Now comes the question: In what structures do the changes occur which cause this loss of function? I believe that, as a rule, they are to be found in the capsular ligament and the synovial membrane; less frequently in the matting together of the tendons. All the large joints have capsular ligaments; the shoulder and hip decidedly so; the knee, ankle, elbow, wrist, fingers, and toes have strong lateral ligaments, and the parts between these completed by thinner bands of tissue, called anterior and posterior ligaments. For all practical purposes we may consider these as capsular ligaments, with laterally thickened bands. On dissecting these joints and then moving the limb, it is found

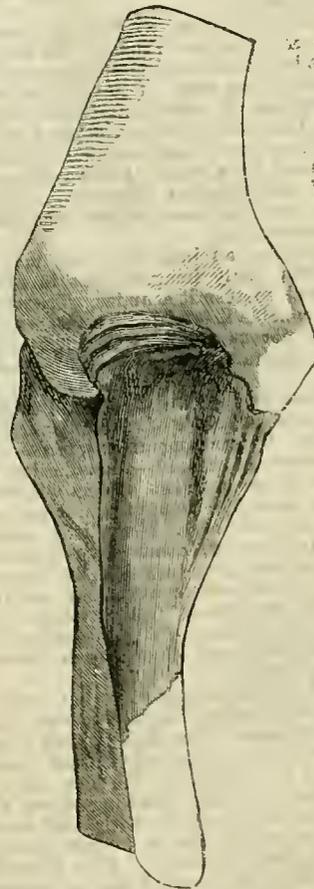

Fig. 2.

Elbow-joint extended; Irregular fold of posterior ligament.

in the right direction; it often does so, but often not. If it is at all sticky from fibrinous effusion, or thickened from the same cause, the probability is that the folding would be irregular, and the joint-movements correspondingly limited and painful, and as long as one worked it passively, this would continue. I have often noticed myself, after a fall or a blow, a species of discomfort in a joint, which has only passed off after working it round several times. This appears to me to be due to a false folding of the ligament. When the muscles work the joint, the ligament is unfolded and drawn into its normal position.

It is a useful, practical plan, in putting up an injury, to tell the patient to move the joint himself; by attempting this he would not only relax the muscles which perform the antagonistic action, as I learnt from a valued teacher, but, if he were unable to exert power enough to do, as he was told, he might still have enough to draw the capsule out of the way and prevent an improper folding. These apparently trivial details will be found on close observation to be of real value. The majority of these adhesions take place as the result of traumatism, or of some inflammatory affection of the joint; singularly enough not, so often after dislocations as after sprains. In dislocations there is a rent in the capsule, and this makes a drainage opening through which the effused fluids escape. As the result of the injury blood or lymph gets effused; this distends the capsule. In whatever position the limb is put up, this effusion would settle to the looses or most dependent part. Take the shoulder again. The arm falls naturally to the side, and is bandaged by the surgeon in that position. (This is not always prudent.) As a consequence the lower part of the capsule would be loose; into this the fluid gravitates and distends it. As it subsequently becomes absorbed the surfaces of the pouch approximate each other, and, if left at rest, become bound together, either by direct fusion of their surfaces or by the intervention of organised bands of lymph.

Adhesions are frequently seen without evidence of change in the membrane or cartilage close to them. We all know, as practical surgeons, that in shoulder ankylosis the greatest difficulty is experienced in raising the arm. I have dissected one of these joints in which ankylosis of some considerable standing existed. After dividing all the muscles which depress the arm, I found myself unable to raise the limb, and on careful examination found this was caused by a fusion of the contiguous surfaces of the lower part of the capsular ligament, with its contained synovial sac. On separating these the arm was easily raised; the rest of the joint was sound.

This fold is sometimes an inch long, and may be even more than that, so you can easily imagine that in many cases great force must be exerted to tear it asunder. The more recent the adhesion, the more capable it is of being stretched; as it increases in age, like all new fibrous tissue, it becomes tougher, and also has a tendency to contract. Great force is then required to rupture it.

I had a case about two months ago, in which, though the patient was under the influence of chloroform, I could hardly rupture the adhesion. By exerting all my force—I am endowed with more than the average amount—the adhesion ruptured with a loud report. One of our resident officers who was giving the anæsthetic and the students thought the bone was fractured; this, however, was not the case. Very little inflammatory disturbance followed, and the movements are now almost normal.

Adhesions may also take place outside the capsule; these are usually the result of rheumatic affections, or are caused by inflammation which has spread from without. The tendons round a joint may also become matted together or fused with the capsule or other parts, and thus impair function. I will tell you another anecdote.

Some years ago I possessed a hunter that had seen his best days, what is commonly called "an old screw"—screwed about the tendons of the forelegs. One day he took a big fence with me, just flinched for a minute as he pitched, but finished the day's work without a sign of lameness. The next day the leg was swollen, and he was evidently suffering from a strain of a tendon. He was treated carefully with cold water bandages until the swelling subsided, and was then prescribed gentle exercise. He simply hobbled along. Then I tried riding him, and once or twice in a half-hearted way attempted to trot or canter, thinking it might be stiffness which would wear off, though I did not quite understand the pathology. The result was painful to both the horse and myself. After some weeks I sold him, as I thought, permanently lame. In a very short time the horse was to be seen careering over the country without a sign of lameness. On inquiring the treatment, it turned out to be the whip again. I was somewhat annoyed not to have tried such a simple remedy more effectually; but I daresay if one had seen the treatment, one would have called the man a brute, though it was a cruel kindness in the long run.

A short time afterwards I had the opportunity of dissecting a horse's leg which had a precisely similar history. Between the flexor tendons were some long, string-like adhesions, evidently

stretched long enough not to interfere with movement. At a part lower down was a small patch of soft adhesions, easily separated, and then the tendons worked freely on each other. It seemed to me probable that when the horse started every day he went lame until these soft adhesions gave way, and then the lameness disappeared. This corresponded with the actual history, the lameness was always more marked after rest, but the whip being applied more freely counteracted this. It is the strain on the adhesion and the loss of mobility that cause the lameness, not the friction of the roughened surfaces. Cases similar to this are not uncommon in man. I had the opportunity of vivisectioning one such.

The patient had an incised wound just above the wrist. As the result, the ulnar nerve and flexor carpi ulnaris tendon became bound down to the deeper parts by fibrous tissue. Excruciating pain resulted on any movement of the wrist, and even without this. I had on two occasions to separate the nerve and tendon from the deeper parts, and finally the nerve remained detached and the pain was cured. The tendon still has a tendency to contract adhesions. The man works, but says he always starts stiff, but that soon wears off. "It is better on Saturday night than Monday morning." The Sunday's rest always makes the part more stiff and painful. Probably, if he rested long enough, the tendon would become fixed again and the wrist movement impaired. The following case is also very instructive.

A. F., aged 26, came to me last winter, complaining of pain, tenderness, and some swelling below and to the inner side of the left knee. Six weeks before, while playing football, he kicked sideways at the ball, with the left leg, at the same time one of his opponents also kicked at it; their legs crossed, and F. felt a sharp pain in the inner side of the knee. The part swelled, he lay in bed for a fortnight, and was then allowed to get about. After another week or ten days he could walk and run all right, and then played football again. He found that he could not "folck a ball" out of the scrimmage with his left leg (that is, hook the ball out sideways with his foot), any attempt to do so causing great pain. After a week or two he had a bad fall with a man on his back, and now comes the interesting part. He felt a sharp pain for a minute or two, and, when that had passed off, the old pain had disappeared, and he thought he was well. The part swelled in the evening, and, when I saw him two days afterwards, there was slight synovitis, and a tender oedematous spot below and to the inner side of the head of the tibia—the original seat of pain. It seemed to me that he had strained the tendons at that spot weeks before; as the result, adhesions formed; these were broken by the fall, and fresh effusion appeared. By gentle exercise and friction he soon recovered complete use of the leg.

Now we should consider the history and symptoms of these cases; a knowledge of the anatomy or pathology is of no use unless we can recognise their external indications. The majority have a history of this sort. They have had a fall, or a blow, or a strain of a joint. If the injury is very severe, there is probably immediate and continuous loss of function. If less severe, the loss of movement may come on gradually and get worse and worse until it is completely abolished. Or, again, there may be a rheumatic, strumous, or specific diathesis, and a slight injury or even exposure to cold may bring on a similar state of things.

In the early stages rest and soothing treatment should be adopted; but if the case goes on to ankylosis, "bone-setting" may be required. I will describe a case.

M. N., aged 45, a strong, healthy woman, with no inherited or acquired predisposition to disease, sprained her right ankle about four months before I saw her. It swelled very much. The medical man who saw the case very properly placed it in splints, and at the end of six weeks left them off, and recommended very careful and gentle exercise, and friction with some liniment. After walking or hobbling, the ankle swelled and became more painful, and walking itself caused her pain. The splints were then reapplied for fourteen days, when she was again to try exercise; the same pain and swelling ensued. Disease of the joint was then hinted at, and, as is usual, all the patient's friends passed their opinion on her case, that which found most favour being the idea that a "bone was out." This opinion she suggested to me at the commencement of our interview. The ankle was slightly thickened, but distinctly white and cold; all the bones were in their normal position, pressure caused no pain, stamping caused no pain; the foot was fixed at a right angle to the leg.

On careful and very gentle examination, slight movement could be detected, but muscular spasm and pain ensued if the movements.

were done at all roughly, and the joint then appeared more fixed, in fact, absolutely so. The diagnosis was clear—fibrous adhesions within or around the joint.

I should also call attention to the fact that the knee of the other leg was distended with fluid, which had appeared subsequent to her attempts at locomotion, evidently due to the increased strain thrown on it by her "dot and go one" style.

Distracting her attention, I gave a sudden wrench to the ankle; a loud report ensued. In a few minutes, after the pain had passed off, the patient could move the joint freely quite two-thirds of its normal movement, and she walked across the room comparatively well. She then said: "I thought the bone was out;" she was firmly persuaded she had heard it go in. It took me five minutes' hard talking to convince her that such was not the case, and then she was only convinced to the extent the gentler sex are "against their will." I did not wonder then that bone-setters often saved themselves the trouble of explaining, but let the patients think as they pleased. This case went on rapidly to complete recovery as far as the ankle was concerned. She has had occasion to consult me again for her knee, which has remained weak.

This case had been treated quite correctly in the early stages, but, as in the case of my father's horse, the whip had not been applied, and so the lameness continued.

There is another side to this question. W. S., aged 24, a healthy countryman, sprained his ankle badly. He saw a medical man, who told him to bandage it. He only lay up for four days, and then walked about. As the result the ankle became worse and worse, and when I saw him about seven months after the accident, there was suppuration and disorganisation of the joint, and amputation had to be resorted to. Successful treatment of these cases lies midway between the two, first a period of rest, and then exercise. The great secret of success lies in judging the exact period at which the one should be changed for the other. No hard-and-fast rule can be established.

In nearly all cases of fibrous ankylosis we find muscular spasm. This alone, in the absence of inflammatory symptoms, or those of new growths or constitutional disease, is sufficient indication for "bone-setting." Many surgeons think it impossible to mistake these affections for each other; there is little danger of doing so when the inflammation or the new growth is well marked, but in their earlier and less acute stages the diagnosis is far from easy. As a rule, I find that the more spasm the slighter are the adhesions.

When the ankylosis is bony, the disease must have existed for a long time, and, the joint being completely fixed, spasmodic action of the muscles is not required to check the movements; they are abolished. The muscles, therefore, waste and undergo fatty degeneration. Pain is a most misleading symptom. The most hysterical, painful case I ever had to deal with was cured by one slight wrench, without even synovitis following it. There was a distinct crack, and the patient immediately moved the joint freely and painlessly, and was extremely grateful. Patients suffering from hysteria pure and simple are not so. In the case of one small adhesion the strain is concentrated on one spot, and consequently is more severely felt. If you pinch a small piece of skin between your finger and thumb nails, acute pain is felt. Pinch a large piece with three times the force, and not half the pain is experienced. Again, pull a single hair of your head, and notice the difference between the pain and that caused by pulling a number together. So it is with the adhesion.

On making an examination of a knee-joint in the dissecting-room at Bristol, I found one small tough adhesion, about the size of a fine piece of twine, between the internal condyle and the back of the tibial spine. In this case the adhesion was stretched long enough not to interfere with movement. My patient, a nervous, sensitive woman, had not the pluck to do so, and consequently suffered severely until the adhesion was ruptured.

Now comes the question, Where is the pain felt? Hilton, in his interesting book on *Rest and Pain*, states that the nerves which supply a joint are branches of those which supply the muscles acting on that joint, and also the skin over it. I will give you a case in point. A man fell over a plank on to his shoulder, bruising the upper part of the joint. Great pain was felt, but only on his attempts to abduct the arm. On passively moving the limb in that direction a soft crepitus could be detected. This movement was also painful. The interesting point is, the pain was not referred to the joint, but to the scapula and side of the neck—the course of the suprascapular nerve. This nerve supplies the upper part of the joint and the supraspinatus muscle which abducts

the limb. Pain was also felt on deep pressure over the head of the bone. Sometimes the pain is experienced immediately over the affected spot, either case being explained by Hilton's theory. I will now refer briefly to some of the more frequent and troublesome complications.

All cases of fibrous ankylosis cannot be cured by one wrench; it is exceptional to find them so simple. When one does get a case it is an easy way of scoring a brilliant result. Cases vary much; each must be judged on its own merits. Those most amenable to treatment are due to simple traumatism in healthy subjects. These recover with marvellous rapidity, and, singular at first sight to relate, it often happens that the longer the ankylosis has existed, the simpler is the cure. The first wrench may require greater force, but as a rule there is less subsequent disturbance in the joint. In these cases the joint, at least that part between the adhesions, has had time to recover its tone, and the adhesions being simple fibrous cords, are just snapped across, and the joint is free. Not infrequently, however, the strain on the adhesions has produced a chronic synovitis, which obscures the primary cause.

Rheumatism is one of the most troublesome complications; every change of weather produces evidence of the constitutional affection in the weakened part, and this of itself contra-indicates movement. I have a troublesome case under my care at the present time. A young man, aged 24, consulted me in February of this year for stiffness of the right hip. Ten years ago this hip was crushed by a waggon wheel, and he is said to have sustained a fracture in that region. He completely recovered from that accident, and has won athletic races since. About seven years ago, he went to Australia. In March of last year he had a bad attack of rheumatic fever, which lasted seven weeks. He was in the bush, and was only seen once by a doctor. After this he found his right hip stiff; he was unable to bend it, ride on horseback, or follow his occupation with any comfort. He went into hospital in Sydney in August. While there he was treated by extension and blisters to the part. The extension caused him great pain. While in hospital he contracted typhoid fever. He left on December 3rd and returned to England. When I saw him in February there was complete loss of function of the hip-joint. Marked lordosis occurred on any attempt to straighten the leg; and very marked muscular spasm existed, especially of the adductor longus. The loss of movement was so complete, that had it not been for the history and the muscular spasm, I should have considered the ankylosis bony. The right buttock and thigh were atrophied, the latter measuring two inches less in circumference than its fellow. If the patient put both heels to the ground, he measured two inches less in height than when standing on the left leg only. The thigh was fixed at an angle of 140° with the body. There was a very marked rheumatic history in the family, consequently my prognosis was guarded.

On producing complete muscular relaxation by chloroform, the very slightest pressure enabled me to fully extend the leg, and move it freely in all directions. Some soft adhesions were felt to give way in the process. As the adhesions were so easily separated I hoped he would soon regain the full use of the limb, but the rheumatic tendency has retarded recovery. The weather has been exceptionally severe, and at every fresh change both the patient and his father have had twinges of rheumatism. The fact of the father suffering at the same time has made the son more patient under the careful and tedious treatment required. The latter gets pain only in the weak hip, very rarely in the knee of the same leg. Whenever the rheumatism appears, muscular spasm ensues, and on attempting passive movements the lumbar vertebrae arch backwards and forwards instead of the normal movement at the hip-joint. By careful treatment the patient, in spite of these drawbacks, is now able to sit comfortably in a saddle, rise up and down to an imaginary trot, throw his leg across the saddle with ease, and I am hopeful that during the summer he will regain almost if not complete use of the joint.

Struma and syphilis are complications requiring great care. If the constitution is really bad, the less one meddles with the case the better. Slight attempts only at movement may be made under chloroform. Many cases of so-called strumous joint-disease depend on a traumatism occurring in a subject debilitated by bad food and improper hygienic surroundings, though they may possibly have inherited a good constitution. In such cases the general health should first be attended to, and when that has been improved, movements may be attempted. The same rule holds good when syphilis is the complication.

Now comes the question of treatment. We cannot do better than refer to my text. The horse had a suppurating knee-joint; it was turned out to grass for three months; before the whip was applied the knee was the same size as the other, and free from inflammation.

The principal symptoms of cases suitable for forcible movements may be summed up as follows. Loss of motion and muscular spasm, especially on rough handling. On very gentle manipulation slight movement can be felt, and that perfectly smooth. Pain on more forcible movement, pain at night, pain on waking in the morning, pain at change of weather, pain on jarring the limb, absence of inflammation, extra coldness of the part, very slight thickening only (if there is much it should be lessened by rest or gentle exercise, blisters and absorbent application, with light friction), the lapse of some weeks before forcible movements are attempted. In the earlier stages forcible movements produce a large amount of fresh effusion, and possibly inflammatory disturbance.

I remember a case some years ago in which I yielded rather to the patient's solicitations, and moved a joint freely in the earlier stage. A large amount of effusion was poured out, and it was only by very careful treatment that suppuration was prevented.

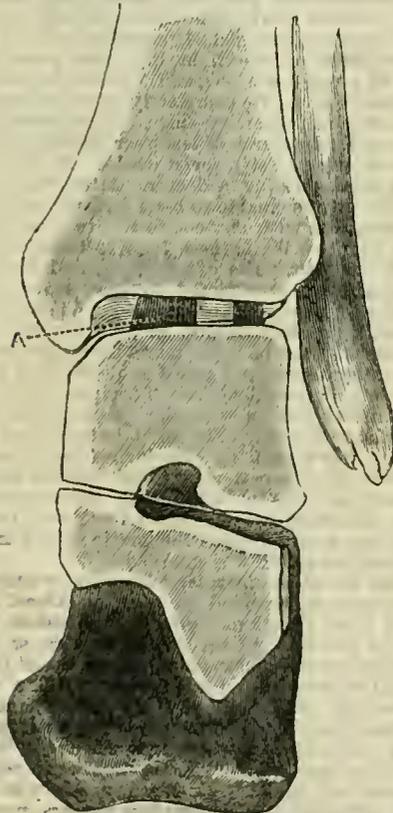

Fig. 3.

Section of ankle-joint showing adhesions (A) between tibia and astragalus; rest of cartilage healthy. No. 1797. College of Surgeons Museum. This diagram was copied from a rough sketch taken from the specimen.

In the earliest stages, that is, directly after an injury, perfect rest should be prescribed. In a few days, if the patient be fairly healthy, absorption of some of the effused fluids will have taken place, and a plastic material remains which can be stretched or moulded by gentle passive movements; these also favour absorption, and should be combined with very gentle friction, remembering the axiom of Hippocrates that hard rubbing binds, soft rubbing loosens. The rubbing should always be done in a centripetal direction. Absorbent remedies may be combined with this treatment. If the case does not progress satisfactorily, or has not come under observation sufficiently early, forcible movements may be required to rupture the adhesions. In suitable cases force should not be spared; in one of mine I had to exert all my strength. I felt that, even if the bone was fractured, the

patient would be no worse off in the long run than if he were allowed to remain as he was. I once saw a humerus fractured by a prominent member of our profession in his attempts to rupture adhesions in the elbow-joint. The patient had a better arm than before operation.

After the adhesions have been ruptured, a day or two of rest should be prescribed, with cooling lotions, and then gentle exercises, active as well as passive. Here is a diagram of a case in which considerable force would have to be exerted to tear through the adhesion.

In cases in which the cartilage has been partially destroyed there may still be movement; the cartilage is replaced by a fibrous material, which fulfils its purpose. I remember a case of compound comminuted fracture of the knee-joint, which was treated in the Bristol General Hospital. I removed several pieces of cartilage from the joint, and yet that patient recovered with a fair amount of movement. There are several specimens in the College of Surgeons Museum which show the replacement of cartilage by fibrous tissue. It is not at all uncommon to find similar evidence with free joint-movement in the dissecting-room; therefore, destruction of cartilage is not sufficient reason of itself to contraindicate forcible movements. Such evidence, however, should

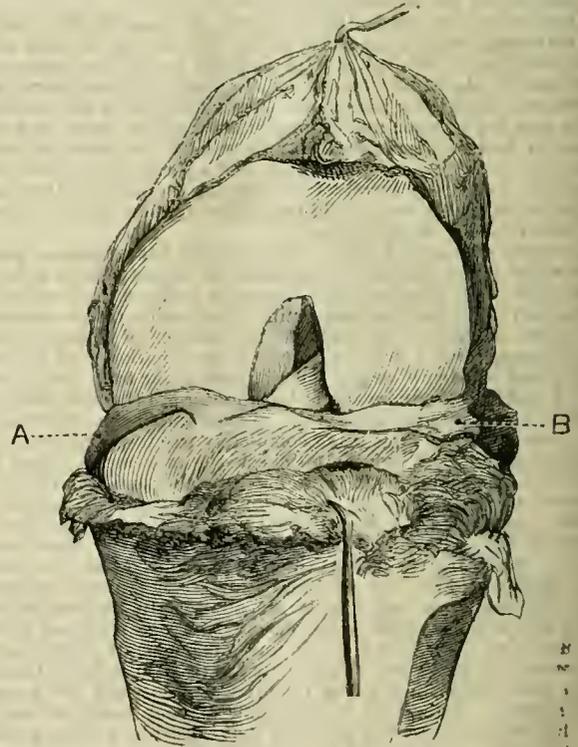

Fig. 4.

Front view of flexed left knee-joint. A Internal, B External semilunar cartilages in their normal position. Skin reflected from femur and tibia.

make us careful as to the amount each case could safely bear, and also particularly careful in the after-treatment. Cartilage itself, as Hunter has told us, is capable of taking on adhesions, without marked change in its structure. Specimen 1797 in the College of Surgeons Museum shows this well (Fig. 3). The cartilage close to the adhesion is smooth and quite unchanged to the naked eye.

Now we come to another class of cases—internal derangements. Many of these are caused by loose bodies in the joints, which may become nipped between the bones. These have special symptoms peculiar to them, and should be removed as soon as possible.

The knee-joint is the most common site of these derangements. It is the most complicated joint in the body. Besides flexion and extension, when the knee is flexed, rotation of the tibia on the femur is permitted. When this is carried to an abnormal degree, there may ensue either a subluxation of the condyle of the femur, or a displacement of a semilunar cartilage. The internal carti-

lage, as you will see by this diagram, is the straighter and longer; the outer is smaller and more circular. The inner, beside being attached to the front and back of the tibial spine, is attached all round the inner half of the head of the tibia by fibrous bands, as well as to the internal lateral ligament. Sometimes this cartilage becomes displaced and nipped between the bones, or it may slip into the notch between the condyles of the femur. The external cartilage is not attached round the head of the tibia, and consequently shifts its position easily, and follows the condyle, and is less frequently displaced than the internal. I will quote a case of displacement of the internal cartilage, and then explain. H. S., aged 25, sprained his knee at football in January, 1886. Synovitis followed, but subsided after some weeks. He regained full use of the joint, but a feeling of weakness remained, for which he wore an elastic knee-cap. In March, 1887, he slipped on the snow, and felt a sharp pain on the inner side of the knee. His leg was flexed and fixed in that position, but on pressing his hand firmly on the inner side of the knee something seemed to slip, and he could then flex and extend the joint freely. The knee, however, swelled and became painful. When I saw him four days after the accident he had slight effusion into the joint; there was œdema and marked tenderness over the upper part of the tibia, at its junction with the cartilage. No pain was experienced on flexing the knee, but only when pressure was thrown on the internal lateral ligament.

ing loose, the bones are allowed to separate, and the tibia is abducted (Fig. 5). All these movements, done sharply and with violence, may cause the condyle to shoot over the edge of the cartilage, and thus become locked; this would be a subluxation. Sometimes not only this happens, but the cartilage gets detached and displaced inwards. While examining this point in the dissecting room one day, I was doing these movements forcibly on a subject, and the cartilage became separated and displaced before my eyes. It happens thus. If the knee is flexed, the back part of the condyle of the femur, when rotated inwards, tends to push the posterior part of the cartilage in the same direction; if the tibia be now rotated outwards, the front part of the cartilage is unsupported by bone, its anterior attachment is carried out with the tibia, and great strain is then thrown on its fibrous attachments to the head of that bone; if these give way, the arc is straightened and the tension relieved, and the cartilage slips outwards. If the bones are much separated, and the movement done suddenly, the cartilage may shoot clean under the condyle into the notch, and lodge there (Fig. 6). When all the fibrous bands are torn, this accident is not unlikely to happen; even when it does, the cartilage can be replaced by extreme flexion of the knee, with subsequent rotations. Mr. Gray, our assistant demonstrator of anatomy, who kindly took some photographs for me, complained that now the cartilage was separated, he could not place the bones in the position de-

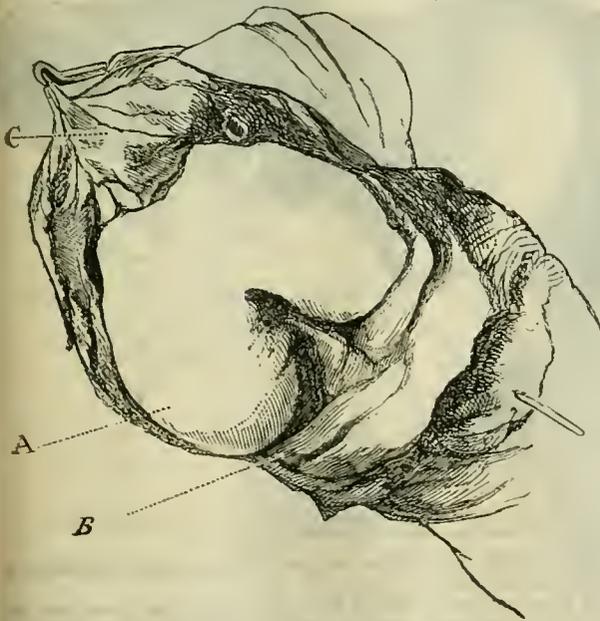

Fig. 5.

The same joint as in Fig. 4; lateral ligaments intact. A. Internal condyle of femur over-riding internal semilunar cartilage B. Knee partially flexed; femur rotated in; tibia rotated out; tibia abducted on femur. C. Patella reflected.

Slight displacement of the internal semilunar cartilage, with strain of the internal lateral ligament, was diagnosed. A felt splint was applied, in the hope that the cartilage would become attached again. The synovitis soon disappeared, and the leg became stronger. At the end of five weeks the patient, who was very anxious to play cricket, said he was quite well, and, contrary to my orders, played. In turning for a quick run, he felt a sharp pain again in the old site. The knee was locked, and could not be replaced without help, and then only after great difficulty had been experienced. This has happened several times since, and I expect to have to operate to fix the cartilage in its proper position. In this case the sprain of 1886 had probably weakened the internal lateral ligament and the fibres which attach the cartilage to the head of the tibia (Fig. 4). In that particular movement of turning sharply, and pushing off with the foot—nearly all the cases I have met with have been caused in a somewhat similar manner—there is a double rotation and abduction. The femur rotates inwards, the tibia outwards, at the same time, the internal lateral ligament be-

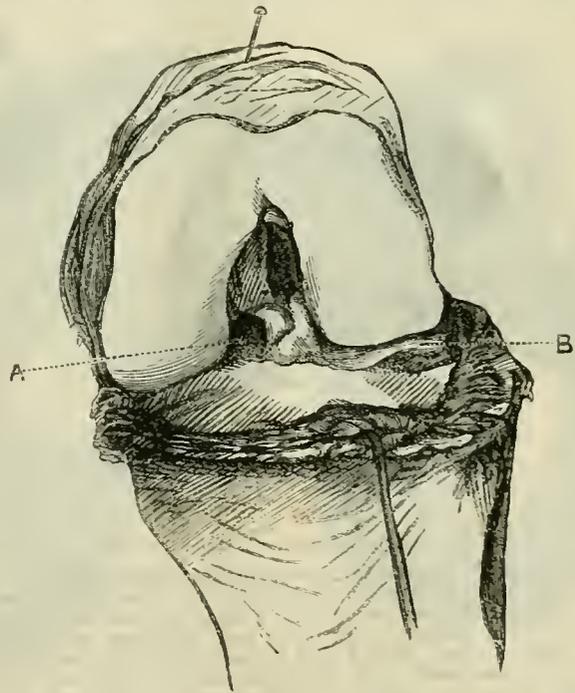

Fig. 6.

A. Internal semilunar cartilage displaced between internal condyle of femur and anterior crucial ligament. Tibia abducted and rotated outwardly in consequence. B. External semilunar cartilage.

scribed without the cartilage slipping between the condyles. Mr. Howard Marsh, in *Diseases of Joints*, refers to three of these cases dissected and described by other surgeons.

When the cartilage is completely displaced between the condyles, the joint movements are less interfered with than when the displacement is partial. In other cases of internal derangements, the fat or synovial fringes, especially when thickened or œdematous, may become displaced and nipped between the bones.

I will describe another case, with its explanation—a hip case. J. H., aged 47, was getting out of a donkey cart when the animal moved on. The patient's right leg slipped on the inside of the shaft, and the left came to the ground. His right thigh was thus forcibly abducted and slightly flexed. He then found that he was unable to walk properly or stoop; he was a very poor man, and said: "If I saw a shilling on the ground I could not pick it up." He hobbled with difficulty into my room about forty-six hours after the accident. All simple remedies had been tried, but

they were of no avail. His leg had the everted, abducted, lengthened appearance seen in subpubic dislocation of the hip. The bones were, however, in their normal relations, there was marked muscular spasm, so that I came to the conclusion it was a disarrangement of something; what I did not exactly know. Acting on the principle that if movement in one direction is particularly painful the opposite movement should be carried to its full extent, and then the painful movement tried quickly, and finding that attempts at extension caused him most pain, I flexed the leg fully on the abdomen and rapidly extended it. The latter movement could then be performed quite freely and painlessly. The patient worked the leg himself, stooped with the greatest ease, and walked round the room in his usual manner. I shall not forget his surprised look as he worked his leg up and down, and said: "Why, it's all right now, Sir." A bone-setter could easily have done this, or an accidental fall might have had the same effect. As it is, a legitimate member of the profession has the credit.

The case puzzled me. I consulted authorities, and all the explanation I could find was that a muscle or tendon might be displaced. On doing the movement forcibly in the dissecting-room,

profession from charges of ignorance or carelessness. Often one feels and knows the truth of these charges. There is a tendency to look on these cases as hysterical or beyond cure. For my own part, I can only say that every year I meet with less hysteria and more definite pathological lesions. Varying degrees of muscular power are required in the treatment, from a force of a few ounces to humour and overcome the spasm of a muscle, to a force of possibly a couple of hundred pounds or even more to rupture dense bands of fibrous tissue.

We should be prepared for any emergency. Accidents may happen in spite of the greatest care and forethought. We should not, for a very remote danger of bad consequences, condemn a large number of individuals to a life-long suffering; for these patients get pain as well as impairment of function. I rarely see inflammatory disturbance follow these manipulations if ordinary care be used. If acute suppuration of a joint should set in, I feel that, thanks to Sir Joseph Lister, we have a very powerful ally at our backs in the antiseptic treatment, an ally that robs these cases of their great dangers to life or limb. I have had the treatment of several cases of suppurating joints, in which not only the patients' life and limb were saved, but a

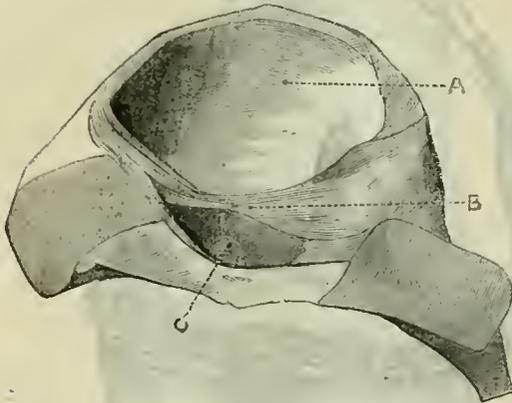

Fig. 7.

Fig. 8.—Head of left femur in acetabulum. Femur abducted. A. Ligamentum teres protruding under transverse ligament.

no muscle could be made to disarrange itself; there is no particular bony prominence to keep out of its place any muscle which may have slipped. No muscle could have been ruptured, as the man did all the movements quite freely and painlessly immediately after manipulation. Then I tried the capsule, but the head of the femur fits too closely into the acetabulum to allow that to be nipped, and a simple abnormal folding would not cause the leg to be fixed. The ligamentum teres was then tried. Professor Humphry, in his interesting book on the skeleton, states that when the thigh is abducted in the erect posture the ligamentum teres is compressed into the lower part of the acetabulum by the head of the femur (Fig. 7). In extreme abduction the ligament and the fatty tissue at its base is driven under the transverse ligament. On doing this movement forcibly and quickly, the ligamentum teres was found to be nipped under the transverse ligament, and this maintained the deformity. On flexing the thigh fully the ligament is drawn back into the joint, and remains there when the leg is subsequently extended. I believe this to be the explanation of my case. The abnormal position was probably maintained by reflex spasm of the surrounding muscles (Fig. 8).

I regret that time will not allow me to enter more fully into the subject; it is most complicated. Bone-setters gain their harvest because we, the legitimate practitioners, too frequently consider the necessary details and delicate manipulations beneath our notice. The loss of function of one joint is often of as much importance to the patient as the loss of a limb. On numerous occasions I have had to defend the reputation of members of our

certain amount of movement as well. In one case the subsequent movement was perfect.

We must not forget that if we do not adopt this practical and legitimate treatment ourselves, we run a great risk of being instructed in our profession by men we contemptuously speak of as "quacks."

The diagrams were drawn from prepared specimens and from photographs taken for me by Messrs. F. Calder and T. C. Gray, of the Bristol Medical School, to whom and to the artist I take this opportunity of expressing my thanks.

BEQUESTS TO DUBLIN HOSPITALS.—The late Mr. Wm. Bannan has left several bequests to Dublin hospitals. Amongst those are the Meath and Sir Patrick Dun's, which will each receive about £6,000.

THE RAILWAY DEATH-RATE.—The return of railway accidents for the year 1887 compares unfavourably, in more ways than one, with that of its predecessor. There were during the year 25 passengers killed as compared with 8 killed in 1886, and these, it should be pointed out, occurred all on one line. There were 538 injured from various causes against 615 in the preceding year, while 8 servants of companies were killed and 109 injured as against 4 and 81 respectively from the same causes in the year before, rendering the total list of deaths from collisions and accidents 33 and injuries 647, whereas only 12 were killed, though 696 were injured, in 1886.

LOOSE BODIES IN THE KNEE-JOINT.

By T. PRIDGIN TEALE, M.A., F.R.C.S.

IN fulfilment of my promise, I beg to record the following cases, which tend to corroborate the opinion of those who think that occasionally, as the result of injury, a piece of articular cartilage with a corresponding portion of bone may become detached, and give rise to the ordinary symptoms of loose cartilage. Further, such a loose body may be removed from the joint, with as complete a recovery as in the case of simple nodule, of cartilage. The first, the case read by my father before the Medico-Chirurgical Society (December 11th, 1885) has been most fully and adequately quoted by Mr. Howard Marsh, in the JOURNAL of April 4th. In this case a blow on the knee was followed in twelve months by sudden lameness and the discovery of a loose body in the joint. It was unfortunately proved *post mortem* that the loose body was a piece of articular cartilage and bone which accurately fitted a shallow cavity in the outer condyle of the femur.

The next case was under my own care at the Leeds Infirmary, and was as follows: J. J., aged 25, a mechanic, on December 4th,

exploring the joint with the finger, there was discovered on the posterior surface of the patella a shallow cavity which exactly corresponded in size and shape with the piece of cartilage and bone removed (Fig. 2).

The patient recovered well; sat up on January 11th, left the hospital on the 14th (the twenty-fifth day after the operation), and on March 12th came to the hospital. "There was no trace of a limp. He could flex the knee to a right angle, and was able to do heavy work with perfect ease."

The next case was under the care of my colleague Mr. Atkinson, with whose permission it is published. In this there is an absence of any evidence of preceding injury.

J. R., a patient in the Leeds Infirmary. On October 7th, 1886, Mr. Atkinson removed two loose cartilages from the left knee and one from the right. There was a history of frequent attacks of pain and swelling of both knee-joints extending over a period of seven years, but not of any severe injury.

January, 1887. He was again admitted into the Leeds Infirmary, as another cartilage had been discovered in the right knee. The cartilage was removed.

On January 31st the knee was excised, and the following condition was discovered (Fig. 3). A piece of articular cartilage about three-quarters of an inch square was partially detached

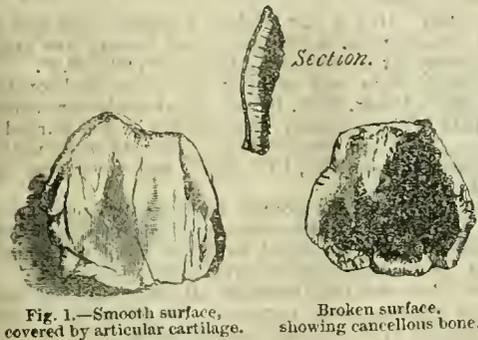

Fig. 1.—Smooth surface, covered by articular cartilage. Broken surface, showing cancellous bone.

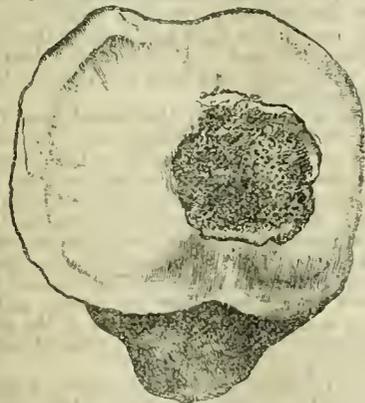

Fig. 2.—Posterior surface of patella, as judged by touch.

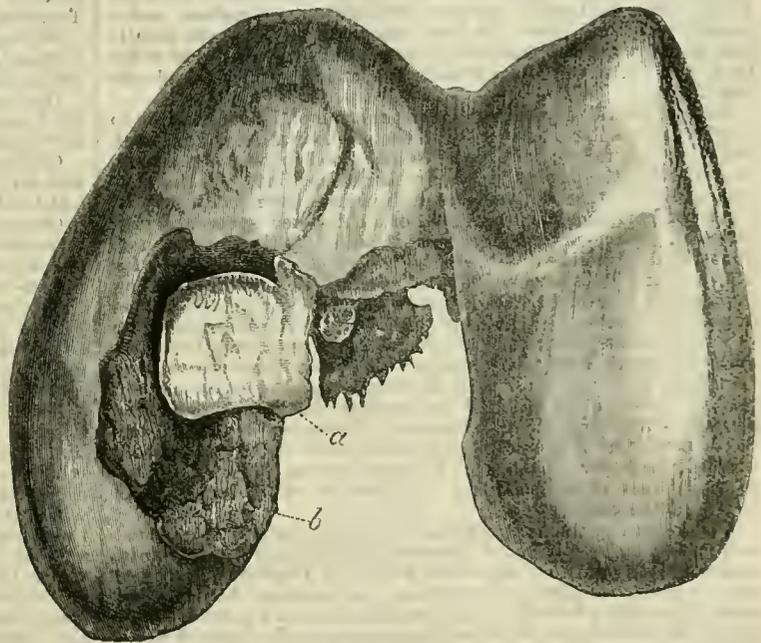

Fig. 3.—A, detached cartilage; B, surface of femur, showing bone, uncovered by cartilage.

1881, caught his foot in a rut, giving the knee a severe wrench, and fell on his hands and knees. By no questioning could any evidence be obtained tending to show that the fall was the result of some foreign body in the joint. With great difficulty, by hopping and leaning against the wall, he reached home. The joint was much swollen immediately, and excessively painful. The patient said that he felt something loose in the joint. Next day, December 5th, he was admitted into the Leeds Infirmary. The joint was swollen, painful, tender to the touch, and especially to pressure over the inner margin of the patella. The house-surgeon, Mr. Edward Ward, thinking that the case might be one of displaced semilunar cartilage, tried the usual manipulation of flexion and extension, with the effect of producing great pain and no amelioration.

December 14th. The dresser discovered a loose body in the joint.

December 21st. The joint was opened, and a loose body, consisting of cartilage and a thin layer of bone (Fig. 1) was removed. On

from the external side of the inner condyle, being attached chiefly at the upper part of its internal border, close to the inter-condyloid notch, by a portion of cartilage and synovial membrane forming a sort of hinge, which allowed the piece of cartilage to flap backwards and forwards. The patient recovered.

THE HOSPITALS ASSOCIATION.—The fourth annual general meeting of the Hospitals Association will be held at the Town Hall, Westminster, on Wednesday next, at 5 p.m., to receive the annual report of the council, etc. The chair will be taken by Dr. J. S. Bristowe, F.R.S., the President, who will deliver an address. Cards of admission can be obtained of the Secretary, Norfolk House, Norfolk Street, W.C.

A MESSAGE has been received from the Home Office, relieving Dr. Burke, who was to have been executed for the murder of his daughter, aged 9, by shooting her. He afterwards shot himself. The reprieve, it is stated, had been petitioned for chiefly by medical men.

THE INTERNAL SEMILUNAR CARTILAGE OF THE KNEE-JOINT SUTURED TO THE HEAD OF THE TIBIA.

By HERBERT WILLIAM ALLINGHAM, F.R.C.S.,

Surgeon to the Great Northern Hospital, and Demonstrator of Anatomy at St. George's Hospital.

It is to add to the literature of this subject, and to try to increase in number the performances of this useful operation, that I bring before you this evening the following case. After reading Mr. Annandale's very interesting paper on this subject, and observing that he had opened the knee-joint with success in eight cases for synovial growth and slipped semilunar cartilage, I determined to follow his advice, and see if I could not assist in bringing this troublesome condition within the province of surgery.

As I am connected with the Surgical Aid Society, I constantly have the opportunity of seeing patients, who inform me that they have been cripples for many years from this malady, and that they have spent the greater part of that period in hospital, undergoing the usual *régime* for slipped cartilage—that is to say, rest, blistering, firing, pressure, etc. When, as often happens, they have derived little or no benefit from these modes of treatment, they are finally committed to the charge of the instrument makers, and a variety of splints tried. In some cases, great good is the result; but, should these appliances fail, the patient is compelled to suffer for the rest of his life from a weak and, at times, painful and useless knee.

Now I should say that, if a careful attempt has been made to remedy the displacement by one of the methods above enumerated, and this has failed, I do not see any good in waiting longer, or subjecting the patient to any further discomfort. On the contrary, I believe that, with strict cleanliness and attention to details, a slipped cartilage may be fixed, or a thickened synovial fringe removed, with no more danger than is caused by the extraction of a loose body from the joint; in both sets of cases, the need for active treatment is at times equally urgent. But before resorting to operative treatment, one should distinguish between two classes of cases—namely, the acute and the chronic. The acute are those in which the displacement has taken place at once, and the coronary ligaments been torn through; cases of this nature may be treated by rest, pressure, etc., with recovery as a not uncommon result. On the other hand, if the cartilage has been loosened by gradual stretching of the coronary ligaments, by no means rare, consequent on much kneeling, little time should be lost in adopting palliative measures. The same recommendation applies to those cases in which acute displacement often recurs, thus tending to become chronic.

With regard to the directions in which the internal and external cartilages may be dislocated, it seems that they may slip forwards, backwards, inwards, or outwards, and that these displacements may be either complete or incomplete; the internal chiefly is the most commonly affected. I may mention that, in a very elaborate paper on this subject, Dr. Scott Lang says that the internal cartilage is dislocated when the leg is rotated outwards; and that, when the external cartilage is displaced, it is from rotation of the leg inwards. He further advises, as an assistance to the treatment of this injury, that, when the internal cartilage is affected, the patient should keep the toes directed inwards, and, in the case of the external cartilage, that they should be kept outwards.

The following is the case I intend to put before you to-night:

In September, 1887, J. W., earman, aged 33, came to me at the Surgical Aid Society, and said that I had seen him some months back when he had applied for a knee-cap. He had stated on that occasion that, about one year previously, when carrying a heavy load, something had slipped in his right knee, and that he had to rest the joint, which was very painful and swollen, for some time; after the first accident he was constantly being laid up with the disordered knee, but rest was of no avail. Each time he returned to his work the old symptoms recurred within the space of a few days. At that time, he said, I had ordered him a strong knee-cap, which, unfortunately, had been of little use.

I then went carefully into his history, and found that he detailed all the symptoms of a slipped semilunar cartilage. Accordingly, as he was a young man and healthy, and as he had asserted that, unless something was done, he would have to give up his work, I proposed that the cartilage should be fixed, and explained

to him all the risks of the operation; these he readily consented to run. I therefore sent him to the Great Northern Hospital, and on September 28th performed the following operation: The right knee was thoroughly washed and enveloped in wet antiseptic bandages for some hours. A vertical incision, two inches long was made over the internal aspect of the joint, the centre of the wound being over the internal cartilage. The joint being opened I introduced my finger with some difficulty, and felt that the internal cartilage could be freely moved about over the head of the tibia, both forwards and outwards. Fixing it with my finger, I then passed a strong needle mounted on a handle through the periosteum at the head of the tibia, and through the semilunar cartilage. The needle was threaded with stout catgut, which was drawn through the cartilage and periosteum, and then tied up tightly, so as to fix the cartilage. After this the joint was disinfected with carbolic lotion, and the cut edges of the synovial membrane carefully brought together with buried catgut sutures. Superficial silver sutures were passed through the skin, no drainage-tube being used.

The leg was then fixed upon a back-splint with a foot-piece which extended up the gluteal fold. Antiseptic dressings were applied, and the whole leg bandaged, so as to obtain firm equal pressure over the knee.

September 29th. Had a fair night. Vomited once, and complained of a little starting in the knee, so an ice-bag was applied. Temperature every six hours showed 97.6°, 98°, 99°, 99.6°.

September 30th. Pain had entirely gone. Ice still continued. Temperature 99.8°, 100.4°, 99.6°, 100.6°. His bowels were confined and he had pain in the abdomen; accordingly he was purged.

October 1st. Had a comfortable night. Bowels acted well, and the temperature fell from 101°, 100°, 98.4°, and never rose again above normal.

October 2nd. I dressed the wound; there was no pus, no effusion into the joint. Antiseptics were reapplied; ice discontinued and the leg not so firmly bandaged, as it was slightly œdematous.

October 3rd. Notes report patient very comfortable.

October 7th. Removed the dressings; all the wound was healed the superficial stitches were removed. No effusion. A pad of cotton-wool applied to the wound, antiseptics being left off.

October 19th. On the leg being removed from the splint, the patient could bend it nearly to a right angle under the thigh; but as it was still a little stiff, and as I did not wish him to use it until the adhesions were sound and firm, I did not let him stand upon the leg until November 1st.

November 26th. He returned from the Convalescent Home at Bognor, saying that his knee was perfectly well. I then advised him to walk about a little, but not to return to hard work for another month. He is now at work, and you will see that, since the operation, he has not been troubled with any discomfort in the joint, which is now perfect. With reference to the operation, I must say that I made a vertical incision instead of the transverse one recommended by Mr. Annandale. I did so, because at that time I was under the impression that he had employed this mode; but shall certainly at a future operation follow his advice, and make a transverse cut, for, by that means, a better view of the interior of the joint may be obtained. There are one or two details in the operation which I think most important.

I regarded the synovial cavity of the knee-joint as I do the peritoneum; that is to say, took great care that no blood should run into the joint, or at least should be cleaned out before being closed up. As we do when suturing the peritoneum, I was particularly careful to bring the two cut synovial edges together, in order that in a few hours the joint might be shut off by lymph thrown out between the edges from the rest of the wound. This point I consider to be of great moment, and must ask my hearers to try a similar plan in any case they may operate upon, for the synovial membrane is a serous sac, like the peritoneum; and therefore, to my mind, should be treated in a like manner. If this is done, I do not think there is much to fear from opening the knee-joint. There is another reason why I do not think there is so much danger, as is generally apprehended, in this operation of opening the knee-joint affected with a dislocated semilunar cartilage, or growths. When attacks of synovitis have frequently occurred, the synovial membrane is not nearly so likely to take on acute inflammation as it is when the serous sac is opened without any preliminary inflammatory attacks. Abdominal disorders furnish us with another parallel to these. This is shown in peritonitis, which, I think, is much more likely to ensue when one operates on a patient whose abdomen has not undergone the preparatory

changes which, I think, take place when the abdominal cavity has been filled with fluid or an ovarian tumour.

The result of my treatment in this case will encourage me to attempt, at some future date, a repetition of the operation. I may mention that I have under my care several patients who are troubled with symptoms of displaced cartilage or growth in the joint, which are constantly slipping or getting pinched between the ends of the bone, thus causing pain and crippling them. I intend, therefore, if I find no improvement after a fair trial, say six months, to open their joints, and remove a fringe or fix a cartilage; and, by so doing, I shall hope to rid them of pain, discomfort, and inability to use the limb.

P.S.—The patient wrote to me on April 16th, 1888 (seven months after the operation), saying he continued quite well.

AN UNUSUAL CASE OF HÆMATURIA.

By THOMAS OLIVER, M.D., M.R.C.P.,

Physician to the Royal Infirmary, and Lecturer on Physiology, University of Durham College of Medicine, Newcastle-upon-Tyne.

THE following case is so unique in my experience that I venture to place it before the profession.

On September 11th, 1887, I was asked to see, in consultation with Dr. Campbell, of Newcastle-upon-Tyne, Miss L. B., aged 11, a pale, emaciated young lady, who for a month had been suffering from hæmaturia, accompanied by high temperature. I was told that when an infant she had suffered from some illness, which had been followed by general desquamation, but whether it was scarlet fever the parents could not say. A few years after this she had measles, and soon after this whooping-cough. A year ago she had a slight attack of hæmaturia, the cause of which was never properly understood. Her recovery was slow, and although the temperature was not taken by the medical gentleman then in attendance, the mother states that the patient was decidedly feverish, particularly towards evening. Ultimately she made a good recovery.

Whilst spending last summer at Cullercoats along with her family, her brother took ill and was brought home only to develop and pass through a very severe attack of typhoid fever. When Dr. Campbell and I met in consultation the boy was convalescent; it was the thirty-second day of the fever. Five days after the illness of this brother was distinctly recognised as typhoid fever our patient had become feverish, and hæmaturia suddenly made its appearance. The temperature ranged from 101° to 103°. Hæmaturia had persisted without any intermission from the commencement of the feverish attack. At times the urine was deep black in colour; it was always plentiful, had a specific gravity about the normal, and was acid in reaction. It was passed without pain, never contained clot, never pus cells or tube casts, but numerous blood cells. A few days before I saw her, vomiting had set in, always coming on immediately after eating, and without pain. Bowels were natural; there was slight cough, no expectoration.

When I saw her she was very ill, much reduced from the fever and vomiting; her tongue was moist and creamy; she was sleepy and seemed heavy and apathetic; pulse from 120 to 124, and it had remained at this all through her illness. Small moist musical râles were heard all over the lower part of the chest; the base of the right lung was rather dull on percussion. The heart's sounds were healthy; liver dullness normal; splenic dullness slightly increased. There was no tumour or increased dullness detected over the region of either kidney, but a degree of pain was experienced when the right kidney was tilted forward. The abdomen was flat, no spots were seen in the skin, no fluid was detected in the peritoneal cavity, no œdema of face, feet, or hands existed. A record of the temperature was unfortunately not kept at first, but on the evening before I saw her it was 104°. From September 2nd to the 18th, the evening temperature generally registered 1° to 3° higher than the morning; the evening temperature being 103° or 104°, whilst the morning was 101° or 102°.

On September 19th the morning temperature suddenly fell from 103° to 99.2°, and whilst on this evening the temperature rose to 100.2°, it never again did so. The morning and evening temperatures were for the future pretty nearly equal, never being higher than 99°.

All sorts of medicines had been tried, iron, gallic acid, quinine, ergot, ergotin, in the view that the hæmaturia might be in some

way or other associated with a specific fever. Sulphur, carbonate of soda, and quinine were given, but all without avail.

After the sudden fall of the temperature on September 19th, blood never appeared in the urine, and the patient had a convalescence which was quite uninterrupted.

Now here was a case of hæmaturia which began with high temperature quite suddenly; both continued for thirty-five days, the high temperature and the hæmaturia each being quite uninfluenced by drugs; then a sudden fall of the temperature occurred, also a cessation of the hæmorrhage, both followed by cure. What was the hæmaturia symptomatic of? There was nothing to suggest stone in the kidney or in the bladder, no enlargement of the kidney pointing to cancer, no history of hæmophilia, no purpura hæmorrhagica, no Bright's disease. The diagnosis, in my opinion, lay between tubercular disease and some peculiar blood condition; and we eliminated the former partly by the good family history we obtained, and the absence of any diseased condition of the lung which we could definitely regard as tubercular; the few râles which we heard in the chest had not been of two days' duration. From the sudden onset of the illness and the high temperature, the continuation of the high temperature and hæmaturia as associated conditions of thirty-five days, the distinct evening exacerbations, their refusal to be influenced by medicines, the enlargement of the spleen, the contemporaneous illness of the brother, and that illness unmistakably typhoid fever, and the fact that brother and sister had been living under identical conditions at Cullercoats, the one taking ill five days before the other; all these led us to regard the hæmaturia as specific, or, in other words, that our patient was also suffering from typhoid fever. Am I right in even suggesting this? All our textbooks speak of the relationship. In scarlet fever we have an illustration of how a poison known to act principally upon the skin and the tonsils may yet attack the glands in the wall of the intestine and the kidney; for as early as the second or third day of the fever the kidney *post mortem* has been found to be the seat of an interstitial or a glomerulo-nephritis. Besides, in typhoid fever itself, is it not the case that while the glands in the lower part of the wall of the ileum are the seats usually selected by the poison, there yet occurs every now and then an inflammation of the lungs with all the physical signs of a pneumonia, a pneumonia difficult to explain as regards its causation and relationship to the typhoid fever, and yet at other times so acute and so severe as to mask the other signs of typhoid fever, of which it is after all but the local expression? I am inclined to think that in our case the kidneys had to bear the brunt of the poison, or as the result of the poisoned condition of the blood, the walls of the renal vessels allowed the blood to escape. If so, then I trust I have made good my claim to this case of hæmaturia being regarded as quite an unusual one.

WOLFFBERG'S COLOUR-TEST.

By SYDNEY H. A. STEPHENSON, M.B. EDIN.,

Clinical Assistant to the Royal Westminster Ophthalmic Hospital.

By the employment of this test Dr. Wolffberg (*Klin. Monatsbl.*, p. 359, 1886) claims to have discovered a simple method of telling in a given case whether defective vision is caused by refractive error or by defect of the light-sense. He employs two discs placed on a background of black velvet; the one is red, 2 millimètres in diameter (R^2), and the other blue, and 7 millimètres in diameter (B^7); if the vision is less than $\frac{1}{3}$ larger, red and blue discs are used. By comparing the distances at which these discs are recognised by the eye under examination, with the degree of visual defect, as ascertained by Snellen's types, Wolffberg believes that he is able to tell whether the defective vision is due to an error of refraction. An eye which reads $\frac{1}{3}$ should see the discs at 5.5 metres; if this be not the case, he concludes that it is suffering from some affection, other than a refractive error, which is likely to affect the light-sense.

