336, while the number of members attending was 3,838. The attendance was greatly in excess of that at any previous meeting, and the amount received and available for the promotion of science was beyond all former records. The total expenditure was £4,258, this sum being met chiefly by the guarantors, 35 per cent. of the sum guaranteed being called up by donations and the proceeds of excursions.

LIVERPOOL.

[FROM OUR OWN CORRESPONDENT.]

Serious Decrease of the Water Supply.—*Small-pox in Liverpool.*—*Hospital Appointment.*—*Police Appointments.*

FOR several weeks past we have had a "restricted" water supply, and within the past month the water has been cut off for several hours during the day as well as during the night. The great works in North Wales cannot be completed for some time yet, so most of the Liverpool water still comes from Rivington. There has, however, been an alarming decrease in the amount of water there, and a water famine has been feared. The Water Committee held a meeting on March 5th. It was then stated that during the past fortnight the decrease of water in store at Rivington amounted to 107 million gallons, or 2,586 million gallons less than on the corresponding week last year. It was announced that means were being taken to obtain water from other sources to meet present requirements. As a matter of fact the Liverpool Corporation have arranged already to obtain from one to two million gallons a day from the Kirkby Well, belonging to the Corporation of St. Helens; and some of this is coming into the city now. The rainfall at Rivington for the fortnight ending February 23rd amounted to 0.163 inches. It has been definitely decided that the new water supply from Vyrnwy, North Wales, is to be conveyed under the Mersey in a specially-constructed tunnel, and not through pipes lying on the river bottom. This, which is the outcome of action taken by the Manchester Ship Canal Company, will of course add greatly to the already enormous expense of the new water system for Liverpool.

Considering the great amount of traffic between this city and Sheffield, it is somewhat remarkable that, until a week or two ago no decided cases of small-pox have occurred here. The medical officer of health has recorded seven cases, most of which were directly traceable to an official in the employ of the Manchester, Sheffield, and Lincolnshire Railway Company, which communicates with Liverpool by the Cheshire Lines Committee.

In fact, the health of the city has been, on the whole, rather exceptionally good for many weeks past.

Dr. William Alexander, so well known by his operation of tightening the round ligaments and other original operations, has been without opposition elected honorary surgeon to the Royal Southern Hospital. The vacancy occurred by the retirement of Mr. Hamilton, whose term of office had expired.

Last week the Watch Committee appointed Dr. Macpherson and Mr. Rhinallt Pughe surgeons to the City Police Force for the north and south districts respectively.

CORRESPONDENCE.

DR. APOSTOLI AND ELECTROLYSIS.

SIR,—In a letter on this subject in the *JOURNAL* of March 3rd, it is stated that this treatment, even in the hands of its originator (in its present form), is full of danger to life. I am able to corroborate Dr. Apostoli's statement that this is not so, for Dr. Keith and I have made 2,567 applications for fibroids and other diseased conditions of the uterus, and, following Dr. Apostoli's directions, have had but one case where there has been any trouble. This patient did not do what she was told to do, and the result was an attack of cellulitis, which rest in bed has cured. After every application the patients have been able to go home, walking, driving, or by train.

We propose at a future time to bring before the profession the results of these applications; but at present I may say that we are treating a lady, who was told nearly three years ago by a well-known provincial abdominal surgeon, that if she did not submit to the operation of hysterectomy she would not live for six months! The tumour was then, and is still, simply an inconvenience from its size—it is not very large, and has already decreased about one quarter after six applications.—I am, etc.,
Edinburgh. SKENE KEITH.

NURSING FOR THE VERY POOR.

SIR,—In many parts of the country attempts have been made to establish permanently a parish nurse, or a nursing association of several nurses for a union of parishes. I do not here refer to towns, but to exclusively rural agricultural districts, where both farmers and tradespeople are poor. These attempts have been more often unsuccessful than the contrary, from various causes; but, without entering into the consideration of all of these, I may state that, in my own neighbourhood, the efforts in this direction have been crowned with eminent success, and I would, therefore, desire briefly to describe our system, and to point out where there is room for improvement, and in what way this improvement could be effected.

Our Nurses' Association was started in the beginning of 1883. Highly trained nurses have proved in other places unsuitable for the general run of illnesses in poor cottages, where there is but little room and means, and often but scanty or poor food to be obtained, and it seemed necessary to form the staff of nurses from women in the same station and circumstances of life as the patients themselves, as the nurse must, in the conditions under consideration, do the cooking and mind the children as well as nurse the mother, where the latter is the patient. Highly trained nurses, as a rule, will not be content with the poor food and accommodation that are to be found in a labourer's cottage, and a second hand is required to attend to the needs of the household, the man's dinner, the children's washing and dressing, etc.

We commenced, therefore, by engaging a respectable widow accustomed to nursing, and willing to act for a moderate fixed salary; others were soon found anxious to join, and as most parishes were either too poor or too small to keep and employ a nurse constantly, an association of parishes was formed. At present there are fourteen parishes and ten nurses. The parishes are limited to those within twelve miles of the secretary's home. In each parish that joins some lady must be found to represent it on the committee, to whom application is to be made by those requiring a nurse, who will watch any case in her parish, and is willing to collect and guarantee a certain annual sum. This sum is fixed at £8 from each parish, with £1 more for every 100 people over 800. There is no central home, but the nurses lodge in different parts of the district. There is a sliding scale of subscriptions and fees at a rate that enables people of each class to keep a nurse for a month for the same cost that they would pay for ten

days' nursing in the ordinary way; subscribers getting the right to have a nurse at half fee. For instance, the labourers' subscription is 2s. annually; they have a nurse for 2s. a week. Gentry's subscription not less than 10s. annually, and fee for nurse 10s. weekly. Board and lodging, also, for the nurse to be provided in all cases, but in specially poor cottages they have an extra allowance from the Association of 2s. 6d. per week. The nurses are paid a fixed annual salary of £26, and board and lodge themselves when not out. The Association puts by £1 a year besides for each nurse, which she receives with accumulated interest on leaving. Young women of 21 or 22 are taken as probationers, and if they show care and interest in their work, and some competence in nursing ordinary cases, we give them a month's training in the City of London Lying-in Institution upon certain conditions.

Our standard of nurses is gradually rising, thanks partly to the popularity of the occupation bringing better women as applicants for vacancies, and partly to the readiness and eagerness with which the medical man's directions and suggestions are adopted, but we feel the want of some training in a general hospital for them, not to the perfection to which a thoroughly-trained nurse is brought, as we have our first-rate nurse in our local village hospital to which the more serious cases are taken, but training for a more limited period, enough to enable our nurses to comprehend something more of the nature of illness, and of her duties in watching and noting what occurs under her eyes. It may consist, for instance, of such elementary instruction as is given in ambulance classes, with some other matters which make up a nurse's daily and hourly duties. Our means, however, are quite inadequate to enable us to pay for this desirable instruction ourselves, but we think that by combined representations from many similar nursing associations to the Committee of the Queen's Jubilee Fund, a grant might be obtained for the purpose, which, together with some fee from the Nursing Association, might be paid to some general hospital, which should undertake in return to give the required training.

If the committees of nursing associations generally throughout the country would make the necessary representation of their needs to the Secretary of the Duke of Westminster, Grosvenor House, their applications would without doubt be considered with ready courtesy and good will, and will probably meet with success; and thus much might be done to increase the efficiency of the nursing of the sick poor, with all its attendant good and advantage. I would gladly give as much information as possible, but fuller particulars with pamphlet (price sixpence) can be had from Sewell, Stockbridge Terrace, London, S.W.—I am, etc.,
Capel, Surrey. J. L. JARDINE, M.R.C.S.

THE BIRTHPLACE OF CONSUMPTION.

SIR,—In last week's *JOURNAL* you have done me the honour of alluding, in one of your leading articles, to a paper of mine dealing with the above-named subject.

The writer of the article does not accept the conclusions that I had ventured to consider probable. His scepticism is, however, based upon an entire misconception of the statistics which he adduces. He has unfortunately attributed much weight to an apparent contradiction between the figures given in the above-mentioned paper and some statistics quoted by me in a health lecture on "Foul Air and Lung Disease." He affirms, as if with my authority, that the "Consumption death-rate from 1865-76" was for England 3.54 per 1,000, for Salford 5.12, for the registration district of Manchester 6.10, and for Manchester township in 1874, 7.7. It is thus made to appear that the alleged breeding grounds of phthisis have really a lower phthisis-rate "than the more healthy regions of the whole area of which they form a part."

With such premisses as these, it is not wonderful that the writer of the article should consider that all the subsequent conclusions of my paper are "vitiated." But he has, by inadvertence, been led here into a serious error, and one that I must beg you to rectify as soon as possible.

The figures that he gives as referring to consumption do not relate to that disease at all, but appear in the Registrar-General's tables, and also in the lecture, as diseases of the respiratory organs, not phthisis. In the Registrar's returns there are two distinct columns, in which deaths from (a) Phthisis, and (b) Disease of the Respiratory Organs, are grouped. The table quoted by me from Mr. Baxendell includes only the latter group, and as these diseases kill about twice as many as phthisis, the death-rate

mentioned by the writer of the article is about twice as large as the true consumption death-rate.

The consumption death-rate in England has never been much more than 2.5 per 1,000. It is now only 1.7, whilst the death-rate from diseases of the respiratory organs is about 3.6.

The consumption death-rate for Salford in 1871 was 2.3, not 5.12, and that for Manchester was 3.6, not 7.7.

Hence my contention is conclusively proved, that the death-rate from consumption in the districts selected is more than twice that of the general phthisis-rate.

It is hardly necessary to notice the writer's other objections to my figures. Still I may mention that, if he had been better acquainted with the districts, he would not have spoken of "shops" as a source of error. There are scarcely any shops, even in the comparatively larger streets. All the streets I have named in the paper are almost wholly composed of small two-roomed "back to back" houses, and they are strictly comparable as to the character of their populations.

Lastly, the writer mentions children's deaths as a source of fallacy; but, in fact, there were scarcely any such deaths amongst those who had died of consumption.—I am, etc.,

Manchester, February 28th, 1888. ARTHUR RANSOME.

MEDICAL OFFICERS AND THE INDIAN COUNCIL.

SIR,—There died a few days ago at Cannes a distinguished lawyer, a man of letters and a member of the Indian Council, Sir Henry J. Sumner Maine, who, the *Times* kindly informs us, was the son of a "medical man."

His place in the Indian Council has been filled, I see, by Sir Charles Turner, K.C.I.E., another distinguished lawyer, at whose appointment we all, who had the honour and pleasure of his acquaintance in Madras, will rejoice.

If we look at the list of members of the Indian Council, however, we find it to consist of fifteen members, of which eight are soldiers, five civilians, one lawyer, and one merchant. Not a single medical officer! And the question which naturally arises to one's mind is, Why is this?

Now India owes a great deal to the medical profession. Old Orme tells us, in his unrivalled *History of Hindustan* (vol ii, book 6, page 8), that to Dr. Broughton, *temp.* 1636, the Honourable East India Company owed its first settlement in Bengal, and that most gallant and accomplished soldier, Sir Neville Chamberlain, G.C.B., G.C.S.I., only the other day, proclaimed it as his opinion, "That the peaceful and civilising influence of the work done in the hospitals and by regimental surgeons on the frontier of India has been in political importance equivalent to the presence of thousands of bayonets."

"The great question to be solved in the future is that of how we can best bridge over the chasm which separates the rulers from the ruled. The means of accomplishing this end may be mainly hoped for in the sympathy to be created between the races; and I think the medical profession will always have it in its power to give most important aid towards the attainment of this object."

And yet not a member of this important profession is deemed worthy of a seat in the Council which directs the affairs of this great dependency of England. Surely there is something wrong here, for it can scarcely be denied that sanitary and medical matters occupy as important a place in our administration of India as even the law.

Much more might be written on this subject, but in deference to your urgent request for brevity from your correspondents I desist.—I am, etc.,

M. C. FURNELL, M.D., C.I.E.
The Riviera, February 20th, 1888.

IMMUNITY OF CERTAIN TOWNS FROM DIPHTHERIA.

SIR,—In reply to the inquiries upon the origin and mode of propagation of epidemics of diphtheria, which the Collective Investigation Committee issued at the beginning of the year, I have been informed, amongst other things, of the complete immunity from epidemics of membranous disease of some towns of considerable size and importance. Will you allow me to say, through the medium of the *JOURNAL*, that the Committee will be glad to receive information of such immunity wherever it has been observed to exist? It will add, of course, to the value of the fact if some details of the situation and character of the town or district be at the same time given.—I am, etc.,

ISAMBARD OWEN,

Secretary to the Coll. Inv. Comm.

5, Hertford Street, Mayfair, March 6th, 1888.

THE IMPROVEMENT OF BRITISH HEALTH RESORTS.

SIR,—The observations contained in your interesting letter on Carlsbad, as to the importance of increasing the attractiveness and usefulness of our own health resorts, are worthy of the earnest attention of all parties concerned, and it has been for years a matter of astonishment to me that something has not been done long ago in the direction indicated, especially during the last few years of agricultural and commercial depression.

The absolute necessity for changes in the working of our commercial system, in order to meet successfully foreign competition, is forcing itself home to the minds of our legislators, and stimulating inquiry into our methods of technical and commercial education, and it may well be asked if something should not be done to raise British sanatoria to a higher level of popularity.

Physicians who practise abroad know at what sacrifices and by means of what rigid economy many invalids contrive to winter abroad, and how many things which to an invalid are necessary comforts have to be dispensed with. It is unfortunately our common experience that such persons are only too often unable to pay even very moderate professional fees, and all this notwithstanding great sacrifices on the part of their relatives at home.

I have often asked myself if many such invalids would not be better in England, where any special advantage of wintering abroad would be counterbalanced by the increased comfort of an English house, English cookery, and the associations of home and proximity to friends, while the expenses of a long, costly, and often uncomfortable journey and sea-passage would be avoided, and the distress of mind incidental to parting whilst in feeble health from the family circle would be spared to the invalid.

To the rich the special advantage of foreign residence will always be attractive; but even to these the long journey will sometimes be a serious consideration.

There are many South Coast sanatoria which, if properly developed, would often enable the invalid to remain in England. My own experience while practising in Devonshire long ago convinced me of this; but, for the completeness of such, an entire re-organisation by the establishment of winter gardens, pleasure grounds, baths of various kinds, libraries, and really good cheap music would in almost every case be required. It is incomprehensible to me that some such organisation as that at Carlsbad—which, with certain local modifications, exists in every spa in Germany—should not have been long since applied in England.

Buxton has been renowned for centuries, and thousands can testify to the value of its healing springs and hardly less valuable, invigorating, bracing air and high altitude. Thanks to what has been done by the Dukes of Devonshire, it has of late years undergone great improvement; but why should the sufferer from gout or rheumatism be unable there to have his treatment varied or modified by baths of Droitwich brine or similar addition, as is in Germany accomplished by the employment of various "mutter-lenge," pine-needle extract, etc.? The *Kurtaxe* of a German bath is never felt as a burden, but in the aggregate produces a sum which enables all the expenses of the *Kurhaus*, gardens, etc., to be defrayed.

So far from its being cheaper, to take a "cure" in an English watering place, it is much cheaper to go abroad to such places as Homburg, where the expenses of living are so much less than at an equally fashionable English health resort as to more than make up for the extra expense of the journey. I feel sure that the experiment only needs to be tried in a really intelligent manner in order that it may be found to be a great pecuniary success.—I am, etc.,

EDWARD DRUMMOND, M.D.

3, Piazza di Spagna, Rome, February 24th, 1888.

RULING OF THE JUDGES IN CASES OF INSANITY.

SIR,—In the *JOURNAL* of February 25th, Dr. Forbes Winslow directs attention to the contradictory ruling of two judges in cases of insanity. On the day previous to the trials referred to, a man was tried for murder at Worcester before Lord Chief Justice Coleridge. By order of the Treasury two medical experts had examined the prisoner. I was subpoenaed as a witness for the Crown. We were all asked by the Judge for our opinion as to the state of the prisoner's mind.—I am, etc.,

G. W. RICHARDS, M.D.
Stourbridge.

MEDICO-LEGAL AND MEDICO-ETHICAL.

THE IRISH CONJOINT SCHEME: THE KING AND QUEEN'S COLLEGE OF PHYSICIANS v. THE APOTHECARIES' HALL, DUBLIN, AND OTHERS.

This case began on Wednesday, March 1st, and terminated on Saturday before the Vice-Chancellor. The plaintiffs sought a declaration that the Apothecaries' Hall are not entitled to hold a qualifying medical examination under the Medical Act, 1886, or to grant a diploma in respect of medicine within the meaning of that Act, and that the Apothecaries' Hall and the College of Surgeons are not entitled to enter into a combination for the purpose of holding such examination.

Mr. Serjeant HEMPHILL, in stating the case for the plaintiffs, said that in 1692 the College of Physicians was founded, and by the powers granted it had since, after due examination, granted licences to persons to practise medicine. In the thirty-first year of the reign of George III the Apothecaries' Hall was founded, and from that time the governor and company of the Apothecaries' Hall had a shop for the sale of medicines in Dublin, and held examinations under the Act, and granted certificates to persons who passed the examinations that they were properly qualified to practise the profession of apothecary. Shortly after the passing of the Medical Act, 1886, a scheme was formed for a combination between the College of Physicians and the College of Surgeons. The governor and company of the Apothecaries' Hall applied to the General Medical Board on November 9th, 1886, for an examiner in midwifery and surgery, and that application having been communicated to the College of Physicians, they wrote pointing out that the Apothecaries' Hall had no power to grant a diploma in medicine, and it was only empowered to grant a certificate in pharmacy. The College of Surgeons, however, entered into a combination with the Apothecaries' Hall, and the Medical Council appointed, on May 19th, 1887, two examiners in surgery to the Apothecaries' Hall. No examinations, however, had since been held at the Apothecaries' Hall, but advertisements were issued for a conjoint qualifying examination to be held by the two bodies, and it was to prevent this intention being carried out that the present injunction was sought. The College of Physicians submitted that the Apothecaries' Hall was not a medical corporation capable of granting medical diplomas, or capable of entering into a combination with the College of Surgeons to grant diplomas, and that the effect of allowing such a body to grant diplomas would be to lower the status of the profession. They, therefore, asked the Court to declare that the Apothecaries' Hall was not entitled to hold a qualifying examination in medicine under the Medical Act, or to enter into a combination with the College of Surgeons to do so. The position of Members of the College of Physicians was wholly different from that of apothecaries, and this was intended, both by charter and statute. Physicians alone were entitled to practise medicine in Dublin and throughout the country, while the business of apothecaries, who were really given a monopoly, was simply to sell and compound medicines, and follow the prescriptions of the physicians. He referred to the Acts regulating the position of apothecaries, and contended there was nothing in them giving them the status of a medical corporation capable of granting a diploma in respect to medicine, nor was such power given to the Apothecaries' Hall by the Medical Act of 1886: nor was the Hall entitled to obtain the aid of the examiners in surgery appointed by the General Medical Council, or to enter into a combination with the College of Surgeons to hold a conjoint qualifying examination under that Act. He submitted that the effect of the statute law was simply to enable the apothecaries to register themselves as they did previous to 1858, and at the passing of the Act in 1886 the Hall was not in a position to grant a medical diploma. The claim of the Apothecaries' Hall to confer medical diplomas was wholly inconsistent with its Act of Parliament, by which it should stand or fall, and was in contravention of the rights of the King and Queen's College of Physicians and of the provisions of the Medical Acts. The Apothecaries' Hall had no right, and had never acquired any right, to grant diplomas in medicine, and not having it they could not combine with the College of Surgeons with the object in question.

Mr. BEWLEY, Q.C., on the part of Dr. Heard, the Registrar, said it was not the business of his client, to support the contention of either party in this suit.

Mr. PURCELL, Q.C., on behalf of the Apothecaries' Hall, sub-

mitted that the case made on the other side was unfounded in fact, untenable in law, and was wholly unjustifiable. On the true construction of the Acts of 1858 and 1886 the Apothecaries' Hall was clearly entitled as a medical corporation to combine with any other medical or surgical body named in the Act of 1886 for the purpose of carrying out qualifying examinations and granting medical diplomas. So far back as any records existed about apothecaries, they had been under the common law and by usage practitioners in medicine. They had that status even before any charters had been granted, and before their own Act of 1791, which did not restrain their status in that respect. From the Act of 1791 to the present hour the apothecary had been, by virtue of his position, a practitioner of medicine. His clients had been most anxious to combine with the Colleges of Physicians and Surgeons for the objects contemplated by the Act. The General Medical Council, by their resolution of June, 1863, had decided by a large majority that the licence of the Apothecaries' Hall was a licence to practise medicine. The present was not the first attempt on the part of the College of Physicians to destroy the status of the apothecary. It was only one of a series of attempts made during the past thirty years, all of which had failed. Every effort had been made by the General Medical Council to induce the College of Physicians to enter into this combination, in order that all the examining bodies might be in union for the purpose of having one strong licensing body in Dublin.

Serjeant CAMPION, for the College of Surgeons, said his clients had acted on the opinion of the General Medical Council that the Apothecaries' Hall were a medical corporation, competent under the Act of 1886 to combine with them for the purpose in question.

Serjeant JELLETT, on behalf of the College of Physicians, said that the Medical Act (1886) clearly distinguished between medical corporations pure and simple and medical corporations capable of granting diplomas in medicine or surgery. In order to hold a joint examination in medicine, surgery, and midwifery under them, there should be a combination of two or more medical corporations, of whom one at least was capable of granting a diploma in surgery. Universities could grant both those diplomas. If, therefore, the Apothecaries' Hall had combined with a university, they would have been entitled to do that which they claimed to do; or, if they could combine with both the Colleges of Physicians and Surgeons, they would be in a position to hold the qualifying examination and grant the diploma. Failing to obtain those combinations, the only course open to them was to apply to the Council for examiners in both medicine and surgery, who would hold for them an examination the passing of which would qualify the person to be registered under the Act of 1858.

The VICE-CHANCELLOR: Do you concede that the Apothecaries' Hall are a corporation competent to grant a diploma conferring on the holder, if he has passed the qualifying examination, the right to be registered under the Act of 1858?

Serjeant JELLETT said he did. The position of the Licentiate of the Apothecaries' Hall in Ireland was quite different from that of the Licentiate of the Apothecaries' Hall of England. By the charter of the College of Physicians of Ireland the whole domain of physic, both as to theory and practice, had been given into their hands.

The VICE-CHANCELLOR said if he thought it necessary to go into the many important and interesting questions which had been so elaborately opened by counsel at both sides in order to arrive at a conclusion, he should have thought it desirable to postpone his judgment; but as in his opinion the case turned on a narrow point of law, arising on the construction of the Act of 1859 and the Medical Act of 1886, and involving but very indirectly the subjects so discussed, he did not think any advantage would be gained by taking time for further consideration. The Acts he mentioned were to be read as one Act. The Apothecaries' Hall claimed the right to combine with the College of Surgeons for the purpose of holding a qualifying examination, under the Act of 1886, in medicine, surgery, and midwifery. The College of Surgeons had the power of granting a diploma in surgery. The Apothecaries' Hall claimed to be entitled, under the Act of 1886, to grant a diploma in medicine. The College of Physicians insisted that a combination of these two bodies to grant a diploma in medicine was illegal, because no right of doing so existed in the Apothecaries' Hall. Under Section 15 and Schedule A of the Act of 1859 licentiates of the Apothecaries' Hall of Dublin were entitled to registration on production of a document evidencing or conferring their qualification, namely, the licence, under seal of the Apothecaries' Hall, and on the payment of a certain fee. A Licentiate of

that body, therefore, belonged to a body capable of granting a diploma, and, reading the two Acts together, to a body capable of granting a diploma in medicine. The Apothecaries' Hall was one of the constituency of learned bodies, including the Universities and the Colleges of Physicians and Surgeons, by whom the Medical Council was provided to be elected, and was made co-ordinate in authority and power with the rest of them. A great deal of argument had been addressed to the question of whether it was a wise thing on the part of the Legislature to have included the Apothecaries' Hall in Ireland in the list of bodies entitled to be styled qualifying bodies. It was said that the nature of their profession was of an inferior grade, and that the nature of their instruction was inferior and inadequate, and that therefore it was an error on the part of the Legislature to have put them on the Register with the power of practising as persons registered as medical practitioners could do. He dissented from all the parts of that proposition. He was satisfied that the apothecary was something very much beyond a mere druggist and chemist or compounder of medicines, and should be prepared to hold, if necessary on statutory recognitions and legal decisions both in England and Ireland, and on the evidence before him as to practice, that the apothecary was a person capable of lawfully practising as a medical practitioner in respect of medicine at least. In addition to that, the educational qualifications of apothecaries since the Act of 1859 had been on a very different footing from what they were at the time of the passing of the Act of 1791. He need only refer on that point to the affidavit made in the case of Dr. Montgomery, the Secretary of the Apothecaries' Hall, which showed that candidates for their licence were required to produce certificates of having attended lectures on chemistry, materia medica, botany, anatomy, pharmacy, physiology, and the theory and practice of medicine, and were also required to pass examinations in all these various subjects. He also stated what had been done to provide competent examiners, and, which was a matter of great importance, that the certificates of attendance were accepted by the Faculties of Physicians and Surgeons of Glasgow and Edinburgh. The College of Surgeons in Ireland, though at first they refused those certificates, yet afterwards formally rescinded that decision and accepted them. Therefore if it were necessary to go into the question it would be found that the Legislature had not been guilty of opening a door to unqualified uneducated persons. He believed that for a century and a half, or more, the apothecaries had been accustomed to practise to a certain extent as medical practitioners. But deciding the case on the question of law, he held that under the two Acts mentioned the Apothecaries' Hall were entitled to grant a diploma entitling the holder to registration as a medical practitioner, and to combine with the College of Surgeons to hold qualifying examinations in medicine, surgery, and midwifery. These matters were all under the control of the General Medical Council, who were bound to see that the education was sufficient, and, if not, to bring the matter under the consideration of the Lord Lieutenant. Therefore the case of the relation was not sustained, and the information should be dismissed with costs.

AN ARSENIC POISONER.

THE numerous refinements in the art of poisoning that have been introduced of late years have not, it would appear, caused those who wish to get rid of relatives or acquaintances wholly to dispense with the old-fashioned plans. We learn from a Boston contemporary that a woman, named Robinson, has lately been convicted at Cambridge, Massachusetts, of the murder of her brother-in-law by the administration of arsenic. The indictment charged her with the murder of seven persons, all within the space of five years, namely, her landlord, husband, sister, brother-in-law, daughter, nephew, and son, that being the chronological order in which the deaths occurred. All died with the usual symptoms of arsenical poisoning. She was first tried for the murder of her son, but the jury were unable to agree; the next count taken was for killing her brother-in-law, and on this charge she was found guilty in the first degree. Suspicion was not aroused against her until during the illness of her son, the last victim, arsenic having been detected in the matters vomited by him. She was arrested on the day before he died, and arsenic was subsequently found in his body. The bodies of the others mentioned above were then severally exhumed and examined, with the result that arsenic was found in the viscera in each instance. The alleged motive in at least four of the cases was the insurance money on the lives of her victims. The chief reason of

her success—for in many respects she was a clumsy performer—was no doubt that she moved about from place to place, so that her several victims were under the care of different medical men, otherwise she must have been found out long before. These murders only afford one more instance of the extreme necessity there is that medical men should always be on the alert, and in the case of an illness commencing suddenly or gradually in an adult with vomiting and purging for its most prominent features the possibility of arsenical poisoning should always be borne in mind.

A WOULD-BE SUPPLANTER.

A. G., writes: I have held a club appointment for nearly six years; the appointment is held subject to a three months' notice on either side, and I am re-elected at every annual meeting of the club. At the last annual meeting a letter was read from a medical man, applying for the post of medical officer to this club. I may say that this person had not been officially asked to apply for the post, neither had any complaints been laid against me by the officers or members of the club.

I was led to understand, when I took the appointment, that so long as I discharged my duty honourably, the re-election was a mere matter of form—to comply with the club rules.

* * * Although there is no rule laid down in the *Code of Medical Ethics* that directly bears on the case of our correspondent, he may nevertheless accept it as a fact, that such questionable conduct as that alleged against his would-be supplanter is not only in contravention of the true spirit of medical ethics, but of the great moral law of "doing unto others as we ourselves would wish to be done by."

CHRISTMAS CARDS.

THE exceptional question submitted by L. S. A., is too indefinitely expressed to enable us to grasp the special point involved therein. Why it should be "unprofessional (as our correspondent puts it) for a medical man to send out Christmas cards," in accordance with time-honoured custom, we fail to comprehend.

INCOME TAX.

K. asks: Can I deduct keep of horses—and if so, how much do they allow per horse—wages of groom and of surgery boy, rent of surgery? I believe I can deduct £120, if my return is under £100, and also any insurance premiums that I pay. There is another important item which I think would affect a good many men. Supposing a man going into practice has to borrow say £1,000 to buy with, and of course has to pay interest, say £50 per annum, can he also deduct this £50?

* * * K. has a right to deduct all professional expenses, consequently rent of surgery, costs of keeping horses, wages of groom, and wear and tear of carriage, harness, etc. As regards interest of borrowed money, he cannot deduct it as a professional expense, nor is it right he should, for in paying the interest, he can recoup himself by deducting the income tax from the interest. But, and this is most important, he may deduct the interest from his gross income to arrive at his net income. This will often enable a person to get abatement. There are so many of these rules connected with the assessment, that K. is recommended to apply to the Income Tax Repayment Agency, 25, Colville Terrace, W. It will help him in getting a fair assessment in the first instance, in appealing against an unjust one, and in getting back past income tax. Very possibly he might be entitled to three years' refund.

ADVERTISEMENTS IN LOCAL PAPERS.

In reply to "Nota Bene's" question, we would refer him to the *Code of Medical Ethics*, page 52, in which he will find the principle clearly laid down that "to advertise in a local paper change or addition of consulting hours," etc., is in contravention of medical etiquette, and derogatory to the profession.

EXPENSES OF AN ASSISTANT'S ILLNESS.

DR. D. (Durham).—Illness and consequent temporary loss of service does not terminate the contract. The parties have apparently agreed to treat it as now at an end; but the assistant is entitled to salary up to the date when the contract ceased. As regards expenses of apartments, etc., the strict rights of the parties are, under the circumstances stated, hard to ascertain. It seems that the removal took place as a matter of mutual convenience, and it would seem reasonable that each should bear some part of the extra expense consequent on it.

RECENT RULING AS TO EXPERT EVIDENCE.

DR. ROCHE.—What the leading article in the *JOURNAL* took exception to, was the exclusion of the expression of opinion (on the mental state) by the medical witnesses when giving evidence; it being for the jury to return a verdict when all the evidence is placed before them.

LUNACY CERTIFICATES: ACTIONS FOR DAMAGES.

INFELIX.—We have been unable to find the report, but the cases of *Weldon v. Rutherford*, and *Weldon v. Semple*, were tried we believe at the end of 1855 or beginning of 1856. They were reported in the *Times*, and are no doubt to be found in its index.

W. V. B.—If an action is brought to recover the money alleged to be due, the defendant can be ordered to produce his books, and to state on oath the amount he has received. It is desirable however to have some independent evidence that some money has been paid, before commencing proceedings.

T. M. W.—We should think two guineas a fair charge.

NAVAL AND MILITARY MEDICAL SERVICES.

RESERVE OF ARMY MEDICAL OFFICERS.

A ROYAL WARRANT is announced on the above subject, the text of which will doubtless appear in Army Orders in the forthcoming *Monthly Army List*. The substance of the warrant is as follows:—It is expedient to provide for the establishment of an army medical reserve of officers. The ranks of officers will be those of surgeon-major and surgeon. Medical officers of militia, yeomanry cavalry, and volunteers, who may be permitted to join the reserve, will be required to undertake to perform army duties at home, under rules to be fixed by the Secretary of State for War, and to act under the orders for administrative purposes of the Director-General of the Army Medical Department. Acting-surgeons and honorary assistant-surgeons will be permitted to join if they have passed the prescribed examination for proficiency. The rank of surgeon-major will be conferred on those surgeons of the auxiliary forces who join the reserve on completion of twelve years' service, from date of first appointment to the auxiliary forces, and the rank of surgeon will be granted to acting-surgeons and honorary assistant-surgeons of Volunteers. No officer will be appointed who is not medically fit for service, and whose character and qualifications are not in all respects satisfactory. They will be liable to be called to army service at home in times of great national emergency, to take the place of such of the medical staff of the army as may be withdrawn for active service, and when so called out will receive the pay and allowance of their rank.

We hope to be able to give the Warrant in full, with some comments, in our next; meanwhile, we would advise all concerned, before taking any action, to scrutinise well both its terms and objects.

HONORARY SURGEONS TO THE VICEROY IN INDIA.

IN the year 1881 Lord Ripon instituted the appointments above named; three were given to officers of the Army Medical Staff serving in India, and three to medical officers of Her Majesty's Indian army. Medical officers holding appointments as honorary physicians and surgeons to the Queen wore a gold-embroidered sash as a mark of distinction. In like manner the honorary surgeons to the Viceroy of India were distinguished when in military uniform by an aiguillette. We have just received a copy of an official memorandum, addressed by the military secretary to the Viceroy to the honorary surgeons, a copy of which we append, informing them that this aiguillette, in deference to military jealousy, can no longer be worn by them, and that an application on the part of the Viceroy to the authorities at home for permission to substitute the sash worn by honorary surgeons to the Queen for the aiguillette was refused. The Viceroy's aide-de-camps wear exactly the same marks of distinction as those holding the same appointment on the Queen's honorary staff; but it appears that this mark of distinction and recognition of an honourable position is one that cannot be worn by "doctors," and they are accordingly subjected to the indignity, in the face of the whole army of India, and of society there, of having this symbol of honourable rank torn from them to gratify the *orgueil* of a class, and the almost insane determination on the part of the military authorities to heap contempt on a body of officers on whom they are in their hour of utmost need dependent for their very lives.

To the gentlemen thus insulted it appears to us there is but one course open: immediate resignation of the "honour" conferred on them; and for those to whom a like "honour" may in future be tendered a polite refusal to accept it.

The fixed policy of the authorities seems to be to drive everyone in the shape of a gentleman out of the medical service of the army, and to prevent men of the same class from entering it. They are certain in the long run to effect their object.

MEMORANDUM.

EXCEPTION having been taken by the military authorities to the honorary surgeons of the Viceroy wearing an aiguillette, it was proposed that a sash similar to that worn by the honorary surgeons to the Queen should be worn instead of the aiguillette. This was referred home, and the request has been refused by the Home authorities.

It is hereby notified that that part of the circular dated December 18th, 1881, referring to the wearing of aiguillettes, is entirely cancelled, and the gold aiguillette is not to be worn in future by honorary surgeons to His Excellency.

By Command, WILLIAM BERSFORD, Lieut.-Col.,
Medical Secretary to the Viceroy.

Military Secretary's Office, Calcutta,
January 21st, 1888.

NAVAL MEDICAL REPORTS.

INSPECTOR GENERAL DONNET, R.N., in a paper recently read before the Epidemiological Society on malarious fevers, etc., strongly urged that naval medical officers should have some recognised official channel through which they could make known to the public their wide and varied observations on the etiology, particularly of climatic diseases. This very distinguished officer again writes to us, as he did a good many years ago on this subject, and we express now, as we did then, our entire sympathy with his views. But we much fear his wish is now even less near realisation than it was then. In recent years, instead of relaxing, the Treasury has tightened its purse-strings over the publication of both military and naval medical reports. It costs money, and in these times of retrenchment our government are not likely to be induced to emulate the liberality of France, Russia, and Holland in publishing such reports. The value to the profession of the extended and varied observations of the medical officers of the public services is indeed very great. But if these experiences are to be collected and published, we suspect it will have to be through private enterprise. As far as this JOURNAL is concerned we shall always be happy to do what we can in this direction.

THE NAVY.

FLEET-SURGEON W. G. RIDINGS has been placed on the retired list with the rank of Deputy Inspector-General. He entered the service as Surgeon July 11th, 1856; became Staff-Surgeon September 22nd, 1866; and Fleet-Surgeon May 3rd, 1877.

Staff-Surgeon ANTHONY GORHAM, M.D., has been promoted to the rank of Fleet-Surgeon. He ranked as Surgeon from November 12th, 1867, and as Staff-Surgeon from March 23rd, 1881. He served as Surgeon with the Naval Brigade during the operations in the Malay Peninsula in 1875, and was noted for promotion when qualified (medal with clasp).

Staff-Surgeon T. C. HICKEY, M.B., has been promoted to be Fleet-Surgeon. He was appointed Surgeon September 7th, 1867, and Staff-Surgeon March 15th, 1879.

The following appointments have been made at the Admiralty:—THOMAS FULLER, M.D., to be Surgeon and Agent at Shoreham and Fishergate; C. L. VASEY, Staff-Surgeon to the *Curagoa*; JOHN DUDLEY, Staff-Surgeon, to the *Brisik*; JEROME BARRY, Surgeon, to the *Curagoa*; D. J. P. McNABB, Surgeon, to the *Banterer*; JAMES TRIMBLE, Fleet-Surgeon to the Royal Marine Artillery Division at Eastney; G. R. D. CHARLTON, Surgeon, to Sheerness Dockyard; J. W. O. UNDERHILL, Surgeon, to the *Pembroke*; additional.

THE MEDICAL STAFF.

DEPUTY SURGEON-GENERAL J. B. C. READE, C.B., is promoted to be Surgeon-General, ranking as Major-General, vice T. W. Fox, M.B., who has been granted retired pay. He entered the Army Medical Service as Assistant-Surgeon March 24th, 1854; became Surgeon April 19th, 1861; Surgeon-Major, March 1st, 1873; Brigade-Surgeon, November 27th, 1879; and Deputy Surgeon-General, October 23rd, 1881. He served with the 2nd Battalion Rifle Brigade throughout the Eastern campaign of 1854-55, including the battles of Alma and Inkerman, and siege of Sebastopol; was wounded on November 14th, 1855, at the explosion of the French siege train (medal with three clasps, and Turkish medal). He was with the same battalion during the whole of its service in suppression of the Indian mutiny, including the actions at Cawnpore, capture of Lucknow, and numerous affairs during the Oude campaign (medal with clasp). He was also engaged in the Afghan war in 1878-80, was mentioned in despatches, and received the medal granted for the campaign. He was nominated Companion of the Bath in 1886. He is an Honorary Surgeon to the Governor-General of India.

Surgeon-Major F. B. SCOTT, M.D., C.M.G., is promoted to be Brigade-Surgeon, ranking as Lieutenant-Colonel, vice W. B. Ramsbotham, M.D., retired. Brigade-Surgeon Scott's previous commissions are dated: Assistant-Surgeon, October 1st, 1862; Surgeon, March 1st, 1873; and Surgeon-Major, April 28th, 1876. From *His Army List* we learn that he received the special approbation of the Madras Government, followed by that of His Royal Highness the Commander-in-Chief, for his services rendered while in medical charge of the 18th Hussars during a most virulent outbreak of cholera in the regiment at Secunderabad in May, 1871. He served in the Zulu war of 1879; organised the Bearer Company, made the hospital arrangements at the Fort Pearson base for the Ekowe Relieving Column, served afterwards with the 2nd division on the personal staff of Lord Chelmsford and in medical charge of the Headquarters Staff, was present in the engagement at Ulundi, where his services were described by Lord Chelmsford as having been "of the greatest value"; he accompanied the 17th Lancers in their charge and pursuit of the enemy, and by rendering timely aid to a lancer who was dangerously wounded prevented his falling into the enemy's hands, and served subsequently to the end of the war as Senior Medical Officer of Port Durford and that line of communication between Ulundi and the Tugela (mentioned in despatches, medal with clasp). Served in the Egyptian war of 1882 on the personal staff of Major-General the Duke of Connaught, commanding the 1st Brigade, and was present at the battle of Tel-el-Kebir (C.M.G., medal with clasp, and Khedive's star).

Surgeon-Major T. P. O'DWYER, M.D., is also promoted to be Brigade-Surgeon, vice F. P. Staples, retired. His commission as Assistant-Surgeon bears date September 30th, 1864; Surgeon, March 1st, 1873; and Surgeon-Major, September 30th, 1876. He served in the Egyptian war of 1882 in command of No. 2 Bearer Company, and was present at the action of Kassasin on September 9th, and at the battle of Tel-el-Kebir (mentioned in despatches, promoted Surgeon-Major with relative rank of Lieutenant-Colonel, medal with clasp, and Khedive's star). He was also engaged with the Nile expedition in 1884-85 as Secretary to the Principal Medical Officer (mentioned in despatches, clasp).

Surgeon-Major A. MORPHEW, at present serving in Bengal, is directed to proceed to England during the present trooping season, and is detailed for duty with troops.

Surgeon W. HALLAHAN, M.B., on arrival from England, is directed to do general duty in the Burmah Division, Madras command.

THE INDIAN MEDICAL SERVICE.

SURGEON H. ST. C. CARRIERS, Madras Establishment, Civil Surgeon at Tellicherry, and acting Principal Medical Storekeeper, is appointed Civil Surgeon of Rajahmundry, in succession to Surgeon-Major H. M. G. Archdall, who has returned to the Military Department, but to continue to act as Principal Medical Storekeeper, until relieved by Brigade-Surgeon R. B. Pearce.

Surgeon J. N. VAN GYZEL, M.B., Acting Chemical Examiner, is appointed Civil Surgeon of Negapatam, vice Surgeon T. H. Pope, but to continue to act as Chemical Examiner until relieved by Surgeon-Major C. J. M'Nally, M.D.

Surgeon H. HERBERT, Bombay Establishment, is placed on general duty in the Northern Division.

Surgeon-Major C. F. OGILVIE, M.D., Bombay Establishment, has been granted leave out of India for one year on medical certificate.

Surgeon-General W. J. MOORE, C.I.E., Bombay Establishment, has retired from the service from February 25th, on a pension of £950 per annum payable in England. He entered the service November 20th, 1850, and rose to be Surgeon-General April 1st, 1885. He served with the Persian Expeditionary Force in 1856-57, and was present at the landing at Hallah Bay, and at the capture of Bushire (medal with clasp).

Deputy Surgeon-General JOHN PINKERTON, M.D., Bombay Establishment, is appointed Surgeon-General with the Government of Bombay, vice Surgeon-General W. J. Moore.

Surgeon-Major J. G. PITCHER, Bengal Establishment, Civil Surgeon of Howrah, is appointed to be Civil Surgeon of Darjeeling.

Surgeon T. C. MOORE has been admitted to the Madras Establishment from November 2nd.

Surgeon-Major T. C. H. SPENCER, Madras Establishment, has returned to duty from sick furlough.

The Queen has approved of the following admissions to the Indian Medical Service—

To be Surgeons, dated March 31st, 1887.—*Bengal*.—W. H. W. ELLIOT, JAMES MURRAY, W. R. CLARK, G. F. W. BRAIDE, R. J. MARKS, C. E. SUNDER, M.A.

KER, A. R. JOLLIFFE, ANDREW BUCHANAN, P. O. W. HAILEY, L. G. FISCHER, WILLIAM VOST, JOHN GARVIE, C. E. L. GILBERT, H. W. G. MACLEOD, C. C. MANIFOLD, and G. B. IRVINE. *Madras*.—W. G. McEVoy, F. J. CRAWFORD, M.D., DAVID SIMPSON, ROBERT ROBERTSON, T. C. MOORE, A. H. JACOB, and W. H. KARNEY. *Bombay*.—C. H. L. MEYER, L. F. CHILDE, HERBERT HERBERT, and T. D. O. BARRY.

To be Surgeons, dated October 1st, 1887.—*Bengal*.—A. E. ROBERTS, D. M. DAVIDSON, F. P. MAYNARD, J. C. LAMONT, A. H. NOTT, ALBERT COLEMAN, W. W. WHITE, M.D., D. T. LANE, M.D., R. C. MACWATT, W. H. E. WOODWRIGHT, W. J. BUCHANAN, J. K. CLOSE, M.D., J. M. MACNAMARA, M.D., H. M. BRATHOON. *Madras*.—W. H. M. INGHAM, P. J. DEWES, J. O. PINTO, P. O. H. STRICLAND, and T. W. STEWART. *Bombay*.—JOSHUA HOLT, T. H. GRIFFITH, J. L. T. JONES, and W. E. JENNINGS.

Surgeons G. B. FRENCH, W. R. CLARK, G. F. W. BRAIDE, M. A. KER, A. R. JOLLIFFE, P. O. W. HAILEY, L. G. FISCHER, W. VOST, J. GARVIE, C. E. L. GILBERT, H. W. G. MACLEOD, and C. C. MANIFOLD, all of the Bengal Establishment, have passed the examination in Hindustani by the lower standard.

Surgeon J. A. CLARK, late of the Bengal Establishment, died at Ayr, N.B., on March 3rd.

The undermentioned officers have leave of absence for the periods specified: Surgeon-Major T. ROBINSON, M.B., Bengal Establishment, for one year and 125 days on private affairs; Surgeon-Major G. M. J. GILES, M.B., Bengal Establishment, Surgeon Naturalist to the I.M.S. Investigator, for one year on private affairs; Surgeon-Major E. PALMER, Bengal Establishment, Medical Officer 9th Native Cavalry, for one year on private affairs; Surgeon-Major M. J. T. J. BLANGHARD, Madras Establishment, for six months; Surgeon-Major J. HUNTER, Madras Establishment, in medical charge of the 5th Native Infantry, for one year; Surgeon H. D. MASANI, Bombay Establishment, Medical Officer, 30th Native Infantry, for six months on private affairs.

THE VOLUNTEERS.

MR. JAMES HUNTER, M.B., who has been Acting Surgeon to the 5th Volunteer Battalion Argyll and Sutherland Highlanders (late the 1st Argyll Volunteers), since January 9th, 1884, is now appointed Lieutenant in the same corps.

MR. CHARLES DOWNING has been appointed Acting Surgeon to the 3rd Volunteer Battalion Welsh Regiment (late the 2nd Glamorgan), and Mr. P. P. LANGFORD is appointed Acting Surgeon to the 21st Middlesex (Finsbury).

Surgeon-Commandant JAMES CANTLE, M.B., has resigned his commission in the London Division of the Medical Staff Corps; his appointment bore date April 1st, 1885.

ARMY MEDICAL OFFICERS AND THE SERVICE CLUB.

X. writes from the Junior United Service Club, London, S.W.: Twenty candidates of various ranks in the army and navy, from sub-lieutenant upwards, were up for election to this club on February 25th. Amongst the candidates were two officers of the Medical Staff, and with the exception of these two officers all the others were duly elected. I know nothing personally or by repute of these two blackballed officers, but as they were proposed and seconded by officers of standing in the service, presumably there is nothing against them except that they belong to the Medical Service. I bring the matter to your notice as another instance of the class feeling which exists even in club military life.

INDIA AND THE COLONIES.

INDIA.

SURGEON C. J. ADDISON, Medical Staff, who successfully established an ambulance association in Quetta last year, has now organised with much success a similar association under the patronage of Major-General D. MacFarlan (commanding the Sirhind Division) at Umballa. Dr. Addison's lectures on "First Aid" are, we understand, being attended by a large class.

A COMMITTEE meeting of Lady Roberts's Homes in the Hills for Soldiers' Nurses in India was held on Friday, March 2nd, at 37,

Wimpole Street, under the presidency of Her Royal Highness Princess Christian. Arrangements were made for developing the organisation with a view of receiving further subscriptions. The amount collected since January 1st, 1888, is £1,108, in which sum is included a donation of £100 from Her Majesty the Queen.

HOSPITAL AND DISPENSARY MANAGEMENT.

THE VICTORIA DISPENSARY, NORTHAMPTON.

The annual report presented at the annual meeting of the Northampton Royal Victoria Dispensary, after stating that the Society now contained over 17,000 members, 6,454 of whom were paid up, and that there had been 3,000 fresh admissions during the year, proceeded to show that £1,820, 19s. 11d. had been paid to the five members of the medical staff as follows: Mr. Moxon, £435 18s. 6d.; Mr. Evans, £286 1s. 4d.; Mr. Cogan, £140 13s. 11s.; Mr. Spurgin, £362 6s. 3d.; Mr. Rae, £595. At first sight this amount looked large, but this was really not so, as 69,492 attendances had been made during the year—42,542 at the patients' own houses. Thus only 6d. per visit or attendance was paid, but still no complaints whatever had been made. In addition to this, over 63,500 prescriptions were made up; and at the dispensary 500 permanent and 592 temporary teeth were drawn. Altogether there was upwards of £2,485 paid for ordinary members, and £148 10s. 6d. by honorary members during the year, which, with a balance brought forward, made the receipts £3,815 1s. 7d. The expenses of the institution were over £2,576 0s. 5d., which left in hand £1,239 1s. 2d., a rather larger favourable balance than last year.

THE LEEDS GENERAL INFIRMARY.

The annual report of this important institution contains some especially interesting features. The number of inmates for the year was 4,601 against 4,167 in the preceding year. The number of out-patients was 23,000. The average cost of each in-patient was £2 12s. 10d. The annual subscriptions had slightly fallen off with one most important exception, those from the working classes. The income from the subscriptions of the working men showed a noble increase. It amounted to £3,646 for the year as against £3,738 annual subscriptions from other sources, and showed an increase of £1,515 over that of the preceding year. In addition to this there had been a gift of two ambulances from the work-people of Leeds, for which £328 was raised. A new semi-convalescent hospital will be opened in May, with accommodation for forty-two beds. This is provided by the benefaction of Mr. North, who will defray the entire cost, which is something over £5,000. A further requirement is for isolation wards for violent patients and those having infectious diseases. It is proposed to erect a new building for isolation, pathological, and out-patient purposes, of which the cost would not be less than £20,000. The receipts from Hospital Sunday amounted this year to £1,799 as against £2,101 last year.

CHILDREN'S HOSPITAL, SHEFFIELD.

The Children's Hospital has been undergoing alteration and enlargement, and at the annual meeting, held on March 2nd, the report stated that the new buildings would be ready for use by April. The buildings comprise boys' and girls' wards, which would hold fifteen beds each, isolating room, operating room, and suitable offices. They have been erected on vacant land at the back of the old building, and are connected to the old block by a covered way. The buildings have been so constructed that a second story can, if necessary in the future, be erected. The old building has been altered inside, and in future will be used only for out-patients, and the accommodation of the matron and her staff.

ROYAL BERKSHIRE HOSPITAL.

The annual meeting of the governors of this institution was enlivened by resolutions, of which notice had been given by Mr. Leveson Gower, to the effect (1) that no two members of a firm or family be on the active staff at the same time, excepting under special circumstances; (2) that no medical or surgical officer be more than twenty years on the active staff, or after sixty years of age. These resolutions had been precluded by some very silly anonymous letters which have appeared in the local papers, and there was a good attendance of governors in consequence. I

quickly appeared, however, that Mr. Gower had really nothing to say of any weight in support of his resolution, and the whole feeling of the governors, medical and non-medical, was evidently altogether opposed to laying down such restrictive rules, which, however applicable in great cities, where there is a considerable supply of first-class medical men and medical schools supplying young medical men aiming at consulting practice, for whom it is desirable to make room, have a much more doubtful application to small towns, where the precisely opposite conditions exist. The upshot of the whole matters discussed was that Mr. Gower's resolution found no one to support it, and was only seconded as a matter of form by a gentleman who disagreed with it. The Royal Berkshire Hospital has long been known for excellent work and for efficient arrangements, and the governors wisely thought that, when no case whatever was made out, it was better to leave well alone.

MEDICO-PARLIAMENTARY.

HOUSE OF LORDS.—Friday, March 2nd.

Lunacy Acts Amendment Bill.—The LORD CHANCELLOR, in moving the second reading of this Bill, said that there really was nothing to explain with which the House was not already fully acquainted, the Bill having been passed three times through their lordships' House without any substantial changes. It would be enough to recall shortly the leading points in the Bill, which were:—1. The introduction of a judicial authority for ordering the detention of a person as a lunatic; 2. orders of detention to come to an end unless renewed; 3. protection to medical men and others against vexatious actions where they have acted in good faith; 4. restrictions on opening new private asylums; 5. various amendments with a view to consolidating the Lunacy Laws. It would be remembered that the Bill was accepted by him from Lord Herschell, to whom it was handed down by Lord Selborne. While dealing with some subjects of a very delicate and controversial kind, it had been accepted as a valuable measure in all quarters, though, no doubt, regarded as in the nature of a compromise, and not indeed going so far as he himself might desire. It had already received very full and careful consideration in their lordships' House, and having been adopted at some stage of its history by each party represented in another place, it might be expected to be received in a like spirit there. If this House should pass the Bill in good time no blame would attach to the House or the Government if the Bill did not become law this session.—The Earl of MILLTOWN echoed the wish of the Lord Chancellor that the Bill might become law, and that no obstructive tactics elsewhere would prevent so important a measure from being added to the Statute Book. He regretted, however, that the Government had not taken steps to put an end to the scandals which were alleged to exist in connection with licensed houses. As long as what Lord Shaftesbury called "the evil system of profit" continued to exist, as long as the incarceration of a fellow creature should result in profit to anyone, so long might they expect a continuance of the scandals to which he alluded. He noticed, therefore, with regret that existing licensed houses were not to be interfered with. The only way to prevent scandals would be by a thorough system of visitation, but the present system could not be thus described, the Lunacy Commissioners being too few in number to inquire closely into the cases of 80,000 lunatics. He favoured a scheme under which county authorities should establish houses for paying patients. The authorities, he felt sure, would be the gainers. There was a large number of persons in asylums who were supported at the public expense, and who were able to support themselves; and if provision were made for receiving paying patients at moderate rates, the expenditure of the counties might be considerably reduced.—The Bill was then read a second time.

Tuesday, March 6th.

The Pharmacy Acts Amendment Bill.—The House went into committee on this Bill.—The Earl of MILLTOWN moved to insert the following clause:—"It shall be unlawful for a duly-qualified keeper of an open shop for retailing, dispensing, or compounding poisons to keep open shop in more places than one unless he shall engage and employ at each branch shop a person who would himself be a duly qualified keeper of an open shop for retailing, dispensing, or compounding poisons, and such person is *bona fide*

occupied in such branch shop; provided always that each partner in a duly qualified partnership may keep a separate open shop for retailing, dispensing, or compounding poisons. Every keeper of an open shop for retailing, dispensing, or compounding poisons acting in contravention of the preceding section shall for all such contravention be liable to pay a penalty of £5, and the said penalty may be sued for and recovered in the manner provided by the Pharmacy Act, 1852, for the recovery of penalties under that Act." He pointed out that it was the practice of druggists to open branches and put unqualified persons in charge of them. This practice was distinctly in contravention of the Act of 1863, but it had been held that under the Act, prosecutions could not be sustained.—Lord HERSHELL pointed out that the amendment only dealt with branch shops, and there was nothing in it to prevent the proprietor absenting himself entirely from his chief establishment and leaving it in charge of some unqualified person.—After some further discussion, the amendment was agreed to, and the Bill passed through committee.

HOUSE OF COMMONS.—Friday, March 2nd.

Non-resident Parochial Medical Officers.—Sir W. FOSTER asked the President of the Local Government Board whether it was a general rule to appoint in country districts parochial medical officers who were resident in the districts; and, if so, why this rule had not been followed in the Waters Upton District of the Wellington Union, in the county of Salop.—Mr. W. LONG, in reply, stated that as a general rule guardians, when the circumstances admitted of it, appointed as district medical officers medical practitioners who resided in the districts for which they were to act. In cases such as that referred to the appointment was annual, and the guardians in December last, by 15 votes to 3, determined to reappoint the non-resident practitioner, who had held the office for ten years with, it was stated, perfect satisfaction to the guardians and to the patients. The officer was daily in the district, and it was a condition of his reappointment that he should have a surgery in the district, where he was to attend at least two days a week. The only objection to the appointment had been made by the unsuccessful candidate, who had been resident in the district about fifteen months. Under the circumstances the Board assented to the appointment.

Monday, March 5th.

M. Pasteur's Exportation of Microbes.—In reply to Mr. HOWARD, Baron H. DE WORMS said that Her Majesty's Government could not interfere with the transmission of microbes by M. Pasteur to Australia. The Australian Government was fully aware of the objection which had been raised as to the possibility of the proposed method proving injurious to other animals besides those it was desired to exterminate. Whether or not that objection was well founded he offered no opinion.

OBITUARY.

THOMAS ELIZARD CURLING, F.R.C.S., F.R.S.

Consulting Surgeon to the London Hospital.

We regret to announce the death of Mr. T. B. Curling, for many years surgeon to the London Hospital, which took place at Cannes on March 4th, after a short illness.

Mr. Curling was elected through the influence of his uncle, Sir William Blizard, assistant surgeon to the London Hospital at a very early age. He was little more than 21 when he obtained the appointment, and for some years rumour states that he found it by no means a pleasant office, owing to a certain feeling of opposition which existed in the minds of his senior colleagues. He had a long period of service as assistant, and afterwards the twenty years permitted by the rules of the hospital as full surgeon.

Although never what is called "brilliant," either as an operator or a teacher, he was always painstaking and accurate. He was a just and upright man in all the departments of life, and always willing to assist those whom he thought deserving of help, and to give credit where it was due. His clinical experience had been very large, and in later years his opinion in consultation was always much valued by his colleagues.

In person Mr. Curling was tall and thin, and never bore the appearance of strong health. During the later years of his life, and

especially after the death of a son to whom he was much attached, he became extremely pale, and so feeble that fears were entertained that he was the subject of pernicious anæmia. Mr. Curling became a Member of the College of Surgeons in December, 1832, and was elected an honorary Fellow eleven years later in December, 1843.

The most important perhaps of his original observations was the discovery of the association of ulcers of the duodenum with burns on the skin. His paper on this subject was published in 1842. His larger works, however, on Tetanus (a prize essay), on Diseases of the Testis, and on Diseases of the Rectum, abound in careful clinical research.

During the early part of his life Mr. Curling resided in Broad Street, City, but about 1858 he removed to Grosvenor Square, alleging to his professional friends that he knew where his best patients came from. At this date his practice was chiefly in reference to diseases of the testis, and this was possibly never a very successful speciality. It afterwards developed more in the direction of the rectum. Mr. Curling was a Fellow of the Royal Society, and this honour, like others, had fallen to him early in life. He had been an Examiner at the College of Surgeons, his term of office commencing in 1871. He was elected to the Council of that body in 1864, in the same year with Mr. Le Gros Clark, and he was President in 1873. In 1834 he carried off the Jacksonian prize for his essay on "Tetanus." Mr. Curling had studied his profession widely, and took a deep interest in it. He never did slovenly work, but took great pleasure in collecting information on any new topic that had claimed his attention. Although his practice became eventually somewhat special, yet that his tastes were by no means limited may be shown by reference to the papers which he wrote for the *Medico-Chirurgical Society*. His first, in the twentieth volume, 1837, was on Atrophy of Bone. Two years later he wrote on Congenital Absence of the Pericardium, and on a case in which worms were voided by the urethra. In the twenty-third volume there was a paper on what could then be described as a rare species of hydatid found in the human liver, the *echinococcus hominis*. In volume twenty-five was his original observation on acute ulceration of the duodenum in cases of burn. A few years later he was investigating the literature of cases of hypertrophic development of the digits in connection with a remarkable example of it then under his observation at the London Hospital. Of these cases easts are to be found both in the London Hospital Museum and in that of the College of Surgeons. In the year 1844 we find him again contributing to the Society's *Transactions* on the subject of hydatid, and also on the treatment of varicocele. After these papers follows one on a fatal case of large hæmatocele, and in 1850 a very important report on "Two Cases of Absence of the Thyroid Body and Symmetrical Swellings of Fat Tissues at the Sides of the Neck, connected with Defective Cerebral Development." In this paper we have in some sort the germs of modern doctrines as to the association between absence of the thyroid and general changes in nutrition (myxœdema of Gull and Ord). This respectable list by no means comprises all Mr. Curling's papers in the *Medico-Chirurgical Transactions*, nor does it exhaust their variety as to subject. In the thirty-sixth volume he wrote on Cystic Disease of the Testicle, and next year on a case of Traumatic Aneurysm of the Ophthalmic Artery, consequent on Injury to the Head, cured by Ligature of the Common Carotid. His last, and perhaps his most important, paper was in the year 1860, and was entitled *An Inquiry into the Treatment of Congenital Imperfections of the Rectum by Operation*, founded on the Analysis of One Hundred Cases, nine of which occurred in the practice of the author.

It is about fifteen years since Mr. Curling resigned his surgery at the London Hospital, under the rule of the institution, and very much to the regret of his colleagues. He was then elected consulting surgeon, and he remained for several years longer actively engaged in private practice. Declining health induced him at length to leave London, and for some years past he had lived at Brighton, and had retired wholly from professional pursuits.

A not uninteresting reminiscence of Mr. Curling and of a past generation is the circumstance that it was through him that a paper on the possibility of seeing the fundus of the eye and the usefulness of such investigation as an aid to diagnosis was presented to the Royal Medical and Chirurgical Society. This was in 1846, Mr. Curling being then assistant-surgeon to the London Hospital, and Mr. Cumming, the author of the paper which thus foreshadowed the ophthalmoscope, one of its house-surgeons.

Mr. Curling was by nature somewhat cold, and did not lay him-

self out either to make friends or to obtain praise. His character was, however, one of singular honesty and straightforwardness, and he had a kind heart. He secured and kept the deep respect of all who knew him.

RICKARD PATRICK BURKE TAAFFE,

M.D., M.S.LOND., F.R.C.S.ENG., S.S.C.LOND AND CAMB.

DR. TAAFFE, medical officer of health for Brighton, died at his residence in that town on Saturday, March 3rd, in his 60th year. His last illness, which lasted for nearly four months, was of an obscure nature, and it needed a *post-mortem* examination completely to clear up the cause of death. This apparently resulted from exhaustion accompanying the formation of a fetid urinous abscess which had its origin from perforation of the upper dilated portion of the left ureter, which was plugged about two inches and a half from the kidney by a small calculus. The patient was under the able care of Mr. Jowers, and was seen in consultation by Sir James Paget.

Dr. Taaffe was born in the west of Ireland, but came to England early in life. He received his professional education at St. Bartholomew's, and, as will be seen by the heading of this notice, distinguished himself by taking the highest qualifications in medicine, surgery, and sanitary science. He came to Brighton in 1856, and entered into partnership with the late Sir John Cordy Burrows, upon the dissolution of which he engaged in independent practice. In 1858 he was appointed Assistant-Surgeon to the Brighton and Sussex Eye Infirmary, with which institution he was connected as Consulting Physician at the time of his death. Dr. Taaffe in 1874 became the first medical officer of health for Brighton, and the important duties of this office he carried out with assiduous attention until his last illness laid him aside. He was President of the Brighton and Sussex Medico-Chirurgical Society in 1877-8, President of the Section of Public Medicine at the annual meeting of the Association lately held in Brighton, and in 1881 took a prominent part in the proceedings of the Brighton Health Congress. The Royal Alexandra Hospital for Sick Children owes its existence almost entirely to the subject of this notice, and he at all times took the liveliest interest in its well-being. It was in connection with the opening of this hospital that the Prince and Princess of Wales, with their daughters, visited Brighton on July 21st, 1881; and on this occasion Dr. Taaffe, upon formally asking the Prince to declare the building open, presented His Royal Highness with a gold key made to fit the principal lock of the building. Shortly after the opening of the new hospital Dr. Taaffe was presented with a gold watch and chain, and cheque for £253, in part recognition of his great services to the institution. Dr. Taaffe leaves a widow and two sons to mourn his loss.

JOHN WHITE, M.D.GLAS., L.F.P.S.

DR. JOHN WHITE, a well known practitioner on the south side of Glasgow, died on March 2nd, of inflammation of the lungs. A native of Kirkwall, he studied in Glasgow University, where he was for a time Demonstrator of Anatomy under the late Professor Allen Thomson. In 1874 he was President of the Southern Medical Society. He died at the age of 57, and leaves a widow and grown up family, the eldest son being a recent graduate of Glasgow, now in practice in Balfour.

UNIVERSITY INTELLIGENCE.

CAMBRIDGE.

It is worthy of note, as proving that Cambridge medical students take their full share in the activities of the University, that the stroke of the University boat, Mr. J. C. Gardner, of Emmanuel, is studying medicine at the Cambridge School.

The Council of the Senate has reported against the proposal to grant the degrees and membership of the University to women.

PROFESSOR MACALISTER is nominated an elector to the Professorship of Chemistry.

BRUSSELS.

To the list of names of gentlemen who passed the Doctorate Examinations of the University and were admitted to the degree of M.D. published in the JOURNAL on February 25th, p. 443, should be added G. B. Flux, L.S.A.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

HEALTH OF ENGLISH TOWNS.—During the week ending Saturday, March 3rd, 6,121 births and 3,875 deaths were registered in the twenty-eight largest English towns, including London, which have an estimated population of 9,398,273 persons. The annual rate of mortality per 1,000 persons living in these towns, which had been 20.9 and 21.6 in the two preceding weeks, was 21.5 during the week under notice. The rates in the several towns ranged from 13.4 in Sunderland, 14.3 in Bradford, 16.0 in Huddersfield, and 17.5 in Bolton, to 25.5 in Derby and in Cardiff, 25.7 in Manchester, and 34.2 in Blackburn. The mean death-rate in the twenty-seven provincial towns was 21.2 per 1,000, and was 0.7 below the rate recorded in London, which was 21.7 per 1,000. The 3,875 deaths registered during the week under notice in the twenty-eight towns included 366 which were referred to the principal zymotic diseases, against 405 and 429 in the two preceding weeks; of these, 136 resulted from whooping-cough, 59 from scarlet fever, 42 from measles, 39 from "fever" (principally enteric), 37 from diphtheria, 28 from diarrhoea, and 25 from small-pox. These 366 deaths were equal to an annual rate of 2.0 per 1,000; in London the zymotic death-rate was 2.3, while in the twenty-seven provincial towns it averaged only 1.8 per 1,000, and ranged from 0.0 and 0.4 in Halifax and Sunderland, to 4.4 in Sheffield, 4.5 in Wolverhampton, and 4.8 in Blackburn. Measles caused the highest proportional fatality in Wolverhampton and Plymouth; scarlet fever in Cardiff and Blackburn; whooping-cough in London, Norwich, Leicester, Bolton, and Wolverhampton; and "fever" in Cardiff, Derby, and Nottingham. The 37 deaths from diphtheria in the twenty-eight towns included 24 in London, 5 in Manchester, and 2 in Sheffield. Of the 25 fatal cases of small-pox recorded during the week under notice 21 occurred in Sheffield, 1 in Leeds, 1 in Manchester, 1 in Nottingham, and 1 in Bristol. The Metropolitan Asylums Hospitals contained 13 small-pox patients on Saturday, March 3rd, of which 7 had been admitted during the week. These hospitals also contained 1,295 scarlet fever patients on the same date, against numbers steadily declining from 2,600 to 1,309 in the thirteen preceding weeks; there were 84 admissions during the week. The death-rate from diseases of the respiratory organs in London was equal to 5.9 per 1,000, and was slightly below the average.

HEALTH OF SCOTCH TOWNS.—In the eight principal Scotch towns, 825 births and 592 deaths were registered during the week ending Saturday, March 3rd. The annual rate of mortality in these towns, which had been 22.5 and 22.6 per 1,000 in the two preceding weeks, further rose to 23.4 during the week under notice, and exceeded by 1.9 per 1,000 the mean rate during the same period in the twenty-eight large English towns. Among these Scotch towns, the lowest rates were recorded in Greenock and Perth, and the highest in Paisley and Glasgow. The 592 deaths in these towns during the week under notice included 66 which were referred to the principal zymotic diseases, equal to an annual rate of 2.6 per 1,000, which exceeded by 0.6 the mean zymotic death-rate during the week under notice in the large English towns. The highest zymotic rates were recorded in Edinburgh, Glasgow, and Leith. The highest proportional fatality of measles occurred in Edinburgh and Leith, and of whooping-cough in Glasgow and Leith. The 9 deaths from diphtheria recorded in these Scotch towns during the week included 2 in Paisley and 4 in Glasgow. The mortality from diseases of the respiratory organs in these towns was equal to 6.3 per 1,000, against 5.8 in London.

HEALTH OF IRISH TOWNS.—During the week ending Saturday, March 3rd, the deaths registered in the sixteen principal town districts of Ireland were equal to an annual rate of 35.3 per 1,000. The lowest rates were recorded in Londonderry and Lisburn, and the highest in Galway and Limerick. The death-rate from the principal zymotic diseases in these towns averaged 4.0 per 1,000, and was highest in Newry and Lisburn. The 230 deaths registered in Dublin during the week under notice were equal to a rate of 34.0 per 1,000, which considerably exceeded the rate recorded in any recent week. The 230 deaths included 25 from the principal zymotic

diseases (equal to an annual rate of 3.7 per 1,000), of which 6 were referred to whooping-cough, 5 to scarlet fever, 5 to "fever," 3 to measles, 3 to diphtheria, 2 to diarrhoea, and 1 to small-pox.

POOR LAW MEDICAL OFFICERS' ASSOCIATION.

At a meeting of the Poor Law Medical Officers' Association, held at their rooms, 3, Bolt Court, Fleet Street, on Tuesday, March 6th, the case of Mr. Marshall, of Mitcham, who has been called upon to resign his appointment to the Mitcham Schools for alleged insufficient attendance, was fully discussed, and it was considered by the Council, from the evidence before them, that the charge (even if proved) was not of such a nature as to warrant compulsory resignation of a public servant after thirty-two years' continuous service. The Council, therefore, passed a resolution that their secretary should write to Mr. Marshall, asking him to lay his case before the Local Government Board.

PAYMENT FOR MEDICAL ATTENDANCE IN SANITARY HOSPITALS. NEMO writes: Is it legal for a local Board (urban sanitary authority) to empower to attend and pay their medical officer of health for medical attendance on a person suffering from an infectious disease, who has been removed to the hospital provided by the local Board medical officer, not a Poor Law medical officer?

. It is no part of the duties of a medical officer of health as such, to act as medical officer of an infectious hospital provided by his Sanitary Authority, and to attend patients therein, unless he has specially undertaken to do so. Under Section 131 of the Public Health Act, 1875, the Sanitary Authority have power to provide medical attendance, etc., for patients in their hospital, and they can if they see fit, appoint their medical officer of health to act as medical officer of the hospital, and pay him a reasonable sum for his services. Such arrangements are very general. Sometimes an annual honorarium is assigned, whilst in other districts the payment is by a fee for each case.

SMALL-POX IN SHEFFIELD.

MEDICAL OFFICER OF HEALTH.—We do not see the least reason for doubting the accuracy of the report to which you refer. It has no doubt been prepared with due exactness, and the statements it contains are in accordance with previous experience. See Report of medical officer of Local Government Board for 1881.

BIRTHS AND DEATHS.

DR. W. JLIFFE (Derby) writes: In your statistics relating to the public health for the year 1887, and published in the JOURNAL of March 3rd, with regard to Derby, I think you have omitted the registered number of births and deaths for the week ending December 31st, 1887, as both births and deaths in your list are below what we make them here. If this be so, does the same mistake apply to the whole of the large towns given by you?

. As stated in the first paragraph of the article [referred to,] the statistics for all the towns, including Derby, are a summary of the weekly returns of the Registrar-General, and relate to the fifty-two weeks of 1887, ending Saturday, December 31st. The figures relating to the last week of that year have, therefore, been duly included throughout.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

ST. LUKE, MIDDLESEX (Population, 51,364).—Dr. Yarrow always takes pains to secure accuracy in his returns of vital statistics, and in his report for 1886 he shows that the death-rate for the year was 22.8 per 1,000. This rate, though slightly in excess of that for the previous year, has been corrected, as far as possible, by deductions for non-parishioners, and by the addition of parishioners who died in outlying institutions. The annual returns have for some years shown a steady increase in the mean duration of life in this parish, evidenced by the larger number of deaths occurring amongst persons at an advanced age; and, in 1886, 258, or 22.0 per cent. of the total deaths were among persons over 60 years of age. There was also considerable improvement in the returns of infantile mortality, the deaths of infants being at the rate of 46.4 per cent. of the whole, as compared with 55.0 and 57.3 per cent. in 1885 and 1884 respectively. The deaths registered from zymotic diseases were as follows: measles 39, scarlet fever 5, diphtheria 4, whooping-cough 32, fevers 6, and diarrhoea 68. The deaths from diarrhoea, with five exceptions, were of children under 5 years of age. There were in this year no cases of small-pox or typhus fever. The returns in all the principal zymotic diseases may be regarded as exceptionally favourable; there were fewer cases of sickness under each heading, and the total number of cases was less. The vaccination returns show that only 4.7 per cent. of the children whose births were registered in the parish during 1886 remained unaccounted for as regards vaccination at the time the returns were made, and doubtless many of these unprotected children have since been vaccinated. The record of the sanitary work of the year shows that the health-officer and his staff have been fully occupied.

MEDICAL NEWS

MEDICAL VACANCIES.

The following Vacancies are announced:

- BRITISH SEAMAN'S HOSPITAL,** Constantinople, St. Petersburg.—Resident Medical Officer. Salary, £180 per annum, with furnished apartments, etc. Applications to H. M. Consul, St. Petersburg.
- CITY OF ABERDEEN.**—Medical Officer of Health. Salary, £300 per annum. Applications by March 14th to W. Gordon, Esq., Town Clerk, Aberdeen.
- CLOUGHIER UNION.**—Medical Officer, Agricultural Dispensary. Salary, £115 per annum, and fees. Applications to Honorary Secretary of Committee of Selection on March 14th.
- COTTON HILL LUNATIC HOSPITAL.**—Assistant Medical Officer. Salary, £100 per annum, with board, etc. Applications by March 10th to the Medical Superintendent.
- EAST LONDON HOSPITAL FOR CHILDREN,** Shadwell, E. Resident Clinical Assistant. Board and lodging. Applications by March 22nd to the Secretary.
- GLENUMUCK PAROCHIAL BOARD,** Parishes of Glenmuick, Tullock and Glengairn.—Medical Officer. Salary, £15 per annum. Applications by March 20th to the Inspector of the Poor, Ballater.
- HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST,** Brompton. Resident Clinical Assistants. Applications by April 7th, to the Secretary.
- LEICESTER INFIRMARY AND FEVER HOUSE.**—Assistant House-Surgeon. Salary, £50, with board, etc. Applications by March 10th to the Secretary, 24, Friar Lane, Leicester.
- LIVERPOOL DISPENSARIES.**—Two Assistant-Surgeons. Salary, £80 per annum, with board, lodging, etc. Applications by March 24th, to R. R. Greene, Esq., Secretary, Leith Office, Moorfields, Liverpool.
- LUDLOW UNION.**—Medical Officer, Manslow District. Salary, £70 per annum, and fees. Applications by March 10th to W. J. Holyoake, Esq., Clerk, Poor-Law Office, Ludlow.
- MALE LOCK HOSPITAL,** Dean Street, Soho.—House-Surgeon. Salary, £50 per annum, with board and lodging. Applications by March 19th, to the Secretary, Lock Hospital, Harrow Road, W.
- OWENS COLLEGE,** Manchester.—Professor of Obstetrics. Applications by March 20th to the Registrar.
- ROSS-SHIRE,** Parish of Rosell and District.—Resident Medical Officer. Salary, £82 per annum. Applications by March 17, to R. J. Billanders, Esq., Fortrose.
- ST. HELEN'S FRIENDLY SOCIETIES' MEDICAL AID ASSOCIATION.**—Resident Medical Officer. Applications by March 20th to Mr. H. Whittle, Secretary, 55, Argyle Street, St. Helen's, Lancashire.
- UNIVERSITY OF EDINBURGH.**—Additional Examiner in Botany. Salary, £75 per annum, and £10 a year travelling expenses to a non-resident of Edinburgh. Applications by March 15th, to the Secretary.
- WEST LONDON HOSPITAL,** Hammersmith Road.—Clinical Assistants. Applications to Secretary.
- YORK COUNTY HOSPITAL.**—Assistant House-Surgeon. Salary, £50, with board and lodging. Applications by March 15th to the Secretary, R. Holtby, Esq., 5, New Street, York.

MEDICAL APPOINTMENTS.

- BALLANCE, J. D.,** L.R.C.P., M.R.C.S., appointed Resident Accoucheur to St. Thomas's Hospital.
- BIDWELL, L. A.,** M.R.C.S., L.S.A., appointed House-Surgeon to St. Thomas's Hospital.
- BLAOKER, A. B.,** M.B., B.S., M.R.C.S., L.R.C.P., L.S.A., appointed House-Surgeon to the Belgrave Hospital for Children, S.W.
- BROWN, C.,** L.R.C.P., M.R.C.S., appointed Assistant House-Surgeon to St. Thomas's Hospital.
- BULSTON, H. T.,** M.B., B.C. Cantab., L.R.C.P., M.R.C.S., appointed Clinical Assistant in the Special Department for Diseases of the Throat at St. Thomas's Hospital.
- BURWELL, Pierard Richard,** L.R.C.P., M.R.C.S., appointed House-Physician to the Middlesex Hospital.
- CALVERT, J. T.,** M.B. Lond., L.R.C.P., M.R.C.S., appointed Non-Resident House-Physician to St. Thomas's Hospital.
- COOK, S. B.,** L.R.C.P., M.R.C.S., appointed Assistant House-Physician to St. Thomas's Hospital.
- CRISP, E. H.,** L.R.C.P., M.R.C.S., appointed Clinical Assistant in the Special Department for Diseases of the Throat at St. Thomas's Hospital.
- CROWTHER, J. W.,** M.R.C.S. Eng., L.S.A., appointed House-Surgeon to the District Hospital, West Bromwich, vice B. K. Woodhouse, M.B., C.M. Edin.
- DEWAR, John, M.B.,** C.M. Glasgow, appointed Medical Officer of the Parish of Dunipish, Skye, vice Dr. Campbell, deceased.
- DIXON, J. R.,** M.R.C.S. Ed., L.R.C.P. Ed., L.M., appointed Resident Medical Officer to the Bournemouth Friendly Societies Medical Association.
- DURKENT, T. A.,** L.R.C.P., M.R.C.S., appointed Clinical Assistant in the Special Department for Diseases of the Skin at St. Thomas's Hospital.
- FRASER, W. David, M.B.,** C.M. Edin., appointed Medical Officer to the Collieries of Cardenden, Denend and Dundonald, in Fifeshire.
- HARDY, W. E.,** M.R.C.S., L.R.C.P. Lond., appointed Assistant House-Surgeon to the East Suffolk Hospital, Ipswich.
- HARRIS, W. J.,** M.R.C.S., L.R.C.P., appointed Assistant House-Surgeon to the Birmingham General Hospital, vice W. Chamberlain, resigned.
- HARRISON, H. E. M. B.,** M.R.C.S., appointed Junior House-Surgeon to the Metropolitan Hospital, Kingsland Road, vice F. A. Sprent, M.R.C.S. Eng., L.S.A., resigned.

- HAWKINS, F. S., B.A., M.B., B.S. Oxon., F.R.C.S.,** appointed House-Surgeon to Guy's Hospital.
- HEATHERLEY, F. M.B., B.S., F.R.C.S.,** appointed House-Physician to Guy's Hospital.
- HOGAN, E. F.,** appointed Medical Officer to the Coolran Dispensary, Monmellick Union, vice T. G. B. Hatton, L.R.C.P. Edin., L.M.D. Glasg.
- HOOLE, Henry, M.D. Lond., M.R.C.S. Eng.,** appointed Surgical Registrar and Anesthetist to the National Orthopedic Hospital, vice A. W. Wheatley, M.B., M.R.O.S. Eng., L.S.A., resigned.
- JOLY, E. N.,** M.R.C.S. Eng., L.R.C.P. Lond., appointed Resident Medical Officer to the French Hospital, Leicester Square, vice J. G. Westlake, L.R.C.S.I., resigned.
- LANCASTER, Frank, L.R.C.P. Lond., M.R.C.S., L.D.S. Eng.,** appointed House-Surgeon to the National Dental Hospital, Great Portland Street, W., vice Charles A. Pattinson, L.D.S. Eng., resigned.
- LOTZ, H.,** L.R.C.P., M.R.C.S., appointed Clinical Assistant in the Special Department for Diseases of the Ear at St. Thomas's Hospital.
- MARTIN, D. C., M.A., M.D.,** appointed Resident Medical Officer to the Stourport Friendly Societies Medical Association.
- MARRIOTT, Hyde, M.B., B.Sc. Lond.,** appointed House-Physician to University College Hospital.
- MOORHEAD, H.,** L.R.C.S.I., L.M., appointed Medical Officer to the Monte Dispensary, Athlone Union, vice R. V. Kelly, L.R.C.P. Edin., F.R.C.S., resigned.
- NAIRN, H.,** L.R.C.P., M.R.C.S., appointed Resident House-Physician to St. Thomas's Hospital.
- ORD, W. W., M.A., M.B., B.S. Oxon., M.R.C.S. (Ext.),** appointed Resident House-Physician to St. Thomas's Hospital.
- ROBERTS, E. T., M.B., C.M. Edin.,** appointed Assistant House-Surgeon to the Children's Hospital, Birmingham, vice L. A. Hawkes, M.B., C.M. Edin., resigned.
- ROUCE, C. F., M.B., B.S.,** appointed House-Physician to Guy's Hospital.
- SANSON, H. A.,** L.R.C.P., M.R.C.S., appointed Clinical Assistant in the Special Department for Diseases of the Skin at St. Thomas's Hospital.
- SOLES, R. V.,** L.R.C.P., M.R.C.S., appointed Assistant House-Surgeon to St. Thomas's Hospital.
- STARR, E. T. C.,** L.R.C.P., M.R.C.S., L.S.A., appointed House-Surgeon to St. Thomas's Hospital.
- STEWART, Donald, M.D.,** appointed Honorary Surgeon to the Throat and Ear Hospital, Nottingham.
- TONGKING, J. H.,** L.R.C.P., M.R.C.S., appointed Clinical Assistant in the Special Department for Diseases of the Ear at St. Thomas's Hospital.
- WILLIAMS, A. H., M.A., M.B., B.C. Cantab.,** appointed House-Surgeon to Guy's Hospital.
- WILLIAMS, Lionel, M.R.C.S.,** appointed Senior House-Surgeon to the York County Hospital, vice E. G. F. Morris, M.R.C.S. Eng., resigned.

UNIVERSITY COLLEGE.—The annual general meeting was held at the college on Wednesday, February 29th, Mr. Eric Erichsen, F.R.S., President, in the chair. In moving the adoption of the report, the Chairman alluded to the proposed Albert University of London, and said it should be fully understood that University College was not in any way animated by hostility to the existing University of London. The following were admitted life-governors of the college: Sir F. Leighton, P.R.A.; Professor E. S. Beesly; Professor H. S. Foxwell; Professor D. Oliver; F.R.S.; Sir J. N. Douglass, F.R.S.; Mr. W. H. Perkin, Ph.D., F.R.S.; Mr. H. H. S. Canynghame; Mr. L. H. Courtney, M.P.; and Mr. E. Maunde Thompson, LL.D. The following were elected fellows of the college: Mr. Walter Asburner, B.A.; Miss Louisa Macdonald, M.A.; Miss Alice L. S. Riding, M.A.; Mr. J. J. Powell, M.D.; Mr. S. Rideal, D.Sc.; Mr. R. D. Roberts, D.Sc.; and Mr. P. D. Turner, M.D.

THE PORTSMOUTH HOSPITAL.—The report presented at the annual meeting of the Portsmouth Hospital showed that the work of the hospital had been well maintained. The number of in-patients for the year had been 773, exceeding the total of 1886 by 108. In the out-patient department the cases treated numbered 3,226, and casualties 1,424. The Committee had, after due consideration, arranged to receive probationers for training as nurses, and also to maintain a staff of competent nurses to attend private families. Dr. J. Ward Cousins and other gentlemen present expressed great regret at the retirement of the Chairman, the Rev. E. J. Grant. Dr. Cousins pointed out that in the improved hospital there would be bed space for at least ninety-eight patients, and in the children's department for thirty-six.

NEW MEDICAL LIBRARY IN PARIS.—A library in connection with the pathological museum of the Hôpital St. Louis has just been opened. It contains the most important works in every branch of medical science, and numerous French and foreign medical journals. It is open free to all practitioners and students of medicine. French and foreign physicians are invited to contribute their own works to this library, the foundation of which is due to the efforts of the medical and surgical staff of the Hôpital St. Louis, and which is under the patronage of the Administration of the Assistance Publique.

MEETINGS OF SOCIETIES DURING THE
NEXT WEEK.

MONDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 P.M.—Professor Charles Stewart: On Locomotion and Allied Phenomena (Lecture I).

MEDICAL SOCIETY OF LONDON, 8.30 P.M.—Mr. Herbert Allingham: On the Causes of Failure to Find the Colon in Lombar Colotomy, and how they may be obviated. Mr. Malcolm Morris: Is Common Psoriasis a Constitutional or Local Disease?

TUESDAY.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, 5 P.M.—Dr. W. J. Mickle: The Goulstonian Lectures: Lectura III. On Insanity in Relation to Cardiac Disease and Phthisis.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8.30 P.M.—Mr. Marmaduke Sheild: A Case of Neglected Dislocation of the Humerus, followed by Paralysis of the Nerve of the Hand and Forearm, treated by Excision of the Head of the Humerus. Dr. W. Hale White: On the Naked-eye and Microscopical Variations of the Human Thyroid-body.

WEDNESDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 P.M.—Professor Charles Stewart: On Locomotion and Allied Phenomena (Lecture II).

BRITISH GYNECOLOGICAL SOCIETY, 8.30 P.M.—Specimens will be exhibited by Dr. Savage, Dr. Heywood Smith, and others. Dr. Inglis Parsons: On the Changes produced by the Constant Current in Uterine Myomata. Dr. John Shaw: Electricity in Gynaecology: a Contribution to its Study. Medical batteries and other Electrical apparatus will be exhibited.

HOSPITAL FOR CONSUMPTION, Brompton, 4 P.M.—Dr. Theodore Williams: The Uses of the Pneumatic Cabinet in Lung Disease.

ROYAL MICROSCOPICAL SOCIETY, 8 P.M.—Mr. G. Masee: On the Type of a New Order of Fungi.

EPIDEMIOLOGICAL SOCIETY OF LONDON, 8 P.M.—Mr. B. G. Corney: Epidemic Cerebro-spinal Fever in the Fiji Islands in 1885.

HUNTERIAN SOCIETY, 8 P.M.—Adjourned Special General Meeting.

THURSDAY.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, 5 P.M.—Dr. W. H. Dickinson: The Lumleian Lectures: Lecture I. The Tongue as an Indication of Disease.

PARKES MUSEUM OF HYGIENE, 5 P.M.—Miss M. A. Chrelman: On Physical Culture.

HARVEIAN SOCIETY OF LONDON, 8.30 P.M.—Clinical Evening. Mr. A. Q. Silcock: 1. Osseous Union in a Case of Fracture of the Patella treated by Malgaigne's Hooks; 2. A Case of Conjugate Lateral Deviation of the Eyes. Dr. Sidney Phillips: Case of Hemiplegia in a Child, accompanied by Spasmodic Movement. Mr. Herbert Page: A Case of Traumatic Empyema and Pneumothorax. Cases by Mr. Treves and others.

NEUROLOGICAL SOCIETY OF LONDON, 8.30 P.M.—Cases and Specimens, 8 P.M. Dr. Sharkey: 1. Fatal Case of Tumour of Auditory Nerve; 2. Case of Atrophy of Frontal and Parietal Lobes consequent on Prolonged Spinal Paralysis. Dr. Buzzard: 1. Sequel to a Case of Multiple Paralysis of Cranial Nerves; 2. Case of Peripheral Neuritis; 3. Case of Cerebral Tumour. Drs. Hadden and Sherrington: Sections showing ascending Degenerations in Spinal Cord. Dr. Hadden: Ruptured Brachial Plexus; Question of Operation. Dr. Hale White: Pyrexia in Rabbits from Lesions of the Corpus Striatum. Dr. Beevor: Case of Bulbar Paralysis, with Clonus of Lower Jaw.

FRIDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 P.M.—Professor Charles Stewart: On Locomotion and Allied Phenomena (Lecture III).

CANCER HOSPITAL, Brompton, 4.30 P.M.—Mr. F. Bowreman Jessett: On the Treatment of Cancer and Malignant Disease.

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 7.30 P.M.—Dr. Louis Parkes: Death-rates as Tests of Healthiness. Mr. C. A. Watts Parkinson: Notes of an Epidemic of Pneumonia.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the announcement.

BIRTH.

LOUDON.—On the 3rd instant, at Richmond Villa, Lea Bridge Road, Leyton, Essex, the wife of John A. Loudon, M.B., C.M.Edin., of a daughter—stillborn.

DEATHS.

MASON.—On March 5th, 1888, at 20, Belmont, Bath, Mary Anne, the wife of Frederick Mason, M.R.C.S.E., etc.

MORIARTY.—On February 13th, at Shahajampur, North-West Provinces, India, Janet, wife of Surgeon-Major M. D. Moriarty, M.B., Civil Surgeon, and second daughter of James Irving, M.D., late Surgeon-General of Bengal, aged 29.

STEWART.—On the 6th instant, at his residence, The Briars, Sandown, I. W., John Burdett Stewart, M.D., F.R.C.P., formerly of Southall Park, and The Shrubbery, Southall, in the 95th year of his age. Friends will please accept this, the only, intimation. No flowers.

WELTORTH.—Whitworth, William, L.R.C.P.Lond., M.R.C.S., at Portslade, on the 25th ultimo, aged 26.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY.....	10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's (Ophthalmic Department); and Royal Westminster Ophthalmic.—2 P.M.: Metropolitan Free; St. Mark's; Central London Ophthalmic; Royal Orthopaedic; and Hospital for Women.—2.30 P.M.: Chelsea Hospital for Women.
TUESDAY.....	9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's; St. Bartholomew's (Ophthalmic Department); St. Mary's; Royal Westminster Ophthalmic.—2 P.M.: Westminster; West London; Cancer Hospital, London Ophthalmic.—2.30 P.M.: West London (Ophthalmic Department); Brompton.—4 P.M.: St. Thomas's (Ophthalmic Department).
WEDNESDAY....	10 A.M.: National Orthopaedic.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: Middlesex.—1.30 P.M.: St. Bartholomew's, St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: London; University College; Westminster; Great Northern Central; Central London Ophthalmic.—2.30 P.M.: Samaritan Free Hospital for Women and Children; St. Peter's.—3 to 4 P.M.: King's College.
THURSDAY.....	10.30 A.M.: Royal London Ophthalmic.—1 P.M.: St. George's.—1.30 P.M.: St. Bartholomew's (Ophthalmic Department); Guy's (Ophthalmic Department); Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Central London Ophthalmic; Hospital for Diseases of the Throat; Hospital for Women.—2.30 P.M.: North-West London; Chelsea Hospital for Women.
FRIDAY.....	9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.15 P.M.: St. George's (Ophthalmic Department).—1.30 P.M.: Guy's; Royal Westminster Ophthalmic.—2 P.M.: King's College; St. Thomas's (Ophthalmic Department); Central London Ophthalmic; Royal South London Ophthalmic; East London Hospital for Children.—2.30 P.M.; West London.
SATURDAY.....	9 A.M.: Royal Free.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: King's College.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Middlesex; Royal Free; Central London Ophthalmic.—2.30 P.M.: Cancer Hospital, Brompton.

HOURS OF ATTENDANCE AT THE LONDON
HOSPITALS.

CHARING CROSS.—Medical and Surgical, daily, 1; Obstetric, Tu, F., 1.30; Skin, M, Th., 1.30; Dental, M, W, F., 9.

GUY'S.—Medical and Surgical, daily, 1.30; Obstetric, M, Tu, F., 1.30; Eye, M, Tu, Th, F., 1.30; Ear, Tu, F., 12.30; Sklo, Tu., 12.30; Dental, Tu, Th, F., 12.

KING'S COLLEGE.—Medical, daily, 2; Surgical, daily, 1.30; Obstetric, Tu, Th, S., 2; o.p., M, W, F., 12.30; Eye, M, Th., 1; Ophthalmic Department, W., 1; Bar, Th., 2; Skin, Th., 3; Dental, Tu, F., 10.

LONDON.—Medical, daily, exc. S., 2; Surgical, daily, 1.30 and 2; Obstetric, M, Th., 1.30; o.p. W, S., 1.30; Eye, W, S., 9; Ear, S., 9.30; Skin, Th., 9; Dental, Tu, 9.

MIDDLESEX.—Medical and Surgical, daily, 1; Obstetric, Tu, F., 1.30; o.p., W, S., 1.30; Eye, W, S., 8.30; Facial and Surgical, daily, 1.30; Obstetric, Tu, Th, S., 2.

ST. BARTHOLOMEW'S.—Medical and Surgical, Tu., 9; Skin, Tu., 4; Dental, daily, 9.30; o.p., W, S., 9; Eye, Tu, Th, S., 2.30; Ear, Tu, F., 2; Skin, F., 1.30; Larynx, F., 2.30; Orthopaedic, M., 2.30; Dental, Tu, F., 9.

ST. GEORGE'S.—Medical and Surgical, M, T, F, S., 1; Obstetric, Tu, S., 1; o.p., Tu., 2; Eye, W, S., 2; Ear, Tu., 2; Skin, W., 2; Throat, Th., 2; Orthopaedic, W., 2; Dental, Tu, S., 9, Th., 9.

ST. MARY'S.—Medical and Surgical, daily, 1.45; Obstetric, Tu, F., 1.45; o.p., M, Th., 1.30; Eye, Tu, F., 9; Ear, M, Th., 3; Throat, Tu, F., 1.30; Skin, M, Th., 9.30; Electrician, Tu, F., 2; Dental, W, S., 9.30; Consultations, M., 2.30; Operations, Tu., 1.30; Ophthalmic Operations, F., 9.

ST. THOMAS'S.—Medical and Surgical, daily, except Sat., 2; Obstetric, M, Th., 2; o.p., W, S., 1.30; Eye, M, Th., 2; o.p., daily, except Sat., 1.30; Ear, M., 12.30; Skin, W., 12.30; Throat, Tu, F., 1.30; Children, S., 12.30; Dental, Tu, F., 10.

UNIVERSITY COLLEGE.—Medical and Surgical, daily, 1 to 2; Obstetrics, M, Tu, Th., F., 1.30; Eye, M, Tu, Th, F., 2; Ear, S., 1.30; Skin, W., 1.45, S., 9.15; Throat, Th., 2.30; Dental, W, F., 10.30.

WESTMINSTER.—Medical and Surgical, daily, 1.30; Obstetric, Tu, F., 3; Eye, M, Th., 2.30; Ear, M., 9; Skin, Th., 1; Dental, W, S., 9.15.

LETTERS, NOTES, AND ANSWERS TO
CORRESPONDENTS.

COMMUNICATIONS respecting editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

In order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the office of the JOURNAL, and not to his private house.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate beforehand with the Manager, 429, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication. CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

QUERIES.

CHRONIC SWEATING IN THE AXILLÆ.

M. B. asks for advice in the treatment of a case of a young man, age 27 years, who has been troubled with chronic and profuse sweating in both axillæ for the last seven or eight years. He perspires as freely during the cold winter weather as during the hot months of summer. He has tried lotions of alum, dusting powder (equal parts of oxide of zinc and starch powder). He is very clean in his habits, washing the axillæ several times in the day.

TREATMENT OF EPILEPSY.

B. asks for suggestions for the treatment of a case of epilepsy in a girl of 16, where the bromides of potassium or ammonium are almost prohibited by their aggravating action upon an ulcer of the leg, which exists as a complication in the case.

DURATION OF INFECTION OF WHOOPING-COUGH.

P. asks how long the infective properties cling to the individual who has whooping-cough, in other words, the subsidence of which of the symptoms or group of symptoms would justify one in pronouncing the individual incapable of spreading the disease. Also, whether a child who has for a time lost the whoop and characteristic expectoration, but who has a relapse with a return of those symptoms, is again actively infective.

REMOVAL OF Hairy MOLE.

M. would feel obliged for opinions and suggestions with regard to the treatment of a congenital and hairy pigmentary patch (mole) about one inch square in extent, and situated on the malar prominence, about an inch from the lower eyelid. He asks, would ethylate of sodium remove the hair follicles, and pigment without causing contraction of skin afterwards, or would it be better practice to remove hairs first by electrolysis (as described by Mr. Gilbert Smith in the JOURNAL, January 23rd, 1886), and subsequently to cauterise with the object of removing pigment, in which case as the hair follicles have been removed, the cauterisation might not require to be done so deeply?

LETHAL CHAMBERS.

R. C. H. asks: Can any of your readers kindly inform me whether the lethal chamber, first described, I believe, by Dr. B. W. Richardson for destroying dogs, is suitable for the same purpose for horses? If so, the address of the place where it is in use would be esteemed a favour.

** The lethal chamber is at the Dogs' Home at Battersea; it is not of sufficient size for the destruction of horses. A scientific slaughter-house is in course of construction, under the superintendence of Dr. Richardson, at Croydon; it is designed for killing sheep, oxen, and other animals used for food.

ANSWERS.

IDIOSYNCRASY TO QUININE.

J. H. (Kersal) writes: Referring to "H. G. H.'s" communication in the JOURNAL of February 25th, on the above subject, allow me to mention a case in which I gave one-quarter-grain doses of quinine, with the result of producing flushing of the face, irritable rash, dryness of throat, headache, and buzzing in the ears. To satisfy my incredulity that so small a dose of quinine could be the cause of these symptoms, I got my patient to take—much against her will—a half dose in my presence, and the same result followed within half an hour, though in a somewhat modified form. Recently I had occasion to again prescribe for the same lady, and gave her a mixture containing ten-minim doses of liquid extract of cinchona, forgetting at the moment her extreme susceptibility to the influence of quinine. The consequences were the same as those she had experienced five years before. The lady was subject to occasional attacks of acute eczema.

Let me also name another case in which a small dose of morphine gives all the signs of physiological action. One-twelfth of a grain causes violent headache and sickness, and a suppository, containing only one-eighth of a grain, produces retching and constipation.

DR. THOMAS M. WATT (Hovingham) writes: I had a patient who twice, when she took quinine in fullish doses for neuralgia, was attacked with erythema, which I can describe only as *ferox*, and which was followed by shedding of the whole cuticle in small patches. I kept as curiosities for a long time the epidermis of both palms, complete from wrists to roots of digits. On the first occasion I was told by the patient that "it was the medicine." The second time I was convinced, and I never gave the quinine again.

QUININE IN PREGNANCY.

B. GUY N. STEPHEN (Cyprus Medical Service, Nicosia) writes: In the JOURNAL of February 4th, 1888 (page 279), Dr. P. O'Connell asks whether quinine has any action on the uterus, and inferentially raises the question as to whether it is a safe drug to use during pregnancy. The belief that a large number of drugs have a specific action on the uterus, and are dangerous to use during pregnancy, is a very common one among all classes of patients at home and abroad, and was so amongst medical men; but accumulating gynecological and medico-legal experience is daily diminishing the list of drugs that are capable of originating uterine action, in the absence of strong predisposition and when given in doses not dangerous to the maternal life itself, and the experiments of Professor Chiara, of Milan, afford very strong evidence that quinine is not among the number. Besides this, the clinical experience of any medical man practising in a country where malaria is rife will enable him to further affirm that the drug may be safely trusted not to originate parturient uterine contractions, even in cases where the predisposition to such action already exists. In this country, for instance, quinine is fearlessly given to pregnant women of all sorts, and frequently in, according to English notions, enormous doses, and without causing any evident uterine action. Given on the other hand, during actual labour, and especially in cases of uterine inertia from exhaustion, it is undoubtedly in moderate doses of seven to fifteen grains, a very powerful stimulant of the uterine contractions, which it assists by arousing the general nervous forces of the system, and not by grace of any specific action; in support of which utter affirmation, I would cite the fact that whereas malarial fever, left to

itself, is a constant cause of premature parturient action in otherwise healthy uteri, I have on a large number of occasions been enabled to arrest an abortion by large doses of quinine.

REPORTS OF VISITATIONS OF EXAMINATIONS.

REPORTS of visitors of examinations, and reports on those reports, have been published from time to time by Messrs. Spottiswoode and Co., for the General Medical Council. There are, in all, twenty-three volumes or pamphlets. The *Visitation Report, 1881-2, with Remarks Thereon by Bodies Visited, etc.* (price, 7s. 6d.), and the *Final Report by the Visitation of Examinations Committee* (price, 2s.), are the most recent.

STAMMERING: ORAL INSTRUCTION OF THE DEAF AND DUMB.

IN reply to numerous correspondents who have recently sent inquiries about the treatment of stammering and the instruction of deaf and dumb children, we may state that the Association for the Oral Instruction of the Deaf and Dumb (School and Training College for Teachers), has its office at 11, Fitzroy Square, W., and that the director, Mr. William Van Praagh, is also prepared to give advice and instruction as to the treatment of stammering, stuttering, and other defects of speech.

GLYCERINE AS AN INJECTION.

MR. J. BUNTING (Torquay) writes: In reply to "W. H. B.," I have not found glycerine diluted with water act nearly so well as when pure; in very cold weather it is better to warm it, and I find Mr. Balmanno Squire's urethral syringe the best and easiest for a patient to use; it holds the exact dose.

DR. C. PALMER (Burton on Trent) writes, in answer to "W. H. B.'s" question as to the injection of glycerine, that Messrs. Arnold and Son, of 34, West Smithfield, have made for him a very nice little instrument, a small india-rubber ball with a vulcanite nozzle.

IMPROVED GAS LAMPS.

F.R.C.S. ENG. asks to be informed as to the most efficient and least deleterious gas light which can be recommended.

** There appears to be little, if any, reason to doubt that the gas lights which provide for flame being supplied with heated, instead of cold air, are those which as a class comply with our correspondent's description of being the most efficient and least deleterious. The reason of their superiority lies in the fact that the combustion of the gas is more completely effected than in other forms of burners. The former kind are generally known in the trade by the name of "regenerative" burners, and can be readily recognised by their arrangement for the flame burning within a closed glass; they are now in comparatively common use. The principle was introduced some years ago by Mr. F. Siemens. The application of it has since been considerably modified by himself as well as by various other inventors and manufacturers. These lights differ in efficiency among themselves. It is an important consideration that this form of gas light admits of the entire products of combustion being readily carried away from the room by a suitable arrangement of the lamp, and if this is effected, all deleterious influences are entirely avoided.

NOTES, LETTERS, ETC.

THE PALMER CASE.

MR. J. VOSE SOLOMON (Birmingham) writes: Don't paint the Devil blacker than he is. In the discussion reported in the JOURNAL of February 25th, on the Coachford poisoning case, which took place at the Royal Academy of Medicine in Ireland, the Rev. Dr. Haughton is recorded as stating that had Palmer, the Rogeley poisoner, been acquitted for poisoning Cook, he would have been put on his trial for poisoning his mother, whose liver was found to contain six or seven grains of antimony. In this statement there is some mistake, inasmuch as old Mrs. Palmer (the mother) lived during the trial under an assumed name, in lodgings in the Bristol Road, Birmingham, and was attended during that time by a surgeon named Onion, since deceased. Mrs. Palmer's identity was not discovered until after her son had met her the gallows. During the trial the old lady's ailments were confined to great mental perturbation, which was not relieved by her doctor talking about the trial at Stafford, and his assurances that he believed Palmer would be hung.

ARREST OF DEVELOPMENT BY UNFAVOURABLE ENVIRONMENT.

D. H. G. writes: I have rather an interesting example of arrest of development under unfavourable conditions.

Last spring I hatched, in a small aquarium, where there is not much sun, some toads' spawn. The tadpoles gradually died off about the time their legs ought to grow—the usual length of their lives in confinement, as far as my experience goes—but three were alive at Christmas, without having gone through further development, and one is still in full vigour as a large tadpole now nearly twelve months old.

SYRUP OF TAR IN WINTER COUGH.

MR. WILLIAM FRASER, B.A., M.B., Univ. Dub. (Devon), writes: My attention was yesterday drawn to an article in the JOURNAL on Syrup of Tar in Winter Coughs, by Dr. William Murrell. I beg to say that we (Dr. W. S. Gervis and myself) have been using a similar product for the past eight or nine years; and if Dr. Murrell will turn to the *Lancet*, vol. i. 1882, page 1062, he will find a very short note from me under the heading of Nightmare Produced by the Internal Use of Tar, where I say that tar seems to work wonders in chronic bronchitis; and I must say that time has only confirmed our trust and confidence in the said mixture. My way of making differs from that of Dr. Murrell; his is not fit for use for some days, mine, on the contrary, can be used almost at once. My way is as follows: Get a jam pot, put in pulp, aënic 3ij; sacch. sec. ʒiv; piels liquide ʒij; mix well, add liq. potass ʒij; boiling water ʒij or ʒij; mix. Transfer to a bottle and fill up to make a pint; shake well, and filter through fine muslin into your shelf bottles. The product is of a light brown colour, of which I put from ʒiv to ʒi in a six ounce bottle of water; a tablespoonful every four or six hours; the efficacy of this is often increased by ʒj tinct. scille. The liq. potass. is an addition to

NOTES

ON

TWO CASES OF LAPAROTOMY

FOR

PENETRATING GUNSHOT WOUND OF
THE ABDOMEN; RECOVERY
IN ONE.

WITH REMARKS ON RECENT STATISTICS.

By ARTHUR E. J. BARKER, F.R.C.S.,

Surgeon to University College Hospital; Teacher of Practical Surgery
at University College.

THE following cases are a contribution to the study of a class of injuries which, though they have received far greater attention abroad, and especially in America, than in this country, must doubtless have a keen interest for all surgeons.

CASE I.—A. T., aged 23, a French jeweller, was admitted into University College Hospital under my care on November 20th, 1887, at 3.20 A.M., having shot himself in the abdomen about half an hour previously. He was suffering from moderate shock, and though quite conscious when spoken to, seemed dazed and frequently groaned. His pulse was 56, and markedly dicrotous (from subsequent observation this was probably its normal condition); it was of good volume. The skin was normal, and the temperature in the rectum 98.2° F. He had not vomited. He lay on his right side, with his knees drawn up; his breathing was slow and shallow, with an occasional catch. There was a small bullet wound, with blackened edges, over the border of the costal cartilages on the right side, one inch from the middle line, at the level of the tip of the ensiform cartilage. The pistol was a small "pin-fire" weapon carrying a conical ball 11 millimètres long, 7 millimètres in diameter, and weighing 60 grains. There was little or no external bleeding from the wound, and no evidence of fluid in the abdomen except a suspicion of dulness in the right flank, but there was much tenderness on pressure over the abdomen.

I first saw the patient at about 5 A.M., two hours or so after the injury, when he was beginning to recover from shock. Feeling confident from the situation of the bullet wound that the ball must have entered the abdomen and have struck the liver, and fearing that the slight dulness in the right flank was commencing effusion of blood, I had little hesitation in deciding on laparotomy in order to check hæmorrhage, suture any lesions if present, and cleanse the abdominal cavity. Having, therefore, made every arrangement for complete antisepsis, the operation was done at about 6.30 A.M.

I first made an incision two inches and a half long over the tip of the ensiform cartilage, and on drawing its edges apart could see the opening in the peritoneum through which the ball had entered the cavity. Nearly under this, and at the attachment of the falciform ligament to the liver, was a patch of ecchymosis under the serous covering of the organ, which suggested the point at which the latter had been struck by the bullet. There was no corresponding breach of surface of the liver, either here or elsewhere, though I carefully examined most of the anterior surfaces of the left lobe by pressing it down and throwing the light well between it and the ribs, and also by passing my hand over it. The surface of the organ was, however, stained with blood, and a dark clot was seen extending directly downwards in the middle line. This was about the size of the little finger when drawn out, and led me to think that it came from the track the ball had taken. I therefore prolonged the incision to the umbilicus, and found some more and larger solid clots lying underneath the abdominal walls and upon the colon and omentum.

The first point was now to see that the stomach was not injured, and a careful examination of its surfaces as it bulged up into the wound, as well as the fact that it was tense with gas, clearly indicated that it was not perforated. It was therefore pressed back into the abdomen, and the transverse colon lying just below it was hooked up and drawn out of the wound to the extent of about eighteen inches for careful inspection. This also was found

intact, but the omentum along its lower border was noticed to be much blood-stained and covered with clots ranging from one the size of my thumb downwards, apparently derived from lesions of some of its own vessels. These clots were therefore carefully disentangled from the omentum, and the latter was wiped clean, and while this was being done the bullet was found in its folds, and a moment later a small round wad. From the position of the bullet it appeared quite clear that it had struck the liver at the insertion of the falciform ligament, and had glanced off it and passed between the abdominal wall and the stomach and transverse colon as nearly as possible in the middle line, to become entangled in the folds of the omentum, some of whose vessels were torn. It seemed highly improbable, therefore, that any other viscera were injured. Nevertheless, all the coils of small intestine exposed by the incision were carefully examined; then sponges wrung out of sublimate solution were thrust into both flanks and the recto-vesical pouch, but came out unstained. The viscera exposed were then thoroughly cleansed by sponging, and were adjusted with the omentum over them, after which the abdominal wound was closed in the usual manner. The bullet track in the abdominal wall was also scoured well, rubbed with iodoform, and a very fine short drainage-tube was passed into it as far as the peritoneum, but not through the latter. Firm bandaging over a salicylic wool dressing completed the operation. The latter was well borne, and when the anæsthetic was recovered from there was no vomiting and only moderate pain, easily relieved by a little morphine. The patient was fed for some days with nutrient suppositories. The temperature rose the same night to 103.6°, the pulse to 100, and the patient became rather restless, but twenty-four hours after operation both were normal, and remained so practically to the end of the case. The dressings were changed on the sixth, tenth, and sixteenth days, union having taken place by first intention, except in the bullet track, which, however, closed rapidly, the patient leaving hospital on the twenty-first day quite well. The bowels had acted normally several times.

CASE II.—M. F. G., aged 37, an American, was admitted on the following night, November 21st, at 8.30 P.M., having been shot in the abdomen about half an hour previously with a Colt's revolver carrying a conical bullet 15 millimètres long, 9 millimètres in diameter, and weighing 143 grains. I saw him a few minutes after 9 o'clock, and found him quite comfortable, with no trace of shock and not suffering in any way. The shot had been fired at close quarters, and the ball had struck the abdominal wall $3\frac{1}{2}$ inches internal to the right anterior superior iliac spine and half an inch below it, and had emerged 3 inches behind the same iliac spine and also half an inch below it. From neither opening was there any bleeding at this time, but the clothes were considerably stained with blood. From the position of the wounds it appeared probable that the ball had passed through the soft parts external to the peritoneum and without entering the abdomen. This was explained to the patient, and also the necessity of giving an anæsthetic so as to make a thorough exploration. His assent was at once obtained, on the understanding that he was to be allowed to come to as quickly as possible in order to see his friends, who had been sent for. On enlarging the anterior wound a slit was seen in the tendon of the external oblique muscle, and through this a probe slipped into the abdominal cavity, while a considerable quantity of blood welled up from the latter.

It was plain then that a full exploration of the abdomen should be made, but it was necessary to let the patient know his condition and see his friends before going further. He was therefore allowed to recover from the anæsthetic, when he at once gave his consent to any operative treatment which might be necessary, his friends too acquiescing readily. It was not, however, until 1.5 A.M. that the operation was begun, owing to some delay on the part of the police authorities in taking the patient's depositions. All arrangements for complete antisepsis having in the meantime been made, I commenced the exploration at that hour by a four-inch incision in the direction of the fibres of the external oblique, and having the bullet wound in its centre. When the abdomen was thus opened blood mixed with clots, but without a trace of fæces or odour, escaped to the extent of three or four ounces. Knowing from a rather large experience of gunshot wounds the extraordinarily erratic course of conical bullets in some cases, my first care was to make out the track of the ball in this instance. The incision having passed through the aperture of entrance in the peritoneum, the aperture of exit had to be found if possible, and on sponging out the blood it was seen not

Cases of Abdominal Section Performed on Account of Gunshot Wound. (Continued from Sir William Mac Cormac's List, BRITISH MEDICAL JOURNAL, May 11th, 1887, page 1033.)

No.	Operator and Reference.	Age and Sex.	Time after Injury.	Special Symptoms.	Nature of Intra-peritoneal Injuries.	Treatment.	Result.	Remarks.
33	Charles T. Parkes, (Chicago.) <i>Annals of Surgery</i> , Nov., 1887.	Adult male	4 hours	Revolver shot. Moderate collapse; pulse very fast, face pale; considerable bleeding from internal wounds. Two bullet wounds 4 inches to left of median line in a line one above the other, and 1½ inch apart; one had passed out of the body below last rib at outer side of erector spine.	Five perforations of small intestine; perforation of left kidney; no special bleeding from it. Vomited much food during operation.	Four-inch median incision; much blood removed from peritoneal cavity. Kidney not removed; antiseptic dressing. Rallied well from operation but died of bleeding from kidney.	Died in about 24 hour after operation.	The wounds had been easily cured and both they and the abdominal cavity were in a satisfactory condition for moriem.
34	Charles T. Parkes, (Chicago.) <i>Ibid</i>	Male, 41	16 hours	Blush over right half of abdomen. Breathing entirely thoracic; the abdominal walls hard and motionless.	Bullet wound 2 inches inside right iliac spine. Much fecal matter in wound. Bullet had just entered and left the abdominal cavity and buried itself in the thigh.	Incision in median line, six large quantities of fibrin, color, fecal matter and fat evacuated. Washing with weak boracic lotion. Intestine much inflamed. One large wound of small intestine found and sutured with out difficulty. The whole intestinal tract examined, no further lesions found.	Died 16 hours after operation.	Apparently death was due to shock.

38	F. J. Skelly, M.D. (Petersburg.) <i>Journal of Surgery</i> , July 1887, p. 49	Male, 21	A few minutes	Six wounds, that is of both hands, right hip, and abdomen. Very pale; great pain in right iliac region.	No wound of intestine. Bullet imbedded near the spine. Venous blood in peritoneum. Bullet had entered midway and a little below a line from umbilicus to right iliac spine, and had passed upwards and inwards for about 3 inches.	Chloroform. Median laparotomy, no complete antiseptic could be provided. Intestines drawn out, held in warm towels (not aseptic). Abrasion of peritoneum dusted with iodoform. Abdomen wiped out with new sponges hastily cleansed in carbolic acid and rain-water.	Recovered	Patient distinctly tuberculous with tubercles in the peritoneum and a cavity in right apex. No bad symptoms during convalescence, which was rapid.
39	A. E. Barker	Male, 23	3½ hours	Shock, slow diastolic pulse; great tenderness of abdomen.	Bruise of liver and slight tearing of the omentum. Clots of blood, bullet and was removed from the latter.	Median laparotomy under spray, etc. Thorough exploration of abdomen. Bullet and wound found entangled with clots in omentum below colon; toilet of peritoneum.	Recovered, no bad symptoms	The slow diastolic pulse probably a normal condition; it lasted all the time patient was in hospital.
40	A. E. Barker	Male, 37	5 hours	No shock; no pain; very little bleeding; nature of wound only discovered on enlarging bullet track.	Double perforation of ileum 3 feet above cecum. Abdomen on right side contained much blood and clots; no faces or gas.	Wound much enlarged; perforation of parietal peritoneum sutured. Perforated portion of gut excised completely, and ends of bowel brought together by continuous suture of fine silk, reinforced by row of interrupted suture. Abdomen sponged out.	Died	Peritonitis & pneumonia found post-mortem but no evidence trace existed. Suture of the bowel was perfectly complete, and sound union had taken place.
41	Dr. Sévastopolov, (Constantinople.) <i>Revue de la Soc. de Chir.</i> , T. XIII, 1887, p. 273. Operation 1880	Male, 30	1 hour	Revolver wound (5 or 5.5 mm.) in middle of line joining right iliac (inferior) spine and umbilicus. Fecal fluid in wound with blood pressure caused escape of intestinal gas. Patient anxious.	Oval wound of small intestine with a long loose flap of its wall. Wound too long to be sutured.	No special preparation. Surgeon not supplied with usual instruments. Wound enlarged vertically, 15 centimetres with scissors, cutting the whole depth of abdominal wall, including peritoneum. One litre of blood escaped with clots from abdomen, the intestines followed soiled with faeces. Resection of a wounded portion of bowel; ends invaginated, Lembert's suture, one thread, retaining the coil near the wound.	Recovered, no bad symptoms	Abdominal cavity washed out with carbolic solution, warm. Iodoform-dressing of wound.

42	A. S. Friddy, M.D., (Keyville, Va.) <i>Journ. Amer. Med. Assoc.</i> , Nov. 19, 1887, p. 619	Male, 60	4½ days	Severe shock, restless, anxious, hicough, no vomiting. Shot from 32 calibre revolver had passed from a distance of 6 to 8 feet into the abdomen, at a point half an inch below and internal to anterior superior spine (? side.) Nothing abnormal on palpation except pain	Six-inch rent in the descending colon large enough to admit the hand, which was passed into the rectum. Much fecal feces in the abdomen. Intense tympanites	Expectant treatment to morning of Sept. 9th, when all the symptoms of severe peritonitis were present and patient was very weak. Then laparotomy median, careful antiseptic, complete examination of intestines, 6-inch rent in descending colon sutured with continuous catgut. Iodoform freely used over intestines. Abdomen washed freely with 1 to 1,500 hyd. bichlor. Abdomen drained with small tube. Operation lasted 55 minutes	Recovered	Suffered much shock and nearly died from injudicious feeding, but ultimately recovered.
43	J. W. Dean, Records of St. Louis City Hospital, unpublished	Male, 16	Not given	Condition very bad at time of operation	Injury of small intestine	Laparotomy: suture of intestine, cleansing of abdominal cavity	"	Stomach wound had entirely closed: extravasation of blood in breath: slight peritonitis.
44	H. H. Mudd, (not fully reported.) <i>Journ. Amer. Med. Assoc.</i> , Nov. 1887, (Table p. 579.)	Male, 17	3 days	Condition at time of operation good	Injury of liver and stomach	Laparotomy: suture of stomach	"	Operation unsatisfactory on account of inability to cleanse peritoneal cavity.
45	N. B. Carson, <i>St. Louis Courier of Medicine</i> , March 1887	Male, 25	6 hours	"	Wound of small intestine and mesentery	Laparotomy: suture of wounded viscera and resection of 2½ inches of intestine	"	Attempt was made to enter abdomen in median line, but prevented by old adhesions. Origin gunshot wound opened up. Patient recently seen in full work.
46	J. Prince, (not reported.) <i>Journ. of Amer. Med. Assoc.</i> , November 1887, (Table p. 579.) Operation performed June 25, 1886	Male, 30	1 hour	"	Injury of ascending colon	Laparotomy: suture of wound in bowel	Recovered	Patient a negro lad. Operation done under difficulties.
47	S. C. Medical News, April 30, 1887, p. 480. Operation December 19, 1886	Male, 15	7 hours	Condition of patient at time of operation fair. Restless, anxious, much thirst, pulse weak, emphysema of external wound. Rectal temperature subnormal. Blood passed with a motion before operation. Feces escaped from wound	Perforation of ascending colon and of small intestine. Bullet entered left groin, emerged 1½ inch to right of umbilicus. Appendix epiploica was found bleeding and tied	Laparotomy: median 3 inches; suture of wounded intestines (after paring of edges) by Lembert's stitches. Feces removed from abd. cavity, which was then irrigated with hot carbolic water	Recovered, no bad symptoms	
48	M. Freyer, <i>Deutsche Med. Wochenschr.</i> , July 15, 1886	Male, 19	6 hours	Patient collapsed at time of operation	Injury of small intestine	Abdominal wound enlarged and intestine resected outside of cavity	Recovered	
49	W. Parham, <i>New Orleans Medical and Surgical Journal</i> , 1887, New Series, xiv, 508	Male, 34	2 hours	Patient suffering from shock	Injury of small intestine, ascending colon, and bladder	Laparotomy: suture of wounded viscera	Died	
50	Ditto, ditto	Male, 22	3 hours	"	Injury of small intestine and external iliac artery	Exploratory laparotomy	Recovered	
51	F. Pickett, <i>Med. Press and Circ.</i> , N. Y., <i>Buffalo</i> , 1886, 5, 6, 1, p. 241	Male, 13	Not given	Patient's condition good	Wound of abdominal wall	Laparotomy	"	Ball extracted from liver.
52	V. F. Smart, <i>Burrill's Medical Journal</i> , Vol. I., 1885, p. 375	Male, (?)	"	Patient suffered from shock	Wound of liver	Laparotomy	"	No bad symptoms.
53	J. W. Heddens, (St. Joseph, Mo.) <i>Annals of Surgery</i> , Dec. 1886, p. 628. From <i>Franz. Med. Assoc. State of Missouri</i> , Operation early in year 1886	Male, 30	"	Wound in epigastric region from pistol. Complained immediately of great pain in right side, shoulder, and back, with dyspnoea	Eleven wounds, of small intestine, one at ileo-caecal junction; all were jagged and varied in size. Omentum torn and bleeding at one point. A large vein wounded at upper and right side of pelvis, (died), found to be the external iliac, near Poupart's ligament	Laparotomy from wound downwards for 5½ ins. Pieces of cloth removed from abdomen, together with four ounces of blood. Antiseptic dressing	"	Pulse fell alarmingly at one time during operation, but rose at once on irrigating the abdominal cavity with hot water. Sank steadily after operation. Slight evidence of peritonitis <i>post mortem</i> . No other wounds found.
54	H. H. Packard, <i>Medical News</i> , March 26, 1887, p. 339	Male, 33	Shortly after, about 1 hour probably	Marked collapse. Temperature 97.5, pulse 120, respiration normal. Food and some blood vomited. Bullet (calibre .38) entered 2 inches to left of umbilicus and ½ inch below it. No escape of fecal matter discovered, but blood was found in peritoneum	Wound of liver	Antiseptic laparotomy in median line after wound had been enlarged. Peritoneal cavity irrigated with 1 to 15,000 hyd. bichlor. Intestines systematically examined. Joles sutured by Lembert's method; catgut being used. At one spot about 1 inch of bowel resected with V-shaped portions of mesentery. Lembert's sutures. Operation very prolonged, (probably over 2 hours.) Drain-tube in peritoneum	Dead 14 hours after operation	

Cases of Abdominal Section, etc. (continued).

No	Operator and Reference.	Age and Sex.	Time after Injury.	Special Symptoms.	Nature of Intra-peritoneal Injuries.	Treatment.	Result.	Remarks.
55	Dr. Lange, <i>Med. News</i> , Male, 11 Nov. 26, 1887, p. 630. Operation Oct. 13	Male, 11	24 hours	No shock. Pulse 112 to 120. No pain but marked tenderness on pressure to the left. Some tympanites and abdominal wall was tense	No No. 22 pistol ball entered 1 1/2 inch below navel, and 1 inch to left. Seven perforations of small intestine. Three pairs of brown fluid found in the peritoneum, no feces	Laparotomy at once in a line with the belly wound. Wounds closed with gut in 6 instances, one was already closed firmly	Recovered without a bad symptom	Bullet not found. Good union did not take place in abdominal incision.
56	R. T. Munly, (<i>N. York Med. News</i> , Sept. 24, 1887	Male, (?)	2 hours	Abdomen greatly distended, evidently by fluid	Double perforation of descending colon. Wound of interior mesenteric artery	Laparotomy in middle line; exit 3/4 gall. of blood. Bleeding was from branch of inferior mesenteric artery which was ligatured. Perforations closed by Lembert's sutures	Recovered	Bullet not found. Good union did not take place in abdominal incision.
57	C. E. Case, (<i>Toronto Med. News</i> , Sept. 24, 1887, p. 379	Male, young	—	General condition fair. Temperature 98.5, pulse 110, slight tenderness of abdomen, pain dull in umbilical region	Pistol ball 32 calibre entered 2 1/2 inches and to right of umbilicus, emerged 3 inches to the right of the spine	Laparotomy antiseptic. Considerable quantity of blood in peritoneum. Wound of bile duct above to 1 in. below the umbilicus. Considerable quantity of blood in abdomen. Lembert's suture. Warm hypospholite used for cleaning. Abdomen washed out with warm water. Rubber drainage-tube. Operation lasted 1 hour 10 minutes	Recovered	Convalescing at time of report, which is very short.
58	J. M. Fox, (<i>Philadelphia Med. News</i> , Nov. 12, 1887, p. 568	Male, 17	3 1/2 hours	General condition fair. Temperature 98.5, pulse 110, slight tenderness of abdomen, pain dull in umbilical region	Bullet wound 3/4 inch below and 1 1/2 inch to left of umbilicus. Wound of mesentery of transverse colon of jejunum, mesentery of latter. Bullet lodged in back. No fecal escape. Intussusception of ileum noticed and reduced at operation	Median laparotomy from 2 1/2 in. above to 1 in. below the umbilicus. Considerable quantity of blood in abdomen. Lembert's suture. Warm hypospholite used for cleaning. Abdomen washed out with warm water. Rubber drainage-tube. Operation lasted 1 hour 10 minutes	Recovered	Drain-tube removed on July 30th.

more than half an inch from the first, and just below the cecum. At first it was thought that the latter viscera had been wounded, but this was not so. The bullet then had only just entered and left the abdominal cavity in the fold between the anterior wall and iliac fossa, a strip of peritoneum only half an inch broad separating the two wounds. It was a question then whether the intestine was wounded, but this was soon set at rest when the adjacent coils were drawn out, two wounds being found in one coil which exactly corresponded to those in the peritoneum, against which it had rested when the bullet was fired. These wounds were round, with slightly bruised edges, from which the mucous membrane did not protrude. They bled freely, but no feces escaped from them, the bowel appearing to be quite collapsed on either side. Fearing that to simply suture these two wounds would seriously narrow the lumen of the bowel, I at once excised a wedge-shaped portion of the gut, including the injured part. The bowel was first thoroughly emptied by pressure, seized on either side in the fingers of an assistant, and two cuts were made with a scissors, reaching to the mesenteric attachment of the intestine. In this way a complete ring of the latter, about half an inch broad at the injured aspect, was removed, the mesentery being only slightly notched. The parts having been now thoroughly cleansed, the serous surfaces of the mesenteric notch were brought together by a continuous suture on both sides, and the cut edges of the bowel having by this means been apposed on their proximate aspect, they were united by a continuous suture of fine silk, taking up only the serous and muscular coats just at the edge, the needle coming out on the cut margin at each stitch. This suture was begun at the mesenteric aspect of the bowel, and went completely round the latter, care being taken that while it brought the edges into contact, it should not narrow the lumen of the bowel.

A second row of interrupted silk sutures was now introduced to reinforce the first. These took up the serous and muscular coats just beyond the first row, and, when secured, the latter was completely hidden. There was no difficulty in controlling the contents of the bowel with the fingers, or in suturing the bowel without contamination of the stitches. All the coils of small intestine within reach were now drawn out of the abdominal wound, and very searched for further injury with a negative result. They were then washed with sublimate solution, 1 to 1,000, and

before they were returned the abdominal cavity was thoroughly sponged out, special attention being given to the flanks and the recto-vesical pouch. When every thing appeared quite clean the intestines were returned, and the wound was closed in the usual way with silk, a drainage-tube being left in the track of the ball, and reaching well into the abdomen. A salicylic wool dressing completed the operation, which had lasted one hour twenty-nine minutes. The patient bore it very well, and did not suffer from shock. The next day he was fairly comfortable, only complaining of pain in the wound; but he was very thirsty, and ate a great deal of ice. Pulse 115, temperature 99° to 101°. He vomited occasionally, but only a little odourless, white fluid. He was kept well under the influence of morphine. There was no distension of the abdomen. His urine required to be drawn off every six hours; it was high coloured, and very acid. On the second day after operation he seemed very well, but could not retain anything taken by the mouth; he had been having prepuised suppositories every six hours. Pulse 120, temperature 101° to 102°. On the third day he seemed much better, but still vomited occasionally, though only the ice water and a little mucus. Pulse 120, temperature 101.2° to 101.8°. He was able to pass water himself, and also passed flatus. The wound was dressed for the first time under the spray, and the drainage-tube was shortened. On the fourth day he was still better, though the pulse remained at 120, which he still occasionally brought up in small quantity, but to have a favourable odour, and to become yellow. The abdomen, too, was more tense than before, and the patient did not look so well. I therefore began to fear that there might be some obstruction of the bowel near the seat of operation, or possibly some collection of matter, though there was no dullness of the abdomen anywhere. In consultation with my colleagues it was determined to release the stitches in the wound, and explore it with the finger. This was done at midnight, but no collection was found, and the sutured part of the bowel was felt to be in a satisfactory condition. The next morning (fifth day) he seemed weaker, though not so sick; but his strength was improved by injection of stimulants in the afternoon. His temperature had risen somewhat to 101.6° to 102.6°, and the pulse was 130. During the night he became weaker, though less sick, and at 4.45 he died quietly (sixth day).

The *post-mortem* examination was made by Mr. Bilton Pollard, whose notes contain the following facts. The small intestines were very much distended, especially in the umbilical region; there was no gas, lymph, or pus anywhere in the abdominal cavity, but the coils of the bowel in the distended area were slightly greasy. The large intestine was not at all distended, and seemed out of the area of inflammation, which had affected the small intestine solely. The latter in the neighbourhood of the wound was more adherent than elsewhere. The portion of bowel sutured, which was in the ileum about three feet from the cæcum, was in a perfectly satisfactory condition. Union had taken place thoroughly between the cut ends, and the bowel was not obstructed in any way. Tested with considerable pressure, it was perfectly air and water tight. There were about two drachms of blood-stained fluid in the recto-vesical pouch, about half a drachm in the right flank, and three drachms in the left. There were a few spots of extravasated blood in the omentum, which occupied its normal position, but was adherent to the edge of the wound by recent lymph. There was much hypostatic pneumonia in both lungs, especially on the right side; the other organs were healthy. It will be seen from these notes that the cause of death was a very moderate amount of peritonitis limited to the small intestine, and in addition no doubt the hypostatic pneumonia told unfavourably. Indeed, there was so little to be found in the abdomen indicating peritonitis, except the distended coils of bowel, that there was some hesitation in accepting this as the cause of death: But the absence of any other lesion except the pneumonia, left no alternative. A septic condition, in the ordinary use of the term, did not exist; the spleen was quite normal and other evidences also failed: in short, one turned away from this necropsy with an intensified feeling of disappointment, because the patient had so very nearly recovered.

These two cases appear to me to possess each its own special interest. In the first there can be but little doubt that a fatal peritonitis would have occurred had not the bullet, its wad and the clots which surrounded it, been removed from the folds of the omentum by abdominal section. Again, laparotomy enabled us to exclude from consideration all other injuries of viscera, without subjecting the patient to any special risk in exploration. The case is also of interest in being the first successful laparotomy for gunshot wound of the abdomen recorded in this country. I trust it may encourage other surgeons to very prompt action in similar cases, so that the conclusions arrived at in America as to the propriety of immediate laparotomy in all cases where penetration of the abdomen is proved, may be justified by our experience too.

The second case, although a source of the keenest disappointment to me, has in no wise shaken my belief in the rule that every case of the kind should be treated immediately by abdominal section: indeed, it strengthens that belief in every way. What little peritonitis there was no doubt started from some spot in the peritoneum not thoroughly cleansed from matters escaped from the wounded bowel. Whether a more perfect antiseptics could have been carried out by a median incision and irrigation may be a question of opinion, but I am strongly inclined to think that it could, though at the time I decided that the extra time and strain upon the patient's powers involved in a double incision and its concomitants would be too dear a price to pay. That the median incision should be the rule in the vast majority of such wounds of the abdomen I am convinced, and this view will be shared by everyone who carefully studies the literature of the subject. This literature is now becoming a large one. Sir William MacCormac's classical monograph sufficiently attests this by the numerous cases there quoted. But even in the short interval of only a few months which has elapsed since he published his collection of thirty-two operations for gunshot wound of the abdomen, almost an equal number of cases have been put on record, chiefly in America, and numerous discussions have taken place on this subject. These cases I have been at the pains to collect and tabulate. A study of the results of these operations is most encouraging. They show a greatly lessened mortality, year by year, and also that much more desperate cases may be saved by surgical interference than has hitherto been supposed: I give them as fully as is possible in such a table, and allow them to speak for themselves with only one comment. It will be seen that, whereas out of the 32 laparotomies for gunshot injury of the abdomen included in Sir W. MacCormac's list, only 7 recovered, there are here collected 26 fresh cases of the same kind, with 16 recoveries and 10

deaths. Combining the two tables, we have 58 cases with 23 recoveries and 35 deaths. The numbers start in this table where Sir W. MacCormac's end, that is at 32.

THE GOULSTONIAN LECTURES

ON INSANITY IN RELATION TO CARDIAC AND AORTIC DISEASE AND PHTHISIS.

Delivered before the Royal College of Physicians of London.

By WM. JULIUS MICKLE, M.D., F.R.C.P. LOND.,

Medical Superintendent, Grove Hall Asylum.

LECTURE II.—AORTIC VALVE LESIONS.

OF cases of aortic valve lesion, the chief and predominating condition, I make four sub-groups: (1) aortic stenosis; (2) aortic regurgitation; (3) aortic semilunar valve disease, with no very marked local signs, and aorta not very much affected, if at all; (4) disease of aortic valve and arch.

First Sub-group: Stenosis of the Aortic Ostium.—Of eight cases; varying in age at death from 24 to 47 years, the average was almost 40, only one being young. At death the insanity had lasted from nine months to sixteen years in different cases. The relation, in time of incidence, of heart disease to insanity was difficult to appraise in several cases; distinctly prior in some, it was distinctly subsequent in others. Naturally, these cases were not all pure examples of aortic stenosis; in two there was also aortic incompetency, as well as aneurysm of thoracic or of abdominal aorta, and in three others—at least at one period or at several periods—slight mitral incompetency was added.*

Of these patients, three were monomaniacs, in one of whom the heart disease distinctly preceded the mental; in the others the order of incidence was doubtful. In the first-mentioned of these (with aortic aneurysm a complication) at first the delusions were of persecution, for example, "was plotted against, conspired against by women, illegally detained and ill-treated;" and thereafter hallucinations of hearing. Finally, with advancing disease of heart and aorta came delusions of direct bodily injury and persecution, producing horrible pain compared to "electric batteries playing on him."

Of the others, one—a deteriorated wreck of former mingled hypochondriacal and expansive monomania, become demented—often screamed shrilly, was rambling, incoherent, paroxysmally excited and noisy, and on some of these occasions suddenly destructive; finally he uttered merely a jargon, a medley of words. The other, a subject of mingled expansive and persecutory monomania (with imbecility), and hallucinations of all the special senses except of touch; together with the advancing heart disease, pulmonary congestion, and recurring attacks of dysenteric diarrhoea, became deluded as to poison in the food, and as to influences of a hostile kind brought to bear upon his bodily state and health.

* *Heart.*—Average weight 13.51 ozs. av. Aortic valves variously diseased, thickened, atheromatous, rigid, deformed, stenotic. Mitral valve similarly diseased in some, but less in degree, and the aperture in some widened. The pulmonary and tricuspid valve much less often and much less severely affected than the preceding. Muscle of heart often friable, flabby, or pale. Left ventricle markedly hypertrophied in most, and in some distinctly dilated also; the other cardiac chambers only in a few distinctly dilated, or hypertrophied, or both. Coronary arteries atheromatous in some. The aorta in several aneurysmally pouched; more or less atheromatous, nodular, rugose, calcareous; irregular elevations, yellow patches, puckers, and wavy markings studding the inner surface.

† *Brain.*—In some of general paralysis; in others slightly wasted.

‡ *Spleen.*—Average weight 5.9 ozs. av. In many firm, coarse, fibrotic; capsule often irregularly thickened, opaque and adherent, or pigmented; occasionally cicatrised.

§ *Kidneys.*—Average weight of each 4.83 ozs. av.; often more or less granular; some partially destroyed by old local lesions. Of the larger kidneys, some were pale yellow, firm; a few were pale, homogeneous, fatty.

¶ *Liver.*—Average weight 54 ozs. In some slight cirrhosis; frequently "hepatic venous congestion;" patchy opacity or thickening, cicatrices, or adhesions of capsule.

‡ *Lungs.*—Usually old pleuritic adhesions; frequently hypostatic oedema, congestion, or even pneumonia; occasionally calcification, brown induration, or cirrhosis of lungs, cured phthisis, caseous bronchial glands.

1 In the reprint of the article published in the JOURNAL (May 11th, 1887), Sir W. MacCormac added two cases, making a total of 32.

Three others were general paralytics. In one, epileptiform attacks were frequent; hypochondriacal and melancholic symptoms throughout more than usually intercurrent. Demented and ataxic, he for a time took on absurd ideas with expansive tinge, for example, "has oak trees inside him," not infrequently lugubrious and depressed, he felt "very old." Another, at times conscious of being diseased in the head and, then, recognising his delusions as such, had apoplectiform attacks, confusion, drowsiness, amnesia, occasional, excitement, dementia; later, depressed, hypochondriacal, stubborn, bellowing; later on, *agitation silencieuse*; finally fatuity. In another, there was at first circular general paralysis, with successively maniacal, lucid, depressed, phases; later, delusions as to poison, and hence refusal of food; delusions of impending injury from those about him, fear; later, variable, restless, excited, violent at night; by day confused and incoherent, muttering about "thousands" and "millions."

In the seventh case the cardiac disease preceded insanity. The son of a drunkard, after an erratic course, rebellious to control and resistive of all regulating influences, and during which he was syphilitised and alcoholised, he fell more deeply into drink; under delusion, made a homicidal attack; became much excited, attempted suicide, and fell into the abyss of melancholia attonita, from which, dying of rapid, caseous, pneumonic phthisis, he roused sufficiently before the end to speak again, and to express delusions as to adverse influences brought to bear upon him, and fear of hostile entities.

The eighth had at first delusions as to military officers being brought to England under his charge, to be tried for an attempt to murder him. On this soon supervened profound amnesia as to dates, passing of time, order of occurrences, or recollection of them. Occasionally were seeming hallucinations of hearing.

Summary.—Thus the cases of stenosis at the aortic ostium, with change of its sigmoid valves, in which the cardiac most probably influenced the mental state, showed some or other of the following—mental depression; ideas of persecution, of adverse influences, of direct bodily injuries, inflicted pain, etc. Possibly, also, sudden intercurrent outbursts of mental excitement and violence of act. Others in whom the sequence of events was doubtful, or in whom the heart disease followed the mental, exhibited similar tendencies (some indistinctly), to which may be added delusions as to bad or poisoned food, and perhaps refusal of it for a time.

Second Sub-group: Aortic Regurgitation.—Of several marked cases of incompetency permitting regurgitation at the aortic gateway, as the chief morbid cardiac condition, the ages were from 30 to 50, and the average 38 years, at death, at which, also, the insanity had lasted from a few months to four years, except in a complicated case of seventeen years' duration; and in all but this last one the heart disease either distinctly or apparently preceded the insanity. In two there were both regurgitation and obstruction at the aortic orifice.* Two were general paralytics. One of these cases began with headache, vacant expression and manner, failing memory and speech, delusions as to his own identity, and declaration of himself as various other persons. Then general paralysis became more manifest, with big ideas, and some hypochondriacal ones concerning his eyes and head. From this he passed into a relatively lucid state, recognising his former delusions as such, but being childish and somewhat demented. Finally, he also became rambling and incoherent in his descriptions, and died in a state of supervenient stupor, or apoplectiform seizure, with pulmonary congestion and hypostatic pneumonia. General paralysis in the other was insidious in its onset; observed to be eccentric, the patient also made mistakes in performing military duties, so as to be unfit to carry them on; and was subject to sudden outbreaks of dangerous passion and destructiveness; of markedly impaired perceptive, reasoning, and mnemonic powers, he became quiet, obedient, childish, incoherent, demented, extremely amnesic; at times smiling and pleased, at times devoid of emotional feeling and expression.

Another, maniacal, in some respects resembling a general para-

lytic, at a comparatively early date was sleepless, loquacious, abounding in expansive delusions as to wealth, rank, titles; continued partly the same throughout, being also restless, prone to interfere, troublesome, talkative, and sleeping badly at night; agitated and noisy if thwarted in his impracticable wishes; obstinate, and requiring much attention and tact in management.

Were we to stop here, these cases might seem to indicate that at least aortic regurgitation is particularly liable to be followed by (if not a factor in) insanity of a more or less expansive kind, and exhibiting emotional exaltation. Cases similar to these may have led some, but not its originator, Milder, to the idea that aortic orifice and valve disease is apt to occasion, or to be associated with, insanity presenting the maniacal rather than the melancholic type. To make suggestion on this point will occupy us under the fourth sub-group of aortic-valve cases; and here I hasten to add an example of what I believe to be more accurately tenable as insanity produced by, or influenced in its production or aspect by, regurgitation of the blood stream at a dilated aortic gateway, and incompetency of its now decreased lunatic valves.

Here, with insanity supposed to be of several weeks' duration, on admission, but possibly of three or four months', and with obviously chronic cardiac disease, were well-marked aortic diastolic murmur, also purplish, leaden, marbled congestion, of irregular distribution, about the trunk and limbs. Suffering from cranial pain, the patient heard imaginary voices, took the delusions that he was followed everywhere by persons who prevented him from earning a living and tried to murder him; and restlessly he muttered. Admitted, he still asserted that these persons followed him, talked about him, accused him of various crimes and his sister of being "on the streets," and once they tried to murder him, on which occasion, although he took refuge in a shop, he did not see or hear his supposed would-be murderers, nor could he say who they were, or assign any reason why they should speak or act so; and he denied having done any wrongful criminal act. Hallucinations of hearing, only, were acknowledged as having existed, and these as occurring at night solely. Later on, he was restless at night, getting out of bed, anxious, in fear, declaring there was a conspiracy to injure him in some way he could not definitely explain, and that his bed had an evil smell (hallucination). Later on, he refused to rise from bed or dress, and struck the attendant who insisted on his rising. Still later, were delusions that particular females got under his bed at night, or came to share it with, and thus annoy, him.

That of such complexion, as in this last case, is the mental modification dependent on regurgitation at the aortic ostium,—rather than a likeness to or identity with that found in the three cases preceding it, which presented expansive symptoms, otherwise explainable by the co-existent organic brain affection, and, as it were, in spite of severe aortic valve and cardiac disease,—also, I think, some support from the next case I will mention here—that of the chronic lunatic in whom incompetency of the aortic semilunar valves, as well as abdominal aortic aneurysm, came in the course of the insanity. The aortic *bruit* was double at times, and a diastolic apex murmur was sometimes heard.

A soldier becomes eccentric, surly, attempts homicide, has delusions as to a conspiracy against him in the regiment, and that he is ordered "to act daft;" becomes sullen and threatening in connection with hallucinations of sight and hearing as to "persons who plot to get him out of the regiment," and has the delusion that his and others' voices pass out and injure the townspeople; later, that everything went against him in the army, and the regimental doctor's mesmerism still affected him. Later on, quiet, subdued, confused, of bad memory, incoherent and irrelevant in replies; he says he "would rather be dead than live with his body as it is," and speaks of a powerful mysterious influence still exerted on him by "a change of his number in Ceylon;" hallucinations of sight and hearing continuing. After cardiac disease and abdominal aneurysm are well-marked, at various times he is dull, emotionally depressed, "has people inside his skin hurting him," "flew at night." At times suddenly noisy and threatening about being kept in bed; delusions as to the occult constraint on him, his limbs, extraordinary personal bodily injuries inflicted on him, or that his breath is stopped by thick air, or that he is soaked through with medicine; hallucinations of hearing; is sleepless, he says, and troubled, and devoid of self-control because of a book he has read, and makes other delusional statements. Here we have a depressed modification of the emotional state, and delusions of personal injury and constraint more marked when the

* Heart, average weight, 29½ ozs., av. Incompetency of aortic valve, with various degrees of deformity, thickening, atheroma, fibrotic change, cohesion. The left ventricle hypertrophied and dilated, usually much so, big and rounded; while in one case the left auricle, and in one the conus arteriosus of the right ventricle were noticeably and unduly capacious. The aortic sinuses of Valsalva were usually much changed, and the aortic arch (in some the whole thoracic aorta) more or less nodulated, calcareous, atheromatous, or dilated. The spleen, weighing from 4½ to 9½ ozs., and on the average 6½ ozs., had in some cases capsular adhesions or irregular thickenings. The liver, on the average, 5½ ozs. In some unduly firm, or presenting passive "hepatic venous congestion." Average weight of each kidney, 6½ ozs.

cardiac and aneurysmal diseases were becoming more disabling and severe.