If vision be impaired by simple ametropia, the discs should be seen with each degree of vision at a certain constant distance from the eye. Wolffberg believes that he has ascertained these distances by experiment, and he has constructed a table from which can be seen at a glance the distance at which the discs ought to be recognised with each degree of vision. If the defective vision be caused by defect of the light-sense—which is supposed to influence colour-vision more than form-sense—the distances at which the discs will be seen will correspond to constant distances,

shown in a second table, and ascertained by discovering at what distance emmetropic eyes were able to recognise the discs when the illumination was reduced by gradually diminishing the amount of solar light.

Dr. Boehm (*Klin. Monatsbl.*, November, 1887), from a large number of experiments made in Wolffberg's *clinique* and at his suggestion, believes that he has not only confirmed the above conclusions, but also that, by means of this test, he is able to detect the presence of astigmatism; since this impairs the form-sense in a much higher degree than does spherical ametropia, but has not a proportionate effect on the colour-sense.

An able and lucid review of Wolffberg's and Boehm's papers was published in the *London Medical Record* by Mr. W. Adams Frost (*London Medical Record*, Art. 7583, December 15th, 1887), at whose suggestion I made the experiments about to be described.

It is obvious that if Wolffberg's data were correct, we should have a valuable addition to our methods of diagnosis, but as my investigations on the subject do not confirm those data, I have thought it advisable to place them on record.

The observations were carried out on a fairly large number of intelligent children and adults, and the apparatus used was obtained from the source recommended by Dr. Wolffberg. The patients were first made to understand what was expected of them by being shown discs similar in every respect to those actually employed in the test, except that they were of different colours. The real test-discs were then placed at such a distance from the patient that they were invisible to him, and they were gradually approximated until they were recognised. Wolffberg adopts the opposite course, gradually increasing the distance until they become invisible. Although this difference in our respective methods of employing the test might explain trivial discrepancies, it would certainly not account for the totally different results obtained.

My experiments were limited to finding out the distances at which the discs were seen; (1) in eyes whose vision = $\frac{5}{6}$; (2) in spherical ametropia of known amount; (3) in spherical ametropia of artificial production. My original intention was to endeavour to verify all Wolffberg's conclusions, but when I found that the results obtained from the above three classes of cases did not coincide with his table, I thought it useless to proceed further, since the trustworthiness of Wolffberg's whole scheme depends on the integrity of his facts with regard to emmetropia and simple myopia and hypermetropia.

The conclusions which I have reached are as follows:

1. *As to the Distances at which the Discs could be seen by Eyes with V. = $\frac{5}{6}$.*—Many eyes were unable to recognise the coloured discs at 5.5 mètres. The majority of those examined could not distinguish the Bl⁷ disc beyond 5.0 mètres, and in some cases not beyond 3.0 mètres. According to Wolffberg the two coloured discs should be visible at the same distance from the eye, but in most of the cases examined the R² disc had to be held 0.5 to 1.5 mètres nearer the eye than had the Bl⁷ disc before it could be recognised. Many patients had great difficulty in saying the exact distance at which the discs could be seen. So far as I could see there appeared to be no definite constant distance at which different eyes whose V. was $\frac{5}{6}$ could recognise the discs.

2. *Myopia and Hypermetropia in which Corrected Vision = $\frac{5}{6}$.*—The distance at which, with each degree of vision-defect, the discs could be recognised did not correspond with Wolffberg's table. In different experiments persons who had the same degree of defective vision did not see the discs at the same distances; for example, A. (myope) had V. = $\frac{5}{6}$, and saw R² at 0.5 mètre, and Bl⁷ at 1.0 mètre; whilst B. (myope), who also had V. = $\frac{5}{6}$, saw R² at 1.25 mètres, and Bl⁷ at 1.75 mètres.

3. *Myopia and Hypermetropia produced by Convex and Concave Glasses.*—In this class of cases, also, the distances at which the discs were seen in the different degrees of visual defect did not agree with Wolffberg's table; often the results obtained from the two eyes of the same person with the same amount of defect in each gave different results; no two cases ever coincided exactly one with the other; and frequently a person when re-examined gave widely different answers from those obtained at the first examination.

In practically all cases it was found (a) that R² had to be held nearer to the eye than had Bl⁷ before it could be recognised; (b) that the worse the vision the nearer had both the coloured discs to be held to the eye, in order that they might be clearly seen; for example, V. $\frac{4}{5}$ sees R² at 3.5 and Bl⁷ at 5.0 mètres; V. $\frac{3}{4}$ sees R² at 2.5 and Bl⁷ at 4.0 mètres; V. $\frac{2}{3}$ sees R² at 1.0 and Bl⁷ at 2.0

mètres; V. $\frac{1}{2}$ sees R² at 0.75 and Bl⁷ at 2.5 mètres; V. $\frac{1}{3}$ sees R² at 0.5 and Bl⁷ at 1.75 mètres; V. $\frac{1}{4}$ sees R² at 0.33 and Bl⁷ at 1.0 mètre.

Although this test possesses some scientific interest, I fear that it is of no practical value as a help to differential diagnosis: and although there may be—and in all probability is—some ratio between form and colour-sense, I am driven to the conclusion that Wolffberg has not correctly ascertained it, and that his test is open to many sources of error from its purely subjective nature.

THERAPEUTIC MEMORANDA.

SALINE PURGATIVES IN THE TREATMENT OF TYPHLITIS AND PERITONITIS.

At a recent meeting of the Midland Medical Society I showed a patient who had recovered from an undoubted attack of acute peritonitis secondary to typhlitis. In this case opium and belladonna failed to give relief, while the administration of sulphate of magnesium and sulphate of sodium in half-drachm doses with ten minims of tincture of belladonna every four hours was quickly followed by improvement, the motions, at first liquid, becoming more and more solid till normal stools were passed. Two or three slight relapses in this case were at once checked by the mixture and the man rapidly recovered, there remaining a small induration in the right iliac fossa.

Since the above case was recorded, I have had under my care at the Workhouse Infirmary a severe case of typhlitis. I gave the same mixture as in the first case, with great relief; in fact, enemata of soap and water and of glycerine failed to evacuate. After continuing the medicine for a week the bowels failed to act, and in a few days the abdomen was distended, there being dulness in each flank, with a distinct thrill on percussion, all the signs, in fact, of fluid in the peritoneal cavity being present. The patient was very prostrate, having been allowed only a pint of peptonised milk and a pint of beef-tea a day. I gave him three ounces of whisky, and the next morning he passed an enormous liquid motion containing scybala. I continued the stimulant, and allowed him another pint of milk. He continued to pass large motions with scybala, the enlargement of the abdomen and other signs of fluid in the peritoneal cavity completely disappearing. Evidently the saline aperient had caused a large flow of fluid into the intestine, but the bowel was not sufficiently powerful to evacuate it; restoration of tone by stimulants at once enabled the bowel to empty itself. At this time another complication appeared in the form of a painful swelling of the left parotid gland, which, however, subsided without suppuration. Finally, the patient completely recovered, and was discharged six weeks from the time of his admission.

It seems to me that in typhlitis due to fecal retention, and in peritonitis from the same cause, saline purgatives are of great value, especially if enemata fail to act. In moderate doses they do not cause peristalsis, their action is quite painless, and they are exceedingly useful in washing away hardened scybala. During their administration the abdomen should be frequently examined, and any accumulation of fluid in the intestines treated by stimulants.

C. W. SUCKLING, M.D., M.R.C.P.

Birmingham.

JAMBUL IN DIABETES.

A WOMAN suffering from diabetes was admitted into the Newbury District Hospital on September 24th, and during the whole of her stay there she was dieted. For the first nine days she was given a tonic mixture of quinine and iron. The average daily amount of urine was 98 ounces, with an average specific gravity of 1041.5.

During the next ten days she was given half a grain of opium, at first three times, and afterwards four times, a day. The average daily amount of urine was 91.3 ounces, with an average specific gravity of 1040.

During the next eleven days she took jambul, at first two grains and a half, and afterwards five grains three times a day. The average daily amount of urine was 138.3 ounces, with an average specific gravity of 1041.5.

I tested the urine frequently, and always found that sugar was present. The jambul was given in parts containing two grains and a half each, obtained from Thomas Christy and Co. It is as

well to publish facts about new drugs, whether they be favourable or the reverse.
ROBERT BIRCH, L.R.C.P.Lond.
Newbury.

SULPHONAL.

AFTER seeing the articles upon the new hypnotic "sulphonal," on April 21st, I obtained a supply of the drug. I did not find that it was soluble in eighteen or twenty parts of boiling water. It required considerably more, and immediately on cooling it crystallised out; neither did I find it soluble in 100 parts of water at the ordinary temperature.

Its effect upon patients was very discouraging. For several hours after taking the drug no appreciable effect could be observed, but during the greater part of the following day there was extreme drowsiness, also considerable cyanosis. The price is 16s. per ounce.

The best mode of administering sulphonal is to mix with pulv. tragacanth co. and water.
Nettingham. T. ERNEST LOVEGROVE, M.R.C.S.

PHENACETINE.

As an antipyretic I have found this drug to act admirably in from four to twelve grain doses, having greater and more prolonged effect upon the temperature than antipyrin, and producing no rigors, vomiting, or nausea, but rather a sense of well-being, the patient frequently becoming cheerful and demanding food. I hear that it has been used with marked success in the treatment of neuralgia.

LEYLAND ROE, L.R.C.P., M.R.C.S., etc.

PATHOLOGICAL MEMORANDA.

CLUB-FOOT AND OTHER CONGENITAL CONTRACTIONS.

Mrs. M. D., aged 33, was confined for the ninth time on April 12th, 1887. The confinement was normal, but the child (a male) had double talipes equino-varus. Shortly afterwards the mother requested the nurse to show her the child's feet, and, on observing the deformity, remarked "I thought so." She then confessed to having entertained an "impression" to the effect that the child's feet would be "turned," and the existence of this impression was corroborated by her husband. Two months thereafter I performed the usual tenotomy operations, and the subsequent treatment with splints and bandages was successfully carried out almost entirely by the mother. With this she was more or less employed until within a few weeks of her next confinement, which took place on April 3rd, 1888. On this occasion the presenting part was the breech, and the child (a small male) was dead when born. This child also had double talipes equino-varus, while both hands presented a somewhat crushed appearance, the fingers being flexed and closely applied to the palms. On attempting to open the hands, the little, ring, and middle fingers were found to be firmly held in this position, and could not be extended by a force short of violence, while the thumbs and index fingers were unaffected. Moreover, both knees were drawn up, the thighs forming with the abdomen about a right angle, and any endeavour to straighten the legs by pushing down the knees succeeded only at the expense of raising the chest from the horizontal, doubtless due to contracted psoas and iliacus muscles pulling on the spine.

As to the cause of these deformities I can find in the family history no evidence of heredity.

I have mentioned the employment of the mother during her last pregnancy as being, in relation to the causation of the second case, possibly something more than a concurrent association.

The complete symmetry of these contractions suggests a central cause, and seems in opposition to the theory of their being modifications of intra-uterine attitudes from mechanical causes. Be the explanation what it may, the cases I presume, from their infrequency, are not without interest.

Glasgow. J. A. WILSON, M.B., C.M.Glasg.

At a public meeting held at Perth on May 18th, it was decided to form in that town a centre of the St. Andrews Ambulance Association, and a committee was appointed with that object. The opportunity was taken to present Dr. Simpson with a large and handsome silver salver, bearing a suitable inscription, in recognition of his valuable services to ambulance work in Perth. Dr. Ward, who had assisted Dr. Simpson in connection with the lectures, was presented with a silver-mounted walking-stick.

ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.

THREE CASES OF STONE IN THE BLADDER SUCCESSFULLY TREATED BY SUPRAPUBIC LITHOTOMY.

(By Mr. FREDERICK PAGE.)

CASE I.—Seven years ago a Durham pitman, aged 25, took from the bed of the river Wear a pebble which he introduced into his urethra, and manipulated into his bladder. He seems to have felt but little inconvenience till four months ago, when urgent symptoms of stone in the bladder reminded him of his folly. On admission, January 30th, 1888, he was suffering a good deal physically and mentally. On February 7th suprapubic lithotomy was performed, and a round phosphatic stone the size of a thrush's egg removed. Peterson's bag was used, the bladder being distended with warm boracic lotion. The wound was closed with a continuous catgut suture, a drainage-tube being introduced at its lowest part between the separated muscles, but not into the bladder. The bladder was not sutured. A soft catheter was retained in the bladder for four days; it was then removed, and passed at intervals for three other days. On the twelfth day the patient passed by the urethra ten ounces of urine, none having escaped from the wound since the seventh day, showing that the bladder wound had healed in a week; but very little urine escaped from the wound at any time, showing that the bladder was effectually drained by the catheter. The nucleus of the calculus was found to be a piece of rough stone, about the size of a horse bean, and so hard that a section of it could not be made with a saw. The man suffered hardly any inconvenience from the operation, and the whole of the wound, with the exception of tract of the drainage-tube (which closed on the sixteenth day) healed by first intention.

CASE II.—A boy, aged 6 years, admitted February 25th, 1888, with symptoms of stone in the bladder of two years' duration. On February 28th a uric acid stone, coated with phosphates, the size of a large cobnut, was removed by suprapubic lithotomy. The wound was closed with a catgut suture, a small drainage-tube being introduced at its lower angle down to but not into the bladder. A soft rubber catheter was secured in the bladder. No urine escaped from the wound till the fourth day, when the catheter becoming blocked for a short time, some found its way through the drainage-tube. On the seventh day the catheter was removed in consequence of its causing pain. Urine then escaped from the wound for one day. On the eighth day after operation the child passed water naturally, no urine escaping from the wound again. The tract of the drainage-tube closed on the tenth day, the rest of the wound having healed by first intention.

CASE III.—A. B., a Northumberland pitman, aged 23, admitted February 27th, 1888, with symptoms of stone of two years' duration. Suprapubic lithotomy, as in Case I, was performed on February 29th, when an oxalate of lime calculus, the size, shape, and colour of a large Spanish chestnut, was removed. The soft rubber catheter was withdrawn on the sixth day. Some, but very little, urine escaped through the drainage-tube daily till the ninth day, when the patient passed naturally at one time nine ounces of water, after which none escaped from the wound. The tract of the drainage-tube closed on the thirteenth day, the rest of the wound having healed by first intention.

REMARKS.—It must I think be admitted that in cutting into the bladder above the pubes fewer important structures are liable to be wounded than in lateral lithotomy. It cannot be denied that the suprapubic incision is more direct and less extensive than the lateral. There are certainly reasons for preferring the high operation. The three cases reported above could not have done better had they been treated by lateral lithotomy, and it seems to me if suprapubic should be found, as time goes on, to be as successful as lateral lithotomy, the question as to which operation is the better must be answered in favour of the obviously more direct and simpler method. The points to be attended to in the after-treatment of a case of suprapubic lithotomy are I think to keep the bladder empty, and to provide for the direct escape of urine from the wound till the cut in the bladder is

healed and the cicatrix strong enough to resist the presence of urine in the partially distended bladder. If these principles can be readily carried out, and they are possible, I should expect to find suprapubic supplanting lateral lithotomy.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MAY 22ND, 1888.

Sir E. H. STEVERING, M.D., President, in the Chair.

On the Value of the Tubercle Bacillus in Clinical Diagnosis.—Dr. PERCY KIDD and Mr. H. H. TAYLOR presented a communication, the object of which was to emphasise and illustrate the value of the sputum test when systematically applied to all cases of disease of the respiratory organs of doubtful nature. The paper dealt only with cases in which other recognised methods of clinical investigation failed to indicate a definite diagnosis. In the great majority of the cases described, numbering over ninety, positive results were obtained, only a few negative cases having been included where the value of the evidence was tested by *post-mortem* examination. The detection of the tubercle bacilli in such cases was often extremely difficult, and repeated examination might be necessary where the number of the bacilli was very small. The time required for such investigations was, however, well repaid when, as often happened, a positive diagnosis could be arrived at without delay, and without waiting for the progress of the case to decide the point. Success depended largely on the following points: judicious selection of the sample of sputum; method of preparation and staining; careful examination with suitable appliances. The cases described fell into five main groups: 1. No physical signs of disease of the respiratory organs. 2. Laryngeal disease of uncertain nature, without definite pulmonary signs. 3. Signs of bronchitis, with or without emphysema. 4. Signs of pleurisy. 5. Signs of doubtful import—(a) anomalous physical signs, (b) slight signs at the apex, (c) signs confined to or most marked at the base. The tubercle bacillus had been found to be of little use for purposes of prognosis.—Dr. C. T. WILLIAMS congratulated the authors on what he considered an important and practical paper. He was quite ready himself to confirm nearly every point. Some of the divisions of the cases brought forward by the authors were almost verbatim reproductions of part of a book on Pulmonary Consumption he had recently published. Great care had been spent by the authors on the subject at Brompton Hospital, and he was pleased to hear their results; but he thought it would be a pity if attention to the bacteriological part of the subject interfered in the least with the careful examination of all previously available physical signs. He had had visits from some Germans who had had bacilli found in their sputa by a pharmaceutical chemist, and whom the chemist had proposed to treat; that was a result not to be approved. In diagnosis of laryngeal disease he thought examination of sputa for bacilli of great value, and perhaps of even greater value in cases of bronchitis and emphysema where the tubercle was masked by the other diseases. In two small groups of cases beyond those the author had mentioned he thought the examination very useful, namely, in cases of pyrexia and wasting without any physical signs of disease of the lung. In some of these he had found the bacillus before the physical signs; and again in some senile cases where bronchial catarrh masked tubercular disease. In cases of physical signs at the bases only it often happened that the original attack had been at the apex, where it had become quiescent and recrudesced at the base. He did not agree with the conclusions of Dr. Kidd and Mr. Taylor that the bacillus was of little use in prognosis. That the results were disappointing he would allow; but the bacillus was sometimes important in cases of arrested phthisis in whom the process might come on again; it might be of special importance in giving or refusing medical consent to marriage.—Dr. G. HERON agreed to the importance of the presence of the bacillus in settling a tubercular diagnosis in some cases of laryngeal disease, and some of bronchitis and emphysema. In work at the Victoria Park Hospital for some six years, he had paid some attention to the inferences in prognosis to be drawn from frequent examination, and he thought they were of great importance. If he found a case in which the number of the bacilli remained small during several weeks of examination, he thought the prognosis much better than of one in which the

number remained steadily large, and this though he might never have seen the patient.—Dr. DOUGLAS POWELL valued Dr. Kidd's and Mr. Taylor's paper very highly, as it was time now to come to some conclusions on these matters. He agreed with them that the bacillus was valuable in diagnosis, and not of much use in prognosis. For prognosis in a distant patient, such as Dr. Heron had suggested, he would as soon take a report of his weight, or of his physical signs, or even a photograph. In laryngeal cases he agreed it was valuable for diagnosis, and might show phthisis when an aneurysm masked the physical signs. In cases which had been continuously and carefully watched he had sometimes known physical signs come before bacilli.—Dr. J. K. FOWLER wished to bear testimony to the examination for bacilli in cases of spare men with some bronchitis and emphysema. They were not infrequently cases of arrested phthisis. Recently, in a life-insurance case of considerable importance of this class, he had been very much indebted to the examination of the sputa by Mr. Taylor, as showing a concomitant and probably antecedent tuberculosis.—Dr. PERCY KIDD, referring to some remarks of Dr. Williams as to the similarity of some parts of their divisions of the subject and passages of his book, remarked that their list was drawn up some time before his book was published, and he could only be glad that they had arrived independently at such similar results. The cases of senile phthisis he had mentioned would probably have come under their heading of bronchitis and emphysema. Dr. Williams had asked after the *post-mortem* state of the apices of the lungs in a case he had described as basic, and he could say from personal examination that it was one of those rare cases in which the apices were completely non-tuberculous. The point they had wished to make with regard to prognosis had perhaps been a little misunderstood. They had so often found cases in which the disease was in very rapid progress, with a constantly very scanty supply of bacilli, and a chronic stationary case in which the bacilli were very abundant, that they considered the abundance of the bacilli to add little to their other means of prognosis. If there were no other means of prognosis, the rule of many bacilli indicating acute and active disease, though it had a great many exceptions, might be of some considerable service; but what they had meant was that, in the present state of knowledge, very nearly as good a prognosis could be made without an examination of the bacilli as with it.

The Removal of Bony Growths from the External Auditory Canal.—Sir W. B. DALBY read this paper, which dealt only with those tumours of ivory hardness whose point of origin is the osseous portion of the external auditory canal. The method of removing them, which the author introduced in 1874, consisted in grinding and cutting them away with an ordinary dentist's drill. He now employed an electric drilling machine which admitted of 5,000 turns per minute, but the rate of the revolution could be controlled. The extraordinary facility with which bone could thus be cut was shown. The method of operating was described in detail: the drills, burrs, and small trephines were shown.—Sir WILLIAM DALBY, rising at the request of the President, explained some of the specimens and instruments. In some of these cases of exceedingly hard, bony tumours, in the external auditory meatus, it was found sufficient to bore a hole through their base, for that damaged their nutrition, and led to their death and removal by easier means; but the boring of this first hole was no easy matter in a narrow canal where reflected electric light and absolute stillness for the operation were requisite, and burrs made of the best steel in the world were sometimes destroyed to the number of twenty or thirty before any serious impression was made, when they were revolving at a rate of 3,000 times a minute. However, thanks to the admirable ingenuity of Mr. Augustus Winterbottom, they now had the most perfect instruments, and could cut these bony growths as they liked, a very great contrast to much rough-and-tumble sawing and gouging he had seen in surgery. He could not help thinking that when the surgical world realised fully what could be done with the rapid and delicate cutting of bone, they would make more use of it.

SOUTH EASTERN BRANCH: EAST SURREY DISTRICT.
THURSDAY, MAY 10TH, 1888.

T. A. RICHARDSON, M.R.C.S., of Croydon, in the Chair.

Febrile States and Antipyretics.—Dr. GOODHART read a paper on certain innominate febrile states and the use of antipyretics. He showed that there was too great a tendency to assign all febrile states to a definite class and to treat them accordingly. Some

cases were improved by allowing a less restricted diet than was required in enteric fever, for example. He described several cases of continued fever (illustrated by charts of temperature, etc.) which were not capable of diagnosis; cases where the diagnosis was not clear as to tubercle or typhoid; cases of "fæcal fever" with coated tongue and offensive breath; cases of severe anæmia with pyrexia, which in his experience often terminated fatally; purpura, with pyrexia and varicella gangrænosa. There appeared to be two classes of cases: 1, where the pyrexia was hurtful; 2, where it was not so distinctly injurious. Many indications pointed to there being a nerve centre for controlling heat-production, and probably in the latter class of cases the fever might be due to some disordered action of this centre, and antipyretics might be useful. That they reduced the fever was certain. On the whole, Dr. Goodhart preferred antifebrin as having least disadvantages, but thought that in the first class of cases, where there was a distinct morbid agent, antipyretics were of little use and might be injurious unless used with great discretion. In the less serious cases, where they appeared to act beneficially, the improvement was frequently not the result of the medicine.—A discussion followed, in which Drs. DUNCAN, PARSONS SMITH, COLES, Mr. RICHARDSON, and Mr. WRAY took part.

Electrolysis in Urethral Stricture.—Mr. BRUCE CLARKE described the treatment of stricture of the urethra by electrolysis, showing a battery with galvanometer and the necessary bougies, solid and hollow. A pad placed over the sacrum was attached to the positive pole of the battery, the urethral bougie being attached to the negative pole. About 5 milliamperes was the average current. Having examined the urethra thoroughly with a urethrometer, pass a bougie slightly larger than the stricture, note the time, and allow the current to pass; press very gently against the stricture, and in 5 to 10 or 30 minutes the bougie would probably pass through. After ten days a larger bougie might be used. There was some smarting, and perhaps slight discharge for a day or two.—Mr. GOLDING-BIRD thought that the class of cases likely to be permanently cured by electrolysis would also be curable by simple dilatation.—Mr. BRUCE CLARKE pointed out the safety of the method by electrolysis; he had had no ill effects from it.

Local Treatment of Eczema.—Dr. PHILPOT read a paper on the local treatment of eczema. After insisting on the necessity of getting at the cause of the disease in each case, and treating it, he maintained that locally the guide for treatment was similar to what obtained in other inflammations, acute or chronic, namely, in acute cases rest, cleanliness, antiseptics; removal of all sources of irritation and disturbance; in chronic cases exercise and stimulation. Acting on these principles he described the various soothing applications for acute cases, showing specimens of Dr. Unna's preparations for eczema, which combined the principle of giving rest by support and applying antiseptic remedies. For chronic cases with thickened epidermis, salicylic acid was a valuable application.

THE CLINICAL SOCIETY OF MANCHESTER.

TUESDAY, MARCH 20TH, 1888.

S. WOODCOCK, M.D., President, in the Chair.

Laryngeal Growths.—Dr. SIMPSON showed two patients with laryngeal growths. One, a young woman in good health, had a papillomatous growth rising from the anterior third of the left vocal cord, and another attached below the cord. He had removed them with forceps several times almost, if not quite, completely; but the tendency to return was very troublesome, notwithstanding the subsequent application of strong astringents and chromic acid. The growth after removal was now, however, much less rapid than it was before. The other case was that of a young man in good general health, a carter, and therefore a good deal exposed to the weather. He attributed his throat affection to repeated colds. Springing from the false cords were two fleshy-looking lobes or thickish flaps projecting inwards, meeting and overlapping each other in the middle line. A smaller similar growth projected forwards from the mucous membrane of the right arytenoid, at its inner edge. During inspiration these flaps were drawn downwards over the glottis, seriously obstructing inspiration. In forced expiration they were driven upwards, and might be seen to vibrate rapidly. The voice was rather rough but strong. The true cords were concealed by the growths. No operative procedure had taken place, but their removal would be attempted with the cutting forceps or laryngeal guillotine, probably the latter.

Spasmus Nutans.—Dr. OWEN showed an example of this affection in a child aged nine months. When seven months old her head was noticed to move in an unusual manner. There were slight lateral movements, the face being turned from side to side, with occasional nutation. There was slight nystagmus. The child had cut two teeth during the past six weeks, and the gums over the upper central incisors were swollen.

Paramyoclonus Multiplex.—Dr. OWEN showed a case of symmetrical spasm of certain muscles of the trunk and face. The patient, a girl aged 13, first came under notice in 1883, with the following history and symptoms. There was no history of rheumatism. She was said to have had scarlatina ten years before, since which she had always had twitching movements, principally of the shoulders, but also of the face. During the past two years she had had spasmodic movements affecting the upper part of the abdominal muscles. The diaphragm was distinctly involved; also the recti abdominis, sterno-thyroid, and erector spinae muscles. The twitching of the shoulders and of the face was said by the mother to alternate with spasm of the trunk muscles. There was partial control over the spasm of the abdominal muscles. The spasm of the muscles was in appearance exactly such as occurred from electric shock. There was no cardiac murmur, but the diaphragmatic spasm caused a respiratory puff, which, when heard at the cardiac apex, exactly simulated a mitral murmur. She had been treated with large doses of arsenic, and with electricity. The affection had now (1888) existed fifteen years. The girl still showed the spasmodic affection of the abdominal muscles, but in a much less marked degree.

Formation of Medio-Tarsal Joint.—Mr. STANMORE BISHOP explained, with the aid of diagrams and preparations, a view of the formation of the medio-tarsal joint. He showed by extracts from various authors that the prevailing view of this joint amongst orthopædists was that of a transverse articulation passing straight across the foot at the level of the astragalo-scapoid junction, and including the calcaneo-cuboid joint. The view he upheld was the more strictly anatomical one of a ball and socket, the ball being the head of the astragalus, the socket being formed by the scaphoid, os calcis, and the ligaments connecting them, the calcaneo-cuboid joint being entirely excluded. He suggested the following arguments as bearing out this idea: (a) The conformation of the bones themselves. (b) The mode in which the various bones were united by ligaments. (c) The method of insertion of muscles into the various bones of the foot, and the especial absence of any muscular attachment to the astragalus. (d) The movements of the various segments of the foot upon one another. (e) The position of the various bones in certain deformities. If this should prove to be correct, a distinct modification of the shoes at present in use would become necessary.

REVIEWS AND NOTICES.

ON THE PRACTICAL VALUE OF WOLFFBERG'S APPARATUS FOR THE QUANTITATIVE ESTIMATION OF THE COLOUR-SENSE. By B. HERZOG. Inaug. Diss. Königsberg, 1887.

AFTER reading this pamphlet, it is impossible not to agree with the conclusion of the writer, that Wolffberg's test as a means of differential diagnosis is practically useless. Wolffberg believes that when vision is impaired solely in consequence of an error in refraction the colour-sense fails in a definite proportion, so that for each degree of visual acuity there is a corresponding colour defect; when the vision is impaired from other causes, such as opacity of the media or affections of the optic nerve, the colour-sense is impaired more than the visual acuity. The colour-sense was estimated by the distance at which certain coloured discs were visible, and the visual acuity in the ordinary way. Tables were given showing the distances at which the discs should be visible for each degree of vision in both conditions. If these data were correct, it is evident that the test would enable one to say at once whether the defect in vision was due solely to an error of refraction or not. These results of Wolffberg have attracted some attention, since Boehm has published extensive statistics compiled from examinations made in Dr. Wolffberg's clinic, which appear not only to corroborate his conclusions, but to give even more definite results.

HERZOG points out that the mode of examination is one which is open to many sources of error. In the first place, he asks, are

we to require the discs to be merely seen as objects, or is their colour to be recognised? Then it is obvious that if, as Wolffberg recommends, the discs are gradually withdrawn till they become invisible, memory and imagination render it extremely difficult to fix the exact moment of disappearance; and this difficulty is by no means entirely removed when the test is reversed. He, moreover, found that many normal emmetropic eyes could not recognise the discs at the prescribed distances, and that some eyes which were not normal, and had sub-normal vision, could recognise them at the distance proper to a normal eye. Although in most cases of astigmatism the form-sense was impaired to a greater extent than the colour-sense, this was not sufficiently constant to render it available for differential diagnosis.

Dr. Herzog's pamphlet is written with every appearance of strict impartiality, his facts are clearly stated, and have evidently been collected with great care, and it is impossible not to feel that he has good ground for the conclusion that "Wolffberg's test method does not render superfluous a single test previously in use."

THE PASSAGE OF AIR AND FÆCES FROM THE URETHRA. By HARRISON CRIPPS, F.R.C.S., Assistant Surgeon to St. Bartholomew's Hospital, etc. London: J. and A. Churchill.

THE author has had under his own observation three patients suffering from that most miserable complication which forms the title of this monograph. In two of these cases the primary disease was cancer, in the third the cause of the passage of air and fæces was obscure, and some slow growing tumour might have existed in the neighbourhood of the parts concerned. A tumour was detected in the right breast.

Mr. CRIPPS has avoided an error common amongst men who rely too much on large personal experience. Relatively speaking, three cases of the rare condition in question represent a large experience. He admits that his cases naturally lead him to believe that communications between the intestine and the bladder are generally the result of malignant disease. But he demonstrates that the result of further research, extended to the records of other surgeons, shows that entero-vesical fistulæ are more commonly established by inflammatory processes.

Mr. Cripps has collected 63 cases, and when the series are subdivided according to the ascertained causes of the abnormal communication between the bladder and intestine, the following statistical information is obtained. Cases where the cause was inflammatory, 45; cancerous, 9; traumatic, 2. There remain 7 cases where the cause was unascertained. The author's subdivision of the "inflammatory" group is of high interest to the surgeon. Excluding 16 from the entire 45, abscess accounts absolutely for 15, stricture for 8, ulcer (intestinal rather than vesical) 4, stone 2. The 63 cases are also grouped thus, according to the seat of the fistula on its intestinal aspect, deducting 6 "unascertained." The fistula was found in the rectum in 25; colon, 15; small intestine, 12; colon and small intestine, 5. The passage of air and fæces into the bladder is dangerous as well as distressing alike in the inflammatory, the cancerous, and the other cases. Putrid urine sometimes finds its way into the bowel (though this accident is not the rule), and other obviously unfavourable conditions break down the patient's health. Hence 22 out of 30 "inflammatory" cases in which a clear life-history was given, and where no surgical interference was deemed advisable or found practicable, ended fatally.

Mr. Cripps is not in favour of exploratory abdominal section, for, after examining museum specimens, he has come to the conclusion that adherent intestine could not be safely detached from the bladder. He strongly advocates colotomy, and maintains that the descending colon should be chosen, after a very close examination of the parts combined with careful consideration of the symptoms, for should the communication involve the cæcum or small intestine, the operation would be worse than useless.

The author's analysis of the entire series is most instructive, and the collected cases, as originally reported, form a valuable appendix. Mr. Cripps appears to have established two facts. First, entero-vesical fistula is generally of inflammatory origin. Secondly, the primary disease is more frequently situated in the bowel than in the bladder.

THE Clothworkers' Company have sent a donation of £25 to aid in maintaining and extending the work of the Parkes Museum in practically teaching the laws of health.

NOTES ON BOOKS.

The Practice of Medicine and Surgery applied to the Diseases and Accidents incident to Women. By W. H. BYFORD, A.M., M.D. Professor of Gynecology in Rush Medical College, etc., and HENRY T. BYFORD, M.D. Surgeon to the Woman's Hospital of Chicago, etc. Fourth Edition. Revised, rewritten, and very much enlarged. With 306 illustrations. (London: J. and A. Churchill, 1888.) Dr. Byford's new edition contains some good chapters on the anatomy and physiology of the female organs, examination of the pelvis, tubal disease, and other subjects to which great attention has lately been directed by practical and scientific authorities. The authors (for Dr. Byford informs the readers that Dr. Henry Byford must practically be considered an author in this edition) treat the subject of tubal inflammatory diseases in a very temperate and satisfactory manner, and strongly condemn indiscriminate operating. Some rare but important tubal diseases, recently described by operators and pathologists, pass entirely unnoticed. Especially commendable are the passages on Apostoli's electrolysis. In noting the alleged electrolytic action of the current, the authors observe: "Just how this can occur to any considerable depth in living tissue without destroying its life along the course of the current, any more than the stomach can digest itself, would however seem incomprehensible." They warn the readers that "the dangers of this treatment are great, unless the operator is thoroughly competent and extremely careful. However," they continue, "a minute study of the technique as taught by Apostoli, renders his method a perfectly safe one to employ." But the puncture of the tumour from the abdomen must always be attended by some danger, and also requires the use of an anæsthetic." Thus do the Drs. Byford impartially treat one of the most important undecided questions of contemporaneous gynecology.

North London or University College Hospital. Report of the Surgical Registrar for 1886. (London: printed by J. Truscott and Son, 1887.)—Though dated December, 1887, the report of the Surgical Registrar for 1886 does not reach one's hands until the second quarter of 1888. The delay is doubtless inevitable, as the voluminous mass of observations and statistics contained in the volume has to be compiled by an officer otherwise very much occupied by the daily routine of the wards. We have in previous years described the excellent arrangements of these reports, and Mr. Bilton Pollard and his assistants have fully maintained the high standard of excellence reached by previous issues.

Mechanics and Experimental Science, as required for the Matriculation Examination of the University of London. By EDWARD AVELING, D.Sc. (Chapman and Hall.)—Mechanics and experimental science now replace the natural philosophy and chemistry heretofore required as the "science" subject of the matriculation examination of the London University. This is a carefully arranged textbook by an experienced hand, planned to meet the requirements of the new examinations. Indented side-headings give the key to each paragraph, and enable the student reading to classify and test his knowledge as he goes on; or, when reverting to his earlier reading, examples and problems are furnished for solution, and a good set of examination papers (taken from those actually set) is supplied at the end of the book. It is a thoroughly practical textbook for students "working up" for examination.

Galloway's Fundamental Principles of Chemistry. (London: Longmans.)—This book aims—and very successfully, as we think—at teaching the fundamental principles of chemistry by a new method. The language of the science and the method of expressing chemical changes are taught by a series of progressive exercises, so that one early learns to attach due meaning to the materials and processes with which chemistry deals. The principles both of chemical physics and pure chemistry are taught by examination questions and exercises, which are well selected, and are chosen largely from the papers of the London University and other examinations. The book is very complete, very interesting and very practical. It appears to us to be based on a very sound view of the way in which students are most likely to acquire knowledge clearly and soundly, and it will, we think, be popular and successful as a textbook.

GENERAL COUNCIL

OF

MEDICAL EDUCATION AND REGISTRATION.

SESSION 1888.

Tuesday, May 22nd.

JOHN MARSHALL, F.R.C.S., F.R.S., President, in the Chair.

New Members.—The following gentlemen were announced to have been appointed members of the General Medical Council: Dr. George Yeoman Heath, as representative of the University of Durham for five years from December 13th, 1887; and Dr. Hector Clare Cameron, as representative of the Faculty of Physicians and Surgeons of Glasgow for five years from April 2nd, 1888.

President's Address.—The PRESIDENT pointed out that the vacancy left by the expiration of Dr. Matthews Duncan's tenure of office as a Crown nominee had not been filled. He announced that two trustees had been appointed, of which he (the President) was one. He mentioned that the Executive Committee had sanctioned the registration of 202 additional foreign medical qualifications, and that two notifications had been received from the Privy Council relating to a separate Colonial Register for New Zealand and Ceylon. In reference to the "recent adoption of very harsh proceedings" in Switzerland against certain medical practitioners duly qualified to practise in this country, but residing in the Swiss Republic in order to attend to the wants of their own countrymen, the President assured the Council that the interests of the profession were thoroughly comprehended and would be carefully guarded by the Privy Council under the existing law. He observed that the formation of either a colonial or a foreign Register was not yet within measurable distance. Four cases of misemployment of unqualified assistants and four of "covering" had been submitted to him by the Registrar, in only one of which did the evidence appear to justify an inquiry. He pointed out that a misapprehension existed as to the rôle of the Council, which was purely judicial, all evidence in support having to be brought to it from without. He then alluded briefly to the programme of business before the Council, involving the reception of reports from various committees. These reports, however, were at present confidential, pending communication with the several inspectors as to certain modifications, previously to their being transmitted to the respective bodies concerned. He suggested, therefore, that the reports in question should be referred to a small subcommittee for that purpose. It appeared that in no report yet received was "the standard of proficiency required from candidates" called in question. In conclusion the President announced that then and on future occasions, committees, with the exception of the Business Committee, would be re-elected at the close instead of at the beginning of the session. He looked forward to a brief but interesting and fruitful session.

On the motion of Mr. WHEELHOUSE, seconded by Sir JOHN SIMON, a vote of thanks to the President for his address was agreed to, and the address was ordered to be entered on the minutes.

Dr. GLOVER, while expressing his regret that the reports were not to be laid before them at present, admitted that it would scarcely have been possible. Alluding to the President's statement that the reports were not to be presented to them in their original shape, he deprecated any modifications in view of the reports of previous visitations, on the ground that they would be more interesting as they stood.

Dr. QUAIN having pointed out that the President's address was not open to discussion, the matter was allowed to drop.

Portrait of Mr. Joseph Henry Green.—The PRESIDENT read a letter from Sir Henry Acland, in which he begged the Council to accept the donation of the portrait of the second President of the Council, Mr. Joseph Henry Green, as a companion to the portrait of Sir Benjamin Brodie, the first President.

Dr. QUAIN proposed that the letter be entered on the minutes.

Sir JOHN SIMON, in a few graceful and eloquent words, expressed the pleasure he felt at the sight of the portrait of his illustrious master in former years. He claimed for Mr. Green the initiative of the great principles of medical reform, especially as concerned the question of preliminary education.

Business Committee.—Mr. WHEELHOUSE (Chairman), and Drs.

STRUTHERS and AQUILLA SMITH were appointed members of the Business Committee.

Reception of Tables of Results.—Dr. STRUTHERS moved that the following tables be received and entered in the minutes; Professor HUMPHRY seconding: 1, showing results of professional medical examinations during 1887; 2, showing results of preliminary examinations during 1887; 3, showing exceptional cases in regard to length of courses of study during 1887; 4, showing results of professional dental examinations during 1887; 5, showing results of competition for commissions in the department of the royal navy; 6, showing results of examinations by the College of Preceptors.

Dr. AQUILLA SMITH called attention to certain discrepancies on the part of the tables referring to the M.D., and in view of the fact that information as to the preliminary examination was refused by several bodies, he moved that the report be referred to the Educational Committee.

Sir DYCE DUCKWORTH called attention to the fact that in the examinations for the M.D. of the University of St. Andrews, there appeared to have been no rejections.

Mr. PETTIGREW explained that in reality three out of twelve candidates among the older men had been rejected, and there had been two rejections among the younger candidates.

The REGISTRAR observed that the tables had been drawn up in accordance with the latest information received from the respective bodies, but that in consequence of the large number of applications necessary to obtain such information, the printing had been done under circumstances of great difficulty.

Mr. MACNAMARA asked the President whether the Council was entitled to demand certain information from the various educational bodies, and whether such replies as "impracticable," "cannot be given," etc., were considered satisfactory. He urged that unless the Council were in a position to require such information to be given, it was *infra dig.* to ask for it. He suggested that a remonstrance should be addressed to the bodies who had failed to comply with the request of the Council for information.

In reply to Dr. HERON WATSON, the REGISTRAR explained that no returns had been received from the Army Medical Department.

Dr. GLOVER asked for information as to the examinations of the University of Durham for practitioners of over fifteen years' standing. He said that there were no examinations of greater interest to the profession generally.

Sir WALTER FOSTER objected to the entry upon the minutes of reports which had been shown to be full of inaccuracies.

The REGISTRAR explained that by so doing the necessary corrections were obtained from the various bodies, and were then inserted in the revised minutes.

The PRESIDENT, in reply to Mr. MACNAMARA, said that the Council had no power to require the information in question to be given.

It was then resolved that the foregoing tables, subject to corrections, be received and entered on the minutes.

Report of the Pharmacopœia Committee.—Dr. QUAIN, in moving the adoption of the report of the Pharmacopœia Committee, congratulated the Council on the fact that there was a profit of £1,209 8s. 2d. on the *Pharmacopœia*. A report received from Professor Atfield on the *Pharmacopœia* for 1887 had been printed, and a copy would be handed to members. Dr. Quain then alluded to the reply of the Lord President of the Privy Council to a letter from the solicitor to the Medical Council on the subject of the *Pharmacopœia* being the standard authority for the composition and preparation of the medicines therein described, which had been considered by the Committee, and in consequence of which the Committee recommended that the solicitor be requested to prepare a statement showing the Orders in Council or clauses in Acts of Parliament which relate to the subject. He mentioned that it had been decided by a magistrate that there was no authority to make any work a standard of the strength of drugs, and that, in consequence, it was possible to sell laudanum containing only half the quantity of opium and paregoric, which did not contain any opium at all. He pointed out that, if this were permitted, fatal accidents might easily arise, as, for instance, with paregoric without opium, a teaspoonful of which might be given to a child without danger, whereas the same quantity of the preparation from another chemist would contain a dangerous dose of opium for a child.

The report was ordered to be received and entered in the minutes.

Various reports were then ordered to be received and entered in the minutes.

An "Appointed Day" for Ceylon.—A communication from the Lord President of the Privy Council, naming January 1st, 1888, as the "appointed day" under the Medical Act of 1886 for the colony of Ceylon was received and entered on the minutes.

Employment of Unqualified Assistants.—The REGISTRAR read a report by the Executive Committee bearing on the circumstances under which a registered medical practitioner would render himself liable to the censure of the Council in reference to the employment of unqualified assistants. In the opinion of the Committee:

"A registered medical practitioner would render himself liable to the censure of the Medical Council in case of the employment of an unqualified assistant in the practice of medicine, surgery, or midwifery on behalf and for the benefit of such registered practitioner, either in complete substitution for his own services, or under circumstances in which due personal supervision and control are not, or cannot be, exercised by the said registered practitioner."

The Executive Committee furthermore took the opportunity of stating, in reference to the procedure known as "covering," that in its view a registered practitioner covers an unregistered person when he does, or assists in doing, or is party to, any act which enables such unqualified person to practise as if he were duly qualified.

In submitting to the General Council this report on the reference, the Executive Committee would, however, call attention to the following resolution passed by the Council on April 21st, 1883 (Vol. XX, p. 91):—

"That the Council ask for legislation to the effect that any registered practitioner practising for gain, who knowingly and wilfully deposes a person not registered or qualified to be registered under the Medical Act to professionally treat on his behalf, in any matter requiring professional discretion or skill, any sick or injured person, shall be subject to the same, legal liabilities as a person who falsely represents himself to be a legally qualified medical practitioner: but with special proviso that such enactment shall not hinder any duly regulated training of pupils in medical schools or otherwise by legally qualified practitioners, nor the use of trained pupils in partially treating the sick or injured under the direction, supervision, and responsibility of such practitioners, nor any legitimate employment of nurses, midwives, or dispensers."

On the motion of Sir WILLIAM TURNER the report was ordered to be received and entered on the minutes.

Registration of B.A.O. Degree.—Communications in regard to the registration of the B.A.O. degree were received and entered on the minutes, to the effect that, in virtue of a resolution passed on April 23rd, 1888, by the Irish Branch Council, the Registrar was directed to remove from the Register any degrees of B.A.O., which he may have registered.

Appointment of Additional Examiners to the Apothecaries' Society.—Mr. BRUDENELL CARTER, in asking the Council to sanction the appointment of five examiners instead of three, said that the experience of the last twelve months had shown that the surgical department of the examining board was somewhat undermanned. He claimed that the conduct of the examinations, as shown by the tables before them, was fully on a level with that of the other examining boards of the country. He then compared these results with those of the Conjoint Examining Board, and showed that at the final examination in surgery of the Conjoint Board, 84 were rejected and 123 passed (1 rejection to 1.46 passes), as against 79 rejections and 119 passes (1 to 1.5) at the Apothecaries' Society. Grouping together medicine and midwifery, the results were 1 rejection to 3 passes under the Conjoint Examining Board, and 1 rejection to 2.3 passes under their own Board, so that, if anything, the figures were in favour of their own examinations.

The motion was seconded by Sir JOHN SIMON, and agreed to.

Sir WILLIAM TURNER expressed a hope that the Examination Board of the Apothecaries' Society would improve their means of examining candidates in anatomy, their present means being altogether inadequate.

Mr. BRUDENELL CARTER then asked that Messrs. Makins, Walsam, Andrew Clark, Arbuthnot Lane, and W. Adams Frost be appointed surgical examiners in virtue of the foregoing resolution. He alluded to the proposal to appoint Mr. Frost as an evidence of the desire of the Society to obviate the reproach that there was no one on the Board to examine in ophthalmic surgery.

A discussion ensued as to the propriety of receiving the request in this form instead of by a formal letter from the Society of Apothecaries; but on the President pointing out that it would be difficult to refuse, seeing that the request had been admitted by the Executive Committee, the motion was ultimately agreed to.

The Council then adjourned at 4 P.M., there being no other business ready to be proceeded with.

Wednesday, May 23rd.

JOHN MARSHALL, F.R.C.S., F.R.S., President, in the Chair.

Report of the Education Committee.—The Council having resolved itself into Committee, Dr. STRUTHERS moved the adoption of the Report of the Education Committee. He reviewed the report in question, and pointed out certain differences in the curriculum insisted on by the various licensing bodies, insisting in particular on three points of contrast. First in regard to the four years' study which all required, the English and Scotch schools only required attendance for three winters and two summers, whereas the Irish schools required four complete years. The next point was a very important one, bearing, as it did, on a considerable period of time being required to elapse between the examination in anatomy and physiology and the final examination. In that respect the Scotch schools were very much behind the English and Irish schools. This regulation provided that the last two years should be devoted to practical study. Thirdly, as regarded the attendance of students on cases outside hospital work, in which respect the Scotch schools seemed to be in advance of the others. He added that he thought examiners required too much from candidates, and expressed the opinion that the examiner should be a younger man, since older men were apt to expect a knowledge which could only come with experience.

Mr. WHEELHOUSE, referring to the first recommendation embodied in the report, "That all candidates for the final examination be required to produce evidence that they have attended for six months the practice of a public dispensary, or the outdoor practice of a hospital, or have acted for six months as assistant to a registered practitioner," observed that it was generally agreed that the present system of medical education was deficient in minor but very important respects. He alluded to the advantages of the old system of pupilage, but admitted that the Council were very unlikely to sanction any return to that system, although they were very anxious that the benefits thereof should be acquired by the student. He said there was a vast amount of clinical material of which no educational advantage was taken, in the dispensaries, etc. If this could be utilised, then the student would obtain the benefits without the inconveniences. He said that if the examining bodies could be induced to make provision for these matters to be learned, and above all examined in, the problem would to a great extent have been solved. He then moved the adoption of the first recommendation, the motion being seconded by Dr. CHAMBERS.

Mr. MITCHELL BANKS denied that the advantages of pupilage could in any way be held to compensate for the loss of time which it would involve. Pupilage would have to be done either before, during, or after the usual curriculum. If before, he doubted whether much useful information would be gained; he did not see how it could be done during the curriculum, except in the holidays; if at the end, then it would mean an extension of the curriculum. He could not see how it was to be superintended, and it would consequently be done in a perfunctory manner. He alluded, in terms of commendation, to the system which obtained in Scotland, where in the dispensaries students visited the sick in their homes and learned how to prescribe. He regretted that nothing of the kind existed in England.

Sir JOHN SIMON asked that it should be emphasised that something additional was intended to what already existed.

Mr. BRUDENELL CARTER suggested that the recommendation should be limited to England and Ireland.

Mr. MITCHELL BANKS thought that the paragraph did not render clear what the Committee required, as to students attending home practice.

Sir JOHN SIMON asked that the words "under proper supervision," should be added, and also the word "authorised" before "public dispensary," "hospital," and "registered practitioner."

Dr. BANKS saw great difficulties in carrying out in Dublin any system of visiting in connection with the dispensaries. He said that, so far as the assistantship was concerned, there was no such person as an assistant in Ireland.

Dr. GLOVER said that, if the system of government by committees was to continue, the least that could be done was to supply early copies of the reports, which in the present instance had been received too late to admit of serious consideration. He proposed, as an amendment, that the word "pupil" should be substituted for that of "assistant." Pupilage was already recognised by the Royal Colleges, and could therefore not be open to serious criticism. He observed that the medical officers of dispensaries were general practitioners, and therefore, if they could be trusted to teach, so might any general practitioner. He denied that the diseases which it was desired that the student should learn to recognise were in any sense minor diseases, as, for instance, measles, whooping-cough, etc.

Mr. MACNAMARA said that the scheme sketched out by Mr. Banks would never be tolerated in Ireland. Before attempting to legislate, for Ireland, Englishmen and Scotchmen should endeavour to know something about the condition of things there. Moreover, the hours at the dispensaries and hospitals were the same; the student could not be at both. He said there was an outdoor department or dispensary attached to every hospital. As to the assistantship, the assistant in Ireland was a mere dispenser.

Dr. LEISHMAN cordially approved the practice of attending home patients; but admitted that it was not always possible. The attempt had been made at Glasgow, and had failed, and it was not worth while to pass a resolution which it might not be possible to enforce.

Dr. BRUCE seconded Dr. Glover's amendment, which was agreed to. He said that the only way to ensure, the system being properly carried out was to insist upon it at the examinations.

Sir GEORGE MACLEOD observed that the scheme for house visiting in Glasgow had, been strongly opposed by the practitioners, who derived their fees from the very class who would be visited, and they could not wish to effect the ruin of these practitioners. Another difficulty arose with reference to teaching students on the subject of fevers, the interference of the sanitary authorities having put a stop to that.

Dr. HEATH observed that the plan of house visitation was in vogue in Newcastle.

Mr. TEALE said the Council were getting into a dilemma, and would either fall foul of Ireland or confine themselves to what had already been done.

Dr. BANKS said that not 50 per cent. of the candidates at examinations had ever seen a case of scarlet fever. He was unable to see any means of giving effect to the clause in question.

Mr. BRUDENELL CARTER asked for a definition of what was meant by "public dispensary," of which there were several categories. He considered the "registered practitioner" part of the clause the most satisfactory, provided that precautions were taken to ensure that the person authorised was in a position to impart the requisite knowledge. He also advocated naming a definite period for the pupilage.

Dr. MOORE deprecated any measure which would be at the expense of sound hospital training. He claimed that in Ireland there was every facility for the student to familiarise himself with the commoner types of disease. He objected to the idea that the general practitioner was competent to teach.

Rev. Dr. HAUGHTON expressed his sympathy with the object of the Committee; but the plan would be altogether inadmissible in Ireland. He suggested that a register should be kept of the attendance of students at the dispensaries attached to hospitals.

Professor HUMPHREYS was opposed to anything being added to the burden which the student was already called upon to bear, especially if it tended to interfere with hospital practice. The cases seen by the student at the hospital were of a kind he might not meet with elsewhere. He thought much more importance should be attached to a proper knowledge of the principles of medicine than to mere practice. Home visiting might be good for the student, but he doubted whether it would be equally advantageous to the patient, and he quite understood the reluctance of the authorities in Ireland to allow the dispensaries to be used for educational purposes.

Sir DYCE DUCKWORTH declined to believe that the men they turned out at the present time were one whit below those produced under the old system. They could not expect to turn out a man fully equipped in every branch of the profession and provided with the experience of a practitioner of ten years' standing. He said that the answers of young men at examinations showed them, as a rule, to be well prepared practically. He then alluded in very glowing terms to the system of the out-patient department at St.

Bartholomew's Hospital, a better system than which, he opined, could not be conceived.

Dr. HERON WATSON said that the decision of the Committee was not the parting of the roads, but the meeting of the ways. He thought that if recommended by the Council the various bodies would consider the best method of giving effect to their wishes, and they would be left perfectly free to adopt whatever plan they might think fit. He suggested that the result of the present system had been to give an undue preponderance to the scientific element of medical education, which might, he thought, tend to remove the student from the mere human sentiments which should accompany him into the houses of the sick poor. What students required was to be broken-in to deal with patients in a humane and considerate manner.

Sir WILLIAM TURNER asked in what form the recommendation was to go down to the various bodies, and said that the question ought not to be looked at apart from previous recommendations. He suggested that the present recommendation should be made an extension of the one which they had already made, so as not to appear to be something new.

Dr. STRUTHERS said that when a student went as pupil to a practitioner there was a double advantage, for if the pupil learned something, the practitioner was also taught things he would not otherwise have known.

Dr. GLOVER, in reference to the assertion that all practitioners were not fit to teach, said that neither were all hospital surgeons and physicians. He thought they might fairly leave the student the choice of his instructor. As to the additional burden thereby laid on the student, he suggested that they might lighten it in other directions; but in any case it was cruel to send a man forth who was ignorant of subjects which would go to make up five-sixths of his future practice. He said he was unable to follow Sir Dyce Duckworth in his eulogy of the out-patient departments of hospitals, and he denied that every variety of disease could be studied there. If the employment of students was not always to the advantage of the patients at their homes, neither was it at hospitals, for example, in a case of pneumonia, which had to be examined by a number of students.

Sir DYCE DUCKWORTH said that the list of diseases met with in hospitals practically only excluded scarlet fever and small-pox.

The PRESIDENT said that No. 15 of the original recommendations contained a cover for everything that had been suggested.

It was then moved by Mr. WHEELHOUSE and seconded by Dr. CHAMBERS that the recommendation be adopted by the Council.

Sir Wm. TURNER objected very strongly to the insertion of the word "recognised" before "registered" practitioners, which he thought invidious and unnecessary.

A discussion ensued as to the propriety of inserting the word "recognised," in which Mr. BRUDENELL CARTER and Dr. HERON WATSON took part.

The PRESIDENT explained what was intended by the insertion of the word "recognised," and said that it was very important that they should have something more than merely "registered practitioners." The practitioners ought to have not only the skill but the opportunities of teaching.

After some discussion, the recommendation was proposed as follows:

"That in addition to the requirements at present in force with respect to hospital attendance and duties, all candidates for the final examination be required to produce evidence that they have attended, under proper supervision, for six months the practice of a recognised public dispensary, including the visitation of patients at their own homes, or the outdoor practice of a recognised hospital, or have acted for six months as pupil to a registered practitioner, either holding such a public appointment or having such opportunities of imparting practical knowledge as shall be satisfactory to the examining bodies."

The motion was then agreed to *nem. con.*

Examination in "Fever."—Rev. Dr. HAUGHTON then rose to propose the adoption of Recommendation No. 2:

"That all candidates for the final examination be required to produce evidence of having studied the subject of 'fever' in its various forms, as far as local circumstances will permit, for a period of not less than three months, under recognised clinical instructors."

He claimed for the University of Dublin that it was the first body to require a certificate of special attendance on fevers. Their example had since been followed by the other bodies in Ireland

with the best possible results. He protested against the idea that sanitation was shortly to render an acquaintance with fevers unobtainable, and urged that by enabling an adult population to grow up without having had any of the "fevers" the way was opened to terrible subsequent visitations. He said that students would not go to the fever hospitals because the teaching there was not of a very high order.

Dr. BANKS said that all the examining bodies in Ireland required this course of study. He said that students avoided the fever wards, and for this reason the course had been made compulsory. He seconded Dr. Haughton's motion.

Dr. MOORE doubted whether three months was sufficient to learn much of fever.

Sir DIXIE DUCKWORTH pointed out that practically only scarlet fever and small-pox were excluded from the London General Hospitals.

Dr. GLOVER asked whether the "recognised clinical instructor" might be a general practitioner.

The discussion was then adjourned.

On the motion of Sir WILLIAM TURNER, the report from the Dental Committee on the case of George Thomas Ockleford Crocker was then received and entered on the minutes.

The Council then adjourned.

Thursday, May 24th, 1888.

JOHN MARSHALL, F.R.C.S., F.R.S., President, in the Chair.

Case of Mr. Richard Percy Woodroffe. — The meeting having been opened, Mr. Richard Percy Woodroffe, Licentiate of the Apothecaries Hall, Dublin, 1884, was summoned to appear to answer a charge of unprofessional conduct, inasmuch as he has acted as cover to John Stamford Walton, an unqualified practitioner of Northallerton, in Yorkshire, thereby enabling him to practise as if he were legally qualified. The complaint was made to the Council by Mr. Lumley, the medical officer of health, and it was on this information that the summons was issued. It appeared that the father of the unqualified practitioner was a medical practitioner and coroner for the North Riding of Yorkshire. He died in 1874, and since that time Walton had carried on the practice, without a qualification, being actually a student at the Newcastle School of Medicine and coroner for one of the Ridings of Yorkshire.

The SOLICITOR for the Council (Mr. Farrar) read the declaration of Mr. Lumley, medical officer of health, bearing on the facts alleged. Mr. Farrar pointed out that the declaration was in itself *prima facie* evidence, seeing that Mr. Lumley might be prosecuted for perjury thereupon. The Council could not examine witnesses on oath, and, therefore, must decide what credence to attach to the evidence. The whole question for the Council to decide was whether Walton had carried on the practice for thirteen years or so as an unqualified practitioner, and whether Woodroffe had acted as his cover since he had been acquainted with Walton. He (Mr. Farrar) had brought the gist of the matter before the Council in an impartial manner, and it would now be for the Council to hear the respective parties. A copy of the declaration had been sent to Mr. Woodroffe.

The PRESIDENT called upon Mr. Woodroffe to say whether he had any reply to make either himself or through his Counsel.

The Rev. Dr. HAUGHTON thought that as Mr. Woodroffe had been charged with having signed certificates of death in cases which he had not attended, the Council ought to have names and dates of cases put before them. As it stood, the charge was of the vaguest nature, and the Council ought to have particulars before it.

In reply to the Solicitor for the defendant, Mr. LUMLEY said as he was medical officer of health he had a weekly return of the deaths in his district, and he found the certificates of cases attended by Walton had been exclusively signed by Woodroffe for the last two years. He had not brought those papers with him, but if the Council desired he would furnish them.

In reply to the Rev. Dr. HAUGHTON, who again desired to have names and dates, Mr. LUMLEY said he had not been asked to furnish such particulars.

Mr. MUIR MACKENZIE (Standing Counsel) submitted that it was not sufficient to give certificates signed by Mr. Woodroffe.

Mr. LUMLEY said that his contention was that Mr. Woodroffe did see these cases for Mr. Walton, not that he signed them without having previously seen them. He would produce particulars of further cases if the Council required them.

The Solicitor for the defendant asked Mr. Lumley if he had any further specific charge against Mr. Woodroffe.

Dr. QUAIN was of opinion that the matter ought to be adjourned until Mr. Lumley could produce his proofs.

After some remarks from Dr. GLOVER, Mr. LUMLEY complained that he had not yet had an opportunity to open his case. If allowed he would prove his case to demonstration.

The PRESIDENT advised him at present to answer questions simply Yes or No.

Sir W. TURNER was in favour of adjourning the matter.

Mr. MUIR MACKENZIE submitted that they must proceed in order. It was right that Mr. Woodroffe's solicitor should ask questions of Mr. Lumley on his declaration.

After some further questions had been put by the defendant's solicitor, Mr. LUMLEY said, in reply to Mr. MACKENZIE, that the surgery was attached to the house in which Mr. Walton lived and in which Mr. Woodroffe was a lodger. He had seen certificates signed "Walton and Woodroffe." The house was owned by Mr. Walton. Mrs. Walton, the mother, had not been there for fourteen years. He identified the writing of the notification in a case of fever signed "Walton and Woodroffe" as being that of Walton. Mr. Lumley then went into a number of instances of alleged improper practice by Walton, going back as far as 1876. He produced various bills sent out in Walton's name and received by Woodroffe. They were known as "Dr. Walton and his assistant."

Some discussion took place as to the evidence showing that Walton practised, which Mr. LUMLEY asserted was to his personal knowledge. The name of Woodroffe did not appear in connection with the practice. Mr. Lumley said he had no witnesses to call, because he had been told that it was not usual.

The SOLICITOR for Mr. Woodroffe (Mr. WAISTELL) then read part of a declaration setting forth circumstances which had caused a great deal of ill-will between the parties. He said that in no case had a certificate of death been given unless Mr. Woodroffe had been actually in attendance. He contended that his client had in no sense acted as a cover. The name of Walton on the bills was that of the elder Walton, who died in 1874, the practice being carried on for the benefit of his widow. His client knew nothing of the circumstances when he came to Northallerton, and he said it was very hard that he should have been arraigned on such a vague charge. He contended that no case had been made out against his client. The money was received on behalf of Mrs. Walton, to whom the house belonged, the surgery being detached.

Mr. WOODROFFE then answered certain questions. In reply to Mr. PETTIGREW he said that he acted as sole manager for Mrs. Walton. In reply to Dr. QUAIN as to what his position really was, he said he merely went to take charge of the practice for the widow. He said he received a salary, but Mr. Mackenzie pointed out that there was no mention of a salary in the agreement. He had agreed to take the salary in lieu of a commission. He received the money and gave it to Mr. Walton for his mother. He had never seen Mrs. Walton. He kept no statement of accounts of moneys received and handed over.

Mr. Woodroffe was closely cross-examined as to his alleged position of manager to Mrs. Walton.

In the continued cross-examination Mr. WOODROFFE said that the agreement was drawn up when he went as manager to Mrs. Walton, but it was not reduced to writing till a year afterwards.

Mr. MUIR MACKENZIE: I thought the negotiations for the agreement took place before you went?

Mr. WOODROFFE: So they did. It was drawn up but not signed.

Question: On what terms did you go for the first year?—Answer: I went as manager for Mrs. Walton. I was on trial.

Question: Is that usual?—Answer: I believe it is. Gentlemen in practice often go six months on trial.

Question: You are a medical practitioner?—Answer: Yes.

Question: And Mr. Walton is your pupil?—Answer: Yes.

Question: Whose pupil was he before you went?—Answer: I do not know.

Dr. CAMERON: Have you any knowledge of how the business was kept up between the death of the elder Walton and the period at which you became Mrs. Walton's manager?—I know nothing about the practice before I went there.

Mr. MUIR MACKENZIE: Did you know that Mr. Walton had been prosecuted by the Apothecaries Society?—Answer: I did not know anything about it.

Mr. MUIR MACKENZIE: What particular part does Mr. Walton take in this practice?—Answer: He is my pupil, and he goes and

the patients. I did not know that there was anything wrong. Question: Does he go to see patients in the first instance?—Answer: He does sometimes, but not always.

Question: Does he attend all his lectures?—Answer: Yes. Mr. MURIE MACKENZIE: He never told you he had been prosecuted by the Apothecaries' Society?—Answer: He never told me.

At this juncture Mr. Woodroffe said that he had withdrawn from the practice, and did not intend to go back to it again. He withdrew the moment he was summoned before the Council. He was not frightened.

Question: Did you know that it was contrary to the rules of the Council?—No, I did not know it was contrary to the rules; and when I found I was doing wrong I withdrew at once.

The defendant apologised humbly for the error into which he had fallen, and said he should not have done it if he had known that it was wrong.

Strangers were then requested to withdraw, and the Council proceeded to deliberate in private.

Strangers having been readmitted after two hours' absence, the PRESIDENT, addressing himself to Mr. Woodroffe, said that the Council had given every attention to his case, and had considered it at great length. He informed Mr. Woodroffe that, in the opinion of the Council, he had been guilty of the offence alleged against him; further, that the Council had taken a very merciful view of the circumstances of the case, and, in view of his expressions of contrition and his promise not to repeat the offence, had decided not to proceed further therein, beyond requesting their President to convey the expression of their opinion. The President then dilated upon the gravity of the offence of which Mr. Woodroffe had been declared guilty. He pointed out that it was an offence against the profession and against society, inasmuch as it enabled a man to act and appear as if possessing a legal status to which he had no claim. He exhorted Mr. Woodroffe to be warned by what had occurred, and to avoid any repetition of the offence, for the Council, he said, were firmly resolved to proceed against a practice which they regarded as constituting the gravest possible offence of which a professional man could be guilty. He pointed out, in conclusion, that Mr. Woodroffe had exposed himself to the risk of being expelled from his profession with dishonour, and only owed his escape to the merciful view taken by the Council of the circumstances of the case.—Mr. Woodroffe, having expressed his gratitude to the Council for their merciful consideration, then withdrew.

Case of *George Thomas Ockleford Crocker*.—A resolution was passed enjoining the Registrar to remove the qualification of L.D.S.Glasgow from the Register as applying to Mr. Crocker, the said qualification having been withdrawn by the College consequent upon an infringement of the College regulations against advertising.

The Council then adjourned.

REPORTS AND ANALYSES

AND

DESCRIPTIONS OF NEW INVENTIONS,

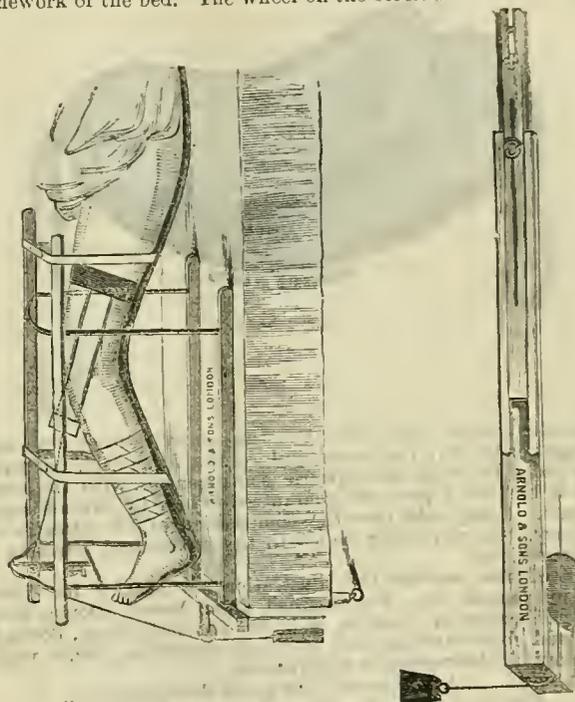

IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

SPLINTS FOR FRACTURE OF THE FEMUR.

THE two splints figured below represent two methods of treating fracture of the femur. The one is the extended straight position, with the stirrup extension obtained by the usual plan of strapping applied on each side of the limb below the knee. The other is a cradle with a rise and falling pulley, and the stirrup extension applied each side of the thigh. A piece of wrought iron, reaching from behind the buttock to the toes, bent at any suitable angle, acts as a stay and back splint. Lateral holes are punched in the thigh part and in the lower part below the knee, for the purpose of passing leather straps through. The limb may then be hung to the bars of the cradle. I have had holes punched in the iron which reaches behind the buttock. A band or strap can be passed through and around the trunk. I use a perineal band as well, for the purpose of fixity and to steady the splint to the limbs. In children up to seventeen years of age the straight splint or long Liston is the one generally used.

The first splint depicted I have found most useful. It will do

for either leg, and by means of the sliding slot can be used for children or adults. As a rule it is better to have a smaller one made for children below sixteen years of age, but a full-sized splint may be used if the case is treated in a full-sized bed. It simply increases the length of the cord from the stirrup to the wheel at the end of the splint. The pulley I have attached to the splints, which is a distinct advantage, as sometimes it is impossible in private practice or colliery work to fix a pulley to the framework of the bed. The wheel on the block at the end of the

splints is placed at an elevation for good traction, so that the heel of the foot is kept a finger's breadth off the bed, and the foot remains at a right angle and in good line. The limb is fixed either by means of the Scotch plan, the long sheet and pins, or by bandaging from above the ankle up. A good broad flannel spica bandage should be always applied; it gives such support and steadiness to the limb when the bed-pan is used. Another broad bandage should fix the trunk. I use a perineal band smeared over with zinc ointment to avoid any chafing. This, if wished, can also be used as a strong counter-extension by fixing it to the sliding slot, pushing the slot upwards and fixing it with a screw. This should only be slightly made taut by the slot each morning. I trust for counter-extension by the bed being raised on blocks. The block at the end of the splint should be fixed down to the framework of the bed by two pieces of bandage. The splint is equally useful in hip-joint disease. The cradle is meant for cases of fracture of the neck of the femur or lower third of the bone, where the bent position is the more desirable to place the limb in, for comfort and readiness in the use of the bed-pan; this position is the best. The traction I have obtained by the stirrup strapping applied on each side of the thigh, the cord passing over a rise and falling pulley, the latter fixed at any desirable angle. The shortening that occurs in cases of fracture of the femur will, to my mind, entirely depend on the character of the fractured ends, rather than any special mode of treatment. To obviate this, the extension method with stirrup strapping seems the best after the irritable condition of the muscles has subsided.

I have used the straight splint in twenty cases; Dr. Evan Jones, of Aberdeen, and Dr. Brown, of Tredegar, tell me they have found it very useful in their works district. They are made by Messrs. Arnold and Sons, West Smithfield, London.

R. NELSON JONES, L.R.C.P.Lond., M.R.C.S.Eng., Swansea.

THE saving of life effected through the instrumentality of the Royal National Lifeboat Institution during the year 1887 amounted to no less than 33,243 lives.

THE PNEUMATIKON.

THE instrument I have devised is a modification of Jefferies's respirator, but so adapted that a piece of lint, thoroughly impregnated with an antiseptic fluid, can be placed between two layers of wire gauze. It will be seen, therefore, that the instrument thus answers the double purpose of an inhaler and a respirator combined, warming the external atmosphere thus transmitted through its medium, and medicating it at the same time by means of the

antiseptic vapour. The patient is thus enabled to go out either by night or by day, fearless of evil results from cold, nocturnal fogs, and other such atmospheric contingencies, with the assurance of breathing pure air guaranteed to him by this antiseptic medium. I may add that the composition of the latter is not arbitrary, but may safely be left to the experienced selection of the practitioner.

I need not explain the illustration; it speaks for itself. The instrument can be obtained from Messrs. Down, Bros., surgical instrument makers, of 3, St. Thomas's Street, Borough, S.E., and sole manufacturers of the pneumatikon, under which name my inhaler-respirator is registered.

J. BRINDLEY JAMES, M.R.C.S. Eng., etc.,
President of the West Kent Medico-Chirurgical Society.

SCHACHT'S DIGESTIVE FLUIDS.

UNDER the above title, Messrs. Giles Schacht and Co., of Clifton, Bristol, have brought out a series of very attractive preparations. "Pepsina Liquida" (Schacht) can fairly be classed among the most elegant products of modern pharmacy. It is a bright, nearly colourless solution, entirely free from any disagreeable odour, and with a pleasant taste. We find by experiment that it possesses the peptonizing power claimed for it by the makers; namely, that one fluid drachm will, in from 2 to 4 hours, render soluble under proper conditions, 1,000 grains of "comminuted egg albumen." This term is employed by the makers to represent what is defined in the *British Pharmacopœia* as "hard-boiled white of egg passed through wire gauze of 26 meshes to the linear inch, and made of No. 32 brass or copper wire."

Pepsina liquida cum bismutho is a combination of Schacht's well known liq. bismuthi, with "pepsina liquida." As a pharmaceutical preparation it is all that can be desired, and it will probably be found of considerable value in the treatment of cases in which want of digestive power is associated with gastric irritation.

Another preparation named pepsina liquida cum bismutho contains in addition one grain of soluble euonymin in each fluid drachm. The remaining member of the series is pepsina liquida cum euonymin. This consists of one grain of euonymin dissolved in each fluid drachm of pepsina liquida (Schacht), and is likely to be useful in cases in which a hepatic stimulant, together with a food solvent, is required. Liquor bismuthi sedativus (Schacht) should rather be termed a mixture than a solution, since each fluid drachm contains, besides pepsina liquida and liquor bismuthi, $\frac{1}{4}$ grain hydrochlorate of morphine, 2 minims of dilute hydrocyanic acid, and 5 minims of tincture of nuxvomica. All the above preparations are miscible with water, and form with it permanently clear solutions.

THE PHARMACOPŒIA AS A STANDARD.

An interesting question is raised by Professor Attfield in his report for 1887 on the *British Pharmacopœia* as to the extent to which that official compilation is, or should be made to be, the legal standard by which retail traders of all kinds are bound in preparing and selling medicinal articles comprised therein. So far as physicians' prescriptions are concerned, the *Pharmacopœia* is the sole legal standard of the strength of the substances which he prescribes. The question bears rather upon the strength of medicinal substances included in the *Pharmacopœia*, but which are purchased by the public on their own responsibility. Take, for example, the tincture of opium, commonly asked for under the designation of laudanum. A right has been claimed, and, so far as magisterial decisions can settle the question, maintained to set the strength of opium of any morphine strength and of any alcohol strength that the vendor may please. Further, certain grocers and storekeepers not legally qualified to vend poisons claim the right to sell, and do sell, not merely official and other not poisonous drugs of indefinite strength, but even well-known opiates under well-known names, if only they omit the opium from the preparation. Paregoric, for instance, containing opium, is largely sold, and, according to a magistrate, legally sold. As Dr. Quain remarked, in bringing this report to the notice of the General Medical Council, the practice is one which may easily give rise to dangerous and even fatal mistakes. A mother who has given teaspoonful doses of the non-opiated paregoric to her infant with impunity, may, without the slightest warning, be served by a more conscientious dealer with a product of which a teaspoonful would contain what may be, for an infant, a poisonous dose of opium. The best course to pursue will probably be to insert such names as laudanum, paregoric, etc., in the *Pharmacopœia*, and then take the necessary steps to establish the legal obligation to sell only drugs of the strength, nature, and quality authorised by the official publication. The matter is one which concerns the public very much more nearly than the medical profession, but the establishment of a proper standard of strength will arm the authorities in their efforts to represent the public on the part of unscrupulous tradesmen who at present take advantage of the ambiguity of the law on this point to sell opiates without opium, and generally to operate to the detriment of an indiscriminating public.

THE FUTURE POSITION OF SANITARY INSPECTORS.

IN the course of an interesting presidential address delivered by Dr. Alfred Carpenter at the meeting of the North-West District of the Association of Sanitary Inspectors in Liverpool, he made some remarks on the future status of these officers, which possess a special importance at the present moment. While admitting that decentralisation was to some extent a good principle, it would be a misfortune if sanitary inspectors were left entirely at the mercy of the local authorities, which often contained members who were the greatest offenders against public health. "The healthiness," he said, "of the extreme twigs upon which the sanitary tree depends for its development and growth must affect the growth and the development of the trunk of the tree. If, therefore, the sanitary inspectors are not healthy and right, the whole growth is unsound." While leaving to the parishes the right to select properly-educated inspectors, he urged that the appointment ought to be *ad vitam aut culpam*; and that a charge of neglect of duty ought to be proved to the satisfaction of the County Council and its medical officer of health, who, he said, must have his existence provided for in the Bill, and who, though appointed by the County Council, should himself be only removable with the approval of the Local Government Board.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1888.

SUBSCRIPTIONS to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the West Central District Office, High Holborn.

The British Medical Journal.

SATURDAY, MAY 26TH, 1888.

RESEARCH WORK OF THE BRITISH
MEDICAL ASSOCIATION.

THE MAMMALIAN HEART.

SUCH knowledge as we possess of the changes which go on in the tissue of the beating heart has been obtained almost entirely from experiments upon the batrachian heart. Hardly any accurate work has been done upon the mammalian organ. The report of the Committee of the British Association (1843) upon an investigation of the movements of the heart by simple inspection; a paper by Czermak and Piotrowsky (1857), upon the persistence of movements of the heart; and another by Kölliker and Müller (1856), on the occurrence of electromotive changes accompanying the systole, are the most important investigations made upon the mammalian heart, and represent fairly well the position of physiological science in regard to this subject. Therefore the important communications of Drs. Waller and Reid (On the Action of the Excised Mammalian Heart, by Augustus D. Waller, M.D., and E. Waymouth Reid, B.A., M.B., *Philosophical Transactions*, 1887, and A Demonstration on Man of Electromotive Changes accompanying the Heart's Beat, by Augustus D. Waller, M.D., *Journal of Physiology*, vol. viii, No. 5), conducted, on the part of Dr. Waller, in his capacity of Research Scholar of the British Medical Association, are of extreme interest, having regard not only to the results obtained, but to the novelty of some of the methods employed, and to the minute care taken to avoid error.

During a course of experiments upon the electromotive action of various tissues, it was found that in the case of the mammalian heart the electromotive variations outlast visible contractions, and that the contractions are of an extraordinarily prolonged character. The observers, therefore, carried out a series of experiments with the galvanometer, the graphic method, and with Lippmann's capillary electrometer. With the latter instrument the observations were rendered more accurate, and also recorded permanently in the most beautiful manner, by photographing the movements of the column of mercury on a travelling plate. In this way slight movements, observable with difficulty or not at all by the unaided eye, are clearly evident, as shown by the plates which accompany the articles. For the observations the hearts of cats, dogs, rabbits, guinea-pigs, rats, and sheep were used. The duration of contracting power in the excised heart was

found to be surprisingly prolonged, even though mere fibrillation was not noticed; but only complete ventricular contractions, such as could be recorded by a lever resting on the heart. In a rabbit's heart spontaneous beats were observed for seventy-two minutes, and beats in response to excitation for an hour and a half *post mortem*. Force of contraction, it was found, declines rapidly at first, more slowly at later periods; frequency of contraction diminishes with fair regularity. A bigeminal character is frequently seen, and is more pronounced at the base than the apex. When irregularity of beat occurred, a period of rest was followed by a beat of unusual force; beats in groups, and occasionally an extreme irregularity, in the form of irregular rapid fibrillation (delirium cordis) were seen. As time elapsed after removal, the ventricular beat became quite independent of the auricular beat, and was found to outlast it. Such were the general results observed. Special attention was paid to the duration of systole in the excised heart, and the influences which cause its increase or diminution. On removing the heart from the body the systole became greatly prolonged, and the prolongation was exaggerated by placing the heart in a chamber surrounded by ice; in one experiment the duration of contraction in a heart so treated was ten seconds. The full effect of cold was to produce total abolition of contractility, both spontaneous and induced by stimulation; this could, however, be restored by the application of warmth. A constant temperature of 40.6 degrees caused rapid decline of contractility, and no prolongation of systole. Therefore, it will be noticed that the mammalian heart agrees with other tissues in showing great excitability and rapid decline at high temperatures, small excitability and slow decline at low temperatures.

A similar prolongation of the latent period of stimulation was also observed under the influence of cold, a common latent period being 0.5 sec., and on one occasion in the rabbit's heart it reached 2 secs. This is longer than has been observed in the frog's heart, and generally, when the results are compared with those of Burdon Sanderson and Hermann, it is seen that the mammalian heart is more susceptible to difference of temperature than is that of the frog.

Nothing appears to have been hitherto done to determine the presence of a wave of contraction in the mammalian heart, such as has been shown by Engelmann, Marchand, and Burdon Sanderson, with the help of the rheotome and galvanometer, to occur in the frog's heart. Moreover, the mechanical method has not been employed at all, even in the frog, for the record of such progressive contraction. By the application of two levers applied to the heart at a certain distance from each other, Drs. Waller and Reid obtained some curious results. In the ventricle of the frog's heart the result of other observers mentioned above, who, using the galvanometer, showed a wave of contraction passing from base to apex, were confirmed. In the mammal's heart, however, the results were markedly different: though it must be mentioned that they were not so uniform as in the case of the frog. The contraction of the apex in cats, rabbits, dogs, and sheep generally preceded that of the base, even though all precautions were taken to avoid error. When a contraction was provoked in a quiescent heart by direct stimulation, it was found that the wave of contraction proceeded from the

part irritated to the parts beyond, and that both the mammalian and frog's hearts behaved alike in this respect. The rapidity of the wave was much greater in warm-blooded than cold-blooded animals, was greater in large than in small hearts, and progressively decreased after excision of the heart.

The galvanometric experiments upon the frog's heart confirm those made by former observers. Kölliker and Müller have shown that the contraction of the mammalian heart is accompanied, or rather preceded by, an electromotive change. This Drs. Waller and Reid now show to be frequently diphasic, and to persist long after visible contractions have ceased. If the heart be quiescent and be then irritated, it is found that a diphasic variation occurs, which indicates in its direction, first, negativity of the proximal electrode; secondly, negativity of the distal electrode. Local injury, when the heart is inexcitable and apparently dead, develops negativity of the injured to all other parts. This easy production by injury of local negativity caused occasional irregularities in the galvanometric results; sometimes, for instance, stimulation produced merely a simple and not a diphasic variation, probably because a touch near one of the two electrodes had developed permanent negativity of that spot. A diphasic variation indicating negativity starting from the distal electrode was never seen; but an exceptional result was that local excitation might give rise to a single variation, indicating negativity of the distal electrode. This is explained by the supposition that there exists in such a case a greater excitability of the tissue in the neighborhood of the distal electrode.

The above experiments refer to artificially-excited beats in an otherwise quiescent heart. When the heart was beating spontaneously, the galvanometric readings were not constant. When viewed by the naked eye, the spontaneous contraction of the mammalian heart is apparently simultaneous in all parts. As mentioned above, the proof of the presence of a wave of contraction by the graphic method was not altogether clear; it is now seen that the record of the galvanometer on this point is obscure, and it is presently to be noted that the electrometer gives indications of a contraction occurring almost simultaneously in all parts of the ventricle. These are points which require further research, and upon them Drs. Waller and Reid express themselves cautiously.

The experiments with the capillary electrometer are specially interesting. The movements of the mercury were magnified by a half-inch objective, the image taken 90 centimètres behind the lens, and photographed upon a sensitive surface travelling more or less rapidly. Changes which were not shown by the galvanometer appear clearly with the electrometer. A diphasic variation was frequently shown when the galvanometer showed only a single change of potential. But, in spite of the extreme delicacy of the electrometer used in the way described, the electromotive change accompanying the beat of the ventricle was sometimes seen to be monophasic. This must be assumed to be really the case—not a mere fusion of two phases by reason of imperfection of the instrument. Further, such monophasic variation occurs during the earlier moments after excision, giving place subsequently to a diphasic variation. The natural conclusion to be drawn from this is,

that in the very active mammalian heart the ventricles contract with such synchronism of their various parts that the excitatory change is practically simultaneous in all parts, and, as the authors think, postulates the existence of nervous channels of conduction, since such simultaneity is inconsistent with the slow nature of muscular transmission.

In the second paper mentioned, Dr. Waller shows how the electromotive changes can be demonstrated even on the human subject. Electrodes leading from the front and back of the chest, when connected with the capillary electrometer, show distinct electrical variation with each beat of the heart. This might be due to mechanical alteration of contact between the electrodes and the chest-wall, caused by the heart's impulse. To disprove this, the electrodes may be led off from the hands or from one foot and one hand placed in two dishes of salt solutions. Still the variation occurs, though less markedly. The crucial test, however, is that by accurate measurement the electromotive change can be shown to precede the contraction of the ventricle by 0.015 second, when the systole lasts 0.35 second. This time difference corresponds with that obtained by Donders for the rabbit's heart *in situ*.

We may add that the research has received the *mention honorable* of the Académie des Sciences, a distinction which is greatly to be valued, and upon which we congratulate the workers.

WOLFFBERG'S METHOD: THE COLOUR-SENSE AS A TEST OF REFRACTION.

IN the present day, when objective methods of estimating the refraction of the eye have been brought to such perfection, it is hardly to be expected that anyone proposing to institute a new test of a purely subjective character would obtain a hearing. But the results claimed to have been obtained by Wolffberg (*Klin. Monatsbl.*, 1886, p. 359) were so very definite, and appeared to be so fully confirmed by Dr. Boehm (*Ib.*, 1887, p. 429) that the temptation to overlook the obvious faults in the method and to give it a fair trial was irresistible, more especially as it was claimed on its behalf that it rendered it possible at once to say whether a given defect in vision was due (a) to a spherical error of refraction, (b) to astigmatism, (c) to a cause unconnected with refraction. A claim such as this has never yet, we believe, been advanced in support of any test, and it is needless to point out, if it could be substantiated, Dr. Wolffberg and Dr. Boehm would have made a discovery of the first magnitude.

In another column will be found a paper by Mr. Stephenson, giving an account of some experiments he has made for the purpose of testing some of the conclusions arrived at by Wolffberg and Boehm, and a short notice of a monograph by Dr. Herzog which deals fully with the whole subject. The conclusions of both these authors, arrived at quite independently, are so entirely opposed to Dr. Wolffberg, that unless he can reply to them, disproving their facts and refuting their arguments, no one will be likely to spend time in using his test.

The test really depends on instituting a comparison between the visual acuity (tested by Snellen's letters in the ordinary

way), and the colour-sense (estimated by the distance at which certain coloured discs are visible). Wolffberg, from experiments on natural and artificial ametropia, believes that he has found the distance at which the discs should be visible for each degree of impaired vision, when such defect is due to an error of refraction. Other causes impair the colour-sense more than the form-sense. By producing different grades of impaired vision by lowering the illumination Wolffberg believes that he has obtained data for estimating the effect of diseases which impair the light-sense—obviously a debatable conclusion. Boehm confirms all these results; but, as he worked in Dr. Wolffberg's clinic and at his instigation, his results can hardly be said to have been independently obtained. He attaches much importance to the fact that astigmatism impairs the form-sense to a greater extent than the colour-sense, so that a conclusion can be formed whether there is spherical ametropia or astigmatism.

It will be seen, therefore, that the whole stability of this test rests upon the accuracy of certain facts; and if these are proved to be untrue, or not constantly true, the whole fabric falls to the ground. That a method of examination which is purely subjective, in which the patient's answers cannot be verified, should give such very definite results, is surprising. If anyone will try the test on himself, he will at once find that it is by no means easy to fix the exact moment at which the disc becomes invisible, and we are surprised that Drs. Wolffberg and Boehm do not attach more importance to this difficulty. Slight discrepancies, therefore, might easily be overlooked; but when patients with the same defect of vision see the discs at 5 and 3 metres respectively, when the same patient varies, when the two eyes of the same patient with the same refraction vary, when discs of different colours, which the authors state are visible at the same distance, are seen at different distances, it is impossible to avoid a suspicion either that the ratio between the colour and form sense is not so definite as has been stated, or that the test does not afford a reliable means of estimating that ratio.

As far as we can ascertain, the only point in which Herzog confirms Wolffberg's conclusions is that in the majority of cases of astigmatism the colour-vision is impaired to a less extent than the form-sense; but, as this was also the case in some eyes which were not astigmatic, the fact cannot be utilised for diagnosis.

To our mind, however, the most damning piece of evidence against the accuracy of the authors of the test is the statement, made both by Dr. Herzog and Mr. Stephenson, that the majority of eyes with normal vision do not see the discs at the prescribed distance, and the cases adduced by the former, in which the discs were seen at the proper distance although the eye was suffering from progressive disease. We do not see how Wolffberg's and Boehm's results can be explained unless we assume that in conducting the experiments the patients were permitted to know what answers they were expected to give, a point which should, of course, be most scrupulously guarded against in any subjective test.

PROFESSOR EWALD, of Berlin, has been named director of the medical wards in the Augusta Hospital, in succession to Professor Senator.

IMMIGRATION AND OVER-POPULATION.

THE Anglo-Saxon race, as in spite of the pedantic objections of some historians we persist in calling ourselves, is just now much exercised on the over-population question. Theoretical articles in monthly reviews, and the more circumstantial evidence given to the Parliamentary Committees now sitting to investigate the sweating system and pauper immigration have stirred men's minds. A "Committee for Inquiring into the subject of Over-population," has held a semi-public meeting, so largely attended that it has been necessary to arrange to hold future "conferences" in a more roomy apartment, and Willis's Rooms have been chosen for the purpose. The United States of America, assailed on both their eastern and western seaboard, have some time ago forbidden the entry of pauper immigrants from Europe on the east, and the immigration of the Chinese on the west. Finally Australia has precipitately attempted to forbid the influx of Chinese labourers into territories which Western Europe was still inclined to regard as boundless.

Against the Chinaman it is urged in general that his ways are insanitary, and specifically that his methods of raising vegetables for the market are distinctly dangerous to health. Miss Gordon Cumming, in one of her delightful works of travel, has given a description, the more vivid from its studied restraint, of the system of market gardening in China, which leaves a very unpleasant impression. The pail-system of sewage disposal is universally adopted in its crudest and most primitive form, and as the same method is pursued by Chinese immigrants, there seems to be good ground for the opinion expressed by competent authorities in Australia, that such diseases as typhoid fever may be transmitted through fresh vegetables grown by Chinese market gardeners. Fresh excreta mixed with water and applied directly to growing lettuces, much as an English gardener may add a little guano or other fertiliser to his watering pot, might very well be the direct means of distributing the disease. The objection is of a totally different kind to that which some thoughtless persons have made against sewage farms; in the latter the liquid sewage runs in channels between the rows of vegetables, filters through soil to the roots, and even if any noxious principles escaped destruction in the earth, they would be subjected to the marvellous metabolic processes of the living cells of the plant; moreover, a laborious research conducted in France, has shown that vegetables grown on sewage farms do not contain dangerous forms of bacteria. But when recent excreta are applied in the haphazard method favoured by the Chinese, the dangers are different and greater, for the surfaces of the growing leaves may be directly contaminated.

The Australians will, no doubt, settle the question of Chinese immigration for themselves, and will probably follow the example set by the United States. In this country, too, it seems not impossible that the pressure of public opinion will compel the Government to follow the example set by the United States on their other coast, and introduce some measure to place the admission of pauper immigrants under strict surveillance. Our hospitals daily afford evidence of the abject poverty and hideous diseases which are the only possessions of too many of the miserable foreigners who have within the last

decade swayed into certain districts of East London. But we must not suppose that even the most complete check to pauper immigration would solve the "over-population question." The Committee to which reference has been made above has taken up a large and somewhat delicate subject. It has chosen for motto *Lux quia lex*, and this alliterative jingle expresses fairly well the chief remedy which we can hope to apply. Speaking generally, it is the most ignorant and least worthy classes which multiply most rapidly, so that our civilisation, it is said, is threatened by a kind of law of the survival of the unfittest, traceable to a mere surplus of numbers. The pressure of "bad times" and the increasing difficulty of earning a living to some extent, as statistics show, tend to lower the birth-rate; but education, moral, mental, and physical, is the only real remedy, and this will take many years, even generations, to produce an effect.

STUDIES IN THERAPEUTICS.

VI.—PARAPHENACETIN.

THE aromatic series of carbon compounds seems destined to supply us with a very large number of drugs, useful in treatment. We are already familiar with antipyrin (dimethyl-oxychinicin), and antifebrin (acetanilide). The latest discovery is that of phenacetin, or para-acetphenetidin, a body closely allied to antifebrin. This body was first prepared by Dr. O. Hinsberg, of Elberfeld, who, in conjunction with Professor Kast, subjected it to physiological research. The results of this research have led Dr. Koller, of Vienna, to make an extensive use of it clinically for its antipyretic properties. The results of his experiments are embodied in a small pamphlet from which the following facts are taken: Phenacetin is inodorous, tasteless, very slightly soluble in acid chyle or pancreatic extract at body temperature. It has no effect in reducing normal temperature, but it is claimed that in all cases of pyrexia even small doses (4 to 7 grains) never fail to produce a perceptible effect in diminishing the fever. No ill-effects such as nausea, vomiting, and collapse, which sometimes follow the use of other antipyretics, have been observed. Altogether, fifty cases of a most varied nature have been treated with the new febrifuge. Of these, tuberculosis, pneumonia, morbilli, and enterica form more than half. The plan adopted was to administer the antipyretic when the continued high temperature seems likely to be prejudicial to the patient, that is to say, in long-continued temperature of 102 degrees to 104 degrees F. The reduction of temperature took place slowly, the maximum effect being produced in about four to six hours; this point being reached, the temperature again rose, so that in eight to ten hours all effects have passed off. Nocturnal exacerbations in phthisis were found to be not prevented, but only delayed; but the rise of temperature under these circumstances was unaccompanied by rigors. Moreover, during treatment, the patients became cheerful and able to take food. The fall in temperature was not usually accompanied by perspiration; when this takes place, Dr. Koller says that care is required in exhibiting the drug. In one case of this kind, temperature was reduced as low as 95 degrees F., which caused some alarm. The patient's temperature rose, however, under the influence of rubbing and warm bottles, and no signs of collapse appeared. It is also stated that a com-

paratively large initial dose is more effective than several successive doses. It would be interesting to ascertain whether in the case of phenacetin, as in that of antipyrin, a tolerance was produced after prolonged exhibition. Phenacetin exerts no diuretic action, and passes out of the body quite harmlessly by the kidneys; its presence in the urine may be detected by the red reaction given by ferric chloride. It would be interesting to know during what length of time this red reaction can be observed as a clue to the rate of excretion. Judging by the properties of allied bodies Dr. Koller has made experiments on the antiseptic properties of phenacetin, but owing to its great insolubility, no definite results have been arrived at. The main deductions from the paper seem to be as follows:—1. That phenacetin is an antipyretic. 2. That its use is not usually followed by disagreeable results. 3. That a single large dose is more serviceable than successive small ones. 4. That the fall of temperature takes place less promptly than when other antipyretics are used, but lasts longer. This seems to be most likely due to the great insolubility of the drug, which is one of the greatest drawbacks.

THE Emperor of Germany has conferred on Professor Virchow the honour of the Red Eagle of the second class.

THE Prince and Princess of Wales have promised to open the new Great Northern Central Hospital in Holloway Road on Monday, June 25th.

THE Cavendish Lecture of the West London Medico-Chirurgical Society will be delivered at the West London Hospital, Hammer-smith, on Friday, June 1st, at 5.30 P.M., by Sir William Stokes Professor of Surgery in the Royal College of Surgeons in Ireland, who will take as his subject 'The Altered Relation of Surgery to Medicine.'

MEDICINE AND POLITICS IN ALSACE.

By a decree of the Governor of the Department, the Société de Médecine de Strasbourg has been dissolved; in other words, the authorisation which is required by law for all meetings of more than twenty persons has been withdrawn. No reasons are given for this rigorous decision, and the disappearance of this venerable society has given rise to general expressions of regret.

GROCCERS NOT PHARMACISTS.

THE Correctional Tribunal of Privas (France) recently sentenced a grocer to a fine of 500 francs, with costs, for having sold fluid extract of cinchona, santenin lozenges, mercurial ointment, etc., to the detriment of the local retail chemists. In view of this decision, the sale of Epsom salts, chloride of lime, or carbolic acid must expose unwary tradesmen, other than chemists, to very serious pecuniary risks. This stringency may have something to do with the comparative rarity of cases of accidental poisoning in France, which are so lamentably common in this country, where the laws restricting the sale of poisons are, to all intents and purposes, inoperative.

MECO-NARCEIN.

DR. LABORDE has called the attention of the French Academy of Medicine to the valuable soporific qualities of a product derived from opium, to which he proposes to give the name of meco-narcein. Narcein as ordinarily prepared is comparatively insoluble, and therefore has very little physiological effect. He has succeeded, however, in obtaining a product quite free from mor-

hine, and consisting of narcein mixed with various unknown kaloids. A fifth of a grain induced a calm sleep in a dog weighing thirty pounds, without any apparent after-effects. It would appear to be devoid of the preliminary exciting effects of morphine, and does not derange the digestive apparatus. Dr. Laborde recommends it in the treatment of insomnia of nervous origin, in broncho-pulmonary affections characterised by cough and excessive secretion of mucus, and finally in morphinomania.

SUCCESSFUL OVARIOTOMY IN A PATIENT AGED EIGHTY-TWO.

M. HOMANS, of Boston, removed, on January 28th, 1888, a papillo-tous multilocular cyst of the left ovary from a widow, aged 82. The temperature rose on the sixth day to 100.5°, but subsided the next day, and the patient returned to her home on March 1st. The tumour had been observed for two years. Its solid portion weighed thirteen pounds, its fluid contents one pound and three quarters. The case is described in the *Boston Medical and Surgical Journal* for May 3rd, 1888, where it is asserted that no case is recorded of ovariectomy in a patient over 78 years of age. Olshausen, however, notes that Schröder successfully operated on a patient aged 79, and on another aged 80. Dr. Miner described in the *Buffalo Medical and Surgical Journal*, September, 1866, the removal of a multilocular ovarian tumour weighing nineteen and a half pounds from a woman, aged 82. She died fourteen days after the operation. Dr. Homans's patient probably the oldest who has recovered from ovariectomy.

POISONOUS WINE.

FEW months since, a large number of the inhabitants of Hyères were suddenly stricken down with a disease, the symptoms of which were colic, anorexia, puffiness of the face, photophobia, and partial paralysis of the extremities. For a time these symptoms were attributed to an epidemic of severe influenza. The number of the victims rapidly increased, until upwards of 300 persons were suffering. It can easily be imagined that the suddenness and mystery of the visitation excited a great deal of consternation among the inhabitants. Matters went on thus till the month of April, when Dr. Roux, who had in the meantime been carrying out an inquiry on lines of his own, arrived at the conclusion that the course and character of the affection pointed to the effects of poison rather than to any known disease. After much painstaking research, he succeeded in incriminating a particular wine supply, and at once brought the matter to the notice of the authorities, basing his opinions on the facts (1) that the effects observed were in direct proportion to the amount of wine absorbed; (2) that no such symptoms had presented themselves, except in those who had partaken of the incriminated supply; and (3) that the members of a family who, for any reason, had not taken the wine, had escaped the symptoms. The authorities seized the stock of wine and arrested its proprietor, who will be kept in prison pending the final report of the analyst, who is stated to have found arsenic in the wine.

AN UNMERITED CENSURE.

An inquest recently held in Oswestry terminated in a severe and quite undeserved censure on Dr. Fuller, a much respected practitioner in the town. The facts were simple. A man, aged 45, was admitted into the cottage hospital suffering from retention of urine due to a long-standing stricture of the urethra. The retention of urine having been relieved by the passage of a catheter, Dr. Fuller ordered the removal of the patient to the workhouse, as he was free from pain and quite comfortable, and was not then properly a case for treatment under the rules of the institution, which limits the admission of cases to accidents, and those of an urgent nature. The patient died four days after his removal to the workhouse, and for some reason unknown to us

Messrs. Blaikie and Cartwright, who attended him during those four days, were not summoned to give evidence at the inquest. As already stated, the jury added a rider to their verdict censuring Dr. Fuller for accelerating the death by the indiscriminate removal of the patient to the workhouse. This censure is certainly not justified in the slightest degree by the evidence, two very full reports of which have appeared in the local newspapers. We cannot help believing that had the additional medical evidence to which we have referred been called for, the rider would never have been added. The indiscriminateness on which the jury laid so much stress really consisted in the hearty dinner and quantity of beer of which the deceased partook after his retention had been relieved.

WOODHALL SPA.

A NUMBER of medical men and others accepted on Tuesday last the invitation of the proprietors of the unique bromo-iodine spa at Woodhall, Lincolnshire, to inspect the hotel, new pump room, and baths which have been recently erected at that place. Till lately the valuable iodine spa at Woodhall has enjoyed little more than a local reputation; it deserves a world-wide celebrity. A short time ago a syndicate composed of Sir E. R. Webster, Q.C., M.P., Mr. Edward Stanhope, M.P., Mr. Henry Chaplin, M.P., and others, was formed to develop what there is reason to anticipate may prove to be a popular and highly useful health resort. Plans of a new hospital have also been prepared by Mr. Waller, of Boston. At a luncheon, presided over by Mr. E. Stanhope, M.P., Dr. Burney Yeo took up effectually the parable which Mr. Ernest Hart has propounded with so much general acceptance in these columns, and pointed out that those who desired to promote the prosperity of English spas must bring about developments in the way of recreation and public amusements, which few of them at present possess. The invalid, he rightly said, did not merely want water and baths; there must be the means of recreation, for the invalid who was well amused was half cured. The Speaker of the House of Commons rather reproached English medical men for neglecting the spas of their own country; but it is not so much the doctors as the municipalities and the proprietors who have been at fault. We hope that a new era is opening, and that Woodhall spa will help to lead the way. Mr. Ernest Hart, in his letters from Carlsbad, has given a detailed account of the very simple and effective method by which the municipality of that little far-away hamlet developed its attractive series of public buildings, *Trink-halle*, musical promenades, *cafés*, woods, and gardens, without drawing upon the slender purse of the town. This lesson should not be lost upon our English municipalities and spa syndicates.

THE TUBERCLE BACILLUS.

THE paper which Dr. Kidd and Mr. H. H. Taylor laid before the Royal Medical and Chirurgical Society on Tuesday, May 22nd, on the results of the examination of sputa for the tubercle bacillus was one well worth attention. Attention on the part of those present was comparatively easy, as Dr. Kidd took the wise course of reading the paper himself, with selections from the cases related, and relieved the Honorary Secretary of the difficult task of emphasising just those points which the authors think important, and passing lightly over the subsidiary parts. It is a practice we could wish was more generally adopted at this Society. The paper was the result of some years of careful and continuous microscopical study, carried on alongside of clinical observation at the Brompton Hospital. During the years that have now elapsed since Koch's discovery of the bacillus of tubercle, clinical observers have been endeavouring to come gradually to a just estimate of what they have thereby gained. They have gained, say Dr. Kidd and Mr. Taylor, some indisputable points in dia-

gnosis of tubercular disease of the lungs and throat, and along with that in treatment, but little in prognosis, as compared with what was possible before. Many of the factors of prognosis had previously been long and carefully studied, and the results of that study are not contradicted, and not much added to by the fresh knowledge of the bacillary origin of the disease. One or two speakers claimed rather more for it in prognosis, but such claims were in part satisfied by the full acknowledgment of its usefulness in diagnosis, and in part must be put to the searching test of long experience. Dr. Kidd's and Mr. Taylor's paper dealt only with the deductions from the sputa, and, in careful and prudent fashion, declined to enter on the larger questions of the possibilities and methods of infection, and the development of any anti-bacillary treatment. These are matters which need most careful and continuous study, after the enthusiasm of a new discovery has passed through its first stage of excitement, and on which the next generation will probably have more to say than we.

"TRAUMATIC HYSTERIA."

Cases not infrequently occur in which the victims of railway accidents, who have or have not been subjected to actual wounds, develop secondary symptoms after a considerable lapse of time, involving paralysis and disorders of the sensory apparatus. The evidence given in respect of such cases in courts of law is usually very conflicting, the medical witnesses for the plaintiff testifying to the existence of this or that symptom, while the professional experts on the other side are unable to see anything more than "hysteria." It may fairly be considered how far such an expression as "hysteria" ought to be used in such cases. The impression which it conveys is decidedly detrimental to the injured party, who may be suffering from one form or another of those functional disorders which not infrequently follow injury, and which, in the present state of ignorance as to their nature, are conveniently, but certainly inaccurately, grouped under the vague and misleading title of "hysteria." At a recent meeting of the Medical Society of London, Dr. Beevor showed just such a case. The patient was a lad who had contused his hand, and the injury was followed in a day or two by gradual firm contraction of the right hand. Anæsthesia of the integument up to the shoulder supervened, with loss of muscular sense; but the movements of the arm and forearm were unimpaired. The lad was otherwise healthy, and had nothing to gain by simulating an affection, the reality of which was, moreover, amply demonstrated. There is no lack of such cases on record, and the point of interest is their bearing in actions for damages on account of injury. The symptoms are as directly the effect of the injury as would be erysipelas or tetanus, and it is not easy to see why an endeavour should be made to distinguish between one and the other in so far as the legal position is concerned. That there is still very much to be learned with respect to the nature of these ill-understood phenomena is painfully evident, and they deserve special attention on account of their peculiar medico-legal interest.

ONE-CHILD STERILITY.

A CONSIDERABLE proportion of women never bear more than one child, and this fact is easily explained, for pregnancy may be complicated or followed by disorders which damage the genital apparatus. Dr. Kleinwächter observed 90 cases where women had been but once pregnant, and on that occasion at a more or less remote period, out of 1,081 patients in his gynecological practice. In 21 of the 90 cases the pregnancy had ended prematurely. He classed the causes of sterility after a first pregnancy into ten groups, based on a careful study of the 90 cases. The groups were thus arranged in order of frequency: 1. Sequelæ of inflammatory processes arising during the puerperium; 2. catarrhal endometritis; 3. sequelæ of inflammatory processes not puerperal in

origin (43 cases came under one or other of these groups); 4, displacements of the uterus; 5, neoplasms of the uterus; 6, constitutional sources of sterility established after the first pregnancy; 7, impaired potency of the husband, well authenticated by the clinical history; this condition has more than a negative influence on the uterus and ovaries; 8, super-involution or atrophy of the uterus; 9, new growths in the ovary; 10, uncertain or unknown causes. Under Group 6 were included cases where anæmia, cachexia, obesity, or emaciation arose after the first pregnancy. As the cases could not readily be kept under observation after their discharge from hospital, or after dispensing with the physician's services, Dr. Kleinwächter could come to no conclusions as to treatment. His observations are to be found in the eighth volume of the *Zeitschrift für Heilkunde*.

SYRINGOMYELIA.

DR. ALLEN STARR, Clinical Lecturer on Nervous Diseases at the College of Physicians and Surgeons, New York, has recently contributed to the *American Journal of the Medical Sciences* a memoir of considerable importance on "Syringomyelia; its Pathology and Clinical Features." Dr. Starr affords his readers a good summary of the opinions of authorities upon this condition, where abnormal cavities are present within the spinal cord. Syringomyelia differs from hydromyelus, which is a congenital affection where the central canal is dilated, the cavity being lined with cylindrical epithelium. Syringomyelia is, on the other hand, acquired. Such is the distinction drawn by Dr. Starr and other writers, but Drs. Frederick Taylor and Whipham, whose valuable papers on syringomyelia in the *Transactions of the Pathological Society of London* have apparently been overlooked by Dr. Starr, do not employ the terms in so definite a sense. In syringomyelia proper the cavities represent the breaking-down of small gliomata, although Leyden, Westphal, and Taylor maintain that the cavities are more probably developed from the central canal itself. From a summary of clinical records Dr. Starr concludes that certain symptoms in a certain combination are characteristic of syringomyelia. First, there is progressive muscular atrophy, with paralysis affecting some or all of the muscles of one limb, and usually extending to the opposite limb and to the body. Again vasomotor and trophic disturbances are observed in the affected limb, manifested by coldness, blueness, bullous eruptions, ulceration, abscesses, and even atrophy and fragility of the bony structures, and a diminution in the excretion of sweat. Lastly, there is a loss of the sensations of pain and temperature in the atrophic part, whilst the senses of touch and location may be preserved. The causes of syringomyelia have not been precisely defined, and nothing is known of the treatment of this disease, which may progress slowly, or come to a standstill, or terminate suddenly.

MEDICAL SELF-HELP.

IN the presence of the numerous and touching appeals which we have recently published on behalf of medical men who have been overtaken by sudden calamity from unforeseen sickness, accident and financial disaster, it is gratifying to be able to note the growth of providence and the extension of membership in the Medical Sickness and Life Assurance Society. The quarterly report which we recently published showed the remarkable growth of the invested funds of this Society, now amounting to upwards of £20,000 in the course of four years, and the satisfactory fact that all the funds show a good surplus, while the management fund shows in the same time a saving of nearly £2,000, which is placed to the credit of the members. At the last monthly meeting of the Society, sickness payments were ordered on account of cases of practitioners, members of the Society, disabled from practice by locomotor ataxy, phthisis (2), compound fracture of the leg and of the arm, myelitis, pneumonia, pyæmia

Menière's disease, acute rheumatism, enteritis. Two of these cases are likely to require, and will receive, a continuous payment for the rest of life, the diseases being permanent and involving total disablement. The Society is one of purely mutual character; there is no eleemosynary element in its constitution. The Managing Committee, however, are unpaid; and the whole of the profits accumulated are the property of the members. The members claim their payments due as a matter of right, and it is a subject for hearty congratulation that an association which puts self-help within the reach of every practitioner in sound health, and enables him to provide against accident, misfortune, sickness, and disablement from old age, is prospering so remarkably, and continues to receive almost daily applications for membership. Prospectuses, tables of premium, forms of proposal, and all information are furnished on application to Mr. C. J. Radley, 25, Wynne Road, Brixton, London, S.W.

NECROPSY OR DISSECTION.

WITH reference to the alleged instance at Victoria Park Hospital of the performance of a *post-mortem* examination in opposition to the wishes of the relatives, we are requested to state the following facts. The patient died somewhat suddenly after rallying from a fit. At the commencement of the serious symptoms the friends were telegraphed for, and a porter afterwards sent to the address given. The friends were, however, not forthcoming. Some hours after the death of the patient the *post-mortem* examination was performed. It is the custom to ask permission in every case for a *post-mortem* examination, but, in the event of the relatives not arriving, this is always performed. In this case the father did not arrive till after the examination (which was an ordinary one) was made. So far from being treated abruptly, the father was given every opportunity of stating his grievance before the committee of the hospital, and no such expression as has been reported—that "they should do as they liked"—was ever used to him. An idea seems to be prevalent that the body was "dissected," such as was not the case. In an ordinary *post-mortem* examination, such as was performed in the instance under consideration, it is impossible, without specially looking, to discover whether an examination has been made or not. The practice of *post-mortem* examinations in hospitals or elsewhere is to be governed by good sense and consideration for the feelings of relatives rather than by reference to legal rights. The law is singularly silent on the subject. In a test case raised by the Vigilance Committee and heard at Bow Street in June, 1882, Mr. Flowers stated that the question for decision was whether making a *post-mortem* examination could be considered to be offering an indignity to a human body. This point was decided by Lord Chief Baron Pollock in the case of *Regina v. Feist*, which came before the Court for Crown Cases Reserved in 1858. The Chief Baron held that there was nothing wrong or against good feeling in making a properly conducted *post-mortem* examination, so that a medical officer who, in the course of his ordinary duties, makes such an examination does not violate the law.