Although he did not definitely become insane, I may mention the case (not counted in my statistics) of an attendant, of robust frame, moderately athletic habits, active mind, cheerful, somewhat buoyant disposition, fond of conversation, sociable, and free from special sources of anxiety or care. Unaware of special disease, he became depressed, gloomy, brooding, silent, taciturn, forgetful; nor could his wife elicit from him any definite reason for this; in vain, by reading, conversation, and other arts, did she seek to rouse him permanently from this state; he would soon relapse, although the condition varied much from time to time. Interest in his work failed, his duties were performed without life, mechanically, and in a defective perfunctory way. Feeling general physical *malaise*, and pain in the hepatic region, and suffering from pulmonary symptoms, he consulted me as to his health. Examination revealed severe aortic regurgitation, the leak working backward on lungs and liver. He left, and a few weeks later died of his cardiac disease.

Here, also, I may mention (although, like the last, not included in my statistics) a case of aortic valve disease in a young melancholic, with hallucinations of hearing voices which swear at him through the wall and tell him to cut his throat.

Third Sub-group: Aortic Valve Disease; no very marked local Signs; Aorta not very much Affected, if at all.—Next there is a small group of cases which I shall not linger to discuss. Usually the valve's crescentic flaps were thickened, rigid, unduly opaque, and usually more or less coherent or fused together. These hearts also presented various degrees of flabbiness; but, with these comparative exceptions, they were not gravely diseased, had not undergone any very marked degree of compensatory hypertrophy, and no very great abnormality of cardiac function or physical state had been noted; nor in them was there any severe degree of disease of arcuate aorta; therefore, they do not serve our present purpose. One was a case of hypochondria, one of dementia secondary to mania, one of placid, gay syphilitic dementia with congenitally feeble mind, and one of melancholic general paralysis in a syphilitic subject.

Fourth Sub-group: Disease of Aortic Valve and Aortic Arch.—Aortic valvular thickening, rigidity, fibrotic change, or atheroma; and marked atheroma or nodulation, or even ectasis or dilatation of aorta.

In this sub-group there were, conjointly, marked disease of the lunulate aortic flaps and of the aortic arch, or in some instances of the whole thoracic aorta, but morbid physical cardiac signs were moderate or even slight, and the valvular alteration did not lead to marked obstruction or regurgitation of the kind I have just been discussing, or to the grosser sorts of cardiac hypertrophy, dilatation, and so on.

Although they number twenty, yet four of these cases are mentioned elsewhere in these lectures as illustrating some other point, and the following is a summary of the remaining sixteen only.

Varying from 27 to 66, the age at death, on the average, was 42½. The order of precedence was doubtful in some; of the rest, in about one-half the insanity seemed to have preceded the heart disease, and in about one-half the heart disease the insanity.*

Mental State.—Five were general paralytics, and one other a general paralytic, recovered as to the physical state. In all but one were more or less expansive symptoms; in several with marked maniacal states, as well as the usual dementia, and in one with hypochochondriacal symptoms. The remaining one was an example of the demented form of general paralysis. Some of these general paralytics were syphilitic.

Three others were syphilitic cases, as (a) a syphilitic, demented, amnesic, emotionally weak subject of right hemiplegia and general spasmodic tremor; (b) a syphilitic, melancholic, and suicidal, apathetic, confused patient, with rare fleeting excitement, later *melancholia sine delirio*, but later still with delusions as to hos-

* Of the aortic valves in these cases, there were, in order of relative frequency, and differently combined in different cases, some of the following changes: cusps thickened, rough, opaque, coarse, occasionally much deformed, or rigid, or fibrotic, calcareous, nodulated at their bases; or with corpora Arantii overgrown or fused together, or with dilated aortic sinuses of Valsalva. Aortic arch more or less atheromatous, deformed; in some ridged or calcified in parts. The kidneys were much granular and atrophied in only two cases; but in the majority were one or more of the following changes: slightly granular surface, or slight adhesion of capsules, or slight ordinary cystic change. Two cases had pale, or yellowish, or fatty-looking, and one case somewhat lardaceous, kidneys; one kidney contained a creamy collection; in one case was premature and obscuring decomposition of the kidneys.

tility, annoyance, and the general malevolence of those around him; and (c) a syphilitic, excitable, suspicious, moody, phthisical subject.

Three others were monomaniac; one chiefly of the persecutory type, one chiefly expansive, one partaking of both characters, but the persecutory element being the fundamental basis left after the early maniacal excitement had cleared up. In all three, more or less deterioration, mental incompetency, tendency to confusion, and to incoherent, rambling replies had occurred before death together with persistent hallucinations in two.

Of the remaining four, three were secondary dements, their dementia being consecutive to melancholia or mania; and one was demented, amnesic, yet with some absurd, expansive ideas, and with emotional facility (diabetes mellitus, destructive lesion of striate body and crura, secondary degeneration thence downwards).

These cases show a state of heart and aorta which seems as if it might often well be an early stage, or less marked degree, of the changes found in the severe examples of incompetency or of constriction at the aortic orifice, forming the first two sub-groups; and in which, with marked signs of cardiac affection and of disturbed circulation, and grave alteration of heart and aortic valves, were also severe change and deformity of the thoracic aorta. In some cases an originally more active inflammatory basis is a requisite foundation of the eventual changes we have studied under the marked examples already grouped as stenosis, or as incompetency, of the aortic lunate cusps; but the slighter cases, composing the present fourth sub-group of lesions of aortic valve, throw light, in my opinion, upon those graver cases, and elucidate those (of aortic valve incompetency especially) in which we found a clinical history telling, rather, of excitement, grandiose delusions, and emotional exaltation, than of suspicion, ideas of persecution, self-abasement, or melancholy; which former set of symptoms, as I stated at the time, I believed not truly to exemplify the modification of mental symptoms by the aortic valve disease and its results and associated conditions; while I proceeded to illustrate by other cases what I take to be the mental phenomena or modifications really dependent on a widened aortic gateway, or one defectively guarded by its crescentic folds. Whilst, as regards aortic stenosis, we found chiefly melancholy, delusions of persecution, of adverse influences, of direct bodily injuries, and, in some, occasional sudden outbursts of noisy excitement, violence, or destructiveness.

I believe that many of the cases in this fourth sub-group originated in the way following: under excitement, or co-existent with some expansive mental disorder, there is great physical activity, and much strain is thrown upon the circulatory organs. Before becoming insane, the future subject of such insanity often is active, engaged in strenuous effort, under a never ceasing urgent industry and activity, whether in toil or in the pursuit of pleasure. Energetic, pushing, free-eaters, free-drinkers of intoxicating liquors, ever ready to plunge with zest into work or play or debauchery—these persons, while sane, strain their hearts and aorta and other blood-vessels; and, should they become insane, are apt to get at first some excitable and expansive form of mental disorder, and, in some cases sub-inflammatory or active degenerative states of brain and cord. But whether as preceding or following the outbreak of insanity, the powerful heart, working irregularly, fitfully, at times violently, pumps the stream of blood forcibly into the systemic arteries; the kidneys, too, are overwrought, their function is embarrassed, the blood imperfectly depurated, and disease of the aorta and aortic valves follows (comes almost as part of the general condition), that of the aorta being often primary and assisting to bring on a valvulitis, or slower indurating or degenerative change, in the aortic semilunar valves, casting, as it does, upon them a still greater strain, and inducing a further irregularity in the circulatory movements of the blood and of its impact on the crescents of the aortic valve.

Here, at first, is increased arterial tension, but in the later stages, if with kidneys relatively affected in but slight degree, the tension remains normal, or is lowered, and there is no advance beyond a moderate degree of the disease of valve and arcuate aorta. Usually with this latter condition, and in a merely incidental way, is associated some deterioration of the former mental state; but not the production of the symptoms I have found to be those ordinarily seen with disabling aortic valve disease and its concomitant affections and conditions.

Now, let the same change proceed further; let the valvular orifice become constricted or become unduly patent; let the signs,

respectively, of obstruction of the bloodstream, or those of the regurgitation of incompetency, come into being; and let the kidney become more affected than before, and still there may be, on the mental side, merely a deterioration of the former excited or expansive state, inasmuch as other influences may intervene and prevent the development of true characteristic cerebral symptoms in disabling aortic valve disease, and these very imagined cases would represent and explain those with expansive symptoms which I discussed, under aortic regurgitation especially. Thus we reach at least one probable reason why aortic valve disease has been erroneously held by some to be characteristically associated with excitement, in contrast with melancholia, supposed by the same to characterise mitral disease.

Here we might well branch off into the subject of other cases of disease affecting the thoracic aorta, but, before passing to that, it is desirable to insert a few brief summaries as to forms and conditions of cardiac disease other than those already examined. And, first, as to disease gravely and about equally affecting both the mitral and the aortic valves.

Both Mitral and Aortic Valves (with other changes).—Here, come fourteen cases, but six of these are also mentioned elsewhere: Varying from 32 to 84, the average age at death was 53 years—the highest average we have met with thus far. With regard to the cardiac sounds, pulse, and other physical conditions, the abnormalities of these, marked in some cases, were in a few comparatively moderate only; yet I need not linger to analyse these signs and symptoms in cases so complicated, but note, by the way, the frequency of feeble, irregular, intermittent heart's action and pulse in the more aged patients; also that, while it was difficult to estimate with certainty the order of precedence of the two sets of symptoms, the morbid cardiac seemed to precede in more cases than did the morbid mental condition, but in many of the examples this point cannot be decided with certainty, so slow and insidious were they.*

Mental State.—Six were general paralytics. On the whole, these presented more irritability, surly moroseness, and intolerance of examination, interference, or management (and perhaps more depression) than the ordinary average run of cases of general paralysis. Some of them, too, were of long duration and aberrant course.

Three were senile demented. Two of these were extremely restless, excited, noisy, destructive; and one of these latter had delusions as to being "poisoned."

Two were subjects of "organic dementia," one being a case of dementia with organic local destructive brain lesion, and the following clinical succession: epileptiform fits; dementia; improvement; maniacal excitement; fits; left hemiplegia; fits; death. The other (glioma cerebri) was restless, confused, "lost."

Three were either deteriorated monomaniacs or chronic maniacs. (a) Deteriorated, demented, muttering, confused, depressed state, following on delusions of change of sex. (b) Chronic mania, with periods of depression; latterly quiet, depressed, deteriorated, phthisical. (c) Persecutory monomania; delusions of being tormented; later, depressed, solitary, taciturn; lastly, delusions that his bodily organs are "eaten into."

Somewhat resembling those already given under the aortic-valve sub-groups, these cases differ from the latter chiefly in (a) the relatively prominent position held in the present group by senile dementia, and by dementia associated with still grosser organic lesions than uncomplicated senile dementia is, the proportion of aged cases being high and unusual in this present group; and (b) in the relatively somewhat stronger number of general paralytics in this than in the above four combined aortic-valve sub-groups. Mentally, those of the present group also resemble aortic-valve much more than they do mitral cases, although several constituent members of the group showed something of the mental complexion observed in many mitral stenotic cases.

More or Less General Hypertrophy and Dilatation of Heart.
—Of the twenty-two cases coming here, twelve are also made use of in exemplification of other points. At death the average age

was 45.6 years, the range being from 27 to 72. The cases being linked together by the existence of hypertrophy and dilatation, very differently distributed in the several cases, and associated or not with intrinsic valvular changes varying in seat and extent, the physical signs necessarily differed much in the several cases, and so did the necroscopical records. The average weight of the heart was 14.36 ozs. av., and was brought down very much by hearts dilated but not, or not much, hypertrophied.

Left ventricle hypertrophied in 10, dilated in 17	
" auricle " " 4, " 14	
Right ventricle " " 7, " 17	
" auricle " " 4, " 14	

In three or four of these dilatation was slight only.**

Mental State.—Four were melancholic, depressed, deluded; most of them terminal, deteriorated states.

Six of monomania, about equally divided, collectively or individually, between the expansive and depressed forms.

Four of general paralysis; of which one was expansive, loquacious, restless, interfering, obstinate, difficult; another demented, restless, noisy, filthy, brutish; another slightly expansive, childish, querulous at times; and the last one successively expansive,—maniacal,—hypocondriacal, abusive, querulous,—demented, dolorous.

Three of dementia from organic brain disease, or coming on comparatively early in life.

Two of senile dementia.

Three scattered single cases of other forms, depressed rather than expansive.

But let us examine a little more closely. Of the six monomaniacs, one throughout was of the persecutory form (electric batteries playing on him, conspiracies against him); one, formerly expansive, was latterly depressed, quiet, sombre; in one the earlier mingled expansive and persecutory form had deteriorated into a relic of the latter element, associated with more querulousness; one, formerly exalted, latterly got delusions of extraordinary influences on his powers and constraint on his speech, hence his delusional silence; one, formerly expansive, eventually took delusions about dead bodies and sulphur burning near him, and about bodily illness, and was childish and somewhat demented; and in one early excitement and hallucinations, and subsequently mingled expansive and persecutory monomania, were to a large extent replaced, latterly, by delusions about "poison" in the food, and hostile influences brought to bear upon his body and his health.

Take these monomaniacal cases, take also the particular general paralytics of the group, take the melancholic cases and the depressed delusional states, take the demented and senile demented, and we find the tendency of more or less general hypertrophy and dilatation of the heart is to be associated with depression, melancholia, moroseness, sulkiness, and also with dementia, amnesia, and a general deterioration and defect of the mental powers, rather than with any symptoms of pure active mania, or symptoms of a more exalted or expansive form. Undoubtedly a number of the cases in this group presented expansive symptoms, but these were chiefly found in the earlier stages of some of the protracted cases. Exceptions to this exist where the compensatory hypertrophy has been full and complete, and the heart drives with ease a powerful stream of blood to the brain; obstruction outside the heart, if more than usual, being nevertheless overcome with comparative facility. Yet the usual tendency of heart disease which ends in hypertrophy and dilatation of any extreme degree and wide extent is to disable the heart and circulation; and disablement of heart and circulation tends to defective quality and quantity of arterial supply to the brain, to venous congestion thereof, and to mental depression, moroseness, sulkiness and irritability, or querulousness, rather than to any actively gay or exalted symptoms. Concomitantly, and in some cases partly due to the heart disease, is the dementia observed in so large a proportion of the cases of this group, and in some of them grave brain degeneration as well.

The mental symptoms in this group of somewhat general dilatation and hypertrophy of heart resemble those found with mitral

* Average weight of heart, 13.2 ozs. av. The mitral and aortic valves presented some of the following changes: thick, opaque, coarse, atheromatous, occasionally stenotic or incompetent; occasionally, in the aortic valves, also, enlarged corpora Arantii, or more irregularly or roughness than in the mitral. In a few cases, similar but less change of tricuspid or pulmonary valves. The ventricles and auricles, one or more, hypertrophied or dilated, or both in some instances; the left ventricle most frequently, next the right ventricle and left auricle. The heart muscle often more or less flabby, or even degenerate; in two cases, the heart laden with fat externally; in two cases, marked old pericarditic adhesions. The heart diseased in many examples, and variously so.

** In 16 one or more sets of valves were considerably diseased. In 15 the heart-muscle was in one or several of the following states: pale, flabby, friable, yellowish, of dull hue, granulo-fatty; and in one was syphilitic. In 20 there was considerable disease of aorta. The kidneys, whose average weight per kidney was 5.5-12ths ozs. av., had a degree of granular change in one-half, and in a few more were pale, fatty, or presented other alterations. Average weight of spleens 8.1 ozs. av. Half of them unduly firm or hard; of many the capsules thickened, pigmented, or calcified.

more than those with aortic-valve lesions; but there is a greater chronicity, and a greater variety in the mental depression, and relatively more dementia in this than in the mitral group. And that this resembles the mitral rather than the aortic-valve group is, of course, largely due to the fact that the latter is weighted in one direction by the fourth sub-group of aortic-valve cases, that in which valvular change is conjoined with grave alteration of the arch, and in which, as we have already found, is a considerable proportion of cases with expansive and active mental symptoms, and a well conserved vital energy.

PARTIAL DILATATION OR HYPERTROPHY OF HEART.

I have not included here the cases of slight or comparatively mild cardiac changes. Of such mild kind is the majority of the cases in which cardiac dilatation or hypertrophy is due solely to the long-protracted, irregular violence of the heart's action, or strain of it, under persistent or frequently recurring mental excitement in chronic cases of insanity, or the respiratory embarrassment of the depressed forms. Yet in some of the more extreme cases under this group, as well as other groups already mentioned, mental excitement or depression probably had some share in the production of dilatation or hypertrophy, notwithstanding the operation of such factors as valvular lesion, or organic disease of brain, kidney, or lung.

Here would come twenty cases in which the condition was very marked; but, inasmuch as many of these quite partial hypertrophies or dilatations—that is, those affecting one chamber very chiefly or even exclusively—are due to, or connected with, either a preceding valvular change, or else incompetency of a valve, healthy in itself, but unduly patent owing to dilatation of a cardiac chamber; and, inasmuch as eleven of the present group are of that nature, and therefore coming under some of the preceding heads; I take here the remaining nine only.

In them, the average weight of the heart was about 12.4 ozs. In five the hypertrophy, with or without dilatation, very chiefly or solely affected the left ventricle; and in four the right ventricle, or it and the right auricle. The former were mostly general paralytics with—at least, in the advanced stages—well-marked symptoms of emotional depression. The latter were chiefly cases with well-marked pulmonary disease (tubercular phthisis), and mostly with irritability, moroseness, depression, taciturnity, mental deterioration; and one, with both right chambers immensely dilated and hypertrophied, was an asthmatic monomaniac (formerly of considerably exalted type), with typical changes of lung ("large-lunged vesicular emphysema,"—Sir William Jenner²⁷), and of all the large, hard, congested viscera.

Any valve disease that existed in a few of these was comparatively slight and unimportant. In the former sub-group of five cases, there was obstruction to the systemic circulation from the brain disease of general paralysis, and in two also from the coexistent decided renal disease (in one there being subacute nephritis, in the other granular atrophy), while a third showed very slight granular change. This obstruction induced left ventricular hypertrophy; whereas, in the latter group, phthisis pulmonalis or asthma threw heavy work on outrophic right cardiac muscles, leading to their hypertrophy, the left not becoming similarly affected.

An interesting deviation from the above arrangement was the case of one who, besides phthisis, had hypertrophy of left ventricle only, in a marked degree, old adhesions of pleura to the pericardium dragging the latter leftwards, and finally two fluid ounces of pericardial fluid, and sub-pericardial œdema over the right side of the heart. Although their cortices were thin, the kidneys weighed 6 and 5½ ozs. Latterly, he was irritable, morose, intolerant of examination, and bit attendants who held him. The irascibility, sullenness, and bad temper were more like the symptoms frequent in phthisis pulmonalis in the insane, than either the querulousness or apprehensive fear so often observed in embarrassing or disabling heart disease.

This case conveniently leads us to glance at the heart in phthisical insane persons.

But before doing so I must mention a form of heart disease, hinted at above, often consecutive to mental disorder, but often apparently of constitutional origin, and connected with or forming part of the general vascular and circulatory condition natural to the individual, and becoming morbid in degree before or after the onset of insanity. I refer to moderate hypertrophy or dilatation of the right side of the heart, unaccompanied by marked

valvular disease. Cases of this kind are scarcely represented in my statistics, inasmuch as they are comparatively slight or moderate degrees of organic change, are cases, therefore, of a kind which I have excluded from consideration here, for the reasons already mentioned. By others the pure cases of this kind are usually mixed with cases presenting also hypertrophy of the left ventricle, and to this combined and impure (that is, mixed) group is attributed a causation by the strain on the heart due to prolonged mental and physical excitement and over-exertion, as well as by the obstruction and interference with cerebral circulation occasioned by the obscure changes of minute vessels in some forms of insanity. This has been found mostly in dementia and in chronic or recurrent mania. Thus, Dr. Burman,²⁸ drawing this conclusion, however, from a single examination of the living cases in an asylum, reported that he found hypertrophy of right heart, with apex beat in the epigastric region, in 10 per cent. of the cases of consecutive dementia, in 15 per cent. of chronic and recurrent mania, and in 3½ per cent. of melancholia; yet the addition of examples complicated by replacing or by modifying murmur yielded proportions very different from these.

But I think some further discrimination is necessary here, and that in a moderate number of cases, slight or comparatively moderate dilatation of the right side of the heart is consecutive to insanity, or springs from the same general vascular and constitutional condition as that which predisposes to the insanity, and that these cases take the depressed form; and the anguish of the melancholic and hypochondriacal patients, with the interference with respiration thereby engendered, further aggravates this tendency to dilatation of the right heart, or even dilatation and some hypertrophy.

As Mr. J. A. Hingston²⁹ said, with enlargement of veins, a general tendency to varicosity, the mind is usually unaffected, but occasionally mental symptoms arise "from dilatation of the right side of the heart superinducing premature old age. Patients thus affected never are strong-minded or courageous, they have no heart for great things, but are timid and vacillating. They end by being fatigued. Gout is often at the bottom of this malady."

The Heart in Phthisical Insane Persons.—Of the insane who die, or die chiefly, of phthisis pulmonalis, there are not a few whose hearts are more or less hypertrophied, and of full or over weight, like the patients mentioned in the preceding group, with hypertrophy of right ventricle or of both right chambers. For example, at the moment of writing, I observe the notes of a case not included in my statistics. This male patient, formerly of medium size, and weight, died phthisical at the age of 38, with a heart as much as 12½ ounces in weight, mottled, pale, flabby, friable, without any disease of coronary arteries, but with slight atheroma of aortic sinuses of Valsalva, and some pericarditis.

Nevertheless, the majority of the phthisical insane die with small, wasted hearts, which usually also are flabby, friable, and not seldom somewhat granular or granulo-fatty, that is to say, exhibiting that form of degeneration under the microscope. This occurs more frequently than I had supposed it to do before the space of time during which I regularly examined the heart, microscopically, in almost every case in which I made a necropsy.

In the phthisical, and in the tubercular, insane I have met with several examples of another form of cardiac affection, consisting of tuberculosis of the myocardium or pericardium, not infrequently with pericarditis. What I might say here on this subject I have already published³⁰ in the *Lancet* several years ago, together with two examples of the affection, since when I have met with two more examples. It is a secondary change, and unimportant in relation to our present subject.

Fatty or Granular Degenerate Hearts in the Insane.—Only a fraction of the examples of fatty or granulo-fatty degeneration of the heart I have observed in the insane can be taken up here.

Of the twenty-five cases which happen to come in the notes analysed, in twenty-four were necropsies, and one is a living case. But six of these cases of microscopically fatty heart had severe valvular or other cardiac or aortic disease; in these few cases, therefore, the effects of the fatty heart, and its relations, are too much complicated for our purpose, whatever may have been the importance of the fatty change as a factor in the state of brain-nutrition. Deducting these, the remaining nineteen cases are adapted to our present purpose, and these alone are utilised

in the following. In many the fatty change was later than insanity.

Age.—The average age at death was about 44½ years.

Weight of Heart.—The weight of the heart varied from 6½ to 17½ ounces. The average was just over 11 ounces.

Degenerate Muscle of Heart.—The muscle of the heart, whether pale, or of dull appearance, or mottled by pale and by congested patches, was in all cases flabby, friable, and in a state of granulo-fatty or granular degeneration. By which I mean that either the striæ were indistinct, the substance blurred, and bead-strings of fatty molecules were seen; or else there was a homogeneous appearance of the fibres, free fat-molecules, indistinct striæ, and granular collections, or the fibres also readily splitting up; or the muscle was of a granular appearance, the transverse striæ quite blurred, almost effaced, but fatty corpuscles or beadlets absent.

Coronary Arteries.—Of the cases in which the point was noted, in two-thirds were more or less atheroma, or whitish, or whitish-yellow opaque thickenings, or nodules and calcified patches, in the coronary arteries, occasionally in the left one only.

Lungs.—In nine cases of the present group the lungs were more or less phthisical; one of these was fibroid phthisis or cirrhosis pulmonum.

Mental State.—In 6, delusions of persecution, ill-treatment, annoyance
 „ 4, dementia, secondary or primary.
 „ 3, later stages of general paralysis.
 „ 4, mental depression, melancholia (following violent excitement in 1).
 „ 2, senile mental affections.

19

To particularise: *I Sub-group.*—In six were several of the following symptoms: delusions of persecution or annoyance; for example, patient says he “is followed by women who talk about him;” or, as in another case, “torment him.” Next most frequently came delusions of bodily injuries inflicted upon them, such as being “throttled,” or of injuries done to their health by real or imaginary persons. In some the alleged injuries were of an extraordinary kind, were perhaps called “tortures,” or attributed to the malpraxis or malevolence of the medical man; in others the alleged injuries were vague (as part of general ill-usage), or only threatening or impending. Occasionally were delusions as to the food being noxious; or ordinary hypochondriacal delusions, for example, as to the stomach being “full of fool.” Hallucinations may or may not exist.

In some were restlessness, and irritable, angry, excited, ill-tempered, querulous, hostile states of mind, or even hatred, associated with delusions such as the above; or obstinacy, contrariness, and threats or acts of violence and destructiveness; or, in one or two, sadness; or latterly in some, confusion and incoherence; in several cases, symptoms such as the above more or less superseded previous intermingling expansive ones.

II Sub-group.—In four was dementia; one of these, formerly maniacal, latterly was profane, obscene, gross; one, at first maniacal, then threatening, insulting, with slightly expansive ideas; became a restless, impulsive, silent, destructive window-breaker, but finally quiet and more demented. A third for many years was a nervous, apprehensive, easily-startled dement; in the fourth, dementia followed on early depressed delusional states.

III Sub-group.—In three was the demented third stage of general paralysis. Simultaneously, one of these was also impatient, denunciating, morose, selfish, jealous, foul-mouthed, profane; another, depressed, weeping, stupid; the other, obstinate, morose, demented, brutish.

IV Sub-group.—In four was melancholia, with delusions of evil impending or even actual injuries, conspiracy, poisoned food, false accusations against the patient, with self-abasement; or refusal of food under the delusion of being followed by those to whom it belongs; or vague fears of poisoned food, of being electrified by a touch, or killed, of being about to be burned, or injured by medical treatment; or assertions by the patient that he has “no swallow and no stomach, and the Dr. cut off his privates;” or he is taciturn, hallucinated, depressed, apathetic, amnesic, incoherent. Here I may add another case. After an early outburst of excitement under vague terror and with imperfect consciousness, the patient had ideas of ill-treatment and of hostility to him, vague apprehension, anxiety, nervousness, semi-terror; and early delirious confusion, rapid failure of heart, and death under the onset of moderate pneumonia and congestion of lungs.

V.—Besides the above, were a case of mania in old age, and one of senile dementia.

Although an accompaniment or even a factor in the causation of symptoms such as the above, fatty heart is not always an unmixed evil; indeed in some cases it may be a preservative lesion, for when the arteries are diseased it may be safer for the subject to have a feebly-acting heart than a normally strong and vigorous one, as taught by Sir William Jenner.³¹

Anemic and spanemic as are many of these insane, yet the fatty degeneration in the above cases was more associated with a general deterioration of tissues than due to the defect of the oxygen-bearing elements of the blood in grave and prolonged anemia. Fatty cardiac degeneration from this latter cause has been found in almost all cases of pernicious anemia, as originally observed by Drs. Addison and Wilks, and this degeneration of the heart in ordinary anemia was made prominent in Dr. Coupland's Goulstonian Lectures³² several years ago.

Syphilitic Hearts.—As might well be expected, the four cases I have to offer in which the heart was syphilitic exhibit the most various states of mental symptoms, and present nothing characteristic, or on which one can fasten.

One of these cases of syphilitic heart I³³ published in full in the *British and Foreign Med. Chir. Review* some years ago, and cited cases observed by Drs. Wilks, Ricord, Lebert, John Morgan, Virchow, Haldane, Aitkin, and Mr. Jonathan Hutchinson. Interesting pathologically, these cases of syphilitic heart are scarcely to our immediate purpose, and I leave them.

Aneurysmal Hearts (four cases).—All the patients were males, aged at death 34, 38, 44, and 50 years, respectively, and in all the left ventricle was the aneurysmal chamber.

One was the subject of dementia, amnesia, childishness, and some depression, with excessively feeble circulation of blood, and tendency to peripheral ulceration and gangrene.

Another latterly, and differently from his previous mental state, had delusions of the fumes of sulphur and of corpses affecting him, and of darts of fire coming on him.

Another, who had previously been in a mingled expansive and hallucinated state, with occasionally some ideas of being annoyed, latterly took marked delusions of annoyance by hallucinatory voices (chiefly women's), and including the voices of persons who “had been burned alive;” said he was “300 years old,” and made absurd, incoherent, childish statements, especially on religious topics.

Another, having at first had hallucinations and depression, undefined alarm or excitement, for years with delusions of being sent to the asylum to be killed, of persons sent for the purpose, attempting to take his life, and these delusions occasioning proxymal excitement and violence; became subsequently the subject of more circumstantial delusions—for example, people “rise in his mouth,” “reply to him,” “sit on his mind,” “breathe on him,” and while thus persecuting him, desire and intend to take his life.

Without further comment or recital of the cases in detail, we may now add a summary of the modifications of mental state coincidently with disabling cardiac aneurysm. Usually in these cases of aneurysmal heart, when in an advanced stage of more or less physically disabling cardio-aneurysm, the tendency was to a modification of the previous insane mental state in the direction of delusions of annoyance, physical injuries, and damaging acts and influences hostile to the patient's bodily state and health, and sometimes taking the strangest forms; or, persecution of another sort, and chiefly by hallucinatory voices; while other delusions and hallucinations of sombre tinge, relating to death and corpses, were observed in two. The comparatively recent case of mental disease following the cardiac was a complicated one, and its dementia and depression not necessarily related to our present topic.

AORTA: ITS DISEASED STATES IN RELATION TO INSANITY.

Here we take up (1) aneurysm, (2) nodulation, and (3) more ordinary atheromatous change of the aorta.

1. *Aneurysm of Aorta.*—One might have spoken of the frequency of heart disease in soldiers. Very frequent also is arterial aneurysm, both facts holding a relation to the comparatively large amount of cardiac disease or aneurysm, and the large military element, in the cases for some years under my care.

³¹ Address at Leeds (JOURNAL, July 31st, 1869, p. 115; *Med. Times and Gazette*, July 31st, 1869, p. 142).

³² *Lancet*, April 30th, 1881, p. 689; *BRIT. MED. JOURNAL*, April 23rd, 1881.

³³ *Brit. and For. Med. Chir. Rev.*, July 1876, p. 176.

Of the two lesions chiefly affecting the aorta in soldiers, (a) the passive limited opacity (sometimes fatty), and (b) the fibroid growth, Brigade-Surgeon F. H. Welch³⁴ concluded that it is the latter which, disintegrating, so often leads to aneurysm, or to implication of aortic valves, or to hypertrophy of cardiac chambers; this growth is connected with syphilis in a major degree, with rheumatism and alcoholism in a minor degree; while the chest constriction and forced temporary exertion of the soldier act as adjuvants to the disease of aorta in the production of aneurysm. On the other hand, it has been held³⁵ that syphilis is only the predisposing and not the direct cause of the aortectasy.

The frequency of heart disease in soldiers was attributed by Surgeon-Major A. B. R. Myers³⁶ to the prejudicial constraint of the uniform and accoutrements, so obstructing circulation as to lead to abnormal strain of the heart, a strain which may be brought about or aggravated by disease of the aorta, such as aneurysm, which latter, in the young soldier, often appears to be due to an acute inflammatory softening, brought about by some severe distension of the affected vessel.

Not accepting mechanical strain alone for heart disease in the soldier, nor syphilis alone for his aneurysm, Surgeon-Major W. E. Riordan³⁷ made the aneurysms of soldiers to be usually secondary to heart disease, and the heart disease to be due to drill and discipline; the early drill, with violent exercises and alteration of form of chest, changing the condition of circulation much, the discipline causing mental anxiety and worry. Now, to a large extent, this is only the older idea of mechanical strain, but ignoring the (real) aggravating influence of the soldier's uniform and accoutrements thereupon.

Entirely omitting small pouches or dilatations not giving rise to marked local or systemic symptoms, and not the cause of death, I bring forward eleven extreme cases, eight of the thoracic aorta, and three of the abdominal. Here I can only find space for the insertion of a few particulars as to the mental state.

During, and for some time prior to, the attainment of large size by the still growing aneurysmal tumour, in one were peculiar delusions of being tormented, grievously hurt, "destroyed," and his bones bored into, by snakes, scorpions, weasels, in body and limbs. Once he had "seen" and once he had "heard" them. He says his body is full of snakes, scorpions, rats, and weasels, which eat him up, gnaw on the bones, etc. "They are the most horrible varmint ever known." Later, often feels his head and hand falling off; has "pains all over," worse in trunk and head, equally on the two sides, and "boring pains through both jaws." "Is eaten up alive; some of the 'varmint' make sores, which others eat, every day. It began the same way six or seven years ago. Millions of snakes and scorpions got inside him, and began eating his body. They now push out his ribs, first at one side then at the other, and eat them, and finally level them down; they also push out and eat the jaws." Later, being short of breath, he says it is "forced out by the 'varmint' inside him." "His chest is all sores, and every inch of his body is the same." Interapical tubular respiration, profuse clammy sweat. Later, respiration made in a sudden, rapid, audible way, as if by one taking breath after a long exertion. Later, tracheal wheezing. Still later, he says the top of his head, especially its left side, and the ribs are "split out," furred, sweating face; brassy cough. Once, subsequently, he says the vermin "carry pocket knives, and during the last twenty-four hours have been scraping his ribs, first on the edge and then in the broad, and finally they bend them, and go through the perforation of breaking them." Dyspnoea, orthopnoea, giddiness, reeliness, and "a blindness" (as he called them), with cold and purple hands, ear-tips, nose, and lips preceded somewhat sudden death.

Of another, the certificates stated that he had the delusions that he was plotted against, conspired against by certain women and a captain —, and also by the men of the regiment; that, in an excited way, he demanded immediate trial, or redress, refused to answer questions about himself, and was restless and excited in appearance.

On admission, the delusions continued, but he was taciturn, and complained of pain in the chest and dyspnoea (much relieved by treatment), with congestion of lungs and expectoration, at first ear, then streaked with blood. So the case went on. He said

the men watched him and talked about him in India, and therefore he was sent into hospital. There were dyspnoea, congested lungs, blood-streaked sputa, constant hacking cough, occasional severe pain in serobiculus cordis, right infraclavicular and subscapular regions. He retrograded steadily, suffered much from orthopnoea, moaning, restlessness, *malaise*; declared that a galvanic battery was constantly applied to him by Captain — and others; this they "took off," he said, on the approach of the asylum medical officers. He asserted that he distinctly heard them talking about him, and what they would do to him, and saying "give it him," etc., and often he urgently pressed to have the police brought in, or to be allowed to make oath before a magistrate as to these hallucinations, and secure the protection afforded by law against his persecutors. Of anxious and painful expression of countenance, gloomy and anguished, he was a type and sample of the mental and physical suffering engendered by aortic aneurysm. Œdema, vomiting, anorexia, icteroid and livid countenance, and, finally, painful delirium and orthopnoea, preceded death.

Another was formerly the subject of monomania of persecuted and hypochondriacal type, blended with some expansive ideas; for example, "God and others speak to him in visions; internal voices cause him to speak and act without power of self control." He had hallucinations. "His wind-pipe," he said, "is worked up and down; has two personalities in his body; there are two meanings in what he says; has been sent here in mistake for someone else; a false nerve is worked on his body." He made treacherous homicidal attacks on attendants. Later on, quiet, depressed, sullen, irritable, complaining of his detention, and subject to delusions of ill-treatment.

Dr. Sibson's conclusion, that the symptoms during life are less formidable in aneurysms that end by rupture of the sac than in those which kill without such rupture, is just what we would expect as a general rule, and as such is easily explained on the ground that those which kill without rupture do so by their pressure-effects, which are formidable and painful.

It is well known that some cases of aortectasy, owing to their position and other circumstances, are almost unattended by any symptoms indicative of pressure; yield only local, innocuous physical signs; even when fatal give rise to no special functional disorder or organic change, or pain of any other part until death, or until rapid changes in the tumour, rupture, or leakage, set up some painful distressing symptoms shortly before the close of life. Aortic aneurysms, too, far more readily in the insane than in the sane, may not lead to complaint, as in one or two of the cases in my statistics, and as may still more readily be the case if the heart be fatty and friable, as in an example by Dr. T. B. Worthington,³⁸ in which sudden death from rupture of a previously undetected thoracic aortic aneurysm occurred in a quiet, silent, taciturn melancholic. And I³⁹ described a case in which thoracic aneurysm was unattended by symptoms until hæmorrhage from it occurred about twelve days before death.

In such cases we do not expect to find any marked or, indeed, any distinct, modification of the mental symptoms as a consequence of the aneurysm, its pressure or other effects, that is to say, as a consequence of the construction put upon, the interpretation arrived at of, the pressure effects and circulatory disorders engendered by the aortic aneurysm, that construction and this interpretation being those of a morbid mind. Consequently it is in cases such as those of some aspects of which I have just given a brief summary that we find symptoms which I believe to be those most likely to arise when aneurysm of the aorta modifies the previous mental state by its effects upon the important parts and structures adjoining it, and of these upon the brain. Into the other cases of large thoracic aortectasy I need not enter; they were not attended by characteristic mental modifications.

Abdominal Aortic Aneurysms.—In three insane patients under my care the cause of death was aneurysm of the abdominal aorta. It is perhaps unnecessary to give summaries of these cases, especially in view of the limitations imposed by waning space. Suffice it to say that in these cases of abdominal aortic aneurysm we find illustrations of the interpretation put by the insane mind upon the symptoms, especially the pains, discomfort, arising from the

³⁴ Tabulation of cases from the *Neurological Register of the Royal Victoria Hospital*, etc., and *Lancet*, November 27th, 1875, p. 769.

³⁹ *BRITISH MEDICAL JOURNAL*, December 18th, 1875, p. 755. "Grave Lesions of both Corpora Striata: Recovery from Hemiplegia: Extensive Cerebral Regeneration; Dementia: Death twelve days after Rupture of Intrathoracic Aneurysm."

pressure and other effects of the aneurysm; and we find that interpretation taking the form of delusions of definite types, or showing a tendency thereto. We trace in these abdominal aneurysmal cases at least the same character of delusions as to local bodily injuries, damages, personal injuries, hostile influences and effects, and delusions of mingled persecutory and hypochondriacal types, as in some thoracic aneurysmal cases. Yet the abdominal aneurysms were complicated with more or less heart disease, and, therefore, were not pure cases.

Of these eleven cases of large aneurysms of thoracic (8) and abdominal (3) aorta, only five gave evidence of nodulation of the aorta; and of these the majority not so very markedly as many other cases. This brings us to

Nodulation of the Aorta: Cases.—Here I mention twenty-seven cases, of which five are described under aortic aneurysm, and several others presented small aneurysms or pouches.

Age.—At death the average age of all the cases was 38.8 years; of the five with large aneurysms, 42 years; of the rest, 38.05 years.

Condition of Aorta.—The aorta becomes irregularly nodulated by greyish, somewhat translucent tissue, the elevations formed by which, and sometimes projecting boldly into the lumen, eventually contain opaque or yellowish patches; or the semi-translucent elevations are more or less rigid; or at a subsequent, or even at an early, stage the internal surface of the aorta presents small, rounded, opaque, whitish, thickened patches; or in one part flattened, whitish prominences, at another dull-whitish or yellowish patches and infiltrations; these at points may be undergoing incipient erosion, or the elevated, fibroid, whitish and slightly bluish, semi-translucent formations may be associated with yellowish and calcareous patches, or the fibroid thickening with yellow deposits here and there. Still later, and commingled, are puckers, yellow patches, calcareous plates, and whitish, somewhat translucent, round elevations projecting between the depressions; or nodules are surrounded by stellate cicatrices, and, of the nodules, the large ones have sometimes firm, yellowish-white centres. The condition is chiefly a deforming inflammatory change of endoarterium, and is usually included under the name "atheroma."

Syphilis.—As to the question of syphilitic causation. In six, were distinct histories of antecedent syphilis; scars on penis, or on tongue, in several cases. In a case or two each, syphilitic rashes, enlarged inguinal glands, nodes on periosteum or bones, or syphilitic headache. In several cases, syphilitic lesions, gummatous or inflammatory, of brain, meninges, or or both. Calvaria dense, or of worm-eaten appearance internally; meninges of brain very tough, dural hamorrhage or rusty films, excessive "adhesion and decortication," or irregularly distributed sclerosis of brain cortex or other parts, including pons and medulla oblongata; syphilitic arteritis in vessels at brain-base, or elsewhere. In one there was a syphilitic gumma in the wall of the heart; in another a gummatous patch in a coronary artery. In seven were gummatous traces in the liver; in seven (mostly the same) old perihepatic adhesions; in three, irregular thickenings of the capsule. The spleen showed traces of gumma in four; in two, old perisplenic adhesion membranes; in two, irregular thickenings of the capsule.

Mental State.—Fifteen were general paralytics. A larger proportion of these cases than usual presented marked emotional depression and corresponding delusions and actions, being either melancholic or hypochondriacal. Some were of the demented form of general paralysis, and many were inclined to the early exhibition of restless, excited, destructive, troublesome, and degraded states. Yet, in some, grandiose ideas were well-marked, either intermingled with or modified by the depressed ones, or

* **Heart.**—Heart on the average 11 ozs., av.; its muscle flabby, friable, in half the cases. Marked hypertrophy of left ventricle in five cases, and dilatation in three of these; right ventricle hypertrophied and dilated in three cases. These include a case of dilatation, and a case of hypertrophy and dilatation, of all four cardiac chambers. Heart muscle softened in half, and in half the coronary arteries diseased. Chronic aortic-valve disease existed in ten cases, also. In one more was acute, ulcerative, aortic valvulitis; mitral valve disease in seven, and comparatively slight. Kidneys granular in ten, mottled in three, soft in two; other changes in single cases.

Average weight of spleen, 6½ ozs. Capsule in many thickened irregularly, or adherent, or pigmented. Usually of undue firmness, the spleen in four cases presented cicatrices, apparently of old gummata. Whitish thickened plates, of cartilaginoid hardness, affected the capsule in a few cases.

Old perihepatic adhesions, irregular thickened patches, of the capsule of the liver, were observed in many cases. In seven the liver was cicatrised, as in the manner due to former gummata; one liver was lardaceous. In a few was very slight cirrhosis.

standing revealed in the more ordinary form. Of the groups of general paralytics described in my work on the subject, the third and fifth would be those relatively represented in larger proportion by the cases just mentioned, and, with unusual frequency, the cerebral changes included irregularly but widely distributed cortical or other somewhat localised palpable sclerosis, or tough meninges, or an extensive distribution of that change which I⁴⁰ have termed "adhesion and decortication."—One case of lead sclerosis, resembling general paralysis. Three cases of syphilitic dementia and emotional depression. Three of monomania, chiefly of persecutory or of hypochondriacal type; some of them much deteriorated, but in two of them the earlier symptoms largely, the later slightly, expansive. Three of delusions of annoyance, of being tormented by women or others, with hallucinations, or resembling querulous or persecutory monomania, but not markedly systematised. In some of them, at times, was an expansive tinge. Two of dementia, of different forms, following melancholia or mania. Total, twenty-seven. (Accompanied, not caused by nodular aorta).

To begin with, several groups of facts stand out here in strong relief.

(a) The relative frequency with which aortic nodulation is found in general paralytics (certainly in military general paralytics), at least double their share relatively to other forms of mental disease and ratio of necropsies; so, also, the relative frequency with which comparatively localised sclerosis affected their brain cortex, or other parts, or with which the meninges were unusually tough or markedly adherent to the cerebrum over an extensive area; and the relative frequency with which melancholia, dementia, and restless degraded states predominated, as compared with the more usual clinical aspects of general paralysis.

(b) The relative frequency with which there is some history, some clinical indication, or some necroscopic evidence, of syphilis (irrespective of the aortic change itself).

(c) Other points are: that most of these patients were comparatively somewhat young, or of early middle age; excluding the very markedly aneurysmal, an average age at death of only 38 years; and, again,

(d) That the heart was not so often or so extremely diseased as to be the dominant factor in the morbid drama, either clinically or pathologically. The coexistent heart affection was, on the whole, oftener and more severe in affecting the aortic rather than the mitral valves, a fact which brings these cases much into line with a group already discussed under aortic-valve affections, and composed of examples of coexistent aortic valve and arch disease; in relation to which I showed how these cases arose chiefly in persons of sanguine temperament, active circulation, vigorous vitality, and bodily and mental activity, abounding energy, free livers, eaters and drinkers, and by no means frigid to the other sex; who, becoming insane, tend, on the whole, to have expansive symptoms, at least in the earlier stages, rather than depressed ones. Avoiding repetition of that discussion, here, I merely add that the aortic disease and the similar changes affecting distant blood vessels, even if in a minor degree, account for some of the hypertrophies found in a share of these cases, and chiefly of the left ventricle. And the last of the points here is:

(e) That among coincident changes, were frequently degrees of splenic induration, and of renal granularity, or else a mottled state; and then there was the relative frequency of traces of gummata of liver and spleen, of perihepatitis and perisplenicitis of a past date.

That the larger arteries of the body may be affected by syphilitic lesion has long been known. Lancereaux even cited observations of the kind from the older writers on the subject; and Bäumler,⁴¹ even a dozen or more years back, collected other examples. But it is especially from the medical officers of the British army that has come the view as to the very frequent dependence of aortic disease upon syphilis. Thus Brigade-Surgeon Francis H. Welch adduced a large amount of evidence to show that aortic endoarteritis, as distinguished from mere opacity or fatty degeneration of the inner coat of the vessel, in the majority of cases was connected with syphilis. In most cases of aortic aneurysm he found that syphilis was the only diathetic condition to which the vascular disease could be attributed. And in 60 per cent. of the cases of syphilis, terminating fatally through special lesions, aortic nodulation was found. He concluded that in

⁴⁰ *Journal of Mental Science*, Jan., 1876, pp. 571-6. *Ibid.*, Apr., 1874, p. 29; and *General Paralysis of the Insane*, second edition, pp. 282, 364, etc.

⁴¹ *Ziemssen's Cyclopaedia of Practical Medicine* (Trans.) vol. iii, p. 213.

soldiers there is often "a lesion of the aortic walls characterised by the presence of a fibroid growth in the deeper layers of the internal coat which as a rule ultimately disintegrates, and that this growth is connected with syphilis in a major degree, and with rheumatism and alcoholism in minor degrees as exciting agencies. There is also a lesion of the aortic wall, characterised by limited opacity and fatty change of the inner coat; this is common in all diseases associated with prolonged general deterioration." And it was the former of these two kinds of textural derangement of the vessel-wall which was so often the precursor of aneurysm.

Practically, very similar views were held as to the frequency and effects of syphilitic arteritis in military patients by Professors Aitkin⁴² and W. C. Maclean.⁴³

More Ordinary Changes of Aorta.—Here I bring thirty-five cases, a number which I might easily increase.*

Mental Condition.—In nine, general paralysis, of different forms.

In nine, dementia with local organic disease of brain, or widely-spread atrophy, and including cases from syphilitic affection of brain, and one of epileptic dementia.

In seven, deteriorated, incoherent, feeble-minded states supervening in monomania, or occurring in chronic alcoholic insanity; many with expansive elements formerly.

In three, monomania of mingled form, but the expansive element more marked in the earlier stages, the depressed or persecutory in the later.

In three, paroxysmal maniacal excitement; delusions of annoyance, hostility, evil intent, poison in food, and as to surrounding and ubiquity; or expansive delusions, and hallucinatory visions.

In four, either melancholic hallucinations and delusions, for example, "is robbed," "is told by a spirit to cut his throat," "is peculiarly affected by air;" and perhaps suicidal or apathetic states; or delusions of hostility and malevolence, or unsystematised delusions of persecution.

Total, thirty-five. (The state of aorta a concomitant, not a cause).

Of the thirty-five, eleven have already been mentioned under "aortic valve and aorta" disease, the fourth of the sub-groups I made of affections of the aortic valve. These I might have omitted, and in place of them taken others with less or no valvular change; but the thirty-five cases fairly illustrate the average associations and combinations of the ordinary disease of aorta, and the conditions coincident therewith, except that senile dementia is comparatively little represented, the examples of that form, included, having also organic changes of a grosser kind than that at the basis of simple senile dementia. In order to select the present group from cases of aortic change taken indiscriminately, we should exclude examples of extreme cardiac or valvular affection in which that affection completely dominates, and in which the coincident ordinary aortic atheroma is an affair of comparatively little moment, and we should exclude also the cases of marked aneurysm of arcuate aorta, as well as those of aortic nodulation.

Here apply many of the remarks and the general principles and conclusions mentioned in my commentary on the sub-group of aortic valve affections, presenting coincident disease of aortic valve and arch; for here also do we find that in many of the cases in which aortic atheroma is marked at the necropsy there is an expansive mental element and excitability, in the early years

at least, even if later on there comes a demented or a painful and worried state, or one of imagined persecution; and we find that the diathetic conditions which favour the production of aortic atheroma, as a relatively marked change, also co-exist with, and even favour, the production of activity, mental and physical, free-living, and so forth. And with these also is the influence of the sanguine temperament. Hence mental disorder is apt to be active, expansive, often subsequently degenerating into a state of disagreeable, painful hallucinations and delusions, and eventually into a worse failure of mind and incoherence. But the widespread vascular changes, so often coexistent, promote diffuse degeneration of nervous tissue elements; promote, too, local destructive lesions, visible to the naked eye, and destroying masses of nervous substance; and not only so, but also setting up a number of secondary degenerative changes in neighbouring or else in systematically-connected and comparatively distant parts of the nervous system; and not only so, but also tending eventually to atrophy of the nervous organs. Therefore it is that we find a large proportion of the cases with aortic atheroma end, on the mental side, in dementia, while some consist chiefly of dementia from the first; in them also are local and general motor and sensory symptoms prominent.

But in the later stages of many cases there are depressed or psychically painful symptoms, and if the aortic is only part of a general atheroma—or in some cases where this is not so—melancholia, or states such as of unsystematised delusions of persecution and annoyance; or, again, the persecutory or hypochondriacal forms of monomania, may be observed. I am speaking of very marked atheroma; yet atheroma in its slighter degrees is so common a condition with advancing years, that we may speak of slight aortic atheroma as the usual, nay almost the normal, senile condition. Nevertheless, when it is very marked, atheroma is usually co-existent with cardiac lesion or degeneration, which dominates the situation, or else with disease of the peripheral vessels, which is far more important than the aortic atheroma. Therefore, with atheroma affecting the arterial system widely, and associated with embarrassed circulation, it is no matter of surprise, but, rather, to be anticipated, that the imperfectly supplied and badly-nourished nervous system evinces emotional depression, mental suffering, mental failure, dementia.

Statistical Summary of the Preceding Heart, Cases of Disease of.

Total Cases.		Or excluding Cases also coming under other Heads.	
29	6 in 1st	Three mitral valve sub-groups.	1st 6
	7 ,, 2nd		2nd 7

11		Large aneurysms of aorta.	2
27		Nodulation of aorta (including some cases with smaller aneurysms).	23
35		Ordinary atheroma of aorta.	24
228			157
About 8		cases of heart disease introduced to illustrate some points, and not included above.	8
236			165

Of the 236 instances of diseased conditions, 163 were of heart and 73 of aorta.

Of the 165 separate diseased individuals, 107 were entered under "heart" only, and 48 under "aorta" only.

Besides the above were many hearts in phthisical subjects already mentioned but not enumerated. I shall not take up the consideration of cases of embolism and thrombosis (often cerebral). Before me is an incomplete table containing fifteen of the cases I have seen, to which others are to be added.

The distribution of prizes to the Volunteer Medical Staff Corps by Her Royal Highness the Duchess of Albany, on Saturday, March 17th, has, on account of the death of the Emperor of Germany, been indefinitely postponed.

⁴² *Practice of Medicine*, vol. ii, p. 644.

⁴³ *BRITISH MEDICAL JOURNAL*, 1876, vol. i, p. 283.

* The average age at death was 42.5-71 years. The changes were of the ordinary atheromatous kind, irregular thickening of the internal coat, or internal and middle coats, of the arch of the aorta; opaque whitish slightly raised patches, sometimes a gelatinous appearance, but more often yellowish patches, some of them eventually becoming calcareous. The surface of the aorta may be rendered more or less irregular, slightly ridged; the change often affected the sinuses of Valsalva, or the arch near where it springs from the heart. In a majority, one or both of the coronary arteries were more or less affected in a manner similar to that described for the aorta.

In fourteen the heart was more or less hypertrophied, partially or generally; in some of these the left ventricle alone was hypertrophied, or was so more than the other chambers, where several were so affected. In the great majority the hearts at the necropsy were more or less flabby, friable, or softened. In eighteen, was very decided aortic-valve disease; of these, in one was marked constriction at the aortic valve, and in two marked incompetency of it. In thirteen, was some mitral disease, on the average less severe than that of the aortic valve and orifice in the cases just mentioned; in one of them there was marked mitral regurgitation.

Some of the large cerebral arteries at the base of the brain were atheromatous, or otherwise conspicuously diseased in ten cases.

The renal changes were as follows, and usually more than one of them existed in the same case. In nine the granular, in three the ordinary cystic change, eight with capsules adherent or greatly thickened, two atrophic, and one indurate, yet not distinctly granular; three entered either as "mottled" kidney, or as "subacute nephritis," and one lardaceous.

ABSTRACTS OF THE MILROY LECTURES ON SOME GENERAL CONDITIONS WITH REGARD TO EPIDEMICS.

Delivered at the Royal College of Physicians of London,
February and March, 1888.

By ROBERT LAWSON, L.R.C.S.Ed.,
Inspector-General (Retired) Army.

LECTURE III.—EPIDEMIOLOGICAL ASPECTS OF YELLOW FEVER.

Symptoms.—The Lecturer said that, from a clinical study of yellow fever in Jamaica during the years 1856-60, he had formed the opinion that the distinctive characters of the disease were:—
1. That it usually terminated in death or convalescence from the fourth to the seventh day, but that either event might occur as early as the second or as late as the tenth or twelfth, or even later. 2. That the general yellowness of the eyes and surface commenced at various periods in different individuals and epidemics. 3. That the urine presented certain symptoms, namely, on the evening of the third or morning of the fourth day traces of albumen; on the fourth day a considerable sediment, consisting almost wholly of vesical epithelium; on the fifth day an equally copious sediment consisting almost exclusively of granular renal tube casts. The urine by this time was scanty, contained much albumen, a diminished quantity of chlorides and urea, and, if there were much yellowness, some bile pigment; the excretion might be completely suppressed. From the third day the feces, when formed, were greyish, or yellowish white, with an intermixture of black matter, when fluid consisting of mucus of the above colour, or coloured by bile or blood. 5. As the urine and feces assumed these characters there was a tendency to black vomit, and hæmorrhages (so-called) from various mucous surfaces, or even from the skin. As to the character of the fever, it was necessary to recognise that the disease occurred both sporadically and in epidemics in a periodic (remittent or even intermittent) form, as well as in a continued form with a paroxysm of seventy-two hours, followed by the characteristic symptoms of the disease.

Mode of Origin of Epidemics.—Two views were held as to the mode of origin of the disease in a locality; one attributed it to causes in operation in the locality at the time, the other supposed that it must have been introduced by persons recently arrived from another locality where it was prevalent. In the great majority of examples adduced in support of the contagiousness of yellow fever, no attempt had been made to exclude a local cause. In numerous well-authenticated instances persons have contracted yellow fever in a locality where the disease was prevalent, have removed to a healthy locality, and passed through the fever there without affecting anyone about them, and that even when their numbers were considerable. The case of H.M.S. *Bristol* frigate was quoted as a particularly striking example; from this boat, soon after her arrival in Sierra Leone (December, 1865), where there was a severe epidemic, a party of 116 officers and men were sent to the receiving ship *Isis*, which had had several cases on board; the party slept on board the *Bristol* each night, and did not go ashore. Though the crew of the frigate included many young men fresh from England, and consequently quite unacclimatised, not a single case occurred in anyone who had not been on board the *Isis*, though a large number were engaged in immediate attendance on the thirty-eight cases which occurred among those who had. The case of H.M.S. *Brilliant* was quoted as a well-marked example of a ship's company contracting yellow fever on shore, while the ship herself was quite healthy; a severe outbreak occurred; the ship went to sea, and after the period of incubation had expired no fresh attacks occurred.

Alleged Instances of Contagion.—There was, it was said, no well authenticated instance of yellow fever having been communicated by persons who had contracted it on board an affected ship to other persons on shore who had not come within the range of the emanations from the ship. The instances, supposed to have been afforded by the *Anne Marie*, at St. Nazaire, and by other vessels, were examined and shown to be capable of bearing a different interpretation.

Influence of Local Conditions.—The behaviour of yellow fever in Barbadoes was next discussed at great length, and while it was shown that the disease on many of the occasions when it was in-

duced did not spread, certain local conditions were pointed to in connection with swampy ground, which appeared to stand in intimate connection with the outbreaks. The instances of the United States steamship *Susquehanna* and of H.M.S. *Orion* were quoted as instances of ships acquiring the condition necessary for producing yellow fever without communication from a previous case. Statistics and official reports were quoted in support of the proposition that certain epidemics of yellow fever in Bermuda sprang up at different points in the islands without the previous introduction from elsewhere of persons labouring under the disease. It was clear, therefore, that such an introduction did not constitute a necessary factor in the development of the conditions required to produce yellow fever, while the immunity which followed more extensive importations of persons labouring under the disease into healthy localities, or during the healthy part of the year at those which are occasionally subject to the disease at certain seasons, went far to prove that the introduction of cases of the disease had no influence in determining an epidemic. The potential factor must be widely diffused by aerial means, but in a form incapable of giving rise to the disease until it meet with a suitable soil for further development. The immediate exciting cause was clearly particulate, and was given off from a collection of mud in a ship's hold, or from a marshy or damp spot on shore.

A CASE OF ANGIOMA OF THE LARYNX.

By PERCY KIDD, M.D., F.R.C.P.,

Assistant-Physician and Pathologist to the Hospital for Consumption, Brompton.

AMELIA M., aged 50, came to the out-patient room on December 2nd, 1887, complaining of loss of voice. With the exception of two attacks of bronchitis twenty years and twelve months previously, she had not been troubled with cough or expectoration. For the last eight or nine years, "perhaps longer," her voice had been very weak, and frequently had been lost completely. Menstruation occurred every fortnight, and was excessive, otherwise her health was fairly good.

The patient was a spare woman, with a fresh complexion, but was profoundly nervous, and could only speak in a whisper. Her face flushed on the slightest excitement. The pulse in the right brachial and radial arteries was smaller than in the corresponding vessels of the left arm, but the pulse on each side was very small and weak. The chest presented no abnormal signs. On laryngoscopic examination a small tumour was seen springing from the anterior extremity of the left vocal cord. This tumour, oval in shape and imperfectly bilobed, had a dark-red colour like that of a ripe raspberry, its surface being faintly granular, but not uneven. The growth was attached to the upper surface of the vocal cord by a flat ribbon-shaped pedicle, which permitted free movement. During deep inspiration the tumour at times slipped down into the subglottic region, and was almost lost to view, re-appearing on phonation. The appearance of the tumour is roughly indicated in the accompanying diagram.

The mucous membrane of the larynx in other respects was perfectly healthy in every part. The vocal cords presented no trace of congestion, but, when phonation was attempted, they exhibited curious oscillating choreiform movements towards the median line. On inspiration abduction was normally performed. Examination was rendered somewhat difficult by the patient's nervousness, which gave rise to spasmodic contraction of the sphincter muscles at short intervals.

Bromide of potassium and simple lozenges were prescribed, and the patient was advised to have the growth removed. A fortnight later, that is, at her second visit, the throat was sprayed with a small quantity of a 2.5 solution of cocaine, and the tumour was easily seized with Mackenzie's laryngeal forceps, and removed entirely. Very little bleeding followed, but the patient was so

hysterical afterwards that she had to be kept in the hospital for a couple of days. Since then she has attended as an out-patient.

The left vocal cord was much congested for a few days after the tumour was removed, but the injection soon diminished, and a small, translucent, oedematous swelling was noticed at the part where the growth had been attached. This has now disappeared, and the only morbid appearance which remains is a slightly swollen and congested condition of the left vocal cord, mainly affecting its anterior third. The patient's voice began to improve almost immediately, and is now quite normal.

The vocal cords still exhibit the same choreiform movements of adduction during laryngoscopic examination. The patient comes every few weeks to show herself, and was last seen on March 6th, 1888, when her condition was that which has just been described.

Microscopical Examination of the Tumour.—The growth consists of a system of cavernous, vascular spaces of various sizes. Some of these spaces are partially obliterated by thrombosis, others are quite free from thrombus. Blood corpuscles are seen here and there in the lacunæ, but in most cases they have dropped out during preparation of the sections. In many places remains of thrombosed spaces are visible, and there is a considerable quantity of coarsely fibrillated tissue having a lamellar arrangement (organising thrombus), situated between the individual lacunæ, especially towards the base and near the free surface of the tumour. The growth is covered by a laminated pavement epithelium like that investing the healthy vocal cord, but not marked by the usual papillary indentations. Between the epithelium and the angiomatous tissue there is a thin layer of loose, delicately reticulated connective tissue containing scanty round and branching cells and capillaries.

The vascular spaces are bounded by thin walls, which consist of glassy-looking, homogeneous connective tissue, lined by an endothelial membrane, and contain no unstriated muscular fibres. The structure of the tumour is thus seen to be that of a cavernous angioma, closely resembling the form of angioma not infrequently found in the liver. Its origin is doubtful, though from the prevailing cavernous structure, and the complete absence of cellular growth, it seems clear that it was essentially an angioma. The history would seem to show that it developed in adult life.

Angioma is an extremely rare form of laryngeal tumour. Sir Morell Mackenzie, in his work on *Diseases of the Throat*, says that he has only met with two growths of this kind, "one grew in the right hyoid fossa, the other from the right ventricular band." "A similar growth," he says, "has been observed in the former situation by Fauvel."

I can find no mention of angioma of the larynx in the pathological textbooks of Cornil and Ranvier or Ziegler.

OBSTETRIC MEMORANDA.

PUERPERAL CONVULSIONS IN A PRIMIPARA.

J. G., aged 25, married nine months, eight months pregnant, was taken prematurely in labour on Sunday, February 26th, caused by having, on the evening of the 21st, when seeing her mother off by the train, slipped and fallen into a carriage just as the train was starting.

I was called to her at 12 P.M. and found the membranes ruptured and the labour well advanced, the head presenting. The patient was flushed and excited in manner, but quite sensible and not much distressed by the pains. The infant, an undersized female, was born at 12.45 P.M. The placenta followed readily, and there was very little loss. I stayed with her some three-quarters of an hour, and left her apparently doing well.

At 4 A.M. I was summoned, and reached the house about 4.20 A.M. Shortly before 4 A.M. she complained of a strange feeling of oppression in the head, and was seized with a violent attack of eclampsia. The convulsions were general, the tongue being bitten, and a quantity of bloody froth escaping from the mouth. On arrival the convulsion had ceased, but the patient was maniacal and wandering. Twenty grains of chloral hydrate were given by the mouth, and she shortly fell asleep.

At 8.30 A.M. I was again sent for, as the convulsions had recurred at intervals, the first attack coming on within half an hour of my leaving the house. I prescribed a mixture with ten-grain doses of potass. bromid. to be given every hour or two, and visited

her soon after. She had then recently had a convulsion, and was violently maniacal; the jaws were closed, and it was found impossible to get her to swallow. I at once injected thirty grains of chloral in warm water into the rectum. This produced a speedy result, as the patient became quiet, and in a few minutes fell asleep.

With some difficulty I introduced a catheter, and drew off about an ounce and a half of cloudy urine. This, on being tested, was found to be highly albuminous, quite a third albumen.

At 4 P.M. she was seen by my partner, Dr. Beeby, who gave by the mouth thirty grains of bromide of potassium. She was then quieter, but dull and semiconscious, having had a convulsive seizure, but of less severity, a short time before. Altogether, from 4 A.M. until 4 P.M. she had ten fits of convulsions, the first five by far the most severe, and the intervening periods occupied by maniacal excitement, except when sleeping for a short time after the doses of chloral.

I saw her again at 7 P.M. She was then more excited, and had not slept. I administered by rectal injection forty grains of bromide of potassium, with twenty grains of chloral hydrate, and dusted five grains of calomel on the tongue, which she protruded when desired. She slept well during the night, and in the morning early the bowels acted freely, the motion being dark coloured and very offensive. She now awoke conscious, recognised her mother, and passed urine voluntarily. This urine when tested contained only a trace of albumen. From this time she made uninterrupted progress, the mammary secretion became established, and she was able to nurse her infant.

The patient was a fair, slightly made, delicate woman. During pregnancy she had suffered from a severe attack of pleurisy on the left side, and after recovery had an attack of intercostal neuralgia. At 17 years of age she had an attack of scarlet fever. She herself had not suffered from convulsions previously, but a brother, at the age of 14, after scarlet fever, had a series of convulsive attacks lasting over some time.

It is a curious fact that the patient lost all recollection of the events connected with the labour, and of all that happened in the days preceding it up to the date of her mother's visit on February 21st.

Her recovery seems in great measure due to the effects of the chloral and bromide of potassium administered, and shows the value of the injection of drugs by the rectum when a patient is unable to take medicine by the mouth.

Bromley, Kent.

HERBERT J. LOTT, M.D., C.M.

SURGICAL MEMORANDA.

A CASE OF SUBSPINOUS DISLOCATION OF THE HUMERUS.

OWING to the rarity of this accident, I think the following case may be of interest:

E. H., aged 52, a strong, muscular labourer, came to the infirmary on February 8th, 1888, stating that while excavating for foundations a fall of earth occurred, and knocked him backwards against the side of the trench, his left elbow being driven forwards and inwards, and at the same time upwards. He complained of great pain in his left shoulder and arm, which he could only move very slightly. It was found that he had a subspinous dislocation of the humerus, the diagnosis being easy. There was distinct flattening of the shoulder and prominence of the acromion, while the head of the humerus could be plainly felt lying on the dorsum of the scapula below the spine, and nearly halfway between the head of the scapula and its internal border. The elbow was directed forwards, and could be made to touch the side with some difficulty. There was an inch and a half of shortening. The reduction was easily effected by means of extension at right-angles to the body and external rotation. The man made a good recovery, being able to move his arm well and touch the top of his head with his hand in three weeks' time.

W. E. ATBLAND, M.R.C.S.

House-Surgeon to the Northampton General Infirmary.

NURSING OF THE POOR.—The seventh annual report of the North London Nursing Association states that the number of cases nursed last year was 1,363. Over 200 medical practitioners in the neighbourhood, it was stated, had availed themselves of the services of the nurses during the past year, or nearly double the number who applied during the former year.

GREAT BRITAIN, IRELAND, AND THE COLONIES

LIVERPOOL ROYAL INFIRMARY.

A CASE WHERE A SUPPURATING SPLEEN WAS OPENED AND DRAINED.

(Under the care of Dr. CATON and Mr. REGINALD HARRISON.)

[From notes by Mr. L. VAUGHAN PARRY.]

THE following case (which in the first instance was under the temporary care of Dr. Davidson, and then of Dr. Caton in the Liverpool Royal Infirmary, and was subsequently transferred to Mr. Reginald Harrison for surgical treatment) will be read with interest in connection with a somewhat similar instance recorded in the JOURNAL of November 12th, 1887, from the practice of the Burdwan Municipal Hospital.

T. D., aged 30, was admitted on December 9th, 1886, complaining of shooting pains in both legs, particularly the left, with some swelling. He had not resided abroad, nor was there any history of his having suffered from any form of malarial fever. He appeared to have been a temperate man, confining himself to drinking a moderate amount of beer daily. He had an attack of acute rheumatic fever five years ago, and had suffered a good deal in this way since. He was by occupation a painter, and was a good deal exposed to damp and cold. He had a rather severe fall some time previously, and was unconscious for three days. He also appeared to have suffered from a severe attack of bilious vomiting three years since. His present illness seemed to have commenced a month ago with shooting pains and swelling in the lower limbs, from the groin downwards.

On admission he presented the appearance of a fairly nourished, healthy-looking man. There was no jaundice colour, the skin being white and free from oedema, except over the abdomen. There was no oedema of face; there was fluid in both knee-joints, and the right metatarso-phalangeal joints were swollen and tender. Pulse 84, temperature 100°. Cardiac dulness increased. A thrill felt below the nipple, and a systolic murmur audible over second left costal cartilage. Slight dulness over the bases of both lungs. On examining the abdomen the liver dulness was found increased to four inches and a half. On the left side a dull area extended downwards from the last rib for four inches, and this dulness could be traced forwards up to within half an inch of the umbilicus. There was pain and tenderness on pressure in both lumbar regions, especially in the left. The urine was normal in colour; specific gravity 1012; acid; a trace of albumen. He frequently had retention; he stated that a year ago he passed blood for twelve hours; he had never had any rigors.

During the next few days increasing pain and tenderness in the left lumbar region and in the left side, above the iliac crest, was complained of. On the 11th the temperature rose to 102.4°; on the 13th a distinct tumour was discovered coinciding anteriorly and superiorly with the area of dulness referred to above, on the left side, and posteriorly terminating at the anterior superior iliac spine. On the 15th he suffered much from pain in the lumbar regions and thighs. The urine was found to contain pus, which previously had been absent, also hyaline casts and granular epithelium. The blood presented an abnormal amount of white corpuscles. The splenic dulness was found to be continuous with that of the tumour; on these grounds splenic abscess or tumour was diagnosed. On the 17th the tumour, which was increasing in size, first manifested fluctuation. On the 24th, fluctuation being distinct, and there being much pain and tension, with a temperature of 102°, an aspirating needle was introduced two inches above the iliac crest, and nineteen ounces of dark chocolate coloured fluid were withdrawn. The microscope showed this fluid to contain multitudes of altered red corpuscles and leucocytes.

The patient was better on the whole for some days after the aspiration, but the tumour was not much diminished, and on January 3rd it was needful to repeat the operation. Thirteen ounces of fluid, similar in character to the first, were withdrawn; the fluid was quite sweet. On the 17th ten ounces more were withdrawn. On the 21st the patient was attacked with acute abdominal pain. He was becoming emaciated, and it became clear that the medical treatment pursued (the details of which are, for

the sake of brevity, omitted) needed to be supplemented by surgical interference.

On January 21st Mr. Reginald Harrison saw the case in consultation with Dr. Caton and Dr. Davidson, and advised that the tumour should be opened into freely from the lumbar region. An incision was made parallel with the last rib on the left side. On reaching the sub-peritoneal fat and connective tissue the finger was passed underneath the rib in an upward direction, when it entered a large collection of matter. About thirty ounces of pus, of a dirty yellow colour, escaped through an opening, which was freely enlarged with the finger. It was noticed that masses of broken down tissue, which were proved to be splenic on further examination by the microscope, were present in considerable quantities in the discharge. A large drainage-tube was introduced after the abscess cavity had been washed out with a weak solution of carbolic acid.

The patient rapidly improved after this operation. The discharge was very free for some days, and contained many pieces of broken down splenic tissue. In the course of time the discharge became entirely purulent. On March 4th another incision was made by Mr. Currey in the neighbourhood of the original wound to facilitate drainage; this was followed by an improvement in all the symptoms.

Steady progress continued until June, when there was some hardness and pain felt along the line of Poupart's ligament on the left side; this eventually proved to be a collection of matter. The patient being placed under ether, Mr. Harrison made an incision above the line of Poupart's ligament, and after making a deep dissection through the abdominal muscles, a collection of matter was discovered beneath them. This abscess appeared to be an independent one, as no connection between it and the lumbar collection could be made out.

After this the patient's recovery was uninterrupted, and he left the infirmary quite well on August 22nd, 1887. He has since reported himself, and was in good health.

Undoubted instances of acute inflammation of the spleen terminating in suppuration are, it is believed, exceedingly rare. As the whole process of this affection terminating in the recovery of the patient is illustrated in this instance, it has been thought worthy of record as bearing upon a subject about which there appears to be, in this country at least, but little clinical experience.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MARCH 13TH, 1888.