PHYSIOLOGISTS' ON MONT-BLANC.

THREE enterprising French gentlemen went last summer to the top of Mont Blanc for the purpose of making a series of meteorological and physiological observations, and remained there for two or three days, in order to obviate the errors which, so far as physiological observations are concerned, would be inevitable if made while still suffering from the extreme fatigue incidental to so laborious an ascent. As it was, none of them had the courage, on attaining the goal, to put up the tent, etc., which with great difficulty had been brought up, and they fell asleep with their heads on the boxes of instruments. The thermometer, when placed on the snow, registered 19° C. below zero. M. Richard and one of the guides suffered from severe headache, with feverish symptoms.

The least effort—even ordinary movement—caused such fatigue that they were compelled to lie down during the greater part of the day. They had masks to preserve the skin of the face from the biting cold, and the usual spectacles to avoid snow-blindness. The travellers suffered from almost complete anorexia, and they noticed that tea immediately made them ill. The second day tracings were taken of the pulsation of the carotid and radial arteries. One of the guides was quite prostrated with headache and high fever, and was only got down with great difficulty. Once down, a good meal, a denser air, and a milder temperature soon restored them to their normal condition of health.

CORPORAL PUNISHMENT IN ELEMENTARY SCHOOLS.

THE matter of corporal punishment still remains a vexed question with schoolmasters and magistrates. We have great sympathy with the schoolmaster who tries to do his duty and finds chastisement in school necessary. Reasonable chastisement is a useful discipline; if properly administered it is not harmful to the body, while it often improves manners and stimulates learning. Teachers have a right to some authoritative decision as to the power of administering chastisement without incurring legal liability thereby. This is not a matter for fine sentiment and feeling, but for deliberate judgment and action. Let the Education Department and the Home Office confer, and define in a code the ages under which children may corporally be punished, and the mode and extent of administration. Corporal punishment may produce some aches and pains, but it interferes with health less than confinement after hours, or deprivation of food. The teacher should not fear to do his duty, and the law should support him in doing it for the child's good and the maintenance of a wholesome discipline.

UNIVERSITY COLLEGE HOSPITAL.

A MEMBER of the medical staff of University College Hospital is credited with an expression of profound regret that, when an accidental fire occurred in that venerable building during the course of some Christmas festivities, the active workers who extinguished the flames did not turn their attention to removing the patients, leaving the building to be consumed by the devouring element. It is an open secret that the structure is very imperfectly adapted to its purpose, and that many members of the committee have long entertained the opinion that to further patch and repair was mere waste of money, and that the true economy would be to pull down and rebuild. The late Sir Francis Goldsmid, a generous benefactor of the hospital, as he was of the College, held this view so strongly that his large legacy was contingent on this course being adopted, and, when a decision adverse to the proposal was reached, the legacy lapsed. Plans have actually been in existence for years, and some money has been raised; yet it is reported that the committee propose to waste further sums on tinkering at the sanitary arrangements, which once again have been found so patently defective that the hospital will probably have to be closed for six weeks this summer.

STILLBORN CHILDREN AND WORMIAN BONES.

DR. GRACE PECKHAM contributes to the *New York Medical Record*, April 14th, 1888, an article on "Wormian Bones in Fontanelles, and their Effect in Childbirth." From the experience of three cases, very similar—indeed, almost identical—in character she has been led to infer that large Wormian bones in the fontanelles, especially in the posterior, may endanger the child during parturition. They may prevent the overlapping at the sutures, so that during the second stage of labour, when the pressure is greatest, the intra-cranial contents may be gravely damaged by pressure. In all three cases the patients were primipare, and

there was nothing abnormal in the measurements of the maternal pelvis and fetal heads. The presentation was left occipito-anterior in all the cases. The labours progressed slowly but normally through the first stage, but the second stage was very slow, lasting two or three hours. As there was a constant expectation that the labours would terminate naturally, no instruments were used. All these children were stillborn. In the first two cases the abnormality gave rise to confusion in determining the presentation; in the third, previous experience rendered diagnosis easy. The bones were two in number, triangular, and lying on each side of the middle line, the suture which divided them being continuous with the sagittal; their bases lay towards the occiput, their apices touched the parietals. These bones must be distinguished from the remarkable "interparietal," "epactal," or "lambdoid" bone, the "os Incae" said to exist in 20 per cent. of the skulls of the ancient Peruvians. The interparietal bone is single, and represents failure of union of the upper with the lower part of the occipital portion of the occipital bone. Dr. Peckham insists on the facility with which Wormian bones in the posterior fontanelle may be diagnosed during labour, and raises the question: Can the dangerous pressure-effects be avoided by the prompt and early use of instruments? She turns the attention of obstetricians to the subject.

INTERNATIONAL CONGRESS ON ANTHROPOLOGY.

THE Congress announced to be held at Columbia College, Brooklyn, U.S.A., June 4th to 7th, will discuss a variety of subjects affecting medicine and public health. There will be sections for anthropology, ethnology, ethnography, prehistoric archaeology, and history of culture. Under anthropology there will be considered the effect of physical surroundings on man, with the influence of the present system of education; the physiology of the mind, the relation between physical states and psychical phenomena, heredity, criminal biology, and sociology. Under ethnology there fall to be discussed the laws of human progress as affected by food, narcotics, disease, sexual relations, language, the arts and sciences, government and laws, religions, and civilisation. The President is Dr. E. C. Mann. Among the medical English Vice-Presidents are Professors Flower, Huxley, and Victor Horsley; Sir Crichton Browne, Drs. T. S. Clouston, Norman Kerr, Henry Maudsley, George H. Savage, and L. S. Forbes Winslow. English law is represented by Sir J. FitzJames Stephen, and Sir Henry Maine. Other Vice-Presidents are Sir John Lubbock, Professor Häckel of Jena, Professor Virchow of Berlin, Professor Carl Vogt of Geneva, Dr. Kraus of Vienna, and Dr. Morell of Ghent.

ECTOCARDIA CURED BY A PLASTIC OPERATION.

PROFESSOR LANNELONGUE, of Paris, recently presented to the Académie des Sciences a very remarkable case of deformity of the chest wall, with ectopia of the heart, which he had dealt with successfully by operation. The patient was a female child, six days old, well-formed in every part except the thorax. On the front of the chest over the middle of the sternum there was a circular ulcer, rather larger than a franc piece, the base being formed by a yellowish membrane which appeared to be becoming gangrenous. It was already detached from the edges of the ulcer at several points, and thus only imperfectly closed the aperture into the chest. Each beat of the heart pushed it forwards, and on applying the finger during systole the hardening of the ventricular wall as they contracted could be distinctly felt. The inner ends of the clavicle articulated below with the first rib, and appeared to be free internally and above: the sternum was entirely wanting between them. This gap in the osseous wall of the chest extended downwards in the middle line; the sternum appearing to be represented on each side only by a narrow strip of bone running downwards and ob-

liquely inwards," and finally joining the corresponding piece below the median ulcer already referred to. The deficiency in the bony chest wall was therefore of the shape of an isosceles triangle, the apex being below at the ensiform cartilage and the base above at a line joining the inner ends of the two clavicles. The side of the triangle measured 4, and the base 3 centimètres. The circular ulcer was as it were inscribed in this triangle. On inspiration the chest wall corresponding to the malformed part of the skeleton was drawn in, so that a hollow half an inch deep was formed at the upper part; in expiration, on the other hand, it bulged markedly forward. A few days after the little patient was first seen, the remains of the "obturator" membrane at the bottom of the ulcer disappeared; the pericardium was seen to be entirely wanting; the apex of the heart projected outside the chest, and the whole anterior surface of the ventricles was exposed. The hole in the skin became gradually smaller owing to the formation of large fleshy granulations, which pressed on the apex and ventricles of the heart, and it was obvious that immediate surgical interference was necessary to prevent most serious disturbances of the circulation. M. Lannelongue therefore made two vertical incisions on each side, $1\frac{1}{2}$ centimètre to the outer side of the ulcer; the flaps thus formed were sufficiently loosened to allow of their internal edges being brought together over the opening in the chest wall, where they were fixed by three hair sutures. Only a few drops of blood were lost; the operation was not followed by any constitutional disturbance, and the wound was entirely healed in twenty days. Two months after the operation the child was in perfect health. M. Lannelongue points out that in this way he transformed the case from one of "ectocardia" into one of "subcutaneous ectopia." He thinks it possible that the ectopia, which is at present extra-thoracic, may in time, as the heart develops, become intra-thoracic. Professor Verneuil, in presenting M. Lannelongue's communication to the Academy, remarked that this was the first time such a procedure had ever been attempted.

SCOTLAND.

SIR GEORGE HUSBAND BAIRD MACLEOD, Knight, Regius Professor of Surgery in the University of Glasgow, has been made a Deputy-Lieutenant of the County of Dumbarton.

GLASGOW MATERNITY HOSPITAL.

THE directors of this hospital intend to open, on June 11th next, a west-end branch, at 491, St. Vincent Street. Patients will not be received into the west-end house, but will be attended from it, free of payment, at their own houses. Students will continue to take their first six cases from the hospital in North Portland Street, but will be allowed to take additional cases from the branch. This arrangement will be of great service both to students and patients.

ORIGIN OF HOSPITALS.

IN his admirable lecture on Life in One Room, Dr. J. B. Russell, Medical Officer of Health for Glasgow, made the statement that "hospitals for the sick are the special product of Christianity." As this represents a very common belief, our readers may be pleased to have the following references to authorities on another view of the subject. They are taken from a letter in the *Glasgow Herald*, of May 17th. Professor Monier Williams says that "the first hospitals for diseased men and animals are known to have originated with the Indian Buddhists" (*Nineteenth Century*, p. 77, July, 1882). In the fourth century B.C., an edict was promulgated in India by King Asoka, commanding the establishment of hospitals throughout his dominions (*Westminster Review*, October,

1887). Bosworth Smith, in his *Mohammed and Mohammedanism*, p. 253, says we owe the origin of hospitals to the Indian Buddhists, and of lunatic asylums to the Mohammedans. And Prescott, in his *Conquest of Mexico*, p. 16, says that hospitals were established in the principal cities of ancient Mexico for the cure of the sick and the permanent refuge of disabled soldiers.

THE "JOHN REID" MEDICAL PRIZE.

THIS prize, founded by Miss Mary Reid in memory of her brother, the late John Reid, surgeon, Glasgow, is awarded for the best original research bearing on any of the departments of medical science, conducted in one of the hospitals or laboratories of Glasgow. The prize, which is of the annual value of £25, was, at a meeting of the trustees held on May 17th, awarded for one year to Mr. Robert M. Buchanan, Glasgow, for an able paper on the Absorption of Amyloid Material, and the Amyloid Change in Hodgkin's Disease.

PROSECUTION UNDER THE VACCINATION ACT.

AT Alloa Sheriff Court the Rev. E. M. Pulsford was charged by the Parochial Board with a contravention of the Vaccination Act by refusing or neglecting to vaccinate his daughter. Mr. Pulsford, who has been twice previously convicted, pleaded guilty, and said he understood it was within the province of the Parochial Board to drop prosecution after the first conviction. The Sheriff stated he had no choice in the matter. The policy of the Act was to make vaccination compulsory, and if boards only prosecuted once that would not be compulsion. He then imposed a fine of 5s., with 30s. expenses, or seven days' imprisonment. It may be noted here that, as will be seen from the Registrar-General's report, only four deaths from small-pox occurred in the eight principal Scotch towns during 1887.

SEVERE THUNDERSTORM IN SCOTLAND.

ON Saturday, May 19th, a most terrific thunderstorm broke over Glasgow and the south-west of Scotland, causing much damage to property and live stock, and causing four deaths. Two young boys were killed on Glasgow Green. On the body of the one there was only a slight mark on the chest, but that of the other was much scorched, especially about the head and chest, and the hair was entirely burnt off one side of the head. A piece of tin in this boy's pocket was fused by the current, and a large hole, a foot wide and about four feet deep, was made in the ground near where the boys were standing. About the same time two men were struck down in Paisley Road in the outskirts of Glasgow; one was killed, and the other rendered insensible. No marks were found on the body in this case. A young man was also killed near Bathgate. Professor Grant, of the Glasgow Observatory, states that the thunderstorm was the most severe recorded in the annals of the observatory.

THE GOVERNMENT AMENDMENTS TO THE UNIVERSITIES (SCOTLAND) BILL.

WITH the view of rendering the principle of affiliation of colleges clearer, and settling the relations of those colleges to the universities, the Secretary for Scotland is going to introduce certain amendments in committee. The most important of these are the following: The words "affiliation" and "incorporation," are to be struck out of the Bill altogether, and replaced by "added to." On Clause 6, which deals with the powers of the University Court, it is proposed that that body shall have power to administer and manage the whole revenue and property of the University, including the contributions for university purposes from any college which may hereafter be added to the University, provided always that no member of a university court who represents any college which may hereafter be added to the university shall sit or vote

as a member of such court, while it is engaged in the administration or management of any university funds or property, other than the contributions to be severally made by the university and any such added college, as hereinafter enacted. The following new clause is to be introduced after Clause 14. The Commissioners and, after the expiry of their powers, the University Court, may if they think fit make ordinances to extend any of the universities by adding new colleges to them, under regulations to be laid down by the Commissioners, subject to the following conditions: 1. The university court and the college, which it is proposed shall form part of the university, shall be consenting parties. 2. The approval of the Universities Committee shall be signified. 3. The college shall have been under its existing constitution placed on a permanent footing, and shall be sufficiently endowed, in the opinion of the Commissioners. 4. The university and any college or colleges which may be added to it shall severally contribute for the general purposes of the university, as increased by such addition, such annual sum as the Commissioners may determine. 5. When such college is established and on a permanent footing, and under its constitution the college funds are managed by persons other than the teachers, such funds shall continue to be managed as heretofore, subject to the control and review of the university court. 6. The university court or any college which under this act shall have been made part of the university may resolve that such college shall cease to form part of such university.

IRELAND.

THE portrait of Dr. John Halahan, Professor of Anatomy and Midwifery, 1788, and that of Dr. Croker King, first president, have been presented to the Royal College of Surgeons by the surviving relatives of those gentlemen respectively.

THE LOCAL GOVERNMENT BOARD AND DR. MAGNER.

WE learn that the Local Government Board for Ireland have refused to sanction Dr. Magner's appointment as medical officer of Timoleague Dispensary unless he gives a written promise not to connect himself further with any illegal combination or conspiracy while holding office. Dr. Magner has replied to a communication from the Board to this effect, that if they expect him to resign his membership of the National League before obtaining their sanction to his appointment, he must refuse to give any such undertaking.

FEES FOR EXAMINING LUNATICS.

DR. BLAKE, of Tuam Union, lately examined a lunatic, and obtained a magistrate's order for his fee; but, on applying to the guardians for the amount due, it was refused. He applied again, and the guardians, instead of paying, which they ultimately must, directed their clerk to write to Dr. Blake, pointing out the great injustice that would be done the ratepayers if the fee was required to be paid; that they considered his position such that he should be slow to take advantage of an order which simply was giving paupers relief. Most people, we would imagine, would regard the refusal of the guardians to pay the fee demanded as an act of injustice towards Dr. Burke.

UNVEILING OF A PORTRAIT OF THE QUEEN AT THE ROYAL COLLEGE OF SURGEONS, IRELAND.

ON Tuesday, May 22nd, His Excellency the Lord Lieutenant of Ireland unveiled a full-length portrait of Her Majesty in the Royal College of Surgeons, at Dublin. There was a very large and distinguished attendance. The portrait, which is by Mr. Catterson Smith, represents the Queen standing on a dais, attired

in a black satin dress trimmed with white lace. She wears a miniature crown, and the blue sash of the Order of the Garter. Dr. Anthony H. Corley, President of the College, read an address, to which the Lord Lieutenant made a suitable reply. In the evening Dr. Corley entertained a large and distinguished company at dinner in the Albert Hall. Among those present were the Lord Lieutenant, the Lord Chief Justice, the President of the Royal Academy of Medicine in Ireland (Dr. Robert McDonnell, F.R.S.), Lord Justice Fitzgibbon, the Provost of Trinity College, the Lord Chancellor, Dr. Fitzgibbon, Colonel Sir West Ridgway, Sir Robert Ball (Astronomer Royal), and Sir George Porter. The only toasts proposed were "The Queen," "The Prince and Princess of Wales," "The Lord Lieutenant of Ireland," "The President of the Royal College of Surgeons," and "The Universities and the Medical Corporations of Ireland." The company then proceeded to the board-room, where some excellent singing was listened to. The evening passed off brilliantly.

PRESENTATION TO DR. A. H. CORLEY, PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS.

ON Monday last a number of the pupils, past and present, of the Carmichael College of Medicine met to present an address to Dr. Corley, President of the College of Surgeons, and Lecturer on Surgery in the Carmichael School. The address was accompanied by a silver salver and a pair of handsome claret jugs. Dr. Gordon, who occupied the chair, bore testimony to Dr. Corley's popularity and eminence. Dr. Corley made a suitable reply.

THE AMALGAMATION OF DUBLIN SCHOOLS.

ON Friday, May 18th, a special meeting of the Fellows of the College of Surgeons was held, pursuant to requisition, for the purpose of considering the question of amalgamation of schools. Dr. Corley presided. The subject was introduced by Mr. Thomson, who pointed out the disadvantages which resulted from a multiplicity of schools in Dublin, and concluded by moving: "That, having regard to the interests of medical education in Dublin, it is desirable to diminish, as far as possible, the number of private schools, and that, with a view to carrying out this principle, it be an earnest recommendation to the Council to take such steps as may be necessary to effect, on equitable terms, an amalgamation of the existing private schools with those of the Royal College of Surgeons." Dr. Kidd seconded the motion, which was supported by Dr. McDonnell, Professor Thornley Stoker, Mr. Barton, and Mr. Wm. Stoker, and opposed by Professors R. Macnamara and Hamilton, and Mr. Wharton. A division then took place, with the result that the motion was carried by 39 to 16. It was further directed that a special meeting of the Fellows should be summoned to examine any scheme of amalgamation. The schools which it is thus sought to unite with the College School are the Carmichael and the Ledwich. The difficulties in carrying out such a union are great, but they are by no means insurmountable. Certain professors and lecturers would, of course, retire, and for a time there would be more than one occupant of several of the professorships; but seeing that the three schools have about 500 pupils altogether, and that the majority of these would still be retained, the pecuniary result would be satisfactory even at once. As the staff diminished the value of the chairs would be considerable. Mr. Thomson, in his speech, very properly urged the necessity of having such subjects as anatomy and physiology taught by men whose whole time could be devoted to them, and he pointed out that it was only in this way that the scientific reputation of the Dublin School could be raised. The subject has now made a distinct advance, the proposal having for the first time been approved at a meeting of the Fellows, and it is to be hoped that nothing will interfere to prevent its being examined in a fair spirit.

GIBSON AND WIFE V. JEFFRIES AND HILLS.

MAY we appeal to the readers of the JOURNAL on behalf of Messrs. W. C. Jeffries and A. P. Hills, the defendants in an action tried last July at Guildford before Mr. Justice Cave, and reported in your issue of August 13th? Damages to the amount of £500 were then sought to be recovered on the ground of alleged negligence and unskillfulness in the use of forceps during the confinement of Mrs. Gibson, one of the plaintiffs. The jury found for the defendants, and no medical man can read the report of the trial without feeling that the action ought never to have been brought, and that any practitioner who applies the forceps and accidentally ruptures the perineum, or any medical man who is compelled by illness to employ a *locum tenens* is liable to be treated as were Messrs. Hills and Jeffries.

Although costs were given against the plaintiffs, the latter not being in a position to pay, Messrs. Jeffries and Hills will have to pay their own law costs, amounting to £150, and are just now being pressed for payment by the solicitors. There are special and personal reasons known to us that make this a particularly deserving case, and, while it is impossible to remedy the injury, anxiety, and worry through which Messrs. Hills and Jeffries have had to go, we hope that the law costs will be met by subscription among their medical brethren. We would further suggest that this is a case which would be most appropriately dealt with by small subscriptions from a large number of medical men, as it is one deserving such widespread sympathy. The trustees of the "Bower and Keats Fund" have just contributed £50 towards the expenses of Messrs. Jeffries and Hill, but a balance of £100 still remains to be provided.

Subscriptions will be acknowledged in the JOURNAL, and may be sent to Mr. Kettleby, 10, George Street, Hanover Square, W.

GRAILY HEWITT, M.D.,
GEO. GRANVILLE BANTOCK, M.D.,
F. DAWTREY DREWITT, M.D.,
C. B. KETTLEBY, F.R.C.S.

ASSOCIATION INTELLIGENCE.

NOTICE OF QUARTERLY MEETINGS FOR 1888. ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member *by the Council* or by any recognised *Branch Council*.

Meetings of the Council will be held on July 18th, and October 17th, 1888. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before each meeting, namely, June 27th, September 26th, and December 28th, 1888.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No member can be elected by a Branch Council unless his name has been inserted in the circular summoning the meeting at which he seeks election.

FRANCIS FOWKE, *General Secretary*.

BRANCH MEETINGS TO BE HELD.

STAFFORDSHIRE BRANCH.—The third general meeting of the present session will be held in the Bell Library and Medical Institute, Cleveland Road, Wolverhampton, on Thursday, May 31st. The chair will be taken by the President, Mr. W. D. Spanton, at 3 o'clock in the afternoon. The following papers will be read:—Dr. C. A. McMunn: Excretion of Reduction Products of Hæmatin in Disease. Dr. Alfred H. Carter: Practical Considerations on the Nature and Treatment of Chronic Cardiac Disease. Mr. E. Hurry Fenwick, London: The Electric Illumination of the Bladder and Urethra, and its Value in the Diagnosis and Treatment of Obscure Vesico-Urethral Diseases. Dr. McMunn will show a simple method of adapting a photographic camera to the microscope.—T. VINCENT JACKSON, Wolverhampton.

HAST YORE AND NORTH LINCOLN BRANCH.—The annual meeting will be held at the Infirmary, Hull, on Wednesday, May 30th, at 1.30 p.m. Gentlemen who intend to make any communication, or to propose any resolution, are requested to inform the Secretary not later than May 20th.—E. P. HARBRY, Honorary Secretary, 80, Spring Bank, Hull.

MIDLAND BRANCH.—The annual meeting will be held at Nottingham on Thursday, June 14th, at 2 P.M. Members desirous of reading papers, exhibiting cases, etc., are requested to communicate with the Secretary before May 24th. Candidates for election by the Branch Council must send in their forms of application by the same date.—W. A. CARLINE, M.B., Honorary Secretary, Lincoln.

SOUTH-WESTERN BRANCH.—The annual meeting of this Branch will be held at the Devon and Exeter Hospital, Exeter, on Tuesday, June 26th, under the presidency of Dr. John Woodman, F.R.C.S. Notices of motion or communications to be intimated to the Honorary Secretary without delay, and it will facilitate arrangements if members will inform the Honorary Secretary as soon as possible if they hope to be present at the meeting. The following motion was passed at the Council Meeting on May 2nd:—"That inasmuch as the annual meeting assumes more or less the character of a day of recreation, and with a view of encouraging the district meetings, the business of the annual meeting shall be confined to the President's address, the business of the Branch, the exhibition of cases or of specimens with notes, and the annual dinner."—P. MAURY DEAS, Wotton House, Exeter, Honorary Secretary.

NORTH OF ENGLAND BRANCH.—A meeting for the exhibition and discussion of microscopic specimens will be held on May 31st, at 3.30 P.M., in the dissecting-room of the College of Medicine, Newcastle-upon-Tyne. The Secretary will be glad to hear from any of the members who have interesting slides of any description. After the meeting there will be an informal dinner at 5 P.M., at the Douglas Hotel.—G. E. WILLIAMSON, 22, Eldon Square, Newcastle-upon-Tyne, Honorary Secretary.

LANCASHIRE AND CHESHIRE BRANCH.—The annual meeting will be held in Liverpool about the 13th of June. Gentlemen wishing to read papers or show cases are requested to communicate to CHAS. ED. GLASCOTT, M.D., 23, Saint John Street, Manchester, Honorary Secretary.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH.—The annual meeting of this Branch will be held in the Birmingham Medical Institute, on Wednesday, June 14th, at 3.30 P.M.

SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT.—A meeting of the above District will be held in the board-room of the new hospital, at Hastings, on Tuesday, June 12th. Dr. Bagshawe will preside. The Chairman, Mr. Ticehurst, and Dr. Penhall, will contribute short papers on cases. Gentlemen interested in hospital construction will be at liberty to inspect the new building. Communications as to papers, etc., should be addressed to T. JENNER VERRALL, 97, Montpellier Road, Brighton, Honorary Secretary.

BATH AND BRISTOL BRANCH.—The sixth ordinary meeting of the session will be held at the Museum and Library, Bristol, on Wednesday evening, May 30th, at half-past 7 o'clock, G. F. BURDER, M.D., President. The following cases will be exhibited at 7.30 P.M. precisely:—Dr. F. St. John Kemm: Graves's Disease treated with Strophanthus. Mr. J. Michell Clarke: Pseudo-Hypertrophic Paralysis. The following communications are also expected:—Mr. J. Ormerod: Spina Bifida, with Specimens. Mr. C. F. Pickering: The Treatment of Discharge from the Ear. Dr. J. G. Swayde: The Hour of Delivery. Dr. H. Waldo: Embolic Hemiplegia.—E. MARKHAM SKERRITT, R. J. H. SCOTT, Honorary Secretaries, Clifton.

METROPOLITAN COUNTIES BRANCH: EAST LONDON AND SOUTH ESSEX DISTRICT.—The annual meeting for the election of officers will be held at the Forest Hotel, Chingford, on Thursday, June 7th, at 6 P.M. At 6.15 P.M. (sharp) the members and their friends will dine together. A. DURHAM, Esq., President of the Branch, will preside. Tickets, 5s. each, exclusive of wine. Members wishing to be present are requested to communicate with the Honorary Secretary not later than Saturday, June 2nd.—J. W. HUNT, Honorary Secretary, 101, Queen's Road, Dalston.

SOUTH MIDLAND BRANCH.—The annual meeting of the above Branch will be held at the Blechley Park Hotel, Blechley, on Thursday, June 14th, at 2.45 P.M. The new President, H. VEASEY, Esq., invites the members to luncheon at the same place previously to the meeting, from 1.30 to 2.30 P.M., at which meeting and luncheon every qualified medical man will be a welcome visitor. Gentlemen accepting the invitation are requested to intimate the same to the Honorary Secretary not later than June 11th. The arrangements for a combined meeting this year of the Cambs and Hunts and South Midland Branches having fallen through, the informal reciprocal visits of members, to whom it may be convenient, at the respective meetings, would be most agreeable, and are hereby invited. Agenda:—Usual business of annual meeting. Resolution on subject of "Fees to Medical Witnesses," etc. Communication from Chairman of Parliamentary Bills Committee on Subject of "Lunacy Acts Amendment Bill" (see JOURNAL, May 12th, p. 1028). The following gentlemen will be proposed as new members of the Association and Branch: John Henry Lloyd, Esq., Bedford; J. Nell Whitfield, Esq., Northampton; A. E. Godfrey, Esq., and Weatherley, Esq., Northampton Infirmary. Gentlemen wishing to read papers for discussion, cases, etc., are requested to send the titles of the same without delay to the undersigned. The following have been promised: Mr. Milligan: Case of Strangulated Umbilical Hernia: Operation for Radical Cure: Recovery. Dr. Jones: Physical Indications in Heart Affections.—C. J. EVANS, Honorary Secretary, Northampton.

PERTHSHIRE BRANCH.—The next meeting of this Branch will be held in the Lecture Hall of the Perthshire Natural Science Society, Tay Street, Perth, on Friday, June 1st, at 4 P.M. The President, Dr. Trotter, in the chair. Agenda:—Dr. Trotter: Scarlet Fever during the Puerperium. Dr. W. B. GOWANS: Case of Poisoning by Hydrochloric Acid, with Specimen. Election of a Representative to be present at the annual meeting of the Association in Glasgow during August.—W. B. GOWANS, M.D., Secretary, 6, St. Leonard's Bank, Perth.

DORSET AND WEST HANTS BRANCH.—The next meeting will be held at Sherborne, on Wednesday, May 30th. The business meeting will be held at the Yeatman Hospital, at 2.30 P.M. The following are the agenda:—Election of Branch Council and of new members. Election of a representative of the Branch on the Council of the Association. Election of a representative on the Parliamentary Bills Committee. Place and date of the summer meeting. Dr. John Robert Thomson, to move the addition of the following words to By-law 8 relating to the election of members of the Branch Council, "Personal canvass will disqualify." Dr. William Vicary Snow, to propose a resolution on the

recent action of the Committee of Management of the Dorset County Hospital. Discussion: Pleuritic Effusion. Communications: Dr. Leach: Four cases of Empyema. Dr. Isambard Owen (London): Some Points of Interest in connection with Collective Investigation. Mr. Marsh: Short Notes of a case of Lawson Tait's Operation for Extension of Perineum, with an Uncommon and Unfortunate Termination. Dr. Greves: A case of Cerebral Tumour (specimen), with Remarks on the Diagnosis of Intra-Cranial Tumours Implicating the Cortex of the Brain. Dr. Davison: A case of Infantile Scurvy. Dr. Mac Donald: On Epilepsy, with Notes of a Case and Pathological Specimens. Dinner at the Digby Hotel at 6.30 P.M.; charge, 6s. each, without wine.—WILLIAM VAWDREY LUSH, M.D., Weymouth, C. H. WATTS PARKINSON, Wimborne, Honorary Secretaries.

SOUTH-EASTERN BRANCH: EAST SURREY DISTRICT.
A MEETING of this District was held at the Greyhound Hotel, Croydon, on Thursday, May 10th, at 4 P.M.; T. A. RICHARDSON, Esq., of Croydon, in the chair.

Communications.—Papers, abstracts of which will be found at p. 1114, were read by Dr. GOODHART, Mr. BRUCE CLARKE, and Dr. PHILPOT.

Dinner.—After the meeting, seventeen members and visitors dined together.

METROPOLITAN COUNTIES BRANCH: WESTERN DISTRICT.
A MEETING was held on Wednesday, May 16th, at the St. George's Union Infirmary, Fulham Road, Brompton, S.W. Dr. CHARLTON BASTIAN, F.R.S., Vice-President of the district, was in the chair, and about twenty members and visitors were present. The minutes of the preceding meeting were read and confirmed.

Chronic Ulcer of the Tongue.—Mr. BUTLIN, F.R.C.S., read notes of three cases of chronic ulcers of the tongue, in which the disease had resisted all medicinal treatment, and even scraping and freshening the edges. The ulcer was removed in each case by the knife by incisions passing deep into the substance of the tongue. The disease had existed for from eighteen months to three or more years. The author recommended the adoption of this method of treatment in cases of long-standing lingual ulcers in which other measures failed to cure.—A discussion ensued, in which Drs. BASTIAN, JAMIESON, and Mr. NOBLE SMITH took part.

Orthopedic Appliances.—Mr. NOBLE SMITH gave a demonstration of his more recent modifications of appliances in orthopedic surgery. Light splints in place of heavy instruments; the substitution of metal rods, which could be bent by the surgeon, for the highly-tempered irons usually made; the simplification of joints in instruments used after operations for club-foot, to save complication and expense; and the limitation of the restraining influence of all apparatus to the parts absolutely requiring restraint, were among the more noticeable points referred to. The treatment of contracted and relaxed joints and the application of fixation apparatus to diseased spines were also included in this practical demonstration.—A discussion followed, in which Drs. BASTIAN, JAMIESON, SHELDON, and Messrs. BUTLIN, S. BURTON, and STEELE joined.

Cases.—Dr. WEBSTER, the medical superintendent of the Infirmary, then exhibited patients suffering from diseases of much clinical interest, including a marked case of pseudo-hypertrophic paralysis, lateral sclerosis, and a rare form of skin disease.

Votes of Thanks.—The proceedings closed with the usual votes of thanks.

SOUTH-EASTERN BRANCH: WEST KENT DISTRICT.
A MEETING of the above district was held at the Hospital, Gravesend, on April 27th, R. J. BRYDEN, Esq., in the chair.

Next Meeting.—It was decided that the next meeting should be held at Maidstone in November, and that Dr. Shaw should be requested to preside on the occasion.

Election of Honorary Secretary.—A. W. Nankivell, F.R.C.S., was unanimously re-elected Honorary Secretary of the District for the ensuing year.

Communications.—The following papers were read and discussed. 1. Dr. P. HORROCKS: On Puerperal Fever. 2. Dr. TANSNILL: On Symmetrical Gangrene.

Dinner.—Twenty-eight members and visitors subsequently dined at the New Falcon Hotel.

BEQUESTS.—Sir Francis W. Grant, Bart., of Monymusk, Aberdeenshire, has bequeathed £1,000 to the St. George and St. James Dispensary.—Lady Tite, widow of Sir William Tite, C.B., has bequeathed £800 to the Hospital for Women, £100 to St. George's Hospital, and £100 to the Royal Free Hospital.

BRITISH MEDICAL ASSOCIATION.

FIFTY-SIXTH ANNUAL MEETING.

THE fifty-sixth Annual Meeting of the British Medical Association will be held at Glasgow, on Tuesday, Wednesday, Thursday, and Friday, August 7th, 8th, 9th, and 10th, 1888.

President: John T. Banks, M.D., D.Sc. (Hon.), F.K.Q.C.P.I., Regius Professor of Physic in the University of Dublin.

President-Elect: Professor W. T. Gairdner, M.D., LL.D., Professor of Medicine in the University of Glasgow.

President of the Council: Thomas Bridgwater, M.B., J.P., Harrow-on-the-Hill.

Treasurer: Constantine Holman, M.D., J.P., Reigate.

An Address in Medicine will be delivered by Thomas Clifford Allbutt, M.D., Consulting Physician, Leeds General Infirmary.

An Address in Surgery will be delivered by Sir George H. B. Macleod, M.D., Surgeon in Ordinary to Her Majesty in Scotland.

A Special Address on his "Recent Investigations in Surgery" will be given by William Macewen, M.D., Lecturer on Clinical Surgery, Glasgow Royal Infirmary.

An Address in Physiology will be delivered by John Gray McKendrick, M.D., LL.D., F.R.S., Professor of Institutes of Medicine, University of Glasgow.

All the rooms required for the purposes of the meeting will, by the kindness of the authorities, be provided in the University of Glasgow.

Humanity Class Room.

A. MEDICINE.—*President,* T. McCall Anderson, M.D. *Vice-Presidents,* W. L. Bowles, M.D.; George F. Duffey, M.D. *Honorary Secretaries,* J. McGregor Robertson, M.D., 400, Great Western Road, Glasgow; Robert M. Simon, M.D., 27, Newhall Street, Birmingham.

Chemistry Class Room.

B. SURGERY.—*President,* George Buchanan, M.D. *Vice-Presidents,* James Dunlop, M.D.; Charles Robert Bell Keetley, F.R.C.S. *Honorary Secretaries,* David Neilson Knox, M.B., 8, India Street, Glasgow; Walter Pye, F.R.C.S., 4, Sackville Street, Piccadilly, London, W.

Medical Jurisprudence Class Room.

C. OBSTETRIC MEDICINE.—*President,* Thomas More Madden, M.D. *Vice-Presidents,* William Leishman, M.D.; J. Halliday Croom, M.D. *Honorary Secretaries,* William Walter, M.D., 20, St. John Street, Manchester; W. L. Reid, M.D., 7, Royal Crescent, Glasgow.

Greek Class Room.

D. PUBLIC MEDICINE.—*President,* Henry Duncan Littlejohn, M.D. *Vice-Presidents,* James Christie, M.D.; D. Page, M.D. *Honorary Secretaries,* Ebenezer Duncan, M.D., 4, Royal Crescent, Crosshill, Glasgow; John C. McVail, M.D., Holmhead, Kilmarnock.

Hebrew Class Room.

E. PSYCHOLOGY.—*President,* James C. Howden, M.D. *Vice-Presidents,* James Rutherford, M.D.; Julius Mickle, M.D. *Honorary Secretaries,* A. R. Urquhart, M.D., Murray House, Perth; Alex. Newington, M.D., Ticehurst, Sussex.

Anatomy Class Room.

F. ANATOMY AND PHYSIOLOGY.—*President,* John Cleland, M.D., LL.D., F.R.S. *Vice-Presidents,* R. J. Anderson, M.D.; Henry Edward Clark, F.F.P.S.G. *Honorary Secretaries,* John Barlow, M.D., 27, Elmbank Crescent, Glasgow; Charles Barrett Lockwood, F.R.C.S., 19, Upper Berkeley Street, Portman Square, W.

Law Class Room.

G. PATHOLOGY.—*President,* Sir William Aitken, M.D., LL.D., F.R.S. *Vice-Presidents,* Alexander Davidson, M.D.; Joseph Coats, M.D.; Charles Roy, M.D., F.R.S. *Honorary Secretaries,* G. Sims Woodhead, M.D., 6, Marchhall Crescent, Edinburgh; J. Lindsay Steven, M.D., 34, Berkeley Terrace, Glasgow.

Midwifery Class Room.

H. OPHTHALMOLOGY.—*President,* Thomas Reid, M.D. *Vice-Presidents,* J. R. Wolfe, M.D.; C. E. Glascott, M.D. *Honorary Secretaries,* Henry Bendelack Hewetson, M.R.C.S., 11, Hanover Square, Leeds; A. Freeland Fergus, M.B., 41, Elmbank Street, Glasgow.

Biblical Class Room.

I. OTIOLOGY.—*President,* Thomas Barr, M.D. *Vice-Presidents,* John Astley Bloxam, F.R.C.S.; J. J. K. Duncanson, M.D. *Honorary Secretaries,* Johnstone Macfie, M.D., 23, Asbton Terrace, Glasgow; James Black, F.R.C.S., 16, Wimpole Street, London.

English Literature Class Room.

J. DISEASES OF CHILDREN.—*President,* Walter Butler Cheadle, M.D. *Vice-Presidents,* James Finlayson, M.D.; Henry Ashby,

M.D. *Honorary Secretaries,* George S. Middleton, M.D., 23, Sandyford Place, Glasgow; W. Arbuthnot Lane, M.S., F.R.C.S., 14, St. Thomas's Street, S.E.

Conveyancing Class Room.

K. PHARMACOLOGY AND THERAPEUTICS.—*President,* James Morton, M.D. *Vice-Presidents,* John Dougall, M.D.; Theodore Cash, M.D., F.R.S. *Honorary Secretaries,* Alexander Napier, M.D., 3, Royal Terrace, Crosshill, Glasgow; Sidney Harris Cox Martin, M.D., 60, Gower Street, London, W.C.

Divinity Class Room.

L. LARYNGOLOGY AND RHINOLOGY.—*President,* Felix Semon, M.D. *Vice-Presidents,* George Hunter Mackenzie, M.D.; Peter McBride, M.D. *Honorary Secretaries,* D. Newman, M.D., 18, Woodside Place, Glasgow; A. E. Garrod, M.D., 9, Chandos Street, Cavendish Square.

PROGRAMME OF PROCEEDINGS.

TUESDAY, AUGUST 7TH, 1888.

9.30 A.M.—Meeting of 1887-1888 Council. Randolph Hall.
11.30 A.M.—First General Meeting. Report of Council. Reports of Committees. Service in the Cathedral. Bute Hall.

8.30 P.M.—Adjourning General Meeting from 11.30 A.M. President's Address. Bute Hall.

WEDNESDAY, AUGUST 8TH, 1888.

9.30 A.M.—Meeting of 1888-89 Council. Randolph Hall.

10.30 A.M. to 2 P.M.—Sectional Meetings. Address in Medicine by Thomas Clifford Allbutt, M.D., F.R.S. Bute Hall.

THURSDAY, AUGUST 9TH, 1888.

9.30 A.M.—Address on his Recent Surgical Investigations by William Macewen, M.D. Bute Hall.

11 A.M.—Meeting of Council. Randolph Hall.

10.30 A.M. to 2 P.M.—Sectional Meetings. Address in Surgery by Sir George H. B. Macleod, M.D. Bute Hall.

7 P.M.—Public Dinner. St. Andrew's Hall.

FRIDAY, AUGUST 10TH, 1888.

10.30 A.M. to 1.30 P.M.—Sectional Meetings. Address in Physiology by John G. McKendrick, M.D., F.R.S. Bute Hall.

SATURDAY, AUGUST 11TH, 1888.

EXCURSIONS.

ANNUAL MUSEUM.

THE Annual Museum will be held on August 7th, 8th, 9th, and 10th, in the Examination Hall of the University of Glasgow, and will be arranged in the following six Sections:

SECTION A.—Food and Drugs, including Antiseptic Dressings, and other Chemical and Pharmaceutical Preparations. (Honorary Secretary, R. S. Thomson, B.Sc., M.B., C.M., 3, Melrose Street.)

SECTION B.—Pathology, comprising Casts, Models, Diagrams, Microscopical Preparations, and Micro-organisms. (Honorary Secretary, J. Lindsay Steven, M.D., 34, Berkeley Terrace.)

SECTION C.—Anatomy, comprising Special Dissections, Methods of Mounting, Abnormalities, Drawings, Medals, etc. (Honorary Secretary, J. Yule Mackay, M.D., 34, Elmbank Crescent.)

SECTION D.—Physiology, consisting of Apparatus, Microscopes, Microtomes, and Microscopical Preparations of Normal Histology. (Honorary Secretary, J. McGregor Robertson, M.A., M.B., C.M., 400, Great Western Road.)

SECTION E.—Instruments and Books, including Appliances—Medical, Surgical, and Electrical. (Honorary Secretary, J. Macintyre, M.B., C.M., 173, Bath Street.)

SECTION F.—Sanitation (1) Domestic Sanitary Appliances, embracing all improvements applicable to the Treatment of the Sick in Private Dwellings. (2) Personal Hygiene, including Dress and Gymnastic Appliances. (3) Ambulances, Carriages, and all other Appliances used for the Conveyance and Treatment of the Sick and Wounded, either in Civil, Naval, or Military Practice. (4) Drawings, Models, and Apparatus illustrative of the Ventilation, Lighting, and Draining of Hospitals. (5) Hospital Furniture. (6) Sanitary Appliances in connection with Educational Institutions and Public Buildings. (Honorary Secretary, I. 2, 3, Robert Pollok, M.B., C.M., Pollokshields; Honorary Secretary, 4, 5, and 6, A. W. Russell, M.A., M.B., C.M., Western Infirmary.)

Intending exhibitors should communicate as early as possible with the Secretary of the Section in which they propose to exhibit, as the Museum Catalogue must be complete one month before the date of meeting. Inquiries as to advertisements in the Catalogue should be sent without delay to Dr. Thomson, 3, Melrose Street, Glasgow.

Honorary General Secretaries of Museum Committee, A. Ernest Maylard, B.Sc., M.B., 54, Berkeley Terrace; R. S. Thomson, B.Sc., M.B., C.M., 3, Melrose Terrace.

FRANCIS FOWKE, *General Secretary.*

SPECIAL CORRESPONDENCE.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

Oxypropylendiisoomylamine.—Common Salt in Migraine.—Hygiene of Newborn Infants.—Vaccination Institution.—Hydrophobia in France.

At a meeting of the Société de Biologie on April 21st, M. E. Louise read a note upon the action of oxypropylendiisoomylamine on the circulation and respiration. From a considerable number of experiments on dogs that had undergone tracheotomy, it appeared that the inhibitory action is destroyed by the influence of the poison, and the heart's action becomes violent and disorderly; the pressure increases in the arteries, and the vessels of the nervous centres receive a rush of blood, causing disturbance. During the fits the heart is tetanised; this causes general congestion of the veins, which no doubt helps to prolong the epileptiform attack. The animals during the minor attack express terror or fury, which is naturally, as in the convulsive fits, the result of the anatomical connections between the brain and the heart, which render constant the exchanges and reciprocity of action between the two organs. At the same time that the heart is affected there is considerable diminution in the number of inspirations and augmentation of their amplitude.

The *Annales de la Société Médico-Chirurgicale de Liège* indicate the prevention or cure of migraine by the ingestion of a certain quantity of salt. The treatment was discovered by chance. Dr. Rabow advised a young man suffering from *petit mal* and aura to swallow some kitchen salt at the first symptoms of the aura, according to the method of Nothnagel. The prescription was carried out with success. The patient's aunt, who had suffered from migraine for several years, also adopted the plan of taking a half-spoonful or so of salt at the first appearance of the symptoms which preceded her attack of migraine. She succeeded in preventing the access, or at least of subduing it at the end of half an hour. Dr. Rabow, encouraged by this observation, employed the same remedy in other cases with equally good results. In six cases sea salt administered at the beginning of the access has produced remarkable results. With some patients, however, the method has failed. It is probably to some reflected phenomena that the above result is due.

At the meeting of the Association Française pour l'Avancement des Sciences, on April 2nd, a note from Dr. Haro, of Montpellier, was read, on a new decision of the municipality concerning the hygiene of young mothers and newborn children. Dr. Haro suggested to the Mayor of Montpellier to join to the *livret* the first principles of hygiene for women during pregnancy and confinement and newborn children. The Mayor received the proposal favourably, and at the session of the Conseil Municipal, March 7th, it was decided that the instructions drawn up by Dr. Haro, and approved by the Conseil Départemental d'Hygiène, should be added to the *livret* presented to newly married couples by the civil officer.

The formation of a Medical Institute for Vaccination, which has long been contemplated, is about to be accomplished. A commission has been formed, composed of MM. Peyron, Levrand, Vaillant, Chautemps, Dubrisay, Risler, Brouardel, Priust, Du Mesnil, Lépine, Bezançon, Mourlan, Bandouin des Salles. This Commission has consulted MM. Chauveau, who founded the Institute for Vaccination at Lyons; Nocard, director of the Vaccination College of Alfort; Vaillard, who is appointed vaccinator at Val-de-Grace; Chambon and Launay, vaccinators; Gallois and Bouvard, architects. The result of the inquiries made by this Commission will be submitted first to the Council of Inspection, and subsequently to the Municipal Council.

A Hygienic and International Exhibition will be opened at Ostend on June 3rd; particulars concerning which may be had by applying to the secretary, M. L. de Vriese, rue des Regnesses, Ghent.

M. Léon Colin, in his report on the death, caused from hydrophobia, of the soldier Marinot, draws attention to the great increase of this malady, and urges the enforcement of the measures unanimously voted by the Academy of Medicine. M. Pasteur being of the same opinion, the Hygienic Council appointed a commission to draw up a notice, which is to be posted up publicly. In this notice it is stated that hydrophobia being considerably on the increase, all dogs found wandering alone will be seized, those

without collars to be killed immediately, those with collars will be kept three days, and killed if not claimed.

BERLIN.

[FROM OUR OWN CORRESPONDENT.]

THE change of weather has had the best effect on the condition of His Majesty the Emperor. Sir Morell Mackenzie on May 17th for the first time allowed his illustrious patient to be brought into the magnificent park of Charlottenburg Castle. There he spent some time in a large and lofty tent which had been constructed for him in the quietest part of the garden, and afterwards drove in a low carriage drawn by a quiet old pony, a present from his royal mother-in-law. The experiment turned out very favourably. The evening fever, which already before had nearly totally disappeared, did not recur. His appetite and sleep are excellent. His vigour and elasticity of better days are beginning to return. He can already walk without help through the rooms of the castle, and he is in excellent spirits. It may be added that Professor Virchow, who has just returned from Egypt, could not find any carcinomatous cells in the sputum, but only pus cells. Though this negative result does not of course prove anything, it is naturally enough looked upon as encouraging by the German public. Though there is no longer any doubt about the malignant nature of the growth, this sudden and unexpected improvement gives grounds for hopes that the life on which such vast issues depend may still be prolonged for some time.

GLASGOW.

[FROM OUR OWN CORRESPONDENT.]

The Glasgow Meeting of the Association.—Pollution of Loch Long and Loch Gailhead.—Glasgow Botanic Gardens.—Andersonian Chemical Society.—Compensation for the Loss of an Eye.—Health of Greenock.—Vital Statistics for Scotland.—Orphan Homes of Scotland.

ARRANGEMENTS for the meeting at Glasgow are now very well advanced. The various sectional office-bearers are busy arranging for papers and discussions, and details for the accommodation of sections within the University have been definitely settled. Socially the meeting promises to be a marked success. The Corporation of the city and the University authorities are heartily co-operating with the various entertainment committees to make the visit to Glasgow a memorable and enjoyable one. There have been already arranged a *conversazione* to be given by the Principals and Professors of the University, a *conversazione* to be given by the Corporation of the city, and a garden party in the Botanic Gardens to be given by the Faculty of Physicians and Surgeons. Then it is expected that the Committee will be able to provide for the members visiting the International Exhibition, which has already achieved a phenomenal success, and ought to be to members of the Association a source of much attractive interest and pleasure. For the Saturday's excursions, no fewer than ten separate tours have been arranged, so that strangers will have an opportunity of seeing all that is finest in the firth, lake, and hill scenery, for which the west and middle of Scotland are famous.

Memorials from inhabitants of the shores of Loch Long and Loch Gailhead have been prepared for presentation to the Secretary for Scotland craving for immediate action being taken by the Government on the lines indicated by the recent report of Mr. Fletcher. The fishermen have also memorialised the Government on the subject.

The Corporation of Glasgow and the proprietors of the Botanic Gardens are likely to come to some agreement which will permit of the gardens being opened for the public enjoyment at a moderate charge. The gardens have been closed because of the Corporation calling for payment of £50,000 lent on the security of the gardens. This call the proprietors could not meet. The gardens have thus been shut up pending a decision being arrived at as to what is to be done with them. They are opened in the meantime only temporarily, the main question not yet being settled.

Professor Crum Brown, of Edinburgh, lectured to the Andersonian Chemical Society on May 18th on "Some Points of Interest in Chemical Theories." He expressed and illustrated the view that chemical theories, if not combined with a living knowledge of the actual facts and relations, were a poor sort of algebra, and that common sense was worth a bushel of formulae. Professor

Dittmar, who presided, moved a vote of thanks, and thanked Professor Crum Brown for having broken a lance in favour of common sense as an essential element in all chemical investigations.

In the Sheriff Court of Glasgow a boy has been awarded £65 as compensation for the loss of his left eye. He was in the employment of the Clydesdale Iron Works, and was set to fix a punch in a punching machine. In doing so part of the apparatus broke and a fragment struck his eye, destroying it. The sheriff decided that the boy was ignorant of the work and unqualified for it, and ought not to have been set to do it. He therefore awarded damages and expenses.

Dr. Wallace, the Medical Officer of Health of Greenock, reports that during April the death-rate was lower than at any time since 1875. The total mortality during the month was 94, equal to a rate of 15.6 per 1,000. In the same time 11 cases of infectious disease were reported, including 1 of typhus fever, 1 of scarlet fever, 3 of measles, 3 of whooping-cough, 1 of diphtheria, and 2 undefined.

The thirty-third annual report of the Registrar-General was recently issued. The estimated population of Scotland at the middle of 1887 was 3,991,499, of whom 1,934,215 were males and 2,057,284 females. During the year there were registered 124,375 births, 74,500 deaths, and 24,851 marriages. For every hundred estimated population there were 3.12 births, 1.87 deaths, and 0.62 marriages. The births show a lower proportion than in any previous year. The deaths were rather less in proportion in the preceding year, and the marriage-rate is a little in advance of that for 1886. The excess of births over deaths is 49,875. The highest birth-rate in the eight chief towns was in Paisley, the lowest in Perth. In the former city it is 370 per 10,000, and the birth-rate for Glasgow is 369, the Perth rate is 275. Of the total number of births, 43,057, 8.46 per cent. are illegitimate, namely, 3,643. In Aberdeen the percentage is 10.6; in Glasgow, 8.3; in Edinburgh, 8.5; in Paisley, 6.5, and in Greenock, 5.4. Of the total births in the eight towns, 22,025 were of males and 21,032 of females, the proportion of boys to girls being as 104.7 to 100. The deaths in these towns were 23,068 (males, 13,793; females, 14,275), representing a rate of 216 in every 10,000. The Paisley rate was 260 per 10,000; Glasgow, 231; Aberdeen, 218; Dundee, 212; Greenock, 198; Edinburgh, 197; Perth, 184; and Leith, 175. In all cases except Glasgow and Leith, these rates are an increase over those of 1886; and in all cases except Aberdeen and Paisley, they show a decrease on the mean for the preceding ten years. As to deaths among children under five years of age, 74 out of every 1,000 succumbed in Glasgow, in Paisley the number was 72, in Edinburgh 56, and in Perth 52. Of the total mortality the deaths among children made 47.3 per cent. in Greenock, 44 per cent. in Glasgow, 35.1 per cent. in Edinburgh, and 34.8 per cent. in Leith. The marriage-rate was 79 per 10,000, or a total of 10,266. In Glasgow it is highest at 86, and in Greenock lowest at 62. In the eight principal towns only 4 deaths from small-pox were recorded during the year.

On May 17th 120 boys and girls rescued by the Orphan Homes of Scotland sailed from the Clyde for Canada, under the care of Mr. Quarrier, the founder of the Homes. Mr. Quarrier explained at a farewell meeting that between 400 and 500 children had been rescued in the previous twelve months, and that there were at present 1,100 children in the Homes. During the year he had received money to build two new houses, and the total money received had been £14,000. He had rescued during the past seventeen years something like 5,000 children, and he calculated that that meant a saving in rates of about £200,000.

LIVERPOOL.

[FROM OUR OWN CORRESPONDENT.]

Post-graduate Course.—Funeral of Dr. Rich.—The "Cat."—Meeting of Sanitary Inspectors.

A POST-GRADUATE course of lectures is being delivered at the School of Medicine by the professors and demonstrators. The entries have been fairly numerous. This is the first time that a course of this kind has been attempted in Liverpool, and the success of the scheme that has been already attained augurs well for its future.

The funeral of the late Dr. A. C. Rich, whose early death was recorded in the JOURNAL of May 19th, took place on that day, and was attended by a large and representative gathering, both of members of the profession and of the general

public. A detachment of the 5th Lancashire Volunteers, to which regiment the deceased was surgeon, was present at the cemetery, and the path to the grave was lined by a number of the *employés* in the Liverpool postal and telegraph service, of which he was medical superintendent. A contingent of police constables was also present, the men wearing the badge of the St. John Ambulance Association, in connection with which Dr. Rich was a frequent lecturer; and there also attended representatives of charitable institutions which had enjoyed his gratuitous services.

A somewhat lively correspondence has lately appeared in the daily papers with regard to the punishment of criminals by flogging with the "cat." At the recent assizes several prisoners convicted of violence to the person were sentenced to the lash, and one of the leading Liverpool journals expressed a fear that by its use our large prisons would be converted into a kind of shambles. The "cat" consists of nine thin cords, eighteen inches long, fastened to a wooden handle twelve inches in length. The cords are not knotted, but the free ends are fastened off with fine twine. When applied it does not cause an abrasion, and the resulting ecchymoses have generally disappeared before the end of a week.

At a meeting of the Association of Sanitary Inspectors of Great Britain, held here on May 19th, resolutions were carried in favour of the due qualification of inspectors, and fixity of tenure of office; and setting forth the need of a uniform Public Health Act for the whole kingdom.

CORRESPONDENCE.

RESEARCH AT THE COLLEGE OF SURGEONS.

SIR.—In your last issue appeared an announcement inviting Fellows and Members of the College to apply for the privilege of using the new laboratories of the College of Surgeons in Lincoln's Inn Fields, and you were able to publish the conditions under which the privilege can be obtained, and the subjects of research which it is proposed shall be carried on. To those of your readers acquainted with research work, the conditions of study as laid down by the Council cannot be other than a marvel. Any Fellow or Member of the College, when applying to be permitted to work in the laboratory must send in a prospectus or description of the proposed investigation with as complete a list as possible of the necessary apparatus and instruments he will require. This has to be approved of by the Council. If the applicant is successful in his application to carry on the research he proposes, he is prohibited from undertaking any new line of research other than that originally approved by the Council without their previous sanction. If any assistance be required the investigator may provide it, but the person, or persons, proposed must be approved by the Council. It seems almost incredible that any committee, any one member of which was acquainted with research work, could have drawn up such a set of conditions. The merest tyro at research work knows full well that the conditions required by the Council are impossible. Everyone with even a slight knowledge of research work before beginning an investigation of a subject has some ideas as to how he will conduct his researches; these he may doubtless submit to the Council, but if he has had much previous experience in original work he knows full well that such a programme is utterly worthless. Before he has completed the preliminary investigation of his subject he will as likely as not find it necessary to modify considerably or even entirely change the mode of his procedure. This, however, he is prohibited from doing by the conditions under which he is permitted to use the laboratory without the consent of the Council.

It is by no means an exaggeration to assert that an experienced investigator would, in all probability, have to go to the Council six or eight times in the course of an investigation on a single subject for permission to alter his programme, each time submitting to them a course of investigation, which further research would prove useless, or yield only negative results. It is only by experience and results obtained during each stage that even a highly trained investigator can determine the course and methods he must adopt in order to work out a subject successfully. Exactly the reverse of this is expected by the Council of the College, who

expect him to apply with all the methods ready cut and dry. Unless the conditions of study are modified in this respect, the Council are taking, without doubt, the most effectual way to obstruct good research work. This is much to be regretted, as it is in their power to bestow a great boon on those members of the profession who are able and willing to carry out work in which we, as a nation, are far behind our neighbours on the Continent.

It is evidently not the purpose of the Council to provide an experienced head of the laboratory who shall give counsel and assistance to those working in the laboratory, but it seems strange that the investigator must be further handicapped by requiring to have the person or persons from whom he obtains such assistance approved of by the Council. When we contrast the regulations required by the Collège de France, the various German universities, and the University of Cambridge, of those who are willing to carry on research within their walls, we are forced to the conclusion that only inability to be absent from London for a sufficiently long period would induce men to use the Collège laboratories. In the former they are untrammelled by any hard and fast lines such as are laid down by the Collège of Surgeons, and they have likewise the advantage of the assistance in their researches of a professor or superintendent of the laboratory of great experience in research work, to whom they may at once apply for counsel and advice.—I am, etc.,

A FELLOW OF THE COLLEGE.

THE CHAIR OF HYGIENE AT NETLEY.

SIR,—The announcement made in the JOURNAL of May 19th that it is proposed to appoint Deputy Surgeon-General Marston, C.B., to the Chair of Military Hygiene in the Army Medical School, has created what is known as a "sensation" throughout the service at home, and will doubtless be regarded with like astonishment in all parts of the world where this JOURNAL circulates. Dr. Marston is a medical officer of ability—no one disputes the fact, and his best friends do not say that his public services have been overlooked. There is, however, an objection to this appointment which should be fatal to it—Dr. Marston is not a chemist. Is it right and fitting, is it even decent, that the successor to Professors Parkes and De Chaumont should be a man of whom such a thing can be truthfully said? It is true that this officer during the illness of the late professor delivered, as we have heard, some very good lectures on hygiene, embracing such parts of this great subject as did not require any special chemical knowledge; but it is equally true that he took no part in the special laboratory instruction, which, as is well known, formed the most important part of the course under Professors Parkes and De Chaumont. Dr. Marston himself would be the first to give a reason for this, to wit, incapacity. It is no discredit to Dr. Marston to say that he is not a master of this branch of science. We cannot be specialists on every subject, but if this appointment is made, the discredit will lie at the doors of those who made it.

There is only one word of three letters in the English language that will adequately characterise what will be an injury to the school, and an insult to the memory of the eminent men who filled this responsible post with honour to themselves and advantage to the State. I should not write thus strongly but that I know that my indignant sentiments are also those of the great mass of the

ARMY MEDICAL DEPARTMENT.

ELECTRICITY IN GYNÆCOLOGY.

SIR,—May I ask Mr. Lawson Tait to substantiate or withdraw a remark made by him in the JOURNAL for May 19th to the effect that I had proposed electricity "for the arrest of hæmorrhage in cases of ruptured tubal pregnancy?" I think I may safely assert that such a preposterous proposal never entered anyone's head but Mr. Tait's, and I now challenge him to bring forward the least particle of evidence upon which a rational man could found such a reckless assertion. What I have proposed and still confidently recommend is the electrical treatment of extra-uterine gestation in its early or pre-rupture stage. This plan of treatment has been for many years successfully employed in America, and is now thoroughly established and adopted by the most eminent gynæcologists of that country. I have used it, and have the honour of being the first in Britain to publish a successful case. It was related at the Brighton meeting of the Association; and Mr. Tait, who says: "He is not aware that any opposition, or abuse, or ridicule, has been directed towards the advancement of electrical

treatment," speaking after the reading of the paper, said: "He offered objections of the very strongest kind against the use of the electric current in such cases because he considered it as one of the most nonsensical proposals which had ever been submitted to a surgical audience."

Mr. Tait also maintained that electrical treatment ought to be carried out by an accomplished electrician. Now, the two cases of extra-uterine gestation treated in this country before mine were done according to the advice and with the assistance of an accomplished electrician, and in both cases a dangerous electrical method was adopted, ending in the death of both women. The position of the electrician to the gynæcologist is similar to that of the organ-blower to the organist; one supplies the force, the other directs it. But by a mechanical arrangement easily mastered the organist can blow with his foot and play with his hands. So ought the gynæcologist to master the use of the battery and direct its force with safety and efficacy, for the management of a battery can be learnt in as many hours as it takes years to make a skilled gynæcologist. What does an electrician know about the passage of a sound, or the selection of a safe spot for galvano-puncture, or the condition of a patient necessary to render the use of electricity safe?

I quite agree with Dr. Playfair that the gynæcologist is the only person in a position to carry out the details of electrical treatment without risk. It matters not whether the effect of the galvanic current be polar or interpolar, or whether the catalytic results originate in caustic, electrolytic, or cataphoric actions, or in the influence which electricity has upon the vasomotor or trophic nerves. The electrician can give us theories on these subjects, but the clinical experience of the gynæcologist must decide whether the battery is to take its place as an important electro-therapeutic agent and be permanently used by the gynæcologist.—I am, etc.,

JAMES H. AVELING.

Upper Wimpole Street, W., May 21st.

TEA AND TEETH.

SIR,—Your correspondents appear to have been unaware that in the cities of the United States of America, where tea is consumed in much smaller quantities than in this country, the teeth decay more rapidly than with us. The climate, the many indigestible articles of diet, the extreme nerve-tension of the Americans, and other causes affecting the nerve and general health of that great people tend to induce a dyspeptic condition which always seemed to me to be largely responsible for their premature dental decay.

At the same time there can be little doubt that the white bread and tea (a common though defective staple diet of too many of our own population) is a frequent cause of gastric trouble. Next to tea, alcohol, by its depravity of the digestive apparatus, has always seemed to me to interfere with tooth nutrition and soundness.

It is to be hoped that the correspondence on this subject in your columns will draw permanent attention to the great need for a judiciously-selected, nourishing, non-stimulating, and wholesome dietary.—I am, etc.,

NORMAN KERR, M.D.

42, Grove Road, Regent's Park, London, N.W., May 21st.

SIR,—The alleged influence of excessive tea drinking upon the teeth seems to excite so much interest, that it may be well to bring the matter to a definite and useful issue. It may be taken as an indisputable fact that tea can have no direct effect upon either the teeth or the tissues of the mouth leading to dental disease, and whatever effect it produces in that direction can be brought about only through its influence upon digestion on the general health. There are so many factors in the remote causation of dental disease, that it must be very difficult to demonstrate the exact part which any one of them may take, but there cannot, as some of your correspondents seem to suppose, be any difficulty in the clear recognition of any dental disease co-existent with tea drinking.

Dental diseases are few in number, simple in nature, distinct in character, and easily classified and named. Caries (decay), with its sequels inflammation of the dental pulp (nerve) or periosteum, are by far the most common of dental maladies; and in so far as tea drinking might aid in inducing dyspepsia or any affection accompanied by vitiation of the oral secretions, so far would it become a factor in exciting caries.

A correspondent who writes of dental disease and tea drinking among factory hands, will find many other things in the regimen

of these people to account for the fact which he observes. They usually earn good wages, their food is superabundant and ill cooked; they sometimes take too much beer and coarse spirit; their work is largely sedentary, and carried on in the warm, often moist, atmosphere of imperfectly ventilated rooms, so that they mostly suffer from chronic dyspepsia, and commonly accept it as an evil of life from which there is no escape. Add to this that tooth-brushes are unknown among these communities, and that the teeth remain from childhood covered with tartar, and with the *débris* of food, epithelium, and secretions—a decomposing mass constantly giving rise to formation of acid capable of dissolving enamel—and we have enough to account for the early onset and rapid progress of tooth decay from which they suffer. Some correspondents write, but rather vaguely, of maladies affecting the gums and roots of the teeth. There are well known diseases of this kind. Some of them very much resemble diseases of the hair—various kinds of baldness. In many of these instances, the patient's health being good and the teeth free from ordinary decay (caries), the teeth slowly loosen, and are lost through very gradual absorption of the alveoli, very little or no inflammation being present until towards the end. In most cases the symptoms commence with inflammation, appearing to affect simultaneously the free edge of the gum and the alveolar periosteum. The gum and alveolus slowly waste, the bone in many instances more rapidly than the gum. There is a discharge, varying in quantity, of mucus from within the loosened swollen border of the gum. Tartar may be deposited in vast masses on the exposed surfaces of the roots, but often exists only in the form of small hard black nodules beneath the gum. The disease may affect one tooth only, but more commonly attacks several at the same time, gradually extending to the whole set. The inflammation usually is extremely chronic, with occasional subacute, and, in late stages of the disease, acute exacerbations extending throughout the alveolar periosteum of the affected teeth. This disease, sometimes called pyorrhœa alveolaris, if not a disease of modern life, seems on the increase at the present day. It is probably not commonly of local origin, but beyond the fact that it is usually associated with some form of general ill-health or dyscrasia, it is impossible as yet to determine its etiology.

If correspondents interested in this subject would make accurate diagnosis of the dental diseases which they find associated with tea drinking, the first necessary step in settling the question broached will have been taken, and I venture to express a very decided opinion that tea drinking and tooth decay will be found very rarely, if ever, to exist as cause and effect, or to have any other than a merely *post hoc* relation.—I am, etc.,

40, Wimpole Street.

HENRY SEWILL.

THE RELATIVE VALUE OF THE BROMIDES.

SIR,—For the last two or three years I have thought that the basic element was the cause of some of the uncomfortable symptoms produced when the iodide or bromide of potassium has been prescribed in large and continual doses; and with the intention of, if possible, avoiding them, I have, both in my hospital work and in private practice, prescribed the soda salts instead of the potassium salts, and with marked advantage to some of the unpleasant symptoms, but with no corresponding diminution of the beneficial effects of these drugs.

I would especially mention the loss of appetite, the emaciation and nausea which occasionally happen to patients who have for long had the iodide of potassium prescribed, and the severe epigastric pain which sometimes follows the like administration of bromide of potassium. We should bear in mind that the potassium is most usually given only as a vehicle for the acid element, and it stands to reason that if we can find a more wholesome vehicle that vehicle ought to be employed. But there is moreover another reason, namely, the combining weight of potassium is 39.04, while that of sodium is only 22.99. The combining weight of iodine is 126.53, and that of bromine is 79.75. From these data we calculate that every 10 grains of bromide of potassium contain 6.72 grains of bromine, and that every 10 grains of bromide of sodium contain 7.76 grains of bromine, so that in order to prescribe the same weight of bromine we must give, instead of 10 grains of bromide of potassium, only 8.6 grains of bromide of sodium. So also with the iodide of potassium, a 10-grain dose is represented by a 9-grain dose of iodide of sodium.

Thus we see we are actually giving a smaller quantity of what we contend is a more wholesome vehicle when we prescribe the sodium salt. It is true that at present the sodium salts are little

more expensive than the potassium salts relatively to the amount of the acid element contained in them, but this is probably because the demand for the sodium salts is so much less than for the potassium salts. Soda is really less expensive than potass, so that if the demand for the soda salts increased, they would diminish in value, and would in the end become relatively cheaper than the potassium salts.—I am, etc.,

ROBERT CORX, M.D., F.R.C.P., Assistant Obstetrical Physician to St. Thomas's Hospital.

THE PROPOSED SUPPLEMENTAL CHARTER OF THE ROYAL COLLEGE OF SURGEONS.

SIR,—As an independent Member of the College, I have read with regret that an attempt has been made to patch up the differences at present existing between the Council and Members of the College, by omitting from the proposed supplemental charter certain points assumed to be the only ones in dispute.

Should this attempt succeed it is quite plain that needful reform will be indefinitely postponed, as the Members will have lost the advantage which they now possess in the necessity for a revised charter, and will be as far as ever from having a reasonable voice in the management of their own affairs and the administration of their own property.

I would further suggest that there is no good reason why either Fellows or Members should be, as at present, debarred from borrowing their own books, a privilege which is enjoyed by our American *confrères*, who can even have the books sent by mail to any part of the United States.—I am, etc.,

EDWARD HAUGHTON, M.D.

Upper Norwood, S.E., May 19th.

THE SANITARY CONDITION OF HAILEYBURY COLLEGE.

SIR,—You state in your comments on Dr. Stevenson's last analysis of the well-water (published in the *JOURNAL* of May 19th) that you "have no desire to impugn the quality of the Haileybury water." Your sincerity will, I feel sure, allow me space to point out that, in the course of those comments, you do "impugn" it—unfoundedly, I venture to think—through misapprehension and incorrect statement of the actual facts, and consequent confusion of the inferences drawn from them.

First, in his report, published in the *JOURNAL* of April 23th, your commissioner stated: "I understand that Dr. Stevenson, of Guy's Hospital, has been lately supplied with a sample (of water) for analysis, which will probably throw some light on its present quality." Your commissioner, at the time of his visit to Haileybury, was made aware of the existence and receipt of Dr. Stevenson's previous analyses, if he did not actually examine them; and—since in my letter to him of April 9th I had stated that "a sample of this clearer water is again in Dr. Stevenson's hands for analysis"—it was natural to infer that it was to this, the latest sample, that he referred in the passage I have quoted from his report.

It so happened that this sample miscarried; Dr. Stevenson, wrote to me, under date April 13th, that it had not reached him. Accordingly, fresh samples (of water presenting identical physical characters) were sent to him on April 18th. When, therefore, in your note to my letter, published on May 5th, you challenged the production of "Dr. Stevenson's last analysis, with his notes and remarks thereon, which we presume are by this time in the possession of the College authorities," it was but natural, in all good faith, to send you precisely what you had asked for, and what appeared to be all that you required, namely, the full report of the "last analysis," and the only one made subsequently to those which Mr. Bailey Denton knew to be already in existence at the time of writing his report.

Under these circumstances, was it quite fair to imply that the report sent to you by me had been substituted for the copy of a "previous analysis more applicable to the point at issue," you at the same time not publishing the remarks which I sent therewith, and which explained Dr. Stevenson's reference to the "organic impurities found in the water lately?"

Had you definitely asked for the reports on the earlier analyses, I have little doubt that they would have been at once supplied, accompanied by Dr. Stevenson's letters referring to them, and much modifying a former expression of opinion. At the present time I am not in a position to anticipate in this respect the exhaustive report which is to be laid before the Council on May 23rd.

You remind me that the sample of April 18th "was taken at a very favourable time during the holidays." In return, let me point to the equally favourable analysis (of "a phenomenally pure water"), dated October 11th, 1887—the middle of a full term.

Further, the analysis and report for which you asked (and which, you stated, you would "gladly publish") on May 5th were in your hands on the early morning of May 7th, and their receipt was acknowledged by you. The report was not published until May 19th. This may have been unavoidable, but the apparent delay in the acceptance of your challenge certainly tended to prejudice the position of Haileybury in the minds of some of your readers.

Secondly, in justice to both Dr. Stevenson and myself, I ask for the grounds of your statement (on p. 1079) that a sample of water submitted for analysis, "according to Dr. Shelly, was stated by Dr. Stevenson to have been 'most discoloured.'" That an analyst should state respecting a chalk-water that it was "most discoloured" would, of course, be strong *prima facie* evidence of its impurity; but no such phrase nor any like it occurs in any of Dr. Stevenson's analyses, reports, or letters respecting the Haileybury water; and I have no recollection of having attributed to Dr. Stevenson any expression which he did not use. It is, I submit, unfair to Haileybury to publicly state that Dr. Stevenson at any time described the water in these terms, or that I said he did so.

Thirdly, in justice to Haileybury, I ask the grounds for your statement that samples of water were sent to Dr. Stevenson for analysis "on or about Lady Day" (and again, more definitely, "on March 23rd"), because, on this quite erroneous statement, and in conjunction with the comparatively scanty rainfall which preceded that assumed date, is based the further inference that there was no "cause, atmospheric or otherwise for the discoloration of the deep water in the chalk" at the time when the sample of discoloured water was submitted for analysis.

Now for the facts. The authorities at this time were anxious to submit a sample of discoloured water—and that the darkest obtainable—for analysis. On "March 23rd," and after the fall of "only 1.65 inch of rain" (more correctly, 1.90 inch), the well-water was still bright and clear; and let me repeat, as an absolute fact, constantly verified and quite beyond mere theorising, that the well-water becomes discoloured *only* after *prolonged* and *heavy* rain. Indeed, it was not until April 3rd (that is, eleven days after than the date given by you), when nearly 4 inches (not "only 1.65 inch") of rain had fallen, and after there had been twenty-two (not "twelve") days of rain, that the water was found to be really tinged with yellow and suitable for the special purpose intended. Samples were accordingly sent to Dr. Stevenson on that day (April 3rd). All the above facts were accessible to your commissioner. It was the analysis of this water which was, as you state, in possession of the school authorities on April 7th. It reached them only that morning; it could not be handed over to Mr. Bailey Denton when he called on the master that morning (though he was told of it), as it was required for the meeting of the Council at midday. It was not subsequently asked for.

I hold no brief for Haileybury. To me—to all of us there—it would be vastly more satisfactory to detect, and thus to abolish, a definitely insanitary blot, than to be harassed by obscure and insidious inroads of disease. But I do plead for a fair statement of facts. The JOURNAL possesses a wide circulation, and wields a yet wider influence. The public is often more readily persuaded of evil than braced to impartial judgment. I believe your sincere impartiality may be trusted to correct the misstatements as to facts which I have pointed out, and to retract the false conclusions to which such statements would, if not corrected, obviously lead your readers.

Finally, may I remind such of your readers as are directly interested in Haileybury that the Council will almost immediately have before them a report—minute, lengthy, and most exhaustive—on the whole subject of the recent illness, prepared with most painstaking diligence by an expert whose distinguished ability in his department of hygienic investigation is acknowledged, and who was specially recommended to the Council by the Medical Officer of Her Majesty's Local Government Board as a man eminently fitted for such work?—I am, etc.,

CHAS. EDWD. SHELLY, M.B. Cantab., etc.,
Medical Officer, Haileybury College.

Hertford, May 21st.

THE APOTHECARIES' HALL AND THE TITLE OF ITS NEW LICENCE.

SIR,—The licence of the Society of Apothecaries is, as your correspondent of last week writes, "a full qualification" in medicine, surgery, and midwifery, and it gives to its holder the right to use the excellent title of "Apothecary," which is a designation, in the present day, far more respectable than that of "Doctor." By registering the qualification its holder acquires a right to take and use the additional title of "Surgeon," so that a registered apothecary may describe himself on his door plate, or in any other way, as of yore, "Surgeon, Apothecary, and Accoucheur." For general practitioners, what descriptions can be more respectable; what so respectable, so genuine, so honest?

Your correspondent is so unaware of the fact that the Medical Council have no power to alter the titles conferred by the licences granted by our examining bodies, that he modestly expresses a "hope" that the Council will, upon his request, anonymously made, "take up and decide at once" the question of his title, which, for want of information and reflection, he thinks should be represented by the letters "L.M. and L.S. Lond." Now, what do the public know or care about the initials of our qualifications? To the profession and to lawyers, "L.M. Lond." would imply "Licentiate in Midwifery of the Royal College of Surgeons," which would render any apothecary taking that title, unless he possessed it, liable to criminal proceedings.

It is most lamentable and amazing that members of our profession take no trouble to ascertain the legal value, the scope, the privileges of even their own qualifications, let alone the qualifications of others with whom they have to compete. Only on Friday last a young gentleman practising in Brighton as a general practitioner, without any English qualification whatever, but with two Scotch degrees of the year 1882, asserted in conversation with me, quite innocently and positively, that anyone holding a foreign degree only could put "Dr." on his door and practise in England without fear of legal molestation. However, the gentleman to whom this conversation referred knew better, for upon my demanding of him his christian name for the purpose of a prosecution by the Alliance, he wisely and at once took down his illegal description; but, for all that, the matter, as regards his employer, and who is the most to blame, will be laid before the Medical Council.—I am, etc.,

R. H. S. CARPENTER.

Stockwell Road, May 21st.

NAVAL AND MILITARY MEDICAL SERVICES.

VOLUNTEER MEDICAL ASSOCIATION.

A DEPUTATION will wait upon the Right Hon. the Secretary of State for War, on Tuesday, June 5th, at 1 P.M., relative to the needs of the Volunteer Medical Service. Those volunteer surgeons who are desirous of joining in the deputation are requested to communicate their names at once to the Honorary Secretary of the Association, Alfred Lingard, Surgeon, 3rd M.A.V., at the offices, 26, King William Street, Strand, and to meet at such place at 12 o'clock on the day named.

DEFENCE FUND FOR THE ARMY MEDICAL DEPARTMENT.

OBSERVER writes: I hope the suggestion in a recent issue of the JOURNAL will not be lost sight of, and that a defence fund may be started to protect the interests of the medical staff. I have no doubt sufficient funds will be available, if some person in an independent position, will only set the "ball rolling."

ARMY MEDICAL STAFF.

VERBUM SAP. writes: The only way for medical men to put an end to the treatment they now receive in the service is to agitate for being formed into a corps on the lines of the Royal Engineers. No other course is open to them, and they must be prepared to accept the regimental allowances and pay of a scientific corps. If one such corps can take care of itself, why should not another?

A civilian not content with his position had better enter the service, but let him beware of the reserve, or any half-and-half measures, as dangerous. When Mephistopheles cajoles and is tolerated, the dungeon is nigh and the shackles soon riveted.

MIDLAND VOLUNTEER MEDICAL ASSOCIATION.

At the third annual meeting of this Association, held at Birmingham, the invitation of Lord Burton to hold the annual field-day at the encampment of the 2nd Volunteer Battalion, North Staffordshire Regiment, in August was accepted. Surgeon-Major H. M. Morgan, of the above regiment, was elected President.

Several alterations and additions were made to the rules, among which was one the effect "that all medical officers of yeomanry, cavalry, militia, and

volunteers shall be eligible as members, and that all medical officers retiring with the right to wear the uniform of their regiments, and surgeons holding combatant commissions in the above forces may become (or remain) members of the Association." Surgeon E. L. Freer was re-elected Honorary Secretary.

The question of amalgamation with the Volunteer Medical Association was discussed, and it was decided that the President and Secretary (both members of the Council of the Volunteer Medical Association) should lay the subject before that Council at their next meeting, and report to the members at a special general meeting. The Royal Warrant for a reserve of medical officers was also discussed, opinions being somewhat divided, though it was generally considered to be an unsatisfactory result of the promises foreshadowed.

It was decided to bring the subject again forward at the special general meeting, and in the meantime for members to elicit the feeling of officers of the Medical Staff and the volunteer and medical press upon it as far as possible. The subscription to this Association is 5s. per annum, payable to Edward L. Freer (Honorary Secretary), 7, Newhall Street, Birmingham.

THE NAVY.

DEPUTY INSPECTOR-GENERAL M. W. COWAN, M.D., has been promoted to be Inspector-General. His previous commissions are dated: Surgeon, July 13th, 1854; Staff-Surgeon, September 30th, 1864; Fleet-Surgeon, November 9th, 1876; and Deputy Inspector-General, June 11th, 1883. He served in the Black Sea during the Russian war, and landed at the attacks on Kertch and Yenikale; he had temporary charge of the Russian wounded in the hospital at the latter place; he has received the Crimean medal with clasp for Sebastopol, and the Turkish medal.

Fleet-Surgeon ALEXANDER TURNBULL, M.D., has been promoted to be Deputy Inspector-General. He entered as Surgeon August 12th, 1859; became Staff-Surgeon August 19th, 1870; and Fleet-Surgeon June 2nd, 1880. He has no war record.

The following appointments have been made at the Admiralty: C. J. MANSFIELD, M.B., Surgeon to the *Duncan*; D. T. HOSKYN, M.B., Surgeon to the Plymouth Division of the Royal Marines; J. F. DONOVAN, Surgeon to the *Thunderer*.

THE MEDICAL STAFF.

SURGEONS S. O. STUART and A. DODD, on return from leave in England, are directed to do general duty in the Bombay District, Northern Division, Aden.

Surgeon-Major E. M. D. FITZGERALD, M.D., died on April 26th in Ceylon, at the age of 42. He entered the service as Assistant-Surgeon October 1st, 1867; became Surgeon March 1st, 1873; and Surgeon-Major October 1st, 1879. He does not appear to have had war experience.

Surgeon WILLIAM BATLEY, formerly of the 98th Foot, died at Chichester on May 19th, aged 69.

ARMY MEDICAL RESERVE.

SURGEON CHARLES TANFIELD VACHELL, M.D., 1st Glamorganshire Artillery Volunteers, to be Surgeon-Major (ranking as Major).

The under-mentioned officers to be Surgeons (ranking as Captains):—Acting-Surgeon ROBERT ROSS BROWN, 3rd Volunteer (Kent) Brigade Cinque Ports Division, Royal Artillery (late the 1st Kent Artillery); Acting-Surgeon WILLIAM RICHARD DAMBRILL-DAVIES, 5th Volunteer Battalion the Cheshire Regiment (late the 5th Cheshire Volunteers); Surgeon JAMES DUNCAN, M.B., 7th Lancashire Rifle Volunteer Corps; Acting-Surgeon JOHN PAYNE MASSINGHAM, 1st Shropshire and Staffordshire Artillery Volunteers; Acting-Surgeon JOHN SUTCLIFFE, 2nd Volunteer Battalion of the Duke of Wellington's West Riding Regiment (late the 6th West Riding of Yorkshire Volunteers).

THE INDIAN MEDICAL SERVICE.

BRIGADE-SURGEON A. H. HILSON, M.D., Bengal Establishment, officiating Surgeon-General Gwalior and Saugor Districts, is appointed to officiate as Inspector-General of Civil Hospital, Bengal, during the absence on privilege leave of Deputy Surgeon-General A. J. Cowie.

Sir BENJAMIN SIMPSON, M.D., K.C.I.E., Bengal Establishment, Surgeon-General and Sanitary Commissioner with the Government of India, has leave of absence for 183 days on medical certificate.

The under-mentioned gentlemen have also obtained leave of absence for the periods specified:—Surgeon-Major JOHN BENNETT, Bengal Establishment, Medical Officer to the Maharajah of Patiala, for 300 days on medical certificate; Surgeon H. W. G. MACLEOD, Bengal Establishment, for 182 days on medical certificate; Surgeon-Major P. A. WEIR, M.B., Bengal Establishment, Principal Assistant, Opium Agent, Benares, for one year; Surgeon D. F. DYMOTT, Madras Establishment, Officiating Inspector of Vaccination and Deputy Sanitary Commissioner, for three months; Surgeon A. P. FERGUSON, Bombay Establishment, for six months in extension on medical certificate.

Surgeon-Major W. C. COLES, M.D., F.R.C.S., retired, Bombay Establishment, died on May 17th at Bourton-on-the-Water, Gloucestershire, in his 71st year.

THE VOLUNTEERS.

THE under-mentioned gentlemen are appointed Acting-Surgeons to the corps specified:—CHARLES APERILL, 5th Volunteer Battalion Cheshire Regiment (late the 5th Cheshire); R. T. MEADOWS, M.B., 2nd Volunteer Battalion Duke of Cornwall's Light Infantry (late the 2nd Cornwall).

Surgeon and Honorary Surgeon-Major J. VANCE, M.D., of the 4th Volunteer Battalion Essex Regiment (late the 4th Essex), has resigned his commission, which dated from May 3rd, 1867; he is permitted to retain his rank and uniform.

Surgeon and Honorary Surgeon-Major T. W. THURSFIELD, M.D., 2nd Volunteer Battalion Royal Warwickshire Regiment (late the 2nd Warwickshire), has also resigned his commission, with permission to retain his rank and uniform; his appointment bore date November 14th, 1868.

Mr. H. G. READ has been appointed Surgeon to the London Division of the Volunteer Medical Staff.

At the 33rd annual festival dinner of the Poplar Hospital for Accidents, held last week, the Secretary (Lieutenant-Colonel Fenehan) announced subscriptions amounting to £1,349 1s. 9d.

MEDICO-LEGAL AND MEDICO-ETHICAL.

THE L.S.A. AND SURGICAL FEES.

M. and L.S.A.L.—An L.S.A. reduces a fracture of leg; the case terminates quite satisfactorily; the patient disputes the payment (£3 3s.), being thus advised by a new medical practitioner in the town, as the L.S.A. is not also a M.R.C.S. Is not the L.S.A. entitled to his fee?

* * * In reply to our correspondent's special question we are constrained to admit that, although he is indisputably morally entitled thereto, he cannot legally enforce payment of his fee of £3 3s. in the case in question, inasmuch as a person registered with a medical qualification only cannot recover for professional attendance in a surgical case, and *vice versa*. For any medicines, however, which he may have prescribed as subservient to the surgical attendance, he is entitled to charge for and recover. Comment on the new medical practitioner's reputed advice to the patient is unnecessary.

A HYPOTHETICAL CASE.

J. E. C. writes: A, B, and C are practising in the same district (residing, say, within a mile of each other). A is desirous of removing, and succeeds in securing a purchaser (D.) for his practice. Are B and C committing any breach of professional honour or etiquette in competing for appointments held by A, and which they know A is using his influence to have transferred to D, as his successor? The case is a hypothetical one; consequently, there are no attendant conditions to be taken into consideration.

* * * In the absence of knowledge of the attendant essential conditions of the "hypothetical case" submitted, we are not in a position to advise J. E. C. thereon further than that, if the vacancy of the appointment alluded to is advertised, or otherwise publicly made known, and there are no surrounding circumstances which dictate abstention from opposition to D, as the proposed successor to A, we see no valid ethical objection to B, and C, competing for the appointment.

A MEMBER.—The prolonged and evidently deliberate omission of the resident medical practitioners to return "A Member's" call of courtesy, constitutes a regrettable breach of professional etiquette, and, to our mind, indicates but too clearly a feeling of other than fraternal regard for the newcomer, whose advent must necessarily more or less interfere with their respective practices.

UNIVERSITY INTELLIGENCE.

PROFESSORIAL CHANGES IN FOREIGN UNIVERSITIES.

DOCENS DR. ENGELHARDT has been appointed as an Extraordinary Professor of Gynaecology at the University of Jena.

DR. JOS. BAUER, Extraordinary Professor in the University of Munich, has been named an Ordinary Professor of the Propædeutic Clinic there.

DOCENS DR. HERMANN HAAS, of Prague, recently died in that town owing to typhoid fever contracted in the practice of his profession.

DR. CURSCHMANN, the Director of the Hamburger Städtisches Krankenhaus, has received and accepted a call to Leipzig as Director of the Medical Clinic there, in the place of Professor E. Wagner.

DR. GEIGEL has been named Docens for Internal Medicine at Würzburg.

PROFESSOR SILVESTRINI, of Parma, has been named Ordinary Professor in the Medical Clinic at Palermo.

DR. A. RIVA, Extraordinary Professor at Pisa, has been named an Ordinary Professor in the Medical Clinic at Parma.

DR. S. KOSTJURIN has been appointed Ordinary Professor of General Pathology at Charkom.

DR. PODWYSSOTZKI, jun., has been named Extraordinary Professor of General Pathology at Kiev.

CAMBRIDGE.

CAVENDISH COLLEGE.—An examination will be held on Tuesday, July 24th, and following days, according to the results of which it is intended to award eight scholarships of £30 a year, provided that candidates of sufficient merit present themselves. Candidates must be under 18 years of age on October 1st, 1888, and may offer for examination one or more of the following subjects: classics, mathematics, natural science, modern languages. The scholars elected will be required to come into residence at Cavendish College in October, 1888, and commence study for a tripos or the engineering course. Medical students may conveniently combine their medical work with the course for the natural science tripos. It is also intended to offer in June, 1889, three scholarships of £30, to be competed for by students of the College who will then have resided not longer than one year. The College fee for board, lodging, and tuition is £25 for each of the three university terms, and £15 for residence (optional) in the Long Vacation. Further information can be had on applying to the Bursar, Cavendish College, Cambridge.

At the Congregation on Thursday, May 24th, Mr. Squier Hinnell, of Pembroke College, was admitted to the degrees of M.B. and B.C.; and Dr. Stegfried Ruhemann to the degree of M.A. *honoris causa*.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

STATISTICS OF NOTIFICATION OF DISEASE.

THE following table, drawn up by Dr. Biddle, of Kingston, gives for the twenty-eight large towns of England the zymotic death-rates for each of the six years, 1881-86, together with the averages before and after the enforcement of the notification clauses. The towns are grouped so that the average death-rate may be obtained for each of three conditions—namely, (1) where no system of notification is in force; (2) where the householder alone is under the penal clause; (3) where it is compulsory for both householder and medical attendant to notify.

Dr. Biddle's figures show that the zymotic death-rate is greater

Zymotic Death-rate per 1,000 in the Twenty-eight Large Towns of England.

For the Six Years, 1881-86, inclusive.		London.	Brighton.	Plymouth.	Bristol.	Wolverhampton.	Birmingham.	Liverpool.	Leeds.	Sheffield.	Hull.	Cardiff.	Norwich.	Nottingham.	Bradford.	Portsmouth. Group I.

Group II.

Group III.

GROUP I: 3,168, say 3.17.

GROUP AVERAGES.

GROUP II: 2,689, say 2.67.

GROUP III: 3,138, say 3.14.

In these towns there is no compulsory notification, and the average of 3.17 is equivalent to 20,830 deaths from zymotic diseases, on average in one year, out of a population of 8,606,411.

In these towns the single (householder's) notification is in force. The percentage of 2.67 is equivalent to 1,413 deaths from zymotic diseases, on an average in one year, out of a population of 529,163.

These towns were under the dual system either during the whole period or during the years below the thick line, but under no system whatever above such line. The average of 3.14 applies only to those years when the dual system was in operation, and is equivalent to 6,145 deaths from zymotic diseases, on average in one year, out of a population of 1,958,233.

HEALTH OF ENGLISH TOWNS.—In the twenty-eight large English towns, including London, which have an estimated population of 9,398,273 persons, 5,410 births and 3,398 deaths were registered during the week ending Saturday, May 19th. The annual rate of mortality, which had declined from 18.9 to 17.6 per 1,000 in the three preceding weeks, rose again during the week under notice to 18.9. The rates in the several towns ranged from 14.2 in Nottingham, 15.3 in Leicester, and 16.3 in Halifax to 23.5 in Salford, 24.5 in Norwich, and 25.6 in Blackburn. In the twenty-seven provincial towns the mean death-rate was 19.7 per 1,000, and exceeded by 1.8 the rate recorded in London, which was only 17.9 per 1,000. The 3,398 deaths registered during the week under notice included 140 which resulted from whooping-cough, 43 from diarrhoea, 49 from diphtheria, 37 from scarlet fever, 32 from measles, 30 from "fever" (principally enteric), and only 9 from small-pox; in all 330 deaths resulted from these principal zymotic diseases, against 329 and 288 in the two preceding weeks. These 330 deaths were equal to an annual rate of 1.8 per 1,000; in London the zymotic death-rate was 1.8; it also averaged 1.8 in the twenty-seven provincial towns, and ranged from 0.0 in Plymouth and in Halifax to 3.5 in Blackburn, 3.7 in Salford, 3.8 in Wolverhampton, and 4.4 in Sheffield. Measles caused the highest proportional fatality in Nottingham and Wolverhampton; scarlet fever in Bolton, Cardiff, and Blackburn; whooping-cough in Manchester, Salford, and Sheffield; and "fever" in Salford and Wolverhampton. Of the 39 deaths from diphtheria recorded during the week under notice in the twenty-eight towns, 29 occurred in London and 3 in Norwich. The 9 fatal cases of

after than before the Act is enforced, except in two cases—namely, Halifax, in which the death-rate declined from an already good average 2.3 to 1.7, and Sunderland, where only one year is given to afford an average for the after state of things; and even here the record has been beaten in a previous year.

In Portsmouth the effect of the Act has been to raise the zymotic death-rate from 3.3 to 3.5 per 1,000; in Manchester the zymotic death-rate was only 2.3 per 1,000 in the year preceding the Act, but has averaged 3.4 since; in Salford it has risen from 3.4 to 3.7; and in Newcastle it has plunged from 2.9 to 3.6. Dr. Biddle adds: "If the calculations based on the appended table be correct, as I believe they are, and we further wish to know what the respective effects of the single and dual systems would be, if enforced over a population of 30,000,000, we find that the former would save 15,000 lives per annum, whilst the latter, if not positively destructive of life, would be of no sort of compensatory value as a death-preventive."

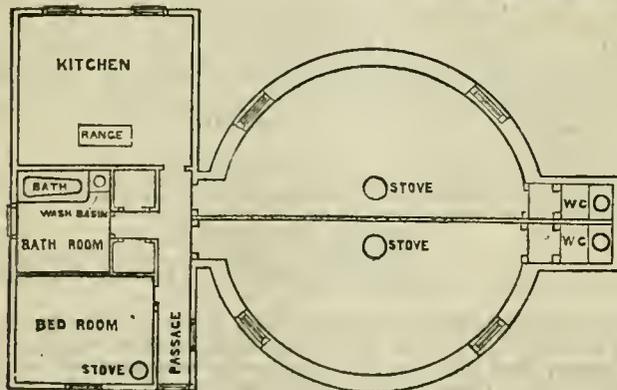

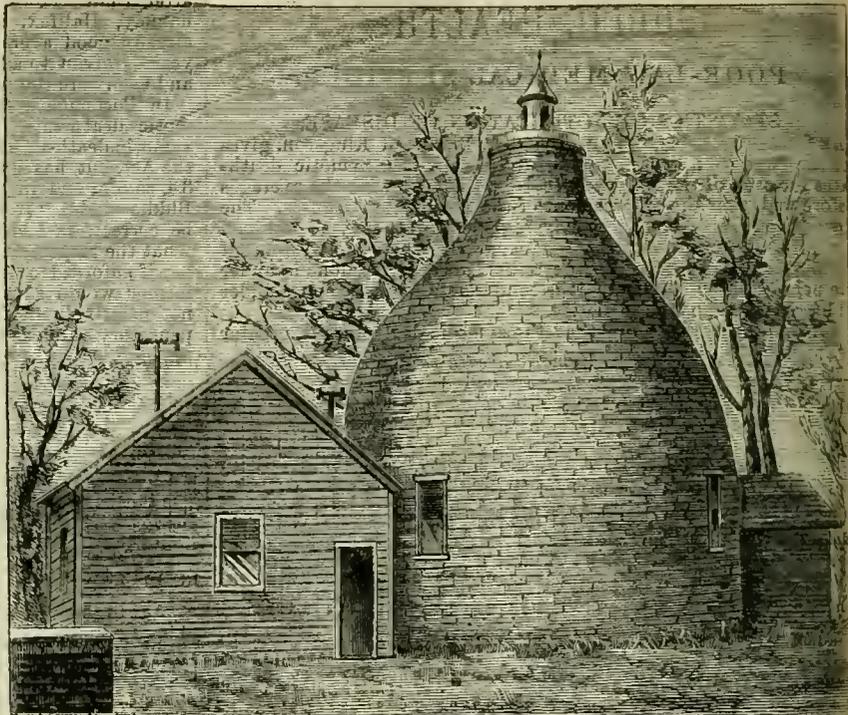

small-pox included 8 in Sheffield and 1 in Bristol. The number of small-pox patients in the Metropolitan Asylums Hospitals on Saturday, May 19th, was 6, not one having been admitted during the week. These hospitals also contained 915 scarlet fever patients on the same date, which showed an increase of 11 upon the number at the end of the previous week; 82 cases were admitted during the week, against 91 in the previous week. The death-rate from diseases of the respiratory organs in London was equal to 3.5 per 1,000, and was slightly below the average.

HEALTH OF SCOTCH TOWNS.—During the week ending Saturday, May 19th, 900 births and 488 deaths were registered in the eight principal Scotch towns. The annual rate of mortality, which had been 19.5 and 21.1 per 1,000 in the two preceding weeks, declined to 19.3 during the week under notice, but exceeded by 0.4 per 1,000 the mean rate during the same period in the twenty-eight large English towns. Among these Scotch towns the lowest rates were recorded in Paisley and Greenock, and the highest in Edinburgh and Glasgow. The 488 deaths in these towns during the week under notice included 41 which were referred to the principal zymotic diseases, equal to an annual rate of 1.6 per 1,000, which was below the mean zymotic death-rate during the same period in the large English towns. The highest zymotic rates were recorded in Edinburgh and Glasgow. Eleven fatal cases of whooping-cough and 10 of measles were recorded in Glasgow. The mortality from diseases of the respiratory organs in these towns was equal to 3.8 per 1,000, against 3.5 in London.

SWINTON SMALL-POX HOSPITAL.

THIS hospital, which is represented in the accompanying sketch and plan, consists of a circular brick building 30 feet in diameter, with a wooden floor and a wooden ceiling at a height of 11 feet 3 inches. It is divided into two wards by a double boarded partition down the centre. There are four windows and four 8-inch fresh air inlets, and two outlets in the ceiling. There is a closet for each ward built outside the brickwork, but communicating with the ward by double doors. The hovel is surmounted by one of Boyle's 3 feet air pumps, which, with an average wind, entirely renews the air in the building four times per hour.

The administrative department is built adjoining of double lined boards, and roofed with boards covered with a waterproof felt. It consists of an entrance passage, a kitchen 16 feet \times 14 feet, containing a cooking range, a bath-room 10 feet \times 8 feet with hot and cold water, two pantries, and a nurses' bedroom 12 feet \times 10 feet, all 10½ feet high. There is one tortoise stove in each ward, and a smaller one in the nurses' room. The cost for erection was £128; for stores, bath and fittings, £44; for 16 beds and furnishing, £50 18s.; total, £222 18s.

THE CLOSURE OF CONTAMINATED WELLS.

Two recent magisterial decisions with regard to the closing of contaminated wells—one at Enfield and the other at Birmingham—have called the attention of medical officers and others to the powerlessness of the Public Health Act to ensure the closure of wells containing contaminated water. At a meeting of the Society of Medical Officers of Health, held on Friday, May 18th, presided over by Dr. A. HILL, of Birmingham, this important question was discussed.

Mr. LLOYD raised the question what, in the words of the 70th section of the Public Health Act, constituted "water injurious to health?" The presence of sewage matters in a potable water even when in large quantity, appeared not necessarily to do so, though if the sewage contained the germs of disease, it would. Was the chemist, by means of variation in the chemical composition of the water, able to detect the injurious one? In reply, he said Dupré, Frankland, and Wanklyn had shown that no sufficient chemical variation to be of a decisive character existed. It was equally impossible to prove the presence of disease germs by the methods of the bacteriologist, and such proof, even though possible, was practically prohibited. Recognising these facts he had, when re-

porting upon contaminated water, simply stated the water contained sewage, and was therefore unfit for drinking purposes, and this had sufficed in most cases to ensure the closing of the wells; but recently a contested case at Enfield was lost, on the ground that the report did not use the words of the Act. Enfield it was stated, had for several months past been suffering from more or less continued diphtheria, the source of which the Local Board of Health had been actively engaged in trying to discover. A sample of the water submitted to him on December 20th, gave the following result. Total solid matter, 83.72; loss on heat, 7.00; oxygen absorbed, 0.157; chlorine, 8.40; equal to common salt, 13.84; nitrogen as nitrates, 2.28; free saline ammonia, 0.084; organic albuminoid ammonia, 0.008. He, therefore, condemned the water as containing sewage, and as totally unfit for drinking purposes. The owner of the well disputed his report, and an analysis on his behalf was made by Mr. Gregory, who found practically the same result, with the exception of the nitrates, which he gives as 4.22, and who reported "a perfectly safe water to use for drinking and domestic purposes, being free from any trace of sewage contamination." In view of the conflicting evidence, the magistrate decided to send a sample to Dr. Bell, at Somerset House, and he, in his report, stated that his results did not differ materially from the previous analyses. It was evident, he thought, from the large quantity of saline matters present, that it passed through a stratum of earth largely charged with sewage or organic refuse, and carried down with it various products resulting from the oxidation of the organic matter which, though not dangerous to health, was very objectionable. As to how such a sentence came in the Act, he thought it was taken for granted that the mere presence of sewage in potable water was *prima facie* evidence that the water was injurious, and that view was supported by the fact that in the Sixth Report of the Rivers Commission on Domestic Water Supply, river water receiving sewage, and shallow well waters were designated dangerous without any consideration of the quantity of pollutions. So long as Somerset House was made the court of appeal, it practically amounted to an inability to close polluted wells.—The CHAIRMAN referred to his own recent experience at Birmingham in a case commented on in the JOURNAL last week. He did not consider the average chemist fit to be an arbitrator of the physiological significance of a polluted well, because chemistry by itself was totally inadequate to decide the question whether the pollution

May 26, 1888.]

was injurious or not. Microscopy was equally inadequate to answer the question. He knew only one test, and that was the one of illness or death produced by the use of the water. If after the drinking of polluted water such marked effects were produced as seen in the case of the Broad Street pump during the cholera epidemic of 1866, then the medical officer would have no difficulty. Such proofs were not to be got in the case of all polluted waters, and the only other course for them to pursue was to condemn all waters found polluted with animal and excrementitious matters. Unfortunately they had not the arbitration of the question in their own hands. They were settled for them by the special pleading of lawyers, who impressed their views on the minds of magistrates, without any special training in chemistry, physiology, or law. Dr. Hill pointed out how difficult it was to prove drinking water to be absolutely "injurious to health," and he thought the intention of the Legislature was to say "dangerous," hence all their difficulties. The lawyer would say, "If, after drinking that water for twenty-five years, a man still remains in perfect health, do you mean to say that that can be injurious?" He (Dr. Hill) did not mean to say anything of the kind. He contended that it was a dangerous water, and might become injurious at any moment. It was, he contended, impossible to bring a case of the kind before the Court with any prospect of a verdict. It was an important question which affected the whole kingdom. Individually they had no power. In such cases the medical officer should have the support of a barrister, and not be left alone to fight the battle, as he had been, against two leading barristers and six London chemists. They must, he said, bring all the combined influence they could upon the Legislature, and agitate for an alteration of the expression "injurious" in the Act to what no doubt was intended and alone was reasonable, namely, "dangerous."—Dr. RIDGE said the occurrence of four cases of typhoid in one of five houses supplied by a shallow well ten feet distant from the houses in gravel soil, gave rise to the proceedings referred to. They had every condition likely to produce pollution of the water, if there had been the least leakage of any of the numerous drains.—Mr. SHIRLEY MURPHY: I suppose Dr. Bell did not state it was injurious to health?—Mr. LLOYD: "Not absolutely dangerous" were his words.—The CHAIRMAN said he had known a well with 0.005 of organic ammonia produce typhoid fever and a number of cases and death.—Dr. DUFFIELD expressed surprise that no reference was made by Dr. Ridge to the enteric fever cases. Physiological proof was wanted, and there it was. They would like to know something about them.—Dr. RIDGE said he was unable to supply the information.

It was proposed and resolved to refer the cases in question to counsel for consideration, and to take such steps as they might deem advisable.

GUARDIANS AND MEDICAL OFFICERS.

WE are very glad to be able to announce that the Local Government Board has refused to confirm the resolution of the Holborn guardians, calling upon Mr. Marshall to resign his office of medical officer to their schools at Mitcham. It is satisfactory to know that members of the medical profession are not always to be ridden over by Boards of Guardians at their sweet will. No doubt the support accorded to Mr. Marshall by his professional brethren at Croydon has assisted the Local Government Board to come to a right decision in his case.

SIR ROBERT RAWLINSON ON METROPOLITAN SEWAGE.

THE sewage precipitation works of the Board of Works at Barking and Crossness fill Sir Robert Rawlinson as a sanitary engineer with astonishment and as a ratepayer with indignation. He considers that the outfalls ought never to have been established, and that the present outlay of more than a million sterling, and half a million per annum to keep the works going, can only aggravate existing evils. The sludge precipitation and sludge barges would be huge and costly abominations. The officials of the Board were wilfully sinning against light and evidence obtained by themselves and furnished by Royal commissioners. They ought to know that the only way to deal with crude sewage economically was to irrigate the land with it, as at Berlin, and at scores of places in England—Birmingham, Bradford, Doncaster, and others. He recommended that conduits should be made from Barking and Crossness to Canvey Island or to the Fens, and arrangements made for the application of sewage on the road from both sides of the sewage conduits, and in time every gallon of sewage would

be taken—would be used and paid for by the adjoining farmers and landowners. It is well known that Sir Robert Rawlinson's view as to the application of sewage to land was expressly recommended by Lord Bramwell's Commission, but no action has hitherto been taken with that object.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

JARROW (Population, 30,000).—*Typhus Imported*.—Dr. Campbell Munro refers as usual to the depression of trade in this borough in his report for the year 1886. It is again satisfactory to observe that, notwithstanding the depression was felt with exceptional intensity during the year, the health of the town did not appear to be much affected by it. The death-rate, which in 1885 was 22.1, fell to 20.7. Besides a lower death-rate, the town enjoyed an unusual freedom from infectious disease, the number of cases notified being lower than in any year since 1880. The zymotic death-rate was 3.9, as compared with 4.4 in the previous year. No case of small-pox appeared in the borough during the year. Although measles was excessively prevalent in 1885, only 3 cases were notified in 1886, one of which proved fatal. Dr. Munro mentions that the medical men of the town have been requested by the council to notify all cases of this disease, although it was not compulsorily notifiable under the Jarrow Improvement Act. Of the cases of fever notified during the year, 2 were of typhus and 22 of enteric fever. Each of the typhus cases was imported, and from the second case the disease spread to 3 other members of the household, one of whom died.

KIDDERMINSTER URBAN. *Prevalence of Measles and Sore Throats: Value of Hospital*.—Mr. Corbet is to be congratulated on the satisfactory state of his district, as shown by the decreasing mortality during the past few years, especially in 1887, when the death-rate fell to 16.9 per 1,000. The deaths from zymotic diseases were fewer than in any year since 1884. Measles was the most extensively prevalent, 226 cases coming under notice, whilst doubtless there were many others which were not made known to the authority. Mr. Corbet testifies to the valuable assistance afforded by the Borough Hospital in preventing an epidemic of scarlet fever; 31 out of 49 cases were admitted, and only one death occurred. In the autumn months sore throats were very prevalent in the higher parts of the town. The cases were more troublesome than severe. Inquiry and search were made, but no reason could be assigned for the malady. Seven cases of true diphtheria occurred, of which 5 were fatal.

HOLSWORTHY RURAL (Population, 9,008).—*Diphtheritic Throat Affections Prevalent: Influence of Schools*.—This district was exceptionally free from epidemic disease during 1887. Dr. Linnington Ash states that of the seven principal zymotics, three only were seriously prevalent, namely, diphtheria, whooping-cough, and diarrhoea. The death-rate from these causes was 0.6, out of a general rate of 15.2 per 1,000, and related to six deaths only. The general sickness throughout the year was greatly below the average. There was a remarkable absence of pulmonary diseases, which are usually the scourge of the district, and Dr. Ash considers it more than probable that 1887 will be one of the healthiest years on record. One death from diphtheria was registered, but an epidemic of a disease of a very suspicious character and wide-spread, was prevalent in the northern part of the district. Dr. Ash describes the cases as mild, and partaking of the nature of simple ulceration of the tonsils, with sympathetic glandular enlargement around the throat. There was no evidence of fibrinous exudation characteristic of diphtheria, nor any subsequent symptoms of paralysis. Other medical men shared Dr. Ash's doubts as to the precise nature of the affection, but all agreed that it was eminently infectious. The cases were so numerous that the schools closed themselves by reason of the non-attendance of scholars. Dr. Ash thinks there is increasing evidence of the operation of elementary schools as an important factor in the spread of these epidemic diseases, and of the necessity for closing them on the first approach of any such disorder. The absence of any provision for isolation, and for the precise disinfection of clothing, is a serious hindrance to the effective management of cases, and renders the more necessary an immediate recourse to all available means of precaution. Dr. Ash stigmatises the rude and ignorant use of disinfectants as employed in this part of the country as "a waste of money, a delusion, and a danger."

BATH.—*Imported Small-pox.*—The usual evidence of longevity in Bath is again shown in the annual report of Dr. Brabazon by the fact that of 1,094 deaths during 1886, 117 were of persons aged 80 and upwards. The principal factors in the general mortality were diseases of the respiratory organs and constitutional diseases. Dr. Brabazon reports a very low rate of zymotic mortality—0.4 per 1,000. Whooping-cough was the most active agent in producing this result, causing 15 deaths out of the total of 22 for the year. Nearly all the cases of zymotic disease had their origin without the city. The most serious occasion for anxiety was in the beginning of the year, when small-pox was introduced from Bristol, and, being unrecognised, the patient was allowed to visit his friends with the disease in the pustular stage upon him. Several cases followed, all of which were removed to hospital. One death resulted. Revaccination was carried out and the houses disinfected, and by these means the outbreak was restricted to the districts in which the first case occurred. The corrected death-rate is stated to be 18.03 per 1,000.

RIVER TYNE PORT.—*Thorough Supervision of Shipping.*—Mr. Henry E. Armstrong states, in his report for 1887, that the diminished prevalence of cholera abroad, and its absence from the Tyne, as also the small amount of other infectious sickness coming under observation during the year, are matters for general satisfaction. Owing to the decline of the former disease, the vessels arriving from foreign infected ports were much fewer in number, and, consequently, the work of supervision required in this particular was less arduous than before. At the same time the record of ships inspected during 1887 is, except that for the year 1885, when cholera was so prevalent, the largest since the formation of the sanitary authority. Cases of sickness, infectious and otherwise, to the number of 218, were inquired into, and dealt with as occasion required. Six vessels from abroad reporting "all well" to the customs officers were subsequently found to have cases of serious illness on board. Nine patients were admitted to the Floating Hospital, including 3 cases of scarlet fever, 2 of enteric fever, and 1 of small-pox. They were all discharged cured. As usual, the movements of all vessels reported from suspected places were carefully watched, and deaths at foreign ports or at sea were inquired into. It would be well if the supervision of shipping at all our ports were carried out with the system and thoroughness which characterise the work on the Tyne.