Sir E. H. SIEVEKING, M.D., President, in the Chair.

Case of Neglected Dislocation of the Humerus, followed by Paralysis of the Nerves of the Hand and Forearm, treated by Excision of the Head of the Humerus.—Mr. A. MARMADUKE SHEILD related the case of a man, aged 45, who was admitted into Charing Cross Hospital on September 2nd, 1887, suffering from a subcoracoid dislocation of the left humerus of twelve weeks' duration. There had been much swelling and severe pain after the accident. Signs of implication of the median and ulnar nerves were marked, the hand being almost useless; the radial pulse was also diminished in force. Moderate attempts at reduction under ether failed to move the head of the bone, which seemed fixed. Excision was therefore performed, and the head of the humerus removed at the level of the anatomical neck. Rapid recovery ensued, and twelve weeks after the operation the patient was able to follow his vocation as waiter at a London hotel. The hand was regaining strength gradually, but the muscles of the little finger were still weak. Movements of the shoulder were satisfactory. The method of performing the operation was briefly touched upon, and short accounts of similar operations were related. Reflecting upon the disastrous consequences that might follow the forcible manipulation of ancient dislocations of the shoulder, excision of the head of the humerus was brought forward as a preferable method of treatment for cases like the present, when pain was marked, the displaced bone fixed, and symptoms of nerve pressure evident.—Mr. J. W. HILKE congratulated Mr. Sheild on the success of his case by a method which he believed himself to give great relief in exceptional instances. The procedure, of course, was not in any way novel; it had been advocated long ago by Von Langenbeck in his *Archiv*, and was laid down as the standard practice by Hüter and others in

German textbooks.—Mr. W. ADAMS thought the operation had been well devised, and had given success as complete as could be in such conditions, where, indeed, no other operative course was open. Neglected dislocations of this kind were not very common. He had himself met with a similar case at the Queen Square Hospital in 1879, which had remained unpublished. The patient had had an accident as porter and lamplighter, but no dislocation had been suspected: his deltoid muscle wasted, and he lost power in the arm, and for that was sent to Queen Square Hospital about two years after the accident, when the head of the humerus was found to be lying on the dorsum of the scapula. The head of the bone was excised just below the surgical neck, and after about a year the patient became again fit for the lighter duties of a railway porter. Again, in 1885, he had met with an unsuspected dislocation of the femur in a child which he treated by excision of the head of the bone, with a satisfactory result. He expected that the operation would become more widely practised.

—Mr. HOWARD MARSH asked whether Mr. Sheild had made the division of the bone through the anatomical or surgical neck; some expressions in the paper seemed to leave the point doubtful. He could bear willing testimony to the complete success of the operation, for he had examined the patient when he had been present at a previous meeting. He told the story of a less fortunate case which had been in St. Bartholomew's Hospital, in which there was much wasting of the muscles and excruciating pain for a long time. There were very many close adhesions which Mr. Baker had in part broken down, without relief. Then the case came under his care, and he attempted to stretch the brachial plexus, an operation he had found very difficult, and which had made the man no better. After that Mr. Savory had excised the head of the bone, but the pain remained about as severe as ever.—Mr. HOLMES had listened with great interest to Mr. Sheild's paper because he had always maintained that in some cases of unreduced dislocation excision was the best method of treatment, but he had had no opportunity of performing the operation himself. It was usual for pain after unreduced dislocation of the shoulder gradually to subside, and to leave the patient with an arm that was of some use to him, and temporising measures of passive motion, etc., were often advised. He looked himself with great suspicion on subcutaneous section of the neck of the bone, or subcutaneous sections of the adhesions, and thought them more dangerous than open excision, considering the large number of important vessels and nerves close to the bone in the axilla. Dislocation might do much injury to vessels, as in a case he had brought before the Clinical Society in which the artery was bruised and leaked, and a very large blood swelling resulted. He had been unable to persuade the man to allow any excision of the head of the bone as he advised, and death had ultimately resulted. When excision was allowed in appropriate cases it furnished a better limb than ankylosis or any irregular attachment of the dislocated bone to the scapula. They owed many thanks to Mr. Sheild for showing them a good instance of this.—Mr. R. W. PARKER asked if Mr. Sheild attempted to reduce the bone after exposing it. He had been much interested by the case related that evening, and also by an essay by Paul Bruus, of Tübingen, advocating similar treatment.—Mr. H. W. PAGE thought it would be well to remember that the case in which Mr. Sheild had operated was one in which there was paralysis of the hand and forearm from pressure by the head of the bone on the nerves, and he imagined his primary object had been to relieve that pressure. He had found himself that a very small relief of pressure might produce considerable results; in two cases when he had seemed to do little more than free the musculo-spiral nerve from not very constrictive surroundings, it had led to great benefit.—Mr. SHEILD felt much obliged for the spirit of general approval with which his case had been received. Among previous cases he had heard of another from Sir W. MacCormac about eight years ago which was alluded to in the *St. Thomas's Hospital Reports*, in which the surgical neck of the humerus had been divided and the head excised, but the result of the operation was not stated. In his own case he had divided the anatomical and not the surgical neck of the bone, from a wish to relieve pressure as much as possible, and also to avoid disturbance of the parts. He had rounded very carefully the end of the bone which was left in the wound, so as to make it as like the real head of the bone as possible. He had made no attempt to reduce the head of the bone when it was exposed, and indeed he doubted if it would have been possible, so tightly was the bone held by adhesions, and also he expected that if the bone had been reduced the dislocation would

have recurred. To relieve the pressure on the nerves and vessels was, as Mr. Page had said; his main object; it was soon obtained, and the patient, as soon as he felt himself getting much better, paid little attention to the passive exercise and use of galvanism, which would probably have produced a still more complete recovery than had been actually effected.

On the Naked Eye and Microscopical Variations of the Human Thyroid Body. By W. HALE WHITE, M.D.—The author said the thyroid body was not sufficiently examined for it to be known how variable it might be in patients dying of diseases which, as far as we knew, were unconnected with the gland. This paper was based on the examination of forty thyroids taken at random from patients dying in Guy's Hospital. The size of the organ was very variable. It was as a rule smaller in adults over 50 than in those under 50. Its shape was very inconstant. Save in myxœdema the size and shape were unconnected with the fatal disease. The same was true of the size of the vesicles, the average of which was one twenty-fifth of an inch in diameter. The more distended the vesicle the flatter the epithelium, and the less the connective tissue between the vesicles. Parenchymatous cells, leucocytes, and red blood-corpuscles, could all immigrate into the vesicles, and there, together with possibly the help of the epithelial cells, form the granular *débris* so frequently seen. Often all the vesicles in the whole of one section might be thus transformed. The indentation on the edge of the colloid matter and holes in its substance were due certainly to its invasion by parenchymatous cells, and perhaps other cells had a share in its production. Sometimes the colloid matter had a double contour, and sometimes it contained oxalate of lime and cholesterine crystals. None of these changes could be associated with any particular disease. The amount of connective tissue was variable. One case of myxœdema in which the organ was completely atrophied, being nothing more than a little fibrous tissue, was described, as was another case presenting the same degree of atrophy in a patient dying of aortic aneurysm. It thus appeared that atrophy of the thyroid did not invariably produce myxœdema. The origin of vesicles from parenchymatous cells was considered. Lastly, the lymphatics were described.—Dr. CHEADLE thought it certainly worth note that there was no myxœdema in the case in which Dr. Hale White had shown such complete atrophy of the thyroid. He considered the myxœdema to depend partly on the early age at which the atrophy occurred, and to be of very slow onset. In two cases Dr. White had mentioned pressure on the recurrent laryngeal nerve, which perhaps had a trophic function, along with atrophy of the thyroid. He should be interested to know if the vessels also were in these cases pressed upon.—Mr. J. BERRY had, during the last two years, examined eighty-three specimens of the thyroid gland, but considered the numbers too small to warrant any general conclusions, but sufficient to suggest some points of interest. He had found very great variations in shape and size; some were large and of a yellow tint, and full of secretion, and these were more common in cases of emaciation. Others were small and red, and with little secretion, and one nearly constant accompaniment of this condition was a good deal of fat on the body. It had been very marked in a case of great obesity, weighing 22 stone. In old age the thyroids were somewhat atrophied, but of the structure remaining a fair amount was normal tissue, and in that respect very unlike the fibrous glands of myxœdema. He had seen a case at Geneva, in which the thyroid had been completely extirpated for five years, but which showed no sign whatever of myxœdema beyond anæmia. The myxœdema which was produced artificially was a much less marked state than the condition that bore that name in England, which perhaps might be better distinguished as cachexia strumipriva.—Dr. W. HALE WHITE said that in the cases of atrophy with pressure on the recurrent laryngeal nerve there had been no pressure on the vessels; and that in the case where he had found complete atrophy after death, Dr. Wilks had noticed no signs of myxœdema during life.

CLINICAL SOCIETY OF LONDON.

FRIDAY, MARCH 9TH, 1888.

HOWARD MARSH, F.R.C.S., Vice-President, in the Chair.

On the Operative Treatment of Dislocated Semilunar Cartilage of Knee-Joint.—Mr. CROFT described the case of a labouring man, aged 39, who was admitted into St. Thomas's Hospital in April, 1887, for well-marked symptoms of dislocation of the internal semilunar cartilage of the right knee-joint. The joint had been attacked by rheumatic inflammation eight years previously,

but had not been permanently lamed by it. The accident which had caused the injury to the cartilage, and consequent lameness, had occurred three weeks before the patient's admission to the hospital. As the man was quite incapacitated from following his employment, and suffered frequently from the displacements of the cartilage, Mr. Croft advised him to submit to a radical operation. In the belief that the anterior extremity of the cartilage had become detached, Mr. Annandale's operation was decided on. The joint was opened on March 5th, 1887. The cartilage was found to have preserved its anterior and posterior attachments, but to have been torn loose from its intermediate connections. It was lying in the intercondyloid space. A tongue-shaped piece, about $\frac{3}{8}$ ths of an inch in length, projected from its upper surface. This had been partly torn up from the upper surface of the cartilage. This was a worse condition than had been expected. The anterior and posterior insertions were cut through, and the cartilage drawn out of the joint. The joint was carefully closed. Drainage was provided for. The operation was done antiseptically. On the fortieth day after the operation the man was discharged cured. He was seen four months later, and then had been in full work for some time. He attended for inspection by the members of the Society. Mr. Croft referred to the few positive data in English works concerning the subject, and drew the following deductions: (a) That the cartilages may be dislocated from their anterior attachments only, from their circumferential attachments only, and from both these insertions. That rupture of the posterior insertion must be very rare, if it ever occurs. (b) That when the circumferential relations are ruptured the cartilage tends to be displaced into the intercondyloid notch. (c) That in such cases as Mr. Annandale's a good result may be obtained by refastening the loosened anterior portion of the cartilage to the tibia, and that in such cases as Mr. Brodhurst's and his own (that above described) the whole cartilage may be safely excised. (d) A working man may preserve a strong, useful, movable knee-joint, though the whole internal cartilage has been excised. (e) Obstinate cases of this dislocation, attended by numerous attacks of pain and disability, may be safely subjected to "inspection," and, if need be, to operative treatment for radical cure.—Mr. ANNANDALE (Edinburgh) said he would confine his remarks to the displacements of the semilunar cartilages and the operation which he had suggested for the relief thereof. He had operated in five cases, the result in all of them being perfect. In four of the cases the internal cartilage was the one displaced, and this was usually the case. He had found it displaced in three different manners; in two of his cases the cartilage was separated at its inner attachment, and was displaced backwards and outwards; in one case the cartilage was separated and folded upon itself; in another case the internal edge was folded over, and the joint had thereby become sometimes locked; this locking occurred also at the operation, when, the joint being opened, it was found that the cartilage was partly in the intercondyloid notch, which was the cause of the locking. In his fifth case, the external cartilage was separated and displaced backwards. As to the operation, he made an incision around but a little below the upper articular surface of the tibia, a little lower than would appear to be necessary for the opening of the joint. The articulation being exposed, and bleeding all stopped, the capsular ligament was opened, and with a blunt hook the cartilage was drawn forwards, and then fixed in position by two or three stitches to the capsular ligament and head of the tibia. In his last two cases he had fixed it with a catgut ligature. He used no drainage-tube, finding it unnecessary. He did not venture to move the joint earlier than six weeks after the operation. At first he used passive movement only, and no active movement until quite a fortnight later.—Mr. DAVIES COLLEY mentioned a case on which he had operated five months previously. The patient was a gentleman, aged 21, who was riding, when his horse reared and fell on his knee, which soon became much swollen. All did well, however, until some six months afterwards, when, as he was playing lawn-tennis, his knee-joint became dislocated outwards, abducted, semiflexed, and fixed. The dislocation was reduced, but synovitis followed, and the dislocation thenceforward recurred frequently, causing severe pain. Often when on horseback he had to roll off his horse in order to rectify the dislocation, which was not prevented by knee-caps, etc. Mr. Davies-Colley then proceeded to operate in the manner which Mr. Annandale had described. He found that the internal cartilage had two rents in it, running parallel, and thus dividing the cartilage into three ribbons. It had doubtless been split at the time of the original accident, im-

proved by the two months' rest which followed it, and then again separated by the sudden strain during tennis. He had stitched the strips together so as to fix them to the internal tuberosity of the tibia. The case did fairly well. There was at first a discharge of gelatinous material from the joint; but after a fortnight this ceased, and the catgut sutures were discharged at intervals. After two months the patient could bend the knee through an angle of about 60°, and he could now walk about four or five miles, wearing a support which kept the knee fixed. Mr. Davies-Colley did not think it would be right to allow the patient to use his joint without support until six or eight months after the operation. He would ask what was the best treatment to adopt in such a case.—Mr. H. ALLINGHAM remarked that he had shown at a former meeting a porter who had dislocated his internal cartilage. In October last, the speaker had cut down upon the cartilage, found it movable, and had fixed it to the bone. The patient was now well, and could walk well.—The CHAIRMAN said that the semilunar cartilage was evidently not necessary to the functional use of the knee-joint. He alluded to a paper published by Professor Kocher, which also supported that conclusion. The cartilage in Kocher's three cases being affected with a fungous disease, he removed it entirely, and the joint was just as good after as it had been before the operation. He exhibited an apparatus recommended for many years past by Sir James Paget, which was very beneficial in many minor conditions of displacement, and which, if worn for twelve or eighteen months, often produced complete cure.—Mr. H. MORRIS thought that one form of dislocation had not been noticed by previous speakers, that which he designated "marginal." It might be produced in two ways: (a) where a sharp instrument ran into the cartilage, and then upon being pulled out dislocated the cartilage outwards; (b) where the knee was dislocated outwards and the semilunar cartilage was forced outwards from the head of the tibia.—Mr. CROFT said his case was verified by inspection of the interior of the joint, in this was its great value; it was not a mere surmise, as were so many other cases in which the joint was not inspected. He thought that possibly in Mr. Davies-Colley's case convalescence would have been quicker and more absolute if the strips of cartilage had all been removed at the time of the operation.

Notes of two cases of Dislocation of the Index Finger, reduced by opening the Joint and dividing retaining Band, after Failure of the usual Methods.—Mr. SYMONDS read notes of these cases. Both were boys, aged 9. In one the accident was caused by a blow from a cricket ball, in the other by a fall on to the finger. The first phalanx was displaced backwards, its base projecting above the level of the metacarpal bone, to a slight extent. The finger could be brought straight, so that the displacement of the phalanx was not severe. The most noticeable feature was a prominence in the palm caused by the head of the metacarpal bone. The skin was tightly stretched over it, and almost perforated. There was also a deep sulcus running round one side of this prominence. Every method was used to effect reduction, including division of the fibrous structures in front and round the back of the metacarpal bone. Finally, by a vertical incision, the joint was opened on its outer side, and while the base of the phalanx was fully exposed, the head of the metacarpal bone was concealed by a fibrous structure, through which it had passed button-hole like. The moment this was divided the head was released, and the dislocation reduced. A small fissure was then observed in each case in the cartilage. This extended into the bone, was evidently the result of injury, but did not contribute to the difficulty of reduction. Primary union with useful joints occurred in both cases. In the second case an attempt was made to divide the retaining structures subcutaneously by the light of the first case. That this failed Mr. Symonds thought was due to the fact that the incision was badly planned. He suggested that in future cases a tenotomy knife should be passed into the joint, and an incision made on the head of the metacarpal bone from before backwards. This, if carried well forward, would have divided the fibrous ring that retained the head of the bone. The fibrous band was considered to represent the anterior ligament.

Dislocation of the Metacarpo-phalangeal Joint of the Thumb Backwards, in which Excision of the Head of the Metacarpal Bone was practised.—Mr. G. R. TURNER read particulars of this case. The injury was eleven days old when first seen, and all attempts at reduction by manipulation and extension having proved unavailing, an incision was made, and the lateral aponeuroses of the flexor brevis divided. The main obstacle to reduction, however, was found to be the tendon of the long flexor, which had slipped

inwards. After forcible traction had been made, this reduction was effected, but the dislocation was so easily reproduced, and the parts were so tense and swollen, that it was thought best to remove the head of the metacarpal bone. The wound healed kindly, and the man recovered with a perfectly movable joint. He was shown to the Society some weeks ago, and, except for a very little shortening, the injured was as good as the sound thumb. The point of interest in the case was the obstacle to reduction offered by the long flexor tendon. Excision of the head of the metacarpal bone in irreducible cases of this dislocation was advocated.—Mr. CROFT had had a case similar to the one mentioned by Mr. Symonds. The index finger was dislocated on to the palmar aspect of the head of its metacarpal bone. Attempts at reduction under chloroform having been made and failed, Mr. Croft made such an incision as Mr. Symonds had advocated on the outer side of the joint, and then, finding the capsular ligament stretched and the bone escaped from it through a button-hole opening, this was enlarged and the lateral ligament nicked. The bone then slipped back directly, and the child did well. He thought the case showed the wisdom in the present day of not leaving such a dislocation unreduced.—Mr. DAVIES-COLLEY asked what was the particular anatomical structure which prevented the reduction in Mr. Symonds's case? In a case of his own, that of a child with dislocation of the first phalanx from the metacarpal bone, the glenoid ligament formed a band or apron which was pushed back before the bone every time an attempt was made at its reduction. This band, when the force was removed, again pushed the bone out of position, and it was found impossible to reduce the bone until the band was divided. The case did well, and after three months only some stiffness remained, but there was a capability of passive movement.—Mr. SYMONDS said that he considered the structure cut by him was the anterior ligament of the joint.

Adenoma of the Pinna.—Mr. BLAND SUTTON described this case. W. S., aged 64, detected three years ago a small tumour behind the left pinna. This tumour was situated over the mastoid process, and was about the size of a nut. It slowly increased in size. He was advised at this time by an eminent London surgeon never to allow anyone to interfere with it. The tumour continuing to increase in size, involved the pinna, extended down the auditory meatus, made its way into the cavity of the tympanum, produced deafness, and incapacitated the patient from playing upon the violin. He was a skilful violinist, and in his leisure hours taught this accomplishment. In December, 1886, the patient presented the following condition when Mr. Sutton saw him in consultation with Dr. Hollings. A tumour of the size of a big orange was found wedged in between the mastoid process and the lower jaw; the pinna projected from the midst of this mass. The auditory meatus was quite blocked by the tumour, and its surface had ulcerated in two or three spots. Mr. Sutton took counsel with his friend Mr. Henry Morris. After due consideration, a full explanation of the risks was submitted to the patient, and he was allowed to decide for himself. The patient was most anxious for the operation, and in January, 1887, the tumour was removed. It occupied the tympanum, and by its pressure had opened up the mastoid cells; indeed, the anatomy of the middle ear was clearly visible. The patient recovered rapidly, and in five weeks was again occupied in his office. Three days after the operation he could again distinguish musical notes, and in a few days more the hearing rapidly returned. In a month from the day of the operation he commenced anew his studies on the violin, and for the next twelve months enjoyed his favourite instrument. Things went on well until February of the present year, when he again felt unwell, and on examining the scar it was clear that there was some return of the tumour. At this time he showed signs of aphasia, which gradually increased until he could not remember any noun, common or proper, not even his own name. As the loss of the memory of words was the only prominent symptom, it was decided to trephine the skull in the situation of the pterion and ascertain the limits of the intra-cranial growth, and if possible again remove the tumour. This was done February 26th. The tumour was far too large and infiltrating to allow of its removal. Three days later the patient died. At the *post-mortem* examination a tumour of the size of a small orange was found in the left middle fossa of the skull; a portion of it had burrowed backwards and projected into the lateral sinus. The tumour had extensively invaded the temporo-sphenoidal lobe, but Broca's convolution had remained unaffected. The primary tumour was found to be an adenoma, but the nature of the intra-cranial portion could not be determined in time for the meeting.

Dry Mouth or Suppression of the Salivary and Buccal Secretions.—Dr. HADDEN read this paper. The patient was a woman, aged 65, who had suffered from no affection which could throw light on her present condition. There was no history of family-paralysis, or of the prolonged use of belladonna. Her month began to become dry some months previous to observation. The tongue was red, devoid of epithelium, cracked in all directions like crocodile skin, and absolutely dry. The mouth generally was dry, and the mucous membrane smooth, shiny, and pale, with a few patches of injection. There was also deficiency of moisture at the back of the pharynx. The tonsils were natural. The salivary glands, as far as could be made out, were natural in size. Common sensation of the inside of the mouth was unimpaired, but the sense of taste was retarded in consequence of the deficiency of moisture. When the mouth became moister later on, the saliva was found to be slightly acid, and to exert no action on a solution of starch. During the time the mouth had been dry, perspiration had notably diminished, and the lachrymal secretion was arrested. The patient received much benefit from the use of jaborandi. A case of similar nature under the care of Mr. Hutchinson was alluded to, and one under Dr. Rowlands, of Liverpool, was communicated by the author of the paper. In conclusion, it was suggested that this condition of dry mouth was due to some disorder of the nervous apparatus.—A MEMBER asked if the patient had any difficulty in digesting food.—Mr. GOLDING-BIRD asked whether, as the reaction of the saliva when it reappeared was acid, Dr. Hadden had first boiled the starch, and added an alkali, before testing the action of the buccal secretion on the starch.—Dr. HADDEN said that his patient's digestion was perfect. The starch was boiled, but no addition of an alkali was made to it, as it was only discovered, after the testing had been completed, that the saliva had an acid reaction.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, MARCH 7TH, 1888.

JOHN WILLIAMS, M.D., President, in the Chair.

Specimens.—Dr. AUST LAWRENCE showed a specimen of Extra-uterine Foetation, with the Primary Gestation Sac.—Dr. HERMAN exhibited a Foetus and Placenta from a successful case of operation at the fourth month, two and a half hours after Rupture of a Tubal Sac.—Dr. PENROSE brought forward a specimen of Left Tubo-abdominal Pregnancy, in which the Corpus Luteum Verum was in the right Ovary.

Scarlatina during Pregnancy and in the Puerperal State.—The two remaining sections of Dr. BOXALL's paper, partly read at the January meeting, were now brought forward. VI. With regard to the clinical relation of scarlatina to puerperal septicæmia, a brief summary of the sixteen cases of undoubted scarlatina was given, and it was pointed out that in one case only were the scarlatinal manifestations associated with signs of septic poisoning. Forty lying-in patients were known to have been exposed to one or more of the above cases of scarlatina. This series was presented in a tabular form, giving the time and duration of exposure and the course of the puerperium. On this evidence it was apparent that such exposure resulted in no detriment to the puerperium. As it might be urged that the 300 patients or more admitted during the prevalence of scarlatina were to a greater or less extent exposed, a chart (together with the percentage tables from which it was constructed) was also appended. This indicated the morbidity (as judged by the temperature) prevailing not only during the whole scarlatinal period, but included, in addition, the three months which preceded the outbreak. From this it was evident that the prevalence of scarlatina in the hospital exerted no appreciable effect on other cases lying-in during the same period. The special value of local antiseptic measures in scarlatina during the lying-in period was discussed. The following conclusions were offered: 1. That infection by the poison of scarlatina generally produced in the puerpera a disease which presents for the most part the usual symptoms of scarlatina, and runs the ordinary course of the disease without the appearance of septic manifestations. 2. That the disease, in addition to the usual symptoms of scarlatina (to a certain extent modified), may occasionally present signs of septic poisoning; that, when present at the outset of the disease, pelvic inflammation and septicæmia may usually be regarded as accidental complications, but, at a later stage, such signs may be the expression of a septic process, analogous to the secondary throat of ordinary scarlatina. 3. That in rare instances the disease may assume a masked

form, in which the ordinary signs of scarlatina are absent, or so slight, and evanescent as to escape observation; and that, in some such cases, the only manifestation of the illness may be found in signs usually referred to septic poisoning.

VII. With regard to the treatment of scarlatina during pregnancy and in the puerperal state, Dr. Boxall, after referring briefly to remedial measures, discussed the means which should be adopted to prevent the spread of scarlatina to pregnant and parturient women. He pointed out the advisability on the one hand of isolating all scarlatinal cases and disinfecting all contaminated articles, and on the other of shielding pregnant and parturient women from the many risks of scarlatinal infection which surrounded them, and, when possible, of removing such patients from any district in which the disease was prevalent. The influence of a third person as a vehicle of infection was discussed with special reference to the conditions under which it was likely to be exercised, and, finally, the measures which might be adopted to counteract that influence were pointed out. It was concluded, finally, that, as the poison might be carried not only directly by the hands, but also indirectly by the clothes and general surface of the body, and possibly also by the breath, and subsequently given off into the atmosphere (from which it was inhaled by the patient), thorough washing and disinfection of the hands was not sufficient to insure protection, but that a disinfectant bath, a complete change of clothing, and active outdoor exercise should be also included in the necessary precautions, and that these measures should be adopted not only by the doctor, but also by all other persons who have been brought into contact with scarlatinal poison, and especially by the nurse, prior to attending on a lying-in woman, or even visiting a patient advanced in pregnancy.

—Dr. DOLAN (Halifax) said that in private practice it would be impossible to carry out all the precautions laid down in Dr. Boxall's valuable paper. From personal experience he found that, contrary to the generally received opinion, the puerperal woman did not appear to contract scarlatina, even though exposed to the danger. The puerperal death-rate did not rise in Halifax during scarlatinal epidemics. Two separate classes of practitioners, the first to attend labours only, and the second to attend cases of scarlatina, could not possibly be established, nor would such a system be necessary.—Dr. PLAYFAIR reviewed some older opinions on Dr. Boxall's subject. Scarlatina had been held peculiarly dangerous, under certain circumstances, to lying-in women. On the other hand, it might run a perfectly normal course. Lastly, the fever was supposed to run a very untypical course in some puerperal cases, appearing practically identical with puerperal fever or septicaemia. Dr. Boxall's valuable observations did not disprove these opinions. His patients, it should first be remembered, were placed in the most favourable conditions, where the graver effects of scarlatina could hardly be looked for. Nevertheless, he admitted that he had observed a very mild form of scarlatina, and also a masked form, resembling cases of septic poisoning. Dr. Boxall had noted the increased susceptibility of puerperal women to scarlatinal infection, the modification of certain symptoms, and the existence of some unknown modifying influence under the circumstances. If so, this influence would be yet more powerful and less impeded in cases unprotected by the precautions enforced at the General Lying-in Hospital. Dr. Playfair suggested a theory which would explain the significance of mild typical scarlatina occurring in some puerperal cases, and of a masked and septic form in other cases. In the one case the disease was contracted through the ordinary chances of infection; in the other it was conveyed directly to the genital tract by the hands of the obstetrician or midwife, or by infected sponges, etc. Twenty-five years ago a lying-in ward was established in King's College Hospital. The arrangement was disastrous, and was at length abandoned. During the existence of the ward there were outbreaks of erysipelas in the surgical quarter of the hospital, and coincident epidemics of puerperal fever in that ward, but the lying-in patients had no symptoms of erysipelas which, on the other hand, were seen in some of their infants. Here was an analogy with the conduct of the scarlatinal poison.—Dr. AUST LAWRENCE (Clifton) believed that some of these cases did not die of the fever itself, but from decomposition of the lochia induced by the poison. In one case the patient was saved by timely washing-out of the uterus.—Dr. HERMAN criticised paragraphs 2 and 3 in the sixth section of Dr. Boxall's paper, which included theories already accepted by others, but though still based more or less on conjectures, Dr. Boxall's conclusions were the result of a sound method of investigation,

for he began with the parent factors, the scarlet fever and the puerperal woman. He had not, like others, started with the case, hunting back for the cause. Still, Dr. Herman was of opinion, comparing the above conclusions with the valuable morbidity tables before, during, and after the prevalence of scarlatina in Dr. Boxall's hospital, that the poison of scarlatina, when communicated to the lying-in woman, produced that disease and nothing else.—Dr. LEITH NAPIER dwelt at length on recent observations with regard to rashes which were not really scarlatinal, and gave his own experience on rubola in the puerperium. These rashes must be remembered in relation to any case or series of cases of alleged mild and not fatal scarlatina in the puerperium.—Dr. BRAXTON HICKS believed that scarlatinal poisoning was frequently mixed with puerperal fever or septicaemia, the scarlatinal element being latent or occult.—Dr. MATTHEWS DUNCAN noted how anti-septic treatment kept away the microbes of suppuration and septicaemia, but did not ward off scarlatina. He believed in the theory that the so-called scarlatina of midwifery and surgery included more than one disease, but he regarded true scarlatina occurring within a few days of lying-in as a disease of enormous mortality. He had observed a red rash, with fever, which began around the wound made in opening a chronic inguinal parametric sinus. The rash spread, but there was no certainty that it represented scarlatina. Dr. Duncan did not believe in the commingling of scarlatina and puerperal fever. When the former disease raged in London, killing 250 a week, there was no increase of puerperal fever. This fact agreed with Dr. Dolan's practical conclusions.

Adjournment of Discussion.—It was resolved by Dr. GALABIN, seconded by Dr. HOBROCKS, that the debate on Dr. Boxall's paper be adjourned. The resolution was carried unanimously.

HARVEIAN SOCIETY OF LONDON.

THURSDAY, MARCH 1st, 1888.

WILLIAM SEDGWICK, M.R.C.S., President, in the Chair.

Treatment of Empyema.—Mr. MANSELL MOULLIN read a paper on the surgical treatment of empyema, based on an analysis of thirty four cases. In sixteen of these a discharging thoracic sinus was already present. He pointed out, that the primary cause of the collapse of the lung was the accumulation of fluid; but that the permanent cause of its non-expansion when the pressure was relieved was the alteration in the structure of the pleura and the lung itself, and that this alteration was the effect of the absorption from the irritating fluid in the cavity. When air had already gained admission without drainage being perfect, so that the pus had decomposed, the thickening of the pleura was much greater and more obstinate than when the empyema had never been operated on at all. Everything pointed, except in children and tubercular cases, which were expressly excluded, to operation as early as possible. Primary resection of a rib was hardly ever required, unless the empyema was loculated; india-rubber tubes very soon wore the ribs away, so that there was little chance of their being nipped as the thorax collapsed. Two tubes must always be inserted, even if they were only a few inches apart; they might be in the same intercostal space, but there must be two for effective drainage. The most convenient situation was the one usually adopted, in the fifth or seventh interspace in the mid-axillary line. Washing out the cavity was quite unnecessary; if air was allowed to pass freely in and out there was no decomposition; the amount of pus discharged diminished almost to nothing, and the cavity rapidly closed in. In old cases the first thing was to establish free drainage by making a second opening; on five occasions it was necessary to trephine the ribs, as the wall of the chest had practically become a solid bony cuirass. In two cases some of the ribs had been resected; in one, two inches of four had been removed, in order to allow the thorax to collapse, but the patient, who was already suffering from amyloid disease, sank from exhaustion ten days after. In the other, portions of only two ribs were excised, as the sinus ran rather round the thorax, following the direction of those ribs, than upwards as in the former case. This was attended with considerable benefit. No trouble was experienced from the intercostal arteries on any occasion. The direction in which the sinuses run must in each case determine where the ribs should be cut, how many should be removed, and how much of each.—Dr. PHILLIPS criticised the view that an operation should be performed early. He had seen good results follow from aspiration. He also thought that two openings were not essential, and was prepared to show cases which had made a steady recovery after one. A hard-and-fast

rule could not be laid down as to the best place for the opening.—Mr. LOCKWOOD said cases often fell into the hands of surgeons after a preliminary aspiration had been tried and failed. He had been accustomed to make two openings and drain from each; washing out was in many cases essential.—Mr. MANSELL MULLIN said, in reply, that though he would not deny for a moment that cases of empyema could get well with only a single drainage-tube, he was sure they stood a better chance with two, as it was impossible that a cavity like the thorax could drain satisfactorily from one; there must be an in-draught and an out-draught. He preferred an opening in the axillary line to one by the angle of the scapula, because there was less tissue to divide and less risk of displacement from movement of the arm, and especially when patients were lying in bed the pleural cavity could empty itself quite as thoroughly through one as through the other.

On the Functions of the Uvula and Epiglottis.—Dr. SCANES SPICER read a paper on the functions of the uvula and epiglottis. The various functions of the uvula in deglutition, phonation, articulation, respiration, and secretion, as set forth by different authorities, were first discussed, and then the author described an important function which had hitherto escaped detection, namely, that the uvula served during normal (nasal) breathing as a conductor, guide, or dripping stone to convey the nasal and lachrymal secretions out of the breath-way on to the lingual tonsil, there to undergo reabsorption into the circulation. These fluids were delivered on to the base of the tongue in a plane anterior to the epiglottis. From the lingual tonsil the unabsorbed portions trickled into the glosso-epiglottic fossae, and thence into the pyriform sinuses or hyoid fossae, along the lateral grooves of the epiglottis. It was mentioned that two previous authors had considered the uvula as a conductor or dripping stone to convey mucus, etc., into the larynx for lubricating purposes, or to the base of the glottis, where it accumulated until swallowed or hawked up. Common experience taught us that such intrusion of fluids into the larynx, as was assumed, caused cough and spasm; these views were hence, in part, the antithesis of the one expounded. The functions of the epiglottis were next considered, and it was pointed out that the balance of evidence was against any deglutition function of the epiglottis, but in favour of its movements and position having an important connection with the pitch, intensity, and the quality of the voice. The author described the epiglottis as a permanent vaulted dam, which kept the salivary fluids, etc., as well as those conducted by the uvula from the nose, out of the larynx, and which shot them off laterally (if not absorbed by tonsillar tissue) into the pyriform sinuses along the grooved spouts of the epiglottis, which projected over these sinuses normally. Clinical observations and experiments bearing on these views, and tending to show their correctness, were given in detail.

MEDICAL SOCIETY OF LONDON.

MONDAY, MARCH 12TH, 1883.

Sir WILLIAM MAC CORMAC, F.R.C.S., President, in the Chair.

Vote of Thanks.—On the motion of Dr. ALTHAUS and Mr. WALSHAM, a vote of thanks was passed to Dr. J. Hughlings Jackson, the retiring President, and the secretary and officers of the Society.

On the Causes of Failure to find the Colon in Lumbar Colotomy.

—Mr. HERBERT ALLINGHAM read a paper on the causes of the difficulty which was sometimes experienced in finding the colon in lumbar colotomy, and the best method of obviating them, which it is proposed to publish in full. Mr. LOCKWOOD said the points alluded to by Mr. Allingham had excited his own interest. He pointed out that Mr. Allingham's figures bearing on the average presence of the mesentery differed from those put forward some time since by Mr. Treves—a difference which, he thought, might be attributable to a difference in the methods of investigation.—Mr. TREVES expressed his surprise that surgeons should pay so much attention at the present time to the bands of longitudinal fibres. He had done a great many colotomies, and had never troubled to look out for the bands. There were ample means of distinguishing between the large and the small gut. He had examined 100 dead bodies, and found that in 52 of them the mesocolon was absent on both sides, in 14 it was present on both sides, in 12 it was present only on the right side, and in 12 only on the left side. He thought the practice of searching for these bands would be a waste of time, and would involve the risk of rupturing the gut.—Mr. HARRISON CRIPPS pointed out

that the operation depended greatly on whether it was undertaken on the distended or on the empty gut. When distended there was seldom any difficulty in finding the colon, but when empty the difficulty might sometimes be almost insurmountable. He advised inflating the colon in such cases. As to the bands, he certainly looked for them, though he did not attach the same importance to finding them as Mr. Allingham did.—Mr. ALLINGHAM, in reply, said that in stripping off the peritoneum the longitudinal fibres were often stripped off as well. He failed to see what objection there would be to opening the peritoneum when this, for any reason, appeared desirable.

Is Common Psoriasis a Constitutional or Local Disease?—Mr. MALCOLM MORRIS first criticised the name "psoriasis," which, he said, ought to be restricted to a particular disease, a typical example of which he showed in a boy. After discussing the manifestations of the disease, he declared its etiology to be "shrouded in obscurity." He asked whether any relation could be shown between psoriasis and any recognised constitutional disease such as the eruptive fevers or syphilis. He pointed out that psoriasis only occurred in healthy subjects, and only involved the skin, not even the mucous membranes. He claimed that the alleged connection of psoriasis with gout was not founded on fact—that gout was comparatively rare in hospital practice, while psoriasis was as common as in private practice. He scouted the idea that struma and gout—two altogether different affections—could give rise to similar cutaneous manifestations. Out of 100 cases in private practice, only 3 had a gouty history, and he quoted Garrod as to the lack of foundation for the belief that gout could give rise to psoriasis. He claimed that psoriasis was, so to speak, a disease of health, and if the standard of health was lowered, whether by disease or drugs, then the eruption faded away to recur on the return of normal health. He quoted several cases in support of this view. He attributed the influence of arsenic in this disease to its action on the cells of the rete Malpighii, whereby the seat of disease was starved. In conclusion, he maintained that drugs only acted beneficially by influencing health unfavourably, and that sooner or later, on their cessation, the disease was sure to recur.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

THURSDAY, MARCH 8TH, 1883.

J. W. HULKE, F.R.S., President, in the Chair.

On Retinal Haemorrhage in the Yellow Spot Region.—Mr. LANG read the notes of a case of a large macular haemorrhage which was absorbed, leaving perfect vision. He remarked that in these cases where the vision was restored it was most probable that the haemorrhage took place between the hyaloid membrane of the vitreous and the retina, and not as hitherto believed between the layers of the retina or in the choroid. In support of this contention he drew attention to the red colour that the light presented to the damaged eye, and also to a folded appearance of a membrane seen in front of the extravasation, and which could only be the displaced hyaloid raised by the haemorrhage. He also explained the circular appearance of these haemorrhages by an anatomical condition noticed by Mr. Marcus Gunn—namely, that at the macula the hyaloid was probably not attached to the retina at all, or at any rate not so firmly as it was around the yellow spot region, therefore a haemorrhage would be likely to be limited in the circular manner so frequently seen.—The PRESIDENT observed that probably the haemorrhage did not own the same source in all the cases.—Mr. SILCOCK believed that De Wecker gave a drawing showing that the haemorrhage was in the choroid. In a case of his own the patient did not find objects red; there was a very small central, absolute scotoma. He inferred that the haemorrhages were choroidal because they were large, and at a point where there was no large retinal vessel, and, moreover, they generally cleared up entirely.—Mr. NETTLESHIP showed diagrams of two cases of large semicircular haemorrhage at the yellow spot; the inferior macular artery, which traversed the blood patch, was found to be obliterated in one case, and greatly altered in the other. These cases showed that the vessel which supplied the blood-effusion was a retinal one. In some of these cases the blood in the early stage was found extending on to the surface of the optic disc; in some the blood burst forwards into the vitreous some days after the extravasation at the fundus. These facts could be readily explained on Mr. Gunn's and Mr. Lang's hypothesis, but could hardly be explained if the blood came from

the choroidal vessels.—Dr. ANDERSON mentioned a case of retinal hæmorrhage where *post mortem* it appeared that the bleeding must have taken place between the retina and vitreous.—Mr. LANG explained that it was only in the cases where complete recovery took place that the hæmorrhage was in front of the retina.

Ciliary Tumours.—Dr. MILES read this paper. He drew a line at primary ciliary origin, traversing Knapp's view of their frequency. Detailing the varieties of these growths, after their division into the two great classes of benign and malignant, he referred to their diagnosis as between ciliary tumours and those confined to the iris, and laid stress on an early and accurate diagnosis, to be followed in the case of iritic tumours by the immediate removal of the affected portion of tissue. He pointed to the value of a beam of light in cases where the diagnosis was doubtful between early ciliary staphyloma and ciliary tumour, and deprecated the differential diagnosis between intra-ocular tumours and harmless retinal separation by acupuncture, adducing examples of its danger. He further referred to the locality of these growths, and corrected his previous statement that they always arose at the inner quadrant. The mode of development was touched on. The "iridodialysis" was explained as taking place in three different ways, each interesting, and suggestive of general infection. By the kindness of members, drawings and sections were shown illustrating the paper.—Professor HIRSCHBERG contributed some fine slides of ciliary and other ocular tumours, the author from his own collection bringing forward specimens and drawings of those rare affections.—In reply to the PRESIDENT, Mr. LAWFORD mentioned that he had lately examined a tumour of the ciliary body, which proved to be a mixed round and spindle-celled sarcoma. The tumour grew from the nasal side.—Mr. SIMEON SNELL had operated on two cases of sarcoma of the ciliary body in persons advanced in years.—Mr. McILHARDY mentioned a point of diagnostic value. He had found that where there was detachment of the retina, with intra-ocular tumour and diminished tension, the tumour had its origin in the ciliary body.—Dr. MILES announced his intention of presenting the series of drawings used in illustration of his paper to the library of the Society.

Sarcoma after Sclerotomy for Glaucoma.—Mr. SIMEON SNELL (Sheffield) related this case. The patient was a man, aged 42, and sclerotomy was performed on March 27th, 1884, for subacute glaucoma; great pain + T2, media turbid, cornea steamy looking, but vision was $\frac{3}{3}$; relief to pain was immediate, vision improved to $\frac{3}{3}$, and tension became normal. He remained well up to the latter end of 1885. The media were clear, and a good view of the interior was obtainable; beyond excurvation of the optic disc there was nothing to note. In January, 1886, he came with two small "lumps," one on the site of the puncture, and the other at counter-puncture for sclerotomy. The sclerotomy had been performed with DeWecker's knife, and thus the wound was limited to the puncture and counter-puncture, and to the width of the instrument. The pain was relieved and the staphylomas subsided with eserine. He returned to work, but he said that during the whole of this year pain was never really absent. In September, 1886, he came with severe pain, and again eserine did some good. At the end of December, 1886, he was again seen, and then in addition to the staphylomas, at the punctures for sclerotomy, was another above and between them; tension was decidedly increased. The lens was more opaque, and a view of the interior was not possible. He still saw large letters by turning the eye outwards. Pain was very severe. Puncture of sclerotic was performed December 30th, with temporary relief, and repeated on January 22nd, 1887. The growths were much enlarged, and were growing. February 16th, 1887, enucleation of globe; besides the outgrowths in front, which reached behind, there were large nodules on sclerotic behind. The optic nerve was divided as far back as possible, and suspicious pieces of tissue removed. Growth returned, and on July 10th the orbit was cleared out, and chloride of zinc paste applied. No recurrence. The tumour was a small spindle-celled sarcoma. It filled the eyeball, except a little space below and to the inner side; it had perforated the sclerotic above, midway between the optic nerve and the cornea, and also at the outer side of optic nerve entrance. Sections of the eyeball, mounted in glycerine jelly were shown.—Mr. LAWFORD asked if there had been any symptom of glaucoma in the second eye.—The PRESIDENT thought it was very difficult to assign cause and effect in these cases, and remarked that sometimes a sarcoma remained dormant for a very long time.—Mr. MILES thought that the case was one where his small beam of light would have been of diagnostic service.—Mr. POWER re-

ferred to the danger of chloride of zinc; he had applied it after clearing out the contents of the orbit in one case, where the patient had much pain afterwards, and died in two days from the artery being attacked by the caustic.—Mr. NETTLESHIP had seen bad results from the use of chloride of zinc to stop hæmorrhage in these cases, and once death, which he attributed to it.—Mr. SNELL briefly replied.

Punctured Wound of Upper Eyelid followed by complete Palsy of the Third Nerve and Optic Nerve Atrophy.—Mr. SIMEON SNELL (Sheffield) related for Mr. W. A. GARRARD the case of a boy, aged 7, who, on April 19th, 1887, fell while holding a piece of stick, which pierced the left upper eyelid just above the margin. A boy pulled it out, but there was no reason to think it had pierced deeply. He was admitted at the Rotherham Hospital. The next day the eye was closed, on the fourth day the eyelid was still drooping, and, on raising it, dilatation of pupil, loss of movements of eyeball, and the characteristics of complete palsy of motor oculi were discovered. The optic disc was normal. On May 9th, Mr. Snell saw the patient; the optic disc was a little paler than its fellow; complete paralysis of third nerve was present; accommodation was paralysed. A few days later recovery commenced by his being able to raise the eyelid a little, and by June 2nd ptosis had disappeared, and the movements of the eyeball were good. When seen in November all affections of motor oculi had disappeared; the optic papilla was atrophic; the vessels were not reduced in size; vision was very imperfect. At no time were the fourth, or sixth, or ophthalmic division of fifth involved. In discussing the nature of the lesion in this case, Mr. Snell said that direct injury to the parts at the back of the orbit was excluded, as the stick did not penetrate. Leber had accounted for cases of monocular amaurosis after blows about the supra-orbital region or head as due to fracture in the vicinity of the optic foramen, and not to interference with the fifth nerve. Holder had pointed out also that in fracture of the base in 60 per cent. at *post-mortem* examination fracture of the wall of the optic foramen was found. Berlin had stated that Nuhn, in 1845, sought an explanation in an injury or rent of the optic nerve within the optic foramen. It seemed doubtful if the blow on the eye in the case related was sufficient to cause fracture, as Leber suggested, but it might have been enough to have driven the eyeball into the orbit, and causing jarring, or compression, of the optic nerve. The question why the third was the only nerve affected was not easy of explanation. The slow onset of the optic nerve atrophy seemed to indicate that the lesion was high up, the degenerative process passing downwards. The almost immediate presence of the third nerve palsy suggested effusion, which would allow of the recovery; the completeness of the palsy pointed to the lesion being close up to, or at the trunk of, motor oculi.—Mr. NETTLESHIP thought that more proof was required that there had not been a penetrating wound of the orbit. The explanation of the case he offered was that there had been such a wound, and he instanced a somewhat similar case where a penetrating wound had passed unnoticed. Some reason was wanted to explain why one nerve would recover and not another; the optic nerve rarely recovered.—Mr. EDGAR BROWNE took the same view of the case as Mr. Nettleship did, and mentioned a case where ecchymosis was due to an unsuspected piece of pipe stem lodged in the orbit.—Mr. FROST had had a similar experience, and the PRESIDENT mentioned a case in which a fatal tetanus resulted from a foreign body in the orbit.—Dr. VAN MILLINGEN had seen ptosis without any other paralysis result from a blow on the orbit.—Mr. SNELL, in reply, said that the patient had been seen at once by a very good observer, and that he himself had been unable to detect any mark on the conjunctiva, and he adhered to his belief that there had not been a penetrating wound; even if there had been, he could not see that it would explain the paralysis of the whole of the third nerve which had been observed in this case.

Pulsating Tumour of the Orbit with Proptosis.—The PRESIDENT showed a case illustrating this condition.—Mr. ADAME FROST thought that the patient's history was at least as consistent with an intracranial as with an intraorbital lesion, and the evidence afforded by the pathology of other cases would dispose him to take this view of the case, unless there were strong evidence in the other direction. In answer to questions, the man had again and again stated that the piece of wood that struck him was as thick as his thigh and weighed many pounds; that it struck him with considerable violence; and that the end was blunt and as large as a fist. It was easy to understand that the penetration of a sharp fragment into the orbit might produce an arterio-venous

communication within the orbit, but surely a severe blow from a blunt body without a perforating wound (as far as was known) would be more likely to produce a fracture passing across the carotid artery in the cavernous sinus. The case presented difficulties viewed from either standpoint.

Card Specimens.—Dr. VAN MILLINGEN: Instruments.—Mr. E. T. COLLINS: Disease of Choroid (? Colloid).—Mr. BICKERTON: Piece of Glass removed from the Anterior Chamber.—Messrs. CRITCHETT and JULER: Case simulating Glaucoma.—Mr. DOYNE: New form of Optometer.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

WEDNESDAY, MARCH 7TH, 1888.

JOHN SMITH, M.D., LL.D., in the Chair.

Specimens, Clinical and Pathological.—Dr. J. DUNCAN drew attention to a method of applying the principle of siphon exhaustion to empyema. With the help of a very simple piece of apparatus he had thus been able to effect almost complete emptying of the chest cavity, the viscera being brought into close apposition with the costal walls. He had been disappointed to find, however, that adhesions did not occur.—Dr. DUNCAN also described a case of hip-joint disease, when an abscess had burst into the ureter, with the distressing results that the urine constantly made its escape by the abscess opening. The patient suffered much discomfort, and incurred considerable additional risk from the tendency to bedsores. This had been obviated by a pretty application of the principle of capillary drainage. Threads of worsted were passed loosely through a piece of india-rubber tube, the mouth of which was inserted into the wound with the ends of worsted projecting. The tube served as a water-tight channel through which the urine circulated till the edge of the bed was reached, where it dripped from the worsted ends into a vessel.—Mr. CATHCART showed a patient suffering from a Colles's fracture, produced in an unusual way. A severe blow had been delivered on the palmar aspect of the hand towards its distal extremity, with the result that the radius was fractured just above its head. There was no lateral displacement.—Mr. CHIENE exhibited an example of uncontracted blood clot. The blood had been drawn in the ordinary way from the horse, for the purpose of demonstrating the contraction and formation of the buffy coat, but the clot had remained uncontracted.—Dr. BRUCE showed a bladder and urethra with extensive diphtheritic-looking membrane attached to the mucous surface. The patient had been frequently catheterised, and there was the suggestion of false passages.

The Clinical Value of Temperature Observations in certain Acute and Chronic Diseases.—Dr. J. O. AFFLECK read a paper on this subject. The remarks were based on personal observations. The value of temperature registration was increased by comparatively greater frequency. Thus a four hours' chart gave information which was omitted in a twelve hours' chart. Speaking of the individual fevers, Dr. Affleck drew attention to the special value of a study of the temperature in typhoid. The usually described clinical course of three weeks was by no means regular. In a large proportion of cases the duration was much longer. When the temperature rose above 103° F. it was to be interpreted as indicating an increase in the ulcerative process. Pulse records should go hand in hand with those of temperature. Sometimes the results appeared contradictory. The temperature fell during defervescence, but temperature registration should be made from time to time. In illustration a temperature chart was shown where the temperature, which fell to normal on the twenty-ninth day, rose again on the sixty-third. With any alteration of diet or similar condition, the temperature was to be watched. His hospital experience was rather opposed to the adoption of internal antipyretic remedies in typhoid. In typhus fever the best results were to be looked for when the temperature fell at the end of the seventh day. In the exanthemata the value of temperature observations was less than in the continued fevers, though here, too, much might be learned by careful study. Thus, for example, the continuance of a higher temperature beyond the usual period suggested the probability of complication, which must be carefully sought for. Similar deductions might be made in connection with croupous pneumonia and acute rheumatism. In the latter frequent temperature records might timeously reveal the onset of hyperpyrexia. A chart was shown where the temperature in one hour had risen from 103° or 104° to 109° F. The early observation of this, followed quickly by the cold bath, might be of the utmost consequence. In chronic disease tempera-

ture observation, though of less striking value, presented many points of interest. Thus in the cases of pernicious anæmia which he had brought before the Society, the temperature had been elevated more or less at first, gradually returning to the normal as improvement took place. In myxo-dema he had shown at a previous meeting how the temperature tended to remain subnormal, in consonance with the experience of Mr. Horsley in the case of monkeys after ablation of the thyroid. The state of the temperature suggested the propriety of the line of treatment by hot baths. Further, he had found that in diabetes, as a rule, the temperature was subnormal.—The PRESIDENT thought the thanks of the Society were due to Dr. Affleck for his most careful and suggestive elucidation of a subject so eminently practical.—Dr. ALLAN JAMIESON corroborated many of Dr. Affleck's facts, and referred to the climatic or atmospheric influence as affecting temperature. In going round the fever wards, Dr. Wood and he had frequently remarked how, on certain days, a large proportion of the temperatures would be raised. They had tried to frame theories on the subject, but so far were not possessed of a good working hypothesis.—Dr. HADDEN was inclined to lay less stress on thermometric records than he did in earlier days. In all cases it was of importance that the pulse and respiration curves should be recorded synchronously.—Dr. CROUSTON drew attention to the value of a study of temperature in mental diseases. Thus in acute mania and in certain stages of general paralysis there was elevation of temperature. Moreover, if medical practitioners would, in all doubtful cases of supposed insanity, take the temperature of their patient, there would be less sending to asylums for mental treatment of patients suffering from acute febrile processes. A number of such awkward mistakes had come under his observation.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

PATHOLOGICAL AND CLINICAL SECTION.

FRIDAY, FEBRUARY 24TH, 1888.

A. S. UNDERHILL, M.D., in the Chair.

Primary Cancer of Liver.—Dr. SIMON showed a specimen of primary cancer of the liver, taken from a man who had had no symptoms except progressive asthenia.

Perihepatitis in a Boy.—Dr. SIMON also showed a specimen of perihepatitis. The liver was from a boy aged 14, who had had ascites two years previously. Cyanosis was marked for some time before death.—Dr. SUCKLING and Dr. CROOKE made some remarks.

The Uterus in Menstruation.—Dr. HOGGEN exhibited microscopic sections of the virgin uterus, taken from a girl who died during the menstrual flux. No shedding of mucous membrane was discernible.

Enlargement of the Liver in Rickets.—Dr. HOGGEN also exhibited sections illustrating the enlargement of the liver in rickets. The specimens showed a cirrhosis of the more diffuse kind (multilobular), with thickening of the bile ducts and multiplication of the biliary canaliculi. The circumference of the lobules was invaded to some extent by a small-celled infiltration of the portal canals, and there was a slight degree of fatty infiltration of the hepatic cells.—The CHAIRMAN remarked that the enlargement of liver in rickets was more apparent than real, owing to the flattening of the chest causing downward displacement of the organ.

Rare Fracture of Olecranon.—Mr. JORDAN LLOYD showed the upper end of an ulna which he had removed during an excision of the elbow for unreduced dislocation of eighteen months' duration. The patient, a man aged 27, had been unable to work since the accident. The olecranon was fractured from its upper end at its posterior surface downwards and forwards into the centre of the sigmoid notch. The fragment had been driven downwards and forwards so as to narrow the notch to a depth of less than half an inch, and had united firmly in this situation. Reduction of the humerus into the contracted sigmoid cavity was mechanically impossible.

Simple Stricture of Oesophagus.—Mr. BARLING showed a specimen from a man aged 60, who had suffered from pain and difficulty of swallowing for four months. The patient died suddenly after sharp pain due to swallowing food. There was no history of syphilis, of injury, or of swallowing corrosive fluids. The stricture was close to the cardiac orifice and encircled the oesophagus, extending vertically for about three-quarters of an inch. There was some destruction of the mucous membrane at the seat of stricture, and marked thickening of the coats external

to that. Microscopic examination of sections from the whole thickness of the stricture showed only inflammatory new formation. There was nothing to suggest malignant growth, nor was there any enlargement of the mediastinal glands.

Salivary Calculus.—The CHAIRMAN showed a calculus of unusual size, removed from the submaxillary gland of a man aged 40.

Prostatic Calculus.—The CHAIRMAN also showed a calculus removed from the prostate of a child aged 6 years, who suffered from incontinence of urine and painful micturition. An ordinary sound failed to detect any calculus, but on passing a soft bougie a distinct grating could be felt. Rectal palpation confirmed the diagnosis of calculus in the prostate. By a median incision it was found encapsuled where the prostate should have been, evidently, some time previously, when smaller, having been washed down with the urine from the bladder. Its weight was 162 grains, length one inch and seven-twelfths, and breadth eleven-twelfths of an inch.—Dr. HOGGEN referred to a case where a salivary calculus was composed of uric acid, the patient from whom it was removed being gouty.

Diseased Suprarenal Body.—Professor ALLEN exhibited a diseased suprarenal body from a sheep, with microscopical sections.

PLYMOUTH AND DEVONPORT MEDICAL SOCIETY.

MONDAY, FEBRUARY 20TH, 1888.

G. JACKSON, F.R.C.S., in the Chair.

Whooping-Cough.—The CHAIRMAN opened a discussion on the treatment of whooping-cough, and stated that he had found lobelia and belladonna in the early stages cut short the disease, whilst vaccination was of temporary benefit.—Mr. WILSON advocated the use of bromides and belladonna, and change of air if chronic.—Dr. BAMPTON preferred to treat the disease on general principles, but considered that chloral and carbolic acid were particularly valuable.—Mr. J. E. SQUARE had had good results with creosotene.

Paralysis from Peripheral Neuritis.—Dr. BAMPTON read a paper on this subject. He related the case of a rheumatic subject who had pain and weakness in the legs, followed by loss of power and numbness, slight swelling of feet, darting and shooting pains in shins. The patient always felt cold. The right hand followed with loss of power and sensation, and later the left arm was attacked. There was absence of knee-jerk, but no eye symptoms. Eventually the patient died of bronchitis, to which she was subject. He also gave an account of a case in an intemperate woman, aged 30. She improved under coffee and strychnine, but died whilst sleeping during the night.—Mr. BRENTON recited a case of alcoholic paralysis, with bladder symptoms, that recovered under quinine and strychnine.—In the course of the discussion, Dr. BAMPTON threw out the suggestion that possibly cases of infantile paralysis were primarily of peripheral origin, caused by acute rheumatism.—Mr. W. WOOLCOMBE considered that the embolic theory explained the phenomena of infantile paralysis.—Dr. BAMPTON suggested that in the initial stage of infantile paralysis, salicylate of soda should be given, relating a case where convulsions were impending, that responded at once to the drug.

SOUTH INDIAN BRANCH (MADRAS).

FRIDAY, NOVEMBER 4TH, 1887.

Surgeon-Major DRAKE-BROCKMAN, Vice-President, in the Chair.

Surgical Statistics of the General Hospital.—Brigade-Surgeon SIBTHORPE read notes, illustrated by an elaborate series of tables, on the statistics of the General Hospital, Madras, for nine years ending 1886. He stated that his objects in so doing were to place the statistics on record for future reference, and to improve the method in which they are recorded. New forms for the annual returns and the new edition of the nomenclature of disease had come into use in 1887. The General Hospital contained 308 beds, distributed as follows: medical, 110; surgical, 152; cholera, small-pox, and special wards, 33; officers' quarters, 13. The average number of admissions of Europeans was 1,498.22, varying from 1,027 in 1882 to 1,562 in 1878; of natives, the average admissions were 2,206.66, varying from 2,093 in 1883 to 2,536 in 1878. Average daily sick: Europeans, average 66.8, varying from 56.21 in 1880 to 75.68 in 1878; natives, average 130.8, varying from 119.72 in 1881 to 139.92 in 1878. Mortality: the total admissions of both Europeans and natives come to 31,454, the total deaths 2,028, or a ratio per centage of deaths to admissions of 6.44. As to the form of the

returns, it was pointed out that the system of returning such a large number of diseases under the heading of "other diseases" (for example, (1) syphilitic affections, (2) scrofula, (3) leprosy, (4) other diseases of this class) was unsatisfactory. The total admissions of Europeans were 10,784, the total deaths 518, showing a ratio per cent. of 4.8 deaths to admissions for the nine years. The total admissions of natives were 20,670, and the total deaths 1,510, showing a ratio per cent. of 7.31 of deaths to admissions for the same period. In a later part of the report it was pointed out that native patients when in a moribund state were frequently removed by their friends. Statistics of a few operations were given, from which the following death-rates may be quoted: Removal of elephantiasis of scrotum, 68 cases; death-rate, 7.3 per cent. Operation for strangulated hernia, 71 cases; death-rate, 46.4 per cent. Internal urethrotomy, 27 cases; death-rate, 7.4 per cent. External urethrotomy or perineal section, 54 cases; death-rate, 24.07 per cent. Major amputations, 108 cases; death-rate, 19.44 per cent.; of the 21 deaths represented by this rate, 3 were due to pyæmia, 6 to septicæmia, 2 to gangrene, and 6 to tetanus. In conclusion, certain improvements were suggested in the way in which the hospital records were kept.—The VICE-PRESIDENT thought that it would never be possible to have reliable statistics of the General Hospital until medical and surgical registrars were appointed.—Surgeon-Major BRANFOOT concurred.—To the notes were appended extracts from the surgical reports of the General Hospital for 1882 and 1883 by Surgeon-Major R. W. COCKERILL, and for 1884 by Surgeon-Major J. J. L. RATTON, M.D.

Ovariectomy.—Surgeon F. CLARENCE SMITH read notes of the case of a Brahmin woman, aged 33, for whom he had performed ovariectomy for a very large cyst.—The VICE-PRESIDENT made some remarks on the case.

Laparotomy.—Surgeon J. SMYTH related the case of a Hindoo woman, aged 42, upon whom laparotomy was performed for enormous distension of the abdomen. Malignant disease was suspected; this was confirmed at the operation, and the whole of the new growth could not be removed. The patient succumbed on the thirteenth day after the operation.—The case was discussed by Brigade-Surgeon SIBTHORPE and Surgeon-Major BRANFOOT.

Cysticercus Cellulose.—Surgeon H. ARMSTRONG read notes of a case of cysticercus cellulose of the brain, which will be published in full.

THE CLINICAL SOCIETY OF MANCHESTER.

TUESDAY, FEBRUARY 21ST, 1888.

S. WOODCOCK, M.D., President, in the Chair.

Enlarged Spleen and Liver in Rickets.—Dr. RAILTON showed a child, 18 months old, who suffered from rickets, and who had an enormously enlarged spleen, and also a considerable enlargement of the liver. The child was perfectly blanched, and there was puffiness in the face and on the backs of the hands and feet. There was no history or appearance of syphilis. Lardaceous disease, cancer, tuberculosis, and leucocythæmia, were each in turn considered and dismissed. The depth of the liver dulness at the right nipple line was 3 inches, its surface was quite smooth, and its border was felt to be somewhat rounded but even. The spleen extended as low as the ilium, was 4½ inches long, and 3½ inches broad. There was no ascites, no enlargement of lymphatic glands either within or externally, the heart, lungs, and urine appeared normal. The blood showed no excess of white corpuscles.

Mitral Stenosis.—Dr. RAILTON showed a patient, aged 14, suffering from mitral stenosis, the result apparently of the chronic rheumatism known as "growing pains." There was no history of scarlet fever, chorea, or acute rheumatism. The superficial cardiac dulness extended upwards to the third rib, but there was apparently no right hypertrophy, and the apex beat was within the nipple line. During the tranquil action of the heart, the apex murmur occurred as a faint roll occupying the diastole, immediately following the second sound, and ceasing before the first sound. If the heart acted more quickly the roll disappeared, and a rough presystolic murmur became audible, leading directly to the first sound. The patient suffered no inconvenience from the disease, except some dyspnoea on exertion; there was no hæmoptysis, œdema, congestion of liver, or other symptoms of failure of the circulation.

Pseudo-Glioma.—Dr. HILL GRIFFITH showed a child, age 4 years and 10 months, blind of both eyes from the condition known as pseudo-glioma following "inflammation of the spine." It

demonstrated the clinical characters of the affection, and remarked on the difficult diagnosis of pseudo-glioma (aplastic cyclitis) and real glioma of the retina, illustrating his remarks by a typical pathological specimen of each.

Spinal Injury.—Dr. WILLIAM THORBURN showed a case of spinal injury sustained in April last. The patient had at that time lateral dislocation of the head and neck, with paralysis of the limbs, and trunk, etc. The dislocation being reduced a few hours after the injury, almost complete recovery has ensued.

Mercury in Ophthalmic Practice.—Dr. EMRYS-JONES read a paper on the value of mercury in ophthalmic practice. He gave the result of his clinical experience for the past twelve years, and enumerated a number of illustrative cases of paralysis of the third nerve, chancre of the eyelid, descemetitis, iritis, retinitis, neuroretinitis, choroiditis disseminata, and atrophy of the optic nerve, in which mercury had been of signal service. He expressed a preference for the treatment by mercurial inunction in most cases, and advocated its rapid administration.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

FRIDAY, FEBRUARY 17TH, 1888.

Port Sanitary Administration on the Tyne.—Dr. HENRY E. ARMSTRONG read a paper in which he gave an outline of the history of the River Tyne Port Sanitary Authority, which consisted of a joint board of representatives from Newcastle, Gateshead, Tynemouth, South Shields, Jarrow, and the local boards on each bank of the Tyne below Newcastle. During recent years great changes in the port had been made by the Tyne Commissioners, who had spent half a million on the various works for widening and deepening the river, making piers, docks, warehouses, and otherwise improving the navigation and developing the trade of the Tyne. The effect of these works was greatly to increase the volume of salt water in the river to a distance of several miles above Newcastle, to the sanitary advantage of the riparian population. The effect of these improvements on the commerce of the Tyne was proved by returns of shipping, shipbuilding, imports and exports, coal, etc., showing the large and increasing trade now done in the port. The hospital accommodation of the Port Sanitary Authority included a pontoon hospital of thirty beds, in three-ward blocks; the original float of ten beds, which will be abandoned on the completion of the administrative block of the pontoon hospital; and a cholera hospital of ten beds, built on the Dutch galliot *Alliance*. The nature and extent of the diseases for which patients were admitted to hospital during the seven years under review, and the ports or countries from which such diseases were brought, were stated in tables. The cholera precautions adopted in the port were described in full. A series of tables set forth the numbers of vessels arriving in the Tyne from cholera-infected or suspected ports. An account of the general sanitary inspection carried on in the port was given. A short statement as to the smoke nuisance and the action taken in respect to it, followed by some observations on the relations existing between the Port Sanitary Authority and the Local Government Board, brought the paper to a close.

Sanitary Administration in New York.—Dr. CAMPBELL MUNRO read a paper on this subject.

MIDLAND MEDICAL SOCIETY.

WEDNESDAY, FEBRUARY 22ND, 1888.

Surgeon-Major TURTON in the Chair.

Fracture of First Rib.—Mr. MARSH read a paper on this injury. He thought that it might be produced: 1, by direct violence to the posterior portion of the rib; 2, by force applied to the manubrium sterni; 3, by force transmitted through the clavicle. Two cases had recently been under his treatment.

Sarcoma of Uterus.—Mr. JORDAN LLOYD showed for Dr. HAY MOIR, of Newhall, a uterus removed *post mortem* from a child aged 3 years. It was the seat of a mixed round and spindle-celled sarcoma, and was as large as a foetal head.

Suprapubic Lithotomy.—Mr. JORDAN LLOYD read a paper on suprapubic lithotomy, with notes of six consecutive successful cases.

Elephantoid Edema of the Face from Lupus.—Dr. SUCKLING showed a woman, aged 45, suffering from this condition. There was no family history of scrofula or lupus, and no family or personal history of syphilis. When 14 years of age, she had some spots like pimples on each cheek, which spread over the ears and nose, and, finally attacking the scalp, caused loss of the hair. About

five years ago the upper eyelids became puffed and the swelling had since extended over the face and neck. The face was much enlarged, and the upper eyelids much puffed, pitting slightly on pressure. The skin of the face was scarred and bleached on each cheek, these patches being connected across the nose. The forehead and upper eyelids were unaffected by the scarring process. The disease had extended along the scalp on both sides, leaving white, bald, cicatricial patches. The neck and face presented patches of eczema, and the skin of the trunk was harsh and eczematous. There was no glandular enlargement, and the patient's general health was excellent.

SUNDERLAND AND NORTH DURHAM MEDICAL SOCIETY

THURSDAY, FEBRUARY 16TH, 1888.

G. S. BRADY, M.D., F.R.S., Vice-President, in the Chair.

Penetrating Wound of Chest.—Dr. GRAY showed a man who had been stabbed at the lower border of the second right costal cartilage. Pleurisy supervened, and forty ounces of serum were removed by two aspirations at an interval of six days. After the second tapping the temperature rose at nights and the chest again filled; twenty ounces of pus were drawn off by the aspirator, and the man was now convalescent.

Urethral Calculus.—Mr. H. S. ROBINSON showed a boy, aged 7 years, from whose urethra he had removed a small calculus. Ten days afterwards, when the wound had almost healed, severe hæmorrhage occurred *per urethram*, and was only arrested by tying in a metal catheter for forty-eight hours.

Syphilitic Psoriasis.—Dr. PROWDE showed a case of this disease. —The CHAIRMAN and Mr. HOPGOOD made remarks as to treatment.

Charcot's Joint Disease.—Dr. PROWDE showed preparations of the knee-joint and head of femur from patients who had previously been exhibited before the Society as well-marked cases of this disease. The head of the femur was found to be completely detached from the neck of the bone, which had to a great extent disappeared.

Abinism.—Mr. P. BLUMER showed a case and gave the family history of it, as well as of another which had come under his observation. —Messrs. LEGAT and SEVILLE made some remarks.

Anæsthetics.—Mr. W. H. MALING read a paper in which he advocated the claims of ether. —A discussion ensued, in which Messrs. ROBINSON, BLUMER, LEGAT, SEVILLE, and HOPGOOD, and Drs. GRAY, SHELMERDINE, and PROWDE took part.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

THURSDAY, MARCH 8TH, 1888.

G. H. HUME, M.D., President, in the Chair.

Cases.—Dr. LYON showed a Boy with Congenital Deformity of Hand. —Dr. ARNISON showed a Child with Multiple Enchondroma of Fingers.

Excision of Portion of Sciatic Nerve.—Dr. HUME showed a man from whom a portion of the great sciatic nerve had been excised for tumour. The tumour was a fibro-sarcoma, was of five months' growth, and occupied the greater part of the back of the thigh. At the operation Dr. Hume found the tumour incorporated with the nerve; the nerve was divided high up, and the growth shelled out; lower down the nerve was cut at the popliteal space. The wound healed by first intention. The patient could now walk well. —In reply to Dr. JAMES DRUMMOND, Dr. HUME thought that the patient would retain his power to walk, judging from his experience of another case similarly treated.

Elephantiasis of Scrotum.—Dr. PROWDE showed a man with elephantiasis of scrotum. The disease commenced ten years ago, when he had stricture of the urethra, followed by perineal abscess.

Sarcoma of Thigh.—Mr. PAGE showed a youth, aged 18, whose left thigh had been amputated for sarcoma. The operation was performed a year ago. The patient was now in excellent health.

Pyosalpinx.—Dr. COLLIE exhibited a pyosalpinx removed from a young woman to whom he was urgently called. She was then in a state of collapse, and in a few hours after she died. The tube had ruptured. Dr. Collie raised the question as to the results that might have been obtained had abdominal section been performed.

Genu Valgum.—Dr. COLLIE exhibited photographs of genu valgum.

Calculi.—Dr. JAMES DRUMMOND exhibited calculi removed by suprapubic lithotomy, from a man, aged 77. —Mr. PAGE showed

eleven urinary and three salivary calculi; one of these latter was removed from the sublingual duct of a patient who had cancer of the tongue.—Dr. CRISP exhibited three calculi, one of which had been removed from the bladder of a woman by dilatation.—The nucleus of one of the calculi exhibited by Mr. Page was a pebble which the patient some years before had placed in and afterwards pushed up his urethra. Remarks were made upon the urinary calculi by Dr. ANDERSON, and upon the relationship of salivary calculi and cancer of the tongue by Dr. OLIVER.

Rhinoplasty.—Mr. RUTHERFORD MORRISON exhibited photographs of cicatrix, and also showing effect of plastic operation; also photographs of new nose.

Charcot's Disease.—Dr. PROWSE showed a knee-joint and head of femur from a case of Charcot's joint disease. They were taken from a man aged 62, who had never had syphilis, and who had no family or personal history of rheumatism or joint affection. Eight years ago symptoms of locomotor ataxy showed themselves. The knee-joint rapidly swelled, and severe pain was complained of. The joint afterwards became dislocated, then the left hip-joint became affected, and this was followed by disintegration of the left elbow-joint. The joint exhibited was completely disorganised, but on its under surface some new growth of bone was discernible.—Dr. OLIVER believed in the association of this joint affection to the locomotor ataxy, and drew attention to the presence of new bony formation in the specimen exhibited—this not being the rule in these cases.—Dr. LIMONT also laid stress upon the recent bony growth in the knee-joint.