TORQUAY (Population, 25,000).—*Favourable Statistics.*—The account of zymotic diseases given by Mr. Paul Q. Karkeek in his report for 1887 may be considered very favourable. Seven deaths only were assigned to these causes, or a rate of 0.28 per 1,000. The cases notified to the authority were 2 of diphtheria, 13 of enteric fever, and 32 of scarlatina. These last were all of a very mild type; 3 were traced to direct importation; a group of 9 were associated with a school; 10 occurred in one parish; and in the others the source of infection could not be traced. Of the 13 enteric fever cases, most were due to sanitary defects, 2 were imported, and 1 was a nurse who contracted her illness while in the discharge of her duties. There was but little autumnal diarrhoea, although the season was unusually dry, and only 3 cases proved fatal; 1 of these was choleraic, and rapidly killed an adult whose health had been previously much enfeebled. The total number of deaths was 333, the smallest figure for twenty-three years. Deducting the deaths of 44 visitors, the death-rate for 1887 was 11.5 per 1,000.

FEES FOR ATTENDANCE ON PRIVATE BILL COMMITTEES.

SANITARY AND POLICE.—It is impossible to lay down a general rule, but, as a rough indication, we would state that a charge of ten guineas a day, and all hotel and travelling expenses, while attending in London to give evidence before a Private Bill Committee, would not be too high if our correspondent were not in the service of the authority; a reduction might then be reasonably expected.

IRISH LUNATIC ASYLUMS.—Dr. W. Z. Myles, Senior Assistant at the Richmond District Asylum, Dublin, has been appointed Superintendent of the asylum at Kilkenny in succession to the late Dr. Barry Delany. The salary is £550 per annum, with allowances.—The Lord Lieutenant has authorised the expenditure of £3,500 for the completion of the sanitary improvements at the Richmond District Lunatic Asylum, and £250 for repairs of the Limerick Lunatic Asylum.

MEDICO-PARLIAMENTARY.

HOUSE OF COMMONS.—Friday, May 18th.

The Royal College of Surgeons.—Dr. FARQUHARSON asked the Vice-President of the Council of Education whether he would lay upon the table a copy of the petition for reform in the constitution of the Royal College of Surgeons of England, signed by 6,000 Members of the College, and addressed to the Lord President of the Privy Council, together with a copy of the statement and contentions in support thereof made to the Lord President by the deputation of members which waited upon him on November 11th, 1887; and whether he would state if that statement was referred to the President and Council of the College for reply; whether any reply was received; and on what grounds the Privy Council had, in the absence of any reply, and without further communication with the Members of the College or their representatives, decided to negative their request for such reform.—Sir W. HART DYKE, in reply, said there would be no objection to lay on the table a copy of the petition and statement of the Members of the Royal College of Surgeons. The statement was referred to the College, and the receipt acknowledged. The Privy Council subsequently decided to strike out the contentious clauses from the draft charter, and the College had agreed to accept the supplemental charter on those terms.

OBITUARY.

JAMES RIGBY, M.R.C.S.E., L.S.A.

WE are sorry to record the death on May 5th, after a somewhat protracted illness, of Mr. Rigby, who occupied a high and honourable position in the profession at Doncaster, where he had practised for thirty-four years. The deceased gentleman was a native of Stockport, born in November, 1825, and commenced his professional career at a time when the old apprenticeship system was still in operation. He was articled to the late Dr. Rayner, of Stockport, one of the earliest graduates of the London University, and subsequently entered at University College, where he passed through his curriculum with great distinction, obtaining gold medals in chemistry and materia medica, silver medals in anatomy and physiology, and certificates of proficiency in other subjects. He also obtained the gold medal awarded by the Apothecaries' Society for general proficiency. He passed the first M.B.Lond. examination in 1848, but did not proceed to take the degree. After qualifying he was elected in 1850 house-surgeon to the Stockport Infirmary. In 1854 he joined the late Mr. Russell, of Doncaster, in partnership, an arrangement which terminated by mutual consent in 1858. In that year Mr. Rigby commenced practice for himself. Associated with the Doncaster Infirmary from its establishment in 1867, and being one of its first surgeons, he held for nineteen years the appointment of honorary surgeon to this institution, retiring in 1886 as consulting surgeon. In 1861 he was elected honorary surgeon to the Doncaster Dispensary, in succession to Dr. Withers Moore, who at this time removed to Brighton. His predilections were for surgery, and he soon acquired a reputation as a successful operator, and was one of the first to perform lateral lithotomy in Doncaster. Towards the end of 1887 he began to show signs of failing health. He had suffered for many years from a discharge from the right ear, pointing to some form of intra-cranial suppuration. In spite of a certain brusqueness of manner, his strict professional integrity and uprightness of conduct, and his quick insight into the nature of disease, were recognised by a select *clientele* to whom he was much endeared, and who knew how to value and appreciate his many sterling qualities. His funeral, which took place on the 7th, was attended by most of his medical brethren and a large and representative gathering of his fellow townsmen.

SANITARY INSTITUTE OF GREAT BRITAIN.—At the annual general meeting held at the Parkes Museum on Wednesday, May 16th, Professor W. H. Corfield, M.A., M.D. (Chairman of Council) in the chair, a report was presented by the Council on the work of the institute during last year, and on the Congress at Bolton in the autumn of 1887. The Chairman gave an address, and the officers for the ensuing year were elected.

INDIA AND THE COLONIES.

INDIA.

WE regret to hear from Madras the sad intelligence of the death of Surgeon-Major John Prendergast, from drowning, at Kirkee. The deceased officer and a subaltern of artillery, Lieutenant Falziner, were out together in a small boat on the Moola Mootha river, when the light craft was capsized by a sudden gust of wind, both the occupants being precipitated into the water. Both lives were lost. Dr. Prendergast's commission dated from March 1st, 1874. He was promoted to the rank of Surgeon-Major when stationed at Quetta, two or three years ago; thence he was transferred to Purandhur, going to Poona in January last, to act as Brigade-Surgeon for Dr. Gaye. Dr. Prendergast received a spear wound in the lungs at Tel-el-Kebir, while in attendance on the wounded, and was for a time dangerously ill at the hospital at Juez. He was stationed at Wanowrie in 1878.

THE Surgeon-General Moore Memorial Fund is, we learn from Bombay, making satisfactory progress. The subscription list, which already shows a substantial sum, includes 500 rupees from His Highness the Gaekwar of Baroda. It has been provisionally determined that the memorial will take the form in the first instance of a bust or portrait, and that any other funds available shall be used to found a medical scholarship or prize; the question, however, will be submitted to a general meeting of the subscribers.

In the list of the Queen's birthday honours, consisting of promotions in and appointments to the Most Distinguished Order of St. Michael and St. George, in the *London Gazette* of Thursday, occur the names of William Raymond Kynsey, Esq., Principal Civil Medical Officer and Inspector-General of Hospitals of the Island of Ceylon, and Anthony Colling Brownless, M.D., Chancellor of the University of Melbourne, who have been appointed Ordinary Members of the Third Class, or Companions of the Most Distinguished Order.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their primary examinations in Anatomy and physiology for the Diploma of Fellow at a meeting of the Board of Examiners on May 21st, 22nd, and 23rd, and when eligible will be admitted to the pass examination, namely:—

H. S. Ballance, King's College; A. E. Berry, Owens College, Manchester; G. F. Blacker, University College; C. C. Braine, Charing Cross Hospital; F. Calder, Bristol Medical School; W. T. Clegg, Liverpool Infirmary School of Medicine; L. Cobbett, St. Thomas's Hospital; A. T. Collam, Charing Cross Hospital; W. C. Devereux, Middlesex Hospital; C. Douglas, St. George's Hospital; T. A. Duker, St. Thomas's Hospital; W. F. Parcombe, St. Bartholomew's Hospital; A. G. Francis, St. Bartholomew's Hospital; J. Galloway, Aberdeen and London Hospital; T. C. Grey, Bristol Medical School; F. Johnson, St. Bartholomew's Hospital; R. Johnson, University College; O. M. Jones, London Hospital; A. S. Kenny, King's College; H. B. Luard, Cambridge and St. Thomas's Hospital; R. H. Lucy, London Hospital; F. H. Napier, St. Bartholomew's Hospital; T. Redmayne, Cambridge and London Hospital; R. H. Russell, King's College; W. T. H. Spicer, St. Bartholomew's Hospital; A. Street, Leeds and Cambridge; E. Teichmann, Queen's College, Birmingham; J. L. Thomas, St. Bartholomew's Hospital; W. T. Thomas, University College; M. L. Trechmann, Edinburgh and St. Bartholomew's Hospital; A. L. Vernon, St. George's Hospital; G. Wilkinson, Cambridge University.

MEDICAL VACANCIES.

The following Vacancies are announced:

ALTINGLASS UNION.—Medical Officer, Duplein Dispensary. Salary, £135 per annum, and fees. Applications to Captain Heighton, J.P., Honorary Secretary, Donard House. Election on June 13th.

ERKS COUNTY ASYLUM, Wallingford.—Assistant Medical Officer as *Locum Tenens*. Two guineas per week, with board, etc. Applications to J. Harrington, Esq., Medical Superintendent.

IRMINGHAM AND MIDLAND SKIN AND LOCK HOSPITAL.—Acting Surgeon. Applications by May 26th to J. R. Hartley, Esq., 13, St. Paul's Square, Birmingham.

BOARD OF WORKS FOR THE WANDSWORTH DISTRICT.—Medical Officer for the Parish of Clapham. Salary, £75 per annum, with increase. Applications by June 12th to the Clerk to the Board, East Hill, Wandsworth.

RECON INFIRMARY.—Resident House-Surgeon. Salary, £100 per annum, with furnished apartments, etc. Applications by June 6th to the Secretary.

BRIGHTON, HOVE, AND PRESTON DISPENSARY.—House-Surgeon. Salary, £140, with apartments, etc. Applications by June 2nd to the Assistant Secretary.

CHELSEA HOSPITAL FOR WOMEN.—Resident Medical Officer. Salary, £60, with board and residence. Applications by May 31st to the Secretary.

CHILDREN'S HOSPITAL, Birmingham.—Assistant Resident Medical Officer. Salary, £40, with board and lodging. Applications by June 6th to the Secretary.

CHILDREN'S HOSPITAL, Birmingham.—Resident Medical Officer. Salary, £30, with board and lodging. Applications by June 6th to the Secretary.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—Assistant Physician. Applications by June 7th to the Secretary.

COUNTIES ASYLUM, Carlisle.—Assistant Medical Superintendent. Salary, £120, with board. Applications by May 29th to Dr. Campbell, Carlisle, Carlisle.

FOLKESTONE FRIENDLY SOCIETIES' MEDICAL ASSOCIATION.—Medical Officer. Salary, £150, with fees and unfurnished apartments. Applications by June 6th to the Secretary, 47, St. Michael's Street, Folkestone.

FULHAM UNION.—Resident Medical Superintendent of Infirmary, and Medical Officer of the Union Workhouse. Salary, £350, with residence, etc. Applications by June 5th to the Clerk to the Guardians.

GENERAL INFIRMARY, Leeds.—Ida Convalescent Home, Cookridge.—Resident Medical Officer. Honorarium of £25 for six months, with board and lodging. Applications by June 1st to W. H. Brown, Esq., 19, Queen Street, Leeds.

GORDON HOSPITAL FOR FISTULA, etc., Vauxhall Bridge Road.—Assistant Surgeon. Applications by May 23rd to the Secretary.

HOSPITAL FOR DISEASES OF THE THROAT, Golden Square.—Resident Medical Officer. Salary, £50 per annum, with board and lodging. Applications by May 26th to the Honorary Secretary.

KING'S COLLEGE HOSPITAL.—Assistant-Surgeon. Applications to the Secretary.

LONDON TEMPERANCE HOSPITAL, Hampstead Road.—Surgeon. Applications by June 18th to the Secretary.

METROPOLITAN ASYLUMS BOARD; DARENTH SCHOOL FOR IMBECILE CHILDREN, Dartford.—Assistant Medical Officer. Salary £120 per annum, with board and lodging, etc. Applications by May 31st to W. F. Jobb, Esq., Norfolk House, Norfolk Street, Strand.

METROPOLITAN ASYLUMS BOARD; WESTERN FEVER HOSPITAL, Fulham, S.W.—Clinical Assistant. Board and lodging. Applications to the Medical Superintendent at the Hospital.

NORTH LONDON CONSUMPTION HOSPITAL, Hampstead and London.—Resident Medical Officer. Salary, £50 per annum, with board and lodging. Applications by June 2nd to the Secretary.

OWENS COLLEGE, Manchester.—Professor of Surgery. Applications by June 9th to the Registrar.

QUEEN'S COLLEGE, Birmingham.—Assistant Medical Tutor. Applications by June 20th to the Secretary.

ST. PETER'S HOSPITAL FOR STONE, etc., Henrietta Street, Covent Garden.—House-Surgeon. Honorarium, 25 guineas, with board, lodging, etc. Applications by May 29th to the Secretary.

SHEFFIELD GENERAL INFIRMARY.—House-Surgeon. Salary, £120, with board, lodging, etc. Applications by June 18th to the Secretary.

SHEFFIELD GENERAL INFIRMARY.—Assistant House-Surgeon. Salary, £80 per annum, with board, lodging, etc. Applications by June 18th to the Secretary.

UNIVERSITY COLLEGE, LONDON.—Professor of Botany. Applications by May 30th to the Secretary.

VICTORIA HOSPITAL FOR CHILDREN, Chelsea.—House-Physician. Honorarium of £50, with board and lodging. Applications by June 2nd to the Secretary.

VICTORIA HOSPITAL FOR CHILDREN, Chelsea.—House-Surgeon. Honorarium of £50, with board and lodging. Applications by June 2nd to the Secretary.

WELLINGBOROUGH AND DISTRICT MEDICAL INSTITUTE.—Medical Officer. Salary, £280, and fees, with dwelling-house, etc. Applications to G. Bayes, Esq., Jackson's Lane, Wellingborough.

WESTPORT UNION.—Medical Officer, Westport No. 2 and Louisburgh No. 2 Districts. Salary, £39 per annum, and fees. Election on June 24th.

MEDICAL APPOINTMENTS.

BIDWELL, L. A., M.R.C.S., L.S.A. (Extension), appointed House-Surgeon to St. Thomas's Hospital.

BRISTOWE, H. C., L.R.C.P., M.R.C.S., appointed Clinical Assistant in the Ear Department of St. Thomas's Hospital.

BULSTRODE, H. T., M.B., B.C. Cantab., L.R.C.P., M.R.C.S. (Extension), appointed Clinical Assistant in the Throat Department of St. Thomas's Hospital.

CALVERT, J. T., M.B. Lond., L.R.C.P., M.R.C.S. (Extension), appointed Non-Resident House-Physician to St. Thomas's Hospital.

COOK, S. B., L.R.C.P., M.R.C.S. (Extension), appointed Assistant House-Physician to St. Thomas's Hospital.

COOKE, O. W., L.R.C.P., M.R.C.S., appointed Assistant House-Surgeon to St. Thomas's Hospital.

CRISP, E. H., L.R.C.P., M.R.C.S. (Extension), appointed Clinical Assistant in the Throat Department of St. Thomas's Hospital.

GOODY, F. S., L.R.C.P., M.R.C.S., L.S.A. (Extension), appointed Ophthalmic Clinical Assistant to St. Thomas's Hospital.

HOBHOUSE, E., M.B., B.S. Oxon., M.R.C.S. (Extension), appointed Resident House-Physician to St. Thomas's Hospital.

JAMES, C. H., L.R.C.P., M.R.C.S., appointed Assistant House-Surgeon to St. Thomas's Hospital.

LOTZ, H., L.R.C.P., M.R.C.S. (Extension), appointed Clinical Assistant in the Ear Department of St. Thomas's Hospital.

LEARD, H. B., M.B., B.C. Cantab., L.R.C.P., M.R.C.S., appointed Resident House-Physician to St. Thomas's Hospital.

NEWSHOLME, Arthur, M.D., D.P.H. Lond., appointed Medical Officer of Health to the Borough of Brighton, *vice* H. P. B. Taaffe, M.D. Lond., deceased.

ROBERTS, Sidney M.P., M.B., M.R.C.S., appointed Senior Physician to the Sheffield Public Hospital, *vice* W. R. Thomas, M.D., resigned; also appointed Lecturer on Medical Jurisprudence at the Sheffield School of Medicine.

SANSON, H. A., L.R.C.P., M.R.C.S. (Extension), appointed Clinical Assistant in the Skin Department of St. Thomas's Hospital.

SOLLY, R. V., L.R.C.P., M.R.C.S., appointed Clinical Assistant in the Skin Department of St. Thomas's Hospital.

SPEMCE, M. H., M.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S., appointed Ophthalmic Clinical Assistant to St. Thomas's Hospital.

STABB, E. C., L.R.C.P., M.R.C.S., L.S.A. (Extension), appointed House-Surgeon to St. Thomas's Hospital.

WATSON, John, M.B., appointed Junior Assistant House-Surgeon to the Hull Royal Infirmary, *vice* F. Savery, M.R.C.S., resigned.

WHEATON, S. W., M.B. Lond., L.R.C.P., M.R.C.S., appointed Resident Accoucheur to St. Thomas's Hospital.

WINDELE, John T., M.D. Aberd., appointed Certifying Surgeon under the Factory Acts for Ovenden and district, *vice* J. Hodgson Wright, M.R.C.S., appointed to the Halifax District.

WOAKES, Arnold, L.R.C.P., M.R.C.S., appointed Surgeon to the London Throat Hospital, *vice* E. Law, M.D. Edin., resigned.

YOUNG, P. W., L.R.C.P. and S. Edin. and Glasgow, appointed Medical Officer to the Parish of Loche, Stornoway, *vice* D. Sinclair, M.B., resigned.

PARKS FOR THE PEOPLE.—A park of fifteen acres in extent has been presented by the Earl of Dartmouth to the inhabitants of Morley in Yorkshire, in commemoration of the Queen's Jubilee.—Ravenscroft Park, Hammersmith, comprising an estate of thirty-two acres, has been jointly acquired by the Metropolitan Board of Works and the Vestry of Hammersmith, at a total cost of £58,000, and has been thrown open to the public.

IN MEMORIAM.—In the church of Westerham, of which place the late Mr. Charles R. Thompson was a resident, a handsome stained-glass window has been placed and an eagle lectern supplied, from a sum amounting to £350, subscribed by his friends for the purpose of raising on the anniversary of his death a fitting memorial to his memory.

LEGAL APPRECIATION OF MEDICAL SERVICE.—The Montpelier *parquet* has distinguished itself by a fit of economy at the expense of its medico-legal experts. Three professors of the Faculty of Medicine, having had their fees diminished by one-third, have retaliated by a resolution declining to give any expert evidence at all in future.

A BACTERIOLOGICAL INSTITUTION AT CRACOW.—A bacteriological institution for the treatment of rabies after Pasteur's method has recently been established at Cracow, Galicia.

DIARY FOR NEXT WEEK.

MONDAY.

CROONIAN LECTURE OF THE ROYAL SOCIETY, Royal Institution, Albemarle Street, 9 P.M.—Professor Kühne, of Heidelberg: Ueber die Entstehung der vitalen Bewegung (On the Source of Vital Movement).

TUESDAY.

WEST LONDON HOSPITAL, 5 P.M.—Clinical afternoon.

WEDNESDAY.

COLLEGE OF STATE MEDICINE, Burlington House, 4 P.M.—Inspector-General John M. Macdonald, F.R.S.: The Organisms occurring in Fresh Water, and the Hygienic Importance of their Presence.

HOSPITALS ASSOCIATION, Town Hall, Westminster, 5 P.M.—Annual meeting, Dr. J. S. Bristowe, F.R.S., in the chair.

FRIDAY.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital), 5.30 P.M.—Cavendish Lecture: Sir William Stokes: The Altered Relation of Surgery to Medicine.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 0d., which should be forwarded in stamps with the announcement.

DEATHS.

PEIRCE.—On May 11th, at Newlands, Redditch, Emily Maria, the dearly loved wife of James E. Peirce, J.P., M.R.C.S. Eng., L.S.A. Lond.

STRANGE.—On May 10th, very suddenly, at 42, Foregate Street, Worcester, Caroline Susan, wife of William Strange, M.D.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY.....10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's (Ophthalmic Department); and Royal Westminster Ophthalmic.—2 P.M.: Metropolitan Free; St. Mark's; Central London Ophthalmic; Royal Orthopaedic; and Hospital for Women.—2.30 P.M.: Chelsea Hospital for Women.

TUESDAY.....9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M. Royal London Ophthalmic.—1.30 P.M.: Guy's; St. Bartholomew's (Ophthalmic Department); St. Mary's; Royal Westminster Ophthalmic.—2 P.M.: Westminster; St. Mark's; Central London Ophthalmic.—2.30 P.M.: West London; Cancer Hospital Brompton.—4 P.M.: St. Thomas's (Ophthalmic Department).

WEDNESDAY.....10 A.M.: National Orthopaedic.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: Middlesex.—1.30 P.M. St. Bartholomew's St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: London; University College; Westminster; Great Northern Central; Central London Ophthalmic.—2.30 P.M.: Samaritan Free Hospital for Women and Children; St. Peter's.—3 to 5 P.M.: King's College.

THURSDAY.....10.30 A.M.: Royal London Ophthalmic.—1 P.M.: St. George's.—1.30 P.M.: St. Bartholomew's (Ophthalmic Department); Guy's (Ophthalmic Department); Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Central London Ophthalmic; Hospital for Diseases of the Throat; Hospital for Women.—2.30 P.M.: North-West London; Chelsea Hospital for Women.

FRIDAY.....9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M. Royal London Ophthalmic.—1.15 P.M.: St. George's (Ophthalmic Department).—1.30 P.M.: Guy's; Royal Westminster Ophthalmic.—2 P.M.: King's College; St. Thomas's (Ophthalmic Department); Central London Ophthalmic; Royal South London Ophthalmic; East London Hospital for Children.—2.30 P.M.; West London.

SATURDAY.....9 A.M.: Royal Free.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: King's College.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Middlesex; Royal Free; Central London Ophthalmic.—2.30 P.M.: Cancer Hospital, Brompton.

HOURS OF ATTENDANCE AT THE LONDON HOSPITALS.

CHARING CROSS.—Medical and Surgical, daily, 1; Obstetric, Tu, F., 1.30; Skin, M, Th., 1.30; Dental, M, W, F., 9.

GUY'S.—Medical and Surgical, daily, 1.30; Obstetric, M, Tu, F., 1.30; Eye, M, Tu, Th, F., 1.30; Ear, Tu, F., 12.30; Skin, Tu., 12.30; Dental, Tu, Th, F., 12.

KING'S COLLEGE.—Medical, daily, 2; Surgical, daily, 1.30; Obstetric, Tu, Th, S., 2; o.p., M, W, F., 12.30; Eye, M, Th., 1; Ophthalmic Department, W, 1; Ear, Th., 2; Skin, Th.; Throat, Th., 3; Dental, Tu, F., 10.

LONDON.—Medical, daily, exc. S., 2; Surgical, daily, 1.30 and 2; Obstetric, M, Th., 1.30; o.p. W, S., 1.30; Eye, W, S., 9; Ear, S., 9.30; Skin, Th., 9; Dental, Tu., 9.

MIDDLESEX.—Medical and Surgical, daily, 1; Obstetric, Tu, F., 1.30; o.p., W, S., 1.30; Eye, W, S., 8.30; Ear and Throat, Tu., 9; Skin, Tu., 4; Dental, daily, 9.

ST. BARTHOLOMEW'S.—Medical and Surgical daily, 1.30; Obstetric, Tu, Th, S., 2; o.p., W, S., 9; Eye, Tu, Th, S., 2.30; Ear, Tu, F., 2; Skin, F., 1.30; Larynx, F., 2.30; Orthopaedic, M., 2.30; Dental, Tu, F., 9.

ST. GEORGE'S.—Medical and Surgical, M, T, F, S., 1; Obstetric, Tu, S., 1; o.p., Tu., 2; Eye, W, S., 2; Ear, Tu., 2; Skin, W., 2; Throat, Th., 2; Orthopaedic, W., 2; Dental, Tu., S., 9, Th., 1.

ST. MARY'S.—Medical and Surgical, daily, 1.45; Obstetric, Tu, F., 1.45; o.p., M, Th., 1.30; Eye, Tu, F, S., 9; Ear, M, Th., 3; Throat, Tu, F., 1.30; Skin, M, Th., 9.30; Electrician, Tu, F., 2; Dental, W, S., 9.30; Consultations, M., 2.30; Operations, Tu., 1.30; Ophthalmic Operations, F., 9.

ST. THOMAS'S.—Medical and Surgical, daily, except Sat., 2; Obstetric, M, Th., 2; o.p., W., 1.30; Eye, M, Th., 2; o.p., daily, except Sat., 1.30; Ear, M., 12.30; Skin, W., 12.30; Throat, Tu, F., 1.30; Children, S., 12.30; Dental, Tu, F., 10.

UNIVERSITY COLLEGE.—Medical and Surgical, daily, 1 to 2; Obstetrics, M, Tu, Th, F., 1.30; Eye, M, Tu, Th, F., 2; Ear, S., 1.30; Skin, W., 1.45, S, 9.15; Throat, Th., 2.30; Dental, W., 10.30.

WESTMINSTER.—Medical and Surgical, daily, 1.30; Obstetric, Tu, F., 3; Eye, M, Th., 2.30; Ear, M., 9; Skin, Th., 1; Dental, W, S., 9.15.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS respecting editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

IN order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the office of the JOURNAL, and not to his private house.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL, are requested to communicate beforehand with the Manager, 429, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication. CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

QUERIES.

OLD MEMBER wishes to know how a young widow (poor) can obtain training as a nurse; where, and at about what expense.

QUIRER asks: Is there any home or institution where the wife of a deceased medical man could be received? She has no means and is hypochondriacal.

THE USE OF COCAINE IN DENTISTRY.

W. W. asks for the experience of those who have tried the injection of cocaine in tooth extraction on the following points: The amount of the drug to be injected into the gum; the time to elapse before extracting after injection; and the cases in which it would not be desirable.

OCCIPITAL HEADACHE.

R.C.S., L.R.C.P. writes: I have now a patient under my care who, for some years, has suffered from a dull, continuous pain of neuralgic character over her occiput and parietal bones, which becomes worse after meals, fatigue, or excitement, and is almost completely relieved by rest in bed, or lying on a couch, or in an armchair, so as to get pressure on the occiput. There is no apparent rheumatic, stomach, liver, or other organic affection. The secretions and excretions are all normal. He is 34 years old, robust, non-smoker, total abstainer, and has always led a very moral and methodical life. Having tried many remedies without much relief, I shall be pleased if some of the readers of your valuable JOURNAL will suggest a treatment for me.

TREATMENT OF LOCOMOTOR ATAXY AT AACHEN.

J. JAS. J. L. RATTON (63, Lee Park, Blackheath, S.E.) writes: A patient suffering from progressive locomotor ataxy underwent the special treatment at Aachen last August. He returned in a decided state of mercurialism at the end of a month, and his constitution was so far broken down that I had some doubts about his pulling through. His gums were so much affected that he would not eat well for about another month. He was advised at Aachen to return again this spring, to renew the treatment for a short course. I am doubtful about the advisability of his doing so, as he has improved as regards his symptoms of his disease, and gained in weight. I fear that a second mercurial course may do more harm than good.

I should be greatly obliged to any of your readers experienced in this matter or their advice on the point.

INUNCTION IN SCARLET FEVER.

CROCOCCLUS writes: In the treatment of scarlet fever, is it a fact that the carbolic acid in carbolic oil for external inunction has any germicidal effect, or is plain oil just as useful, and, if so, is any application known which will both prevent the scales flying about and destroy the germs?

ANSWERS.

FINAL EXAMINATION FOR L.R.C.P.LOND.

R.C.P.LOND. writes: The books usually read for this examination are, on *Medicine*, Bristow or Roberts; *Midwifery*, Leishman or Playfair, preferably the latter; *Diseases of Women*, Hart and Barbour or Galabin, both excellent books; and shortly before the examination, Hall's *Aids to Obstetrics* and Dr. Carter's *Elements of Medicine*.

NOTES, LETTERS, ETC.

WE are asked to state that Mr. C. Lovegrove (Flixton) passed the M.D. examination, second division, of the University of Trinity College, Toronto, on April 5th.

THE LUCE FUND.

	£	s.	d.
Donations up to May 6th	33	7	0
Anonymous Donor	50	0	0
Mr. T. A. White (Switzerland)	1	0	0
Dr. W. A. Satchell	1	0	6
Dr. Barron	0	10	6

Further donations in aid of Mrs. Luce will be gratefully received by Dr. SHEPPARD, 64, Durning Road, Liverpool, or by Dr. CATON, 31, Rodney Street, Liverpool.

BAYFIELD DEFENCE FUND.

R. E. BELLAMY (17, Wimpole Street) writes: Please place the following additional subscription to the Bayfield Defence Fund:—

	£	s.	d.
Mr. T. A. White, M.R.C.S.	1	0	0

A SIMPLE MEANS OF DIAGNOSIS IN CHEST DISEASES.

GEORGE F. P. NICHOLS, B.A., M.B. Cantab., writes to express the opinion that in cases of pneumonia or pleurisy in which we are doubtful of the existence of fluid in the chest, the syringe is not sufficiently used. He says: "For several years, whenever I have felt that knowledge on the point would be useful, I have used this means, not only in the chest, but the liver and elsewhere. It is well to first sponge the skin with a strong carbolic lotion, and make the puncture through lint wetted with some antiseptic, and I generally close the wound with a little piece of wool soaked in collodion. I have never known any harm result, nor have I ever heard of any; that it is almost painless, if done quickly, I know from personal experience. In Dr. Hood's paper in the JOURNAL of May 19th on 'Empyema following Pneumonia,' I see he uses this method, but apparently as a last, instead of a first, resource."

FUGITIVE OEDEMA OF THE EYELIDS.

B. ILLINOWORTH (Acerington) writes: Dr. Tom Robinson has directed attention to an affection which, though not mentioned in works on medicine, is frequently met with in practice. I have seen about six cases of it in four years in a population of 6,000.

The oedema is as often unilateral as bilateral; it is confined to the lower lids; and it is accompanied by great pain in the temporal region of the affected side. In one case which I saw the swelling was so pronounced that it gave me the impression of having originated in a gumboil, and, without inquiring as to the first appearance of the affection, I prescribed for the douloureux. Next day the patient was much worse, and completely prostrate with pain and sleeplessness. I then gave half-drachm doses of the spirits of ammonia, and cured the disease in about twenty-four hours.

It is, I think, due to passive congestion in the infra-orbital region, causing a mechanical block to the passage of venous blood, and consequent local serous effusion. It would appear to bear a close relation to migraine, which is curable by remedies such as ammonia and antipyrin, and always accompanied, if not actually caused, by great cardiac debility.

MANAGEMENT OF FEVER CASES.

MR. DAVID DAVIS (Builth, Breconshire) writes: Yesterday, Sunday, I was called to see a little boy, aged 8 years, the son of a gentleman residing in this town, and found him suffering from scarlet fever. Amongst other symptoms I found that his bowels were somewhat constipated, and ordered him a mild aperient, giving him at the same time a febrifuge mixture. I directed that he should be kept warm, and the temperature of the room regulated to about 55° F. On calling to see my patient again in the evening, Mr. T., the father, in course of conversation, remarked that it was very singular that doctors disagreed so much, and on my asking for an explanation, he showed me a book written by Mr. Pye Henry Chavasse called *Advice to a Mother on the Management of Her Children, and on the Management of their more Pressing Illnesses*, in which he had marked the following sentences: "On accounting give opening physic. Aperient medicines are, in my opinion, highly improper and dangerous both before and during the period of eruption. It is my firm conviction that the administration of opening medicine at such times is one of the principal causes of scarlet fever being so frequently fatal. What is the first thing to be done? Send the child to bed, throw open the windows, be it winter or summer, and have a thorough ventilation, for the bedroom must be kept cool, I may say cold."

Now, Sir, is not the above quotation in direct opposition to the teaching of the present day? I am under the impression that attention to the bowels, a slight febrifuge mixture, and keeping the patient in bed in a warm room, are alone necessary in simple scarlet fever. I have advised Mr. T. to put Mr. Chavasse's book on one side, and listen only to my directions. I am of opinion that much harm might be done by parents reading such works and acting on suggestions such as those quoted. Am I right or wrong?

IDIOSYNCRASY WITH REGARD TO ANTIPIRYN.

MR. U. K. DUTT (70, Portsdown Road, W.) writes: Having heard of a complaint from one of my patients with regard to the taste of antipyrin tablets, I took one before going to bed. The taste was a little bitter, but not at all disagreeable. I let it gradually dissolve in my mouth. No sooner had I finished it than a violent itching, tingling, and burning sensation was felt on the hard and soft palate, and the mucous membrane of the back and top of the nose, followed by sneezing. This I attributed to a cold draught, and took no notice of. But before it had disappeared I felt considerable itching and burning over several spots on the arm and forearm; then on the abdomen, chest, and back; on the penis and foreskin, in successive order; later on the thighs, and then on the hands, and then on the legs, and finally on the feet, back, and lastly on the soles. This was the order of manifestation, and the intensity at one particular spot lasted for two or three minutes, and when it began to diminish there, it began to increase elsewhere in the order indicated. The whole thing subsided in about half an hour. I thought an urticarial rash was coming out, but on the most careful examination I could discover no rash. I always have had urticarial rash a little after eating tinned lobsters, crabs, etc., and the sensation before the rash appears was almost identical.

I have tried another dose of 5 grains to-day with the same result. No appearance of rash is to be seen, even by daylight.

This seems to me to suggest an explanation of the anodyne effect of antipyrin in very large doses as used by Professor Germain Sée. This drug probably exalts the function of sensory nerves, or, at any rate, makes them more irritable in small doses, and then exhausts their irritability or function of feeling pain, and thereby the anodyne effect is produced. Would the body heat be lowered through its influence upon the sensory nerves, the vasomotor system being in intimate connection with the sensory nerves?

PERFORATION OF AN EYEBALL WITH THE KNOT OF A WHIP.

MR. H. PERRY DUNN (11, Nottingham Place, W.) writes: In answer to Dr. Sanctuary's letter in the JOURNAL of May 5th, I quite agree with him that the explanation of the detachment of the knot in my case of perforation of the eyeball (which I am reported to have said was due to the thong having become heated) is not the right one. The only possible explanation of the accident is that which Dr. Sanctuary gives, and which I previously had attempted to make plain at the meeting of the Society on April 6th.

NEALE'S "DIGEST."

DISAPPOINTED writes: I quite endorse the opinion of your correspondent, recorded in the JOURNAL of April 21st, respecting the *Medical Digest*. I found it long since to be a delusion and a snare, pure and simple, in the absence of the volumes of the medical journals (do themselves a library) to which it refers.

UNIFORM OR SWALLOW TAIL.

A MEMBER writes: I hope the following suggestion may meet with approval. It has been the subject of discussion in several quarters; I therefore venture to bring the matter before our members, and test their views.

Should, at our annual meetings, the invitations to the *conversations* and public dinner be marked "uniforms to be worn if possible"? By this means our gatherings would become more brilliant than ever, especially as so many of our members now hold commissions in the army, navy, and auxiliary forces, besides numerous others who may be entitled to wear uniform.

If this matter should meet with approval, I hope the Glasgow Executive Council will take the lead and set the example this year.

THE MANAGEMENT OF CLINICAL THERMOMETERS.

VERDANT GREEN writes: Does everybody know how, when, and where to shake down the mercury in his clinical thermometer? Never attempt to lower the mercury until it has had time to cool. How is it possible to reduce 104° to 85° whilst the metal is in a state of expansion. Wait a few minutes, or better still, until you arrive at the next house, before doing the shaking down.

THE NEW SCHEME FOR THE M.D. ST. ANDREWS.

MR. B. JONES (Leigh, Lancashire) writes: May I be allowed to point out, in reply to numerous inquiries, and to remove misapprehension, that in the new regulations which we seek to obtain at St. Andrews, the number of candidates receiving the degree of M.D. will not be limited, as at present, to ten in each

AN ADDRESS ON PERNICIOUS ANÆMIA, WITH JAUNDICE, AND CASES SIMULATING IT.

*Delivered before the East London and South Essex District of the
Metropolitan Counties Branch.*

By J. S. BRISTOWE, M.D., LL.D., F.R.S.,
Senior Physician to St. Thomas's Hospital.

In this paper I have no intention of attempting to throw any light on the etiology of pernicious anæmia, but I propose to myself simply to give the clinical history of two cases of the disease that have been under my care, to compare them with certain other cases of disease to which they present some resemblance, and to make such comments as suggest themselves.

It will be, perhaps, convenient that I begin by defining pernicious anæmia, as I understand it, and enumerating its more important and characteristic symptoms. Pernicious anæmia is an affection in which, without any organic lesion that has hitherto been discovered sufficient to account for it, without any recognised malarious or similar influence, without any apparent climatic or dietetic default, the blood undergoes progressive deterioration, especially in regard to the number and quality of its corpuscles, and in which the symptoms the patient presents are mainly such as depend on gradual increasing bloodlessness.

This definition, so far as I have gone with it, necessarily includes chlorosis or the anæmia of young women, which usually goes along with some derangement of the menstrual function, and which, almost without exception, if not always, is curable by the judicious administration of iron; and I must confess that it seems to me impossible at the present time to make any trustworthy distinction between the chlorosis of girls and pernicious anæmia, save such as depends on the age and sex of the patients and on the effects of treatment. Chlorosis occurs among young women, and is curable by iron; pernicious anæmia occurs among men and women, usually above the age of 30, and iron is generally without beneficial influence. Nevertheless, I believe, as most physicians believe, that there is a fundamental difference between them; and, moreover, I suspect that the affections now grouped together and labelled "pernicious anæmia" will hereafter be found to belong to several categories.

Pernicious anæmia, for the most part, comes on gradually. The patient progressively loses the warm tint of health, until at length not only his cheeks, but his lips and tongue, the inner surface of his eyelids, his ears, and his finger nails become almost white. Shortness of breath and liability to palpitation come on, phenomena which at first are slight and observed only when he is ascending stairs or undergoing exertion, but afterwards become more or less continuous, or at any rate induced by very slight causes. The action of the heart gets feeble, variable in rate, and sometimes irregular. A hemic murmur usually develops over the pulmonary area. Venous bruits become recognisable in the veins of the neck. The patient complains of noises in the ears, more especially at night-time and when lying down. Dropsical effusions take place into the connective tissue, and mainly in the lower extremities. There is a marked tendency to hæmorrhage from the nose, the mouth, the stomach, the bowels, on the surface and into the substance of internal organs, and beneath the skin. And especially hæmorrhage takes place into or about the retina. The digestive functions commonly suffer; the appetite usually fails; dyspeptic symptoms, with sickness after food, are of frequent occurrence; and, as a general rule, the bowels are constipated. The urine is for the most part unaffected, but sometimes it presents traces of albumen. The patient gets more and more feeble, unable to bear exertion or exposure to cold; but usually there is no great degree of emaciation. He becomes apathetic and forgetful, yet often irritable and fidgety; and if death ensues (as probably it does sooner or later) he sinks from exhaustion, not infrequently preceded by coma, or from some intercurrent complication.

The colour of the skin is usually such as might be caused only by extreme bloodlessness, but not infrequently there is a distinct yellow tinge (affecting also the conjunctivæ), which may be so intense as to be mistaken for that of ordinary hepatic jaundice. But it is unassociated with any disease of the liver; no biliary pigment (at any rate as a rule) finds its way into the urine; and it is due, no doubt, not to the absorption of bile, but to the destructive changes going on in the blood corpuscles and the escape of their colouring matter into the blood serum. The blood becomes thin and watery; and under the microscope there is found considerable and for the most part proportionate diminution of both white and red corpuscles. The blood in several of my own cases was very carefully examined by my pupil, Dr. Copeman, whose observations are published in the last volume of the *St. Thomas's Hospital Reports*, and partly confirm those of previous writers, but present a few additional items of information. He shows that the red corpuscles may be diminished to 30 or 40 per cent. of their proper number—other observers have found them still more largely diminished; that they are mostly smaller, paler, and less consistent than usual, and tend to alter in shape, and especially to become elongated, and to break down; that they do not usually run into *rouleaux*; that mixed up with them are other corpuscles of very small size, and usually of deeper tint than even healthy corpuscles; that the blood-serum has, in some cases, an amber-yellow hue, and that in some, crystals of hæmoglobin (which in healthy blood are hard to obtain) appear spontaneously when the blood is undergoing desiccation. The breathlessness is no doubt mainly cardiac, depending on feebleness of circulation, the effects of which are necessarily exaggerated under the influence of exertion or excitement; but dyspnoea may be partly due also to œdema of the lungs occurring as a part of general anasarca. This general dropsy, though not always present, is a common incident of the disease, and may become very considerable. Both dropsies and hæmorrhage seem to depend partly on poverty of the blood, partly on weakness of circulation, and on thrombosis, which both of these conditions tend to produce. Noises in the ears, which are sometimes rushing, sometimes steam-engine like, sometimes musical, almost always come on sooner or later. They are more or less continuous, and evidently venous. They are sometimes the chief source of complaint on the part of the patient, and frequently prevent him from sleeping. They are related, causatively, to the co-existent venous murmurs in the neck and the hæmic murmurs at the base of the heart, and are, I am inclined to think, the product of a flaccid condition of the vascular walls and relative emptiness of vessels.

I have already pointed out that the urine is sometimes of normal quality and of normal colour to the last, a point of some interest, inasmuch as it implies a continuous and relatively increasing drain on the red corpuscles. In addition to the restlessness and irritability not infrequently observed, and the coma which occasionally supervenes towards the close, patients sometimes have delusions and become maniacal, occasionally suffer from temporary blindness, and occasionally also lose voluntary power and feeling, more especially in the lower extremities. The temperature for the most part is either normal or subnormal, but not infrequently patients present febrile rises which may be either occasional or more or less persistent, but are rarely high.

Finally, although in a large proportion of cases the disease is progressive, and proves fatal in the course of a year or two, undoubtedly there are many cases in which more or less perfect recovery takes place, a recovery attended, however, with liability to relapse.

The first case of what is now generally termed pernicious anæmia which I ever saw—at any rate, to pay it special attention—came under my care in my out-patient practice at St. Thomas's in October, 1857, and was brought by me under the notice of the Pathological Society exactly thirty years ago. The patient was a clerk, 26 years old. During the previous five or six years he had been dyspeptic and fanciful; and during the last two his temper, naturally placid, had been getting irritable and peevish. In 1852 he had had what he termed a "stomach attack," which lasted two or three months, and was followed by some impairment of vision. A few months afterwards he had had a similar but slighter attack; and during the next three or four years he had suffered from two or three relapses, in the last two of which he stated that he had been slightly jaundiced.

His present illness had come on gradually during the preceding six months, with depression of spirits, vertigo, loss of appetite,

trembling in the knees, and pains in the jaws and face. Slight jaundice had been added to the other symptoms after about two months, and latterly occasional matutinal vomiting of bilious fluid. There had been no epigastric uneasiness or vomiting after food; the bowels had been variable, but generally constipated.

He was spare, anxious-looking, and universally though not deeply jaundiced. There was neither general dropsy nor ascites, no fullness or increased dullness in the region of the liver, and no uneasiness or tenderness in that situation. The heart's sounds were normal, the pulse rapid, small, and weak, and the functions of the lungs were healthily performed.

He continued attending as an out-patient until January 19th, up to which date there was certainly no improvement in the symptoms. The jaundice was much the same at the end as at the beginning; the vertigo and occasional headache, the morning bilious vomiting, with feelings like those of sea-sickness, and the condition of his nutritive functions, of his evacuations, and of his physical powers remained unaltered. On two or three occasions he had complained of weight at the chest after food, and for a week of a dull pain to the right of the umbilicus.

On January 19th he was admitted under my care, and died on February 4th. From the 19th to the 2nd there was not much variation in his symptoms. He was extremely weak and somewhat emaciated, with a rapid, feeble pulse. He complained generally of a feeling of giddiness, and of pain about the eyes, especially when he moved. His tongue was pale, and occasionally furred; his appetite was variable. He suffered much from thirst, and frequently vomited bilious fluid. The bowels were generally constipated, and the motions pale, though not wholly untinged by bile; and his urine was high-coloured. The skin was dryish, and both it and the conjunctivæ were very decidedly jaundiced. He complained occasionally of dimness of sight and deafness. His sleep was generally undisturbed.

On February 2nd he suffered more than usual from the deafness and dimness of sight, and occasionally rambled. During the ensuing night and the next day these symptoms, and especially the delirium, increased, and he was at times violent; but he understood what was said to him, and would answer rationally. He continued in the same state (gradually sinking however) until 4 A.M. on the 4th, when death took place.

Various plans of treatment were carried out, but none with obvious benefit; at one time he was dosed with nitric acid and cinchona, at another with iodide of potassium and gentian, at another with iodide of mercury, at another with alkalies.

The corpse was universally but slightly jaundiced, and very pallid. There was some œdema of the back parts of the lungs. The heart was rather large, its substance was pale and soft, and its inner surface especially pale and mottled. Several of the smaller branches of the pulmonary artery were filled with firm but unadherent fibrinous coagula. The liver was somewhat enlarged, but of normal consistence, and of a uniform yellowish-brown tint. The bile-ducts and the gall-bladder were entirely healthy. The spleen weighed one pound, but was normal in texture. All other organs were sound. The muscular tissue of the heart, and especially those parts that were mottled, presented well-marked fatty degeneration, and the liver cells contained for the most part a good many small oil globules. The blood was everywhere remarkably pale and watery, but did not display any preponderance of white corpuscles.

Among the remarks which I appended to my case are the following: "During the progress of this case the persistence of jaundice led me to regard the liver as the organ at fault." "It would be useless now to state the precise diagnosis at which I arrived, for the *post-mortem* examination showed that the liver was structurally healthy, and that there was no essential disease of any other organ."

"Was the case an example of that mysterious form of fatal jaundice" (I referred to so-called malignant jaundice) "which Dr. Alison first described? There may be some reasons for answering this question in the affirmative, but there is at least one important fact against it; the case under consideration was essentially chronic. But was the case really one of fatal jaundice at all? I must confess that on reviewing and comparing the history of the patient during life, and the results of the *post-mortem* examination, there seems greater reason to believe that his death was due to severe and progressive anæmia than to any affection of the liver; that the case was, in point of fact, one of anæmia, attended or followed by jaundice. I founded this opinion, partly on the fact that the patient was ailing, and probably anæmic be-

fore the jaundice made its appearance; partly on the symptoms which manifested themselves while he was under observation, and which, with the exception of the jaundice, were precisely those of anæmia, and partly on the state of the organs as revealed after death, none of them being positively diseased, but several being in such a condition as one ordinarily finds them to be after long-continued deterioration of the blood. If the view here suggested be correct, the case is allied to those examples of anæmia to which Dr. Addison alludes in the commencement of his work on *Diseases of the Suprarenal Capsules*."

That this case was a typical case of pernicious anæmia, and that the jaundice observed was the kind of jaundice not infrequently met with in this disease, I have long had no doubt.

The next case I shall venture to quote is one in which there was also well-marked jaundice, and in which, for several reasons, the true nature of the disease, at any rate what I am disposed to regard as the true nature of the disease, was for some time overlooked.

E. B., a young woman, 27 years of age, was admitted under my care on January 11th, 1886. She had been a patient of mine eleven years previously for rheumatic fever, and two years afterwards was again admitted with rheumatism and pericarditis. I have not looked up the particulars of her illness on these occasions; but I have a distinct recollection that in one of these attacks she was exceedingly ill, and for some length of time in considerable danger. Since that time she has been liable to rheumatic pains and to shortness of breath.

Her present illness was of nine months' duration. At its commencement she went into the Brighton Hospital, where she remained six months. While there jaundice seems to have come on gradually, and she seems also to have had an attack of acute pneumonia, in which her temperature rose to 105° F. In November she came for a short time into St. Thomas's, was jaundiced, and I believe was thought to be suffering from gall-stones. She was then sent to a convalescent hospital. While there the jaundice became more intense, and she suffered much from pain in the region of the heart and right hypochondrium, and from shortness of breath. The catamenia had been absent during the whole period of her illness.

State on Admission.—She was a well-nourished woman, complaining mainly of weakness, shortness of breath, and pain in the præcordium and both hypochondriac regions. She was somewhat anæmic, and presented a general saffron-yellow tint of skin and conjunctivæ. The lungs were healthy. The cardiac dullness was somewhat extended; and the apex-beat in the fourth interspace in the mid-clavicular line. The sounds were healthy, but for the fact of a rough, scratchy systolic murmur in the pulmonic area. There was a rounded lump (apparently part of the liver) to be felt just below the tips of the eighth and ninth cartilages on the right side. Otherwise the abdomen was normal. The tongue was coated; the bowels were confined, but the motions were normally stained with bile, and the urine presented copious urates, but no trace of biliary colouring matter or of bile acids.

During January and February her condition varied, and was by no means satisfactory. She suffered from pains, sometimes persistent, sometimes paroxysmal and severe, referred chiefly to the right hypochondrium, but sometimes to the left, sometimes to the præcordium, and sometimes to the loins. The nature of these pains was not clearly made out; but they were occasionally thought to be due to the passage of gall-stones; occasionally thought to be connected with old adhesions (which undoubtedly existed) of the pericardium; occasionally—and perhaps, on the whole, more commonly—were attributed to congestion of the liver secondary to the cardiac affection. But no gall-stones were found, the motions were always bilious, and the urine never contained any bile-pigment.

She had pains and throbbing in the head, and a sound as of rushing water in the right ear. She suffered also from time to time from slight but obvious rheumatic inflammation of some of the joints. Her pulse was feeble, variable in rate, sometimes irregular, and rarely over 80. Her respirations were often quick and laboured, and occasionally were at the rate of 48 in the minute. She suffered from pretty constant nausea, and occasional attacks of sickness, and twice had epistaxis. During all this period the temperature was almost always slightly above the normal, and not infrequently rose to 100° or 101°, and on two successive days, when the patient felt specially ill, and was complaining of considerable præcordial pain, it rose to 103.2° and 103.4°.

June 2, 1888.]

During all this time the patient's symptoms were assumed to be due directly or indirectly to the maladies from which she had so long suffered; namely, embarrassed action of heart, dependent on adherent pericardium, secondary engorgement of the liver, and recurrent attacks of very slight rheumatism, and it may be added that the right lobe of the liver became more obvious than it was at first below the ribs, and that some enlargement of the spleen also was detected. But she was steadily becoming more and more anæmic, and, early in March, I began to suspect that her symptoms might be largely due to this progressive anæmia. Her eyes were then examined, and it was found that the optic discs were reddened and swollen, the veins were pale and scarcely differing from the arteries in colour, and there were a few choroidal hæmorrhages. The blood (examined by Mr. Copeman) was pale, coagulated rapidly, and contained an excess of fibrine; the red corpuscles were only 36 per cent. of the normal, and on drying broke down with the formation of hæmoglobin crystals. She was now treated with liquor arsenicalis, at first five and later ten minims, three times a day. For the first week or two the anæmia seemed to increase; then manifest improvement took place. She gradually lost her pains and discomforts, and her sense of nausea; she became stronger, and some degree of rosiness returned to her cheeks and lips and finger-nails. On March 19th her eyes were re-examined, and the hæmorrhages were found to have increased considerably in number; but a further examination, on April 3rd, showed that the retinitis had largely subsided and the hæmorrhages almost disappeared. On the same dates the blood also was tested and found improved in quality. The report on April 3rd was to the effect that the blood-corpuscles were larger, more uniform in size, of better shape and colour than they had been a month previously, and that they now formed 60 per cent. of the proper number. Moreover, though they did not run into *rouleaux*, they did not break down when a drop of blood was dried; and hæmoglobin crystals could not be obtained.

She was discharged fairly well on April 21st. She had then lost all her abdominal and thoracic pains, her headache, her nausea and sickness; her yellowness had diminished, though it had not actually disappeared; she had become rosy; her strength had greatly improved, and she had been getting up indeed every day for the last month; her temperature had become normal; she slept well and ate well, and expressed herself as feeling far better in health than she had been for twelve months; but the hæmic cardiac murmur remained, and there was still enlargement of the liver and spleen.

It is important to note that no improvement took place in this patient during the first seven or eight weeks of her residence in the hospital, but that during the last seven or eight weeks, while she was kept under the influence of arsenic, her recovery was progressive and rapid.

There can be no reasonable doubt, I think, that both of the above cases were true examples of pernicious anæmia, and that the light jaundice present was due not to hepatic disorder, but to decomposition of the blood. That the cases were misinterpreted (the former during the whole of the patient's lifetime, the latter during the greater part of her illness) admits, I think, of reasonable excuse. The former case occurred at a time when idiopathic anæmia (apart from chlorosis) had scarcely been studied, and in the latter case the anæmia became engrafted, as it were, on the presence of lesions, which were themselves competent to produce jaundice. I have quoted them, indeed, in preference to other cases which I might have quoted, largely on account of the difficulties they presented in the way of correct diagnosis, but also because of the close relationship there appears to be between the variety of pernicious anæmia they illustrate and the anæmia present in the cases which I now proceed to narrate.

A. T., a girl of 15, was admitted under my care on June 29th, 1887. She had, on the whole, enjoyed good health, excepting that for nearly five years she had been jaundiced, and three years ago was my patient in the hospital with much the same symptoms as those she was now suffering from. Her present illness was of three months' duration, and during all the time she had complained of pains in the side, especially on walking, and latterly of feeling drowsy. She had been laid up for the last week.

State on Admission.—She was a well-nourished, and not specially anæmic girl; but she presented a general saffron-yellow tint, the conjunctivæ being coloured as well as the rest of the surface. She complained only of weakness, and of pain in the right side and in the abdomen. The thoracic organs were perfectly healthy. The spleen was much enlarged, extending down

to the umbilicus; it was freely movable, and presented the usual notch. The liver did not descend below the ribs. In other respects the abdomen was normal, presented no tumour or fluid, and there were no enlarged veins in its walls. There had been no hæmorrhages, and there were none now. The appetite was fair; the bowels were somewhat confined, but the motions were coloured with bile. The urine had a specific gravity of 1015, presented a mere trace of albumen, and was quite free from bile-pigment. The blood contained what appeared to be a fairly healthy proportion of red corpuscles, but there was a slight increase of white. The red corpuscles did not form definite *rouleaux*, but ran into irregular masses. They were of normal shape and colour.

She was in the hospital seventeen days, during which time she was restored to her usual state of health; but the jaundice, the spleen, and the condition of the blood underwent no change. Her temperature was always normal; her pulse varied from 64 to 86. There was no further record of the presence of albumen in the urine.

For some two or three months she continued to visit me as an out-patient, but no further improvement was noted. She was treated during the time she was under my care with iodide of potassium and mercury.

A. R., single, aged 22, came under Dr. Ord's care on September 21st, 1886. She had been a patient of mine in 1879, and of Dr. Ord's in 1884 and 1885. She had complained mainly of weakness, shortness of breath, headache, and pains about the body. She does not seem ever to have had rheumatism or any other serious acute illness; but ever since she had been under observation she had presented a loud systolic murmur, most marked at the left base, which Dr. Ord (I believe) regards as due to some congenital cardiac defect. She has been jaundiced for some years.

State on Admission.—She was a dark-haired, well-nourished girl, markedly anæmic, and at the same time presenting slight but unmistakable jaundice, both of the skin and of the conjunctivæ. The cardiac dulness was not unduly extensive, and the apex of the heart impinged in the fourth interspace, an inch within the nipple line. A well-marked systolic murmur, loudest at the left base, was audible over the whole cardiac area. A venous hum was audible in the neck. The lungs were healthy. The liver extended for an inch and a half below the ribs, but was smooth and free from tenderness. The spleen was very large; its anterior edge (which presented a deep notch) approached the umbilicus; its lower end reached the anterior superior spine of the ilium; it was quite smooth and free from tenderness. There was no ascites, and no enlargement of the superficial abdominal veins. The blood was unduly pale; the red corpuscles were irregular in form, many being oval, and did not form *rouleaux*; there was no excess of white corpuscles. The urine had a specific gravity of 1012, was acid, free from albumen, sugar, bile-acids, and bile-pigments, but presented many uric acid crystals and amorphous urates. The stools were of natural colour. Her pulse was quick; her temperature a little above the normal. She was treated with 5 minims of liquor arsenicalis three times a day.

The patient's symptoms varied somewhat while she was in the hospital. Her pulse was generally rapid and at times irregular; she generally had more or less œdema of the legs and ankles; she had attacks of pain in the sides and in the back, and she felt weak. On one occasion she had epistaxis. The blood was examined on several occasions, and the examinations in the main confirmed the description above given; the red corpuscles, however, were found to be diminished by about one-fourth. The urine never presented any bile-pigment or bile-acids, albumen, or sugar. Her jaundice continued, but on the whole she improved, and she left the hospital on November 10th.

She was again admitted under Dr. Ord's care on July 25th, 1887. She had then been getting poorly for a couple of months, suffering from short breath, nausea and debility. On admission she was practically in the same state as before. There was great anæmia, and light but well-marked jaundice. The blood had undergone no change. The red corpuscles were generally oval or irregular in form, and did not run into distinct *rouleaux*; but the white corpuscles were thought to be relatively increased in number. The urine still contained no trace of bile, and was otherwise healthy in composition. The cardiac murmur persisted, the liver still just emerged from beneath the ribs, and the spleen still extended down to the anterior superior spine of the ilium. She was treated with hypophosphite of soda (ten grains three times a day), to which was subsequently added five grains of the citrate of iron and ammonia.

Again she improved in health; but left the hospital still anæmic, still jaundiced, and with a large spleen, on August 26th.

That the last two cases were of the same nature there can scarcely be a doubt; and that they presented many characters in common with the first two is also obvious. The identity between the last two is implied by the association in both of chronic enlargement of the spleen, chronic yellowness of conjunctivæ and skin, simulating hepatic jaundice, and deterioration in the quality of the blood. It is true that in one of the patients there was a loud cardiac murmur, venous *bruits*, and marked bloodlessness, with such changes in the blood as are found in advanced pernicious anæmia; and that in the other the heart's sounds were healthy, no venous hums were observed, the anæmia was scarcely noticeable, and the microscopic changes in the blood were only slight. But I confess I have a suspicion that the cardiac murmur was hæmic, and, at any rate, all the other differences just enumerated are only such as might be explained by the different stages of anæmia the cases had severally attained.

The resemblances between the last two cases and the quoted cases of pernicious anæmia were mainly the presence, in both series, of jaundice without discoverable disease of the liver, alteration in the quality of the blood with loss, or tendency to loss, of red corpuscles, and the kind of weakness which attends progressive anæmia. Indeed, it might, I think, be argued that they were all four cases of pernicious anæmia, or, at any rate, of the same form of disease; inasmuch as, in addition to the resemblances above enumerated, enlargement of the spleen was present in all. It will be recollected that in my first case, although enlargement of the spleen was not observed clinically, the organ weighed a pound at the necropsy; and that, in the second case, some enlargement both of the liver and of the spleen was detected during life. But, on the other hand, the long duration of the last two cases, and the fact that the patients were both girls, of an age at which ordinary chlorosis is common, pernicious anæmia rare if not unheard of, render this view of their nature improbable. I believe, although I do not pretend to adduce adequate proof of the correctness of my belief, that the first two and last two cases really belonged to different categories.

It may be asked, To what was the large spleen in these cases due? In the last two cases there was no reason to believe it was of malarial, of syphilitic, or of ricketty origin; there was nothing that could have induced lardaceous degeneration; there were no tumours of lymphatic glands or disease of other organs to suggest the presence of lymphadenoma; neither the symptoms nor the condition of the blood was compatible with leucocythæmia; and, lastly, there were no sufficient grounds to attribute the splenic enlargement to portal obstruction. In the first case the structure of the enlarged spleen seemed to be healthy; in the second case it is of course possible that the enlargement of the organ was consequent on portal congestion.

The fact, however, that the spleen was enlarged in all four cases suggests the inquiry whether there was any relation between the presence of jaundice and this enlargement. It is admitted, I believe, by physiologists that one function of the spleen is to cause the disintegration of effete red corpuscles, and that the serum of the blood in the splenic vein is tinged with the dissolved hæmoglobin derived from this source. It seems not unlikely, therefore, that (whatever may be said as to the first two cases) in the last two cases the enlargement of the spleen was connected with an undue destruction of red corpuscles in this organ, and the discharge into the blood-stream of a larger amount of dissolved hæmoglobin than could be got rid of by normal physiological processes, and hence the general staining of the blood-serum and the general yellow tint of the body. But, at any rate, the jaundice in no case presented the characters of jaundice from obstruction of the hepatic ducts, and there is no sufficient ground for attributing it in any one of the cases to disease or disorder of the liver.

The different characters of the cases I have brought forward and the different kinds of treatment adopted in them make it impossible to deduce from their clinical history any valuable information as to the effects of treatment. If my paper had been devoted to the subject of pernicious anæmia alone, I should have been able to confirm the general belief that cases of this disease are in large proportion fatal under any kind of treatment; but I should have been able to show that many cases which appear to be of the same kind undergo great improvement or get well, and that (as is now generally held) arsenic seems to have in a large number of cases a strikingly beneficial influence over the progress

of the disease. Of this beneficial influence my second case is a good illustration.

A CASE OF EXTRA-UTERINE GESTATION CURED BY ABDOMINAL SECTION TWO HOURS AND A HALF AFTER RUPTURE.

By G. ERNEST HERMAN, M.B.LOND., F.R.C.P.,
Obstetric Physician to the London Hospital, etc.

THE following case has more than one point of interest. First, I believe it is unique in the shortness of the interval between rupture and operation. Very few cases of extra-uterine gestation have been operated on while the patient was in collapse from the first hæmorrhage; in most of the published cases hæmorrhage had stopped, and the patient had rallied before the operation was done. I do not know of any case in which the operation was done so soon as two hours and a half after rupture. This promptness of interference was due to the patient's good fortune in being in hospital at the time of rupture.

Secondly, the case is unusual in the lateness of rupture. Tubal gestations usually rupture before the end of the third month, while this one went on for about four months.

Thirdly, if the diagnosis of the first illness be correct, the case is an instance of two successive extra-uterine pregnancies in the same patient, first in one tube, then in the other. There may have been an identical morbid condition of the right and left tubes which occasioned the failure of the ovum to reach the uterus.

Fourthly, the uterine *souffle* was distinctly heard. This is so rare in extra-uterine gestation that it has even been maintained that the presence of a uterine *souffle* justifies the conclusion that a pregnancy is uterine. The case now reported shows that this general rule is not without exception.

H. N., aged 24, admitted December 16th, 1885. (The notes on this occasion were taken by Mr. H. J. Hawthorn.) Until the present illness she had always had good health. She began to menstruate at 15, and was regular every month, the flow being scanty, and only attended with slight pain. She was married at 18, and had two children, the last ten months ago; labours easy; no miscarriages. During the whole of the last pregnancy, and for a month after delivery, she had a copious yellow discharge, and her womb seemed to come down. After the last confinement she was regular, without pain, till September 4th. From this date till October 20th, she saw nothing. She then had a slight discharge of blood, and this recurred every week till five weeks ago, since which time she has been losing continuously and copiously. About five weeks ago, on getting into bed after passing water, she was seized with faintness and a cramp-like feeling at the bottom of the stomach; she broke out into a cold sweat, shivered, and her husband said she looked very white. This cramp-like pain continued severe for about three days and then improved, but soon recurred, and has continued on and off ever since, often preventing her from sleeping. For two or three days after the first attack of pain micturition was painful and the urine scanty. There was no trouble in defæcation.

On admission patient complained of pain in the back and lower abdomen, and was losing blood. The abdomen was tender, and the muscæ held very rigid. *Per vaginam* a hard, convex, very tender swelling was felt, occupying the left posterior quarter of the pelvis, and pressing the uterus forwards and to the right. The sound entered 3½ inches. Temperature was 100° F.

A week after admission the hæmorrhage became slight, but it continued until January 6th. After this date, throughout the patient's stay in hospital, there was no hæmorrhage. No decidua membrane was noticed in the discharge. The temperature, all the time the patient was in hospital, never exceeded 100°.

The pain continued much the same as on admission, generally severe, but with occasional remissions, for about six weeks. Then it improved, and at the beginning of February was only slight and occasional. The mass in the pelvis remained of about the same size for at least a month, and then began to gradually become smaller, harder, and less convex. Patient was discharged on February 14th, 1886.

March 23rd she came to report herself. She felt quite well. Swelling in pelvis smaller than when in hospital. Patient men-

struated last week, the first time for eleven weeks, without pain, flow copious.

The diagnosis made at the time was that the swelling behind and to the left of the uterus was either a dilated Fallopian tube, which was suggested by the position of the tumour and the severity and persistence of the pain, or a hæmatocele from a ruptured extra-uterine gestation. The latter supposition was based on the history of amenorrhœa, followed by a sudden illness, attended with pain, faintness, and pallor. The course of the case seems to me to accord with this diagnosis rather than with the former. It is far from certain, but many cases have been published as "cures" of extra-uterine gestation by electricity in which the diagnosis rested on no better grounds. Had electricity been used in this case, it might perhaps have been erroneously credited with the cure.

The patient came again to the hospital, and was readmitted on February 9th, 1888 (the notes on this occasion were taken by Mr. C. J. Kirton, clinical clerk). She said she had been perfectly well since leaving the hospital until the last four months. She had menstruated regularly and painlessly, the last time being in October, 1887, after which she saw nothing until December 25th, when she menstruated, the flow being rather more copious, but otherwise as usual. Nothing like a membrane was observed in the discharge. In this interval she had noticed nothing that made her think she was pregnant. After December she saw nothing, and she then thought she was pregnant. About December 20th she began to have pain after passing urine. Throughout January, 1888, she had pain in the back and lower abdomen, chiefly on the right side, so bad as to oblige her to keep her bed; this pain she described as continuous, not paroxysmal, and not relieved by lying down. Her appetite became bad, and at times she felt faint.

On the morning after admission she was examined by the resident accoucheur. Her general condition at that time was not such as to suggest any imminent danger; she walked to and from the examination couch. The abdomen was tender on pressure, and there was a rounded swelling rising out of the pelvis as far as to a little below the umbilicus. On vaginal examination the cervix was found pushed forwards, and behind it was a large rounded swelling feeling very much like a retroverted gravid uterus. The sound entered $3\frac{1}{2}$ inches, in the normal direction. A distinct uterine *souffle* was heard over the abdominal swelling. The temperature was normal.

A little before one o'clock on February 10th the patient was suddenly seized with violent pain in the abdomen, so severe as to make her feel faint; she became distinctly pallid, broke out into a cold sweat, and her pulse became small, rapid, and weak. Dr. Herman saw her shortly before three o'clock. The symptoms clearly pointed to internal hæmorrhage, and the history and previous physical signs made it probable that this might be due to a ruptured extra-uterine gestation. Therefore at 3.20 P.M. (that is, as soon as the necessary preparations could be made) Dr. Herman opened the abdomen, first by a small exploratory incision about an inch in length, which gave exit to a quantity of fluid blood. The diagnosis being thus confirmed, the incision was extended to $2\frac{1}{2}$ inches. Much fluid and clotted blood was then expressed by pressure on the abdominal walls. Then a fœtus of about four months' intra-uterine age, which was lying free (except for its umbilical cord attachment) among the bowels was removed. The placenta was found attached, at least mainly, to the right Fallopian tube. This was pulled up and removed, together with the ovary, the stump being tied with the Staffordshire knot. No attempt was made to search for or remove such part of the placenta as might not be attached to the tube. The peritoneum was then washed out with clean warm water. A large drainage-tube was put in, reaching to the bottom of Douglas's pouch, and the wound closed in the usual way. The pulse when the operation was begun was 150. After its completion (4.10 P.M.) 152.

In the evening (8.30 P.M.) the pulse had sunk to 138. The drainage tube was removed on the following day, but it appeared from the subsequent course of the case that this may have been rather too soon, for on the fifth day the patient complained of some abdominal pain, and the temperature rose to 100.5°. On the sixth day there was a discharge of dark bloody fluid from the wound, and the temperature on this and the following day reached 101. It then gradually sank, and after the fourteenth day did not exceed 99. On the eighth day a small drainage-tube was inserted. The discharge continued sanguineous for about five days, and then

became slight and purulent. The drainage-tube was gradually shortened.

March 17th. Patient got up.

March 30th. Discharged feeling quite well.

ON THE TREATMENT OF INJURIES OF THE ABDOMINAL VISCERA.

BY BRIGADE-SURGEON C. H. Y. GODWIN, M.S.,
Assistant Professor of Surgery, Army Medical School,

THE freedom with which surgeons have been for some time dealing with disease of the abdominal and pelvic viscera with such remarkable success has had a considerable effect in stimulating surgeons to inquire whether it was not possible for them to take bolder steps in the treatment of perforating wounds of the abdomen, a class of injury hitherto most fatal in character, whether as the result of stabs or of gunshot wounds. Moreover, the dread of interfering with the peritoneum has, in a measure, passed away, since it has been found that if antiseptic precautions are duly taken, the peritoneum is as tolerant of treatment as any of the other serous membranes in the body.

With a view of inquiring more particularly into the nature of gunshot wounds of the abdomen, and the best methods of treating them, Dr. C. T. Parkes, Professor of Anatomy in the Rush Medical College, Chicago, performed a series of experiments upon dogs by inflicting upon them intentionally gunshot wounds. He operated in this way upon 39 dogs in all; the bullet was of large size—38 or 44 calibre—and the firearm possessed great penetrating and lacerating power. Several most important lessons have been taught by these experiments.

Dr. Parkes says: "There was not manifested in any case any recognisable evidence of shock aside from that following great loss of blood. The transit of the bullet made no noticeable impression upon the pulse or respiration. In every instance where signs of severe prostration became manifest through change in respiration or weakening of pulse, there was found profuse hæmorrhage to account for such condition."

Intense and prolonged shock has always been recognised as one of the most marked symptoms of a perforating wound of the abdomen. By these experiments Dr. Parkes finds himself unable to disassociate this symptom from the condition caused by severe internal hæmorrhage. He tabulates the following conclusions:—

1. Hæmorrhage following shot wounds of the abdomen and intestines is very often so severe that it cannot be safely controlled without abdominal section.
2. Extravasation of the contents of the bowel after shot injuries thereof are as certain as the existence of the wound.
3. No reliable inference as to the course of the bullet can be made from the position of the wounds of entrance and exit.
4. The wounds of entrance and exit should not be disturbed in any manner, except to control bleeding or remove foreign bodies when present.
5. Several perforations of the intestines close together require a single resection including all the openings. Wounds destroying the mesenteric surface of the bowel always require resection.
6. The best means of uniting the wounded intestine after resection is by the use of fine silk thread, after Lembert's method.
7. Wounds of the stomach, small perforations, and abrasions of the intestine can be safely trusted to the continued catgut suture.
8. Every bleeding point must be ligatured or cauterised.
9. Primary abdominal section in the midline gives the best command over the damage done, and furnishes the most feasible opening through which the proper surgical treatment of such damage can be instituted.

Supposing we have before us a wound of the abdominal parietes, the first thing that we shall wish to know is, Does it penetrate? and, if so, are any of the viscera wounded? What symptoms can we rely upon as diagnostic of a wound of the viscera? If the wound is due to a bullet, and supposing it to have passed out, the experiments teach us that we can really form very little idea of its track by comparing the position of the wounds of entrance and exit.

Dr. Parkes remarks: "Nothing can be more uncertain and erratic than the track of a missile through the body."

Sir William Mac Cormac, in speaking of wounds of the bowel,

says: "When the injured intestine is prolapsed through the wound, or the contents of the tube escape externally, the diagnosis is clear; but these occurrences are the exception. Tympanites and discharge of blood *per anum* are valuable symptoms when present; but neither may appear directly after the injury. Emphysema, when it occurs in the wound neighbourhood, is said to be pathognomonic. Shock and pain vary so much as to afford no useful guidance."

On the other hand, the experiments show us that it is nearly certain that if there is penetration there will be injury to the contents. Now, nearly all cases of injury to the intestines prove fatal, and the mortality is due either to hæmorrhage or to septic peritonitis; hence the necessity of a diagnosis without delay. If we are prepared to act upon the probability that, if there is perforation there will also be a wound or wounds of the viscera, can there be any valid reason against our determining the fact of penetration by probing the wound? Heretofore, when the treatment of this class of injuries was merely of an expectant nature, the rule undoubtedly was not to interfere with the wounds, except to arrest hæmorrhage or to remove a foreign body; but when the knowledge is critical, can any harm be done by inserting a perfectly clean aseptic probe? This, I presume, we should do, taking at the same time every precaution that was possible not to disturb the parts unnecessarily, feeling sure that, if we waited for symptoms to develop—or, in other words, for symptoms of septic peritonitis to commence—it would then be too late for an operation. The urgency of an operation is also pressed upon us by the fact, illustrated in these experiments, that when a blood-vessel in the abdominal cavity is wounded, it continues to bleed, the blood poured out does not coagulate, nor does the vessel contract or retract, so that death from hæmorrhage can easily follow the injury of a very small vessel.

This excessive and persistent hæmorrhage from small vessels in the closed cavity of the abdomen is illustrated in another class of cases—namely, in the intraperitoneal hæmatocèle following rupture in cases of tubal pregnancy.

Mr. Lawson Tait writes in the JOURNAL, March 13th, 1886: "In my experience of intraperitoneal hæmatocèle, amounting to something like fifty-three or fifty-four cases, when I have verified the condition, either by *post-mortem* examination or *ante-mortem* abdominal section, the only cause of the condition was the rupture of a tubal pregnancy. In these cases there was a more or less extensive hæmorrhage, occasioned by the rupture of small vessels within the abdominal cavity."

When, however, the abdomen is opened and air admitted, the blood coagulates, the vessels contract, and the natural hæmostatic efforts are called into play. Hence, in the future in these cases, if we hope to save life, we must operate at an early period. There is also another reason forcing us on to the operation. Supposing the intestine to be wounded, there is the certainty of extravasation of its contents, which is equally sure to be followed by septic peritonitis.

If, then, we decide to operate, we choose the middle line, and leave the bullet or knife wounds alone. We should choose the middle line, because here the edges of the wound can be kept in good apposition, because the *linea alba* is less vascular than other parts, because the section of it unites very readily, because there is a less thickness of parts to cut through than if we attempted to divide the muscular walls themselves, and, lastly, because an incision through the *linea alba* gives us more room and greater freedom of manipulation than any other form of incision. Having opened up the abdomen we next proceed to examine the intestines, and if we found only a linear clean-cut wound, we should sew it up by either a continuous or Lembert's suture with fine silk; ascertain that there was no bleeding vessel left untied, then proceed to wash out the cavity with a warm boric or other antiseptic solution, and close the wound. But if the wounds of small intestine were due to a bullet, and were several in point of number, if near together, it will be evident that a resection of the injured gut will have to be carried out.

This has been done in several instances, and quite recently Mr. Barker reported a case in the JOURNAL, March 17th, 1888, when he says: "The wounded gut having been excised, the margins of the bowels were united together by a continuous suture on both sides, and the cut edges of the bowel having by this means been apposed on their proximate aspect, they were united by a continuous suture of fine silk taking up the serous and muscular coats just at the edge, the needle coming out at the cut margins at each stitch. A second row of interrupted silk sutures was

now introduced to reinforce the first. These took up the serous and muscular coats just beyond the first row. This was done on November 21st. The man died on the fifth day, when it was found that union had taken place thoroughly between the cut ends, and the bowel was not obstructed in any way. Tested with considerable pressure it was perfectly air- and water-tight."

Dr. Parkes thought that the Lembert suture alone was quite as efficacious as the more complicated forms of suture, which all require much time and patience to introduce. He describes that the chief difficulty is always to be found at the mesenteric border, where it is difficult to get the serous surfaces in contact owing to the separation of the layers of the peritoneum just before enclosing the bowel, forming thus a triangular space, where the bowel may be said to be not covered by peritoneum.

The cavity of the abdomen must be thoroughly well cleansed, and in these cases there is this difference between operations undertaken for disease and those necessitated by injury. When abdominal section is performed for disease, a simple washing out will suffice; but if there has been a wound of the intestines there will also have been fecal extravasation, and hence there will be greater trouble in the washing out, and some sponging will be possibly unavoidable. Sponges once used to remove fecal extravasation should not be used again in the same operation. In bringing the edges of the abdominal parietes together, it is recommended that the sutures should be passed through the entire thickness of the walls, including both peritoneum and skin, and everything between them; drainage-tubes do not seem to be invariably necessary. When in Paris, attending the Congress of Surgery, held in March last, I witnessed M. Pozzi, when closing the abdomen after an ovariectomy, first sewed the edges of the peritoneum together by a continuous catgut suture; then in like manner the muscular aponeurotic walls; then he included in his interrupted sutures the thickness of the walls external to the muscular coat. He described this in a paper at the Congress, as giving excellent results as regards a firm and unyielding scar. For the different forms of suture that have been recommended for wounded intestine, I would refer to Sir W. Mac Cormac's monograph on *Abdominal Section*, 1887.

In conclusion, I submit that if a person is now brought to hospital with a penetrating wound of the abdomen, laparotomy should at once be undertaken on the grounds that if no viscera are found wounded, the patient's condition has not been greatly altered, and if the intestine is wounded, we are quite sure that septic peritonitis will speedily bring about a fatal termination; but of course all such operations should be undertaken as grave and serious measures, and every antiseptic precaution should be taken to ensure a satisfactory result.

On the other hand, with reference to soldiers in the field, the question is somewhat different, and I cannot help feeling greatly the force of some remarks of M. Delorme, a French army surgeon at the Val-de-Grâce, who, in a paper read at the late Congress, says, when contrasting the case of the wounded soldier with that of the wounded citizen: "Suffering from intense shock, often moribund, he has at first to wait for many long hours before he can be removed, and then not until he has been subjected to some rough and improvised carriage can he receive the aid of the ambulance surgeon, who will have none of the nice appliances of the operating theatre, but merely such as are barely sufficient for the common operations of field surgery. There would not be the quietude necessary for carrying out a delicate and prolonged operation. The very excitement of the combat has affected all alike; time presses. Absorbed as he is by hundreds of cases urgently demanding his aid, the utility of which in their cases is undoubted, can he be blamed who, in circumstances so wretched and unfavourable as these, does not stop to hunt after a wounded intestine?"

However, at first the same objection was brought against antiseptic surgery in the field, yet Russian and German surgeons overcame the difficulty in their last war, and English army surgeons since then have done the same with considerable success. Let us, therefore, hope that, under its salutary influence, army surgeons will yet find a way to succour their comrades, even though they be afflicted with a penetrating wound of the abdomen.

TWO CASES OF ENTEROSTOMY.

By F. BOWREMAN JESSETT, F.R.C.S. ENG.,
Surgeon to the Cancer Hospital.

CASE I. Gastro-Enterostomy.—A man, aged 50, was admitted into the Cancer Hospital on January 22nd, 1887, suffering from intense pain in the pyloric region, accompanied by most violent vomiting and retching shortly after taking food. He had experienced considerable pain in the epigastrium for more than two years; this had not increased very much until within the last few months, though he had from time to time vomited what he described as "coffee-grounds." He had had gastric fever two years ago; he had not been able to eat any solid food for over a twelve-month. In October, 1886, the pains in the epigastrium very much increased, so much so that he was almost afraid to take anything. In December he was seized with most violent vomiting, which lasted almost without intermission for three weeks, the vomited matter consisting of mucus, froth, and "coffee-grounds," and a substance which he described as being like green paint.

The pain continued to increase until his admission into the hospital, but the vomiting had nearly ceased, only occurring occasionally, and during his stay in the hospital before the operation there were no "coffee-grounds" present, the vomited matter consisting nearly entirely of the food he had taken, mixed with a little mucus. He had lost flesh very much of late, and was in such terrible pain that he begged to have something done to endeavour to relieve him. He at present suffered from great tenderness over the pylorus, and although there was no distinct tumour to be felt, yet on deep pressure there appeared to be a good deal of thickening, probably fibrous thickening, of the pylorus, possibly of a malignant character.

It was decided to perform laparotomy, with a view of making a more careful examination of the parts; accordingly, on February 6th, 1887, the patient being placed under the influence of ether, I proceeded to open the abdomen by a median incision extending for about three inches between the ensiform cartilage and umbilicus. The stomach and omentum were discovered to be in their normal condition, but the pylorus appeared to me to be abnormally thickened, and there being no other cause present to account for the violent pain and vomiting, it was decided to proceed to perform gastro-enterostomy.

This was accomplished by pushing the omentum on one side and drawing out about four inches of the jejunum, at the same time withdrawing a portion of the stomach. These parts were supported all round by warm carbolised sponges. Two small apertures were made in the mesentery, close to the intestinal attachment, about three inches apart, and a piece of india-rubber tubing was passed through either opening and made to encircle the gut, thus preventing all circulation of the contents of the bowel. The loop of gut was now laid upon the portion of the stomach to be opened, and a longitudinal fold of the latter, about an inch and a half from the great curvature, was pinched up between the finger and thumb of the left hand, together with a corresponding piece of the gut.

I now cut through the serous and muscular coats of both the stomach and gut, and, still holding the parts between my left finger and thumb, I united the posterior edges of the wound by a continuous suture, the suture passing through the two outer coats of the divided viscera. In this way the serous surfaces were closely united from end to end before either viscus was opened; this row of stitches was carried about a quarter of an inch beyond the incision in the coats of the bowel. I next opened the stomach and intestine by dividing the mucous coat with scissors. All bleeding points were taken up and ligatured with fine catgut as divided. A small quantity of mucus and fluid escaped, which was caught in the sponges. After carefully cleansing the cut surfaces, I proceeded, by means of interrupted sutures of fine silk, to unite the anterior edges of the opening, adopting the Czerny-Lembert stitch. The opening was now securely fastened, but to make it more secure I inserted another row of sutures outside the first, and about an eighth of an inch from it; this row of sutures was introduced with great care through the serous and muscular coats only.

The parts were now dropped back into the wound, and the "toilet" of the peritoneum being complete, I closed the external wound, and replaced the patient into bed. The wound was dressed with iodoform wool.

The patient bore the operation fairly well, and passed a tolerably good night; there was very little retching, and he slept at intervals. He complained of a good deal of pain the next day in the epigastrium; the temperature remained normal. He was fed with enemata of peptonised beef-tea and brandy, and forty minims of liq. opii every four hours. As he complained of a sharp pain in the epigastric region, a hypodermic injection of morphine was given. All went on well until the 10th, three days after the operation, when the patient complained of pain and a feeling of nausea, and slight tenderness on pressure over the wound.

February 10th. Wound dressed for the first time; union appeared to be complete; at midnight of this day he complained of great pain, was slightly confused when awake, and began to vomit thick brown fluid of a most offensive odour; the vomiting lasted until 5 A.M., and at intervals all the next day. Half a pint of warm water, with Condry's fluid, was administered by the mouth and retained. Brand's essence, a teaspoonful every hour, was given. The vomiting now ceased, but the patient got gradually weaker, and died on the night of the 16th, rather more than ten days after the operation.

The *post-mortem* examination revealed that the union between the stomach and jejunum was perfect. There was no peritonitis, and no fluid had escaped from the junction of the intestine and stomach into the peritoneal cavity, notwithstanding the violent retching he had. The cut edges of the mucous membrane had quite united, and there was no other cause discoverable to account for the vomiting than the "kinking" of the gut, which caused all the biliary and pancreatic secretion to be pressed back into the stomach instead of passing by the natural channel.

There was a cicatrix of an old ulcer just at the pylorus, which was somewhat constricted and thickened, probably cicatricial stenosis, but there was no malignant disease. Possibly this was a case in which Loreta's method of dilating the pylorus might have been practised with advantage.

CASE II. Case of Duodenostomy for Cancer of Pylorus. Death One Month after the Operation.—E. W., a married woman, aged 43, eleven children, the youngest 9 months old. No history of cancer nor of phthisis in family; had had much domestic trouble. Patient was admitted into the Cancer Hospital on May 23rd, 1887. She had suffered considerable pain after eating since the birth of her last child nine months ago. During the last three months she had vomited after everything she had taken; during this period she had taken pills and aperients of different kinds frequently. The bowels were never open more than once a week. She vomited about half an hour after everything she took, food returning much as when swallowed; the vomit was very brown, and "all of a boil." Two weeks before admission it was of a very dark colour, like dark blood.

Present Condition.—The abdominal parietes are very atrophied, the movement of the intestines being quite plainly visible. The stomach is seen to be much distended, reaching nearly to Poupart's ligament. In the median line, occupying a position just above the umbilicus and slightly to the left, is a hard, nodular, freely movable growth, the size of a Tangerine orange, continuous with the dilated stomach. After a consultation with my colleagues, at the patient's urgent request that something might be done for her, it was determined to perform laparotomy with a view of attempting to remove the diseased mass, and failing that, either to perform gastro-enterostomy, jejunostomy, or duodenostomy.

On June 4th, the patient being placed under the influence of ether, I proceeded to make an incision about three inches long midway between the umbilicus and xiphoid cartilage. All bleeding points were stopped by pressure-forceps before opening the peritoneum; when this membrane was divided the mass of disease about the size of an orange presented itself in the wound. The mass was freely movable, and had contracted no adhesion whatever to surrounding parts. The disease extended about two inches along the lesser curvature of the stomach. The mesenteric glands were found to be enlarged, the lumbar glands free, the liver healthy.

Owing to the very exhausted condition of the patient on the table, and the state of the mesenteric glands, it was not deemed advisable to subject her to the major operation of pylorotomy, although it was scarcely conceivable to imagine a more suitable case so far as the disease was concerned. From the weight of the growth the attachments of the duodenum were much stretched so as to allow of the portion of gut just beyond the disease being easily drawn into the wound. This was done, and the duodenum

stitched to the parietes, the abdominal wound closed in the usual way, and the patient returned to bed.

The patient bore the operation very well and passed a good night.

June 5th. The patient comfortable; complained of thirst; to have small pieces of ice to suck; temperature normal; pulse 96; to be fed entirely by peptonised beef tea enemata.

June 6th. Complained of slight pain over epigastrium; abdomen soft and flaccid; no tenderness. Tongue moist and clean; temperature normal. The enemata had been administered in three-ounce doses every four hours, and the urine drawn off every six hours. She slept fairly well during the night.

June 7th. The bandage was removed, the wound looked quite healthy, and as the bowel seemed to be firmly attached to the parietes I made an opening into it with a tenotomy knife, large enough to admit a No. 14 catheter. Three ounces of peptonised beef-tea were injected into the duodenum and retained; this was ordered to be repeated every six hours. Abdomen quite flat; no pain; temperature normal.

June 9th. Removed stitches from abdominal wound; powdered starch ordered to be dusted over the abdomen around the opening into the gut.

The patient progressed favourably until the 13th, when the beef-tea returned through the wound shortly after being introduced, and there was a considerable flow of bile from the wound; five grains of sodæ carb. were now added to each injection of beef, and an ounce of port wine was ordered with each enema of beef-tea.

The patient's strength was well maintained; the temperature continued normal, and she was free from pain, but complained of great thirst. As the skin around the wound was looking red and inflamed, I ordered a powder consisting of equal parts of acid. boracic, powdered starch, and oxide of zinc; the parts to be washed at each feeding with carbolised water.

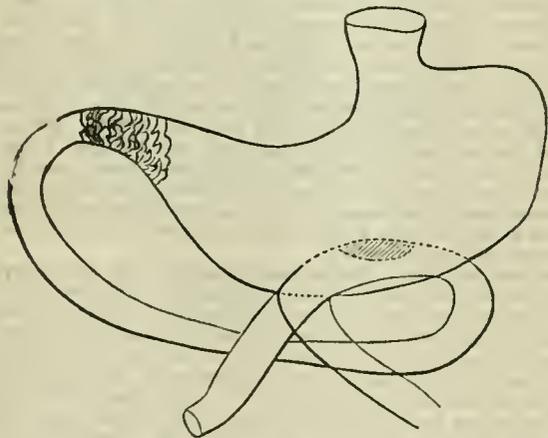

Fig. 1, representing the jejunum united to the stomach on the anterior aspect, the dotted line showing how the kinking may take place.

On June 14th, instead of the ordinary peptonised beef-tea, I substitute zymïn ʒss; with sodæ carb. gr. x. in a powder to be added to each injection of beef-tea. This powder answered admirably. The remainder of the stitches were removed.

June 16th. The patient vomited four porringersful of fermented fluid. This was evidently the collection of gruel, etc., she had been allowed to take the last few days. She was ordered to take nothing by the mouth in future. The stomach was washed out with a quantity of warm Condé's fluid and water, with much benefit. She seemed somewhat easier after this, but the stomach was enormously dilated, and distinct succussion was perceptible. The patient from this point gradually got weaker, and died on July 3rd, exactly one month after the operation.

Had this patient applied earlier, I have little doubt but what pylorotomy or gastro-enterostomy might have been practised with every chance of success; but, as I have said, she was so exhausted that an operation involving any great strain upon her strength would have been impossible. But there is no doubt that the operation performed gave her considerable comfort during the last few weeks of her life.

REMARKS.—The first of these two cases illustrates well how successfully a gastro-intestinal fistula may be formed so far as the union of the stomach and jejunum are concerned. It also suggests a few not unimportant modifications that, in my opinion, might be with advantage adopted. The vomiting that followed the operation was undoubtedly due to kinking of the jejunum just beyond the seat of union with the stomach, preventing the passage of the gastric and pancreatic fluids, and bile. The operation as performed in this case was planned as is usual, so as to bring up a loop of the jejunum as near its origin as possible, and fastening it to the anterior wall of the stomach (Fig. 1). This, of necessity, causes a great risk of the gut doubling upon itself at its efferent end. Now it appears to me that it would be far better to fasten the gut to the posterior wall of the stomach (Fig. 2). This can be done in one of two ways merely by turning the great omentum and colon up and dividing the transverse mesocolon, and thus drawing a portion of the stomach through the opening, and fastening it to the jejunum close to its duodenal origin, or by dividing the gastro-colic omentum in front, and fastening the posterior wall of the stomach to the anterior portion of the last portion of the duodenum. That these two operations would be attended with slightly more difficulty than the operation at present adopted there can be no doubt; but the advantages to be derived are so obvious, that I think the extra trouble would be well repaid.

I would here draw attention to the practice of Dr. Senn, of Milwaukee. He has made numerous experiments on dogs, and adopted the following plan. Instead of stitching the stomach and intestine together, after the Czerny-Lembert method, which he justly says is most tedious, and prolongs the operation considerably, he provides himself with two plates of decalcified bone about two inches in length, an inch in width, and a quarter-of-an inch thick, with a longitudinal opening in the centre five-eighths of an inch long by one-sixth of an inch wide. Four perforations for the sutures are made near the margin of the oblong perfora-

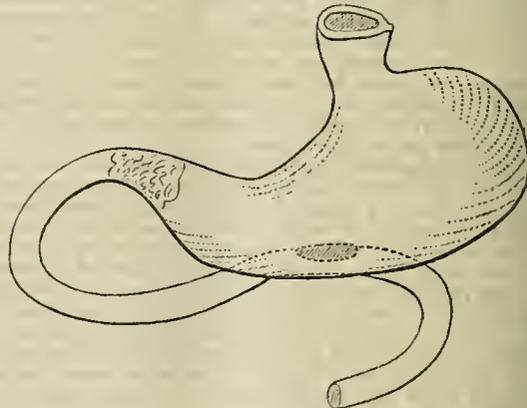

Fig. 2, representing the jejunum united to the stomach on the posterior aspect, the dotted line representing the union behind the stomach.

tion, one at each end, and one at each side. The sutures are attached to these plates by threading two fine sewing needles each with a piece of aseptic silk, twenty-four inches long, which are tied together. The threads are then fastened to the surface of the plate by another thread passing through the perforation in the shape of a loop, and fastened to the back.

The stomach being drawn forward into the wound, a longitudinal incision is made in the anterior surface, and the perforated disc of bone introduced. The lateral sutures armed with needles are now passed through the entire thickness of the walls of the stomach, half way between the angles of the wound. A similar incision is now made into the intestine at the junction of the duodenum and jejunum. The second plate of bone is introduced, and the margins of the wound punctured by the lateral armed sutures when the two wounds are brought *vis à vis*, and the corresponding sutures tied. The serous surfaces of the stomach and intestine over an area corresponding to the size of the plates are then brought into accurate permanent contact by the tying of the sutures. The animals he operated upon recovered, notwithstanding they were allowed to eat immediately after the operation, and the diet was not selected or restricted.

That this method of operating has much to recommend it I think there can be no doubt, as the time occupied in the operation is reduced, according to Dr. Senn, to from fifteen to twenty minutes.

Surgeons in this country doubtless will decline to adopt this method of operating until such time as they have convinced themselves of its feasibility, as, in the first place, the method of passing the sutures through the whole of the coats of the stomach and intestine is directly opposed to all rules of intestinal surgery of the present day. Dr. Senn, however, illustrates his paper with numerous cases in which he has operated in this manner successfully on dogs, under the most adverse circumstances; and, if his reports are to be relied upon, I see no reason why similar operations should not be performed upon the human subject.

These operations on the dead body are perfectly easy of performance, and the time occupied is not a tithe of that consumed in the ordinary operation. In any case I think the subject is well worthy the most careful consideration of surgeons who practise in this department.

A CASE OF INTESTINAL OBSTRUCTION TREATED BY LAPAROTOMY: RECOVERY: REMARKS.¹

By HOWARD MARSIL, F.R.C.S.

Assistant-Surgeon to St. Bartholomew's Hospital, and Senior Surgeon to the Hospital for Sick Children.

EMMA D., a housekeeper, aged 34, who had previously enjoyed good health, except for occasional dyspepsia, was suddenly attacked with intense abdominal pain immediately after an action of the bowels on the 8th of last November. With great difficulty she crawled up to bed, and when seen, half an hour afterwards, by Dr. Qualtrough, of Upper Holloway, was still complaining of very severe pain, persistent in character, but aggravated by frequently recurring paroxysms. There was neither tenderness nor distension of the abdomen. Pulse and temperature normal. Dr. Qualtrough gave her a hypodermic injection of morphine, and ordered her a little ice to suck, and a small quantity of milk and soda-water occasionally. Six hours later she vomited the half digested contents of the stomach. For the next four days, during which she was seen also by Dr. Keateven, she remained in much the same condition. Vomiting occurred twice or three times each day; there was no action of the bowels, but flatus was passed. She still complained of considerable griping pain, and there was fulness of the abdomen, with slight tympanites; the temperature was not raised, and the pulse remained under 90. She presented no appearance of general illness, and said that, except for the pain, she felt well enough to be up. I first saw her on the 13th, five days after the commencement of the attack. She then looked rather pinched and anxious, and was becoming weak; the temperature was normal, and the pulse 85. Sickness had occurred several times during the day, and was increasing in frequency; the bowels had not acted, but flatus was still passed; the abdomen was distinctly, but only moderately, tympanitic; it was tender on pressure in the neighbourhood of the umbilicus.

On the 14th, after a consultation at which Mr. Thomas Smith, who had been previously sent for, was present, and who gave me his valuable assistance, I opened the abdomen in the middle line, below the umbilicus, and on following the small intestine—by tracing it onward from the distended loop which presented itself in the wound, and returning each three or four inches before another portion was drawn out of the wound—I came to a part that seemed fixed. Passing my finger along this, I could feel that a loop had slipped through a hole, apparently about three-quarters of an inch in diameter, in the mesentery. The mesentery in this spot seemed of normal thickness and pliability, and the edge of the opening was so yielding that I could readily stretch it with my finger-nail sufficiently to allow the loop of intestine to be drawn out. The loop was somewhat congested, and the lines above and below, at which it had been constricted, could be distinctly seen, but evidently strangulation had been only partial. The abdominal cavity, which contained a considerable quantity of blood-stained serum, was thoroughly sponged out with weak

carbolic lotion (1 in 80), and the wound was closed with China silk sutures.

After the operation the patient was allowed nothing by the mouth but small fragments of ice, amounting in the first twenty-four hours to less than two ounces. She was fed by the rectum, and kept slightly under the influence of morphine by hypodermic injections. A soft enema tube was passed about six inches into the rectum, and retained there to facilitate the escape of flatus. Twelve hours after the operation the pulse was 84, quiet and regular, and the temperature was 98.4° F. The patient occasionally ejected, without straining, a little bilious fluid. She was tranquil and free from pain.

November 14th. Pulse and temperature normal, tongue clean and moist, no abdominal distension, flatus passed freely from the tube in the rectum; no sickness. Diet: one teaspoonful of beef-tea or peptonised milk alternatively, every hour, and a little ice to allay thirst.

November 15th. A quiet but almost sleepless night. General condition as yesterday, but she was wasting quickly, and complained of intense thirst. To take food in rather larger quantities every hour.

November 16th. Very restless, and in great general distress: very prostrate. Was now frequently sick, ejecting bile-stained fluid. Pulse 100, temperature 101°. Had passed a small green motion, with severe griping pain referred to the umbilicus. At 7 P.M. an enema of warm soap and water was given. This produced a large evacuation of green-coloured soft fæces. The result was remarkable. Before the enema vomiting was frequent, and the patient was so exhausted that her case seemed hopeless, and it was thought that she would not live through the night. Directly after the bowels had acted she fell asleep, and slept quietly and soundly for three hours, and the vomiting entirely ceased.

November 17th. Abdomen distended. She complained of very severe griping pains, which made her grind her teeth. To be fed entirely by the rectum. A yellow evacuation was passed after an enema. She was very restless and thirsty.

November 19th. No vomiting or abdominal pain. Delirious at night; trying to get out of bed. Pulse 125, weak and running. She was very prostrate. To have two teaspoonfuls of beef-tea or milk every hour; rectal feeding to be continued. Hypodermic injection of morphine (one-sixth of a grain) about twice a day.

November 21st. Had a severe attack of retching and purging this afternoon. Was very weak, yet she looked better. Copious herpetic eruption about the mouth; aphthæ on the tongue. The wound had, with the distended condition of the abdomen, reopened to the width of an inch and a half, and a coil of small intestine covered with granulations was exposed. The abdominal wall to be well supported with strapping and a bandage.

November 26th. Still very weak; frequent hiccough; much retching and diarrhoea. Skin covered with a bright red, very irritating eruption; great emaciation; tongue dry; pulse 120.

November 30th. Too weak to move in bed; hiccough continued; considerable distension of the abdomen; pulse 120; temperature 98°.

December 2nd. Much better; tongue moist; passed solid motions; retched only occasionally. Wound slowly closing; distension subsiding.

From this time she gradually recovered. By January 10th she was taking usual diet; the bowels acted naturally; the wound was nearly healed, and she was steadily gaining flesh and strength. She is now quite well.

REMARKS.—No clearer indication could be given of the progress of abdominal surgery than the doubt that at first presents itself, whether this case contains anything that qualifies it for publication. Numerous examples of completely successful operations, involving much more extensive interference with the intestines, have been reported; and thus, in some respects, this instance is commonplace. Yet I believe it should be recorded. In the first place, it is an example of recovery after laparotomy for internal strangulation. In this aspect it is now happily far from unique. Yet the list of such cases is much less extensive than it ought to be, and the instances in which a fatal result follows mechanical obstruction are much more numerous than they are destined to become when sufficient evidence has been collected to persuade those who still hesitate (*a*) that when symptoms which clearly point to the existence of mechanical obstruction are present, it is as incumbent on the surgeon to open the abdomen as it is to operate when there is reason to believe that an external hernia is strangu-

¹ Read before the East and West Sussex District of the South-Eastern Branch.

lated; (b) that the operation must be performed early; (c) that the risk which the operation involves is so comparatively small that it cannot be justifiably urged as a ground for delay.

Secondly, the case is of value because it illustrates and emphasises the fact that symptoms which till recently have been ascribed to peritonitis often depend on what may be called "secondary obstruction"—that is, on obstruction due to the paralysed condition of the gut at the point of injury. The recognition of this fact constitutes one of the most important advances that have lately been made in respect to cases of internal strangulation.

The mode of onset of the attack, and the symptoms observed in the first two or three days of the patient's illness, were of doubtful interpretation. The sudden onset of severe pain that followed the action of the bowels and the development of sickness were strongly suggestive of mechanical obstruction, but their meaning was obscured by the fact that flatus was freely passed, and that there was scarcely any distension or tympanites. Evidently if obstruction was present it was not complete. Another feature that increased the uncertainty of the case was that the patient, for the first two or three days, had the appearance of being in almost her usual health.

These apparently conflicting symptoms were explained and reconciled at the operation. There had been little distension, but persistent sickness, because the obstruction was in the small intestine—I think it was as high as the middle of the jejunum. The patient did not look pinched or collapsed, and flatus was still passed, because the opening through which the gut had slipped was placed in the mesentery, where that structure was too thin and membranous to produce complete obstruction, or even at first to cause any serious injury to the intestinal wall. But in the course of three or four days the continuance of sickness, the fact that no fæces were passed, the appearance of distinct though still moderate tympanites, and the gradually increasing distress of the patient forced the conclusion that mechanical obstruction must be present.

The operation itself was easily performed, as there was only slight distension of the intestine. It is now well understood that the state of the intestine in this respect is one of the most important points in regard to laparotomy for obstruction. Distension adds greatly to the difficulty of every stage of the operation. So far is this the case that in any instance of obstruction the amount of tympanites must always be taken fully into account. Few recoveries take place when it is considerable, and in any case in which operative interference is contemplated the increase of tympanites ought to be regarded as a warning against further delay.

I have had several opportunities of testing the value of searching for the obstruction, not by introducing the hand, but by taking the loop that first presents in the wound, and tracing it onward by drawing out three or four inches for examination and then returning them, so that no more than six inches are ever out of the wound at the same time. In this way the intestine may be traced upwards towards the duodenum, or downwards towards the ileum, till the obstruction is reached, with very little delay, and with no danger if the manipulation is gentle. If, having traced the gut up to the duodenum or down to the ileum—for he cannot tell with certainty in which direction he is travelling—he has found no obstruction, the operator must trace his way in the opposite direction, taking, however, very great care that he does not drop the loop and so break the continuity of his examination.

To relieve her as soon as possible from the discomfort and danger of gaseous distension, I availed myself of the practice recommended by ovariotomists, of raising the patient's shoulders, so that she could the more easily expel flatus from the mouth; and I also introduced a soft tube about six inches into the rectum. Through this, for some hours, flatus continued to escape, to the great comfort of the patient. Both these expedients for removing gas from the intestinal canal should, I think, be adopted in cases of this kind.

The favourable manner in which she bore the operation was remarkable. When I saw her, about six hours afterwards, her pulse was 84, her temperature was normal, and she showed but small traces either of the operation, or of her previous illness.

The return of sickness on the third day after the operation, and the manner in which it was treated, deserve careful observation. It was due, I think there can be no question, to the fact that the piece of intestine that had been partially strangulated was still paralysed, so that the fecal material that was passed into it from above lodged, and so renewed the obstruction. It then became a question whether the intestine would recover its peristaltic

action, and so overcome the obstruction, or whether the obstruction would persist till death occurred from vomiting and exhaustion. It was when the patient's life was thus in the balance that the enema was given, in the hope that it might be the means—by unloading the lower bowel, reducing distension, and indirectly stimulating the flaccid piece of intestine into action—of restoring the patency of the canal. Fortunately this result was attained, and all the symptoms of obstruction disappeared, and did not return. When sickness, coupled as it is so likely to be, with increasing distension, returns in cases of this kind, three courses present themselves: 1. To give an enema; 2, to give an aperient by the mouth; 3, to fasten a distended loop of small intestine to the edges of the abdominal wound and open it. In the present instance the enema secured all that was required, and put an entirely new aspect on the case. Mr. Lawson Tait and others have shown the excellent result that may follow the use of aperients in intestinal distension following some cases of abdominal section, not directly involving the intestine. Aperients, however, must obviously be used with very great caution when obstruction depends on paralysis of the intestine after strangulation, for the condition of the gut at the seat of injury must be a matter of doubt, and the action of an aperient might be followed by perforation. To open the small intestine in the abdominal wound is a step that will avert death in some cases, and the damaged condition of the gut at the point of strangulation and the necessity for immediate relief from obstruction may fully justify its adoption. But it has some serious drawbacks. The patient is generally so exhausted that an anæsthetic, and the sickness which it may provoke, the reopening of the wound, and the necessary disturbance and exposure are each a source of danger. And there is also the highly important question whether, in the exhausted condition of the patient, and in the presence of vomiting, should this continue, safe union will take place between the intestine and the abdominal wall, so that there shall be no escape of fæces into the peritoneal cavity. There is the further point that we are unable to say what part of the intestine will present at the wound, and, therefore, that we cannot be sure that the opening may not be so high up as seriously to interfere with general nutrition. Which of the three alternatives should be adopted must depend on the circumstances of each case; but there is reason to hope that the timely use of an enema, when the symptoms of obstruction return after laparotomy, will often have a valuable effect—at least, it should be tried before anything more serious is undertaken.

When, in consequence of the weakly condition of the patient, the distension of the abdomen, and the retraction of the edges of the wound, the latter reopened, a coil of the small intestine was exposed over an area of nearly six inches in length by two in width. But no harm followed, for the peritoneum covering the gut had become united with that lining the abdominal wall, and the peritoneal cavity was safely shut off. In two other cases I have met with the same condition. In both, as in this instance, the wound gradually closed, and no intestinal protrusion occurred.

It was apparent at one time that the patient was suffering severely from the want of food. She wasted rapidly, complained of intense thirst, and was so prostrate that she could not move even her legs without assistance; her pulse was weak and thready, her face deeply wrinkled, her eyes dull, and her conjunctive congested. But the danger in this direction had to be incurred, for when she was allowed food by the mouth sickness at once returned, and would have been quickly fatal to her. The inability to take food by the mouth persisted till the ninth day after the operation.

JEJUNAL ENTERECTOMY FOR THE CLOSURE OF AN ARTIFICIAL ANUS OF EIGHTEEN MONTHS' STANDING: RECOVERY.

By THOMAS SINCLAIR, M.D., F.R.C.S. ENG.,
Professor of Surgery in Queen's College, Belfast.

THERE appears to be less hesitation in adopting the relatively severe measure of resection of the bowel in the treatment of abnormal intestinal openings than prevailed some time ago. Doubtless some of these conditions yield to simpler plans, such as pad and bandage, plastic operations of various kinds, the use of enterotome clamps and the like, but we have too

many opportunities of proving their inadequacy, not to mention the positive risks attending the employment of some of these means, particularly those last alluded to. Moreover, the anatomical relations are not so uniform in a series of cases as to admit of a routine treatment, some inviting the clamp method, others, without a pronounced *éperon*, contra-indicating resort to it. Frequently also plastic operations, involving transplantations, are attempted under circumstances that offer little or no prospect of success. The following case is illustrative of some of these points, enterectomy being resorted to after failure of the pad and bandage and plaster plans to effect a closure.

The subject was a farm labourer, aged 60 years, who stated that eighteen months prior to his admission to the Royal Hospital, Belfast he had been acutely ill for some days with a groin swelling. The swelling burst; something black escaped, after which the intestinal contents issued freely. Evidently there had been sloughing of a femoral hernia of the right side at this date. Shortly thereafter, according to the patient, the opening showed an inclination to close under the treatment of his previous medical advisers, but latterly had become much larger in spite of this treatment. A considerable quantity of the chyme now flowed from it, more especially when he was not recumbent. Being high up in the alimentary canal this resulted in the loss of much flesh and strength. As it was growing rapidly worse, and as he was quite unfit for work, he was anxious to have some operation done for its cure. Although a moderate amount of faeces passed by the normal channel, an examination of the parts was unfavourable to the adoption of the milder measures. A plastic operation was impracticable, from the very dense cicatricial puckering extending widely around the opening, so dense that the spermatic cord and Poupart's ligament could not be felt in it. A large projection from the anterior lip of the proximal bowel, which could not be repressed, offered another obstacle. Dupuytren's plan by the enterotome clamp was unsuitable, from the want of a safe spur, the flexion of the bowel being only moderately acute. Simple enterorrhaphy, after liberation of the coil from its parietal adhesions and paring of the edges of the opening, suggested itself; but the opening involved more than two-thirds of the circumference of the gut, hence enterorrhaphy would have nearly obliterated the lumen of the gut. Enterectomy remained as the only open course.

Rest in bed for more than a week, with a castor-oil purge every third day, an enema on the evening before and another on the morning of the operation formed the preparatory course. A three and a half inch incision through the artificial anus along Poupart's ligament, with a circular dissection gradually deepened round the opening, was the first step. The spermatic cord was disentangled with much difficulty from the hard cicatricial mass, but the deep epigastric artery was so engaged in it, and so much in the way, that it was double-ligatured and divided. Poupart's ligament and the deep crural arch were also cut before the intestine could be liberated from its intimate connection with these parts. This separation of the bowel, conducted with a view to injure it as little as possible, was tedious, bloody, and difficult. Drawing the coil out upon the thigh, the abdominal wound was plugged with aseptic sponges, and the removal of the segment of bowel proceeded with on the lines recommended by Sir William Mac Cormac in his masterly oration on Abdominal Section for the Treatment of Intra-peritoneal Injury. The intestine was clamped above and below with pieces of drainage-tube held by Wells's forceps, a simple plan which answered very well. Scissors were used for the section, the bowel being cut obliquely to its axis, so as to remove three inches from the concavity, and four and a half from the convexity. This oblique section involved the ligation of ten arteries in the edge of the section. The mesentery was divided close to the gut by successive snips, ten arteries requiring ligatures were tied, and the edges of the mesentery, none of which was cut away, were stitched together. Next, two fine stitches on either side were so introduced as to exclude the nearest uncut terminal arteries, into the sides of the mesenteric triangle near its base, in order to bring them together, and cover as far as possible that part of the gut uncovered by peritoneum. By this means two of the three most important intestinal stitches became capable of insertion by Lembert's method; only the central one was a muscular coat suture merely, and this was much buried by its two immediate neighbours, turning the serous coat well inwards at a point where otherwise this is difficult to accomplish. Two dozen Lembert's stitches were introduced in one row, at intervals of two lines, no stitch being tightened till

all were passed. Ordinary cambric needles were used, and fine carbolised silk for all sutures and ligatures. The edges of the pucker in the mesentery, now folded and redundant, were brought together by a few points of suture, the more efficiently to support the intestinal sutures at this critical spot. Everything having been well flushed with warm boric lotion, the coil was reduced, and the parietal wound closed as far as practicable by silver sutures, a drainage-tube being left in its superficial part, but not reaching into the abdominal cavity. Iodoform, salicylic wool, and an elastic roller completed the dressing.