Aneurysm of Thoracic Aorta.—Dr. OLIVER exhibited an aneurysm of the descending thoracic aorta which had burst into the pleural cavity. During life the man, aged 41, had suffered only from backache. He was pale and emaciated. There was dulness and pulsation below the inferior angle of the left scapula, and here a systolic murmur could be heard. The patient died suddenly.

Aneurysm of Aortic Arch.—Dr. JAMES DRUMMOND showed an aneurysm of the arch of the aorta opening into the right auricle primarily, and afterwards rupturing into the left pleural cavity. The patient had never complained even of pain until three days before death.

Malignant Tumours.—Dr. HEATH exhibited several malignant tumours. One, a scirrhous of the breast, had the nipple so completely retracted as to be quite out of sight. The sides of the groove thus formed were eczematous when the patient was first seen by Dr. Heath, and the two things together led him to the diagnosis of cancer, for the diseased nodule in the breast was extremely small.

Hydatid Cysts.—Dr. HEATH also exhibited several hydatids which he had removed from the abdomen of a woman.—In the remarks which followed, Dr. MANTLE raised the question as to how far retraction of the nipple was to be regarded as diagnostic of cancer. One of his own cases had had retraction of the nipple for the last six years and no cancer.—Mr. PAGE said he was interested in the remarks made by Dr. Heath whilst exhibiting the worms of the echinococcus, as he had two cases of hydatid disease of the liver at present under his care. Tapping and the injection of a weak solution of bichloride of mercury gave the best results.

Chloro-anæmia.—Dr. COLEY read a paper on chloro-anæmia, in which he dwelt on the relationships of this blood condition to diseased states of the gastro-intestinal tract, to tubercle, curvature of the spine, etc. Whilst in many of his cases a mitral systolic murmur had disappeared under treatment, in not a few it so persisted that he could not but regard chloro-anæmia as a cause of permanent mitral regurgitation.—Dr. OLIVER instanced a few cases where dilatation of the left ventricle and mitral regurgitation never disappeared after chloro-anæmia; Dr. MANTLE spoke of the relationship to ulcer of the stomach; Dr. JAMES DRUMMOND spoke chiefly of its cause, from constipation; Dr. EASTWOOD traced it to indigestion; whilst Dr. ANDERSON dwelt more upon its treatment by iron and salines.

Tubercular Laryngitis.—A paper by Dr. LIGHTFOOT on this subject was taken as read.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

THURSDAY, MARCH 1ST, 1888.

M. M. DE BARTOLOMÉ, M.D., President, in the Chair.

Apoplexy.—Dr. DYSÓN showed some specimens from a man, aged 31, who was admitted to the General Infirmary in the apoplectic condition, and died the day following. His previous history was singularly free from illness of any kind. He was coma-

tose, head turned to the left, pupils contracted, the left conjunctiva insensitive, the right much less so. He moved his right arm, but not the left; sensation was apparently abolished in the left arm. On *post-mortem* examination a large hæmorrhage was found in the right optic thalamus, which had burst into the ventricle, pierced the septum, and invaded the left ventricle. The left ventricle of the heart was greatly hypertrophied, the valves fairly healthy; there was well marked early stage of atheroma in the aorta. Both kidneys were small and granular.

Ulceration of Popliteal Artery: Amputation of Thigh.—Mr. COOMBE read notes of this case.

Rupture of the Popliteal Artery, followed by Gangrene and Mid-thigh Amputation.—Dr. KEELING related a case. The lower part of the femur and the popliteal vessels, mounted by Mr. Banham, were shown to the Society.—Remarks were made by Mr. JACKSON and Mr. GARRARD.

Clothing.—Mr. PYE-SMITH read a paper, in which he said that fabrics manufactured from the wool of animals were greatly to be preferred for garments to those made from cotton or other vegetable fibre, being much superior as regards conduction of heat, absorption of moisture, porosity, weight, cleanliness, natural colouring, inflammability, strength, softness, flexibility, elasticity, and durability. Their roughness of surface was advantageous except in the rare cases in which even the finest varieties caused unbearable irritation of the skin. Special stress was laid on the value of socks with a separate compartment for each toe as a preventive of corns and deformity of the toes.—The following joined in the discussion: the PRESIDENT, Drs. PORTER and WATSON, and Messrs. JACKSON, WILLIAMS, and ATKIN.

REVIEWS AND NOTICES.

OPHTHALMIC SURGERY. By R. BRUDENELL, CARTER and W. ADAMS FROST. Cassell and Co. 1888.

THIS manual contains some 550 pages of closely printed matter, for about half of which each of the joint authors is more particularly responsible.

It opens with a capital account in brief of the anatomy and physiology of the eye, following which the methods of examination of the eye are discussed, with succeeding chapters on the diseases of cornea and conjunctiva, all arranged upon the usual lines.

The fifth chapter treats of affections of the iris. Here in some respects the work appears decidedly insufficient. For, while inveighing with some rather smart writing against the practice, too much used in his opinion, of diagnosing an iritis as dependent on some constitutional condition, and directing the treatment accordingly, the author proceeds to the opposite extreme. Thus, while indicating that iritis is often a phenomenon of syphilitic disease, he omits to define, except in the most vague way, the period of its onset. Nor does he mention the occasional occurrence of nodules on the iris, a condition so characteristic of syphilis. Similarly, he says not one word as to the distinguishing points between the iritis dependent on the rheumatic taint and other forms. Iritis is not even alluded to in relation to gonorrhœa. As might be expected from this, few will agree with him as to the treatment of iritis. For all forms indiscriminately he appears to advise the internal use of mercury. The operation of iridectomy is another very favourite means of cure and prevention, while the application of warmth is not mentioned.

The chapter on cataract is clear and practical, but that on glaucoma is distinctly inferior. The position of the incision for iridectomy is described only as immediately behind the corneal margin, while nothing whatever is said as to its course or length. The description of sclerotomy is remarkable, since the author divides, in marked opposition to the practice of every authority, the bridge of scleral tissue, leaving only the conjunctiva, a form of operation long ago discredited as extremely liable to be followed by an unsightly bulging of conjunctiva and iris, and even by sympathetic disease. The section on the normal fundus will be found of great service to young ophthalmoscopists, but it is marred by an unfortunate slip which represents three millimètres increase of height of the swollen disc, as corresponding with one dioptré of hypermetropic refraction by the ophthalmoscope, whereas the increased height should be a third of a millimètre only.

His choice of the term "choked disc," instead of optic neuritis or papillitis, will not be generally accepted. Certainly it is not free from the reproach which he applies to the other terms, that of suggesting what is in many cases an unsound explanation.

When, under the head of embolism, it is stated that the connective tissue of the retina becomes white and turbid, surely it is meant that the retina becomes infiltrated with serum. The statement, though it is perhaps only a question of words, will surely convey a strange impression to the minds of most. The advice given as to the performance of Mules's operation in cases of choroidal sarcoma is open to grave question, notwithstanding the cases of non-recurrence to which the author refers. The same, also, with regard to retinal glioma, in which disease, also, evisceration is spoken of as sometimes practicable.

In treating of tobacco amblyopia it is stated that certain authors describe an increase of interstitial tissue and an atrophy of nerve fibres in the neighbourhood of the yellow spot, whereas the changes in question relate to certain fibres within the optic nerve itself.

The remaining chapters, including sympathetic disease, refraction and the ocular muscles, are clear and extremely well expressed. As a whole the book may be said to be rather defective with regard to treatment by drugs, and to incline rather more often than is usual to operative procedures, especially to iridectomy. But, notwithstanding the defects to which we have called attention, its clearness and conciseness will cause it to be welcomed by students and young practitioners as an agreeable and useful guide to the modern practice of eye diseases.

MANUAL OF MATERIA MEDICA AND THERAPEUTICS. By WM. CRAIG, M.D., C.M.Ed., etc., Lecturer on Materia Medica, Edinburgh School of Medicine. Fifth Edition. Edinburgh: E. and S. Livingstone. 1887.

THIS concise little manual, though intended primarily to assist students attending the author's own classes, possesses several characteristics which have rendered it more generally popular. Special emphasis is laid upon alterations in nomenclature which might otherwise escape attention. The author, in reproducing from the *British Pharmacopœia* such a statement as that the dose of tincture of aconite may be 15 minims, would have done well to have added a word or two of caution or comment.

The volume concludes with a posological table, a schedule of poisons and their antidotes, together with a somewhat meagre appendix of contracted terms in common use. It is beautifully printed, and is altogether a very handy and convenient volume for the use of students preparing themselves for examination.

REPORTS AND ANALYSES

AND

DESCRIPTIONS OF NEW INVENTIONS,

IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

KINGZETT'S "BACTERICIDE."

UNDER the above title, the Sanitas Company, of Letchford's Buildings, Bethnal Green, has brought out a new germicide, oxidant, and antiseptic.

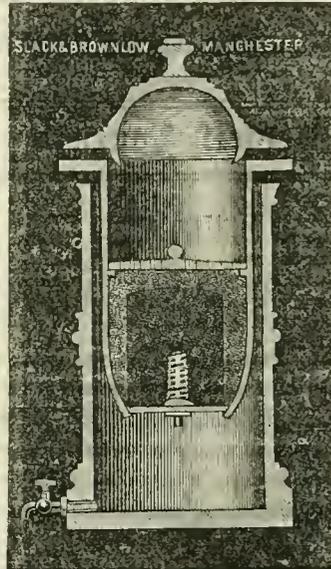

The great power of corrosive sublimate as a germicide and antiseptic, has been repeatedly proved by experiment, and in surgical practice of late years it has been largely and increasingly employed in the antiseptic treatment of wounds caused by operation or otherwise.

Peroxide of hydrogen is an oxidising agent of very considerable power, but we are not aware that until the present time it has been actually used in surgical work. Kingzett's "bactericide," contains in permanent solution 5 per cent. of mercuric chloride (corrosive sublimate) and five volumes peroxide of hydrogen, and it is capable of being largely diluted with water without precipitation.

Such a combination is calculated to be especially useful, since not only are micro-organisms destroyed, and their development prevented by the corrosive sublimate, but it is very possible that the oxidising power of the peroxide of hydrogen may split up and render innocuous those subtle chemical poisons which are produced by micro-organic life.

It is recommended that for general purposes the "bactericide" should be diluted with fifty times its own volume of water. This would of course give a solution containing 0.1 per cent. of corrosive sublimate, or in other words 1 in 1,000. The preparation is worthy of extended trial, and from our own observations we can heartily recommend its employment.

SLACK AND BROWNLOW'S PERFECT FILTER.

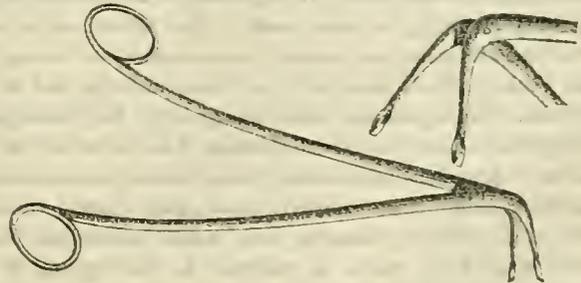

Messrs. SLACK & BROWNLOW, of Manchester, have issued a revised catalogue for 1888, which shows recent improvements made in the construction of their filters. Foremost among these is the "Perfect" filter, which is shown in the accompanying sketch; it is fitted with a movable lining, so that every part is accessible. Messrs. Slack and Brownlow have recently had their filter tested by Alfred H. Allen, Esq., the public analyst for Sheffield, who gives a most satisfactory report, especially as to the power these filters have when fresh of removing dissolved lead from water. This is,

however, not to be relied upon for any length of time.

FORCEPS FOR POST-NASAL GROWTHS.

BEING dissatisfied with the numerous kinds of Löwenberg's forceps now in use, and having occasion to remove some post-nasal growths from the sides of the naso-pharynx, I caused a pair of forceps to be made somewhat similar to the pair depicted by Mr. T. Mark Hovell in the *JOURNAL* of March 3rd, but with an anterior and a posterior cutting blade, so that the lateral growths in the naso-pharynx should be cut off. The whole of each blade has a cutting edge of steel, with a fenestrum behind it, which allows of a growth being seized and cut off in any position save where it

grows round and about the posterior nares, and for this one must use Löwenberg's forceps. It also allows of a growth being cut quite clean through, instead of being torn off as is the case where any description of Löwenberg's forceps is used.

I removed lateral growths in four cases with these forceps in 1887. They were made by Mappin and Co., of 121, New Street, Birmingham.

WRIGHT WILSON, F.R.C.S. Edin., etc.,
Surgeon to the Birmingham Ear and Throat Hospital,
21, The Crescent, Birmingham.

A LECTURE on the "Physical Training of the Greeks and Romans" will be delivered on Thursday, March 22nd, at 5 o'clock, at the Parkes Museum of Hygiene, Margaret Street, Regent Street, by Mr. A. S. Murray, Keeper of Greek and Roman Antiquities, British Museum.

BRITISH MEDICAL ASSOCIATION.
SUBSCRIPTIONS FOR 1888.

SUBSCRIPTIONS to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the West Central District Office, High Holborn.

The British Medical Journal.

SATURDAY, MARCH 17TH, 1888.

MR. STANHOPE ON THE ARMY MEDICAL SERVICE.

MR. STANHOPE'S reply to Dr. Farquharson is, we fear, not likely to improve the relations of the military authorities with the Army Medical Service. It is conceived in the strictest spirit of officialism, and assumes an attitude towards the civil profession which has never heretofore been taken up by any Secretary of State of any of the great service departments, naval or military, British or Indian. The intervention of the civil profession, and especially of the British Medical Association, has, during a long series of years, been accepted by successive Secretaries of State, First Lords of the Admiralty, and Secretaries of State for India with courtesy, consideration, and, if we may venture to say so, with respect. Most of the more important warrants making concessions to the medical services of the army and navy have been issued as the result of representations thus made, whether by deputation, by memorial, or in some other form. The history of the present deadlock is noteworthy in many ways. It began with a thunderbolt out of the blue abolishing relative rank. This official act created great consternation, and caused much excitement throughout the whole medical department at home, in India, and in the colonies. The explanation which was given by Mr. Stanhope to a deputation from the British Medical Association and in the House of Commons to the effect that abolition of relative rank meant nothing since relative rank itself meant nothing did not improve matters, and some concessions which have since been made, in response to the appeal of the British Medical Association, in the form of gazetting medical officers on promotion, have not restored equanimity or contentment in the department, although no doubt they were intended to do so. In view of the immense mass of communications received by the Parliamentary Bills Committee at the office of this JOURNAL, and by Members of Parliament, expressing the profound dissatisfaction of the great bulk of the officers of the department at the absence of any titular or substantive military rank, Dr. Farquharson asked Mr. Stanhope in the House of Commons last session whether he would permit any form of direct or collective expression of the

sentiments from the army medical officers on the subject to be made to him officially, and he replied that he could not allow it, as it was altogether contrary to military discipline.

The report of the Parliamentary Bills Committee at the annual meeting of the Association set forth as impartially as possible the information of which the Committee was in possession as to the existing dissatisfaction in the ranks of the Army Medical Department on the subject of rank. The Director-General of the Army Medical Department, who was present at the meeting, delivered an able and elaborate speech, evidently carefully prepared for the occasion, in which he emphatically denied, not only the validity of the alleged grievances, but the existence of any general dissatisfaction. Thereupon a considerable number of medical officers who were present in Dublin proposed spontaneously to make a statement of their views, which, it was well understood, would confirm the statement in the report of the Parliamentary Bills Committee of the British Medical Association, and which would have invalidated the statement of the Director-General as to the absence of this dissatisfaction. Immediately, however, that it became known that they proposed to do so, intimation was issued to them officially that such an action would be regarded as a breach of discipline.

As a result of the statement publicly made by the Director-General of the Army Medical Department, a special committee was appointed by the Council of the British Medical Association to inquire into the facts; before it were laid, not the collective opinion, but the individual opinions, statements, and argument of nearly 1,000 medical officers, each writing separately, privately and in his individual capacity. Mr. Stanhope now states that this is a breach of discipline, and he declines to listen to the statements of any civilian body, however influential, on behalf of their military brethren. It is obvious that this is altogether a new departure at the War Office, and one which is quite contrary to long-established precedents. If it is desired to treat the army medical officers with this peculiar harshness, to shut the mouths collectively, and to refuse to afford them any opportunity of stating their views individually, except in such a guise shall make it individually perilous, it is obvious that a state of things will be brought about which can but increase the existing dissatisfaction, and which affords no obvious way of bringing about that good understanding which it has always been the object of successive Secretaries of State to maintain with the medical officers of the army department, and with the civil profession, which is professionally interested in the status and welfare of the Army Medical Department.

We are willing to assume that Mr. Stanhope is acting under the momentary impulse of the irritation felt by certain of his advisers whose predictions and declarations on the subject have proved to be ill-founded. It is obvious, however, that the matter cannot rest here, that the civil profession is not likely to be prevented from continuing to feel the interest which they have always manifested in the position of their professional brethren in the public services, and that further Parliamentary action will

follow. Already the profound discontent and irritation existing in the Army Medical Department have communicated themselves to the schools and to the universities. Many of the leading collegiate bodies in the kingdom have made representations in vain to Mr. Stanhope as well as the British Medical Association. The supply of candidates from the schools is seriously threatened by anything which engenders and develops distrust of the War Office, and which brings the conviction that the Secretary of State for War is not disposed to treat the army medical officers with the consideration and courtesy which are due to so important and distinguished a department of the public service.

Mr. Stanhope's reply can only be accepted as a purely official formula. It settles nothing, and it does not advance the interests either of his own department or of the professional elements in the service.

THE RECENT MEETING OF THE EXECUTIVE COMMITTEE OF THE GENERAL MEDICAL COUNCIL.

A GREAT deal of business was got through at the last meeting of the Executive Committee of the General Medical Council. Owing to a temporary indisposition, from which we are glad to learn he had completely recovered a couple of days later, the President was unable to be present, and the chair was taken by the senior Treasurer, Dr. Quain; the Committee worked so hard that all the agenda were got through in one day. The official notification of Dr. George Yeoman Heath's appointment as representative of the University of Durham was received, as was also the formal announcement that Ceylon was, within the meaning of the Medical Act, 1886, a British possession, which afforded to the registered medical practitioners of the United Kingdom just privileges of practising in Ceylon. The opinion of counsel (Mr. Muir Mackenzie), as to the interpretation of Section 21 of that Act, which deals with the registration of diplomas in sanitary science, was received. It was to the effect that it was not necessary that the candidate for the special diploma should be a registered medical practitioner at the time he presented himself for the special examination, but that it was sufficient if he were so registered when the diploma was granted.

The Committee also considered the report which it was required to make to the Council as to the circumstances which would render a medical practitioner liable to the censure of the Council in reference to the employment of unqualified assistants. As the matter is one of such great importance, we are glad to be enabled to reproduce the exact terms of the report of the Executive Committee, which are as follows:—

"A registered medical practitioner would render himself liable to the censure of the Medical Council in case of the employment of an unqualified assistant in the practice of medicine, surgery, or midwifery, on behalf and for the benefit of such registered practitioner, either in complete substitution for his

own services, or under circumstances in which due personal supervision and control are not, or cannot be, exercised by the said registered practitioner. The Executive Committee furthermore takes this opportunity of stating, in reference to the procedure known as 'covering,' that in its view a registered practitioner covers an unregistered person, when he does, or assists in doing, or is party to, any act which enables such unqualified person to practise as if he were duly qualified."

The Committee also called attention to a resolution adopted by the Council five years ago, which expressed the opinion that further legislation was then needed to subject any registered practitioner who deputed "a person not registered or qualified to be registered under the Medical Act to professionally treat on his behalf, in any matter requiring professional discretion or skill, any sick or injured person. . . . to the same legal liabilities as a person who falsely represents himself to be a legally qualified medical practitioner." A further clause excepted any duly regulated training of pupils in medical schools or otherwise by legally qualified practitioners, the use of trained pupils in partially treating the sick or injured under the direction, supervision, and responsibility of such practitioners, and any legitimate employment of nurses, midwives, or dispensers.

A very important memorandum by the President, with opinions thereon by the Council's legal advisers, was, owing to the absence of Mr. Marshall, postponed to the next meeting; the documents dealt with the disciplinary or penal powers of the qualifying medical authorities and of the Medical Council as regards the erasure of qualifications and names from the *Medical Register*. The legal opinion, we understand, was to the effect that fresh legislation is needed to extend and define the powers of the universities and corporations to withdraw qualifications, and of the Council to erase a name from the *Medical Register*, when all the individual's qualifications have been thus withdrawn. If, as is proposed, the qualifying bodies were empowered to withdraw a qualification temporarily, their disciplinary powers, and indirectly those of the General Medical Council also, would be very greatly increased. At present there is no alternative between a mere reprimand, which has, of course, no legal and binding force, and the permanent erasure of a name from the *Register*; some intermediate penalty would greatly strengthen the Council in dealing with questions of discipline.

THE NEW ARMY MEDICAL RESERVE WARRANT.

We publish in another column the text of the Royal Warrant, of which we gave a summary in our last issue.

We fully recognise the urgent need, and would gladly welcome any well considered scheme for the formation of a real reserve of medical officers for army duties; for large and expensive as the economists say the regular full-pay medical service is, it is but barely sufficient for the mere mobilisation of two army

corps, and quite inadequate to meet the wear and tear of a big war.

The Warrant has been talked of for some months, and has not therefore been issued without due deliberation; but though we approach it in the most friendly spirit, we think in the interests of the service and the profession it is open to criticism. It is bald and severe, as such documents usually are, but we find an interpretation to its clauses in the "instructions" appended by the Secretary of State for War. On these instructions we found our comments.

The first instruction is that "no medical officer of the auxiliary forces shall be appointed to the Army Medical Reserve who is not medically fit for service, and whose character and qualifications are not in all respects satisfactory."

If there be any medical officers of the auxiliary forces, now or in the future, "medically unfit," or "whose character and qualifications are not in all respects satisfactory," such, we think, should not merely be debarred from entering the reserve, but at once removed from the corps lists altogether.

The second instruction provides that the names of all officers of the Army Medical Reserve shall be included in a special Army Medical Reserve List. This is necessarily so. But why have we not in the *Army List* a defined list of the retired regular medical officers in reserve up to a certain age? It is strange they are not mentioned in the Warrant. Was not the object in granting them early retirement that they should form such a valuable reserve? The economists, in their outcry against early pensions, ignore this; but we are surprised the Secretary of State and his medical advisers seem to have lost sight of it also.

The third instruction provides that "officers shall be removed from the Medical Reserve List on attaining the age of 65." We fear a very considerable proportion of any reserve will be hopelessly "medically unfit" before the sixty-fifth year of life, so that constant weeding will be necessary to secure efficiency.

The fourth instruction is that "officers of the Army Medical Reserve shall be liable to be called to army service at home in times of great national emergency, to take the place of such of the Medical Staff of the Army as may be withdrawn for active service." When "times of great national emergency" unfortunately occur, we take it that Militia, Yeomanry, and Volunteers will certainly be embodied, so that medical officers of these branches will in any case come out with their corps. But if, in such an event, they are to be called upon to take the place of the regular medical officers, who will fill their shoes in the mobilised auxiliary forces? To stop one gap while creating another is like robbing Peter to pay Paul. We cannot help thinking that, if the threatened reductions on the home establishment of regular medical officers are carried out, a mere Egyptian war or such-like will, as far as our medical reserves are concerned, be held to constitute "a great national emergency."

The fifth instruction is outside "great national emergency," and not even necessarily connected with a reserve; yet, we doubt not, has had something to do with the issue of the Warrant. Here the authorities seek to secure, by a direct binding

"shall," the services of reserve medical officers at "contract rates" when required for duties with troops quartered near their houses. The "rates of remuneration" alluded to in Art. 354 of the Pay Warrant are as follows:—

For medical attendance, which includes cost of medicines, on all persons entitled—officers, men, women, children, servants, certain labourers, etc.

	Yearly.		
	£	s.	d.
If there be less than 10 persons	5	0	0
If there be 10 persons or more, for every complete 25, or portion of 25	10	0	0

We published last week some account of the duties with regular troops, so that medical reserve officers who undertake these duties will be able to judge of what is expected of them for the terms offered.

The sixth instruction is nothing new, being already embodied in the regulations.

The seventh instruction is too broadly stated, and we demur to it. The reserve medical officers, under orders of the Medical Department, would when necessary be undoubtedly severed from their corps. Indeed, this would be unavoidable if the auxiliary forces were embodied and massed together for service, unless some such body as the Volunteer Medical Staff Corps could form field hospitals and bearer companies, and thus allow regimental medical officers to be left with their corps.

The eighth instruction is a routine detail.

Such comments, necessarily hasty, have occurred to us on this important Warrant; we leave those concerned to judge of their fairness or pertinency. What we would like to see is a reserve of medical officers which shall in every way support, but in no way supplant, or be made a handle for supplanting, the regular Army Medical Service.

HER Royal Highness Princess Beatrice, Princess Henry of Battenberg, has been pleased to appoint John Williams, Esq., M.D., to be Physician-Accoucheur to Her Royal Highness.

THE Croonian Lectures to be delivered before the Royal College of Physicians next June by Dr. Donald MacAlister, Fellow of St. John's College, Cambridge, will be on "Antipyretics."

WE regret to notice the death of Dr. Robert Gordon Latham, M.D., F.R.S., the well-known philologist, who was at one time assistant physician to Middlesex Hospital. We hope to publish an account of his career in our next issue.

THE Croonian Lecture of the Royal Society for this year will be delivered by Professor Kühne, the eminent physiologist of Heidelberg, on Monday, May 28th, in the theatre of the Royal Institution, Albemarle Street.

THE annual dinner of the Medical Society of London took place at the Whitehall Chambers, Hôtel Métropole, on Thursday March 8th, the retiring President, Dr. J. Hughlings Jackson, F.R.S., in the chair. Sir Thomas Crawford was also present. Cordial thanks were tendered to Dr. Jackson for the manner in which he had conducted the work of the Society during his year of office.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE approaching annual election of the President of the Royal College of Physicians is, as is not unusual, the subject of much discussion in medical circles in London. In this connection the name of Sir Henry Pitman has been prominently put forward. We are informed, however, that this is entirely without his authority and contrary to his wish.

ROYAL MEDICAL BENEVOLENT COLLEGE.

WE learn with much satisfaction that the festival of Epsom College, which is fixed for April 17th, is likely to be a great success. The acceptances are already so numerous that the Dinner Committee will shortly be under the necessity of closing the list. A few seats, however, will still be reserved for old Epsomians.

TREATMENT OF DIPHTHERIA.

THE *France Médicale* of the 1st February gives the following formula, recommended by Dr. C. Roese for the treatment of diphtheria:—B Oil of turpentine, 15 grammes; spiritus ætheris, 1 gramme. This mixture is given three times a day. Every two hours one tablespoonful of a 2 per cent. solution of salicylate of soda is administered, and a gargle with a solution of chlorate of potash. M. Roese employed this treatment in sixty cases of diphtheria. The number of cases which proved fatal was only 5 per cent.

TREATMENT OF DIABETIC COMA.

To combat the acidity of the organic fluids in diabetic coma, Dr. Jaccoud recommends saline purgatives, and large doses of alkaline substances. Inhalations of oxygen and subcutaneous injection of ether are also beneficial. Excessive fatigue and digestive disturbance should be guarded against; they have a considerable effect in causing diabetic coma. An exclusively meat diet should be avoided. The acid impregnation of the organism (the usual characteristic of diabetic coma), is betrayed by the presence of oxybutyric acid in the urine. This substance is easily decomposed into acetone.

ELECTRIC ILLUMINATION OF THE BLADDER.

ELECTRIC cystoscopy is beginning to be of use in practical surgery. On Wednesday last, at St. Peter's Hospital, a female patient under the care of Mr. Heycock, who had suffered for some time from vesical hæmaturia, was examined with Leiter's incandescent-lamp cystoscope, recently described in these pages by Mr. Hurry Fenwick. A growth the size of a walnut, covered with phosphatic incrustations, was plainly seen on the left side of the trigone. The position, aspect, and character of the growth were immediately confirmed by digital exploration after dilatation of the urethra. Mr. Fenwick has also, we learn, used the apparatus successfully in other cases of vesical tumour and in one of latent calculus.

DILATATION OF THE PYLORUS.

THE operation of dilatation of the pylorus for non-malignant stricture is still upon its trial, and surgeons will be interested to learn that the patient operated upon by Mr. Robert Haggard, of Hull, in March, 1886, has continued to improve since the report of the case was published in these columns (vol. i, 1887, p. 386). She is now, we are informed, perfectly well, and there has been no return of vomiting. The dilatation of the stomach continued for some time after the operation, but gradually subsided, and the organ is now apparently normal in size. The patient herself thinks so well of her state of health, that she has recently married. It may be remembered that at the time of the operation a pair of fine dressing forceps with long alligator blades were with some difficulty pushed through the stricture into the duodenum.

CARBONIC ACID IN DYSPNOEA AND COUGH.

SOME time ago, Professor Brown-Séquard stated that inhalation of carbonic acid gas produced anaesthesia of the larynx; Dr. Weill, of Lyons, moved by this statement, has made use of carbonic acid inhalations in dyspnoea, and finds that, whatever the cause, that distressing symptom is appreciably relieved. In phthisis the results were particularly good, an observation confirmed by M. Linossier (*Lyon Médical*), who said that both the difficulty of breathing and cough were quickly relieved by merely inhaling the gas given off from a glass containing a solution of bicarbonate of soda and tartaric acid in effervescence.

ROYAL METEOROLOGICAL SOCIETY.

AT the ordinary meeting of the Society, to be held by kind permission of the Council of the Institution of Civil Engineers at 25, Great George Street, Westminster, on Wednesday, March 21st, at 7 P.M., an address will be delivered by the President, Dr. W. Marce t M.D., F.R.S., on Atmospheric Electricity, illustrated by experiments; after which Mr. G. J. Symons, F.R.S., will make a short communication on "The Non-existence of Thunderbolts, elucidated by accounts of searches after them and the exhibition of specimens." The meeting will then be adjourned, in order to afford the Fellows and their friends an opportunity of inspecting the exhibition of apparatus connected with atmospheric electricity, including lightning conductors, photographs of lightning and damaged objects, and of such new instruments as have been invented and first constructed since the last exhibition.

DISPLACEMENT OF THE TESTICLE.

AT a recent meeting of the St. Petersburg Society of Russian Practitioners, Professor Vladimir N. Popoff showed (*Vratch*, No. 4, 1888, p. 75) a unique case of ectopia of the testicle in a patient aged 24. The scrotum was found to be normally developed, with the right testicle in its usual situation; but the left half of the scrotum was empty, while exactly at the root of the penis there was a swelling of the size of a walnut, covered with normal skin and containing an oval body which measured about four-fifths of the normal testicle, but felt somewhat softer. The patient said the swelling had been there since birth. He had, however, suffered in early childhood from an inguinal hernia, and Professor Popoff thinks it more likely that the displacement of the testicle developed under the influence of the rupture. The man's sexual power was formerly quite normal, but for about six months he had been impotent. Dr. Popoff could find no similar case in medical literature. Professor Wenzeslaw L. Gruber, the great Russian anatomist, who takes special interest in anomalies, considered the case unique.

ANOMALIES IN THE GENITALS OF IDIOTS AND EPILEPTICS.

IN the *JOURNAL* of February 25th appeared a review of Madame Sollier's work on the dentition of idiots. The result of a series of researches on the genitals of patients similarly afflicted was published in the *Progrès Médical* of February 18th. This task has been performed by Drs. Bourneville and Sollier. These observers found that certain malformations of the male organs were very frequent in 728 cases of idiocy which they examined. These malformations were phimosis, hypospadias, including the least aggravated form where the meatus lies unusually far back, in the normal site of the frænum, varicocele, atrophy or arrested development of the testicle, cryptorchism in various stages, and lastly club-shaped penis. The latter condition signifies a disproportionate size of the glans. The authors note that there is no evidence that this anomaly is produced by bad habits. We believe that they might have safely added that it represents a reversion to a lower type, like the flattened-out ears frequently seen in

idiots and weak-minded persons, and very characteristic of the cars of the higher quadrumana. The authors finally conclude as follows: 1. Idiots and epileptics present very frequent anomalies of the genitals, as proved by careful comparison with sane subjects. 2. These anomalies are least marked in epileptics who have not fallen ill till many years after birth. Their sexual potency, unfortunately, appears less impaired than in more aggravated cases, judging from the relative rarity of cryptorchism amongst them. 3. Atrophy of the testicle is slightly more frequent on the left side. 4. The physical and intellectual degeneration produced by epilepsy seems to exert a distinct influence on the production of varicocele, hardly ever seen in non-epileptic idiots. 5. Epilepsy beginning at birth produces a far more marked arrest of development, especially in the genitals, than when it appears later in life. 6. Idiots, epileptic or otherwise, frequently present a special club-shaped form of the penis, as above described.

ST. THOMAS'S HOME.

WE understand that there is a wide-spread feeling of dissatisfaction among London surgeons with the way in which the institution called St. Thomas's Home is conducted. It will be remembered that the easternmost block of St. Thomas's Hospital has been converted into a home hospital for paying patients; for an inclusive charge of eight shillings a day, they are provided with board, lodging, drugs, skilled nursing, and the services of a highly competent resident medical officer. It is alleged that no supervision whatever is exercised over the admission of patients, and that no inquiry is made as to their social or pecuniary circumstances. A very strong feeling exists that, under the guise of charity, a great injustice is being done to the medical profession, whose patients are, by extensive advertising, induced to enter St. Thomas's Home. It is said to be the practice, in surgical cases which are not treated by the resident medical officer, to call in some member of the St. Thomas's Hospital staff, who has to be satisfied with a reduced fee. Obviously the mere fact that many persons avail themselves of these facilities is no proof that they are deserving objects of this vicarious charity. There are in London a considerable number of nursing homes, which afford, at various rates, the advantages of a home hospital to patients who can there be treated by their own medical men, and there is a general opinion that a public charity like St. Thomas's Hospital ought not to go out of its way to compete for private patronage, and interfere with the ordinary relations existing between medical men and their patients.

DERMOID CYST OF THE MEDIASTINUM.

AT a recent meeting of the Berlin Medical Society, Dr. Loewenmeyer brought forward a tumour of this kind, rather larger than a child's head. It was removed from the body of a man who had been shown to the Society four years previously, his symptoms being then difficult to interpret. Apart from hæmoptysis and a moderate degree of pleuritic effusion on the left side, the attention was chiefly drawn at that time to a projection of the left side of the thorax, with loss of resonance, reaching from the clavicle to the sixth rib. The apex beat could not be felt over the cardiac region, but a thrill was noticed to the right of the sternum, also epigastric pulsation. A precise diagnosis was not made. The patient improved somewhat in hospital, and then went out and worked for a few years regularly, but no symptoms of pressure came on till quite recently, when severe recurring attacks of dyspnoea and cyanosis quickly induced a fatal result. The necropsy revealed a tumour occupying the greater part of the left half of the thorax. Anteriorly it was in contact with the chest wall, having pushed the heart entirely over to the right. Professor Virchow had examined the tumour, which contained in its interior cysts lined with epithelium and filled with soft sub-

stance of gelatinous consistency, but the outer and firmer portion of the tumour was composed of dermoid products, namely, epidermis, hair, fat. Cartilaginous plates were also found. Evidently there had existed abnormality of the chest wall in the embryonal stage of existence of the patient, so that part of the integument had been displaced inwards, and part of the respiratory apparatus outwards, at the time of closure of the thorax.

MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE SOCIETY.

AT a meeting of the Medical Sickness, Annuity, and Life Assurance Society, held on Wednesday, March 14th—present, Mr. Ernest Hart, in the chair, Dr. de Havilland Hall, Mr. S. W. Sibley, Mr. Noble Smith, Dr. Major Greenwood, Mr. F. Wallace, Mr. J. Brindley James, Mr. E. Bartlett—it was reported that seventeen proposals for membership had been received during February, sixteen of which had been accepted after due examination; £146 had been paid during the month in sickness pay for cases of locomotor ataxy, pulmonary disease, severe pneumonia, compound fracture, vesical calculus, etc. There was a sum of £2,000 surplus reserve available, £1,600 of which was ordered to be invested in municipal bonds at $3\frac{1}{2}$ per cent., making a total invested reserve of over £22,000. It was stated that £5,000 of the reserve which had been invested in corporation stocks showed an improvement in market value to the extent of £514, and that the other investments of the Society were in an equally healthy state. Inquiry was ordered into one or two claims in respect to which apparent irregularities had occurred. It was mentioned that since the starting of the Society in 1884 over 1,000 candidates had sent in proposals for membership. Much satisfaction was expressed at the continued prosperity and growing professional usefulness of the Society. Forms of application and copies of the rules can be obtained of the Secretary, Mr. C. J. Radley, 26, Wynne Road, Brixton S.W.

MORTALITY OF MODERATE DRINKERS.

SOME light is thrown on the vexed question of the superior healthfulness of abstinence or moderate drinking by recently published returns. The United Kingdom Temperance and General Provident Institution has two sections of lives. The one section consists of abstainers only; the other of non-abstainers, known drunkards being excluded. During the period of 21 years the number of expected deaths in the moderation section was 5,785. Only 164 fewer deaths actually occurred. The expectancy among the abstaining assured was 3,655, and the deaths amounted to 1,076 less. There is, therefore, the enormous deficiency in favour of teetotal survivors beyond expectancy of fully 26 per cent. The teetotal assured have received bonuses, on an average 24 per cent. higher than have accrued to the restricted drinkers. Authentic returns of the time during which members of friendly societies have received benefit tend to show the comparative freedom from incapacitating illness of abstainers. The *Rehabite Directory* for 1887-8 (quoted by the *Wiltshire County Mirror and Express*) gives some interesting comparisons. Between 20 and 60 years of age the Salford Unity of Rehabites (all abstainers) show only 48 weeks, as against 59.6 weeks of the Manchester Unity of Oddfellows, a superiority of 11.6 weeks. Between 60 and 70 years the Rehabites had 50.1 weeks to 62.5 weeks of the Oddfellows, a difference of 12.4 weeks. Grouping these figures together, the Rehabites had 98.1 weeks as against 122.1 weeks of the Oddfellows, a gain of 24 weeks. The abstaining followers of the son of Rehab also come out well compared with the Foresters. From 20 to 70 years of age they suffered from 98 weeks of ill-health, as opposed to 126.3 weeks among the Ancient Order of Foresters; between 70 and 80 years, from 122 weeks as opposed to 148.2 weeks among the Foresters. Collecting these returns together, the Rehabites

required financial benefits during 220 weeks, and the Foresters during 274.5 weeks, a difference in favour of the Rechabites of 54.5 weeks. There can be little doubt as to the general tendency of these striking tables in favour of the healthfulness of abstaining temperance.

HOW A BLIZZARD KILLS.

A CURIOUS observation has been made from a study of the condition in which the victims of the blizzard, which recently swept over Indiana and a wide tract of the North American continent were found. It seems that death was due not to the cold, but to suffocation; the unparalleled suddenness and extent of the fall of temperature converted the snow into ice crystals, which were ground by the gale to a fine, dry ice-dust, and the air was thus rendered quite unfit for respiration. This would make the effect of the blizzard analogous to that of the dreaded sand storms of the Sahara. It is stated that the number of deaths, so far from being exaggerated, has been a good deal understated by the local newspapers.

SULPHUROUS INHALATIONS FOR PHTHISIS.

A SERIES of observations has recently been made on a method of treating pulmonary tuberculosis, which, if not curative, would appear to possess a beneficial power over the progress of this dread malady. The method consists in the systematic inhalation of an atmosphere impregnated with the fumes of sulphurous anhydride (SO_2); and several ingenious plans of obtaining a constant supply of the gas have been devised, the best of which is a lamp constructed to burn bisulphide of carbon. The simple plan of burning flowers of sulphur in a closed room can, however, be resorted to if desired. Under its influence, it is said, the expectoration becomes more liquid, the mucous surfaces are relieved from the irritation caused by the presence of mucopurulent secretions, and the patient is spared the fatigue of violent paroxysms of cough. In a certain number of favourable cases the improvement in the general health which follows is reported to be sufficient to allow of the cicatrization of cavities and the subsidence of the more disquieting symptoms. The irritating effects of the vapour may be mitigated to some extent by burning opium and gum benzoin at the same time. Some two hundred observations have already been recorded, and the results have been sufficiently good to warrant a more general trial. Caution is advisable in the quantity of the gas, which should not exceed a certain proportion, which must be ascertained by close supervision of the patient during its administration.

CEREBRAL HYGIENE.

THE science of hygiene has accomplished so much good for society, that every one must look to its further development as an object to be desired by all well wishers of mankind. We desire here to refer to a special branch of hygiene which seems to call for more consideration than it has received at the hands of sanitarians. *Mens sana in corpore sano* is the wish of every man, and it is our work to discover the conditions under which this is to be attained and preserved, as well as how to avoid typhoid fever and small-pox. We possess already much knowledge upon these matters, but we need fuller and more precise information; overwork and constant worry lead to brain fever, but we want to know exactly how such agencies produce their effects; we need to formulate the physical signs of fatigued brain exhaustion, and to collect proofs as to the exact nature of their more common antecedents. The signs of rickets are often found in those who suffer from epilepsy, recurrent headaches, and other neuroses; but the exact causal connection has not to be demonstrated, and the frequency of such causation needs to be shown by large bodies of statistics. Syphilis, both

congenital and acquired, may produce brain disease, but how common this cause is we do not know. It is a matter of common observation that climatic and atmospheric conditions affect the working condition of the nerve system; some men work best in warm weather, others have most strength when it is cold. Dr. Warren P. Lombard has contributed an elaborate article on "the variations of the normal knee-jerk, and their relation to the activity of the central nervous system" in the *American Journal of Psychology*, and has there shown the relation of knee-jerk to atmospheric conditions; such exact observations are very important. What is the average strength and capacity for work in a man's nerve system, and how may it be estimated? There is a widely spread opinion that modern civilisation and social pressure have caused some degeneration of brain power, and that insanity and neuroses are on the increase; this is a question of vital importance to us. The effects of present systems of education on the brains of children may not be all for good, yet their object should be to aid cerebral evolution. It would be very interesting to have some exact information as to the brain condition of a large body of school children, founded upon observations carefully carried out.

EAST END SWEATERS.

A NOVEL but by no means an insignificant application was made recently to a magistrate at Thames Police Court, on behalf of an organised trade society of East End tailors by its secretary, himself a tailor, that proceedings should be taken in respect to the insanitary condition of 2,000 dwellings used as sweaters' dens. The complainant stated that he had a right to make the application, because he had reason to believe that the local authorities would not take any action in the matter, although they were fully cognisant of the evil. It would be, in our opinion, rather delicate for a magistrate to accede to such a course without some deliberation, because there was no evidence to show either the existence of 2,000 dwellings used as sweating dens, or that the administration of sanitary law with which local authorities are charged has been neglected to the extent stated. We have had ample proof, however, of the weakness of existing Acts on labour to grapple with this evil in places where adult labour only can be found, and we have also had an exposition of the inattention of local authorities to enforce cleanliness in those places wherein their several jurisdictions lie. But, whatever view be taken of the application, it seems clear that the sweated men and women in the East End are availing themselves of the various revelations lately made by official reports and declarations made in the House of Lords to rid themselves of the bondage under which they groan in having to work in such filthy places. It is singular that the persons complaining are not of the immigrant class, but London born, and it is they who cry out loudest against immigration, although their parents were introduced here under circumstances now so loudly complained of by their children. Mr. Slade stated that if any evidence could be adduced to prove that local authorities would not act after application to them, he would then grant process; but the Act of 38 and 39 Vict. cap. 55, known as the Public Health Act of 1875, says that the local authority has power to cause inspections to be made of any house as to the existence of any nuisance, and such inspection to be between 9 A.M. and 6 P.M.; and if any person make a written complaint that a nuisance exists, the local authority may authorise their officer to inspect, after twenty-four hours' notice, or without notice in case of emergency. A house is defined to include factories and other buildings in which persons are employed in any manufacture, trade, or business. There is nothing to show that other steps can be taken by a complainant, unless power such as is asked for here can be granted under 11 and 12 Vict. cap. 43, upon oath of complainant that by his personal application in writing;

he failed to move the local authority. It is nothing short of a public disgrace that these 2,000 dwelling-houses should be converted into filthy dens of workshops, where not only are persons assembled for daily work, but where the rooms are occupied by the families of immigrants or of workers for the sweaters. There have been reports enough for years past to show that this great evil is not abated, and it is high time that the Acts, now seemingly inoperative, should be made living factors by defining the duties of all local authorities, and making it incumbent upon the inspectors under the Local Government Board, especially the medical staff, to see that local officers do their work as men ought who are entrusted with important duties. The filthy condition of these workshop dens and dwelling-houses, which were built for bedrooms in small houses, where the atmosphere is pestiferous and over-crowding excessive, ought not to be allowed; such places are not to be found amongst our country people, but entirely amongst the foreign population, who import *inter alia* their dirty habits to the East End, at present stocked with at least 30,000 men, women, and children of foreign Jews. If the applicant can make good his case, and can show, as a deponent to facts, that the local authorities have failed in their duty, it will be good *prima facie* evidence that higher powers should be evoked to aid sufferers who seem resolved upon asserting their right as ratepayers to ask that the servants of the vestries be called upon to do their duty even though vested interests should, in some cases, intervene.

NURSING IN BURMAH.

THE first annual report of the Burmah Branch of the National Association for Supplying Female Medical Aid to the Women of India is a record of the important work which the Countess of Dufferin's Fund has, by its extension, been able to accomplish at Rangoon for Burmese women. Failing to obtain the use of the female wards of the Rangoon General Hospital as a maternity hospital, a large bungalow, centrally situated, was rented and opened as a hospital in April of last year. Accommodation has now been provided for 15 in-patients, and the total number of patients up to November 30th, 1887, was 142; of this number, 88 were obstetrical cases; 5 patients died. The Local Government makes an annual grant of 4,000 rupees, and a like sum has been promised by the Municipal Committee of Rangoon. Obstetric cases, except under particular circumstances, are received at the Lady Dufferin Hospital instead of at the General Hospital. Dr. Maria Douglass is the resident medical officer and superintendent, and Brigade-Surgeon Griffith consulting medical officer. It has been decided to grant six scholarships of 10 rupees a month to assist as many needy pupils. The difficulties of the teacher are necessarily great, for no books bearing upon the subjects of instruction have hitherto been printed in Burmese. Of those chosen by the committee for translation, one, *First Aid to the Injured* (St. John Ambulance Association), has already appeared. Dr. Barnes's *Manual for Midwives* and a book on nursing are being prepared for the press. Premises of grants in aid of the education of midwives have been received from Prome, Pegu, and Paungde. The honorary secretary is Dr. T. F. Pedley.

SCHOOLS AND INFECTIOUS DISEASE.

DR. TATHAM, the health officer of Salford, has done well to call public attention once more to the dangers resulting from the attendance at school of children who are suffering from infectious disease, who have not sufficiently recovered from an infectious disease, or who are still suffering from ear discharges or sore throats. He points out that scarlet fever, diphtheritic sore throats, whooping-cough, etc., are at the present time very prevalent, and that there is reason to believe that they are being extensively propagated through the instrumentality of schools. A very large

proportion of the sore throats occurring amongst children of school age are communicable from person to person, and there is ample evidence that children sent to school before they have perfectly recovered from scarlet fever or diphtheria, or whilst their throats are still in an inflamed condition, have, again and again, been the means of communicating disease to their school-fellows. The same remark applies to children who have not perfectly recovered from whooping-cough. School managers and teachers are often blamable, especially when they disregard, or do not fully recognise, the extent of the danger, and when, with an eye to fees and the government grant, they encourage the too speedy return of children to school after illness. But more generally the real culprits are the parents (and by no means the humblest of those only) who persist in sending their children to school solely to get them out of the way, and without consideration of their power of doing mischief to others. Dr. Tatham, therefore, advises managers of schools to refuse admission to any pupil (1) who is suffering from a sore throat, or from discharge from the ears, or (2) who has only recently or but imperfectly recovered from scarlet fever, small-pox, diphtheria, or whooping-cough, or (3) who comes from a house in which either of these diseases prevails, although the pupil himself may be apparently well, unless a medical certificate is produced to the effect that the pupil may return to school with safety to his fellows. It may be well further to draw attention to the provisions of Section 126 of the Public Health Act, 1875, which prescribe a heavy penalty against the wilful exposure of persons whilst suffering from any dangerous infectious disease, and it is desirable likewise to let it be generally known that the sending of a child to school whilst imperfectly recovered from such a disease constitutes exposure, and would render the parent or guardian liable to punishment under the Act.

HAYA POISON AND ERYTHROPHLŒUM.

DR. F. GOLDSCHMIDT, of Nürnberg, has made a further trial of the Haya poison (*Centrab. f. Klin. Med.*, No. 7). He confirms Lewir as to the effects of the above doses, but tried still weaker dilutions—namely, $\frac{1}{2}$ per cent. Instillations of this strength caused perfect anaesthesia within ten or fifteen minutes, and the connective tissue and cornea could be treated in any way, even with the actual cautery, without giving any pain; but the effect only lasted three or four hours, then gradually declining, whereas the large dose took effect for two days or two days and a half. The anaesthesia could be prolonged at will by a daily instillation of a small dose and this fact is important to notice. There was only a slight temporary irritation of the conjunctiva after the $\frac{1}{2}$ per cent. instillation; the pupil did not widen, intra-ocular pressure was not increased, and no corneal turbidity ensued after several days' use of the solution. The iris was less sensitive after several applications, but could not be rendered perfectly anaesthetic. The anaesthetic effects were then tried in the out-patient department (Dr. v. Forster's eye patients), and were found to be excellent. A drop of $\frac{1}{2}$ per cent. solution applied to the eye induced in fifteen minutes perfect insensibility of the cornea and conjunctiva lasting three or four hours. There was at first slight conjunctival irritation, also a feeling of heat in the eye, soon giving place to anaesthesia. If the eye was already inflamed the irritation was still greater. Splinters of iron in two cases were extracted from the eye under its use, and the lachrymal canal was in one case set up without any pain. The anaesthesia was accompanied by vascular dilatation, not, as in the case of cocaine, by vascular contraction. Hence Goldschmidt thinks that the new drug will have a less extensive field of application than cocaine, but, on the other hand, it has not the effects on the pupil which cocaine has, and does it affect accommodation or intra-ocular pressure. Whether it can be used for iridectomies and such-like deeper operations of experience must determine. As to its action on the buccal and pharynx

geal mucous membrane, 1 per cent. solutions had no effect; but it must be remembered that cocaine also requires to be used here in much stronger doses than when instilled into the eye. Goldschmidt obtained some of the drug from Herr Weigle, Nürnberg, but the price is very high at present. Professor Liebreich has a long article on this subject in the *Berliner Klin. Wochenschrift*, February 27th. He is of opinion that the Haya poison is in reality a snake poison from the *Naja Haya* (snake), and that the specimen examined by Dr. Lewin was accidentally contaminated with erythroplœum cortex. Professor Liebreich bases his opinion on the fact that the poison only acted when injected beneath the skin; as to the frogs rendered insensible to pain by it, he declares that they pass into a "leuco-phlegmatic" condition in captivity, already described by Du Bois Reymond, and are insensible to injuries; further, that undoubted Haya (snake) poison supplied to him by Professor Robert Koch caused the local anæsthesia of the eye, and other physiological results attributed by Lewin to erythroplœum; lastly, that a great many substances cause local anæsthesia, especially those which coagulate the blood—for example, iron perchloride, dialysed iron solution, resorcin. Liebreich is somewhat severe in terming some of Lewin's conclusions "a mixture of hypothesis and erroneous observation." Finally, Mr. T. Christy has written to Herr Lewin to say that the name "Haya" was given because a Mr. Hay, of Aden, procured the substance.

SCOTLAND.

GLASGOW TRAINING HOME FOR NURSES.

THE annual report of this Home shows that it continues to grow in the estimation of medical men and of the public. From it nurses had been sent out to 448 cases during the year, an increase of 31 over the preceding year; while 216 patients had been treated in the private hospital, 157 of whom required to undergo operation. The total expenditure was a few pounds short of £4,000. The institution is now practically self-supporting, and during the fourteen years of its existence no less a sum than £26,000 had been earned as fees for nursing.

LANARKSHIRE LUNACY DISTRICTS.

THE General Board of Lunacy has decided to divide the Glasgow Lunacy District, which embraces the whole county of Lanarkshire, into four districts. Of these, three—that of the City of Glasgow parish district, Bavour parish district, and Govan Combination parish district—are mainly town districts, the fourth embracing the remainder of the county of Lanark.

BLIND AND DEAF-MUTE PERSONS IN SCOTLAND.

By the latest return, it appears that the number of blind and deaf-mute persons in Scotland assisted from the poor-rates was, on May 14th last, 987, of whom 345 were blind males and 421 blind females, while of deaf-mutes there were 102 males and 119 females. Of the total number, 352 were housed and 635 were in receipt of outdoor relief. The cost to parochial boards for each adult maintained in special institutions varied from £10 to £22.

MILK ADULTERATION.

At the Glasgow Sheriff Court, on March 9th, a particularly bad case of milk adulteration came up for disposal. The analysis showed, in the case of cream, 22 per cent. of added water and 10 per cent. of boiled starch added for thickening purposes; and in the case of sweet milk, 3 per cent. of water and 6 per cent. of boiled starch. The sheriff marked his sense of the grossness of the fraud by imposing a fine of £10, with the alternative of thirty days' imprisonment.

POISONING BY CARBOLIC ACID.

A CHILD, 6 years of age, died at Cambuslang on March 9th from the effects of drinking carbolic acid. The boy was ill with typhoid fever, and had been left alone for a short time. During this time he got up and drank part of the contents of a bottle of carbolic acid obtained for disinfection. He died in four hours, having speedily become unconscious.

INFECTIOUS DISEASES IN EDINBURGH.

THE daily return of patients in the City Hospital, Edinburgh, submitted to the Town Council on Tuesday, showed the number was the lowest for a year. There were 91 patients under treatment—53 adults and 38 children—and the cases consisted of 36 of scarlatina, 21 of measles, 14 of erysipelas, and 10 of enteric fever. This is in marked contrast to the state of matters a year ago, when it was scarcely possible to accommodate the great number of cases of scarlatina requiring admission.

ST. ANDREWS UNIVERSITY STUDENTS AND DUNDEE UNIVERSITY COLLEGE.

By a majority of votes the Students' Representative Council of St. Andrews University have given the cold shoulder to the proposed amalgamation with Dundee University College. A meeting for the discussion of the subject was held in one of the class-rooms on Monday, when the following resolution was proposed and carried by a large majority of votes:—"That this meeting strongly protests against any proposal which would interfere with the integrity of St. Andrews University, as amalgamation with University College, Dundee, would most certainly do." By amalgamation, the resolution meant any arrangement whereby Dundee University College should become part of the University of St. Andrews, and its officials have a share in the management of the University. A counter motion was proposed, but was defeated by eighty votes to eighteen. Fortunately for both institutions and their probable united future, the resolution passed is of ephemeral and purely academic interest. Any suitable arrangement by which a proper School of Medicine and Science in Dundee may become an integral part of St. Andrews University associated with it in the teaching of medicine and granting of degrees would be of infinite value to both, and would utilise the large field of Dundee for clinical purposes and of St. Andrews University for culture.

THE SCOTTISH UNIVERSITIES' BILL.

A DEPUTATION, representing the University Council Associations of Edinburgh and Glasgow, waited on Lord Lothian at Dover House on March 9th. The deputation consisted of Mr. McKie, advocate, and Dr. Littlejohn, of Edinburgh, and Drs. McVail, Duncan, J. K. Kelly, and Knox, of Glasgow, with the Secretary and Treasurer of the Glasgow Association. The deputation was introduced by Lord Wemyss, and accompanied by an imposing array of Scotch Members of Parliament. Mr. McKie and Dr. McVail, on behalf of the Associations, which now number fully 2,000 members, urged that the University Council under the Bill should be representative of the Senate, the graduates, and the public in equal proportions, and that the Court should be made the University governing body, with sole control of the funds. Dr. McVail urged that power should be given to the universities to affiliate colleges. Lord Lothian, in reply, expressed the belief that the Bill would be found generally to meet the views expressed in a satisfactory manner. He indicated his desire to have the students represented in the Court, with which Mr. McKie and Dr. McVail expressed sympathy. He also indicated that the Bill would be made public in a few days.

MYSTERIOUS EPIDEMIC IN GLASGOW.

Dr. RUSSELL, Medical Officer for Glasgow, is investigating an epidemic disease which has appeared in the Roman Catholic Industrial Schools there. (A telegram received from a high authority in Glasgow states that a large number of boys have been attacked in rapid succession, and four have died. The girls' school, which is a separate building, but with a kitchen common to girls and boys, remained exempt till very recently, when two girls employed in the kitchen became infected—it is supposed by direct contagion. Many of the sick have been removed to the Belvedere Hospital, but as yet no information has been obtained tending to elucidate the nature, or cause of the epidemic, which has some points of resemblance to a very malignant type of influenza, and is often attended by pneumonia, but not by any characteristic eruption, the temperature often rising to 105°, or even higher, but with very marked remissions, not distinctly periodic. In two fatal cases a *post-mortem* examination was made, but nothing very distinctive was elicited. The school is in close proximity to an old graveyard, and otherwise has been regarded as under suspicion from a sanitary point of view. Dr. Russell is preparing a report on the whole subject, and an inquiry is also being conducted according to instructions from the Home Office.

IRELAND.

BELFAST DISPENSARY DISTRICT.

THE Local Government Board has confirmed the decision of the Belfast Dispensary Committee dismissing Dr. Spedding from his position as one of the dispensary officers for Belfast.

OVARIOTOMY IN BELFAST.

A GREAT revival of the operation of ovariotomy has taken place in Belfast within the last two or three years. At the last meeting of the Ulster Medical Society, a very satisfactory series of successful cases performed during the past twelve months was reported, the operators being Professor Sinclair, Dr. Dempsey, Dr. Byers, Dr. Kennedy Wheeler, and Dr. Mackenzie.

BELFAST MEDICAL STUDENTS' ASSOCIATION.

At a recent meeting of this Association, the President reported the result of an interview with Dr. Dunne, secretary of the Royal University, regarding the grievances of the medical students of the Belfast School of Medicine, and stated that his representations had been most courteously received, and that the University had agreed to concede some of the most important points in dispute. A long discussion ensued on some points regarding clinical teaching in Belfast, but finally the whole question was adjourned for further consideration.

FEEES TO MEDICAL OFFICERS OF HEALTH.

A CASE interesting to medical officers of health was decided in the Appeal Court, Dublin, on Saturday, March 10th. The case was brought by the Irish Medical Association, on behalf of Dr. Roulstone, against the Guardians of the Strabane Union. The Court of Queen's Bench had already ruled in favour of the defendants. The question turned upon the construction of the following rule: "We, the Local Government Board, do hereby, in the cases falling within the provision recited, approve of such rate of remuneration, not less than £1 ls., and not exceeding £2 2s., a day, or part of a day, as may be fixed by the sanitary authority, in each case of legal proceedings as aforesaid." The plaintiff contended that the fee was to be paid for each case, while the defendants held that it was only to be paid for the day's attendance. The Court of Appeal now gave judgment, uphold-

ing the decision of the Court below, namely, that the rule prescribes a payment per day. It appears certain that the rule, although clumsily drawn, does mean this. The phrase is "per day," "in each case of legal proceedings as aforesaid." But the discussion suggests that the Local Government Board should have been more liberal in its allowance. The fee "per day," which may mean that the witness has to travel a long distance and give evidence in fifty cases for £1 ls. is a preposterous one. Imagine a barrister being paid in the lump in this fashion. We would suggest that the Irish Medical Association should now seek to have this rule revised. The medical witness ought to be paid a fee of £2 2s. for the first case, and at a smaller rate for those which succeed at the same sitting. Perhaps the new Medical Commissioner, whoever he may be, will signalise his advent by a more liberal view of the value of medical services. When a medical man permits such an estimate to be put on the work of his professional brethren it is hard to expect that others will view it differently.

THE LOCAL GOVERNMENT BOARD COMMISSIONERSHIP.

THE statement which we made last week, on the authority of a Dublin telegram, that Dr. Henry Fitzgibbon had been appointed to succeed the late Dr. Croker King as Medical Commissioner of the Local Government Board, was incorrect; it had, however, some foundation. There is no doubt that the appointment was determined upon, but an unwary divulgence of the fact brought out very strong opposition from the Dublin newspapers, and further set in motion an active member of Parliament, who protested against the intentions of the Government. The original determination has not been carried out, and it is now stated very confidently that Dr. F. F. Maccabe is to be the new Commissioner. To this gentleman there can be no possible objection on the score of his entire fitness for the office. He has been a dispensary medical officer and an inspector under the Local Government Board. He is now medical member of the Prisons Board and Inspector of Reformatory and Industrial Schools. He is generally regarded as a very able administrator, and he is certainly an experienced official. The mode of making these appointments is a very bad one, and in this case it has inflicted a gross injury upon a candidate. Dr. Fitzgibbon was selected, and then as quickly "dropped," owing to political pressure. It is the business of the Government officials who confer these appointments to make them on merit alone, and not for reasons of friendship or influence. There ought to be no undue haste, but a deliberate weighing of the abilities of every candidate before a decision is arrived at. Of course, it is hardly necessary to say, this is not done. Very often it is "first come, first served;" or the importunities of a pushing friend end in carrying away a prize which ought legitimately to go to someone who better deserves it. Even such high personages as Cabinet Ministers are paid by the country to do their duty without favour or affection. It does not add to our respect for them when we find that they must be reminded of this elementary fact so frequently. On March 15th the *Irish Times* announced on authority that "the statement of the appointment of Dr. Maccabe is premature and unauthentic, and will in all probability be found incorrect." But our Dublin correspondent telegraphs that the belief is nevertheless very general that Dr. Maccabe has been appointed, and that Dr. O'Farrell, Local Government Inspector, will succeed him on the Prisons Board.

THE LATE DR. DELAHOYDE, OF DROGHEDA.

DR. DELAHOYDE, the oldest medical practitioner in Drogheda died recently, aged 78. He had for many years held the post of medical officer to St. Mary's Dispensary, Drogheda Union, but resigned last January. It was proposed to present him with a

retiring allowance, but pending the consideration of the matter his death took place. The guardians last week adopted a vote of condolence with the deceased gentleman's family.

THE WATER SUPPLY OF BELFAST.

THE alarming reports which have lately been in circulation regarding the quality of the water supplied to the inhabitants of Belfast are not corroborated by the report just issued by the borough analyst, Dr. Hodges, which is somewhat reassuring in character. Six specimens were submitted to him for examination, and have not been found to differ materially from those examined in previous years. They show, however, an increase of solid matters, both mineral and organic, but these "are chiefly in suspension, and are rapidly deposited on the water being allowed to remain at rest." Dr. Hodges adds that the amount of free and albuminoid ammonia present, and the absence of nitrates (except a trace in one specimen), also the small amount of chlorine, are satisfactory proofs that the organic matter is mainly vegetable in origin. One specimen he regards with suspicion, as it shows an excess of albuminoid ammonia. He concludes by stating that the water is one which is greatly improved by subsidence, and would be still more improved by efficient filtration. The prolonged and unprecedented drought has greatly increased the difficulties of the Water Commissioners, who have in the past earned public confidence by their zeal and efficiency. They are pushing forward the new extensive waterworks as rapidly as possible, and hope to have at least a portion of them in operation by next July or August. Fortunately, a considerable rainfall has now come to relieve their most pressing necessities.

DEGREES FOR LONDON MEDICAL STUDENTS: THE FORTHCOMING ROYAL COMMISSION.

LORD CRANBROOK'S official statement in the House of Lords fore-shadows the early appointment of that Royal Commission for which we asked from the first to consider the applications of the Colleges of Physicians and Surgeons of London for a degree-granting university, and the collateral applications of the Teaching University of London and of University and King's Colleges for like powers. In some quarters this decision of the Government has caused great disappointment, for some at least of the delegates of the two Colleges were led to believe that they had only to ask the Privy Council for the powers which they sought, to obtain them; and if this application had been expressed in a more constitutional and well considered scheme, that anticipation might well have been realised. We pointed out from the first that such an application could only succeed under the conditions giving to the new degree-granting power a suitable representative shape, and creating university powers with due regard to broad and just principles, and without aiming at a special monopoly.

Those counsels did not prevail, and the powers were sought in such a form as jeopardised the principle involved. Under the circumstances the appointment of a Royal Commission became absolutely necessary, and its early issue is very desirable. This will of course put an end to the proposed legal arguments, which would otherwise have been held before the Privy Council, and there can be little doubt that the much wider basis of inquiry which will be opened by the investigations of a Royal Commission, will lead to a broader discussion and a more valuable result than could otherwise have been attained. As to the *personnel* of the new Royal Commission, many rumours are in circulation, none of which have, we believe, at present any solid foundation. Among those mentioned are Lord Selborne, Lord Herschell, Sir Francis Sandford, Sir Lyon Playfair, Mr. Mundella, Mr. Plunket, and representatives of the London University and the two Colleges; but speculations as to the constitution of the Commission are of course complicated by the doubt whether any or which of these gentlemen would be willing to serve. For our own part we should be glad to see such men as Lord Derby and Sir Henry James acting on the Commission. It is above all things desirable that it should be weighty and impartial, and not likely easily to yield to the powerful personal influences which may probably be brought to bear upon it.

ASSOCIATION INTELLIGENCE.

COUNCIL.

NOTICE OF MEETING.

A MEETING of the Council will be held at the Offices of the Association, No. 429, Strand (corner of Agar Street), London, on Wednesday, the 18th day of April next, at 2 o'clock in the afternoon.

FRANCIS FOWKE, *General Secretary.*

March 15th, 1888.

NOTICE OF QUARTERLY MEETINGS FOR 1888.

ELECTION OF MEMBERS.

Meetings of the Council will be held on April 18th, July 18th, and October 17th, 1888. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before each meeting, namely, March 28th, June 27th, September 26th, and December 28th, 1888.

ANY qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member *by the Council* or by any recognised *Branch Council*.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No member can be elected by a Branch Council unless his name has been inserted in the circular summoning the meeting at which he seeks election.

FRANCIS FOWKE, *General Secretary.*

COLLECTIVE INVESTIGATION OF DISEASE.

THE Report upon the CONNECTION OF DISEASE WITH HABITS OF INTERPERANCE, which was presented to the Section of Medicine in the Annual Meeting of 1887 will shortly be published in the JOURNAL.

Reports upon the two remaining inquiries, namely, that into DIPHTHERIA, and that into the GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES, are in preparation, and will be published as soon as ready.

The following inquiry only of the first series remains open, namely, that on THE ETIOLOGY OF PHTHISIS.

A fresh inquiry into the ORIGIN AND MODE OF PROPAGATION OF EPIDEMICS OF DIPHTHERIA has been issued.

Memoranda upon these subjects, and forms for recording observations, may be had on application to the Secretary of the Collective Investigation Committee, 429, Strand, W.C.

BRANCH MEETINGS TO BE HELD.

SOUTH-EASTERN BRANCH: EAST AND WEST SUSSEX DISTRICTS.—A conjoint meeting of the above districts will be held at the Grand Hotel, Brighton, on Thursday, March 22nd. F. W. Salzmann, M.B.C.S., will preside. Meeting at 3.30 P.M.; dinner at 5.30 P.M.; charge 6s., exclusive of wine. The following communications are promised: Dr. Starling: A case of Fibroid Induration of the Stomach (with specimens). Mr. Howard Marsh: Recovery after Laparotomy for Intestinal Obstruction; with Remarks. Dr. Mackey will show: Cases of Lupus Erythematosus, etc. Gentlemen desirous of contributing short papers or cases, should write at once to the undersigned or to Dr. Gostling, West Worthing.—T. JENNER VERRALL, Honorary Secretary, 97, Montpellier Road, Brighton.

SHROPSHIRE AND MID-WALES BRANCH.—The next meeting of the Branch will be held at the Salop Infirmary, on Tuesday, March 27th, at 3 P.M. Mr. W. Eddowes in the chair. Gentlemen wishing to exhibit or read notes of cases, or to bring forward subjects for discussion, are requested to communicate with the honorary secretary, EDWARD CURETON, Shrewsbury.

SOUTHERN BRANCH: SOUTH WILTS DISTRICT.—The next meeting of this Branch will be held at the Bath Arms, Warminster, on Wednesday, March 21st, at 4 o'clock. Dinner at 6 o'clock. Tickets 5s., not to include wine. Members intending to be present, to communicate with the honorary secretary, H. J. MANNING, Laverstock, near Salisbury.

EAST ANGLIAN BRANCH: ESSEX DISTRICT.—The next meeting of the members of the Essex District and their friends will be held at the Saracen's Head Hotel, Dunmow, on Friday, March 23rd, at 2.30 P.M. R. B. Marriott, Esq., Swaffham, President of the Branch, will preside. There will be high tea at the hotel at the conclusion of the meeting. Trains leave Dunmow for Braintree, Colchester, and Ipswich at 6.35, and for Stortford and London at 6.45. The following papers have been promised—R. B. Marriott, Esq. (President): Short Notes on a few cases of Stone in the Bladder. Dr. F. de Havilland Hall (Lon-

don): Remarks on certain Remedies employed for the relief of Pain and Spasm. R. C. Lyle, Esq. (Dunmow): Remarks on two unusual cases of Constipation. Gentlemen wishing to be present will kindly communicate to that effect with the Honorary Secretary on or before Wednesday, March 21st.—C. E. AUBORT, Honorary Secretary.

NORTH WALES BRANCH.—The intermediate meeting of this Branch will be held at the Pwll-y-crochion Hotel, Colwyn Bay on Tuesday, March 20th, at 2.45 P.M., Charles Williams, Esq., President of the Branch, in the chair. After the usual formal business the President will deliver his address, postponed from the annual meeting. The following papers and communications will be read:—Mr. T. H. Bickerton: Two cases of successful Extraction of Foreign Bodies from the Eye. Mr. L. F. Cox: Climacteric Insanity. Dr. F. Inlath: A case of Hystero-Epilepsy of twenty years' duration treated by Removal of Uterine Appendages. Mr. Robert Jones: Some Common Errors in the treatment of Fractures. Dr. John Roberts (Menai Bridge) will show Pneumococci in the sputum of a case of so-called "Creeping Pneumonia." Mr. J. Lloyd Roberts: Disinfection. Mr. Richard Williams: Some remarks on the Removal of Nasal and Aurial Polypi. Dr. E. J. Lloyd will open a discussion as to the question of holding Consultations with legally qualified homoeopaths.—W. JONES-MORRIS, Honorary Secretary, Portmadoc, Baintree.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.—An ordinary meeting of the Branch will be held at 198, Union Street, Aberdeen, on Wednesday, March 21st, at 8 P.M., Dr. Smith, of Kinnairdy, President, in the chair. Business:—1. Minutes, nomination of new members, etc. 2. Ballot for the admission of Dr. John Anderson, Elmhill House, Aberdeen; Professor Cash, Dee Street, Aberdeen; Dr. Hutcheon, Alford; Dr. George Mair, Crown Street, Aberdeen; Dr. Morrison, Rosieburn, Methlie; Dr. Stephen, Belhelvie; and Dr. Whitton, Aberchirder, as ordinary members of the Branch. 3. Communication from Council of Association ament fees payable to medical witnesses in criminal cases. 4. Dr. Gordon: Case of Complete Occlusion of External Auditory Meatus (exhibition of patient). 5. Dr. Gordon: Exhibition of Electrical Apparatus, including a Uretlral Endoscope and demonstration of its Use. 6. Dr. Mackenzie Booth: Case of so-called Spontaneous Combustion, with Photograph. 7. Dr. Edmond: Specimens of Disease of Liver.—ROBERT JOHN GARDEN, J. MACKENZIE BOOTH, Honorary Secretaries.

SOUTH WALES AND MONMOUTHSHIRE BRANCH.—The spring meeting of this Branch will be held at Pontypridd about the second or third week in April. Members wishing to read papers, etc., are requested to send titles to either of the Honorary Secretaries by the end of March, in order that they may be inserted in the circulars.—ALFRED SHEEN, M.D., Cardiff; D. ARTHUR DAVIES, M.B., Swansea, Honorary Secretaries.

METROPOLITAN COUNTIES BRANCH: NORTH LONDON DISTRICT.—The next meeting of this district will be held at the North West Hospital, Kentish Town Road, on the evening of Wednesday, March 28th, at 8.30, when A. E. Durham, F.R.C.S., President of the Branch, will take the chair. Some interesting cases to the hospital will be exhibited. Dr. Hood will read a paper on Empyema following Pneumonia; or Clinical Notes on Membranous Sore Throat. The new committee of this district will assemble at 8 P.M. All members of the profession are welcome to attend.—GEORGE HENTY, M.D., Honorary Secretary, 30, Camden Road, N.

ADELAIDE AND SOUTH AUSTRALIAN BRANCH.

THE monthly meeting was held on January 26th, 1888. The President (Dr. DAVIES THOMAS) was in the chair, and the following gentlemen were present: Drs. Lawley, Gardner, London, Mackintosh, Mitchell, Poulton; Messrs. Aitken, Bickle, Clindening, Corbin, Finnis, Giles, Hayward, Lawrence, and the Honorary Secretary (Mr. Cleland).

New Member.—William Baly, M.R.C.S., was elected a member of the British Medical Association and of its South Australian Branch.

Case.—Dr. POULTON brought forward a man whose ankle he had excised for disease, the result being a useful joint.—Mr. CORBIN exhibited a patient suffering from exophthalmic goitre.—Dr. LONDON showed a case of buphthalmos in a little girl, a patient at the Adelaide Children's Hospital.

Excision of Cancerous Larynx.—Dr. GARDNER read notes of a case in which he had successfully removed the entire larynx for carcinoma, and showed the specimen. He had performed the operation twice, each time successfully. He thought sufficient data had not yet been collected, owing to the paucity of cases—not over 100 in all—to enable surgeons to decide whether the operation was a justifiable one or not. If Hahn's (of Berlin) success could be calculated on, namely, where one at least of his fifteen cases had had no recurrence of the disease after a lapse of seven years, the operation certainly would be justifiable. Unfortunately in Great Britain there was a prejudice against the operation, and he thought the ill-success was mainly due to climatic influences. The artificial larynx he recommended was a vulcanite one made by Dr. Woodburn for him, modelled after Dr. Foulis's original instrument.

Double Mouth.—Dr. LONDON read a brief account of a male infant who was under his care at the Adelaide Children's Hospital, and who lived to three months old. The patient had two mouths, separated posteriorly by a central pillar of the fauces, and leading into a common pharynx, but united anteriorly by a common

buccal orifice, to the upper border of which was attached the remains of the fused adjacent cheeks. These occupied a great portion of the mouth cavities, and extended backwards to the central faucial pillar. There were two tongues, which moved independently, and two pairs of jaws, considerably distorted in parts. There was a third central nostril. The division of the larynx was doubtful. No *post-mortem* examination was allowed.

BERMUDA BRANCH.

A GENERAL meeting of the Branch was held at the Town Hall, Hamilton, on Saturday, January 28th. Dr. PARK TUCKER, President of the Branch, occupied the chair. About twelve members and visitors were present.

Narcotic Inebriety.—By request of the Society, Dr. J. B. MATTISON, of Brooklyn, gave an address on the subject of narcotic inebriety. Attention was called to the increased use of opium, chloral, and cocaine, notably in France, Germany, and America. The genesis of the disease was a physical necessity in most cases. The speaker said in such cases his plan was to establish an entire narcotic disuse by regular reduction in ten days, meantime bringing the nervous system under the sedative influence of bromide of sodium in initial doses of thirty grains at twelve-hour intervals, increasing the dose ten grains daily, and reaching, if required, a maximum of 120 grains at the end of the withdrawal period. The resultant reflex irritation was treated by hot baths, cannabis indica, coca, and electricity, with a subsequent strengthening regimen. The prognosis was good as to recovery, but in most cases sooner or later there was a return to the narcotic due to a renewal of the original cause, or to other conditions beyond control.

Vote of Thanks.—A vote of thanks to Dr. Mattison closed the meeting.

SOUTH-EASTERN BRANCH: EAST SURREY DISTRICT.

THE spring meeting of this district was held at the Queen's Hotel, Upper Norwood, on Thursday, March 8th, at 4 P.M., W. F. R. BURGESS, M.D., of Streatham, in the chair.

Next Meeting.—After reading the minutes of the previous meeting, it was proposed by Dr. THOMPSON, seconded by Dr. A. CARPENTER, and unanimously resolved, that the next meeting be held at Croydon on Thursday, May 10th, and that Mr. T. A. Richardson, of Croydon, be invited to preside.

Representative on Council.—Dr. John H. Galton, was unanimously nominated by the meeting to represent the Branch in the Council of the Association.

Mechanical Treatment of Joint Disease.—Mr. NOBLE SMITH gave a demonstration of recent improvements in the treatment of diseases of the joints, exhibiting numerous splints and other mechanical contrivances, and their mode of application in each particular case.

Possible Danger of Milk Diet.—Dr. ALFRED CARPENTER showed a hard mass of solid cheesy substance vomited from the stomach of a calf fed entirely on milk, and pointed out the possibility of a similar concretion occurring in patients restricted to milk diet.

Hysterectomy.—Mr. H. G. PLUMMER read notes of a case of rapidly-growing soft tumour of the uterus, which, even on abdominal section, seemed so fluctuating that it closely simulated an ovarian cyst. After removal of the uterus with the tumour and the uterine appendages (small cysts being found in the ovaries), the stump was fixed in the lower angle of the abdominal wound. The progress of the case was very satisfactory. The tumour was a myxo-myoma.

Dinner.—After the meeting fourteen members and visitors dined together.

ERRATA.—In the review of Dr. McVail's *Vaccination Vindicated*, published on March 10th, there is an error in the statement with regard to the Kilmarnock statistics. Instead of (p. 541, line 12) "small-pox was accountable for 91 out of every 100 deaths under 5 years of age," read "91 out of every 100 deaths from small-pox were under 5 years of age," also, in the concluding line of the first paragraph of the review, for "Royal Commission," read "Select Committee."

AMBULANCE CLASS, TOBERMORY.—Dr. Shaw, Glasgow Royal Infirmary, examined the ambulance class conducted by Dr. Maxwell, Tobermory, awarded a certificate of proficiency to every member of the class he had examined, and complimented them on the very satisfactory appearance they had made.

SPECIAL CORRESPONDENCE.

VIENNA.

[FROM OUR OWN CORRESPONDENT.]

On the Diagnosis of Carcinomatous and Tuberculous Perichondritis of the Larynx.—Syphilitic Conjunctivitis.

DR. M. HAJEK, assistant to Professor Schnitzler, reports, in a recent number of the *Internationale Klinische Rundschau*, a case of laryngeal disease which he had observed at the Vienna Polyclinic, with the view of showing that the differential diagnosis between cancer and tuberculosis of the larynx sometimes presented the greatest difficulty, even when every possible means of diagnosis was used. A man, aged 55, was, on June 15th, 1887, admitted, for the first time, into the wards of Professor Schnitzler for hoarseness, which had lasted three years, and severe dyspnoea, which had recently supervened. The patient had previously been treated by Dr. Mahl, of Lemberg, who gave the following particulars of the case:—"The patient had, in March, 1886, fallen ill with symptoms of simple laryngitis, and, from three to four months later, Dr. Mahl discovered a growth as large as a bean and having the appearance of a gooseberry, on the right vocal cord. He removed the growth with forceps and cauterised the seat of implantation with chromic acid for some days. The patient's voice greatly improved after the operation. Six weeks later the growth recurred, with vegetations on the edge of the cord. Owing to repeated chills to which the patient was exposed in the course of his daily work (he was a railway servant), considerable swelling of the right arytenoid cartilage, with gradual immobility of the right part of the larynx, also took place. The patient's condition grew worse from that time; cough, dysphagia, and dyspnoea gradually increased."

Laryngoscopic examination in the Vienna Polyclinic revealed the presence of considerable swelling of the epiglottis, and extensive swelling of both ventricular bands and the arytenoid cartilages, the right one being almost immovable. The vocal cords could not be seen, except the posterior end of the left one, which appeared to be moderately congested. The subglottic region could not be seen owing to the great narrowing of the rima glottidis.

External examination of the neck showed that the thyroid and cricoid cartilages were much thickened, and that the surrounding tissue was infiltrated. The cervical glands formed a tumour as large as a man's fist, which at one spot showed distinct fluctuation on the left side.

Examination of the lungs revealed the presence of catarrh of the apex, but the patient had never suffered from hæmoptysis, and there was no tuberculosis in his family. The sputum proved to be free from tubercle bacilli after repeated examinations. The patient had never suffered from syphilis.

Taking all these facts into account, what diagnosis could be come to? Tuberculosis was first thought of. The infiltration of the epiglottis, and the swelling of the ary-epiglottic folds, which was characteristic of tuberculosis, was suggestive of diffuse tuberculous infiltration of the larynx.

The fact, however, that the inter-arytenoid mucous membrane, which as a rule is chiefly affected in tuberculosis, was only slightly swollen, and that no ulceration could be detected anywhere, led Professor Schnitzler to diagnose cancer. There were nevertheless certain features in the case which made the diagnosis of carcinoma doubtful, namely, the size of the enlarged cervical glands, the fact that they were not so solid as they usually are in a case of cancer, and the presence of fluctuation over a circumscribed area, which is also not a common accompaniment of carcinoma of the larynx. All these conditions, on the other hand, were characteristic of scrofula.

The enlargement of the lymphatic glands in carcinoma is generally limited to the sub-maxillary glands, which were solid and never attained any considerable size. The fact that no tubercle bacilli could be detected in the sputum had to be taken into account as far as active tubercular disease in the lungs was excluded by it; it was of no significance, however, as establishing the nature of the laryngeal affection.

Recourse was next had to two kinds of exploration, namely, (1) puncture of the fluctuating cervical gland; and (2) excision of part of the right ventricular band for microscopic examination. The pus which escaped, on incising the abscess quite

resembled that from suppurating scrofulous glands, and it was supposed that a tubercular perichondritis of the thyroid and cricoid cartilages, with chronic œdema and a tubercular cervical gland might be present. There were no tubercle bacilli in the pus, a fact which was not, however, inconsistent with the theory of tuberculosis, as it had been stated by several authors, such as Koch, Garré, Krause, etc., that pus of tuberculous abscesses contained only few or no tubercle bacilli. The microscopic examination of the excised portion of the right ary-epiglottic fold was negative; only the epithelium seemed to have been relaxed. It was, therefore, reasonable to suppose that the whole swelling at the orifice of the larynx was only due to chronic œdema, and that it was not due to the deposition of tuberculous or carcinomatous material. Two possibilities, had, therefore, to be taken into consideration, namely, a subglottic carcinoma with chronic œdema of the larynx and consecutive perichondritis, or primary tuberculous perichondritis of the thyroid or cricoid cartilages. No positive proof, however, could be obtained of either hypothesis.

Professor Schnitzler adhered to his diagnosis of cancer. The condition of the patient grew worse from day to day, and, four weeks after his admission, tracheotomy was performed by Professor von Frisch. Bronchitis developed, and at the end of the seventh week after admission a piece of cartilage was expectorated, to which a little quantity of blood adhered, a fact which did not throw any additional light on the case, as such a condition was met with in tuberculosis as well as in carcinoma. Effusion into the left pleural cavity, together with hæmorrhage from the larynx, supervened in a short time; these symptoms, combined with the horrible fetor of the patient's breath, induced even those who had hitherto doubted the presence of carcinoma, to accept the diagnosis. Professor Schnitzler considered the pleuritic effusion to be of carcinomatous origin. The patient died in a few days after these conditions had been observed, and the *post-mortem* examination, which was made by Docens Dr. Zemann, fully confirmed the diagnosis of cancer, as well as that of a carcinomatous pleuritic effusion.

At a recent meeting of the Royal Society of Physicians of Budapest, Docens Dr. Goldzieher made an interesting communication on conjunctivitis syphilitica. Syphilitic affections of the eyelids had to be divided into three classes, namely, primary lesion (initial sclerosis), exanthem, and gumma. Discussing the various pathological conditions in syphilis of the eyelids, he said that the symptoms of diffuse syphilitic conjunctivitis had not yet been described as a whole. He related two cases which showed that there really existed a sort of granular ophthalmia which was due to syphilis. The first case was that of a man aged 32, who had contracted syphilis six years before, and had suffered from chronic iritis since that date, so that iridectomy had to be performed. For the last few months an inflammation of the conjunctiva had supervened, which had been treated for a long time. On his admission into the hospital, erythema and diffuse swelling of the eyelids, with the formation of granulations in the mucous membrane, were found; besides this, there was swelling of the lymphatic glands in the region of the ear and the neck. After energetic treatment by mercurialunctions for four weeks, the conjunctiva regained its normal appearance, and the patient was discharged cured. The second case was that of a man aged 26, who had contracted syphilis two years previously. Six months before his admission into the hospital he was attacked with conjunctivitis in the left eye, and was, like the first patient, treated without success by applications of the nitrate of silver, sulphate of copper, etc. He presented exactly the same changes in the conjunctiva as the first case, and, moreover, keratitis profunda, iridochoroiditis, and lymphadenitis universalis. After an anti-syphilitic course of treatment, he was also quite cured. Dr. Goldzieher remarked that similar changes of the conjunctiva were observed in syphilitic inflammation of the tarsal cartilage. As the conjunctiva possessed a layer of adenoid tissue, and the infiltration referred to above was only to be looked upon as a follicular vegetation of this layer, the morbid process above described had, therefore, from the anatomo-pathological standpoint, to be considered as being identical with syphilitic lymphadenitis.

SAN REMO.

[FROM OUR OWN CORRESPONDENT.]

THE past week has been an exciting one in San Remo. When I last wrote you Prince William was still here, with Professors von

Bergmann and Waldeyer, and the attention of half Europe was concentrated upon the result of the latter's microscopic examination of the expectoration of the Crown Prince. This result, as I predicted, has not been made known, and the statements made in the daily papers in reference to it are purely speculative and imaginative. I have reason to believe, however, that his observations coincided to a very great extent with those of Virchow, but that his deductions from them differed somewhat materially. The events of the last few days, however, have even thrown the absorbing interest of this subject temporarily into the background. Prince William left somewhat hurriedly on Monday for Berlin on account of the Emperor's indisposition, and on Wednesday his critical state became known, and the subject of the Crown Prince's possible return was discussed. In the evening worse accounts arrived, and it was practically decided that he should go. I believe that Sir Morell Mackenzie very reluctantly came to this decision, as his august patient was gaining ground rapidly day by day. The cough and expectoration had nearly ceased; the latter was only occasionally tinged with blood, a result attributed largely to the introduction of the new cannula made here. The patient was sleeping and eating well, and spending the greater part of each day in the open air. State exigencies, however, were, I believe, imperative, and I understand that Prince Bismarck himself urged the step, if it were in any way practicable. Four or five days before it would have been simply impossible; but the Crown Prince himself, with returning strength, was keen to undertake the journey.

On Thursday morning, after Sir M. Mackenzie had held long and anxious consultations with the Crown Princess, the start was fixed for Saturday morning. All Thursday telegrams from Berlin poured into the Villa Zirio, and by evening it was known that there was no possibility of the aged Emperor rallying. The Crown Prince was much agitated and affected by the news, and on Friday morning at 10 o'clock, when the fatal tidings arrived and were communicated to him, he nearly fainted, being supported for a moment by Dr. Schrader, the household physician. He soon regained composure, and attended during the day to the innumerable despatches arriving. He walked in the garden for some time, and dined for the first time with his family.

I am told a very touching and pathetic incident occurred on this occasion. The new Emperor, upon entering the room, approached the Crown Princess—or, rather, Empress—and invested her with the Order of the Black Eagle.

On Saturday morning the Royal train—a German one—was ready at nine o'clock. The departure was made as private as possible, but, owing to the intense sympathy felt, a large concourse of people assembled outside the station. Beyond the Government and town officials, only a limited number were admitted on the platform, a few residents, and those personally known to their Imperial Highnesses. The scene was a most impressive and almost funereal one, all the Germans being in black and others in mourning, and the day itself being overcast and gloomy. The Emperor and Empress arrived in the last carriage, and were greeted outside the station by the national acclamation of the assembled Germans. The Emperor walked firm and erect, bowing right and left, and shaking hands with many whom he recognised. He was very pale and looked like a man who had gone through a serious illness; beyond this, there was nothing to suggest the operation and malady from which he is suffering, except once, when, wishing to speak to a lady, he put his hand pathetically to his throat. The Empress, with that characteristic so well known in all our Royal Family, recognised each individual with whom she was acquainted, and shook hands and said a kind word to all. She graciously accepted one or two bunches of San Remo wild flowers, of which she is very fond, the customary parting bouquets being, of course, dispensed with.

Sir M. Mackenzie and Mr. Mark Howell travelled in the Royal carriage, the former looking careworn and haggard, and evidently feeling the heavy responsibility attached to him. He is, I am told, confident as to the result of the actual journey, and, while dreading the climate of Berlin, trusts that the Emperor may not remain there except for a short time, but speedily go to Wiesbaden, which is much milder and comparatively warm.

Whatever may be the verdict of German or other professional opinion on Sir M. Mackenzie's management and treatment of this obscure and difficult case, it cannot be denied from one point of view that he has achieved an enormous success. His aim and object has been to prolong the Crown Prince's life. It is freely said here that, had he gone to Berlin with the Crown

Prince instead of the Emperor of Germany, it would have been at considerable risk to his own safety, so great is the fanaticism on this point said to exist in the German capital.

On Friday, the eve of departure, the Empress, in spite of the extreme anxiety and sorrow she was under, graciously received two or three residents, amongst them Dr. Freeman, to whom, I believe, she expressed her intense regret, that circumstances compelled the Emperor's departure at the moment when daily improvement was so marked. She added, however, that it was a necessity. Her Majesty also sent messages of regret to the ladies of the "Home" here, the institution in which she has taken so much interest.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

Lactic Acid in Laryngeal Phthisis.—*Friedländer's Microbe in the Saliva of Healthy Persons.*—*Chlorate of Potash in Epithelioma.*—*Hypodermic Injections of Eucalyptol in Phthisis.*—*Poisoning by Benzine and Nitro-Benzine.*—*M. Terrillon on Ovariectomy.*—*Sanitary Aspects of the Pilgrimage to Mecca.*—*Transport of Sick and Wounded by Water.*—*Disease in Imported Meat.*

The treatment of tuberculous ulceration of the larynx by lactic acid and iodoform; recommended by Dr. Krause, of Berlin, and Dr. Heryng, of Warsaw, has lately been successfully employed by Dr. Luc, in the case of a young woman suffering from laryngeal tuberculosis. The patient was weak and thin; the least fatigue produced dyspnoea, and aggravated the wheezing from which she constantly suffered. At night there was fever followed by profuse perspiration. The voice was completely lost. The patient coughed incessantly, and the sputa contained numerous bacilli. There was dulness, with moist râles at the apex of the left lung. The epiglottis was but slightly affected. The vocal cords were red and swollen, and could not be completely adducted; this was apparently due to infiltration of the mucous membrane covering the arytenoid cartilages, which was studded with excrescences which were especially prominent in the glottis. The appetite was poor. The patient complained of intense pain in the larynx when she coughed or spoke. A few days' rest was prescribed, during which medicinal inhalations were administered. The larynx was anaesthetised by means of a 1 in 5 solution of hydrochlorate of cocaine applied with a brush. The arytenoid excrescences were destroyed by galvano-cautery. At the end of a fortnight the eschars came away. The infiltration of the mucous membrane was considerably reduced. The membrane presented a granulating surface of healthier appearance. The vocal cords were more easily brought together, and the voice was much stronger. During six months the larynx was constantly painted with a 50 per cent. solution of lactic acid. Powdered iodoform was insufflated after each application of the acid. Under this treatment the patient recovered her voice. The stridor and laryngeal pain disappeared; expectoration diminished, nocturnal coughing ceased. Dr. Heryng, who examined the patient after this treatment, regarded the laryngeal lesions as completely healed. This method had no effect on the general tuberculous symptoms.

The report of the *Société de Biologie* of Paris, of December 30th, 1887, contains an interesting communication from Dr. Netter relating to his discovery of the microbe of Friedländer in the saliva of healthy persons. Dr. Netter found in the saliva of three healthy persons a pathogenic microbe capable of causing the death of certain animals. This microbe is a bacillus identical with the organism discovered by Friedländer in the lungs of patients attacked by pneumonia, and known as the diplobacillus pneumoniae of Weichselbaum. It is sometimes associated with the pneumococcus of Fränkel. This microbe is very rare, and the author found it in only three cases out of 180 samples of saliva taken from 105 healthy persons. It is easily cultivated, at the ordinary indoor temperature, on peptonised gelatine, etc., and can be isolated by cultivating in gelose or gelatine the blood of animals that have died after subcutaneous injection of saliva. Its presence may be but temporary, and, as the experiments of Thost have proved, Friedländer's microbe may sometimes also be met with in the nasal mucus of healthy subjects. The presence of this organism in the air-passages may allow it to penetrate into the pneumonic patch, but it does not necessarily follow that it is dangerous to man, for although, when injected into the blood of

guinea-pigs and mice, it rapidly causes the death of these animals, it has no effect whatever upon rabbits. Man may possibly share this immunity, for it has not yet been satisfactorily proved that this microbe is really dangerous to man, and for that it remains yet to show that it is necessarily active in pneumonia, ozena, rhinoscleroma, and otitis. Dr. Netter, after passing in review the observations of Friedländer, Weichselbaum, Fränkel, Talamon, and others on this subject, says that he thinks himself justified in considering pneumonia as always connected with the pneumococcus of Fränkel, the presence of which in the pneumonic patch has been proved to be constant, but that the pathogenic action of Friedländer's microbe in pneumonia is far from being proved, and that where this organism was found it was undoubtedly simply in cases of secondary infection due to the presence of the bacillus in the air-passages, and its subsequent development on the surface of a favourable region. It is, however, worthy of remark that if this microbe is sometimes met with in healthy subjects, it is more frequently met with in the saliva of those who have previously suffered from pneumonia. The author concludes that the pathogenic action of Friedländer's microbe still remains to be determined, and that subsequent studies can alone elucidate the question.

Dr. Hyvernaud has treated 63 cases of epithelioma by local applications of chlorate of potash; of these, 32 were cured, 15 were benefited, and 16 cases were unrelieved. In the successful cases the disease was situated on the skin of the face, nose, eyelids, cheeks, neck, in the lumbar region, on the back of the hand, and on the inner surface of the leg. Chlorate of potash fails as a rule when the mucous membrane is the seat of disease, although two cases of epithelioma of the lips and nostril were cured by it. It is especially useful when the affection is slow in its progress. A 6 per cent. solution slightly heated, or a fine powder of chlorate of potash, is applied to the wound, after it has been freed from scabs. The dressing is renewed once a day or oftener. The effect of the solution is chiefly to heal the wound, while the powder slightly cauterises it. The surface of the tumour or ulcer is thus destroyed, small eschars come away, and cicatrization ensues. In most cases several weeks, or even months, are required to obtain complete cicatrization.

M. Edmond Habert has found subcutaneous injections of eucalyptol and iodoform useful in ordinary phthisis accompanied by bronchial catarrh, and also in emphysema and chronic bronchitis. Cough and expectoration are diminished; the general condition is improved; sleep and appetite are restored. There is, however, no diminution in the number of bacilli in the sputa. The following solutions are employed: R Absolute eucalyptol, 5 grammes; oil of vaseline, 20 grammes. R Absolute eucalyptol, 5 grammes; iodoform, 0.25 gramme; oil of vaseline, 20 grammes. Each Pravaz's syringe contains 0.20 gramme of eucalyptol for the first solution, and 0.1 more of iodoform for the second. The doses, which gradually increase, vary from 2 to 5 centigrammes in twenty-four hours. The solution must be absolutely pure, and the syringe must be properly disinfected. The quantity of liquid injected should not exceed thirty or forty drops. The needle should be introduced a good way beneath the skin.

MM. E. Neumann and Alb. Pabst, in the *Annales d'Hygiène*, have published some observations on the morbid phenomena produced by benzine and nitro-benzine. In cases of slight poisoning the symptoms, which are principally met with in persons employed in dyeing and cleansing, are: headache, vertigo, dizziness, and intoxication, which may reach the unconscious stage. These symptoms rapidly disappear if the patient leaves his work and goes into the open air. Benzine also causes slight trembling in the hands and arms, accompanied by tingling sensations and numbness. MM. Neumann and Alb. Pabst believe that these accidents are not entirely due to benzine. Benzine in a pure state is very expensive, and is usually replaced in dyeing and cleansing establishments by homologous substances which boil at above 130° C. (266° Fahr.) (methylbenzine, or toluene trimethylbenzine, or cumene, etc.), or by a kind of petroleum oil, sold as benzine. In workmen employed in benzine distilleries symptoms of a more serious nature are sometimes observed, namely, intoxication accompanied by delirium; the patient talks incessantly; in some cases his speech is embarrassed, and he stutters. Aphasia which lasts several days is sometimes present; also epileptiform attacks, followed by coma, aphonia, and mental disturbance. Loss of sexual power is, often one of the earliest symptoms of chronic benzine poisoning. Paralysis, facial hemiplegia, disturbances of sensibility (anaesthesia, hyperaesthesia), are also met with.

M. Quinquaud has observed anaemia in workmen engaged in distilling benzine. The pulse is accelerated but regular, the skin hot, the eyes and face are animated. The patient emits a strong odour of benzine; the teeth and gums present a blackish edging, darker than that observed in lead-poisoning, and threatening to spread all over the teeth. The digestive organs are normal. The action of benzine may be compared to that of chloroform and alcohol. Workmen who are addicted to taking large quantities of alcohol are more rapidly and seriously affected than others by the influence of benzine. Nitro-benzine, like aniline, may be introduced by the digestive passages, or by inhalation. The first effects are observed half an hour or an hour after it has been taken. The symptoms consist of general uneasiness, weakness, headache; the skin of the face and extremities assumes a livid, bluish hue; the nails are of a dead blue colour. Cyanosis invades the mucous membranes, the walls of the mouth, the gums, tongue, pharynx, etc. The patients exhale an odour of bitter almonds. Vomiting occurs in certain cases. The vomited matter and the sputa smell of bitter almonds. These first symptoms are followed by dyspnoea and quickened action of the heart, which gradually becomes slower. The pulse is accelerated and weak. Convulsions, cramp, contractions in certain muscles (trismus, opisthotonos, etc.), are observed. There is occasionally loss of consciousness, of sensibility, and of reflex power; the intellectual faculties are not usually affected. The urine has the odour of bitter almonds, and is thick, but free from albumen. In certain cases the affection runs a very acute course, and death speedily ensues. In others the morbid phenomena become gradually more marked, ending in coma or convulsions. These often last several hours, and are followed by death. In some cases coma is followed by the gradual disappearance of all the phenomena. Of forty-four cases of poisoning by nitro-benzine, fourteen proved fatal. These symptoms are frequently manifested by workmen employed in establishments for the manufacture of nitro-benzine. Occasionally they are limited to a general sense of uneasiness, heat in the mouth, pricking in the tongue, cyanosis, and vertigo. Coma is only observed in those who have worn clothes imbued with liquid nitro-benzine for a considerable period. Most of the symptoms disappear if the patient abandons his calling, but they frequently recur when he resumes it.

M. Terrillon has performed thirty-five ovariectomies with twenty recoveries. Four of the patients died, all from exhaustion, after operations of exceptional difficulty. In no case did death occur from peritonitis or septicæmia. M. Terrillon insists on the necessity of using proper antiseptic precautions. He considers it advisable to substitute vegetable sponges or a spongy tissue for ordinary sponges. The cleansing of the peritoneum with boiled, filtered water, is an important matter. M. Terrillon gives purgatives the day after the operation, especially in the case of patients who are troubled with wind, or colic.

In a report by M. Mahé, French Sanitary Officer at Constantinople, on the Mahometan pilgrimage to Mecca in 1887, he states that amongst the 90,000 pilgrims, 605 deaths were known to have occurred, and it was probable that there were in reality three times that number. Dr. Mahé points out: 1. That the station of Camaran, established in 1882 for the landing and inspection of the pilgrims coming into the Red Sea from the Indian Ocean, checks the spread of disease, and is a resting place for those debilitated by the voyage. This control over the pilgrims immediately on landing has prevented the importation of cholera into Hadjaz during four consecutive years. 2. As long as the presence of Christians in the pilgrimage is prohibited, a uniform healthy condition of the pilgrims cannot be hoped for. 3. One of the greatest dangers to the pilgrimage is the extraordinary number of pilgrims from India, with the close crowding and unhealthy state of the vessels which transport them. A new statute is being formulated by the Conseil de Santé de Constantinople, with a view to abolish this evil.

The administration of the sanitary service of the War Department have repeated the experiments made last summer on the transport of the sick by water. In order to see whether this plan could be employed with equal success in winter, a steamboat left the Quai Henri IV., last week for a two days' voyage. The passengers were composed of army surgeons, engineers, and hospital attendants. The boat was heated by different kinds of stoves. The experiment was eminently successful, and proved that this plan, by which the sick and wounded may be conveyed without jolting or shaking, will be of great advantage in time of war.

The Comité Consultatif d'Hygiène de France met the other day

to discuss the importation of fresh meat, especially mutton. A question was raised by the Conseil Supérieur de l'Agriculture as to the necessity of the viscera being left in carcasses imported from abroad, in order to determine the presence of disease. It was decided, after a short discussion, that the presence of the viscera is not indispensable.

SHEFFIELD.

[FROM OUR OWN CORRESPONDENT.]

Lead in Drinking Water: The Action of Peaty Water on Lead.—Inquests without Viewing the Body.—News.

MR. A. H. ALLEN, the borough analyst, read a paper before the Sheffield Literary and Philosophical Society, on March 6th on the Action of the Sheffield Water on Lead. He did not agree with some observers, that incredibly small proportions of lead would produce poisonous effects. His belief was that, except in the case of very susceptible persons, poisoning had usually occurred from the habitual drinking of water containing more than a quarter of a grain per gallon. Anything over that proportion must not be neglected. He referred to the water supplied from Redmires, as being that which acted so prejudicially on the lead piping. Dr. Tidy and his coadjutors believed that the activity was due to the small amount of silica at present in the water, and suggested that it should be subjected to an elaborate system of filtration through flint and limestone, with a view to introducing the requisite amount of silica, which was at least half a grain per gallon, to render it inactive. As, however, the Redmires water contained a sensible quantity of free acid which was of vegetable origin and probably derived from the oxidation of peat, he regarded the presence of this acid as a highly probable cause of the activity of the water. He did not think attempting to neutralise this acidity by bringing the water into contact with limestone would be sufficient. At Keighley it had been necessary to supplement the limestone by placing blocks of quicklime in the conduits. He thought it would be preferable to add the lime in fine powder, or in just such quantity as would neutralise the acid at present in the water. The special activity of the Redmires water just now appeared to be due to the absence of rain. During last year the rainfall at Redmires was under 25 inches, whereas for a whole period of fifty years, the average had been 41 inches. After an exceedingly dry summer, the October rains came in limited quantities, with the result of getting all the acid without the water to dilute it. The President, Dr. Dyson, pointed out that the opinion of medical men agreed with Mr. Allen, that in regions supplied by the Redmires water, patients had suffered from lead poisoning which could not be attributed to anything but drinking the water. He did not think the matter was a light one, for in many instances the damage was lasting.

Following the example of the Sheffield coroner, an inquest has been held by Mr. Busby, without viewing the body, at New Tupton, Clay Cross, on a miner who was found dead in his house on the previous morning. Medical evidence was given that the cause of death was hemorrhagic small-pox. A verdict to this effect was returned.

Dr. McDowell, who has been for several years at the Wadsley Asylum, has been appointed Medical Superintendent of the new Menston Asylum. While congratulating him on his well-earned promotion, his old friends at Sheffield will regret his departure from their midst.

Mary Price died on March 9th in the Fir Vale Workhouse, Sheffield, having just passed her 101st birthday. She was born on March 8th, 1787. Her husband, a soldier, was engaged at the battle of Waterloo, which she witnessed. He died many years ago.

NEWCASTLE - UPON - TYNE.

[FROM OUR OWN CORRESPONDENT.]

The Workhouse Scandal.—Medico-Legal Case at Durham Assizes.—The Pathological Society.—The College of Medicine.

At the meeting of the Newcastle Board of Guardians last week, the master and medical officer of the workhouse were re-elected, though only a few weeks before a Government inquiry had been held to consider the manner in which both officers had lately discharged their duties, with the result that both were called upon to resign forthwith. The master was re-elected by 26 votes to 15, the medical officer by 20 to 14. The Board has thus set the

Local Government Board at defiance, and it remains to be seen what the outcome will be; the ratepayers at a town's meeting held to consider the subject, with the Mayor in the chair, by a very large majority, carried a resolution condemning the re-election of both gentlemen, and also recommending that the result of the meeting should be forwarded to the central body in London. Dr. Harcastle has held the appointment of medical officer for many years, and though not altogether free from blame in the manner in which he has discharged his duties, is yet probably more sinned against than sinning. Until the advent of the present master everything seems to have gone smoothly, but during the past few years the master and medical officer have not been on good terms; bickerings have been constantly going on, the climax being reached during the late outbreak of scarlet fever. The guardians have decided to appoint a resident medical officer, whose duties will be to work under the senior medical officer; a good many candidates are already in the field for this appointment.

At the Durham Assizes last week, before Mr. Justice Charles, an action for negligent treatment was brought by a miner against Mr. Ellis, of Bishop Auckland. The facts of the case are shortly these. Mr. Smith, an unqualified assistant, in the absence of Mr. Ellis, attended the plaintiff's wife in her confinement; a portion of the placenta was left after delivery. She subsequently became very ill, delirious, and unmanageable. Mr. Ellis still being away from home, Mr. Arnold, a Licentiate in Medicine of Durham University, was called in; he prescribed mustard poultices and injections; finally, the portion of placenta was removed, and the woman recovered. Mr. Arnold was submitted to a very severe cross-examination by Mr. Waddy, as to the nature of his qualification, and also as to his antecedents, eliciting many details having no bearing on the case, but which could not tend to increase the value of Mr. Arnold's evidence. Dr. Oliver, one of the physicians to the Newcastle Infirmary, gave evidence that, on examining the woman, he found evidence of inflammation, but it could not be traced to parturition. The judge thereupon dismissed the case.

The last monthly meeting of the Pathological Society was held on Thursday last, and was well attended; the agenda paper was a long one, and many interesting patients and specimens were exhibited. I understand that Drs. Anderson (Seaton Delaval), Murphy (Sunderland), and Gowans (South Shields), were nominated for the post of president for the ensuing two years. The result of the voting will not be known until next session. All three gentlemen are active members of the Society, and have pretty equal claims on the members for election; the contest will be a very close one.

The Council of the College of Medicine, at their last meeting, elected a demonstrator of anatomy, or, rather, a medical tutor, for the primary examinations. Three candidates applied: Dr. Ridley, house-surgeon to the Newcastle Dispensary, who lately passed the primary F.R.C.S., and who is engaged in giving tutorial instruction to students for their first examinations; Mr. Rutherford Morrison, a local surgeon; and Mr. Bennington, a surgeon, now reading for the Durham degree. Mr. Bennington was elected to the post. Mr. Henry Armstrong having resigned the post of Secretary to the College, Dr. W. P. Mears, lecturer on anatomy, was elected to the vacancy.

MANCHESTER.

[FROM OUR OWN CORRESPONDENT.]

Owens College.—The Royal Infirmary.—The Vacant Obstetric Chair.—Small-Pox at Blackburn.

At the half-yearly meeting of the Governors of Owens College, the Duke of Devonshire was re-elected President for another period of five years. The Court has decided that permanent arrangements shall be made for the instruction of women students. So far this regulation does not apply to the medical classes.—At the same meeting the title of Emeritus Professor was conferred on Professor Lund, who has resigned the chair of Systematic Surgery.

Mr. A. M. Paterson, Senior Demonstrator of Anatomy in Owens College, has been elected a Lecturer in Victoria University.

The total sum collected on Hospital Saturday amounts to £2,858, and on Hospital Sunday £4,484.

We understand that important negotiations are being conducted between the authorities of Owens College and the Royal Infirmary Board of Management with the view, if possible, of securing a more intimate relation between these two institutions. At the

present time the clinical teaching at the Infirmary is carried out by the Infirmary staff, and a professor of medicine or surgery in Owens College as such has no beds attached to his chair. Were the College in a position to offer to its professors of the practical subjects not only the position of professor, but beds in a hospital, without doubt there would be a much larger number of candidates for these chairs. Another question under consideration is the division of the hospital fees paid by the medical students. At present the medical students pay a sum for the hospital practice, and for instruction therein, and this sum is divided amongst the members of the Infirmary staff, and it does not appear that the Infirmary funds profit by the large sum thus annually contributed by the medical students. In some hospitals it appears that a separate fee is charged for admission to the hospital and another sum or sums for the clinical instruction therein received. The former sum goes to the Infirmary, and the latter is divided in certain proportions amongst the members of the teaching staff. In Manchester, however, practically all the hospital fees go to the staff.

The vacant chair of Obstetrics will probably be filled about the end of this month.

Small-pox continues to spread in Blackburn, where at present there are nearly thirty cases.

CORRESPONDENCE.

LOOSE BODIES IN THE KNEE-JOINT.

SIR,—In the report (JOURNAL, March 3rd, p. 469) of the brief discussion on this subject at the Medical Society, I am correctly stated to have expressed my scepticism with regard to the possibility of the formation of these bodies by the detachment of portions of the articular cartilages; and I would be glad to state more at length my reasons for this scepticism, knowing that the view which regards this as one of the modes of origin of such bodies is generally accepted.

1. It must be a very extraordinary and violent accident that would break off into the knee-joint a piece of the articular cartilage, with or without bone, of the femur or the tibia. One can scarcely imagine the occurrence of such an accident, or conceive how it could take place. Even a smart blow from a hammer would hardly produce it; and in any event such an accident would be attended with severe shock and confusion of soft parts, ecchymosis and immediately consecutive pain, inflammatory and other trouble, which the sufferer would not quickly recover from, and would not easily forget, but which we do not find forming part of the history in cases of loose bodies in joints.

2. Such a detached or semi-detached fragment could scarcely assume the even-surfaced, spherical, or circular flattened form of a loose cartilage.

3. We have a ready and sufficient explanation of the formation of loose bodies in the growth into the joint of tufts or processes of synovial membrane which may assume various forms, which, naturally containing cartilage cells, may become the seat of cartilage-growth and ossification of the cartilage, which become pendulous as they increase, and by rupture of the pedicle become loose in the joint; and we frequently see the various stages of this process in the same joint. We need not therefore search for other and highly improbable modes of origin. I may observe that the ossification which takes place in them accords with the ordinary process of ossification in cartilage; and a section of one of them does not correspond with that of articular cartilage and bone. This process is quite sufficient to explain the origin of the single as well as of the multiple loose bodies, which latter are common in rheumatic arthritis; and we not infrequently meet with instances in young persons where a solitary loose body, not having yet broken loose from its moorings, retains its attachment to the synovial membrane.

I can scarcely suppose that anyone really believes that a portion of bone detached by the process of necrosis can be converted into one of these bodies, though such a suggestion is actually made in a recent and important work on surgery.

The explanation of the idea that these bodies are sometimes due to the detachment of portions of the articular ends of the bones is, I believe, to be found in the fact that now and then we meet with a loose cartilage which does not present a cartilaginous covering over its whole surface, the bone being more or less ex-

posed at one part, so simulating, though very remotely, a detached fragment of bone and cartilage. But in these instances, so far as I have observed, the exposed bone is smooth, and its exposure is due to the cartilage which covered it having been rubbed off by attrition against some part of the femur or tibia in the movements of the joint; and the attrition may have produced a depression in one of these bones, which may be thought to confirm the idea of the loose body having been caused by a fracture. This is well illustrated by a specimen, in the pathological collection of this University, of a knee-joint with rheumatoid arthritis which I excised, with good result, from a man aged 60. In addition to the usual evidences of the disease, such as wearing away of the articular cartilages and the bones, with bony growths around, and with thickening of the synovial membrane and filamentous processes from it, there are numerous masses of various shapes and sizes, for the most part spherical or spheroidal, consisting of true hyaline cartilage and true bone, some of which are loose in the joint and some hanging from the synovial membrane. One of these, of about the size of a filbert, closely bound down by the fibrous structures on the inner side of the head of the tibia, has by its pressure caused absorption in the articular margin of that bone, and so formed for itself a concavity in which it is lodged. Its form and surface, and the cavity in which it lies would give the impression that it is a detached fragment of the tibia. This, however, is disproved by its similarity to the other masses with which it has no doubt the same origin, namely, from the synovial membrane, and by the fact that it is larger than the cavity which accommodates it, having grown in between the articular surfaces of the tibia and femur, as well as by the absence of any account of an injury that could have caused such a fracture.

Surely the origin of a loose cartilage from a detached fragment of cartilage or bone borders so closely on the impossible, that it ought not to be ranged in the category of the probables by so good a surgeon and pathologist as I know my friend and quondam house-surgeon Mr. Sheild to be.—I am, etc.,

Cambridge, March 6th, 1888.

G. M. HUMPHRY.

MENSTRUATION AFTER HYSTERECTOMY.

SIR,—In the JOURNAL of February 25th, page 415, Dr. Greathead reports an interesting case of menstruation after hysterectomy, with removal of ovaries, and remarks: "I am aware that such a phenomenon has been observed after double ovariectomy." By inference, therefore, one may conclude that Dr. Greathead is unaware of any other case of menstruation occurring after the removal of the uterus and its appendages. If he will refer to the JOURNAL for October 22nd, 1887, he will find the report of a case where, although I amputated the uterus close to the vaginal attachment and removed both appendages, the menstrual period returned at the next period, normal in time and quantity.

In a number of double ovariectomies that I have performed menstruation has occurred once, usually two or three days after operation; in fact, I look on its occurrence as the rule rather than the exception in such cases.

In a case of removal of both appendages for rapidly growing fibroid, which I did twelve months ago, although the tumour has dwindled, menstruation continues as profusely as before, and I am now treating the case by electrolysis, with apparent success.

Fortunately, uterine bleeding does not always occur after double ovariectomy, as a fortnight ago I removed both ovaries for cystoma in a woman three months pregnant, and as there has been no discharge I conclude that she is now safe from miscarriage.—I am, etc.,

A. W. MAYO ROBSON.

Leeds, March 2nd.

METROPOLITAN PROVIDENT MEDICAL ASSOCIATION.

SIR,—The following resolutions have been agreed to by a committee of medical men, appointed to consider the objections to be taken to the scheme of the above Association, and I have been instructed to invite the attention of members of the profession to the subject, and to obtain the signatures of such as are disposed to acquiesce in the views expressed, or to offer suggestions in the matter.

Resolved that:

1. The resolutions adopted at a public meeting, held at the Society of Arts in December, 1887, cannot be accepted as embodying the opinion of the medical profession.

2. That objections to the scheme of the Metropolitan Provident Medical Association are based on the following grounds:

a. Provision for medical attendance on those unable to pay the fees required in ordinary practice is already amply provided for by existing charitable institutions, or by the individual or collective efforts of general practitioners.

b. Measures hitherto taken by the lay public to establish so-called provident medical institutions have invariably resulted in introducing a system of unhealthy competition, detrimental alike to the best interests of the profession, and subversive of its influence with the general public.

c. The wholesale distribution of handbills by the organisers of any scheme of medical relief is to be condemned as much as similar action on the part of individual members of the profession.

3. The committee would further suggest that to carry out the principles embodied in these resolutions it is desirable, in order to preserve the rights of general practitioners, that an organisation be formed for that purpose.

It will be observed that it is proposed to form a definite organisation to oppose this scheme, and the following members of the committee, or myself, will be glad to receive the names of all members of the profession who are willing to co-operate:—Dr. Cohen, 195, Sutherland Avenue, Maida Vale, W.; Dr. Maunsell, St. Mark's House, Bolingbroke Road, S.W.; Dr. Paramore, 2, Gordon Square, W.C.; Dr. Kisch, Abingdon House, Sutherland Avenue, Maida Vale, W.; Dr. Sargent, High Street, Shadwell; Dr. Wainwright, 230, Brunswick Road, Poplar; Dr. Simpson, 110, Lavender Hill, S.W. (treasurer).—I am, etc., F. H. CORBYN, Hon. Sec.

18, Abercorn Place, St. John's Wood, N.W.

P.S.—The resolution passed at the Society of Arts was in favour of establishing metropolitan provident dispensaries all over London.

CONSULTATION WITH HOMEOPATHS.

SIR,—As a member, and a member of the Council, of the Gloucestershire Branch of the British Medical Association, I desire to record my personal protest against the concluding paragraph in the report of the meeting of that Branch in last week's JOURNAL.

The paragraph was as follows: "The result of this meeting was most important, showing the great feeling in favour of admitting homœopaths to equal fellowship, and as far as the county of Gloucester is concerned, having settled the question as to the right of holding consultations with them."

The meeting was not summoned for the avowed purpose of settling this question, and it was not representative of the county or the Branch. The number present was very limited. Cheltenham, Lydney, and Gloucester alone were represented, and the two former of these only by one member each.

I am not here concerned with the merits of the question under discussion, but simply desirous of expressing my dissent from the individual conclusion of the reporter that a meeting, summoned and attended as it was, is to be regarded as settling any important question on behalf of so large a constituency as that of the Gloucestershire Branch of the Association.—I am, etc.,

Gloucester, March 12th.

FRED. NEEDHAM.

TREATMENT OF UTERINE FIBROIDS BY ELECTROLYSIS.

SIR,—Mr. Knowsley Thornton, at the meeting of the West London Medico-Chirurgical Society on March 2nd, stated that he knew of one case of uterine fibroid treated by electricity having ended fatally. When asked to state the case it was found that he had gone, and so I take this opportunity of asking him to give a few of the facts in connection with it, so that those who are now trying electricity may profit by the example.—I am, etc.,

9, Collingham Place, South Kensington. J. INGLIS PARSONS.

CASE OF CEREBRAL ABSCESS.¹

SIR,—In my account of a Case of Cerebral Abscess, published in the JOURNAL of March 10th, p. 530, I have omitted to mention a similar case reported by Dr. Maccwen, in the *Lancet*, March 26th, 1887, which I had accidentally overlooked, and to which my attention was called at the meeting of the Medical Society. I had intended making the necessary correction before the paper was published, but for some reason the proof was not submitted to me.—I am, etc.,

DAVID FERRIER.

34, Cavendish Square, W.

¹ The surgical history of the case, by Mr. Victor Horsley, F.R.S., will be published next week.

NAVAL AND MILITARY MEDICAL SERVICES.

VOLUNTEER AMBULANCE SCHOOL OF INSTRUCTION.

ONE of the largest Volunteer Ambulance classes yet held, numbering 120 members, was brought to a most successful conclusion on Monday, March 12th, at the headquarters of the London Scottish R.V., where the official inspection was held by Surgeon H. R. Cox, of the Coldstream Guards. After the drill and examination of each member, the whole class were awarded the army ambulance certificate, and were highly complimented on their collective and individual efficiency.

On Friday, March 9th, no fewer than fourteen detachments entered for the prize competition, held at the Queen's Hall, Westminster. Surgeon O. M. White, T.H.R.B., and Surgeon Heather Bigg, London Irish R.V., were the judges, and awarded the first prize to a detachment of the Victoria R.V. and St. George's R.V.; second prize to the Queen's Westminster R.V.; third prize to the London Scottish R.V. The Royal Naval A.V. were fourth in order of merit. A prize for old members was taken by the 17th Middlesex (North London) R.V.

Dr. Walter Pearce, of the Artists' Corps, the medical officer instructor, was entertained to dinner by Dr. G. Ogilvie, of the London Scottish, and the officers, non-commissioned officers, and men, of the class, at Anderton's Hotel on Saturday, March 10th. Thirty-one corps were represented, comprising Royal Naval Artillery, Yeomanry, Artillery, Engineers, and Rifle Corps of the metropolitan district. During the evening Dr. Walter Pearce was presented with a handsome silver inkstand bearing an inscription, and an address, with one hundred signatures, expressing the appreciation of his endeavours to perfect the instruction of the regimental stretcher bearers of the volunteer force.

The course of instruction included lectures on barrack and camp hygiene, which were delivered in the anatomical theatre of St. Mary's Hospital, by the kind permission of the Dean of the St. Mary's Medical School.

INDIAN MEDICAL SERVICE.

"A READER" is informed that competitive examinations for appointments in the Indian Medical Service are usually held twice a year, in February and August, and the number of vacancies is advertised some time before. The examination is identical, and held simultaneously with those for the army and naval medical services. All information can be obtained by application to Lieutenant-General A. B. Johnson, C.B., Military Secretary, India Office, Whitehall, London, S.W. There is no absolute physical standard laid down for officers, but all have to undergo a medical examination previous to being allowed to compete for commissions; of course, any serious physical defect or imperfect vision or hearing might be held to incapacitate, but every case would be broadly judged on its merits. India has always afforded a noble field for the medical officer.

INDIAN CIRCULARS.

AS officer of the Medical Staff writes from India that grave dissatisfaction is caused in that country by the "never ending flow of circulars" on "every possible and impossible subject" issued for the guidance of the medical service. One lately obliging senior and junior officers alike to submit to periodical written examinations, was soon cancelled as impracticable.

Especially do medical officers resent the fact that when their hospitals are inspected by the surgeon-general he is accompanied by an apothecary as staff officer instead of by one of his secretary medical officers.

THE RIGHT OF RETIREMENT AFTER TWENTY YEARS' SERVICE.

SURGEON-MAJOR 19½ YEARS' SERVICE writes: From the War Office memorandum in the army estimates just issued, it appears to be the intention of the Government not to allow medical officers to retire on a pension after twenty years' service. Should this be carried into effect a serious breach of faith will be caused, and all the surgeons admitted into the army since the Royal Warrant of November, 1879, will have been obtained under false pretences. I believe they number between five and six hundred, and I recommend that a vigorous protest be at once entered before the appearance of a new Royal Warrant.

ABOLITION OF RELATIVE RANK IN INDIA.

THE *Indian Medical Gazette*, in a retrospective article on the year 1887, refers to the deep feeling excited by the abolition of relative rank, and says that it was naturally looked upon as a deprivation of all rank, with the exception of departmental rank.

"Recent warrants and orders," it adds, "have striven to remove this impression by indicating the value of departmental rank in terms of army rank, and it is rumoured that on each occasion of gazetetting a medical officer, his army rank will be specified as well as his departmental rank. As long as the status of medical officers in the army is clearly indicated, it does not signify much in what manner this is done. We are opposed to the substitution of combatant for departmental titles; but by the use of such compound terms as surgeon-lieutenant, surgeon-captain, surgeon-major, etc., both departmental status and military rank might be easily and conveniently specified."

ROYAL WARRANT.

ESTABLISHMENT OF ARMY MEDICAL RESERVE OF OFFICERS.

VICTORIA R.
Whereas We deem it expedient to provide for the establishment of an Army Medical Reserve of Officers:

Our Will and Pleasure is that the following shall be the conditions under which the said Reserve shall be formed:—

1. The ranks of Officers of the Army Medical Reserve shall be those of Surgeon-Major and Surgeon.

2. Medical Officers of Our Militia, Yeomanry Cavalry, and Volunteers, who may desire and be permitted to join the Army Medical Reserve of Officers, shall undertake to perform Army duties at home under rules to be fixed by Our Secretary of State, and to act under the orders, for administrative purposes, of the Director-General of the Army Medical Department.

3. Acting Surgeons, and Honorary Assistant Surgeons, of Volunteers may be permitted to join the Army Medical Reserve of Officers if they have passed the prescribed examination for proficiency.

It is Our further Will and Pleasure that the rank of Surgeon-Major shall be conferred on those Surgeons of Our Auxiliary Forces who may desire and be permitted to join the Army Medical Reserve of Officers on completion of 12 years' service from the date of their first appointment to the Auxiliary Forces; and also that Acting Surgeons, and Honorary Assistant Surgeons, of Volunteers permitted to join the Reserve shall be granted the rank of Surgeon therein.

Given at Our Court at Windsor, this eighteenth day of February, 1888, in the 51st year of Our Reign.

By Her Majesty's Command,

EDWARD STANHOPE.

Secretary of State's Instructions on the foregoing Warrant.

1. No Medical Officer of the Auxiliary Forces shall be appointed to the Army Medical Reserve who is not medically fit for service, and whose character and qualifications are not in all respects satisfactory.

2. The names of all Officers of the Army Medical Reserve shall be included in a special Army Medical Reserve List.

3. Officers shall be removed from the Army Medical Reserve List on attaining the age of 65.

4. Officers of the Army Medical Reserve shall be liable to be called to Army service at home, in times of great national emergency, to take the place of such of the Medical Staff of the Army as may be withdrawn for active service; and when so called on shall receive the pay and allowances of their rank.

5. Medical Officers of the Auxiliary Forces who may be permitted to join the Army Medical Reserve shall undertake to accept the charge of the Officers and men of any detachment of troops, not having an Officer of the Medical Staff attached to it, at any station at which they may reside, with the rates of remuneration laid down in Art. 354 of the Royal Warrant for Pay, etc., 1887.

6. Officers of the Army Medical Reserve who are willing to offer their services will have a prior claim to employment in the district in which they reside to other Medical Officers of the Auxiliary Forces, or to civilian medical practitioners.

7. The acceptance of appointments in the Army Medical Reserve will in no way modify the position of Medical Officers in the regiment or corps of the Auxiliary Forces to which they belong.

8. Officers wishing to apply for appointment to the Army Medical Reserve will forward their applications, through the Officer commanding the Corps to which they belong, to the General Officer commanding the District, for transmission to the Military Secretary.

ARMY MEDICAL RESERVE.

M.S. writes: Paragraph 4 of the Secretary of State's instructions on the Warrant for the formation of an Army Medical Reserve of Officers, reads thus: "Officers of the Army Medical Reserve shall be liable to be called to Army service at home, in times of great national emergency to take the places of such of the Medical Staff of the Army as may be withdrawn for active service; and when so called on shall receive the pay and allowances of their rank." The italics are my own.

The above is plain enough. It ought to be our care to jealously guard against any encroachment on our privileges, such as the employment of any of these reserve officers, except in cases of national emergency.

Granting that our present rate of pay is good, it would no longer be regarded as such if service in the Medical Staff of the army was little more than perpetual foreign exile, which this reserve of officers might foreshadow, if our interests are not steadily defended.

THE NAVY.

The undermentioned appointments have been made at the Admiralty:—HERBERT M. ELLIS, Staff-Surgeon to the *Orion*; RICHARD A. MOWELL, M.D., Staff-Surgeon to the *Raleigh*; JAMES W. H. HAWTON, Staff-Surgeon to the *Valorous*; HORACE X. BROWNE, and JOHN E. WEBB, M.B., Staff-Surgeons to the *Raleigh*; VALENTINE STONE, to be Surgeon and Agent at Uzon and Montrose; Staff-Surgeons RICHARD G. BROWN and JOHN MACKIE, to the *President*, additional.

THE MEDICAL STAFF.

BRIGADE-SURGEON JOHN MACKENZIE, M.D., has been granted retired pay. He entered the service as Assistant Surgeon, August 5th, 1858; became Surgeon, March 1st, 1873; Surgeon-Major, April 1st, 1873; and Brigade-Surgeon, September 10th, 1884. He served throughout the war in North China in 1860, and received the medal granted for that campaign.

Surgeon-Major and Honorary Brigade-Surgeon JOHN ANDERSON, M.D., C.I.E., has been allowed to commute his retired pay, which was granted April 15th, 1885.

THE INDIAN MEDICAL SERVICE.

SURGEON W. W. WEBB, Bengal Establishment, medical officer of the Meywar Bheel Corps, is appointed to officiate as Civil Surgeon of Bikaner, vice Assistant Surgeon Sahib Ditta, whose services have been replaced at the disposal of the Punjab Government.

Surgeon F. J. CRAWFORD, M.D., Madras Establishment, doing duty with the 5th Native Infantry in the Eastern District, is appointed to the officiating medical charge of that regiment.

The services of Surgeon D. ELICUT, Madras Establishment, are replaced at the disposal of the Public Department.

THE VOLUNTEERS.

SURGEON and Honorary Surgeon-Major J. HUNTER, of the 1st Argyll and Bute Artillery, has resigned his appointment, which bore date February 20th, 1871; he is permitted to retain his rank and uniform.

Acting-Surgeon A. MITCHELL, M.D., of the 1st Volunteer Brigade Eastern Division Royal Artillery (late the 1st Norfolk), has resigned his commission, which dated from December 8th, 1883.

Acting-Surgeon W. BULL, of the 2nd Tower Hamlets (East London) Fortress and Railway Forces, Royal Engineers (until lately known as the Tower Hamlets Engineer Volunteers), has also resigned his commission, dated August 9th, 1884.

The undermentioned gentlemen have been appointed Acting Surgeons in the corps specified: JOHN HILL, 1st Volunteer Brigade Southern Division Royal Artillery (late the 1st Hampshire); WILLIAM YOUNG, M.B., and T. S. KIRKLAND, M.B., to the 1st Linnithgowshire; and NEVILLE WILLIAMS, M.B., to the 1st Volunteer Battalion Prince of Wales's Own West Yorkshire Regiment (late the 1st West Riding of Yorkshire).

MEDICO-LEGAL AND MEDICO-ETHICAL.

UNSUCCESSFUL ATTEMPT TO REFUSE PAYMENT OF FEES.

THE following is one of those cases in which a groundless charge is brought against a medical man by a patient who, failing to obtain repeated applications for payment of medical fees, adopts this mode of retaliating by making serious and unfounded charges.

Dr. Valentine Rees, a medical practitioner residing in Brecon, sued a Captain Luxmore for £98 10s. for professional services rendered to the defendant from the year 1882 to 1885. Dr. Rees had frequently sent in his account, and the defendant had continually promised to pay. In the year 1886 Dr. Rees pressed for payment, when the defendant alleged that the charges were excessive and unreasonable, and at once issued a writ against Dr. Rees for damages for negligence. The plaintiff applied to the court for an order to stay the motion, so that the counter-claim on the action he brought should be tried that day. The plaintiff succeeded in every court, and the defendant's representatives ultimately withdrew their counter-claim. Dr. Rees courted a public judgment, and on being sworn stated that it was not until his solicitor had written a letter to Captain Luxmore threatening proceedings that the amount of his account was disputed, or any complaint made as to the success of his services; on the contrary, the defendant and his wife had frequently thanked him (the plaintiff) for his very careful attention and kind services.

The judge, in giving judgment, expressed his opinion that the charges were not excessive, but extremely reasonable, and pointed out that if the plaintiff had been unskilful and negligent it was incredible that the defendant should have continued to employ the plaintiff a whole year after he had discovered his negligence, and added he knew of nothing more despicable than for a man in any way to throw a serious imputation on his medical attendant, whose professional reputation was essential to his earning a livelihood. After making those charges, the defendant did not venture to come forward and substantiate them, but tried to sneak out of them by not appearing in court. He gave judgment for Dr. Rees with all costs, and also judgment on the counter-claim and costs.

COMPENSATION FOR DISMISSAL.

J.W.—An assistant, though unqualified, does not occupy the same position as a menial servant. The common rule as to a month's wages being the measure of damages does not, therefore, necessarily apply. Supposing the dismissal to be wrongful, the assistant would be entitled to recover as damages the amount of his probable loss consequent on the dismissal. This might include something beyond a month's salary, or might, if he got another engagement, be less.

A FLAMING ADVERTISEMENT.

REPREENSIBLE as are such unprofessional circulars as the one issued by Mr J. A. W. (which, moreover, seems to indicate a new departure from the old devices), we are inclined to think that its stilted foolishness will tend, in some degree, to counteract its claptrap, pretentious professions. Be that as it may, we would, alike in the interest of the profession and the public, impress upon all legitimate practitioners into whose hands such circulars and kindred advertisements may chance to fall, the expediency of sending a copy with a concisely written note, or, better still, a brief memorial signed by two or three local medical men, to the respective colleges of which the inculcated practitioner may happen to be a member, in order that the salutary influence of their disciplinary laws may be brought to bear on the offender.

CHARGE TO THE CLERGY.

HAD "A Member" been an observant reader of the JOURNAL, he could scarcely have failed to note that the question of professional charges to the clergy has been repeatedly replied to therein (twice within the current year), and that it is customary for a medical man to charge "the clergyman of his parish." As to what would, in that case, be a fair fee to charge a clergyman for a visit

and medicine is too general a question for us to give a definite reply to without a knowledge of the surroundings. If, however, our correspondent will refer to the new edition of the *Medico-Chirurgical Tariffs*, he will find the question of charges to the clergy carefully reviewed, and suggestions made.

PAUPER LUNATICS.

A MEMBER.—If the parochial authorities will not deal with the servant girl as a pauper, apparently nothing can be done with her unless she "is deemed to be a lunatic, and is not under proper care and control," in which case the constable, relieving officer, or overseer of the parish or place who shall have the knowledge of those facts shall, within three days after obtaining such knowledge, give information upon oath thereof to a justice, who, in his turn, shall proceed to act as directed in 16 and 17 Vict., Cap. 97, Sect. 68.

ETIQUETTE OF RETIRED PRACTITIONERS.

M.D. writes: I, A., three years ago, disposed of his practice to B. A. continues to live in the same place, and is on intimate terms with B. In the bond of settlement of purchase A. declares not to practise, excepting in consultation with another medical man. A solicitor's family living in the same place (old patients of A.'s, and who, by-the-by, partially executed the deed) are patients of C., who lives three miles off. An accident occurs to one of the family, and A. is immediately sent for, who promptly attends, not in consultation, but to fill up the gap till C.'s arrival.

2. A. occasionally acts as medical referee to an insurance company.
3. A. frequently gives, in a casual way, gratuitous advice as to the use of domestic remedies for ailments. Should not A. absolutely refuse to be made use of in the above way?

"* Although B. could no doubt enforce against A. the fulfilment of the covenants in question, we would counsel him to refrain from such a step, unless the proceedings (not unnatural from force of habit) of the latter entail upon the former an inconvenient pecuniary loss, and, even in that case, the better plan would, in our judgment, be for B. to avail himself of a fitting opportunity to remind A. in a kindly, courteous manner of his presumably unintentional omission to carry out the stipulations contained in their mutual deed of sale and purchase; for any hostile proceedings on the part of B. would not only be calculated to destroy their existing intimacy (a matter of import to B.), but would tend to raise a prejudice against him, and alienate A.'s old friends and patients, and so mar his future professional prospects.

With regard to the case of accident, even supposing that, in that emergency, B. had been called in, it would have been his duty on the arrival of the attendant in ordinary to resign the case to him. B. will, in our opinion, do well not to interpret his legal rights in too strict a sense.

ADVICE AND MEDICINE. 6p.; VISIT AND MEDICINE, 1s.; TEETH SKILFULLY EXTRACTED. 6p.

It is scarcely necessary to assure "Justitia" that any practitioner—be he physician, surgeon, graduate, or apothecary—who may professionally associate himself with the dispensary in question would, under the circumstances referred to, be deemed guilty of unprofessional conduct, and render himself amenable to the disciplinary laws of his college. If, therefore, our correspondent can assure himself of the individual personality of the physician and surgeon alluded to, and can procure satisfactory evidence of his complicity with the chemist, we would advise him to send a copy of the circular, with a brief note or memorial, concisely setting forth the facts, to the authorities of the university and college of which the practitioner in question is a member.

INGRATITUDE.

A COUNTRY SURGEON.—Deeply to be regretted as are such cases of professional ingratitude as that referred to by "A Country Surgeon," we would observe that the one in question has more especial relation to general sentiment than to medical ethics proper; and we are not, therefore, in a position to offer any comment thereon.

PROFESSIONAL BROTHERHOOD.

T.R.C.S. ENG., writes: My father, a M.D., aged 85, for upwards of twenty years member of the General Medical Council, for over half a century filling with success a public professional appointment, and, up to this year of grace, medical officer of a public charity, is now lying in probably his last illness. He is attended by a F.R.C.S.I., who is a hospital surgeon, etc., and who takes fees from this M.D. patient now, as well as on former occasions. My father, in bygone days, had been attended cheerfully by the leading men of the profession in the same fashionable city who would scorn to take a fee from him.

Now, when unforeseen family demands are being made upon his slender purse, I feel it my duty, even at the risk of incurring his displeasure (the having made no complaint) to ask through the *JOURNAL* your opinion upon this piece of "professional courtesy" (vide your answer to "Ex-Branch President" in the *JOURNAL* of March 3rd, p. 494).

"* Such a case is unusual, and it would be advisable to seek advice from other sources.

CONSULTATION WITH JUNIORS.

C.B. writes: May I ask if being requested to meet a man nineteen years younger than yourself, of no special professional prominence, the only difference being that he practises in a city and I in the country, would not be sufficient grounds for declining to meet him? What should be the etiquette on such an occasion?

"* The following is the rule laid down in the *Code of Medical Ethics*, p. 62, for the guidance of practitioners in such cases as that referred to by our correspondent:—

"When a practitioner is called upon to meet his junior in consultation for a second opinion, it will be competent for the former to represent the propriety and advantage of obtaining the assistance of a more experienced prac-

itioner; but if the patient specially desires to have the opinion of any qualified member of the profession, even though a junior, it will be at the option of the practitioner in attendance to acquiesce or withdraw. As a rule, however, a practitioner should never decline to meet another merely because he is his junior, and he will best consult his own interest and that of the profession by a ready and courteous assent to meet any junior of good repute. A contrary course would reflect discredit on himself and the faculty."

HOSPITAL AND DISPENSARY MANAGEMENT.

BELFAST ROYAL HOSPITAL: QUARTERLY MEETING.

THE usual quarterly meeting of the subscribers and life governors of this institution was held on February 27th, Mr. Alexander Tate, C.E., in the chair. The staff reported that during the quarter there were treated in the hospital 560 intern patients, of whom 235 were medical and 325 surgical; 83 operations were performed. During the same period there were treated as extern patients 2,670, of whom 611 were medical and 2,059 surgical; 192 minor operations were performed, and there were 369 cases of teeth extraction. It was stated at the meeting that Mr. Forster Green had withdrawn his proposal to build a new wing to the Consumption Hospital, the required endowment of £15,000 not having been subscribed within the stipulated time.

ULSTER HOSPITAL FOR WOMEN AND CHILDREN.

THE annual meeting of this charity was held on March 6th, the Mayor of Belfast (Sir James Haslett, J.P.) presiding. The report showed that 3,000 patients had attended at the extern department during the year, while 156 cases had been admitted to the wards, and 285 maternity cases had been treated in their own homes. The attendance of patients in the gynaecological department had shown a marked increase. The operation of ovariectomy had been twice performed in the wards, in both cases successfully. Owing to an outbreak of measles, the hospital had been closed for some time, but was now in full working order again. Two vacancies had occurred on the staff during the year, one owing to the lamented death of Dr. James Barron, and the other in consequence of the resignation of Dr. Kennedy Wheeler. Dr. Caldwell had been elected to fill the latter vacancy.

ROYAL MATERNITY AND SIMPSON MEMORIAL HOSPITAL, EDINBURGH.

THE forty-third annual meeting of the Royal Maternity and Simpson Memorial Hospital was held last week, when the report submitted to the directors stated that during the year 280 patients had been admitted to the hospital, and 714 were attended at their own homes. Two deaths had taken place in the hospital. There had been forty-five nurses trained at the institution, and 176 students had received clinical instruction.

GLASGOW OPHTHALMIC INSTITUTION.

THE sixteenth annual meeting of this Institution was held on March 12th. The annual report shows a total of 3,712 new cases treated during the year, of whom 463 were in-patients. These figures are nearly 200 in excess of the previous year. The average period of indoor residence was 20.65 days. Of the total cases treated 3,451 were dismissed cured, and 149 improved. In the sixteen years of the existence of the Institution, not far short of 60,000 patients have received the benefits it affords.

REQUESTS AND DONATIONS.—Under the will of the late Mr. Thomas Jessop the following bequests have been made to medical charities: The Jessop Hospital (founded by him at a cost of £30,000), further £4,000; the Sheffield General Infirmary and the Public Hospital and Dispensary, each £200; Free Hospital for Sick Children and the Blind Asylum, each £100.—Mrs. Bingham has given £500 to the building fund of the Sheffield Public Hospital and Dispensary. She makes the gift in memory of her late husband, and it is her desire that a ward shall be designated the "Edward Bingham Ward."

ST. JOHN AMBULANCE ASSOCIATION.—Two courses of lecture on "First Aid" have recently been given by Dr. R. L. Batterbury at the Town Hall, Berkhamsted, and at the second course, which has just concluded, thirty-one ladies (the full number sent up for examination) were successful in obtaining certificates.

DR. JONES, a former assistant at Earlswood, has been elected medical superintendent of that important establishment.

MEDICO-PARLIAMENTARY.

HOUSE OF LORDS.—Friday, March 9th.

Lunacy Acts Amendment Bill.—The House went into Committee on this Bill. Clauses 1 to 19 were agreed to. On Clause 20 Lord DORMER moved an amendment for the purpose of compelling the workhouse authorities to provide sufficient and proper accommodation for pauper lunatics. The amendment was negatived without a division, and the clause was agreed to, as were also Clauses 21 to 33.—Lord HERSHELL moved to insert the following clause after Clause 33:—"The notice by Section 19 of the Lunacy Act, 1853, required to be sent upon the recovery of a patient, shall state that unless the patient is removed within seven days from the date of the notice, he will be discharged. If the patient be not removed within seven days from the date of the notice he shall be forthwith discharged without further order." The clause was agreed to, as were also the intermediate clauses up to Clause 57 inclusive.—On Clause 58 Lord DORMER moved an amendment with the object of giving to the local authority power to build a hospital or asylum for private patients. The amendment was negatived, and the clause agreed to. The Bill passed through Committee.

Vivisection.—Viscount SIDMOUTH moved that a humble address be presented to Her Majesty for correspondence between the Home Office and the Society for the Protection of Animals from Vivisection, in reference to two recent instances of infringements of the law, and asked whether it would in future be a portion of the duties of the authorities at the Home Office to cause legal proceedings to be instituted in similar cases. In one case the operation was performed on a rabbit, but without anaesthetics; and in the other case a number of animals were inoculated in the presence of a number of persons and without anaesthetics. The law had been distinctly contravened; but, upon the attention of the Home Secretary being drawn to the cases, he replied in the one case that the licence would be withdrawn, and in the other that so long a time had elapsed since the infringement of the law that he did not feel justified in instituting proceedings. Under these circumstances he desired to know whether in future, in cases brought to the attention of the Home Office, it would be deemed its duty to institute proceedings.—Earl BROWNLOW said it certainly was a portion of the duties of the authorities at the Home Office to cause proceedings to be instituted in cases where the Vivisection Act had been infringed, and that duty had in the past been discharged. It appeared that the cases referred to were those of Mr. Hine and Mr. Pemberley. Mr. Hine had a certificate, but clearly exceeded the powers granted by the certificate; and the Home Secretary, on having his attention drawn to the matter, withdrew the licence. Mr. Pemberley had not a certificate, and the explanation was that he was acting as the assistant of Dr. Robertson, who had. It was clear, however, that he had infringed the law; but, having regard to the fact that a considerable time had elapsed, the Home Secretary did not think it was a case in which proceedings should be instituted. There were other extenuating circumstances. Cases could be dealt with by the Home Office according to their circumstances, and it was not necessary on every occasion to take legal proceedings. The Government had no objection to lay the correspondence asked for upon the table.—The motion was agreed to.

The Sweating System.—The Earl of DUNRAVEN moved: That the following lords form the Select Committee to consider the sweating system: The Archbishop of Canterbury, the Earl of Derby, the Earl of Onslow, the Earl of Aberdeen, Lord Clinton, Lord Clifford of Chudleigh, the Earl of Limerick, the Earl of Crawford and Balcarres, the Earl of Dunraven, Lord Sandhurst, Lord Rothschil, Lord Monkswell, and Lord Thring.—The motion was agreed to.

Monday, March 12th.

Pharmacy Acts Amendment Bill.—The report of amendments on this Bill was agreed to.

Teaching University for London.—Lord HERSHELL, in the absence of Lord Granville, asked the Lord President whether he had made up his mind as to the manner in which he would deal with the application for a charter for a Teaching University in London, and other like applications for charters; and whether he had come to a conclusion as to a Royal Commission on the subject.—Viscount CRANBROOK replied that he had come to the determination to recommend the issue of a small Royal Commission to inquire, and he hoped that at no great distance of time it would be able to report.

HOUSE OF COMMONS.—Monday, March 12th.

Scarlatina from the Cow.—Sir H. MAXWELL, in answer to Mr. PICTON, said that some months ago Professor Brown was instructed to make an inquiry into the existence among cows of an eruptive disease of the teats, which it was alleged in one case (the Hendon outbreak) had induced scarlatina in man by the agency of the milk. In the course of the inquiry he availed himself of Professor Crookshank's offered assistance in working out the micro-pathology of the affection. In regard to the outbreak in Wiltshire, Professor Crookshank had stated that he considered the disease was the Jennerian cow-pox. Professor Crookshank had not yet furnished a report on the micro-organism of the cow-disease. A report on the whole subject was being prepared, and would be issued as soon as possible by the Agricultural Department.

Deaths from Want.—In reply to Mr. KILBRIDE, Mr. STUART-WORTLEY said a return was now in course of preparation showing the number of deaths in the metropolitan district in the year 1887 upon which coroners' juries had returned verdicts that they were due to starvation, or were deaths accelerated by privation. As to bodies found in the Thames in the City of London and in the metropolitan district, there would be no objection on the part of the Government to furnish a return.

Army Medical Officers.—Dr. FARQUHARSON asked the Secretary for War whether he had received from the British Medical Association a statement containing an analysis of the opinions of nearly 900 army medical officers with reference to the recent abolition of relative rank, and whether a widespread feeling of dissatisfaction had thus been shown to exist throughout the department.—Mr. E. STANHOPE said: I have received a communication from the British Medical Association purporting to give the anonymous opinions of several hundred medical officers. These opinions must have been obtained and expressed in a manner altogether in contravention of military discipline. Medical officers, like other officers, have a proper channel through which they can be heard, and I am not prepared to accept any civilian association as their mouthpiece. On the general question of rank I can only repeat what I said several times last year, namely, that the status of medical officers is just as it was before, and that as regards titular rank they already hold professional titles for which the exchange to combatant titles, without combatant functions, would be a loss of personal influence.—Dr. FARQUHARSON said he would draw attention to this subject on the medical vote.

UNIVERSITY INTELLIGENCE.

GLASGOW.

THE following changes have taken place in the examinerships in Glasgow University:—For graduation in Medicine: In Anatomy, Mr. Alexander Hill, M.A., M.D., Cambridge; Medical Jurisprudence, Mr. A. W. Macfarlane, M.D., London; Midwifery, Mr. Samuel Sloan, M.D., Glasgow; Medicine and Clinical Medicine, Mr. G. Lovell Gulland, M.A., B.Sc., M.B., Edinburgh. The first three appointments are for three years and the last for one year.

UNIVERSITY OF OXFORD.

MR. WILKINSON OVEREND, B.A. OXON., of St. Mary's Hospital Medical School, has been elected to the Radcliffe Travelling Fellowship (£200 a year for three years).

CAMBRIDGE.

NEW ANATOMICAL AND PHYSIOLOGICAL BUILDINGS.—The Building Sites Syndicate have published a report suggesting the mode in which provision should be made for the various science subjects to be housed in or near the new museums. They recommend that the first work to be undertaken should be the buildings for human anatomy and physiology. Pathology can be temporarily accommodated in the old chemical laboratory, and medicine and surgery in the old anatomical buildings. The report seems well weighed, and is likely to be favourably received. The chief need, however, is ready money.

ASSISTANT TO THE PROFESSOR OF SURGERY.—The Special Board for Medicine recommend that an assistant to the professor of surgery be forthwith appointed to help in the teaching and to supervise the surgical collections in the museum. Professor Humphry, himself *sine stipendio*, has generously offered to provide a sufficient

stipend for the new officer. Mr. F. V. Dickins, M.B., has been appointed an elector to the new professorship of Chinese.

The following degrees were conferred at the Congregation held on Thursday, March 8th:—Robert Michael Simon, M.B., Gonville and Caius, admitted M.D.; Matthew Henry Spencer, B.A., Trinity and St. Thomas's, admitted M.B. and B.C.; Arthur Henry Williams, B.A., St. John's and Guy's, admitted M.B. and B.C.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

GUARDIANS AND MEDICAL OFFICERS.

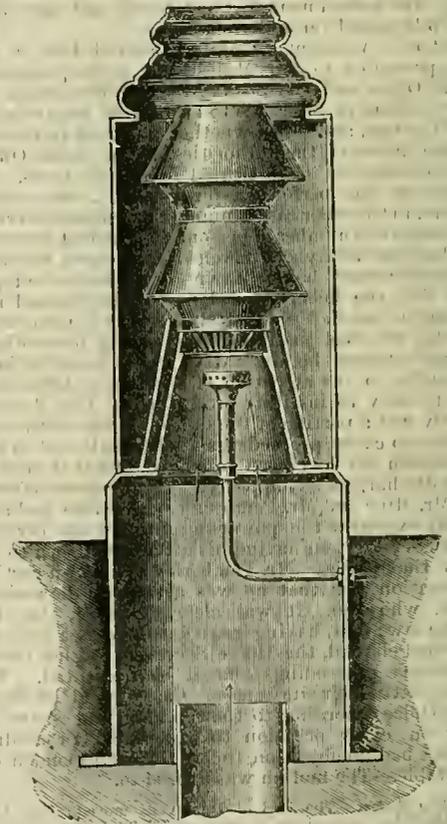

MR. EDWARD MARSHALL, medical officer of health to the Mitcham District of the Croydon Union, and medical officer to the Holborn Union Industrial Schools at Mitcham, appears to be having rather harsh measure dealt out to him by the Holborn Board of Guardians. Mr. Marshall has been medical officer to the schools for thirty years, during which he has discharged his duties without a single complaint having been made against him. A month ago he was suddenly informed that the guardians were dissatisfied with his conduct in his official capacity, and he was called upon to resign. The reason alleged was his neglect to visit the schools under his care with sufficient frequency. It appears that some time ago there was an outbreak of scarlet fever among the patients in the union infirmary, and at the time of the alleged neglect of duty, the disease had begun to show itself in the schools. Mr. Marshall admits that for three weeks he did not visit the schools, but he affirms that during all that time he was in constant communication with the managers of the schools. As soon as any child was taken ill it was at once transferred to the union infirmary, or to the infectious hospital of the Metropolitan Asylums Board, and we are assured that there is absolutely no evidence of Mr. Marshall's absence from the schools having been attended with the slightest ill effect. Nevertheless, a resolution was passed, at a meeting of the board, that, "owing to the pressure of work in his private practice, he (Mr. Marshall) was unable to attend to his duties at the schools," and calling upon him to resign. Mr. Marshall was allowed to appear before the board some weeks ago, and to be heard in his defence. He said that he had not gone to the schools because he kept himself thoroughly informed of everything that occurred, and there was really nothing that required his personal attendance. He was constantly visiting the infirmary, where there were many cases of scarlet fever, and he was seeing a good deal of the disease in private at the same time. It was, therefore, as a matter of fact, better that he should not go near the schools, to which he might easily have been the means of conveying the infection. He had carefully examined the sanitary arrangements at the schools, and had done all in his power to check the spread of the disease among the children. After hearing Mr. Marshall, the board referred the proposal that he should be called upon to resign to the General Purposes Committee, which has now, as we are informed, without making any inquiry into the truth of the allegations against the medical officer on the spot, supported the proposal, and urged the Guardians to insist on his resigning. This Mr. Marshall has declined to do, and we understand that he has appealed to the Local Government Board, begging them to inquire into the whole matter. We hope the Board will accede to this request, and will not allow itself to be put off with general statements of a more or less vague character, but will endeavour to ascertain the precise grounds of complaint against Mr. Marshall, and the specific facts on which they are founded, if any such are forthcoming. Mr. Marshall's appeal for an impartial inquiry by the proper authorities, is deserving of public as well as professional support, as it is of importance, both to medical men holding such responsible public appointments and to the community at large, that Boards of Guardians should be made once for all to understand that they will not be suffered to ride roughshod over medical officers who have faithfully discharged the duties of a thankless office for many years without reproach.

OFFENSIVE PUBLIC URINALS.

C. O. (Newcastle-under-Lyne).—An individual who can prove that the proposed erection will be a nuisance may obtain an injunction to restrain the Town Council from putting it on the site selected. The course to be pursued in such a case is essentially a matter for a lawyer. It would be impossible to give any useful advice without knowing all the facts in detail.

KEELING'S SEWER GAS EXHAUSTER AND DESTRUCTOR.
We are informed by the proprietor that during several months past Richmond, Ealing, Epsom, Leicester, East Dereham, and other towns have applied Keeling's Sewer Gas Exhausters and Destructors to extract and cremate the gases arising from organic decomposition. It is urged that the discharge of sewer emanations through ground level gratings is a crude and indefensible system. Nothing, it is said, conduces to the prosperity of a town or locality so much as a high repute for purity.

It is stated that Keeling's apparatus, has been tested by certain experts chemically as to its destructive power, and mechanically as to its economy. It consists mainly of an iron column with a powerful furnace, which produces an intense heat by the combustion of a small quantity of coal gas, and causes a strong current of air to pass constantly through it in all states of weather. The peculiarity of the furnace consists in a series of ribbed metal cones, which divides the sewer air into minute streams, and subjects it to contact with hot surfaces through a sufficient length to destroy the excess of organic matter which impregnates it.

The Ealing Local Board requested Dr. Russell, of the Chemical Laboratory, St. Bartholomew's Hospital, to test the action of the apparatus on the Ealing sewers, and to analyse the sewer air before it enters the column, and also after it passes through it. Dr. Russell's report was laid before the board on March 1st, and it contains the following description and results of his tests:

"In my first experiment, I introduced into the current of air 0.3 cubic centimetre of ether; this ether was completely oxidised; no smell of ether could be recognised at the top of the stove, only a slight smell of some of the products of the oxidation of the ether. The next experiment was with sulphuretted hydrogen, a gas which in extremely small quantities can be recognised by its smell, and a gas which often occurs in sewers. I generated this gas in a flask, and conveyed it by means of a tube to one of the openings at the base of the stove, so that the air passing through the stove was largely charged with this gas. Although smell is so very delicate a test for this gas, and although this gas was

passed into the base of the stove for half an hour in a tolerably rapid current, not the slightest indication of any undecomposed gas was recognisable at the top of the stove or elsewhere. The smell of the product of oxidation, sulphurous acid, was very perceptible. The above experiments were very satisfactory."

On February 11th the following experiments were made at Ealing Dean. "To test fully the change brought about by passing the air from the sewer through the destructor; two kinds of experiments were made, and in each case the air delivered from the top of the destructor was compared with the air extracted at the same time from the sewer itself. Permanganate of potash is known to oxidise most organic impurities in air, and is the best indicator we have of the amount of such impurities in any sample of air. Two experiments with the air from the top of the ventilator showed, as a mean result, that it required seven volumes of oxygen to oxidise the organic matter in a million volumes of air, or as it is usually expressed, this air contained seven volumes of organic matter in a million volumes. A sample of air collected in a field near contained six volumes of organic matter in the million." A bottle was lowered into the sewer, and by means of an aspirator filled with the air to be tested, it was found to contain twenty-one volumes of organic matter, that is three times as much; thus the heat in the destructor is sufficient to cause "efficient oxidation of the organic matter in the sewer air, any sulphuretted hydrogen present would, as shown by the first experiments, be converted into sulphurous acid, which would act on the permanganate in the same way as the organic matter does."

"The second class of experiments was to determine whether the micro-organisms or germs known to be abundant in sewer air are destroyed by the heating process carried on in this destructor. To determine this, I drew air from the top of the ventilator by means of an aspirator, for thirteen minutes, through sterilised glass wool; this wool was afterwards carefully introduced into a flask containing a cultivating medium. An exactly similar experiment was made with air from the sewer, after four days, the flasks, which had been kept at a temperature most favourable for stimulating growth, were examined; in the air which had the wool through which the sewer air had been drawn there were at least 7,000 distinct colonies or growths; two experiments with air from the top of the ventilator were made, one gave only six colonies and the other fourteen, a striking illustration of how efficiently organisms are destroyed by the method of heating used in this form of destructor. As a definite proof of the high temperature which the cones inside the destructor attain, I placed a piece of sheet lead in the inverted cone immediately above the burner; this lead became melted. The melting point of lead is known to be 617° F."

The following data are stated to be approximately correct. A No. 6 Bray's gas burner, regulated to consume 6 cubic feet of coal gas per hour, will give sufficient heat to exhaust and destroy 3,000 cubic feet of sewer gas per hour, or 72,000 cubic feet in 24 hours. A dozen destructors will be sufficient for a town of 20,000 inhabitants, costing for gas, on an average, £6 per annum, per destructor—less than £100 per annum for the twelve destructors. One destructor will keep a thousand yards of 12-inch sewers clean, say in three directions. The column may also be used as a lamp column.

If sewer ventilation by a furnace is considered a desirable method of meeting the difficulty it would seem that Keeling's destructor is an efficient means of creating a definite extraction of foul sewer air in stagnant conditions of weather, and regardless of external temperature.

WATER SUPPLY OF LARGE TOWNS.

The following notification has been issued in French by His Majesty the King of the Belgians:

By a decree dated December 14th, 1874, His Majesty the King of the Belgians instituted an annual prize of 25,000 francs for the encouragement of intellectual labour. The prize forming the object of international competition in 1893 will be awarded to the best work on the means of procuring abundant and cheap drinking water of the best quality for large towns, and in particular for Brussels and its suburbs, regard being had to the anticipated growth of population, (*Sur la manière de procurer abondamment et au moindre prix aux grandes villes, et spécialement à l'agglomération bruxelloise, la meilleure qualité d'eau potable, en tenant compte de l'augmentation prévue du nombre des habitants.*) Both manuscript and printed essays will be admitted to the com-

petition. A new edition of a printed work cannot take part in the competition unless it contains considerable changes and additions which have appeared, like the other competing essays, within the period of the competition—namely, in one of the years 1889 to 1892 inclusive. The essays may be written in any one of the following languages: French, Flemish, English, German, Italian, and Spanish. Those who desire to take part in the competition must send their essays, written or printed, before January 1st, 1893, to the Minister of Agriculture, Industry, and Public Works, Brussels. The essay which obtains the prize must be printed in the course of the year following that in which the prize is awarded. The award of the competition will be conducted by a jury named by His Majesty the King of the Belgians, and consisting of seven members, three Belgian and the remainder foreigners of different nationalities.

HEALTH OF ENGLISH TOWNS.—In the twenty-eight large English towns, including London, which have an estimated population of 9,398,273 persons, 5,838 births and 4,193 deaths were registered during the week ending Saturday, March 10th. The annual rate of mortality per 1,000 persons living in these towns, which had been 21.6 and 21.5 in the two preceding weeks, further rose to 23.3. The rates in the several towns ranged from 15.0 in Halifax and 15.2 in Derby to 28.2 in Plymouth, 29.5 in Norwich, 30.7 in Blackburn, and 31.3 in Manchester. In the twenty-seven provincial towns the death-rate was 23.5 per 1,000, and slightly exceeded the rate recorded in London, which was 23.0 per 1,000. The 4,193 deaths registered during the week under notice in the twenty-eight towns included 165 which were referred to whooping-cough, 59 to scarlet fever, 49 to measles, 45 to diphtheria, 43 to diarrhoea, 42 to "fever" (principally enteric), and 39 to small-pox; in all, 442 deaths resulted from these principal zymotic diseases, against 429 and 366 in the two preceding weeks. These 442 deaths were equal to an annual rate of 2.5 per 1,000; in London the zymotic death-rate was 2.6, while it averaged 2.3 in the twenty-seven provincial towns, and ranged from 0.0 in Preston and in Newcastle-upon-Tyne, and 0.4 in Brighton and Sunderland, to 4.2 in Oldham, 6.2 in Sheffield, and 6.7 in Plymouth. Measles caused the highest proportional fatality in Bradford and Plymouth; scarlet fever in Oldham and Blackburn; whooping-cough in London, Salford, Leicester, Wolverhampton, and Norwich; and "fever" in Leicester, Norwich, and Derby. Of the 45 deaths from diphtheria recorded last week in the twenty-eight towns 24 occurred in London, 3 in Birmingham, and 3 in Manchester. The 39 fatal cases of small-pox included 29 in Sheffield, 3 in Oldham, 2 in Manchester, 2 in Blackburn, and 2 in London. The number of small-pox patients in the Metropolitan Asylums Hospitals on Saturday, March 10th, was 14, of whom 2 had been admitted during the week. These hospitals also contained 1,201 scarlet fever patients on the same date, and showed a further decline from the number in recent weeks; 100 cases were admitted during the week, against 93 and 84 in the two preceding weeks. The death-rate from diseases of the respiratory organs in London was equal to 6.0 per 1,000, and was slightly below the average.

HEALTH OF SCOTCH TOWNS.—During the week ending Saturday, March 10th, 836 births and 611 deaths were registered in the eight principal Scotch towns. The annual rate of mortality in these towns, which had been 22.6 and 23.4 per 1,000, in the two preceding weeks, further rose to 24.2 during the week under notice, and exceeded by 0.9 per 1,000 the mean rate during the same period in the twenty-eight large English towns. Among these Scotch towns, the lowest rates were recorded in Greenock and Leith, and the highest in Glasgow and Paisley. The 611 deaths in these towns during the week under notice included 76 which were referred to the principal zymotic diseases, equal to an annual rate of 3.0 per 1,000, which exceeded by 0.5 the mean zymotic death-rate during the week under notice in the large English towns. The highest zymotic rates were recorded in Leith and Paisley. The highest proportional fatality of measles occurred in Edinburgh and Leith; from diphtheria in Leith and Paisley; from whooping-cough in Glasgow, Aberdeen, and Paisley; and from "fever" in Glasgow. The mortality from diseases of the respiratory organs in these Scotch towns during the week was equal to 6.7 per 1,000, against 6.0 in London.

HEALTH OF IRISH TOWNS.—In the sixteen principal town districts of Ireland the deaths registered during the week end-

ing Saturday, March 10th, were equal to an annual rate of 32.3 per 1,000. The lowest rates were recorded in Kilkenny and Newry, and the highest in Limerick and Galway. The 224 deaths registered in Dublin during the week under notice were equal to a rate of 33.1 per 1,000 (against 28.4 and 34.0 in the two preceding weeks), the rate for the same period being only 23.0 in London and 18.8 in Edinburgh. The 224 deaths included 25 which resulted from the principal zymotic diseases (equal to an annual rate of 3.7 per 1,000), of which 7 resulted from whooping-cough, 5 from scarlet fever, 4 from measles, 4 from diarrhoea, 3 from fever, and 2 from diphtheria.

THE POST OF PUBLIC VACCINATOR AT WALSALL.

MR. T. W. WILLMORE (Walsall) writes: In reference to the paragraph in the JOURNAL for March 3rd touching the appointment of public vaccinator for Walsall, may I be allowed to add that the guardians, by a vote of eleven to six, re-appointed me to the office in December last.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

WANDSWORTH (Population, 257,742).—*A Curious Case of Hydrophobia.*—The many excellent summaries which make up this report deserve a more lengthy notice than our limited space will allow. Each contains matter of more than local interest, and every effort seems to have been made to ensure their giving a complete and accurate representation of the health of the district. The tables of statistics which concern the whole district are admirably compiled, and display some very important facts. The death-rates of the several subdistricts, inclusive and exclusive of outlying institutions, are given, as well as the amount and density of population and the proportional number of the industrial classes which each subdistrict possesses. The deaths occurring during 1886 are classified according to sex, age, and social position, the relative numbers occurring in each subdistrict being also given. The general death-rate for 1886 was 17.06, varying from 11.2 in the Putney district to 20.0 per 1,000 in West Battersea. This was a lower rate than in any preceding year, with the exception of 1885. It is worthy of note that small-pox was almost entirely absent from the district throughout the year. Whooping-cough, measles, and diarrhoea were the prevailing epidemics, and were attended with more than usual fatality. As a natural consequence, the death-rate of infants was correspondingly high. Considerable interest was excited by a case of hydrophobia. It occurred in the case of a woman rather past the term of middle life. She was ill for three or four days, and died with all the symptoms of hydrophobia, which the *post-mortem* examination, so far as it went, confirmed. The source of infection was very obscure. She had a small dog which she was in the habit of kissing and fondling in various ways. She had an abrasion on the inner side of the lip, and it was considered possible the poison may have been thus communicated. The old dog, which died soon afterwards, was in a wretched state of health at the time—thick viscid saliva constantly dribbled from its mouth. The difficulty was, however, that it did not possess any of the characteristic symptoms of rabies; and the question arose whether hydrophobia could be communicated to man by the saliva of a dog, in a bad condition, but showing no characteristic symptoms of rabies.

BATLEY (Population, 29,500).—*Infectious Hospital Needed.*—During the year 1886 the number of deaths from all causes was 579, being at the rate of 19.6 per 1,000. Dr. Swann's report shows that zymotic diseases prevailed during the whole year with changeable intensity, the death-rate varying from 0.4 per 1,000 in May to 8.5 in September, the rate for the whole year being 3.15. He adds that under existing circumstances it is quite impossible to stamp out or even limit the spread of infectious disease, and that he cannot look forward to being able to cope with any outbreaks until some means of securing the isolation of those who are attacked is provided. It is to be hoped, however, that, under Dr. Swann's strong advice, this state of things will not long continue; and as the inhabitants of the town have displayed great interest in the matter, possibly before long considerable improvement will have taken place.

BACUP (Population, 25,500).—*Hospitals in Readiness but not Resorted to: Infectiousness of Whooping-cough not Recognised by Parents.*—Bacup does not seem to have shared in the general healthiness of the other towns of England during the year 1886. Dr. John Brown reports a considerable increase in the number of deaths, the death-rate being 19.52 per 1,000, as compared with 17.9, in 1885. Owing to the epidemic of scarlet fever, which

carried off 28 victims, the zymotic death-rate was also largely increased. Three-fourths of the deaths were of children under 5. The Hospital at Southall was in constant readiness to receive patients, but in only two cases were its advantages availed of. The success with which these cases were isolated makes the fact, that for the past ten years no cases of infectious disease except small-pox have been sent to the hospital, the more to be regretted. Whooping-cough, which existed more or less through the year, proved fatal to 15 children. More than one half of the fatal cases were complicated with pneumonia, bronchitis, etc. Dr. Brown remarks on the need of care in preventing the spread of the disease, and the ignorance of parents as to its infectious character.

BOOTLE-CUM-LINACRE (Population, 44,000).—*High Mortality from Diarrhoea: Occurrence of Cases of Typhus.*—The death-rate for 1886 (21.04 per 1,000), though somewhat in excess of that for the preceding year, is, in Mr. Sprakeling's opinion, not to be looked upon as excessive when the general character and habits of the population are considered. The depression in trade and the consequent increase of poverty are shown to have had a prejudicial effect as regards the pauper sickness, and it is only reasonable to suppose they had a corresponding effect on the general mortality. The increased number of cases of diseases of the lungs was very marked, and also of those diseases brought on by insufficient and improper food. Seven cases of small-pox were reported during the year. Scarletina was much more prevalent and fatal than in 1885, and there was a very considerable increase of deaths from diarrhoea. As many as eighty-four deaths from this latter disease were registered, eighty-one of which were of children under five years, and many of infants under one year. Four cases of typhus fever came under treatment, and caused much anxiety, owing to the difficulty of isolation. The disease, however, did not spread, and no death occurred. The zymotic death-rate amounted to 3.84 per 1,000.

HOLBORN (Population, 35,850).—*High Death-rate: Hospital Influence.*—Dr. Septimus Gibbon bases his calculations for the year 1886 upon the population at the time of the last census, and hence the 875 deaths which occurred in the district produced a death-rate of 24.4 per 1,000. This is much too high, but as Dr. Gibbon has no reliable means of gauging the extent of the immigration into the district, he prefers to overestimate, rather than underestimate, the death-rate. The year was on the whole a healthy one, although not quite as favourable as 1885. There was a considerable increase in the number of deaths, the mortality from measles, scarlet fever, diphtheria, whooping-cough, and low fever, having risen from 68 to 118. And if correction be made by including deaths of residents in hospitals outside, and excluding those of non-residents within the district, there were 121 deaths from these six zymotic diseases. The three cases of small-pox recorded during the year occurred in common lodging houses, presumably in travellers or tramps, who contracted the disease outside the district. The diminished prevalence and mortality of measles may be in a measure explained by the diminished proportion of children in the population, owing to the continuously low birth-rate. It is satisfactory to note the decrease in the cases of delirium tremens and syphilis. The increase in scarlet fever and diphtheria was exceptional, but fortunately not very great. Dr. Gibbon thinks it is due to the existence of the hospital for children in the district. Certainly nearly all the deaths from diphtheria occurred in that institution. Every possible precaution is taken by the authorities of that hospital to prevent the spread of infectious diseases, but the risks arising from the conveyance of the little patients through the streets, before the disease is recognisable, are unavoidable.

OVER 36 per cent. of the deaths in New York State in 1887 were of children under five years of age. The death-rate at all ages was 23 per mille.

THE annual report of the East London Nursing Society, for nursing the sick poor in their own homes, states that the work was carried on in twenty-three parishes in the East End, and the nurses paid no fewer than 63,000 visits last year. The serious cases were 1,932 in number. The increasing interest taken by the general public in nursing had enabled the society to add to the number of its nurses. There were in all twenty-two nurses, and the cost of each nurse was about £54 a year.

OBITUARY.

ALEXANDER PEERS ADAMS, L.R.C.P.Lond., M.R.C.S.Eng., Surgeon, Madras Army.

We regret to announce the untimely death of Surgeon A. Peers Adams, of the Indian Medical Service. He was born on September 6th, 1855. He received his medical education at St. Bartholomew's Hospital, and obtained the diplomas of Member of the Royal College of Surgeons and Licentiate of the Royal College of Physicians in 1879, and passed into Netley at the February examination in 1880, when fifty candidates competed for twenty-three vacant commissions in the Indian Medical Service. He passed out of Netley at the examination held in August, 1880, and proceeded to the Madras Presidency. He subsequently served in Burmah, where his health suffered severely.

At the meeting of the South Indian Branch of the British Medical Association, held in Madras on October 7th, 1887, Surgeon-Major Drake-Brockman, F.R.C.S., Vice-President, paid the following tribute to his memory:—

"No panegyric is needed in referring to his life or work, for I am sure that all who had the privilege of his acquaintance must have had reason to admire the various qualities with which he was gifted. All who were thrown in his way must have been impressed with the conscientious and efficient manner in which he invariably discharged the various duties which, from time to time, were allotted to him; and it mattered not, whether in the performance of active field operations, or in the engagements which pertain to the lot of a civil medical officer, he was always found ready, willing, and painstaking."

"In the recent Burman campaign his powers had been put to the test, and he did not fail; for we are aware how his conduct and the excellence of his work called for a special representation to the Government. In the different civil charges to which he was at various times nominated, we have also proof of his unswerving attention to the discharge of his duties, and his care and gentleness to the sick who sought his assistance in their distress. His conduct was characterised by a modesty and love of retirement from public observation, which perhaps militated somewhat against his advancement; but that innate characteristic of considering himself of less repute in culture and professional attainments than others with whom he was brought into contact merely confirmed the opinion of those who knew him more intimately, that behind that modest and unassuming demeanour there was concealed a not inconsiderable knowledge of his profession. As we know, he was called upon to fill a number of responsible offices in this city immediately after a prolonged sojourn in the insalubrious climate of Burmah; and had he enjoyed better health, it seems highly probable that he would have finally occupied a prominent position in our midst, and would have given us, as an Association, valuable material for discussion at our monthly gatherings; but it has been ordered otherwise, and we must bow to that dispensation.

"As a friend, in social life, he was ever courteous, refined, and gentlemanly in his bearing and conversation, and although perhaps slow to make new friends, nevertheless, when once a friendship was formed, it was a firm and stable one."

JOHN CROFTON LAWRENSEN, Surgeon-Major, Madras Army.

WE regret to record the death of Surgeon-Major John Crofton Lawrensen, 21st Regiment M.N.I., which occurred at Me-cu, Upper Burmah, on October 4th from enteric fever.

The deceased officer entered the Indian Medical Service on March 30th, 1872, and arrived in India on November 1st of the same year. He served in various military appointments till the outbreak of the Madras famine in 1876, when his services were, with a number of other medical officers, placed at the disposal of the Sanitary Commissioner for duty during that time. During the trying hot months of May, June, July, and August he was in charge of the relief camps in the Kurnool district, for which services he was thanked by the Sanitary Commissioner. In October, 1877, he was appointed to the medical charge of the 21st Regiment M.N.I., and remained with it till the date of his death. In November, 1885, on the outbreak of hostilities in Burmah, he accompanied his regiment on service.

Surgeon-Major Lawrensen was a member of the South Indian Branch of the British Medical Association.

MEDICAL NEWS.

MEDICAL VACANCIES.

The following Vacancies are announced:

- BOROUGH ASYLUM, Birmingham.—Clinical Assistant. Board and residence. Applications to E. B. Whitcombe, Esq., Medical Superintendent.
- BRITISH SEAMAN'S HOSPITAL, Cronstadt, St. Petersburg.—Resident Medical Officer. Salary, £180 per annum, with furnished apartments, etc. Applications to H. M. Consul, St. Petersburg.
- CHARING CROSS HOSPITAL.—Assistant Surgeon. Applications by March 27th to A. E. Reade, Esq., Secretary.
- CHARING CROSS HOSPITAL.—Surgical Registrar. Applications by March 27th to A. E. Reade, Esq., Secretary.
- DENTAL HOSPITAL, Exeter.—Surgeon-Administrator of Anæsthetics. Applications to the Honorary Secretary before March 19th.
- EAST LONDON HOSPITAL FOR CHILDREN, Shadwell, E.—Resident Clinical Assistant. Board and lodging. Applications by March 22nd to the Secretary.
- EDEDERRY UNION.—Medical Officer, Carberry Dispensary. Salary, £135 per annum and fees. Applications to Rev. H. Johnston, Honorary Secretary, the Vicarage. Election on March 19th.
- GENERAL INFIRMARY, Northampton.—House-Surgeon. Salary, £125 per annum, with board, etc. Applications by March 27th to the Secretary, S. P. Bennett, Esq.
- GLENMUCK PAROCHIAL BOARD, Parishes of Glenmuck, Tullick and Glengairn.—Medical Officer. Salary, £45 per annum. Applications by March 20th to the Inspector of the Poor, Ballater.
- HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton. Resident Clinical Assistants. Applications by April 7th, to the Secretary.
- LIVERPOOL DISPENSARIES.—Two Assistant-Surgeons. Salary, £80 per annum, with board, lodging, etc. Applications by March 24th, to R. R. Greene, Esq., Secretary, Leith Office, Moorfields, Liverpool.
- MALE LOCK HOSPITAL, Dean Street, Soho.—House-Surgeon. Salary, £50 per annum, with board and lodging. Applications by March 19th, to the Secretary, Lock Hospital, Harrow Road, W.
- OWENS COLLEGE, Manchester.—Professor of Obstetrics. Applications by March 20th to the Registrar.
- ROSS-SHIRE, Parish of Resolis and District.—Resident Medical Officer. Salary, £62 per annum. Applications by March 17th to R. J. Eilanders, Esq., Fortrose.
- ROYAL LONDON OPHTHALMIC HOSPITAL, Moorfields, E.C.—Junior House-Surgeon. Salary, £50 per annum. Applications by March 24th to the Secretary.
- ST. HELEN'S FRIENDLY SOCIETIES' MEDICAL AID ASSOCIATION.—Resident Medical Officer. Applications by March 20th to Mr. H. Whittle, Secretary, 55, Argyle Street, St. Helen's, Lancashire.
- ST. PETER'S HOSPITAL FOR STONE, etc., Henrietta Street, W.C.—Anæsthetist. Salary, £50 per annum. Applications by March 24th to the Secretary.
- WEST DERBY UNION Workhouse, Walton-on-Hill.—Resident Assistant Medical Officer. Salary, £100, board and lodging. Applications by March 21st, to H. P. Cleaver, Esq., Union Clerk, Brougham Terrace, West Derby Road, Liverpool.
- WEST LONDON HOSPITAL, Hammersmith Road.—Clinical Assistants. Applications to Secretary.
- WESTMINSTER HOSPITAL.—Medical Registrar. Salary, £40 per annum. Applications by March 26th to S. M. Quennell, Secretary.

MEDICAL APPOINTMENTS.

- BERRY, James, B.S.Lond., F.R.C.S., appointed Surgeon to the Alexandra Hospital for Children with Hip Disease, vice Howard Marsh, F.R.O.S., resigned.
- CAMERON, J., M.B., C.M.Glasgow, appointed Surgeon to the Bristol Dispensary vice A. G. Gibbs, L.R.C.P., etc.
- GORDON, James, B.A., M.R.C.S., M.R.C.P., appointed House-Surgeon to the Royal Surrey County Hospital, Guildford, vice H. W. McConnell, M.B., resigned.
- GOREHAM, John, B.A., L.R.C.S., appointed Medical Officer to the Workhouse and Dispensary District of the Oughteraid Union, vice W. W. Brereton, L.K.Q.C.P.I. and L.M., L.R.C.S.I. and L.M., resigned.
- JACKSON, W. F. Marsh, M.R.C.S.Eng., L.R.C.P.Edin., appointed Medical Officer of Health for Smethwick, Staffordshire, vice Mr. William Sutton, deceased.
- MCDOWALL, John G., M.D.Edin., appointed Medical Superintendent to the West Riding Pauper Lunatic Asylum, Menston, near Leeds.
- MACFARLANE, A. W., M.D., F.R.C.P.Edin., appointed Examiner in Medical Jurisprudence in the University of Glasgow.
- MITCHELL, G., M.D., appointed Medical Officer of Templemore Dispensary District.
- MITCHELL, Robert, M.D., M.Ch., appointed Honorary Surgeon to the Bury Infirmary, vice A. B. Telford, M.D., L.R.C.S.E., resigned.
- MOORHEAD, G. A., M.K.Q.C.P.I., appointed Medical Officer of Moate Dispensary.

LORD RANDOLPH CHURCHILL will take the chair at the annual festival dinner of St. Mary's Hospital, which is fixed to take place on May 12th.

BEQUESTS.—Mr. John Manship Norman, D.L., J.P., of Dencombe, Slaughtam, bequeathed £1,000 to the Charing Cross Hospital, and £100 to the Sussex County Hospital, Brighton.—Mr. William Henry Skynner, of Cavendish Place, St. Marylebone, and James Street, Buckingham Gate, bequeathed £500 to the Middlesex Hospital, and £500 to the Westminster Hospital.—Mrs. Mary Hotchkiss, of Harrington Street, Dublin, bequeathed £100 each to the Adelaide Hospital, the Mercer's Hospital, the Coombe Lying-in Hospital, the Hospital for Incurables, St. Mark's Ophthalmic Hospital, and the Convalescent Hospital, all at or near Dublin.—Mr. John William Taylor, J.P. of Almondsbury, bequeathed £200 to the Huddersfield Infirmary.—Mr. John Northage Bradley, of Westhorpe, bequeathed £100 to the Newark Hospital.—The Huntingdon County Hospital has received £100 under the will of Mr. John Seaton.

ANTIPIRYN AS AN ANODYNE.—The *Revista de Ciencias Medicas* of February 20th publishes two cases treated by Dr. La Guardia in the Mercedes Hospital at Havana, in which the power of antipyrin to relieve pain was very marked. A man, aged 64, had been suffering for six weeks from neuralgia of the eighth intercostal nerve of the left side, following herpes zoster of the corresponding region. Iodide of potassium was tried for some days without result; three grains of antipyrin were then given, and next day the pain entirely ceased. In the other case a man, aged 22, suffering from syphilitic nodes on both tibiae, the pain of which kept him awake at night, was ordered three grains of antipyrin every day. On the second day of this treatment he was perfectly free from pain. Some weeks later the nodes began to trouble him again, and the pain was at once subdued in the same way.

LANOLIN IN THE SKIN DISEASES OF CHILDHOOD.—Ointments in which pure lanolin, or lanolin with 10 or 15 per cent. of water, was the basis, are strongly recommended by Dr. Russell Sturgis (*Boston Medical and Surgical Journal*) in the treatment of eczema and urticaria in children. In acute eczema he first directs the affected surface to be cleaned in the usual way, and if weeping copiously, to be then dusted with finely powdered boracic acid; as soon as the inflammation has sufficiently subsided, an ointment of boracic acid ʒij to lanolin ʒj is prescribed. In eczema faciei, with induration, he finds a copious application of pure lanolin thoroughly rubbed in very useful; where the induration is very considerable, the addition of salicylic acid (gr. 5—15 to ʒj) is recommended. Simple lanolin acted most favourably in chronic urticaria.

SAD DEATH OF A MEDICAL STUDENT.—A funeral ceremony took place on Saturday, March 11th, at the newly-constructed chapel of the Westminster Hospital, on the occasion of the death of Mr. F. H. Hibbens, a student, who succumbed to syncope on the fourth day of an attack of scarlet fever. The deceased student had been working very hard, and was out of health, but it is uncertain whether he contracted the disease at the hospital from a case in one of the special wards or in the country. All his fellow students and many members of the hospital staff were present, the deceased having been an exemplary student, and very popular with his fellows.

MILK IN SWITZERLAND.—According to a recent statement the value of the annual production of milk in Switzerland is no less than £7,300,000; in other words, over 410,000,000 gallons are given annually by 662,336 cows and 277,277 goats (the total number of goats being 415,916). Of this quantity 39.6 per cent. is made into cheese and condensed milk, 42.6 supplied in its normal condition for consumption, and 17.8 used in the farmyard for rearing and fattening purposes. There are 2,900 cheese farms in the Alpine regions, and 2,600 in the valleys. The fertile canton of Bern yields the largest supply of milk, after which come the Cantons of St. Gall, Zurich, and Lucerne.

ITALIAN SOCIETY OF HYDROLOGY AND CLIMATOLOGY.—The Società Italiana d'Idrologia e Climatologia, which was founded last September at Pavia when the Congress of the Italian Medical Association was in session, will hold its first meeting at Bologna next October. Its objects are said to be to make medical men in Italy acquainted with the mineral waters of their own country, and to encourage the scientific study of balneology. An exhibition of objects connected with hydrology and climatology will also be held.

LORD DERWENT has been re-elected President, and Sir Charles Legard, Bart., and Sir George Cayler, Bart., Vice-Presidents, of the Royal Sea Bathing Infirmary, Scarborough.

THE ARTS EXAMINATION OF THE SOCIETY OF APOTHECARIES.—The examination in Arts qualifying for registration as a medical student was held in the Hall of the Apothecaries' Society on March 2nd and 3rd. There were 153 candidates; thirty have been placed in the second class, and eighty-seven have passed in some subjects, but have failed in others. The next examination will be held on June 1st and 2nd.

REGISTRATION OF PLUMBERS.—Certificates granted by the Plumbers' Company were issued at Guildhall, on Wednesday last, to thirty-seven master and operative plumbers from Stalybridge, Oxford, Hereford, Sheffield, Leamington, and various districts of London.

At a special meeting of the Forkhill Dispensary Committee, Dr. J. McDowel was elected, by a majority of one, medical officer, in the vacancy caused by the resignation of Dr. McBride.

Mr. G. W. Hastings, Q.C., has been appointed Chairman of the Select Committee on Police and Sanitary Regulation Bills. The Committee will not proceed with business till after Easter.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 P.M.—Professor Charles Stewart: On Locomotion and Allied Phenomena (Lecture IV).

MEDICAL SOCIETY OF LONDON, 8.30 P.M.—Mr. William Adams: On the Successful Treatment of Hammer Toe by the Subcutaneous Division of the Lateral Ligaments. Dr. Borel: On Goitre and its Treatment by Extirpation. Illustrated by 22 cases.

TUESDAY.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, 5 P.M.—Dr. W. H. Dickinson: The Lumleian Lectures; The Tongue as an Indication of Disease. Lecture II.

PATHOLOGICAL SOCIETY, 8.30 P.M.—Dr. Goodhart: Ostetis Deformans. Dr. Wilks: Transverse Furrows on the Nails. Mr. Sutton: An Exostosis. Mr. Eve: On the Inoculability of Lupus. Mr. D'Arcy Power: Sarcoma of the Urinary Bladder. Mr. E. H. Fenwick: Sarcoma of the Urinary Bladder. Mr. Colman: Intestines in Diphtheria. Dr. W. Collier: Tubercular Disease of Suprarenal Capsules. Card Specimens.—Mr. Fenwick: Tumour of Urinary Bladder. Mr. Targett (for Dr. Fry): 1. Cystadenoma of Thyroid. 2. Popliteal Aneurysm. Dr. F. T. Pearce: Advanced Surgical Kidneys. Dr. M. Murray: Cystic Disease of Kidneys.

WEDNESDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 P.M.—Professor Charles Stewart: On Locomotion and Allied Phenomena (Lecture V).

HOSPITAL FOR CONSUMPTION, Brompton, 4 P.M.—Dr. J. Kingston Fowler: On the Diagnosis of Functional from Organic Diseases of the Heart (with Cases).

PARKES MUSEUM OF HYGIENE, 3 P.M.—Dr. A. T. Schofield: On Domestic Hygiene.

ROYAL METEOROLOGICAL SOCIETY, 7 P.M.—Dr. W. Marcell, F.R.S.: On Atmospheric Electricity. Mr. G. J. Symonds, F.R.S.: The Non-existence of Thunderbolts; elucidated by accounts of searches after them, and the exhibition of specimens.

THURSDAY.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, 5 P.M.—Dr. W. H. Dickinson: The Lumleian Lectures; The Tongue as an Indication of Disease. Lecture III.

PARKES MUSEUM OF HYGIENE, 5 P.M.—Mr. A. S. Murray (Keeper of Greek and Roman Antiquities, British Museum): On Physical Training of the Greeks and Romans.

FRIDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 P.M.—Professor Charles Stewart: On Locomotion and Allied Phenomena (Lecture VI).

CANCER HOSPITAL, Brompton, 4.30 P.M.—Mr. F. Bowtman Jessett: On the Treatment of Cancer and Malignant Disease.

CLINICAL SOCIETY OF LONDON, 8.30 P.M.—1. Dr. Ord: Case of Hyperpyrexia and Acute Rheumatism, treated by ice-pack. 2. Dr. Arkle: Two Cases of Hyperpyrexia, treated by cold. 3. Mr. Pearce Gould: Case of Gall Stones; Spontaneous Fracture; Operation; Recovery. 4. Mr. Parker: Living Specimen: A Case of Aneurysm in a child aged 2½ years.

BIRTHS, MARRIAGES, AND DEATHS.

The charges for inserting announcements of Births, Marriages, and Deaths is 5s. 6d. which should be forwarded in stamps with the announcement.

BIRTH.

BARNES.—On February 18th, 1888, at The Bungalow, Prospect Camp, Bournemouth, the wife of Surgeon H. I. Barnes, M.S., of a son.

DEATH.

BINNS.—On Saturday, March 10th, 1888, at the residence of his father, T. Grange, Leeds, Yorkshire, William Binns, Surgeon, of The Cedars, E. Bergholt, near Colchester, aged 43.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY.....10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's (Ophthalmic Department); and Royal Westminster Ophthalmic.—2 P.M.; Metropolitan Free; St. Mark's; Central London Ophthalmic; Royal Orthopaedic; and Hospital for Women.—2.30 P.M.: Chelsea Hospital for Women.

TUESDAY.....9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's; St. Bartholomew's (Ophthalmic Department); St. Mary's; Royal Westminster Ophthalmic.—2 P.M.; Westminster; St. Mark's; Central London Ophthalmic.—2.30 P.M.; West London; Cancer Hospital, Brompton.—4 P.M.: St. Thomas's (Ophthalmic Department);

WEDNESDAY....10 A.M.: National Orthopaedic.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.; Middlesex.—1.30 P.M. St. Bartholomew's, St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.; London; University College; Westminster; Great Northern Central; Central London Ophthalmic.—2.30 P.M.: Samaritan Free Hospital for Women and Children; St. Peter's.—3 to 4 P.M.; King's College.

THURSDAY.....10.30 A.M.: Royal London Ophthalmic.—1 P.M.: St. George's.—1.30 P.M.: St. Bartholomew's (Ophthalmic Department); Guy's (Ophthalmic Department); Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Central London Ophthalmic; Hospital for Diseases of the Throat; Hospital for Women.—2.30 P.M.: North-West London; Chelsea Hospital for Women.

FRIDAY.....9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.15 P.M.: St. George's (Ophthalmic Department).—1.30 P.M.: Guy's; Royal Westminster Ophthalmic.—2 P.M.: King's College; St. Thomas's (Ophthalmic Department); Central London Ophthalmic; Royal South London Ophthalmic; East London Hospital for Children.—2.30 P.M.: West London.

SATURDAY.....9 A.M.: Royal Free.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: King's College.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Middlesex; Royal Free; Central London Ophthalmic.—2.30 P.M.: Cancer Hospital, Brompton.

HOURS OF ATTENDANCE AT THE LONDON HOSPITALS.

CHARING CROSS.—Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; Skin, M. Th., 1.30; Dental, M. W. F., 9.

GUY'S.—Medical and Surgical, daily, 1.30; Obstetric, M. Tu. F., 1.30; Eye, M. Tu. Th. F., 1.30; Ear, Tu. F., 12.30; Skin, Tu., 12.30; Dental, Tu. Th. F., 12.

KING'S COLLEGE.—Medical, daily, 2; Surgical, daily, 1.30; Obstetric, Tu. Th. S., 2; o.p., M. W. F., 12.30; Eye, M. Th., 1; Ophthalmic Department, W., 1; Ear, Th., 2; Skin, Th.; Throat, Th., 3; Dental, Tu. F., 10.

LONDON.—Medical, daily, exc. S., 2; Surgical, daily, 1.30 and 2; Obstetric, M. Th., 1.30; o.p. W. S., 1.30; Eye, W. S., 9; Ear, S., 9.30; Skin, Th., 9; Dental, Tu., 9.

MIDDLESEX.—Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; o.p. W. S., 1.30; Eye, W. S., 8.30; Ear and Throat, Tu., 9; Skin, Tu., 4; Dental, daily, 9.

ST. BARTHOLOMEW'S.—Medical and Surgical, daily, 1.30; Obstetric, Tu. Th. S., 2; o.p., W. S., 9; Eye, Tu. Th. S., 2.30; Ear, Tu. F., 2; Skin, F., 1.30; Larynx, F., 2.30; Orthopaedic, M., 2.30; Dental, Tu. F., 9.

ST. GEORGE'S.—Medical and Surgical, M. T. F. S., 1; Obstetric, Tu. S., 1; o.p., Tu., 2; Eye, W. S., 2; Ear, Tu., 2; Skin, W., 2; Throat, Th., 2; Orthopaedic, W., 2; Dental, Tu., S., 9, Th., 1.

ST. MARY'S.—Medical and Surgical, daily, 1.45; Obstetric, Tu. F., 1.45; o.p., M. Th., 1.30; Eye, Tu. F. S., 9; Ear, M. Th., 3; Throat, Tu. F., 1.30; Skin, M. Th., 9.30; Electrician, Tu. F., 2; Dental, W. S., 9.30; Consultations, M., 2.30; Operations, Tu., 1.30; Ophthalmic Operations, F., 9.

ST. THOMAS'S.—Medical and Surgical, daily, except Sat., 2; Obstetric, M. Th., 2; o.p., W., 1.30; Eye, M. Th., 2; o.p., daily, except Sat., 1.30; Ear, M., 12.30; Skin, W., 12.30; Throat, Tu. F., 1.30; Children, S., 12.30; Dental, Tu. F., 10.

UNIVERSITY COLLEGE.—Medical and Surgical, daily, 1 to 2; Obstetrics, M. Tu. Th. F., 1.30; Eye, M. Tu. Th. F., 2; Ear, S., 1.30; Skin, W., 1.45, S., 9.15; Throat, Th., 2.30; Dental, W., 10.30.

WESTMINSTER.—Medical and Surgical, daily, 1.30; Obstetric, Tu. F., 3; Eye, M. Th., 2.30; Ear, M., 9; Skin, Th., 1; Dental, W. S., 9.15.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS respecting editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

IN order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the office of the JOURNAL, and not to his private house.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL, are requested to communicate beforehand with the Manager, 429, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication. CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

QUERIES.

TREATMENT OF TRACHEAL COUGH.
CANTAR asks for suggestions as to the treatment of tracheal cough in a case where cocaine, expectorants, and potas. have severally failed.

ANSWERS.

T. T.—Of course a Licentiate is as much a member of the profession as a Fellow or Member of any college.

W. BROWN.—"Stip. emul." *stipendium condonato*, signifies that the university received the fees on account of the unusual excellence with which the candidate had fulfilled the exercises for the degree.

CHRONIC SWEATING IN THE AXILLA.
DR. R. L. BATTERBURY (Berkhamsted) would suggest to "M.B." that a little extract of belladonna be smeared on the axilla for a few nights in succession. This will, in all probability, cure the affection, or greatly relieve it; and, if it should return, a repetition of the treatment will keep it in check.

MR. E. MANSELL SYMPSON, M.B., writes: In reply to "M.B.'s" question (JOURNAL for March 10th), I should recommend boroglyceride. Taking the hint from Dr. Whitla, I have used it successfully in cases of foetid sweating of the feet. Pads of lint fastened on to a jersey might be soaked in a warm solution, dried, and placed in the axilla.

"QUINTAN" AGUE.

DR. J. P. HENRY (Dublin) writes: In reply to the query of "T. E. L. L.," I beg to state that the blood in my case of "quintan" ague was not examined for the filaric sanguinis hominis, as, leaving out the fact that the patient had never been in any part of the world where the parasite is common, there were none of the usual symptoms produced by it, such as chyluria, lymphangitis, etc., present. Dr. Manson, of China, while stating that the febrile symptoms occasionally caused by the filaric resemble the paroxysms of ague in their general character, says that they differ from them in the irregularity of the interval, and in its extending over weeks or months. If the exigencies of space had not compelled me to omit a detailed account of the symptoms, "T. E. L. L." would have seen that they were perfectly typical of ague; and even if I had any doubt of the diagnosis, which I had not, the prompt effect produced by quinine would have dispelled it.

Since writing the memorandum of my case, I find that a case of "quintan" ague has been already recorded by Saint Vel (*Gaz. Heb.*, 1863). He also mentions others presenting sextan, septan, and octan types, and one in which the attacks recurred every thirty days. A similar case to the latter was described by Velasco, of Taranto, so early as the fourteenth century. Several of the older writers, such as Dmetos, Tulpius, Muller, and Sprengel, refer to the sextan type, and Thelenius and Binz to the octan. Celso, after describing the ordinary types, mentions the occurrence of a longer interval in the following words:—"Interdum etiam longiore circuitu quædam redeunt; sed id raro evenit."

TREATMENT OF EPILEPSY.

MR. WM. PROWSE (Bleaton) suggests to "B." the administration of Fowler's arsenical solution in medium doses for a lengthened period. The bromides may be persisted in with occasional intermission for the benefit of his patient. Arsenic, in most cases, is a complete preventive of the bromide rash or tendency to the ulcerative process. Mr. Prowse asks whether "B." considers the ulcer curable?

NOTES, LETTERS, ETC.

ENGLISH AND SCOTCH DEGREES.

E. G. (Manchester) writes: In the JOURNAL of March 10th Mr. Pinder (Manchester) complains about what he calls the unfairness of Scotch degrees not being thrown open to English students. Why, the very same rule applies to the University of the city in which he resides. Here an I, an Edinburgh student, with full curriculum, in a position similar to that occupied by Mr. Pinder: I am anxious to obtain a degree, but am debarred from taking that of the Victoria University for the same reason as Mr. Pinder is prevented from taking a Scotch degree. In both instances it is impossible to obtain the degree without having previously complied with the regulations of the particular university.

Mr. Pinder finds fault with the Scotch degrees because they are not thrown open to him. If he wants a degree, why not get that of the Victoria University in Manchester? He has no need to cross the Tweed. Why not be fair, equalise matters, and, if Scotch degrees ought to be thrown open to English students, then throw open English degrees to Scotch students?

CASE OF PERSISTENT SNEEZING.

DR. ARTHUR W. SANFORD, L.R.C.S.E. and P. Edin., (Newcastle-on-Tyne) writes: S. C., aged 10 years, was seized on Friday, February 24th, with persistent and continuous sneezing, a sneeze occurring every fourth second. There was no evidence of acute mischief nor any existing disease to which the sneezing could be traced as a reflex symptom, the only previous history being violent headaches which had from time to time been complained of. Bromide of potash was freely given, but only with the result of procuring a night's rest in every three. The patient was put under chloroform and galvanism was tried, but with no permanent benefit. A blister was put on the nape of the neck, and large doses of the iodide of potash were given on the seventh day, and on Monday, March 5th, the sneezing suddenly stopped, having continued uninterruptedly (with the exception of a few hours' sleep on three nights) for ten days.

TWINS: SPONTANEOUS EVOLUTION

G. F. SYDENHAM, M.R.C.S. (Harwich, Essex) writes: On February 14th I was called to Mrs. R., at 5 A.M., a multipara, aged 36. I found a male child born alive, and the hand of a second protruding at the vulva.

On examination, I found the right shoulder jammed in the pelvis, the head in the right iliac fossa. While examining she had a pain, which forced the thorax deeper into the pelvis, and, during more pains, the thorax, breech, and lower extremities were born; the head quickly followed with occiput anterior. The child, a male, was dead.

THE LUMLEIAN LECTURES

ON THE TONGUE AS AN INDICATION OF DISEASE.

Delivered at the Royal College of Physicians, March, 1888.

By W. HOWSHIP DICKINSON, M.D., F.R.C.P.,

Honorary Fellow of Caius College, Cambridge; Senior Physician to St. George's Hospital; Consulting Physician to the Hospital for Sick Children.

LECTURE I.

THE knowledge which enables many a practical physician to make the tongue an index of diagnosis, treatment, and prognosis is, for the most part, unwritten. It has been handed down to us as part of the tradition of the elders, and few attempts have been made to analyse or educe laws from the accumulation of experience of which it consists. The labour which has been bestowed upon the pulse is in remarkable contrast with the neglect which, in recent times, has been the lot of the tongue. "Various and full of meaning," says a great writer, one whose words must ever be received with reverence within these walls, "are the conditions and appearances presented by the tongue. A patient would think you careless or ignorant of your craft if you did not at each visit look at his tongue as well as feel his pulse." But of late the tendency in this matter has been to agnosticism: it has become the habit with many, and those not the least influential, to look upon the changes which this organ displays as of less and less importance, to regard them as accidental rather than essential, as the results of unimportant local conditions rather than as inseparably connected with constitutional disturbances. "The tongue," said a great surgeon in my hearing, "belongs to the mouth in the first place, and to the general system only in the second." I should have put the general system first; but I will not anticipate my conclusions.

I am about to examine the subject with a fresh appeal to Nature, and, putting aside for the present both ancient faith and modern scepticism, shall be content simply to collect the evidence of the wards and the dead-house, and let the tongue speak for itself. This is simple in theory but in practice complicated, as will become sufficiently apparent, and on this ground I ask not only the indulgence, but the patience of those who honour me by attending.

It is not my purpose to deal with ailments local to the organ, but only with those changes which have their origin outside it, or belong to the system at large. I look at the tongue as a physician not as a surgeon, and regard it as symptomatic of disease rather than as the seat of it. My first endeavour has been to make a trustworthy and usable classification. Many terms have been hitherto applied vaguely and in confusion; tongues have been described as "furred," "coated," or "dirty" almost indiscriminately, while there has been too often a failure to attach due importance to such signs as dryness and nakedness. To secure a working classification I prepared hardened microscopic sections of a number of tongues of many kinds (they amounted to 104), and made with the help of the camera lucida the outlines of those which are now before the College. I was thus enabled to associate the minute and intimate changes with the appearances presented during life to the naked eye. Taking together both naked eye and microscopic appearances, I arranged the series into what, if I may borrow from the botanists, I may call "natural orders," using as guides chiefly such characters as appeared on minute examination to be important, and which, at the same time, were distinguishable with the naked eye during life. It is sufficiently evident that no sub-division, excepting one connected with characters evident to common sight, could have any practical utility. Thus the classification, though made with the help of the microscope, can be applied without it. It might have been more accurate, in some respects, more satisfying to the votary of pure science, could I have relied only on minute anatomy; for there are some changes, especially one—increase of the deep epithelium—which are not easy to be recognised without the use of microscopic sections.

I may say more of this hereafter; putting it aside for the present, I have made a classification which I think will work in practice, in which the minute and essential particulars are conveniently bound up with obvious external characters. The amount and distribution of the superficial or horny epithelium is important, since this essentially constitutes the white covering which is so noticeable during life. Other characteristics are—the elongation of the papillæ; the presence of incrustation, by which the proper surface of the organ is concealed; loss or attenuation of the epithelial layers, by which the surface becomes red, bare, or raw; and the quality of dryness; this last is of great importance, and it may be added that it is recognised only with the naked eye.

The classification may be thus sketched. First comes the condition of health; rather a variable standard—an average state, rather than an absolute one. Next come the stages of addition, then those of subtraction. In the stages of addition the epithelium increases more and more, and finally acquires a superstructure largely composed of foreign material. This is the maximum of clothing; it is succeeded by a process of divestiture, under which the tongue may become not only naked, but flayed.

In detail the first stage is where the papillæ are separately capped with a minute white patch, which consists mainly of horny epithelium; this tongue I call "stippled" or "dotted." As the covering increases, the spots coalesce, cease to be discrete, and become confluent, or at least appear so to the naked eye. To this degree the term "coated" is applied, as indicating continuity. The increased growths on the papillæ form the larger proportion of the surface: the intervals are more or less filled up by the deeper variety of epithelium and adventitious matters. The coat attains its highest development in what may be conveniently designated as the "plastered tongue," of which the covering is thick, uniform, and conspicuous, and often looks as if laid on with a trowel. The term "furred" is restricted to another acquirement—elongation of the papillæ, which remain separate from each other, at least at their extremities, so as to give a shaggy look, or one suggestive of coarse hair or fur. The last stage of increase, one which may succeed upon the furred tongue, or ensue without its intervention upon the coated or plastered, is where the papillæ are concealed by an incrustation, usually dark and dry, by which the surface is overlaid. From this, as the climax of addition, the scale descends through processes of subtraction. The accumulation comes off to expose either a normal surface or one which is imperfect: the former generally when the crust shaves off gradually, the latter when it breaks away abruptly. Irrespective of the formation and removal of crust, there are other modes of waste and defective growth by which the surface of the tongue is swept clean, and its coverings attenuated or even abolished in parts, so that these become absolutely skinless. We now have the several forms of the red, denuded, and raw tongue, and with these the scale finishes.

Classification of Tongues.

Naked Eye.	Microscopic Description.
1. Healthy. Moist.	White epithelium in small amount on papillæ, not continuous or superabundant.
2. Stippled. Moist. Dotted with white.	Excess of white epithelium on papillæ, not extending between them.
2 (D). Stippled. Dry.	Ditto.
3. Stippled and coated. Coat continuous in parts. Moist.	White epithelium on papillæ in excess, with partial filling of intervals.
3 (D). Stippled and coated. Dry.	Ditto.
4. Coated white. Moist. Coat continuous.	Excess of white epithelium on papillæ. Intervals more or less filled up with epithelium and accidental matters.
4 (D). Coated white. Dry. Coat continuous.	Ditto.
5. Strawberry. Coated and injected, especially showing in fungiform papillæ.	Like the coated or plastered, but with more injection.
6. White, plastered. Thick uniform coat, abrupt and striking.	More elongation of papillæ than with coated tongue; more filling of intervals, with superficial accumulation.
7. Furred or shaggy. Moist. Greatly elongated papillæ.	Extravagantly long papillæ, mostly of horny epithelium.
7 (D). Furred or shaggy. Dry.	Ditto.
8. Encrusted, dry, brown. Thick, felted dry coat over papillæ.	Continuous crust on and between papillæ, largely of parasitic matters.
9. Furred or encrusted, becoming bare. Generally dry.	Crust breaking away, together with more or less of normal surface.
10. Denuded. Red. Absence of normal covering.	General absence of all epithelium excepting the Malpighian layer; sometimes of that also.
11. Red. Moist. Dry membranous covering.	Level membrane replacing epithelial processes.
12. Cyanosed.	Injected; hypernucleated; excess of deep epithelium.

Before dealing with these classes individually, I will say a word about the plan I propose to follow. I shall first describe each variety of tongue, and then mention the clinical conditions which have been found with it. With this in view, I have made a habit of arranging cases which have come before me in a tabular form, according to the state of the tongue, annexing at the same time other details. As I must content myself with producing only extracts of these tables, I may say that the particulars systematically noted were: the disease and its duration; the general state as to strength, prostration, and consciousness; the temperature of the body; the arrangements as to food and drink; observations relating to the bowels and stomach, to the nervous system, to respiration with regard to the mouth and nose; the presence of morbid discharges by diarrhoea, diuresis, or suppuration; the amount of the saliva, and the moisture or dryness of the mouth. My performances in this matter have fallen short of my intentions. I had hoped to have made a complete compendium of hospital practice; but many cases, chiefly the less important, have escaped notice, so that my tables include only 366 cases; these must be taken as a sample of hospital experience rather than as hospital experience in bulk. They do not fairly show the relative frequency of each kind of tongue, for the more trivial were more often omitted than those which were striking or considered interesting; but they show, I believe correctly as far as they go, the kinds of disease associated with each. However inadequate, I think these records will be of use, helped out as they must be with a larger amount of unrecorded observation. Having described each tongue with its environment of disease, I shall next regard the association from the other point of view, and, taking a few typical diseases and constitutional states, shall show with what varieties of tongues they are accompanied. Finally, I shall draw together such general conclusions and rules of practice as the foregoing details appear to warrant.

I will now proceed to describe the healthy surface of the tongue so far as is necessary for the purpose in view.

CLASS I.—*Healthy Tongue.*

The healthy condition of the tongue is by no means easy to limit or define. Not only does it change its aspect and character with often inconsiderable deviations from ordinary health, but it presents many differences within this state in different persons and in the same persons at different times. There are congenital varieties in the number and prominence of the papillae; and there are such habitual differences, whether congenital or acquired, in the amount of epithelium, that to some persons it is normal to have a clean tongue, to others not less normal to have a coated one. Thus, whether the tongue be looked at with the naked eye or with the microscope, the range of health is wide; the same degree of coating may be normal in one person and abnormal in another, so that it is impossible to set up an exact ideal and say that all departures from it are the results of disease. Nevertheless, some broad outlines may be adventured outside which pathology begins.

The shape, colour, and general appearance of the tongue in health are so well known that it is only necessary briefly to indicate what must be held to be consistent and what inconsistent with this condition. The shape is not too broad or the end too blunt, as with the flabby tongue of anaemia, of depression after alcoholic excess, and of many other asthenic conditions; nor is it indented with the teeth; nor is it narrowed and sharply pointed, as it is said to be chiefly with acute febrile and inflammatory states. The tongue should be protruded steadily and kept still, neither jerky nor tremulous. In colour it should present a basis or substratum of delicate pink, in which the forms of the papillae are distinguishable by their shape, but not by hyperemia or injection, which conditions are conspicuous in many disorders, notably in scarlatina, as the chief characteristic of the strawberry tongue. The surface may be nearly clean or uncovered, but more commonly presents a superstratum which has been termed "fur" or "coating," to the amount and character of which much importance has been attached. In ideal healthiness this is no more than a delicate white sprinkling or stippling, which may be likened to hoar-frost, a little speck lying like a cap or summit to each of the filiform papillae, their extent not being enough to conceal, but only to modify, the general effect of the colour below. The filiform papillae are more constantly coated than the fungiform: the circumvallate seldom. But this covering, even in perfect health, is not always, even not often, so limited; sometimes it stretches between the papillae, partially fills up the intervals

between them, and spreads more abundantly on the central and back parts than at the sides or tip. The coat is nowhere excessively thick, nor enough quite to conceal the configuration of the surface; it thins gradually without abrupt demarcation; it is not absolutely white, but is greyish where thin, yellowish where thick; the proper tissue, where exposed, is not of a bright, but a dull pink, not exaggerated by injection, so that no striking contrasts of white and red are noticeable. The tongue and inside of the mouth are moist. Saliva can be voluntarily collected and spat out; it can be made to issue freely through a cannula in the parotid duct by placing a little acetic acid on the tongue.

To obtain an idea of the minute and essential changes which give rise to the altered appearances presented to the naked eye, it is not enough—it is, indeed, misleading—to be content with scraping the surface. It is needful to secure sections which show everything down to the muscular tissue; the amount, nature, and disposition of the epithelial investment must receive attention in its whole thickness, as well as the state of the corium with regard to injection, nucleation, and extravasation; and the characters of both apart from disease must be indicated. As the purpose is clinical, it will be enough to describe the upper surface, where what may be called the symptomatic changes are mainly observed.

Starting from within, and using the terms descriptive of the skin, which the covering of the tongue much resembles, we come first to the cutis vera or corium, a layer of dense connective tissue between the muscular tissue and the epithelial. Projections from this form the central parts of the papillae. The injection and nucleation of the corium are its chief points of morbid interest. The nucleation varies much, even in health; it is most abundant within the papillae and near the surface. Upon the corium is the epidermis, of which there are three layers, the deepest, or rete Malpighii; upon this a stratum composed of lozenge-shaped nucleated cells, which correspond, with a difference, to the corneum of the skin; and upon this a horny formation which is special to the tongue, and chiefly forms the white coat.

To take these separately, the rete Malpighii presents in contact with the corium a compact arrangement of columnar cells, in health little more than a single course, which are distinguishable, though not abruptly, from a bulky collection of polygonal cells which complete the Malpighian layer. Towards the surface these cells elongate and flatten, still remaining nucleated, and with rather a quick transition become squamous and form a layer which varies much in different circumstances, by which the surface of the tongue is generally covered. This corresponds with the corneum of the skin, though in the tongue, unlike what happens in the skin, the cells retain their nuclei. On the prominent parts, where the growth is oldest, notably on the ends of the papillae, the cells undergo a further change, losing their nuclei and cellular form and becoming fibrous, losing their power of staining with carmine, but greedily absorbing the aniline dyes. It is this horny epithelium which essentially constitutes the coat or fur, and to which many of the clinical characters of the tongue are due.

The superstructure has but a brittle connection with the rete Malpighii, a line of fracture often presenting itself with much regularity along their junction; on the other hand, the rete Malpighii is intimately attached to the corium, so that not only abnormal, but even exceptional, circumstances are needed for their separation. The Malpighian layer is a very definite and constant structure—the chief landmark anatomically; what is above varies almost infinitely; the deep layer should not be quite bare, nor should the accumulation be such as to be level with, and so obscure, the papillary eminences. The papillae themselves commonly show each a tip of horny epithelium, white to the naked eye, yellow to the microscope. This varies much in health; so much in disease that the characters of coating and furring mainly depend upon it.

On the surface of the tongue, attached chiefly to the prominences of the epidermis, is a varying amount of parasitic growth, chiefly in the shape of the micrococcus. This presents itself chiefly in the shape of rounded accumulations upon the outstanding fibrillae, like the inflorescence of a bulrush. Besides this there are often seen, especially about the papillae, granular heaps of bacteria and other parasitic matters, as well as detached epithelial cells and accidental matters derived from food; but the total bulk of the accumulation, whether parasitic or accidental, bears but a small proportion to the epithelial structure of which the coat or fur essentially consists. The adventitious growth

rather an appendage to the coat or fur than a necessary part of it. In certain conditions of disease, of which more hereafter, the parasitic growth, as well as the epithelial, may be in great excess.

The characteristics of health in the mucous membrane of the tongue may be thus summed up. The corium must not be over-injected or over-nucleated, nor must it present numerously the extravasation of leucocytes. The Malpighian layer must display no excess of proliferation. The middle layer of epithelium, which corresponds to the corneum of the skin, must be present but not superabundant. It should completely cover the rete Malpighii between the papillæ, but should allow these to be prominent at their points of emergence. The epithelial processes of the papillæ should be distinguishable, but not too long; upon these may be a few scattered points of vegetation. Finally, the surface described must be exposed, not concealed by any coat or accumulation, however derived, and it must be normally moist.

I need say little clinically about the healthy tongue. It will at once be seen that the healthy tongue is not the same thing as the tongue in health. There are individual peculiarities in the growth of lingual epithelium in virtue of which some tongues are always coated, others not so when coating might be expected. With some persons a coated tongue is habitual, and not only consistent with health, but a sign of it. On the other hand, diseases like pneumonia, in which commonly the tongue is quickly and thickly coated, may fail to produce this result. It takes time to coat the tongue. In the table two cases of pneumonia are referred to with a clean tongue. One was only in the second day, and scarcely counts. In the other, a not very severe case of pleuro-pneumonia with a temperature of 102°, the tongue remained throughout so far clean that it could not be called otherwise than natural. It displayed a general fine white sprinkling, like April hoar-frost spread, which did not overcome the underlying tint. This absence of coat is quite exceptional in the circumstances, and probably shows habitual but unusual scantiness of the epithelial crop. There are also peculiarities in health which concern the saliva. An old woman, to be later referred to, displayed under capillary bronchitis a red, dry tongue, from which I was disposed to augur ill. She got well and the tongue remained the same; she assured me that it had always been so, and I could only infer that the want of saliva, to which, as I shall presently show, the dryness and bareness of the tongue were due, was habitual and consistent with general health.

There are local and chronic diseases in abundance in which the tongue is normal, few involving pyrexia or any general disturbance. I shall show that this organ responds chiefly to constitutional variations. If the system at large is unaffected, so as a rule is the tongue. It is obvious that the conditions of observation in a hospital, whence my tables were chiefly derived, necessarily presented disease more abundantly than health, so that the morbid associations of the clean tongue are exaggerated.

Saliva abnormally deficient	2

Average temperature of 20 cases, 98.5°. Died, 2; recovered, 8; relieved, 13; not relieved, 1.

CLASS 2.—Stippled or Dotted Tongue.

This presents the first deviation from health. This is an excess of coat or fur, not uniformly spread, but displayed only on the points of the papillæ. The term "fur" is perhaps more suited to an interrupted or punctiform covering than coat, which may be limited to one which is continuous; the fur, however, is here but a mere beginning, which may develop into the coated tongue, or that which will be described as furred or shaggy.

Before proceeding to minute particulars, the naked-eye characters may be briefly indicated. The tongue in this phase presents merely an exaggeration or accentuation of the covering of health; the state may indeed be so nearly that of health that the difference may pass without notice. The tips of the papillæ are covered with white more closely and broadly than within healthy limits, and there is perhaps a little more than the normal contrast between the white summits and the pink intervals. The term "stippled" or "dotted" fairly describes the aspect of the dorsum. To borrow from the nomenclature of small-pox, the acquisition is discrete, not confluent. The spots on the papillæ are usually white, less often yellowish or brownish. The spotting is almost or quite absent on a narrow lateral margin, and also on a small triangular patch at the tip, the apex pointing inwards. These clear spaces are made so by the friction of the teeth at each side, and of the palate or gums at the tip.

The minute changes are to be made out only by examination in section. It is thus made evident that the essential alteration is in the amount and disposition of the epithelial covering. The change is in way of excess, but the excess relates only to the condensed superficial structure, where the cells are flattened, fibrous, and rejective of carmine; not, or but very slightly, to the deeper parts, where the early shape and characters of recency remain. There is as yet no considerable or constant increase in the epithelium of the deeper sort, though there may be indications of a tendency in this direction; and here and there, but as yet not abundantly, excess of nucleation appears in the corium, especially about the papillæ. There is no marked injection of the blood vessels. The intervals between the prominent papillæ are nearly empty, as in health. On their tips is commonly more or less parasitic growth, mostly the micrococcus, gathered, as it is apt to be, upon the projecting filaments. The proportion which these parasitic products bear to the total thickness of the coat or fur can be seen only in section. By mere scraping of the surface a false impression is given of the amount of these superficial products. The crop bears only a minor proportion to the bulk of the coat, the major part of which is epithelial. The parasites are the fringe of the garment rather than the garment itself.

We see in this tongue mainly the evidence of disuse. The length of the papillary processes may be explained by the absence of customary wear, and, indeed, is exactly what want of friction and scour might be expected to cause. There is little evidence of overgrowth in the shape of new epithelium, but only a retention of what must necessarily be old. In the parasitic formation there is nothing special or peculiar, but only what is found in health in less abundance. As with the epithelium, what is indicated is rather the retention of what is old than the development of what is new. We may attribute the accumulation, whether epithelial or parasitic, to the absence of food connected with less of appetite, and perhaps in some measure to the stillness of tongue which illness engenders. I have referred to slight and early evidences of overgrowth of epithelium. This will become more apparent when I speak of more advanced changes.

This variety of tongue presents the first step in morbid acquirement and the first departure from health. A large number of persons could be found with this tongue whose condition is not abnormal. I have tabulated sixty-one cases in which this state of tongue was seen. All were hospital patients, in whom absolute health was scarcely to be looked for; among them acute disease was infrequent, chronic disease common. Heart disease was more numerous presented than any other disorder, occurring in seven. Pneumonia and pleurisy, taken together, were found also in seven; but among these was only one instance of pneumonia in an active and pyrexial state. Rheumatism described as acute was present in five cases, but in only three was this adjective applicable in its fullest sense.

The general absence of pyrexia was striking: the temperature in only three cases reached 102°, in no case was it known to pass

103°. The diet in the large majority of cases comprised solid food. Three patients were kept, for special reasons, as short of liquid as was practicable. In these the saliva was markedly deficient—a deficiency which was noted in but four other instances. Extreme prostration existed in but one, together with acute obstruction of the bowel. Thus this tongue does not belong to pyrexia, and seldom concurs with grave constitutional disturbance of any kind. With the acute obstruction the temperature was normal. It presents itself often with local or organic disease, where there is little fever and seldom much vital failure.

Subjoining the cases where the stippled or dotted tongue was dry, and putting aside one where the dryness was due to diet, a larger proportion of acute disease and of constitutional disturbance is apparent when the tongue is dry than when it is moist.

CLASS 3.—*Stippled and Coated.*

The next step in the acquirement of coat is intermediate between the stippled and the coated, presenting a mixture of the characters of both. The white accumulation is present on the papillæ, but is not limited to them; at the back and along the median fissure it fills up the depressions, so that the tongue, while displaying the dotted character about the anterior and lateral parts, is at the back continuously covered, the continuity being implied by the term "coated." This tongue is one of very frequent occurrence, perhaps more so than any other which can be regarded as morbid; it represents but a slight departure from health; since it partakes much of the class preceding and of that following, it may be dismissed with brief description. A partial stippling may present itself as a stage either in the formation of coat or its removal; an example of the latter is seen in the drawing taken during recovery from pneumonia.

The microscope displays in a more marked manner the characters which have been described as belonging to the stippled class; the papillary processes are elongated and conspicuous, but there is in addition some increase of the deep epithelium by which the intervals are partly filled, the filling up made more complete by detached epithelium and accidental matters. Though the deep epithelium does not present to the naked eye the whiteness of the superficial or horny kind, yet the increase of the latter and the mixing together of the sloping ends of the papillæ give a continuity of whiteness, though only in the central and back parts, where the epithelium is most plentiful. This tongue shows want of wear, together with more evidence of increased growth than in the preceding class.

Looking at this class clinically, we still find a large proportion of chronic disease, but note an increase of acute and constitutional affections. I may observe as an apparent exception that pneumonia is presented less numerously, though acute rheumatism is more so, and typhoid is now introduced. The change in the character of the cases is shown by the increase of pyrexia, though this is still slight compared with what will be seen presently, by the increase of constitutional depression, and by the number of cases in which the state of the patient was such as to necessitate liquid diet.

Dry diet, liquids reduced as far as possible (ascites) 1
 Saliva abnormally deficient (decidedly), including 1 under dry diet 6
 Average temperature of 54 cases, 98.7°.

Died, 7; recovered, 30; improved, 26; not improved, 5; uncertain, 1.

CLASS 4.—*The Coated Tongue.*

The next degree of epithelial excess, whether by retention or overproduction, results in the formation of a continuous coat, or one continuous over the greater part of the dorsum. This covering presents great variety and many indications to the naked eye. There is scarcely an acute or subacute disorder at some period of which the tongue is not coated; this holds good especially with febrile complaints. This state of the tongue is often a step to other changes, those often of more serious import. Two special varieties of coated tongue will receive separate notice; the "strawberry" tongue, which, besides being coated, is much injected; and the "plastered" tongue, in which the coat is superabundant, and has certain characters of recency. Putting these kinds aside for the present, the generally coated tongue is only an advance upon that which is partially so, just as the partially coated tongue is an advance upon that which is simply dotted.

In the ordinary varieties of coated tongue, the coat which is continuous between the papillæ covers the greater part of the dorsum, being thickest where friction is least, about the back and median furrow. It may be dirty-white, greyish, or yellowish. The limitation at the tip and edges is not abrupt; there are no striking contrasts of colour; neither is the coat very white, nor where it is absent is the mucous membrane vividly red. The fungiform papillæ may be visible where the coat is shelving, but they are not remarkably injected as with the strawberry tongue. Such a tongue may be anemic or sodden-looking, especially when the patient is anæmic; the condition chronic, or associated with nervous depression. Good examples of the chronically coated tongue are presented in the drawings from a case of floating kidney and neuralgia under morphine; and in one from a case of chronic dysentery under opium. The coat may be variously tinted by accidental circumstances, especially by colouring matters, which are swallowed or vomited. It may be made bright yellow or olive-green by bilious vomit, or brown by faecal vomit. Iron will sometimes make it inky. Iron and port wine used alternately will sometimes convey a deep brown to the coat, tannate of iron resulting from this combination. I once knew an intensely black colour to be imparted to an otherwise light-coloured coat by artificial teeth. Probably some mercurial amalgam had reacted with sulphuretted hydrogen in the coat and produced the black colour.

The coated tongue may lose its coat in two ways: it may gradually thin off with a shelving edge, exposing a moist and natural surface; or it may break away in flakes after displaying a surface which is red and dry; the former method, implying, as it usually does, the restoration of the healthy surface, is obviously of the better omen.

Often, in circumstances which will hereafter claim attention, the coat becomes dry, brown, and cracked, sometimes presenting rectangular fissures like crocodile's skin. This amounts to what I shall presently describe as the "encrusted tongue," towards the making of which the coated tongue is a step.

Microscopic examination of the coated tongue shows as the essential change excess of epithelium of every kind. The papillæ are prominent, their pillars of corium stand well out, and upon them are long processes of the carmine-refusing epithelium, which is horny, superficial, and old. Between these protrusions is a superabundance of the full-bodied nucleated epithelium such as belongs to the intervals by which these spaces are more or less filled up. In some cases this accumulation is surrounded by a thin layer which has undergone the horny transformation. When this is so, it easily accounts for the continuity of whiteness, since epithelium of this sort is, when moist, white to the naked eye. The continuity of whiteness, however, upon which the definition of the coated tongue rests, is more commonly maintained by the approximation of the long processes, and the filling of the intervals by accidental matters. There is as yet no marked injection, no great evidence of overgrowth in the Malpighian layer, no constant hypernucleation of the corium. What alteration of growth there is is in the direction of too much; but there is no such extravagance, as will be noted in some conditions to be presently considered.

On and about the papillæ parasitic growths such as have been already described are often abundant, but as these are not essential to this variety of tongue, nor add very materially to the bulk of the coat they need no detailed notice.

Clinically, the coated tongue brings with it a further increase of acute and febrile disease. Taking together the moist and dry kinds, pneumonia or pleurisy was present in 10 of 68 cases; typhoid was slightly more frequent than in the preceding classes, while other febrile disorders now intrude themselves into the list. Pyrexia and prostration are both on the ascent, showing that the generally coated tongue is associated with a larger proportion of constitutional affection than where the coat is more partial. It was observed that the saliva was noticeably deficient in a larger proportion of cases than heretofore—in 12 of 68 of the coated tongue, in only 5 of 69 where the coat was partial.

CLASS 5.—*Strawberry Tongue.*

This needs but a brief mention. Usually with what may be called the acute coated tongue, more especially when this approaches the plastered character to be next noticed, the fungiform papillæ show through the coat at the tip and edges. These are often more or less injected, especially with scarlatina, where they

show in a striking manner the increased vascularity of the organ due to its participation in the cutaneous eruption.

The association with scarlatina would have been displayed more prominently in the table but that this disease is not, as a rule, admitted into St. George's Hospital. The strawberry state is sometimes seen in other disorders, most of which are of the acute febrile kind; pneumonia, typhoid, and perityphlitis are presented in the record. Injection of the tongue is an accompaniment of many febrile states, not only giving colour to the substratum, but also promoting the epithelial growth. Pyrexia is generally present with the strawberry tongue, and that to a greater degree than with the antecedent classes.

5. Strawberry tongue; moist.

CLASS 6.—Plastered Tongue.

The variety alluded to as plastered is well marked, has much clinical importance, and demands a separate notice. Clinically, this might be called the coated tongue of acute disease. The coat, which is white, moist, though generally not fully so, and uniform, except at the edges, is spread over the dorsum, excepting a narrow margin and a small space at the tip, with a thickness, smoothness, and definite limitation which suggests the laying on of plaster. The edges, though definite, are somewhat bevelled, and are perforated as they thin with the red fungiform papillæ, after the strawberry style. Sometimes, as in the drawing displayed, taken on the fourteenth day of typhoid, the covering is so white, thick, and fine in grain as to give the idea of plaster-of-Paris or white lead smoothly spread; at other times it is coarser and less purely white, as if a fine kind of mortar had been used. The mucous surface, where exposed, is often redder than natural, especially when the coat is of the whiter kind. The more recent the illness the whiter the coat. When very thick, white, and strongly contrasted with the red margin, the indication is of acute disease—in other words, of disease recent and severe. Were it not recent, the coat would not be so purely white; were it not severe, the thickness could not have come in the time. Each day the tongue becomes less white, and gradually assumes a dirty yellowish or brownish tint. A brown colour associated with dryness and cracks commonly appears when the disease is severe, of long continuance, and attended with prostration. The properties of brownness and dryness may accompany many states of tongue, and will receive further notice.

I may in a few words indicate wherein the minute characters of the plastered tongue differ from that which is commonly coated. The difference is mainly one of degree. The papillæ are now more elongated, even so much so as to resemble those of the shaggy or furred tongue. With this we have more complete filling up of the intervals, and even some overlying of the papillæ with matters partly derived from the tongue itself as epithelium, partly parasitic and partly accidental. This condition is a great way towards the encrusted tongue, the chief difference being in the presence or absence of moisture. The plastered tongue, when dry, becomes the encrusted. In the plastered tongue the hypertrophy of the superficial epithelium, as yet uncomplicated to any great extent, attains its climax.

Clinically, this tongue never fails to arrest attention; it is the ensign of recent acute febrile disease. The chronic coated tongue is distinguishable from the plastered by its dirtier colour, and the less vivid apposition of white and red. Of 32 cases of the plastered tongue, the table shows 8 of pneumonia, 3 of acute bronchitis, 3 of acute rheumatism, 6 of typhoid, and 4 of other acute febrile affections. Pyrexia was marked in 18 cases, while the general average of temperature was 101.6°, a higher level than has yet appeared, save with the strawberry tongue, a nearly allied condition. Prostration, mostly such as belongs to the febrile state, was recorded in 8, while the increased proportion of patients on

liquid diet bears testimony to the same association. The saliva was noticeably deficient in a larger proportion of instances than with any tongue yet before us, save the small strawberry class. This does not imply merely that the tongue was dryish, which might be due to the evaporation caused by the increased heat of the body, but to lessened secretion, as was in some instances ascertained with the cannula. We see a close association with pyrexia which stimulates cell growth, and is probably the chief agent in producing the characteristic epithelial luxuriance, the products of which are abnormally retained partly by reason of the scantiness of saliva.

6. White; plastered; moist.

Cerebral tumour	1	Jaundice (enlargement of liver)	1

Saliva abnormally deficient	13

Average temperature of 27 cases, 101.6°.
Died, 10; recovered, 11; improved, 11.

Before proceeding to other varieties of tongues, I will, now that we have reached in the plastered tongue the climax of simple coating, look back upon the several grades of that condition, and try to collect the instruction which flows from them.

First pathologically. The most important item is the lengthening of the papillæ; and the first question, how far this depends on disuse, from want of food, etc., and how far on overgrowth. Want of wear must have some effect in allowing this elongation, but it would seem to be too rapidly produced to be wholly thus accounted for. A greater length is attained within the short duration of an acute disease than in its longer time of a chronic one, even though it entail more complete disuse. Not only are the epithelial ends to which only the wear applies elongated, but so in many cases are the deeper parts of the column which are unexposed. The epithelium also between the papillæ, which, as being less exposed than they are, must be less influenced by wear, is also in many cases increased in thickness; when it is so it gives strong evidence of over-production as against deficient removal. Coating, therefore, is the result in part of disuse, want of rubbing and washing, as the somewhat increased surface parasites show, but chiefly of morbid overgrowth.

The clinical circumstances give similar evidence. It is true that the greater degrees of coating occur chiefly in patients who are kept without much solid food. On the other hand, in many conditions with which solid food and mastication are almost completely absent, the thick and rapid covering of acute disease does not present itself. I have watched with interest from this point of view cases of stricture of the œsophagus. In three such only the lower degrees of coating were presented, though in all solids were impossible, and in two food was introduced chiefly by the bowel. In a fourth the tongue was dry and furred, but the furring came on with dryness, on which it was apparently dependent. I shall revert to the influence of diet upon the tongue, and simply say here that a comparison between the thinly or partially coated tongue of simple abstinence, and the thickly and generally coated tongue, where a less degree of abstinence is associated with a febrile state, shows conclusively, as it appears to me, that in the latter condition we have something to look for beyond inaction.

I shall refer later to the effects upon the tongue of the limitation of liquid, but it is enough for the present to say that want neither of food nor of drink avails to produce the thick coating which in other circumstances is so characteristic.

A condition which may be briefly referred to in connection with

coating of the tongue is diminution of saliva, though I shall consider this subsequently on a wider basis. As a general rule, whatever be the reason, the saliva lessens as the coat thickens. Taking together the lesser degrees of coat presented with the stippled, and stippled and coated, classes, this secretion was notably deficient in 12 of 170 cases. Taking together the higher degrees of coat in the strawberry and plastered kinds, the saliva was notably deficient in 16 of 39. Thus generally, up to this point, the less saliva the more coat. But it will appear later that almost total absence of this fluid may concur with a tongue which is almost absolutely without coat. For the present it is enough to point out that the deficiency does not alone account for the excess of covering under consideration.

To account for this there remain but two causes which present themselves as probable: the hypothetical existence of a morbid poison as in fevers, and pyrexia. As to poison, looking at the high degrees of coat in the classes of strawberry and plastered, I find that of 39 such cases 14 were of typhoid, febricula, scarlatina, measles, mumps, or pyæmia, and 3 of acute rheumatism. Thus, unless we include pneumonia, of which there were 10 cases, less than half fell within this hypothesis. Among the rest were many cases of local or organic disease, which were clearly outside this supposition. Among these were 3 cases of acute bronchitis, 1 of phthisis, 2 of perityphlitis, 1 of volvulus—enough to show that local disease, or disease not connected, so far as we know, with any blood contamination, may give rise to what may be called acute coating of the tongue.

Pyrexia remains to be considered. When the tongue is normal, so as a rule is the temperature. I have already referred to one case as exceptional in which the tongue remained clean in the presence of pneumonia. Putting this aside, I have already referred to 22 cases in which, in different circumstances, the tongue was reasonably clean; the temperature was raised only once, and then only to 101.5°. Taking now the degrees of coating in ascending order, we find that as the coat increases, so with almost exact correspondence does the temperature.

Relations of Body Heat to Coating of Tongue.

Class of Tongue.	Percentage with Pyrexia.	Average Temperature.
Stippled	4.9	98.5°
Stippled and coated	8.6	98.7
Coated, moist	18.7	99.1
Coated, dry	30.0	99.5
Strawberry	57.1	102.0
Plastered	53.1	101.6

The annexed statement needs no explanation; whether we look at the frequency of pyrexia in the class, or at the average temperature of all cases in it, the figures are equally significant. Taking the strawberry and the plastered tongues as practically the same, the proportion between coat and heat is maintained with remarkable exactness; and we have as yet failed to find any other condition besides heat of body which has as uniform a relation to the alteration in question.

That heat up to a certain point promotes the growth of cells is a fact well known to experimental physiologists. I take it on the authority of Dr. Delépine that a temperature of between 100° and 104° is favourable to the growth of tissues, one of above 105° detrimental to it. It probably very rarely happens that the dorsum of the tongue, exposed as it is, and necessarily cooler than the constantly covered parts, reaches a temperature high enough to lessen growth; almost any degree of elevation possible in the circumstances must be within the limits of that which tends to increase. In pyrexia, therefore, we have, if not the only maker of coat, certainly the chief one.

CLASS 7.—The Furred or Shaggy Tongue.

As the papillæ of the coated tongue continue to lengthen, and adventitious matter to collect between and upon them, the advancing process presents itself in two shapes, which differ as the elongation or the accumulation preponderates. When there is great projection of the papillæ, so that these stand out distinctly, the term "furred or shaggy" represents this condition. Where these shapes are covered in, and levelled over by matter, whether derived from the tongue itself, or from without, the term "encrusted" may be employed. The two conditions occur in many similar circumstances, and are continually intermingled; nevertheless, they occur separately, and must be so described. A stippled or dotted tongue, by increase of each point of coating, may become furred, a process which dryness facilitates. In a different way a thickly

coated tongue may become furred. The lengthened papillæ may present themselves as a coarse pile like plush, and so make the "moist furred tongue." A little drying will cause the threads to collect in sheaves, and so form the "dry furred tongue" which I am about to describe.

To the naked eye and during life the fore part is irregularly rough, with large pointed papillæ, on the tips of which are brown spots, or the whole may be more or less brown. The central and back parts are often covered with irregular pointed masses, such as are represented in the drawing, frequently more or less mixed up with and obscured by dry crust often like crocodile's skin. I have seen after death (in a case of malignant disease of the larynx) much of the hinder region of the tongue covered with a shaggy villous growth, like coarse hair; but in life this hirsute state is commonly much obscured by incrustation.

Under the microscope the chief characteristics of the tongue are the enormously elongated filiform papillæ, every part of which is increased, both the deeper portion derived from the corium and the superficial epithelial part, the latter most so. Micrococci are sometimes present on the tips of the papillæ, but do not add materially to their bulk.

The elongation may conceivably be due either to over-growth or deficient removal; there is often some increase of the deep epithelium, but seldom much; occasionally some over-nucleation of the corium is present. In fine, there is some evidence of hyperplasia, but not enough to account for the striking changes which the tongue presents. These would seem to be mainly due to want of wear, of which the papillary ends, hardened by dryness, are especially resistant. Beyond the resistance which dryness entails, it is possible that the unnatural state of surface which goes with it may act as an irritant and stimulate growth.

As to the clinical relations of this tongue, I have been able to collect, notwithstanding the generality of dryness, a few instances in which the furred tongue was moist, or at least not dry. One of these was of a kind sometimes seen where great elongation of the papillæ is consistent with appetite and health. The only conditions which could be suggested as provocative of the state of the tongue in this case were old age and constipation. I have referred to the state of pile, which may be regarded either as an advanced stage of the coated tongue or an early one of the furred. In the table it is seen to be associated with pneumonia and with anæmia.

The "dry" furred tongue is of more importance than the moist, but it occurs in different circumstances and is by no means uniform in its indications. It may succeed, as has been shown, either upon the dotted tongue or the coated, in the course of advancing disease; it may also occur with retrogressive disease, as when the encrusted tongue sheds its coat so as to expose the subjacent elongated papillæ. The class therefore presents much clinical variety. It has been shown that the furred or shaggy tongue is largely the result of disuse and want of moisture, which latter condition is nearly essential, though not absolutely so. The papillæ harden with dryness, as has been stated, and become abnormally resistant of friction, which, in the absence of solid food and mastication, is diminished. The saliva is obviously deficient, as judged by the difficulty of spitting and by the results of catheterisation of the parotid. It must be stated, however, that the latter operation was not often performed, the extreme illness of the patient often opposing a hindrance. The fact, however, was clear without this test; and the conclusion warranted that the dryness was in general due to want of this secretion.

The accompanying tabulation speaks for itself. I need not allude again to the instance where a profuse hirsute growth was conjoined with sarcoma of the epiglottis and tonsil; here the results of want of friction were chiefly evident, though there was some evidence of overgrowth in hypernucleation. I may next refer to a group of cases in which, as presumably in the last case, the condition was present with little or no pyrexia. This includes two cases of coma from brain disease, two of advanced cirrhosis, one of enlarged liver of uncertain nature, two of diarrhoea, and three of enforced dry diet. Thus, dehydration, be its cause what it may, is a definite factor in producing the tongue in question. In other cases—to wit, typhoid and acute rheumatism—pyrexia was present, but it is clear that this is not essential. It is worth observing how infrequent is pyrexia, and how low its range in the dry tongue now in question, as compared with the plastered moist tongue last discussed. This shows how little of the desiccation is to be attributed to evaporation connected with increased heat of body. And I may make similar negation with regard to

another condition to which dryness and furring have been attributed, namely, habitual openness of the mouth, especially during sleep; I find but three instances in which this attracted notice, and I am persuaded that other causes of drying and furring are far more important.

In short, the dry furred tongue is essentially due to two causes which are connected together—want of saliva and want of wear. Among the causes of want of saliva, the most important is a state of system which cannot be otherwise defined than as failure of nutrition and vital power. With how great a variety of disorders this failure is associated I need not recapitulate; I have expressed the greater degrees of it by the term "prostration."

DONATIONS.—The annual report of the Leeds General Infirmary acknowledges the receipt of £150 from the Yorkshire Football Club, making a total of £1,000 in eight years.—The Trustees of Prison Charities have given 100 guineas, additional, to the National Hospital for Consumption at Ventnor, and 100 guineas to the Metropolitan Convalescent Institution.—The Sheffield Church Burgesses have given £120 to the Sheffield Public Hospital and Dispensary, and £68 to the Jessop Hospital.—The Mary Wardell Convalescent Home for Scarlet Fever has received £100 as "A Jubilee Offering."—Mr. Harold Smith has given £100 to Charing Cross Hospital.—University College Hospital has received £85 from the People's Contribution Fund.

The General Court of the Governors of Guy's Hospital have sanctioned the erection of a residential medical college upon a site immediately adjoining the hospital. It is proposed that the sum required for this purpose, estimated at £20,000, should be raised by private subscriptions among the governors, the medical staff, the lecturers and teachers in the medical school of Guy's Hospital, and their friends. The special appeal fund lately raised, and which is only available for purely hospital purposes, now amounts to £85,000.

THE TREATMENT OF DIPHTHERIA AND TONSILLITIS.

By THOMAS F. RAVEN, L.R.C.P., M.R.C.S.ENG.

FROM time to time communications appear in the JOURNAL, and other medical periodicals, relating to the treatment of diphtheria. Various drugs, applications, and antiseptics are employed, and, when the result is satisfactory, a record is made of successful treatment, and sometimes even the specification of a remedy is announced. The clinical features of the disease, however, are often omitted, and when this is so, the value of the observation must suffer.

It is held by many authorities that sore throat, with membranous deposit, is in itself a sufficient evidence of the disease called diphtheria. The writer of the article on diphtheria, in Quain's *Dictionary of Medicine*, inclines to this view. Others, however, are driven to the conclusion that sore throat, with membranous deposit, occurs sometimes sporadically, sometimes in epidemics (with local appearances exactly resembling those of true diphtheria), which can be clearly distinguished, especially, "after the event," from diphtheria. My own experience compels me to take sides with the latter view. Recently I witnessed, in an institution containing eighty children, a severe epidemic of exudative tonsillitis. The disease was sthenic in type, and the local appearances of wash-leather-like patches of considerable extent upon the pharyngeal mucous membrane were indistinguishable from those of diphtheria. The cases were almost all severe, with temperatures, especially early in the disease, as high as 105°; relapses were common. Three cases of acute rheumatism (with cardiac mischief), one of erysipelas of the face, and one of diffused cellulitis with suppuration (in an adult) were associated with the epidemic. The disease was extremely infectious, and it undoubtedly arose from the poisonous effects of sewer gas. Had I treated the patient with sulphurous acid, or biniodide of mercury, or sulphite of magnesia, or turpentine, I should have been justified, by authority, in recording the successful treatment of sixty cases of diphtheria, by one or other of these remedies. For under careful management, the disease ran its course, and all got well; and, although chlorate of potassium was freely given, I never thought of attributing the recovery of the patients to its employment. During the epidemic albuminuria was never found in any case, nor swelling of the glands at the angles of the jaw; and afterwards there was not a single instance of paralysis or peripheral neuritis.

Within the last few weeks a similar but smaller epidemic has been under my observation. Almost exactly the same symptoms appeared, but the disease was less severe than in the epidemic which I have just given an account of. Thirteen cases of exudative tonsillitis occurred, some mild, some severe. In one case laryngeal symptoms appeared, but subsided in the course of a few days without operation being necessary. All the patients got well, and no remedy but chlorate of potassium was given, and in no case were the sequelæ of diphtheria manifested. The disease, which resulted from the escape of sewer gas into a lavatory and near a bedroom window, was decidedly communicable. This was shown by the fact that when the first case was removed to a lodging for supervision, a little girl in the house contracted the disease.

It is to be hoped that the Collective Investigation Committee, with the new schedules, clear and simple as they are, giving scope to every contributor to record his own experience in his own way, will do good work by collecting sufficient evidence by which a distinction can be definitely drawn between diphtheria and exudative tonsillitis. The subject is one that can hardly be overrated in importance and interest, and most practitioners have experience and notes bearing on the matter.

SCARLET fever has, we learn, broken out on board the Thames training ships *Shaftesbury* and *Exmouth*, lying off Grays. Sixteen cases from the former and one from the latter have been removed to the hospital.

FRENCH ACADEMY OF MEDICINE.—At a meeting of the Académie de Médecine on March 13th Dr. de Saboia, of Rio de Janeiro, and Dr. Lusk, of New York, were elected Corresponding Members in the Section of Surgery. In addition to these two gentlemen, the names of Professor Victor Horsley and Sir William Mac Cormac, of London, Dr. Macewen, of Glasgow, and Dr. Sayre, of New York, were submitted to the Academy.

NOTES

ON A

CASE OF CANCER OF THE PYLORUS
IN WHICH PYLORECTOMY WAS
PERFORMED.

By McCALL ANDERSON, M.D.,

Professor of Clinical Medicine in the University of Glasgow;

AND GEORGE BUCHANAN,

Professor of Clinical Surgery in the University of Glasgow.

MEDICAL HISTORY OF THE CASE BY DR. McCALL ANDERSON.

The following case¹ is worthy of being recorded in connection with the question of operative interference, as it is desirable that unsuccessful, as well as successful, cases should be published.

On January 9th, 1888, on the recommendation of Dr. Samuel Sloan, Mrs. S., aged 48, was admitted into the Western Infirmary complaining of symptoms, referable to the stomach, of four months' duration. Her father died, aged 40, of "chest affection," her mother of "paralysis," at 70; two brothers and two sisters died in infancy, and two sisters, at the ages of 30 and 40, of bronchitis and enlargement of the liver respectively. Her remaining two sisters are alive and well. She herself has had six children, three of whom are dead, one being stillborn, and the other two having died of scarlet fever. Of the remaining three two are well, and the third is at present under my care suffering from chorea. She has always, hitherto, enjoyed good health, and menstruated regularly; but now she seems to be approaching the menopause. She has been a total abstainer all her life.

About four months ago, without obvious cause, she began to complain of flatulence and of "waterbrash," to which symptoms pain in the epigastric region and vomiting were added two months thereafter, and her friends noticed that she was losing colour and getting very thin. The vomiting always occurred two or three minutes after food, and consisted of the ingesta, little altered, and never contained any blood, nor presented the "coffee-ground" appearance. The pain occurred at first only after taking food, but latterly it has been more continuous, and has often been very severe, although she cannot well describe its character. Since her illness commenced her appetite has been very fitful, and has never been very good, although anorexia is not a prominent feature, but, for the last two months, her bowels have been very costive, and she has never had a natural motion.

On examination she was found to be very pallid, very weak, and much emaciated, but she had no fever, nor was there any evidence of disease in any organ with the exception of the stomach.

On placing her on her back and exposing the abdomen, inspection at once revealed a very considerable distension in the epigastric and left hypochondriac regions, having quite the shape of a distended stomach. The great curvature of the stomach was very distinctly indicated, extending at its lowest point as far as the umbilicus, and on passing the hand along its course to the right, it was found to terminate in a hard and nodulated tumour about the size of a hen's egg. This tumour, which was only slightly tender on firm pressure, was freely movable in all directions, and fell very much to the left on lying on that side. There was dulness on percussion over the tumour, but over the rest of the distended stomach the note was tympanitic, and even after fasting for sixteen hours succussion was easily made out.

On January 10th treatment was commenced. She was allowed nothing by the mouth except a small piece of ice when she was thirsty, and a teaspoonful of Carnrick's beef peptonoids thrice daily; but a milk suppository was inserted into the rectum every two hours, and at the alternate hours she had an enema of Carnrick's peptonoids (3 drachms in 3 ounces of warm water). Her bowels were regulated alternately with a simple aperient pill and a warm water enema.

On examination, on January 23rd, it was found that under this treatment the symptoms of dilatation of the stomach had entirely

disappeared, and the tumour was now felt immediately to the right of the left edge of the ribs, and extending nearly to the middle line. On sitting up, however, it descended about a couple of inches. Under the treatment just mentioned she felt very much more comfortable in every respect, and did not seem to be any weaker than at the time of admission.

The symptoms presented in this case led to the conclusion that she was suffering from a cancerous obstruction at the pyloric orifice of the stomach, while the small size of the tumour and its remarkable mobility—which pointed to its being non-adherent—along with the absence of any evidence of implication of other organs, led me to think that it might be a suitable case for resection of the pylorus. Accordingly, after consultation with my colleagues, it was decided to place the whole matter before the patient and her friends, without concealing in any way the great danger of operative interference, and, as they were unanimous in their desire to have it done, she was transferred to the service of my colleague, Professor George Buchanan.

DESCRIPTION OF THE OPERATION, WITH REMARKS THEREON BY
PROFESSOR GEORGE BUCHANAN.

The patient referred to in the report by Dr. Anderson was placed under my care on January 24th, 1888. The danger of the operation was fully represented to her and her husband by me in such form that, so far from recommending or even biasing, I told them that their acquiescence must take the form almost of a request rather than a consent. But they had well weighed Dr. Anderson's words, and quite resolved to have it done.

The operation was done after the manner of Billroth, as detailed in Wölfler's monogram and in Butlin's *Operative Surgery of Malignant Disease*, with one or two slight modifications.

I did not adopt the recommendation that the stomach should be washed out with tepid water for a few days previously to, and also two hours before, the operation. I am confident that if the stomach could be by any treatment put into the state of Mrs. S.'s, such manipulation, a most harassing thing for the patient, would not be required. In her case the stomach was practically empty for days, and on the morning of the operation was so, as was proved at the operation. Such strength as remained to her was not, therefore, taxed in the morning by any such disagreeable process.

She was placed on the table at 11.30 A.M., and was put back to bed at 2.30 P.M. From the commencement of the giving the anæsthetic till the bandaging up of the wound occupied two hours and a half.

There were present, besides others, Sir G. Macleod, Dr. Patterson, Dr. Cameron, and Mr. Maylard who had himself done an operation of the kind two years ago, and as he offered to devote the whole day to be present, he afforded the most valuable assistance in the most trying part of the proceeding, namely, holding up and coapting and assisting in passing the needles through the cut orifices of the stomach and duodenum. Ether was administered by Dr. J. L. Steven with most excellent effect.

I made a vertical incision from the umbilicus to the ensiform cartilage, and without any hæmorrhage cut through the linea alba into the peritoneum. I put my hand into the abdomen and felt nearly opposite the incision, a little to the right side, the end of the stomach with a smooth tumour the size of a large hen's egg surrounding the proximal end of the pylorus. Its right limit was sharply defined at the pylorus, and an almost as clearly defined extremity to the left marked the extent of the stomach invaded. It was freely movable, and there were no adhesions, so that without trouble it could be lifted up to the abdominal wound, and the thin diaphanous webs of the lesser and greater omentum examined. The process of separating the lesser omentum from the upper and the greater omentum from the lower curvature of the stomach is very tedious, as every half-inch has to be secured with a double ligature, and snipped between. When this was accomplished Mr. Maylard used the forefinger and thumb of both hands as a clamp on the proximal part, a flat sponge was placed underneath the stomach and duodenum now drawn up to the wound, and the stomach was cut through. Scissors were used, and the section proved most satisfactory. Not a particle of fluid flowed out, and so far as one could judge the gastric wall, where divided, seemed beyond the tumour.

It is unnecessary to detail all the manipulations with needles and the different modes of introducing them which are necessary, according as one deals with the sewing from within or from outside the viscera. The really critical and difficult part of the

¹ Reported by William MacLennan, M.B., Resident Physician.

operation, viewing it as a piece of skilful manipulation, is where the upper point of the cut duodenum is joined to the lower point of the upper curvature of the stomach, where it has been stitched to close in the upper two-thirds of the gap left by the piece cut off with the tumour.

To do this the assistant must have the stomach end in one forefinger and thumb, and the duodenum end in the other forefinger and thumb, and hold the points in absolute contact; but, besides, must elevate and depress them synchronously with the movements of the surgeon's curved needle, so that the action, to be completed satisfactorily, is composed of the harmonious motion of four hands. So much was I impressed with this, that I can easily conceive that Billroth and his assistants, who have together done the operation many times, ought to accomplish it far more rapidly than the most skilled operator doing it for the first time; and, as the shortening of the time occupied is one of the most necessary desiderata, it is not improbable that increased experience and modification in manipulation may have this effect, and so lessen the primary mortality of the operation. In all, over forty stitches were introduced, besides those used to close the abdominal wound.

When the stomach and duodenum were joined, and just before the abdomen was closed, the parts seemed to fit each other so exactly that it was difficult to realise that four or five inches had been cut away. Also it was satisfactory to notice that neither blood-clot nor any of the contents of the stomach or duodenum had gained admission to the abdomen, though a small vessel in the cut edge of the duodenum had to be ligatured with a fine silk thread.

During the first two hours the patient, who was completely under the effects of ether, was fairly well, but about this time began to show signs of exhaustion, getting very pale, with feeble pulse. Stimulants were carefully administered by subcutaneous injections of ether, enemata of brandy, and small quantities of brandy rubbed inside of the cheeks. But by the time the operation was completed she was in a state bordering on collapse, almost pulseless, cold and white.

She was placed in bed, warmth was applied to the surface, and small quantities of brandy given.

I saw her again at 6 P.M., and by this time the heat was restored and the pulse was fairly good. There was no vomiting, and she declared she felt neither pain nor sickness, but very weak. This rallying went on till midnight, when signs of depression again came on, and she gradually sank till 8 A.M., when she died.

Post-mortem Examination.—On removing the stitches from the abdominal wound the coated surfaces of the peritoneum were found closely applied, seemingly even partly glued together. The abdominal cavity was freely opened in such a way as to obviate the slightest displacement of its contents. They were found precisely as they had been placed at the operation, and not a particle of blood or other fluid had escaped from the line of union. The cut end of the duodenum was lying on the surface of the pancreas, and seemed already to be partly adhering to its peritoneal covering. The stomach and duodenum were carefully removed and laid on a slab, and the stitches kept the parts so well in position that they could be moved about without disturbing the union. The weakest point of union was at the posterior wall of the duodenum, where the stitches were closely placed by interrupted suture, and here, with a little pressure, the point of a probe could be made to pass through the line of union. Here, however, the line of suture while *in situ* was resting on the pancreas, and if the patient had lived adhesion between the peritoneal surface of the bowel and that of the pancreas would have occurred, in fact, had already begun. So far as the anatomical manipulation was concerned, the examination was evidence that the result was just what was desired. The stomach contained about two ounces of brownish fluid. Examination of the seat of the incision showed that the diseased structure had been completely removed. The structure of the tumour removed was cancer of the colloid variety. A small gland in the lesser omentum, seen at the *post-mortem*, was removed, and on microscopic examination proved to be infiltrated with a material somewhat resembling the primary tumour.

REMARKS.—The conclusions I have drawn from the experience of this case, and from a study of the subject² are: 1. That if pylor-

rectomy is to be undertaken with any prospect of success the patient must be urged to submit to it long before he is reduced to a state of approaching inanition by starvation. 2. The success or fatality of the operation itself will be greatly affected by the length of time the abdominal cavity is kept open. 3. The freedom of the tumour from complications, as adhesions and secondary infiltrations, is necessary, but sometimes can only be ascertained during the operation. Meanwhile, as the number of operations performed is still very limited, the question, "Is pylorotomy justifiable or not?" may be disposed of by quoting the two following opinions, one by Mr. Butlin, who has made the question the subject of very extensive study from the history of all the recorded cases; the other from Professor Billroth, the contriver of the operation and the most extensive and successful operator.

Butlin: "The excessive mortality due to the operation, the rapidity of recurrence in what have appeared to be most favourable cases for operation, the return of the symptoms of obstruction in some if not many of the cases, and the fact that there does not appear to be one case which can be claimed as a genuine cure, lead me to doubt whether the operation of resection of the pylorus for cancer is ever a justifiable operation."

From Professor Billroth's assistant: "Wien, Klinik Billroth, February 2nd, 1888. To Professor George Buchanan.—Dear Sir, —Professor Billroth does not only consider the operation of resection of the pylorus as a justifiable one, but he continues operating with good results in many cases, as you will see from the pamphlet following this letter. Of course he does not operate in cases of carcinoma, if there are already infiltrations and adhesions to the liver and pancreas. In these cases he prefers Wölfler's operation or gastro-enterostomy.—Believe me, yours truly, FRITZ SALZER."

Accompanying this letter was a statistical table of the operations done in Professor Billroth's *Klinik* in 1887, three by Billroth and one by Salzer. Three of these recovered and were alive at the time of writing; the fourth died after fourteen days. Surely there is, in the presence of such facts, good reason for a little longer suspending judgment.

I remember the time when one of the most accomplished surgeons of his day publicly asserted that, if a surgeon performed ovariectomy again and it was followed by a fatal result, he might with justice be tried as a criminal charged with culpable homicide; and this owing to the almost uniform mortality from the operation.

I am not an advocate for the very frequent performance of pylorotomy, and I have before stated the conditions which may lead to further success in the future. Meanwhile I would counsel everyone who has the prospect of being called on to do it to practise it frequently on the dead body. The time occupied in passing the stitches can only be curtailed by frequent practice on the parts *in situ*.

As this is one of the surgical manipulations requiring special aptitude and interest and frequent repetition to ensure anything like success. I am of opinion that the operating surgeons of a large community, with so many hospital appointments, might agree to delegate all such operations to one or two young men who would be willing to take it up, and who would accept the duty, not because they could at first do it better than their competers, but because they would cheerfully face the responsibility of keeping up the special knowledge required by mastering everything written about it, and the special aptitude required by the frequent practice of it in the *post-mortem* room.

ST. JOHN AMBULANCE ASSOCIATION.—The course of "First Aid" lectures which were held at Esher and which were attended by H. R. H. the Duchess of Albany, was finished on March 1st, and last week the examination took place, when seventeen candidates out of the twenty-seven composing the class were examined, amongst the number being the Duchess of Albany. The examiner was Dr. Coates, R.N., who, after a searching examination, reported all the candidates, with one exception, as being very well up in their work, amongst the successful candidates being the Duchess of Albany. After the examination, Her Royal Highness thanked the lecturer, Surgeon Lees Hall, for the very pleasant, instructive, and interesting course of lectures given, and which she felt sure the whole class had enjoyed.

CLINICAL LECTURE

ON

THE TREATMENT OF CARBUNCLE

BY SCRAPING.

Delivered at St. Mary's Hospital, January 27th, 1888.

By HERBERT W. PAGE, M.A., M.C.CANTAB.

Surgeon to the Hospital.

GENTLEMEN,—I shall make no apology for offering to you some remarks upon a disease which was thought worthy of a place in the Clinical Lectures of Sir James Paget. I wish, however, to-day to speak more especially on the treatment of carbuncle by that plan of free scraping away which you have seen practised in the hospital, and I do not intend to take up your time by a description of the disease, of the symptoms it presents, or the course it runs. I assume that you are familiar with the usual appearances, and that by the size and severity of the local inflammation, by the angry look, and the boiling out through many openings in the sloughing skin of the unhealthy gangrenous tissue beneath, you are able to say when the term "carbuncle" may be properly applied. I assume also that you know what is the general condition of patients thus afflicted, how, even in cases where there is no such special debilitating cause as diabetes, there has commonly been an antecedent state of ill-health, brought about very possibly by over-work, insanitary surroundings, or insufficient food, and how the carbuncle tends further to increase the debility so induced, by establishing one of those vicious circles which we so continually are trying to break down. As debility led originally to the carbuncular inflammation, so this in its turn increases the debility, until the patient's condition may be one of great danger, demanding the use of every means likely to keep up his strength, and thereby obviate the tendency to die. With these things I assume your familiarity, and if you turn to your textbooks of surgery to find how to treat the patient, you will learn a good deal which is of importance as to maintaining his strength, but you will find little that is satisfactory as to the local treatment of the disease. On this point opinions have differed widely, some surgeons advocating free crucial incisions to relieve both tension and pain, at the risk even of much bleeding, which is clearly a thing not to be lightly regarded in the circumstances; others thinking the separation of the slough may be hastened by pushing small pieces of potassa fusa through the skin-holes into the gangrenous tissue beneath, a plan of treatment from which I hope myself to be preserved; some advising pressure; most recommending the use of well-made and frequently changed hot linseed poultices for the relief of the pain, for the softening and detachment of the sloughs.

With the method by incision Paget deals at length in the lecture to which I have referred; but, without repeating his arguments against it, I may tell you that, from the observation of many cases, he had arrived at the general conclusion that the best of all treatments was to "do nothing," understanding by that phrase that his patients were "carefully fed, washed, cleaned, and bedded, and their carbuncles were very skilfully dressed and washed with proper things, and every care was taken to shut out all untoward influence from them." Thus treated, "no complications occurred, and therefore the cases remained without treatment, as it is said—that is, without medicine, and with no active surgery, no incisions, or anything of that kind." And then he goes on to speak of the value of poultices and perfect cleanliness; of the need in some cases of opium; of the smaller need than is commonly imagined for excessive feeding or stimulants; of the vast importance of letting the patient have very free air. Nor had the experience of ten more years, and the opportunity of having seen a much larger proportion of fatal cases, as we are told in an appended note, led him to deviate from the plan advised when the lecture was given.

Now, all these methods of treatment, whether by incision, by potassa fusa, by pressure, or by poulticing, have this in common, that the tissue which has been destroyed by the violent inflammation is left to be got rid of in Nature's own way, by cessation of the gangrenous process, by the formation of granulation tissue,

and by gradual detachment of the sloughs which have been formed in and beneath the skin. During this slow and tedious process the patient is subjected to many risks, and has much to contend against, the worst of them being exhaustion and pain, septicæmia and pyæmia, and it is from one or other of these last conditions that death commonly ensues.

In speaking of acute septic gangrene, you have heard me advise that the best thing for the patient is to get rid as soon as possible of the gangrenous area or limb, and, as an example, you could not have a better case than that of the lad whose thigh was amputated on the 16th, whose temperature fell at once from 106° to 99°, and who was rescued in the nick of time from a state of supreme danger.

Descending from great things to small, I believe that the risks incidental to carbuncle may be avoided, and the general condition of the patient very rapidly improved, by the free removal of the carbuncle by scraping with a Volkmann's spoon, or rather with Lister's scraper. You know perfectly well the many conditions in which this comparatively new and most useful instrument is employed in surgery: for scraping away unhealthy granulations, strumous or lupoid, diseased glands or synovial thickenings, and in a hundred other ways, but in none is it, I think, of more immediate or practical benefit than for the bodily removal of the sloughing tissue of a large carbuncle. You object to it, perhaps, that there must be severe bleeding, the very thing we spoke of as undesirable in the treatment by crucial incision. Experience, however, shows that there is nothing of the kind. We have been astonished at the singularly little bleeding which has arisen even in the most extensive scraping, and I feel pretty confident that there is no danger on this score.

The mode of treatment is simplicity itself. The patient is anaesthetised, and if the slough has not already begun to boil through openings in the skin, a small central incision, or incisions, is made into the parts beneath, and then with the spoon you scrape out every particle of sloughing tissue, working down into the depths, going from part to part, controlling by gentle pressure any venous oozing there may be here while you are scraping there until the whole slough is cleared out; and such skin as seems to be dead, blue, and bloodless you may cut away with knife or scissors, although it is marvellous how much of apparently worthless skin will return to life, and had better be preserved. Then, having well irrigated the large open wound with perchloride or carbolic lotion, you dust iodoform over it, bandage upon it with some pressure wood-wool pads, and the procedure, which hardly deserves the name of an operation, and which has not taken many minutes, is at an end.

The following cases may be cited in illustration of what has been said and in support of the usefulness and value of this plan of treatment, which I cannot help thinking will come in time to be very generally employed.

CASE I.—R. F., aged 41, admitted April 27th, 1887, looking wasted and very ill, has been out of work for a long time, has been starved, and been mentally much depressed. A carbuncle has been forming between his shoulders for the last eighteen days. It measures eight inches in one diameter, six inches in another, and is boiling out by many openings. He is in great pain. His pulse is very feeble, his morning temperature is 100.2°, and he looks like a man who has been starved. There is no albumen or sugar. On April 29th the carbuncle was freely scraped away; there was no hæmorrhage. The same evening his temperature was 103.6°, and in the following morning and evening 100.6° and 100.4°. He expressed himself as already feeling much better, and thereafter, with a normal temperature, the history is one of rapid improvement. In five days the surface was covered with healthy granulations, and healing took place in the usual way, being helped later on by skin grafts, under the careful dressings of Mr. Kershaw. He left the hospital on June 21st.

CASE II.—H. B., aged 65, the subject of a circular carbuncle, five inches in diameter, on the back of the neck and occiput, was admitted on May 25th. It had begun as a pimple three weeks before, and was now boiling out in a typical manner. He was very weak and ill, and in great pain. On May 26th the whole thing was scraped away; there was no bleeding. The large surface cleaned rapidly, and by June 6th was covered with healthy granulations. His rapid general improvement was in every respect most striking. After the removal of the carbuncle he lost all pain, and soon began to enjoy his food. He was discharged on August 2nd.

CASE III.—X. S., aged 55, was admitted on September 7th. Has

been suffering for some time from cold and indigestion, and looks weak and ill. There is no albumen or sugar. He has a carbuncle four inches in diameter on the back of his neck, which began fourteen days before with aching pain, and the formation of a pimple which rapidly increased in size. The pain is great, although the carbuncle is much broken down. On September 8th the carbuncle was scraped away by my house-surgeon, Mr. Crowle. By September 16th the surface was covered with healthy granulations, and healing forthwith went on in the usual way. His general appearance at once improved, and from the day after the operation he had freedom from pain. Discharged October 4th.

Our latest case was treated yesterday by Mr. Norton, my present house-surgeon. To-day the man looks much better, and is quite free from the severe pain which he was suffering before the scraping.

That each and all of these patients derived immense benefit from the treatment, there could be at the time no doubt, nor is there any, I think, that the risks of septicaemia, pyaemia, and exhaustion were very much lessened. Clearly, it cannot be otherwise than an advantage to get rid as early as can be of so nasty a thing as a carbuncular slough, as I hold it is the right thing to get rid of sloughs however caused. You may remove them too late, you can hardly do so too soon. Many of you know the woman in Manvers ward, who was so long an in-patient because of an extensive burn of arm, breast, side, and axilla, who began on the sixth day to wander and have high temperature, and to be distinctly septicaemic, and who rapidly improved, and whose temperature fell as soon as Mr. Crowle had carefully scraped away the sloughing tissue. So, also, is it with the scraping of carbuncles.

This plan of treatment has, no doubt, occurred to and been practised by other surgeons, but a search through books and journals has enabled me to find only one paper bearing on the subject. The paper "On Scraping in Surgery" was well worth finding (*Liverpool Medico-Chirurgical Journal*, January, 1887, p. 41); and I will read to you what Mr. Teale, the writer of it, says.

"*Carbuncle*.—Probably in no disease involving severe pain, and occasionally threatening life, is treatment by scraping more conspicuously of value than in carbuncle. A central crucial incision of moderate size, with vigorous scraping in every direction in which the scraper can penetrate into the half-dead tissue, will cleanse the diseased mass of much of the half-dead, putrefying, poisonous material. This main attack should be supplemented by smaller crucial incisions and scrapings in the contiguous carbuncular skin, and by numerous small incisions or lancet-punctures into any neighbouring skin, which, though not carbuncular, is oedematous, infiltrated by the spreading poison, and already half-condemned to a destructive career. Having rid the mass as far as possible of all diseased, decaying, infecting material, the resulting cavities and crevices should be well soaked, either with pure carbolic acid, carefully used so as not to scald the skin, or perhaps more advantageously with glycerin acid carbol, so that every crevice where half-dead tissue remains may be soaked and penetrated. Finally, the raw surface is well charged with iodoform, and dressed with salicylic acid or some such absorbent antiseptic material. The result is cessation of pain and feverishness, restoration of normal temperature, and a rapid establishment of comfort, convalescence, and healing."

I could wish for no better encouragement in bringing this mode of treatment to your notice than that it should have found an advocate in Mr. Teale, of Leeds.

BEQUESTS.—Lord Hindlip bequeathed £1,000 to the Burton-on-Trent Infirmary.—The Sheffield General Infirmary has received £500, and the Public Hospital and Dispensary, £250, under the will of Mr. Samuel Fox, of Deepcar.—The Glamorganshire Infirmary and Dispensary has received £500 under the will of Miss Mary Pothergill, of Hensel Castle.—Mr. Henry Browning, of Grosvenor Street, bequeathed £300 to St. George's Hospital.—Mr. George Ash bequeathed £200 to the Kent and Canterbury Hospital.—Mr. Michael Ganly, of Shelbourne Road, Dublin, bequeathed £100 each to the Mater Misericordiae Hospital, St. Vincent's Hospital, the Hospital for Incurables, and the Adelaide Hospital.—Mr. Charles Chevely, of Widford Lodge, Chelmsford, bequeathed £100 to the Essex Idiot Asylum at Colchester, £100 to the Chelmsford Infirmary, and £100 to the Dispensary.—Mr. Thomas Samuel Bolitho, of Trengwainton, Penzance, bequeathed £100 to the local infirmary.

CASE OF CEREBRAL ABSCESS SUCCESSFULLY TREATED BY OPERATION.

BY VICTOR HORSLEY, B.S. (Lond.), F.R.S., ETC.,
Assistant Surgeon to University College Hospital, and Surgeon to the National Hospital for Paralysis and Epilepsy.

(Continued from page 531.)

I SAW the patient on December 9th, 1887, in consultation with Dr. Ferrier. There was a rather offensive purulent discharge from the left ear, the pinna and external auditory meatus being tender; the passage also was a little swollen and narrow. Wiping out the pus completely was rendered difficult by this tenderness, and examination of the membrana tympani consequently very incomplete. It was, therefore, doubtful whether the opening was in the posterior segment, as it appeared to be, or not.

As set forth in the medical history of the case, the otitis was supposed to have commenced six weeks before with *malaise*. Discharge of pus began with severe pain three weeks before admission, but soon stopped, namely, in ten days. It reappeared the day before seeing him, but in much less quantity.

On palpation and gentle pressure the scalp and pericranium were found to be tender at a point which was situated just in front of a vertical line drawn through the external auditory meatus at about the junction of the third and lowest fourths of the distance between the meatus and the sagittal suture. This tender point above the meatus clearly corresponded with the superior temporo-sphenoidal convolution about opposite the lower border of its middle third, that is, vertically under the lower end of the fissure of Rolando.

At the same time, as described in the medical history, there was almost complete aphasia, marked paresis of the right side of the face, and less marked paresis of the movements of the right upper limb, especially those of the hand and digits. In both discs there was intense optic neuritis, the same being accompanied by hemorrhage in the right disc, that is, that of the side opposite to the abscess. It may be remembered that in the case published by Dr. Gowers and Mr. Barker, the optic neuritis was also most intense in the opposite disc. Considering the proximity of the abscess in each case to the fibres of the optic tract this, at the first sight, somewhat extraordinary fact may have a simple anatomical explanation in view of the decussation at the chiasma, and the fact of the lymphatic vessels lying for the most part parallel to the plane of the fibres.

December 10th, 1887. The patient having been put under chloroform, and the previous treatment of the head, including very thorough cleansing of the external auditory meatus with boric acid, etc., having been carried out, as detailed in a paper by myself (see *JOURNAL*, October, 1886), an incision was made of the following T shape. The horizontal limb was almost semicircular, the centre of the convexity being at the junction with the vertical limb. The anterior end of the incision began at the superior temporal ridge, and the posterior terminated at a vertical line drawn behind the middle of the parietal eminence. The junction of this horizontal limb with the vertical one corresponded with the painful spot. The vertical limb was simply carried down in front of the pinna as low as the tragus.

The skin and fat of the flaps thus marked were first reflected, and then the temporal muscle and periosteum were similarly turned off the bone. At the seat of the painful spot the bone was doubtfully yellow. When an inch disc of bone was removed at the same place, the dura beneath was found to be congested, at the same time bulging, without pulsation, and of a dark, almost purplish, colour. It was therefore clear that the abscess was pointing towards this spot. The dura was then opened, and the dark-red oedematous brain tissue bulged strongly through the incision. As it was fairly certain that the abscess extended deeply into the temporo-sphenoidal lobe, the lower half of the circumference of the hole in the bone was cut away into a V-shaped notch. The dura was opened further by another incision vertical to the first, just as in the skin. The brain was punctured with an ordinary trocar and cannula (about 3 millimètres diameter), the pus liberated, being first met with at about the depth of 1 centimètre. The amount

of pus was about half a fluid ounce (3v); it was inodorous and creamy. The cannula was kept in until no pus and only blood oozed through it. It was then replaced by the inner tube of a silver tracheotomy cannula; (this was changed for a smaller silver drainage-tube on the second day after the operation).

Owing to the inodorous, etc., nature of the pus, I thought it wisest to leave the cavity simply draining, and without syringing it out. The issue showed that this was correct in this instance, but of course each case must be treated on its own merits, and it must be obvious that such a procedure as syringing, etc., may be rendered advisable or not, according to other circumstances than those mentioned, such as the point in the abscess wall at which the opening is made, etc. For instance, in this case there is little doubt that the abscess was tapped at or below its centre, and consequently there was no hindrance to the flow of the pus.

The periosteum and temporal muscle were replaced and adjusted round the tube, which they pretty closely enveloped, a matter of satisfaction, since the brain continued to protrude considerably (owing to the usual œdema), after the withdrawal of the pus, and of course such bulging was more successfully opposed by the addition of a layer of muscle in the covering flaps. Finally, the skin incision was everywhere completely apposed by horsehair, and a few silk sutures. The wound was covered with a carbolic gauze, boracic acid powder, and sal. alembroth wool dressing.

The subsequent course of the case was really without incident, save the rapid recovery from all the symptoms. The temperature rose to 101° on the second night after the operation, but fell to normal the next day, and remained so.

December 10th, 11 P.M. Had vomited a little, and was restless. Pulse 124. Slept well after a hypodermic injection of morphine.

December 11th, 9 A.M. Pulse 96. At 6 A.M. vomited a little. No pain. Talked sensibly, but occasionally used wrong words. The aphasia was thus rapidly recovered from, as might have been expected from its special character. The loss of words, still present, was not peculiar to one class, for example, nouns. Wound dressed, and found to be uniting by the first intention.—2 P.M. Pulse 96.—6.30 P.M. Temperature 101°; pulse 108. From this time both the temperature and pulse became normal.

December 12th. Wound dressed; tube changed; answered questions rationally; no pain.

December 13th. Given solid food.

December 14th. Face: still a little weaker on the right side. Upper limb: grasp, right 87, left 93. Tactile sensation normal, and no pain on movement of limb.

December 15th. Wound dressed; tube quite empty; flaps completely healed. A little pus was syringed from the auditory meatus, which had been carefully cleansed and filled with powdered boracic acid at each dressing. At the next dressing this discharge had ceased, and never recurred.

December 23rd. Tube left out; wound simply covered with powdered boracic acid.

January 5th. The paralysis, or rather paresis, had apparently disappeared, but the grip was still deficient on the right side, thus: right 90, left 100. The fundi oculi, examined by Mr. Brudenell Carter, showed no trace of hæmorrhage (noted in right eye), and the swelling of the discs had almost vanished.

During the remainder of the patient's stay in the hospital he showed no further symptom, and was discharged in perfect health. The membrana tympani was intact, but a cicatricial (?) mark was apparently visible behind the tip of the handle of the malleus.

The genesis of the abscess in this case was singular in many respects. In the first place, it seemed as though the acute otitis media commenced at the most three or four weeks before the abscess arose. Further, here was a rapidly developed abscess of considerable size situated high up above the roof of the tympani apparently about an inch of brain substance intervened, and yet the pus, though of course infective, showed no sign of decomposition or indication of being extremely septic in explanation of the acuteness of the mischief.

The localisation was fairly easy in view of the paresis and arthritis, coupled with the tender spot, the pain of which was not continuous with that felt in the meatus.

As regards the operative procedure, I have nothing to add to that is now common knowledge. These cases are fortunately simple, perhaps the simplest, examples of intracranial surgery, but there remains yet the method of diagnosis. This is purely a question of localisation, and of all imaginable suggestive symptoms are more demonstrative than graduated paresis.

THE GOULSTONIAN LECTURES ON INSANITY IN RELATION TO CARDIAC AND AORTIC DISEASE AND PHTHISIS.

Delivered before the Royal College of Physicians of London.

By WM. JULIUS MICKLE, M.D., F.R.C.P.LOND.,

Medical Superintendent, Grove Hall Asylum.

LECTURE III.—INSANITY IN RELATION TO PHTHISIS.

THOSE who have chiefly written on so-called "phthisical insanity" have founded their description partly on cases in which the phthisis came on about simultaneously with the insanity, partly on examples in which phthisis evidently began long after the insanity, partly on others in which the recorded facts as to precedence are fragmentary and valueless. Of these three kinds of case I would reject the last two when offered as examples of phthisical insanity, and would allow to the first only a modified claim to be so entitled.

To work out the subject more satisfactorily, I have arranged three great groups of cases: one in which phthisis distinctly preceded insanity; one in which the two affections apparently came on about simultaneously; and one in which phthisis supervened in the course of well-established, or even chronic, insanity.

First Group: Phthisis influencing the Production of Insanity.—Taking up the first of these groups, it is desired to analyse cases in order to determine the influence of pre-existent phthisis on the production of insanity, or in modifying the clinical aspects of mental derangement subsequently arising partly or chiefly from other causes. In dealing with this as with the other parts of this subject of phthisis and insanity, I purposely exclude all cases of general paralysis, epilepsy, senile dementia, and various other conditions with gross organic brain changes; and I do so inasmuch as in these cases the clinical aspects are chiefly dominated by the intra-cranial lesions. Omitting these, I have had under my care during a term of years at least 106 cases which appeared to have some relation to the decision of the first question we meet—that of the influence of phthisis on the production of insanity—and from which the constituent members of the first two groups are selected. The third group is constructed of other and different material.

Of these 106 cases I found fifty-one not to bear so directly on the question of mental symptoms springing from phthisis as the remaining fifty-five. For in many there was doubt as to the true and precise order and dates of incidence of the phthisis and the insanity, the two either occurring at about the same time, or the history being imperfect; in many of them other causal factors were of predominating importance, and controlled the play of pathological events.

And even of the group of fifty-five, I will exclude some from further consideration in this place, and for various reasons. For example, in several the attack of insanity, supervenient on phthisis, was a second attack; in some a closer analysis revealed either an obscurity of relation or another factor, or other factors, as possibly being predominant; or revealed a possible causation too complex to permit the case to be of value for our purpose. In one or two the complication by cardiac disease, or meningeal tuberculosis, destroyed the simplicity and validity of the example; in some, on a closer scrutiny, the order of incidence of phthisis and insanity was not absolutely clear, the two apparently coming on almost simultaneously, and therefore, possibly, concomitant effects of a general deterioration of system and breakdown of the nutritive and resistive powers of the organism; a view quite compatible with that of phthisis, a form of successful bacillary invasion. For one or other of these several reasons, twenty-one cases in all have been placed in the second line, leaving the thirty-four cases most adapted and reliable for our synthetic purposes, as regards phthisis producing insanity, or modifying the clinical aspects of insanity subsequently arising, or partly so, from other causes: whilst at least twenty-four others out of the 106 will be used to cast a synopsis of those cases in which the precise order of incidence of phthisis and insanity is doubtful, but that incidence nearly simultaneous. Even of the thirty-four left as being those in which

the relations and circumstances of the cases are more clearly defined, satisfactory, and demonstrable, the evidence is not in all cases of the same validity; for the difficulty in assigning accurately the etiological factors in insanity is notorious, and, indeed, in the majority of the insane the causation is complex; the factors influencing the production of insanity usually are not single, individual, and simple, but plural, conjoint, and complex.

These cases I have placed in five sub-groups, namely, persons affected with:

1. Active, in part quasi-delirious, symptoms. Hallucinations.
2. Depressed, melancholic symptoms.
3. (a) Morose, angry mania; or (b) delusions of injury, of persecution, etc. (not systematised); or (c) rarely, gay maniacal excitement (probable organic brain disease).
4. Imperfect or abortive monomania; or monomania.
5. (a) Dementia supervening on feebleness of mind, imbecility; (b) rarely, moral insanity, impulse, and so on.

First Sub-group.—Those in whom mental derangement most clearly and immediately seems to depend on the pulmonary affection are persons, forming a comparatively small sub-group, who, in advanced phthisis, take on active and partly quasi-delirious symptoms. These persons are hallucinated; hallucinated in most cases they certainly are, and probably so in the remainder.

For example: (A) Emaciated, and with softening lungs or with actual cavities, such an one becomes restless, continually dresses and undresses himself; if in bed, gets out of it or attempts to do so; if out of it, or not yet confined to bed, rolls on the floor, and apparently fails to understand what is said to him. And for a time he may quite lose his mental control, and when it is restored, temporarily or partially, there is but a vague and slight recollection of the attack; and for some days or weeks thereafter a state of mental confusion persists, together with a feeling of being weak in mind and of impaired memory, and possibly with transient diplopia. The mental confusion evidences itself in various ways, amongst others by the mistakes made as to the identity of those who are about him, and as to the recollection of times when, and places at which, he has previously met them. Nor does the error of mind concern others only; it is manifested also in an extremely confused recollection by the patient of his surrounding and location, so that, whilst continually occupying one and the same bed, he relates his experiences of being now upstairs and now down, now in one apartment and again in another. And even on trivial matters his statements are self-contradictory. His condition fluctuates, better to-day, coherent and fairly rational; to-morrow, perhaps, he is incoherent, restless, and in bewilderment tries to rise at night, and wander about the room.

(B) The case does not always take this mild form; as compared with which the more urgent conditions may be reached by rougher paths, and with more impressive and more dramatic phenomena. Thus, a subject of advanced phthisis with bronchitic signs having become delirious, and then actively maniacal and raving, thinking his master called him from the street, has rushed to the window, and smashed it, cutting his hand; and subsequently, objecting to go to bed, has slept badly, been incoherent, excitable, and violent, especially at night; has refused food, deeming it to be poisoned, or with difficulty has been induced to take it. Then comes a space of time during which he is usually coherent and free from delusions, but the tranquillity and reasonableness are interrupted by paroxysms, lasting about a day, in which he is restless, fumbles his clothing, undresses himself, is with difficulty persuaded to eat, fails to recognise his doctor, stares as if in terror and at imaginary objects, and is apparently absorbed in his delusions and corporeal illusions. When again lucid, he tells us that in the paroxysms he felt, as it were, people pushing something up the back of his head, but was chiefly in terror and panic-stricken by fear of injury. Practically recovering from active disorder of mind, he dies a few days later, the end being precipitated, rather, by the further encroachment on the limited breathing space, made by intercurrent lobular pneumonia and pulmonary congestion, than by the invasion of a phthisis florida.

(C) This wandering of the mind, this jolting of the mental ploughshare from the furrow, or insane delirium, in a case here and there is found to take another phase; and the flight of ideas is expansive. The morbid conceptions of such an one run on daring enterprise and dazzling project. Although changeable, shifting, phantasmagorical, and expressed in a rambling way, the conceptions are large, generous, and ambitious, but deeply tinged with puerility and grotesque absurdity. For example: It is

owing, he says, to his father's head being turned by a (real) Royal visit to the town, that that parent has sent him to an asylum; and the large factory he himself is about to establish for planning improvements in tramway construction will reduce the cost per yard thereof, to that of "a flannel petticoat," as he inconsequently adds. Restless, he telegraphs to business firms for prices of wood and iron; asserts that he has invented a tramway which will pay splendidly, and talks ramblingly about his inventions, the appointment of surgeons to his factory at enormous salaries, and the erection of chambers for the spiritual benefit of those employed thereat. Correspondingly, and notwithstanding irritability of temper, the feelings are gay, buoyant, possibly exultant, the mental colouring is bright and roseate. Truly, here, "hope springs exulting on triumphant wing," but only to sink in the deluciscent and deepening abyss of physical perdition; the delusion is thrown into bolder relief by its glaring inconsistency with the true; for, in desperate contrast with his large ideas, adventurous schemes and exaltation, is the real state of this sufferer from frequent pulse, diarrhoea, insomnia, advanced pulmonary phthisis and excavation, emaciation, prostration, colliquative perspiration, hypostatic oedema.

(D) Where predisposition is marked, symptoms like some already mentioned may come on at an earlier stage of phthisis; and, if recovery does not occur, assume a more fixed and settled form. Thus, at first, in maniacal agitation, incoherent, sleepless, noisy, restless, and violent to those around, the patient swears, speaks ramblingly on religious topics, declares that those near him are devils; or that he is commanded to destroy his family, because they are infidels. Or he throws himself on the floor, breathing violently, making cries, ejaculating about "God, and the sin of the world," asserts that by shonting he is saving those about him from hell, and hurls his food on the floor. Subsequently, in calmer mood, he is still confused, says he has only been as many minutes here as he has been days in reality; and is depressed in mind, bangs his head, declares he cannot speak, has lost faith in the Lord, has been starved, and must go to prison for neglecting his family. He hears the birds talk to him at night. To him, one month appears as seven, or eight, or nine. He tells how his depression is due to his being "lost," owing to his "not working with the Word;" how his mind wanders, and things that don't belong to it come up in it; and how before he entered the asylum he had been in low spirits, and when on the streets seemed to be ill-used, nicknamed, and accused of crime and of everything wrong. About these ideas there was nothing fixed or systematised. At times indisposed to take food, he smashed the table utensils. Now and then, later on, were delusions and hallucinations, such as concerned his being burnt to death, or seeing flames, or hearing whispers about him at night.

(E) In other cases, with storms of excitement and depression, laughter, weeping, suicidal and other violence, are more vivid hallucinations, and hypochondriacal fancies. Here, with hereditary psychic degeneration and a monomaniacal strain, we get arrest of the advanced phthisis under treatment, and a deferring of the fatal end for years to come. For example, puppies, says one, are alive in his stomach and pain him, or on his abdomen the Saviour rests. His body is in telephonic communication with a factory; he is tied down, and for an immoral purpose; is mesmerised, his food is blood. Later on he obstinately refuses to eat, under the delusion that his relations are killed, put downstairs, and served up to him as his food. He gets strange tastes, and a strong smell of blood. He hears answers and comments on hallucinatory voices. "The birds speak to him, and the same sounds immediately go about the house." Later on he feels "a restraint on the mind," put there for some indefinitely explainable purpose; feels a connection with and hears voices from a factory. The perversion of taste and smell continues, and so does self-abuse. He says his food is manured with the excreta of diseased individuals: personages of notoriety, or of history, are buried near him by hundreds, Cavendish, Burke, Kings Charles I, Henry V, and so on.

Thus, these last two kinds of case link the present sub-group with the next.

Second Sub-group: The Sub-group Characterised by Mental Depression, by Symptoms of the Melancholic Order.—Nearly one-third of the cases of the group we are considering come into this depressed or melancholic sub-group. The limits of space preclude the insertion of detailed histories, such as those before me at the moment of writing, or even of individual summaries of these cases, and, indeed, of more than a very general summary.

Summary.—In all there is emotional depression; downcast, despondent, grieved, some of them are in tears. In very nearly all are suicidal ideas, and in many these are carried out in suicidal attempts. The emotional state is not always merely one of depression, with or without weeping, moaning, and a lugubrious aspect; indefinite fear or dread may possess the patient; he may be afraid to go to sleep, or perhaps, vaguely, of something about to happen. Some are extremely suspicious, or are timid, anxious, careworn, or are listless, or very obstinate, irritable, unsociable, sullen, sulky, slovenly, neglectful, forgetful.

Hallucinations and illusions exist in all, if we include those few cases taking the form of a *melancholia cum stupore*, where, extremely probable as is their existence, it cannot be definitely ascertained. Relatively predominating are the hallucinations of hearing, next most frequent are those of smell, and nearly as many have hallucinations of taste or of sight. At one period or another, or at several, refusal of food is a marked symptom in about two-thirds, and some disinclination for food or anorexia is noted in a few others. Insomnia is a frequent symptom. Some exhibit general apathy, at least at times. A few show marked mental confusion or excitement; and some are inattentive, or mistake the identity of their attendants, taking them for relatives; others wander aimlessly about.

Although only slight and transitory in one case, usually of *melancholia simplex*, delusions are found in all, except in the "thunderstruck" or stuporose, where, too, they doubtless exist. In some they concern the religious feelings and ideas; the patient fancies that he has done some wrong, or is forced to do it by his surroundings, or, cut off from hope of heaven, he bemoans his "poor soul," and has anxious, gloomy thoughts of the future. Some take the delusion that they have been poisoned, and usually by something placed in their food, and delusions as to their medicine, or in a few, as to deprivation of food, may be evinced. Some have delusions as to the hostility and malevolence of those around them, or of absent or of imaginary persons, or of all of these.

(To be continued.)

THE DIFFICULTY OF DIAGNOSIS BETWEEN DISEASE SYMPTOMS AND DRUG SYMPTOMS.¹

By ALFRED CARPENTER, M.D., M.R.C.P.

THE difficulty in diagnosis between symptoms produced by disease and those produced by drugs is not always an easy task to settle even by experts. It is not always easy in the police cell to distinguish between a so-called "dead drunk" person and one who is labouring under the effects of compression of the brain, caused by rupture of a cerebral vessel, or of compression produced by fractured skull. But this is not so difficult as is the task which the physician has to contend with, when called in to advise with another practitioner who has been freely exhibiting active remedies before the second opinion is sought for, or when the patient has been physicking himself with ardent spirits or other narcotics.

Having met with these difficulties on several occasions, I propose to consider one or two of them, and to detail to you some that I have met with in which the treatment, having been based upon imperfect information, was rapidly tending to poison the patient, and certainly would have done so if a change of treatment had not been made. The use of the thermometer, a careful examination of the heart sounds and the character of the heart's impulse, the condition of the respiratory function, the state of the skin, the action of light upon the pupil, and the smell of the expired air from the lungs, will always enable the skilful surgeon to be certain about the police case, unless there is drink and compression combined (not a rare state of things). It is always right to err on the safe side, and to give the patient the benefit of the doubt, if there is any; though it is very unlikely that severe mischief can be produced to the brain, even if the man be drunk, without there being some evidence of its nature, if it be looked for. However, it is not my intention to enter into the consideration of police cases, so much as to refer to some other conditions which the medical practitioner occasionally meets with in the sickroom.

I propose to detail two typical cases for your consideration, just as I met with them, but for manifest reasons giving no public clue to their whereabouts.