The operation occupied upwards of two hours, and the ether was so managed that one ounce sufficed for the whole operation. Having regard to the fact that the enterectomy involved a portion of the jejunum, which, from the great number and depth of the valvulae conniventes was judged to be a portion situated high up in this part of the alimentary canal, the after-treatment was carried out with much caution. Opium, to the extent of fifteen minims of the tincture thrice in the twenty-four hours, was given to minimise peristalsis and intestinal secretion for the first eight days. At no time was it pushed so far as to affect the pupils. Indeed there was no other indication for its employment but that alluded to.

Anything likely to escape complete digestion in the stomach and to excite pancreatic and intestinal activity was withheld as long as possible. Even simple fluids were given in sips, and thirst attended to chiefly by tepid water injections into the rectum. The only things given by the mouth for the first eight days were sips of water, kali water with spirits, and tea without milk. During this time four nutrient enemata, consisting of four ounces of pancreatised milk with two spoonfuls of Brand's essence, were administered on each of the first three days. For the next four days pancreatised beef-tea and pancreatised milk enemata, six to eight ounces each, were given alternately, four during each day. For two more days rectal feeding, in the form of predigested beef suppositories, was continued; but plenty of milk-whey and tea were now given by the mouth, and some lemon juice. On the tenth day after a spontaneous action of the bowels, pancreatised beef-tea and milk were given by the mouth, and rectal alimentation was abandoned. On the following two days, toast, butter, fish, milk, and beef-tea were allowed, and after the fourteenth ordinary meals. Flatus had passed *per anum* freely from the second day forward, and on the tenth the bowels acted of themselves, an event which synchronised with the only febrile temperature (100.4° F.) recorded throughout.

The dressings were removed for the first time on the sixth day, when the incision was found united by first intention, and the silver sutures and drain-tube were withdrawn. The central portion, corresponding to the artificial anus, the edges of which had been refreshed at the operation, subsequently granulated, and was closed before the end of the month. On account of the dense contraction here it was not possible to expedite this closure by suture or plastic operation. The patient rose upon the twenty-second and was discharged on the twenty-eighth day, the parietal wound having closed and the bowels having regained their natural function.

Mr. A. E. J. Barker, in a very interesting communication to the JOURNAL of March 17th upon Laparotomy for Penetrating Gunshot Wound of the Abdomen, has shown by the *post-mortem* examination of one of his cases treated by enterectomy that six days suffice for sound union between the ends of the gut. Possibly a shorter abstinence from food by the mouth than ten days in the present instance would, in the light of this observation, have been sufficient; but the adequacy of rectal alimentation was so pronounced that hunger was not complained of by the patient during this interval. Though quite willing to feed him by the mouth at the end of the first week, it appeared judicious to wait a few days, until either some urgency on the patient's part or some change in his general condition demanded more thoroughgoing nourishment. Mr. Greig-Smith justly remarks in his work upon *Abdominal Surgery*, "under the best form of rectal alimentation yet devised the patient steadily loses ground." Nevertheless one could not have observed the after-course of this case without admitting that the value of rectal feeding was considerable. The patient certainly lost flesh, but the healthy behaviour of the wound and comparative freedom from hunger attested the value of predigested nutrient enemata.

The other noteworthy features in this instance are: the sufficiency of a single row of Lembert's sutures of silk, and the treatment of the mesentery. No triangular segment of mesentery was

excised, and much care was taken to narrow the space between its layers, where it joins the intestine, so as to secure as perfect coaptation of the serous layers at this spot as possible.

CLINICAL MEMORANDA.

FUGITIVE IODISM: ŒDEMA OF EYELIDS.

W. J. H., aged 30, on May 7th complained of frontal neuralgic headache, which had varied in intensity during the preceding ten days. He could not bring to mind having had headache before, but had been, during several years, inconvenienced by an irritable catarrhal condition of his fauces and naso-pharynx. Having applied a chloroform preparation of aconite root with a camel hair pencil horizontally to the forehead from side to side, a full inch above the eyebrows, I prescribed as follows:—R Liq. ferri iodidi, ℥ij; aq., ℥vj; ℥j ter. Soon after the second dose the patient felt a severe cold had come upon him quite suddenly—sneezing, a very copious and steady flow of watery fluid from the left nostril, sufficient to saturate two handkerchiefs. This ceased in one hour as abruptly as it had occurred. Coincident with its cessation a puffiness of the eyelids on the corresponding side ensued; this increased, and on retiring the patient's lids were completely closed. He slept well, and the morning following his eye presented the appearance of having been stung by an insect, as described by Dr. Tom Robinson. The left eyelids, both upper and lower, were equally tumid with a semi-transparent rosy fulness, which the patient said was less than on retiring the night before. There was neither subconjunctival œdema nor any discharge from between the lids. The conjunctiva presented a diffuse pinkness. Over both cheeks, but nowhere else on the body, was an urticarial erythema, fainter on the left than on the right cheek. He felt well; his headache had gone. On May 10th, the phenomena had completely vanished.

REMARKS.—Here is seen a person with a decided catarrhal dyscrasia suddenly attacked with fugitive œdema of the eyelids sequent upon a free catarrhal outpour from the nasal mucous membrane. So far, the symptoms being limited strictly to the one side lends weight to the idea that an extension of the same catarrhal process into the neighbouring loose connective tissue, though this was not related by immediate continuity, had occurred. Another view may be taken; that the transient œdema of the lids was associated with an impediment in the course of the efferent lymphatic circulation occasioned by the turgidity of the nasal mucous membrane.

EXCESSIVE THIRST A SYMPTOM OF MALIGNANT DISEASE.

In a case of malignant disease which came under my care lately, certain symptoms were present which seemed rather difficult of explanation, and may I think be considered unusual. The case was briefly as follows. About three months before her death I was called to see a woman, aged about 50, who had been suffering from dyspeptic symptoms for about five months previously. At this time she complained of pain, nausea, vomiting, and other symptoms of gastric derangement. A tumour was to be felt in the epigastric and right hypochondriac regions, evidently involving the liver and intestines. The case ran a rapid course. About three weeks before death, the most extraordinary thirst came on which nothing could appease. It used to come on in paroxysms, and although her friends tried to keep too much fluid from her, she would clutch wildly at any vessel, and pray for more. Her husband used to say to me, "Her thirst is terrible, surely there must be some great heat in her." I may say that what she drank used almost all to come back again. Constipation, which was troublesome all along, became absolute for the last ten days, evidently from pressure of the tumour on the gut. There was no increase in urinary secretion or febrile symptoms.

SURGICAL MEMORANDA.

ON THE TREATMENT OF SEBACEOUS TUMOURS.

MANY people, the subjects of congenital sebaceous tumours and "wens," object to having them removed, on the score that the remedy is worse than the disease, and the after-consequences may be serious.

The following is the method I have adopted in such cases, and with marked success. With a cataract knife (Graefe's) puncture the cyst, and gently squeeze out the contents; then introduce a very small piece of nitrate of silver. On the following day, by means of a pair of forceps, the capsule of the cyst can be withdrawn, just like the shell of a bean, without any portion being left adherent. In no case has there ever been any return of the growth or any ill effects.

The method, if tried, will be found to have many advantages apart from its simplicity and thoroughness.

T. MURRAY ROBERTSON, M.D. Edin.

PERICHONDRITIS OF THE LARYNX: TRACHEOTOMY: RECOVERY.

THE following particulars of a case which occurred in my practice eight years ago may be of some practical interest at the present time.

R. W., aged 39, pointsman on a railway, consulted me for a troublesome hoarse cough, attended with difficulty in breathing. He had all the symptoms of a severe attack of laryngeal catarrh, and was treated by poultices and counter-irritation, together with the usual remedies and inhalations. The case continued to get worse, the difficulty of breathing increased, and the patient could only articulate in a whisper. On laryngoscopic examination of the larynx, it was found red, swollen, and ulcerated. There was also thickening and tenderness externally. He was now put on large doses of perchloride of mercury, with iodide of potassium and cinchona, at the same time keeping the patient in a warm atmosphere, inhalations being continued. The patient still continued to get worse, and Dr., now Sir Walter Foster saw the patient in consultation with me; he advised the continuance of the treatment, but to be in readiness to perform tracheotomy should the symptoms of dyspnoea increase. The patient got worse, and on the following morning at 5 A.M., I found him so bad, and suffocation impending, that I immediately, with the aid of my then assistant, Mr. Welch, opened the trachea and inserted the tube. The result was immediate relief of the patient's suffering; from being cyanosed he recovered full power of breathing, and became calm and natural in colour. I kept him in a warm atmosphere, with hot sponges constantly applied over the orifice of the tube, and continued the medicinal treatment as before.

The case went on well, the cough gradually lessened, the thickening of the larynx and ulceration subsided. Later on a piece of exfoliated cartilage was coughed up and the expectoration daily diminished, and at the end of one month from the operation, I deemed it advisable to make an attempt to do without the tube. I first experimented by removing it for a few hours, keeping him under close observation the whole time; finding he seemed no worse, I continued to let him remain without it, and at the expiration of a month from the removal of the cannula, the external wound had healed, and the patient continued to breathe quite freely.

The patient is still alive and has had no return of the disease, and but for some feebleness of voice is quite well.

REMARKS.—The success of this case appeared to me to be due to the removal of the cannula at the time when the larynx had so far recovered as to enable the patient to breathe fairly well without it, as the presence of it, acting as a foreign body, seemed to set up some irritation in the trachea, causing exuberant granulations to appear around the orifice of the wound.

Selly Oak, near Birmingham.

URTICARIA DIFFUSA VEL FEBRILIS OCCURRING AFTER OVARIOTOMY.

SOME time ago I removed a small ovarian tumour from a young lady, aged 25. The operation was a very simple one, and the wound healed rapidly, all the sutures being removed by the seventh day, and the pulse and temperature being both normal by that date. Late on the following night I received an urgent message saying "that my patient had been taken with vomiting, and was complaining of pain in the back, headache, and sore throat. The temperature had gone up to 101, and the pulse to 120, and a red rash had come out over her face and chest." When I arrived at the house I found the patient in a state of great excitement owing to the nurse in her fright having said something about scarlatina. Her face was flushed, and her neck, shoulders, and body were covered with a bright red rash. She complained

of swelling and soreness in her throat, and of burning and itching of the skin. Her temperature was over 102°, and the pulse 130. The bowels had acted well, and there was no scantiness of urine. She had not eaten fish or meat, but was still on light diet. In fact there was nothing to account for the attack except that she had on that day heard of the sudden illness of her mother, an old lady of 65 years. The vomiting, pains in the back, sore throat, headache, high temperature, and quick pulse rather alarmed me at first, but the suddenness of the attack and breaking out of the rash, together with the burning and itching of the skin and the state of the tongue, led me at once to diagnose urticaria diffusa. I gave her a dose of white mixture, and ordered 20 grains of sodæ picarb. every two hours, and a lotion of the same, ℞ss. ad ℞j, to allay the itching. I attempted to reassure her, but she was so nervous and excited about her condition, refusing to believe it was other than scarlatina, that I had to give her a full hypodermic injection of morphine in order to quiet her. By the next morning the rash had left the body, but was still visible on the limbs, and within twenty-four hours it had quite disappeared, and the pulse and temperature became normal. The rash was not allowed by desquamation.

I take it that this form of urticaria, attended with a diffuse rash instead of the usual distinct wheals, is uncommon, and might, with such symptoms as were met with in this case, be easily mistaken for scarlatina at first sight. So far as I could judge, this attack was not brought on by any error of diet, and I should be inclined to attribute it to some disturbance of the nervous system.

NORTHAMPTON GENERAL INFIRMARY.

ANEURYSM OF THE INNOMINATE ARTERY: SIMULTANEOUS LIGATION OF RIGHT SUBCLAVIAN AND CAROTID ARTERIES: ARREST OF THE DISEASE.

(Under the care of Mr. PERCIVAL.)

[From notes kindly supplied by Mr. ANDLAND and Mr. WEATHERLY.]

F., aged 43, a charwoman, married, was admitted on July 24th, 1887, under the care of Mr. Percival. Her family history presented nothing of importance, except that her mother, grandmother, and her sister had died of phthisis. She seems to have been healthy all her life, her only illness having been an attack of typhoid fever when

hard skin. There is a pulsating tumour just above the right sterno-clavicular joint, and bulging to the tracheal side of the sternomastoid. It projects upwards about an inch above the clavicle, and is about an inch across; its lower limit cannot be defined. It is distinctly pulsatile, lateral expansion being well marked; is only slightly tender to the touch; the skin over it is not reddened, nor is there any sign of inflammation. The patient complains of a good deal of pain in it at times; her rest is much disturbed, and there is occasionally a certain amount of dyspnoea at night. The voice is distinctly affected, the patient being only able to speak in a husky whisper. It is difficult to get a good view of the glottis, but the false cords are swollen, and there is some paralysis of the right vocal cord. The pulse differs greatly on the two sides of the body, as shown by the sphygmographic tracings given below.

There is a loud rough *bruit* heard in the tumour and over the upper part of the sternum. The patient complains of difficulty of swallowing, and has lately been subject to severe headaches, which are increasing in intensity. No signs of old syphilis can be detected. She was placed on a very limited diet, and 20 grains of iodide of potassium in infusion of gentian given three times daily. An ice-bag was also applied to the swelling, but caused such pain that it was discontinued after the first day. She was kept strictly in bed, and perfect quiet enjoined. This treatment was continued till September 25th, when the patient was heartily sick of it, and anxious for something else to be done. The tumour had meanwhile considerably increased, probably to double its size on admission; the pulsations in it were very strong; there was more pain and dyspnoea, and the voice had sunk to quite a low whisper; the nights were very sleepless, and some prominence of the eyeballs was noticed about this time. On this date, therefore, the patient being placed under ether, Mr. Percival first tied the subclavian in the third part of its course, and then the common carotid; the only noticeable feature in the operation being the difficulty of finding the carotid artery, which was pushed so much outwards by the aneurysm that it was almost at the outer border of the sternomastoid muscle. Both arteries were tied with chromicised catgut ligatures, and both ends of the ligatures were cut short; a small drainage-tube was inserted in each wound, silk sutures applied, and the wounds dressed with iodoform powder and Gamgee tissue. The right arm was enveloped in cotton-wool, also the right side of the neck and head. Twelve hours after operation, the patient was very comfortable, complaining only of slight pain in the head, and some numbness and tingling in the right arm, which was, however, quite warm. After this she went on remarkably well. On the third day the dressings were removed, and the wounds found to be healed by primary union, except where the drainage-tubes had been inserted; these were now removed, and in two more days the wounds were quite healed and gave no more trouble. There was no pulsation in the temporal or radial arteries. She took her food well, and the numbness in the right arm gradually disappeared.

years old. She has two daughters alive and well, and has had besides three children, one born dead, another which died of some severe skin eruption which she describes as small-pox (*syphilis*?), and another which only lived three weeks. She first noticed the

October 10th. The patient had been kept quite quiet in bed; the tumour was certainly smaller and firmer, but with still much pulsation in it and a loud *bruit*; the voice, dyspnoea, and other symptoms had also improved.

tumour two years ago, and it had been slowly increasing in size since then. The patient is a very thin woman, with a very dry

October 30th. Though the patient had been constantly kept quiet in bed, the tumour seemed to have increased slightly, and the

voice was again weaker. She was, therefore, put on a lower scale of diet, and 10 grains of iodide of potassium, with 20 drops of tincture of digitalis, given three times a day.

November 7th. The digitalis was increased to 25 minims.

November 10th. The digitalis had caused such faintness, without exercising any appreciable effect on the tumour, that it was discontinued, and the following mixture substituted: Pot. iod. gr. xxx, vin. antimonialis ℥ xv, tinct. opii ℥ iv, dec. sarzæ co. ℥ i, three times a day.

December 21st. The iodide and antimony had had a marked effect in lowering the force of the circulation; the pulse in the left wrist was very small and weak—in fact, perceptible with difficulty; the tumour was smaller again, and felt harder and firmer, but there was still much pulsation in it, and also *bruit*. Shortly after this date all medicines were discontinued, and the patient was allowed gradually to get up a little more each day without any harm resulting to the swelling; and on January 21st, at her urgent request, was allowed to go home, the tumour being about the size of a bantam's egg, and distinctly pulsatile, but feeling considerably firmer.

April 20th, 1888. The patient presented herself for examination. The tumour was still the size of a bantam's egg, but much firmer; distinct *bruit* over it, traceable up the right side of neck, but nowhere else; no right brachial or radial pulse; no right temporal pulse. Sight good, and equal; no deafness. Heart's apex beat in fifth interspace, in line drawn vertically through the nipple; extent of heart's dulness increased; no *bruits*; heart-sounds clear; voice quite good and strong; still some slight laryngeal cough at times. No difficulty of swallowing, and much less headache. The right arm was slightly smaller than the left, and felt weaker after working some little time. The patient said she felt quite well and strong, and had been doing all her house work and washing. She was anxious to continue her occupation as a charwoman, but was advised not to do too much hard work again—an admonition to which she will probably pay little attention.

REMARKS.—Though an absolute cure cannot be claimed for this case, it still, in my opinion, deserves to be put on record, on account of the complete arrest of all dangerous symptoms. It is now seven months since the operation; the patient has for three months resumed all her active duties, not only without causing any increase in the tumour, but with such comfort that she is anxious to get back to her ordinary hard and laborious occupation. The only medicine that seemed to do good was antimony; this was continued for several weeks until the pulse was most distinctly affected, and it seems to me to have largely contributed to the good result in this case when the tumour began again to increase after the operation.

CHIRING CROSS HOSPITAL.

SUBPERIOSTEAL REMOVAL OF HALF OF LOWER JAW; RECOVERY, WITH ALMOST ENTIRE RESTORATION OF THE BONE AND PERFECT MASTICATORY MOVEMENT.

(Under the care of Mr BELLAMY.)

[From notes by Mr. G. GOLDNEY.]

FLORENCE W., aged 6, was admitted on January 21st, 1887, with extensive necrosis of the left half of the lower jaw. She had already been operated upon, and excision of the entire bone from the outside advised by a hospital surgeon. This the mother would not consent to; and she was placed under Mr. Bellamy's care.

On admission, the child had a most marked strumous aspect, the left side of the face being enormously swollen, the swelling extending over the temporal region. There was a sinus just in front of the external auditory meatus and one below the angle of the jaw.

On January 30th Mr. Bellamy enlarged the opening in the superior sinus, and removed the condyle, ramus, and angle, and opened up the remains of the sinus just under the angle. The periosteum was free and loose and retained the original form of the bone in a most remarkable manner.

February 1st. The discharge was profuse and very offensive, although the cavity had been drained antiseptically. On the 7th the swelling began to decrease, and the discharge was quite healthy. On the 14th a small spicula of bone was found loose and removed from near the symphysis.

The child made an uninterrupted recovery, with the exception of some slight paralysis of the orbiculares palpebræ and oris.

Seen on April 24th, 1888. The two sides of the face are nearly equal in size; there is a small cicatrix behind the angle of the jaw; and on manipulation the new jaw feels somewhat nodulated, no doubt soon to mould itself into proper form. The articulation seems to be perfect, and the movements of the jaw as free as possible. In fact, there is no deformity at all. The teeth behind the first bicepsid have gone.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

FRIDAY, MAY 25TH, 1888.

W. H. BROADBENT, M.D., F.R.C.P., President, in the Chair.

Conclusions of the Myxœdema Committee.—Dr. ORD, as the Chairman of the Myxœdema Committee, read the following conclusions. He admitted that the time taken up in the investigation was protracted, but he claimed that when the results were known the time would not appear out of proportion. 1. That myxœdema is a well defined disease. 2. That the disease affects women much more frequently than men, and that the subjects are, for the most part, of middle age. 3. That clinical and pathological observations respectively indicate, in a decisive way, that the one condition, common to all cases, is destructive change of the thyroid gland. 4. That the most common form of destructive change of the thyroid gland consists in the substitution of a delicate fibrous tissue for the proper glandular structure. 5. That interstitial development of fibrous tissue is also observed very frequently in the skin, and with much less frequency in the viscera, the appearances presented by this tissue being suggestive of an irritative or inflammatory process. 6. That pathological observation, while showing cause for the changes in the skin during life, for the falling off of the hair and the loss of the teeth, for the increased bulk of the body as due to the excess of subcutaneous fat, affords no explanation of the affections of speech, movement, sensation, consciousness, and intellect, which form a large part of the symptoms of the disease. 7. That chemical examination of the comparatively few available cases fails to show the general existence of an excess of mucin in the tissues adequately corresponding to the amount recorded in the first observations, but that this discrepancy may be in part attributed to the fact that tumefaction of the integuments, although generally characteristic of myxœdema, varies considerably throughout the course of the disease, and often disappears shortly before death. 8. That in experiments made upon animals, particularly on monkeys, symptoms resembling, in a very close and remarkable way, those of myxœdema have followed complete removal of the thyroid gland, performed under antiseptic precautions, and with, as far as could be ascertained, no injury to the adjacent nerves, or to the trachea. 9. That, in such experimental cases, a large excess of mucin has been found to be present in the skin, fibrous tissues, blood, and salivary glands; in particular the parotid gland, normally containing no mucin, has presented that substance in quantities corresponding to what would be ordinarily found in the submaxillary gland. 10. That the full analysis of the results of the removal of the thyroid gland in man demonstrates, in an important proportion of the cases, the fact of the subsequent development of symptoms exactly corresponding with those of myxœdema. 11. That, in no inconsiderable number of cases, the operation has not been followed by such symptoms, the apparent immunity being in many cases probably due to the presence and subsequent development of accessory thyroid glands, or to accidentally incomplete removal, or to insufficiently long observation of the patients after operation. 12. That whereas injury to the trachea, atrophy of the trachea, injury of the recurrent laryngeal nerves, injury of the cervical sympathetic, and endemic influences have been, by various observers, supposed to be the true causes of experimental or of operative myxœdema (*cachexia strumipriva*), there is, in the first place, no evidence to show that, of the numerous and various surgical operations performed on the neck and throat, involving various organs and tissues, none, save those in which the thyroid gland has been removed, have been followed by the symptoms under consideration; that in many of the operations on men, and in most, if not all, of the experimental operations done by Professor Horsley on monkeys and other animals, the procedure avoided all injury of surrounding parts, and was perfectly

aseptic; that myxœdema has followed removal of the thyroid gland in persons neither living in, nor having lived in, localities the seat of endemic cretinism; that, therefore, the positive evidence on this point outweighs vastly the negative, and that it appears strongly proved that myxœdema is frequently produced by the removal, as well as by the pathological destruction, of the thyroid gland. 13. That whereas, according to Clause 2, in myxœdema women are much more numerously affected than men, in the operative form of myxœdema no important difference of the same kind is observed. 14. That a general review of symptoms and pathology leads to the belief that the disease described under the name of myxœdema, as observed in adults, is practically the same disease as that named sporadic cretinism, when affecting children; that myxœdema is probably identical with cachexia strumipriva; and that a very close affinity exists between myxœdema and endemic cretinism. 15. That while these several conditions appear, in the main, to depend on, or to be associated with, destruction or loss of the function of the thyroid gland, the ultimate cause of such destruction or loss is at present not evident.—The PRESIDENT congratulated the Society on the completion of this important investigation, and said their thanks were due to the Committee for the enormous work and the zeal and ability which had enabled them to present this summary of the report, and practically the report itself, during the present session. When they heard the conclusions and imagined the enormous amount of investigation and research and inquiry which was embodied therein, four years seemed a comparatively short period for the completion of such a labour. The report would make the present session memorable. It reflected the greatest possible credit upon the Society. It was the most important work yet carried out in its name. Already the labours of the Committee had served to stimulate the carrying out of similar investigations in Germany, where men had been first convinced of the reality of the disease from the labours of the Society and its Committee. He thought the members could hardly thank sufficiently the authors of the report, in which it appeared that the only person not heard of was Dr. Ord, the chairman and director of the investigation. His name, nevertheless, would for all time be associated with the literature of the disease.

Two Fatal Cases of Acute Intussusception occurring in Infants, aged 3 and 4 months respectively.—Mr. R. W. PARKER related particulars of these cases. He drew chief attention to the uncertain onset, and to the absence of symptoms indicative of acute strangulation, such as the *post-mortem* examination proved in these cases to have existed. The pain was not excessive and was short in duration; vomiting occurred only during the first twelve hours, and only after taking the breast; in neither case was much blood-stained mucus discharged from the rectum; and there was never any straining or tenesmus. Constipation was the most important feature. The author argued that the absence of some of the most classical symptoms, or their very slight prominence, was a bad rather than a good sign, especially so in cases where an intussusception was, from other indications, known to exist. Thus, if the gut were tightly strangulated it would quickly become gangrenous, and therefore painless, and as the circulation through the gut would be arrested nothing could pass from it or through it, hence constipation, as well as an absence of blood and mucus. The difficulty of satisfactorily treating such cases was dwelt on.—Dr. FORDYCE BARKER (New York), in response to an appeal from the President, expressed his sense of the compliment, and said that he had seen quite a number of these cases. In early stages of the malady he would inject glycerine in small quantities, such as one or two drachms, with equal quantities of water, until toleration was established; and then continue such injections until quite a large amount was used. He thought that surgery did not seem to offer much chance of curing the condition.—Mr. HARRISON CRIPPS remarked that there was not complete absence of blood-stained mucus, as dwelt upon by Mr. Parker, in his case, though it was present only in small quantities. As to treatment, he was glad that Mr. Parker had called attention to the danger of injecting water, except in an early stage. He had had a similar accident himself, and had since been very careful as to the amount of pressure employed, except quite at the beginning. The patient was a girl, 18 months old, with symptoms which had lasted four or five days. The intussuscepted bowel was felt two inches from the anus. Water was gently injected, and the bowel receded; the head was then inverted, and more water used. The child became faint, vomited, and in two or three minutes died. At the *post-mortem* examina-

tion the strangulated bowel reached to within five inches of the anus. There was a rent of considerable size just below it, and water and oil were found in the peritoneal cavity. The injection had been made very gently with a Higginson's syringe. Another interesting case which came under his notice was that of a child 7 months old with a history of a fortnight's illness, with vomiting and what the mother called diarrhoea, but which turned out to be the passage of the characteristic blood-stained mucus. The symptoms, however, had passed off during the two days just before the child was seen, and the mother had only brought the child along on account of something "sticking out of his back passage." On examination, something that looked like part of a red herring was seen projecting, on gently drawing out which it was seen to lead to what looked like a healthy intestine. Mr. Cripps contented himself with cutting off the slough, and admitted the child under Mr. Baker. The child remained in the hospital for about a month, during which time every day the house-surgeon removed a piece more of this extruded slough. Ultimately the child left perfectly well, but died of scarlet fever eight months later, when a *post-mortem* examination was made, the specimen being now in the hospital museum. The most extraordinary condition of things was found, the small intestine being found directly attached to the anus. There was no trace of ascending, transverse, or descending colon, nor rectum, which must have come away as a slough. This case showed what Nature would sometimes do if she was only given a chance. Early in these cases he advised a trial of injections or laparotomy and the unravelling of the intussusception. Later, where there was much vomiting, he recommended Nélaton's operation, the opening of the most prominent coil of intestine through the abdominal wall. Large quantities of feculent matter would pass by the new opening, whilst Nature might be able to remove the invaginated bowel, and possibly leave the intestine patulous.—The PRESIDENT remarked that no member had spoken of the use of gaseous instead of liquid injections.—Mr. PARKER, in reply, said that, should another opportunity occur, he should remember Dr. Fordyce Barker's suggested plan of treatment. The blood-stained discharge was very slight in his case, and only occurred at the beginning. At the latter part of the case it came only when the finger was introduced into the rectum. In Mr. A. E. Barker's case, which was to have been read there that evening, the tumour was felt from the front of the abdomen. Early treatment he thought should consist of enemata of water, which was possibly better than air, as one could easily calculate the quantity of water which was injected.

Rupture of Intestine without External Wound.—Mr. HERBERT PAGE described two such cases. He said that the interest attaching to the paper by Mr. Mayo Robson and the discussion upon it on February 10th had led him to contribute two cases in which laparotomy was fully considered; moreover, one of them exemplified a point to which no reference was made on that evening. Case I was that of a man aged 50, over whose right iliac region a cab had passed on the morning of April 5th, and who was admitted into St. Mary's Hospital the following day in great pain and with very marked collapse. Rupture of intestine was diagnosed, but the amount of collapse seemed entirely to forbid laparotomy. There was no improvement during the day, and he died the next morning, forty-four hours after the accident. A rupture of the small bowel was found four feet and a half above the ileo-cæcal valve; and, in addition to some smaller contusions in the cæcum and neighbouring ileum and much mesenteric extravasation, there was a knuckle of deeply-congested gut an inch and a half in length. It was thought that, even if laparotomy could have been done soon after the accident, when diagnosis probably could not have been at all sure, and the ruptured portion had been satisfactorily dealt with, this other piece of bruised intestine could hardly have been left alone. The danger of leaving it—namely, of secondary perforation from sloughing—was by no means imaginary, as was shown by the history of the second case, that of a lad aged 18, who was butted in the belly—left iliac region—while at play with some other boys. He instantly had intensest pain, and when admitted to St. Mary's, sixteen hours afterwards, on July 27th, gave a history of incessant vomiting since the accident. There were external signs of severe contusion, and marked evidences of local peritonitis to which his symptoms were regarded as due, but there was nothing specially suggestive of perforation, or of the need for opening the abdomen. Opium was accordingly given, and during the next three days there was undoubtedly improvement. On the night of the 30th, however, there was sudden and alarming col-

lapse. He rallied from this, and for three days seemed doing well again, but on August 3rd collapse returned. From this there was no decided rally, and he died on August 6th. Necropsy revealed extensive hypogastric peritonitis, and offensive pus in the left iliac fossa, where the blow had been sustained. A perforation was found in the small intestine, in the centre of a deeply congested sodden portion. This opening had thickened edges, and was surrounded with lymph. It was believed that this perforation occurred only on the fifth day after the accident, as the result of the sloughing of a portion of severely contused gut, and the author pointed out that had laparotomy been done when the lad first came to the hospital, no more difficult question could well have presented itself than that of determining whether this contused piece ought or ought not to have been resected. In neither of the cases was it thought that the chances of successful laparotomy were anything but the very poorest, but yet, as laparotomy alone gave a hope of life, it was, perhaps, right to operate, even though gravity of symptoms and uncertainty in diagnosis seemed to forbid it. It must be rare to meet with cases of abdominal injuries where there was no complication of any kind, or in which a simple rupture in one place was the only lesion, and these were considerations to be borne in mind when laparotomy was undertaken or entertained.—Mr. CROFT read the notes of a similar case in a man, aged 34, admitted on March 16th, 1887, having been injured in a row seventeen hours before. On admission his temperature was 103°. He at once cut down, and found three different lesions: a ruptured ileum, a lacerated mesentery, and a perforated omentum. The peritoneum was irrigated with a warm solution of boracic acid. An artificial anus was made, but it was found necessary to close this. On the second operation, on April 4th, the laceration was sutured, the operation taking two hours and a quarter, and the man being very prostrate. The man died thirteen hours after the operation from sheer exhaustion. He considered the case to be a crucial one in the history of intestinal surgery, as showing that resection of the bowel might be safely undertaken even when acute septic peritonitis had been set up. He strongly advocated early exploratory laparotomy, with resection if necessary. In cases of doubt an exploratory incision should always be made. He would divide the cases into three classes: 1, those in which laparotomy was done for exploratory purposes; 2, those done later, where the diagnosis was already established; 3, those later still, in which septic peritonitis had occurred. Everything was in favour of exploratory laparotomy, as stated in an able paper by Dr. Chavasse. If the abdomen were opened with all precautions, the patient was afterwards no worse off than before, even if no lesion of intestine were found, whilst, if a distinct laceration of the bowel had occurred, then was the time to operate. He thought the establishment of an artificial anus was not so successful as resection of the injured intestine and immediate closure of the external wound. In his own case he had followed the advice of several eminent metropolitan surgeons. The operation saved the man's life at the time; but in consequence of the malnutrition resulting from the too early escape of partially digested food he could not bear the tedious second operation of resection of the bowel. Had the resection been done at first he believed the life would have been saved. When the case was known to be one of ruptured intestine the surgeon should promptly decide in favour of resection. The peritonitis already established might be thereby abolished by the antiseptic method of operation.

Case of Stone in which Lithotomy was Performed Twice within Two Months.—Dr. WARD Cousins (Southsea) described the case, and said that it suggested the purely local character of some urinary formations. The patient, aged 40, a fish dealer, was admitted into the Royal Portsmouth Hospital in January, 1882. There was no family history of gout, rheumatism, or urinary trouble. He had suffered thirteen years from renal and vesical symptoms, and had constantly passed small stones and gravel; altogether he had discharged over half a pint. He had been a great sufferer, and during the nine months before his admission he had been confined to bed. The urine was extremely offensive, and loaded with muco-pus. It often contained blood and small clots. The left loin was extremely tender and painful, and he had had many attacks of orchitis in the same side. On sounding there was no ring or thud, but the bladder was filled with an immovable mass. Two ounces and a quarter of stinking concretion of the consistency of fresh mortar were removed by lateral lithotomy. He left the hospital well in a month. Three weeks later he returned with a stone lodged in the neck of the bladder. After many failures to

seize it with long forceps, and other efforts to return it into the bladder, so that it could be crushed, median lithotomy was performed. He was again discharged, apparently well, in three weeks. During the past six years he had enjoyed good health, and had daily carried on his business. The urine had been frequently examined. It still contained a trace of muco-pus and albumen. No renal elements had been detected by the microscope. The urea was always a little below the normal, varying from 1.3 to 1.7 per cent. Since the operations he had never passed any gravel or particle of stone. He was in good health on May 20th, 1888. The dried concretion removed from the bladder at the first operation, and also the urethral calculus extracted at the second operation, were exhibited. Dr. Cousins then remarked that the history of the case, the symptoms, and the persistent discharge of small concretions clearly indicated that the patient was the subject of chronic calculous pyelitis, and that part of the renal gravel passed along the urinary passages and escaped through the urethra, while another portion was trapped in the bladder. At the time of the operation the calculous mass presented throughout a uniform appearance. In consistency it resembled fresh mortar, and there were no traces within it of concentric deposition. An analysis of the symptoms suggested the presence of a compound renal and vesical disease, although the most urgent manifestations pointed clearly to disorder of the bladder. A group of renal symptoms, radiating from the left groin, were present throughout the illness, but these were in a measure overlapped by the characteristic signs of bladder trouble. The composition of the urine, however, and the continuous discharge of small concretions, rendered the existence of chronic pyelitis or nephro-pyelitis clearly evident. With reference to the treatment, the dangerous and prostrate condition of the patient suggested an immediate effort to clear out the bladder, and to establish continuous drainage. The presence of a foreign body of some kind was certain from the examination; at the same time, the absence of any click or thud, the roughness of the surface, and the immobility of the mass, rendered it probable that some complication would have to be encountered. The lateral incision was selected for the purpose of obtaining a thorough exploration of the bladder. The operation insured a free and incontinent escape of urine with complete rest for the diseased organ, and removed at once all painful micturition and straining. It permitted, moreover, the effectual drainage and washing out of the diseased vesical cavity. The cystotomy had a very beneficial influence over the whole urinary tract, as the discharge of all the renal products was secured directly after their formation. The second lithotomy was done to relieve the acute sufferings of the patient after many failures to remove the calculus through the urethra, or to return it into the bladder, so that it could be seized with a lithotrite. During the last six years the patient had enjoyed good health. The old vesical symptoms had never recurred, and he had never passed a particle of calculous matter. Still the cure was not actually complete. The urine contained a few pus cells mixed with epithelium shed from some part of the lining membrane of the urinary passages. Ought the case to be regarded in the light of a local trouble, and all its manifestations the outcome of a chronic calculous pyelitis? Or, on the other hand, must it be considered as a constitutional disease? The subjects of urinary concretions were generally described as labouring under some sort of diathetic tendency. Sometimes the existence of a special diathesis was only a conjecture, and pathological processes limited to the urinary track itself were quite sufficient to explain the precipitation and concretion of the ordinary constituents of the urine. The disorder in this case probably broke out in the pelvis of one kidney by the occurrence of a pyelitis. Then followed the deposition of the uric acid in the solid form. At the same time the inflammatory elements themselves served as points of deposit for the formations. The cause of the pyelitis was obscure, and whatever morbid forces might have been active during its initial stages, when once it was established it could be fairly regarded as the chief factor in the production of the renal gravel and small concretions. With a concentrated condition of the urine, a persistent obstruction to its discharge, and the presence of muco-purulent secretion, some of the exciting causes were present which tended towards the deposit of calculous matter, without an abnormal increase in the excretion of uric acid.—Dr. ORD thought the consideration of the case very important, and suggested that a committee should report upon it.—Dr. MAGUIRE referred to Sir W. Roberts's researches upon the matter.—The PRESIDENT nominated Dr. ORD, Dr. MAGUIRE, and Dr. GARROD, with Dr. WARD Cousins, as a com-

mittee to report upon the case, and expressed the hope that the report might be concluded in time to permit of its publication with Dr. Cousins's case in the forthcoming volume of the Society's *Transactions*.

The session then terminated.

HARVEIAN SOCIETY OF LONDON.

WM. SEDGWICK, M.R.C.S., President, in the Chair.

Value of Antiseptic Precautions in Internal Urethrotomy.—Mr. BRUCE CLARKE drew attention to the fact that though this operation had been advocated for many years in certain cases of stricture, which did not yield readily to dilatation, yet it had never been generally accepted by surgeons. This was due partly to the fact that its results were not supposed to be good, and partly to the dangers of the operation itself. As to its results, it was often urged that the worst strictures were always those in which urethrotomy had been performed. Of course, this was perfectly true, but it would be fairer to state that it was only the worst strictures that were submitted to urethrotomy. If strictures were neglected after the operation they of course recurred, and this gave a certain currency to the idea that it was the internal urethrotomy that had made them relapse. The dangers of the operation itself were, he maintained, dependent on septic fever; and it depended either on self-infection from a septic urethra or on dirty instruments. The latter source of infection could be easily guarded against by the thorough cleansing of instruments and catheters, whilst the purification of the urethra was no easy matter. To effect this, however, as far as possible, the urethra should be irrigated with sublimate 1 in 2,000 for several days beforehand, and when the stricture had been divided, the bladder should be washed out with a similar solution, and then with hot water at a temperature of 105° F. After this a catheter should be tied in for twenty-four hours. By this means the urine came very little into contact with the urethra, and septic infection was avoided. Fifteen cases were related in which the plan had been tried by the author, and he alluded to some others in which he had suggested the plan to other surgeons. The results were very successful.—Mr. SWINFORD EDWARDS said that in the last six internal urethrotomies which he had performed he had not only carried out the suggestions laid down by Mr. Bruce Clarke in his paper, but had administered boracic acid in ten-grain doses three times a day for two days before the operation, and for a few days subsequently, with a view of sterilising the urine, as suggested by Dr. Palmer in the *American Medical Practitioner and News*, August, 1887. In none of these cases did urinary fever supervene; but brilliant as was internal urethrotomy, he believed that the time was soon coming when it would be almost, if not entirely, supplanted by electrolysis for strictures in the deep or fixed urethra, which were unfitted for the simple treatment of dilatation.—The PRESIDENT spoke in favour of corrosive sublimate as an antiseptic; but he regarded the prolonged suppression of urine and the other severe symptoms which had followed the operation in the case referred to early in the paper as more due to shock than to blood-poisoning.—Mr. BUCKSTON BROWNE was interested in finding that in an advocate of electrolysis in the treatment of urethral stricture still practised the operation of internal urethrotomy. He should like to know why electrolysis was not employed in the cases just detailed. He had practised internal urethrotomy now for fifteen years, and had never lost a case; he therefore knew nothing of septicæmia as following the operation. He took great care to insure the utmost cleanliness of all instruments employed. He entirely dissented from Mr. Clarke's view that urethral fever was of septic origin, and maintained that the most perfect antisepticism would never do away with urinary fever in certain cases, after urethral operations, because the fever was caused by urethral shock or irritation acting reflexly through the nervous system upon the excretory renal apparatus.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

WEDNESDAY, MAY 9TH, 1888.

R. THORNE THORNE, M.B., President, in the Chair.

Age, Sex, and Season in Relation to Scarlet Fever.—Dr. WHITELEGGE read a paper in which he said that a detailed analysis of upwards of 6,000 notified cases showed that the liability to scarlet fever was slight in infancy, reached its maximum in the fourth or fifth year, and diminished every year afterwards. The severity

of attack, however, was greatest in the first two years of age, and lessened year by year throughout childhood and adolescence; in adult life there was apparently a slight increase again, the reality of which was open to doubt. Females were more liable to attack than males at all ages after infancy, and notably between 20 and 35 years, when the charge of children gave special facilities for infection; but the attacks in males, though less numerous, were more severe, and the death-rate was consequently higher among males in childhood. The scarlet fever death-rate reached its maximum in the third year of life in both sexes. Forty-two per cent. of the cases and 65 per cent. of the deaths occurred in the first five years of life; 40 and 26 per cent. respectively in the second quinquennium, and 11½ and 5 per cent. in the third. The advantage of postponing an attack was twofold; each year of age beyond the fifth diminished the susceptibility to attack, and each year of postponement lessened the average severity of attack if it should occur. Probably about two-thirds of the adult population had escaped attack altogether. As regarded season, the maximum of cases and of deaths occurred in October, and the minimum in April. It was probable that a scanty rainfall was favourable to the spread of disease. Besides the annual or seasonal curve, it was possible to construct a weekly curve, showing the number of attacks upon each day of the week. The result of this experiment in regard to 1,100 cases in Nottingham was to indicate a marked reduction in the number of attacks on Wednesdays, presumably due to less facility for infection on Sundays. Diphtheria and enteric fever were now known to be affected by other influences besides the accident of exposure to contact with previously infected persons. Scarlet fever had many points of resemblance to these two diseases, notably in its seasonal curve, and in this and other respects was in strong contrast to the typically infectious diseases such as small-pox, whooping-cough, and measles. One exceptional mode of infection in scarlet fever had been brought to light by Mr. Power's Hendon inquiry, but was probably not of frequent occurrence. Infection from a previous case was the obvious explanation of many cases of human scarlet fever, and might be true of all, or nearly all; but it could not be the whole truth. Some further explanation was needed to account for the well-marked seasonal and other variations in the prevalence of the disease.—In the discussion which followed, the PRESIDENT, Dr. MURRAY, Dr. LAWSON, Dr. MCKELLAR, Dr. E. C. SEATON, and Mr. BUTTERFIELD, took part.

SOUTH INDIAN BRANCH.

FRIDAY, FEBRUARY 3RD, 1888.

Deputy Surgeon-General S. B. ROE, M.B., C.B., Vice-President, in the Chair.

Traumatic Pleuropneumonia.—A case of pleuropneumonia following an accident to the chest was reported by Surgeon-Major E. F. DRAKE-BROCKMAN. The wheel of a dog-cart passed over the lower part of the right chest, and, though there was considerable pain in that side, with depression of the shoulder, and a painful catch on deep inspiration, no evidence of fracture of the ribs could be obtained. The patient had a sharp attack of pleuropneumonia, but recovered. Mr. Drake-Brockman commented on the rarity of the occurrence of internal injury to the lung and pleura by an accident which did not cause any damage to the external structures or ribs.—Surgeon-Major MACKINNON stated that inflammation of lung frequently occurred in prize-fighters after pugilistic encounters, even when no external marks of violence were present, the cause being probably traumatic.—Surgeon-Major BRANFOOT mentioned a case he had seen in which no injury to any of the ribs was detected after a most careful examination during life, but at the *post-mortem* examination one rib was found fractured, and pleural effusion had also taken place.—Brigade-Surgeon SIBTHORPE had also met with a case in which it was impossible to detect fractured ribs during life.

Subperitoneal Uterine Fibroid.—Surgeon-Major BRANFOOT showed a specimen of subperitoneal fibroid tumour of the uterus which had become the seat of primary cancerous deposit. The patient was a Hindu, aged 50. The growth was adherent at its upper and posterior part to the intestines, with a small abscess-cavity between the coils of the intestine and the left Fallopian tube and left ovary. There was much thickening also at this spot, with soft cancerous growth invading the mesenteric glands. The lumbar and left axillary glands were also much enlarged by secondary growth.

Mycetoma.—Surgeon F. CLARENCE SMITH exhibited a patient

who was suffering from fungus disease of the right hand and right axillary region. The disease had existed in the palm of the right hand for probably about five years, but he had been able to do agricultural work until two years before admission, when he fell off the top of a hut six feet high, the palm of his right hand at the time of the fall striking the earth, causing two days' pain; this gave a still greater increase to the size of the hand; and the fingers, which were until then unaffected, also swelled. At the same time the pain shot up the inner side of the arm to the axilla, where in a few days small nodular growths appeared. After detailing the condition of the sinuses in the axilla and palm which existed when the patient was shown, Mr. Clarence Smith observed that he had been able to discover only one other recorded case in which the disease clearly seemed to have been spread by the lymphatics to the glands above the seat of the disease, and pointed out that implication of the axillary glands immediately followed a blow on the affected hand. He had not found any previous record of a case in which the axillary glands were affected. The other case in which glands above the seat of the disease were affected was that recorded by Mr. D. Dymott (*Indian Med. Gaz.*, 1881); in that case the glands of the groin were diseased.

ROYAL ACADEMY OF MEDICINE IN IRELAND.
SECTION OF SURGERY.

FRIDAY, APRIL 13TH, 1888.

A. H. CORLEY, M.D., President, in the Chair.

On Suprapubic Lithotomy and Vesical Suture.—Mr. KENDAL FRANKS read a paper on this subject. The dangers of former methods were septic infection, urinary infiltration, and injury to the peritoneum. These were met by antiseptics, suture of the bladder, and by a combination of vesical with rectal distension. He then referred to the case of a man, aged 65, who had suffered from stone in the bladder for two years. He was a tall, large, heavy man, with a deep perineum and a large prostate, and on account of these conditions the suprapubic operation was performed on May 10th, 1887, the rectum and bladder having been both distended. The distance of the prevesical fold of peritoneum from the pubes was three inches. Three stones were extracted of nearly equal size, shape, and weight, without any facets, and weighing in all 666 grains. The bladder was sutured—first, by Lembert's method, with catgut, and then a second row of sutures, continuous, were inserted so as completely to cover in the first row. The external wound was drained from the prevesical space to the upper angle of the wound, and the bladder was drained with a soft rubber catheter, passed *per urethram*, which was kept *in situ* for five days. The bladder wound healed by first intention, and at no time was there any leakage of urine through the wound. The patient passed water without the aid of a catheter on the twelfth day and subsequently. The drainage-tube was retained in the wound until the tenth day, and Mr. Franks explained that this was done to prevent any mischief being done should the bladder sutures not hold. He recommended that the drainage-tube should always be retained in the external wound for at least seven days, as statistics showed that the vesical suture might yield as late as the sixth day. The patient was out of bed and walking about the wards on the fourteenth day. The calculi were uric acid, and measured $1\frac{1}{2}'' \times 1''$, $1\frac{1}{2}'' \times 1\frac{1}{2}''$, and $1\frac{1}{2}'' \times 1\frac{1}{2}''$ respectively. Mr. Franks showed that the objections to the vesical suture were more theoretical than real, and that when it succeeded it attained the ideal in suprapubic cystotomy. Statistics showed that up to 1886 it had been performed fifty-six times, and had succeeded in seventeen cases, being a percentage of 32 per cent. Since 1886 a few cases only had been published. The causes of failure in suturing of the bladder in the high operation were—(1) an anatomical one, that the external coat of the bladder in this region was fibrous, and not serous; (2) a thinned and diseased condition of the bladder walls; (3) injury to the edges of the wound by the manipulations employed to extract the stone; (4) a putrid condition of the urine. The advantages of suture were a shortened convalescence, ten days being on an average gained, and an effectual preventive against urinary infiltration.

Suprapubic Lithotomy.—Mr. F. ALCOCK NIXON read notes of the case of a gentleman, aged 81, who had, fifty-seven years before, suffered from "bleeding from the bladder and a stoppage of water." The bleeding occurred at intervals every five or six years for fifty years. The bladder was opened above the pubes, and two calculi were removed, one weighing 2 ozs. 30½ grs., the other

150½ grs. They were composed of the ammoniaco-magnesian and calcium phosphates. The bladder was sutured and drained, a tube was placed in the abdominal wound, and a catheter retained in the bladder. The temperature, which was 101° F., became normal on the evening of the third day; the urine became acid; the patient was quite free from pain, able to take food well and enjoy long periods of sleep. On the fifth day he died suddenly from syncope, from which he previously suffered on several occasions. After death the wound in the bladder was found to be healed, except about half an inch in the centre, from which urine had escaped through the abdominal wound for a short time on the second day, while the catheter was plugged with a blood-clot. There was no trace of peritonitis or of cellulitis.

Vesical Tumour removed by Suprapubic Cystotomy.—In the unavoidable absence of Dr. HEUSTON, this paper was read by Dr. ALFRED SCOTT. The patient, aged 48, suffered for four years from symptoms of vesical irritation, accompanied at gradually decreasing intervals by hæmorrhage of an arterial character, which for the later five months came freely at each period of micturition in a considerable quantity. A tumour was diagnosed by sounding, situated on the right side of the bladder, in addition to which a roughened condition of the bladder throughout was noticed. The presence of the large tumour was also demonstrated by rectal examination. The bladder being now washed out, a portion of the tumour came away, which was proved by Dr. Alfred Scott to be papillomatous in its nature. On March 15th, 1888, the bladder was opened by the usual suprapubic method, and a tumour somewhat larger than an orange, composed of three lobules, attached to the right wall of the bladder by narrow pedicles, was removed, as were also a number of smaller growths about the size of hazelnuts. The hæmorrhage, which was very copious, was at once controlled by a solution of tannic and gallic acids, subsequent to which the bladder was illuminated by the electric light, and then a stream of a weak solution of hazeline was passed into the bladder until it returned clear. The bladder was now closed, except sufficiently to allow of the introduction of a drainage-tube, care being taken to close the areolar spaces in connection with the bladder-wound. Subsequent to operation the patient progressed favourably for twelve days, the urine becoming normal in its character; but then the temperature suddenly rose to 104.2 F., the patient became delirious, and, although the temperature was subdued by quinine within twenty-four hours, the patient gradually sank and died sixteen days after operation. Dr. Bewley, pathologist to the Adelaide Hospital, performed a *post-mortem* examination, and found that there was no peritonitis, the bladder being firmly united to the abdominal parietes at the seat of the wound, which was healthy. The bladder was contracted; the anterior wall normal; the posterior thickened and cutting hard. In the centre of this surface a space about the size of half-a-crown, was covered with white flocculi of seemingly gangrenous tissue; this was the seat of the removed papilloma. The spleen and kidneys were healthy, there being no evidence of septic infection.—Mr. W. THORNLEY STOKER said that Mr. Franks had not referred to what was attracting a good deal of discussion in connection with suprapubic lithotomy; namely, the class of cases in which that operation should be selected. As far as any rule had yet been established on the subject it was this, that suprapubic lithotomy was to be performed in the adult in cases where the stone was too large to admit of its probably successful removal by perineal operation; that is, where the stone exceeded two ounces in weight, or where, because of its hardness or the great size of the prostate, there was not a likelihood that lithotripsy would be successful. Another question was as regards its performance in children. The suprapubic operation ought to be selected in all cases of stone in the bladder in children where lithotripsy could not be performed, as it did not endanger the child's procreative apparatus. There was a remarkable difference in the mortality of children on whom the operation was performed on the Continent as compared with those at home. While the mortality on the Continent was over 20 per cent., it appeared from Sir William Mac Cormac's paper that up to March last there had been 33 cases operated on in England without one death. Among adults, the mortality following the operation would be found to be about the same as that in the lateral operation for lithotomy—20 or 22 to 30 per cent. But in Dublin the mortality in perineal operations had not been so high. The suprapubic operation was one that had not as yet arrived at perfection, because, like many other operations, it was undergoing development since the introduction of antiseptics, and he looked forward to the time when the mor-

tality of from 20 to 30 per cent. would be materially diminished. —Mr. TOBIN suggested, with reference to the different expedients of obtaining room to make an incision, holding the patient's legs aloft. He had tried the experiment on a subject in the *post-mortem* room. Having half filled the bladder, he measured the amount of space uncovered by the peritoneum, while the subject was lying flat on the table. He then raised the subject, holding the legs aloft, and on measuring again he found he had double the space with the subject in the raised position that he had when prone.—After some remarks by Mr. J. H. SCOTT, Mr. M'ARDLE said that on the successful suturing of the bladder suprapubic lithotomy would greatly depend; and hence he called attention to a method which contra-indicated double suture as usually applied—namely, what was styled by Brenner "lace suture." After separating the mucous from the muscular coat, a thread was passed round the wound in the bladder through the *umbucosa*, two or three millimètres from the wound-border. A second thread was next passed through the muscular layer, three or three and a half millimètres from the wound-border, going round the wound in the same way, being further from the wound at its angle. The sutures were then drawn and tied in the order of introduction, so that all the walls of the bladder were collected into a dense mass at the point of the opening. In experiments on dogs it was found that the bladder thus closed withstood much higher fluid pressure than after button or ordinary double suture. He did not advocate this suture where the bladder wall was normal, since the usual double suture had succeeded in all cases favourable for its application; but when the bladder-wall was thinned or softened he would expect from the lace suture the best results. Brenner, its originator, claimed for it, among other advantages, that the bladder became functionally active immediately, and the catheter need not be retained; that the wound surface was very small, and healed quickly; and that the scar was thick and solid, and that only two small threads were left in the wound.—Deputy Surgeon-General JOYNT did not think that a case had been made out for suprapubic lithotomy to displace the lateral operation, with which he had been familiar in India, where he had operated in not less than one hundred cases. Out of that number he could only recollect one fatal case, and whether that was due to the operation or not he could not now say. He could understand, however, that the suprapubic operation would be an acceptable one in women, there being a good deal of trouble in operating on them. He had had cases in which he removed stones one inch and a half in circumference from young girls by dilatation of the urethra, aided by incision.—DR. CHANCE inquired what measure of distension was advisable, having regard to the fact that exploration was sometimes followed by a sharp attack of erythronitis.—MR. THOMSON was glad to hear Deputy Surgeon-General Joynt, whose great experience in India carried authority, say a word in favour of lateral lithotomy. With regard to removing big stones by the suprapubic operation, another operation was being practised now in India very successfully, in which there was no cutting at all; namely, an operation introduced by two distinguished graduates of Irish Universities—Surgeon-Major Keegan and Surgeon-Major Meyer. The results they had had from the crushing of stone quite eclipsed any from the cutting operations, and they were not deterred by the number of stones in the bladder. He believed the dangers in the suprapubic operation were not less than with lateral or median perineal operations, and that as large stones had been removed by the lateral operation as by the suprapubic.—THE RESIDENT said that Irish surgeons should speak with humility of the subject; for Dease had written that stone was a very rare affection in Ireland. Even after lithotrity had been introduced and established, Mr. Peel, one of the best operators in the city, used to protest he could not see in a cut in the perineum any such dangers as were imagined by some operators. At present cholapaxy, where it could be carried out, seemed most successful, and least trouble to the patient. He did not think enough had been said of the dangers of the lateral operation to rush to the suprapubic as a substitute. There were some cases in which the suprapubic might be the best, but it was not so in all.—MR. STANLEY took a more hopeful view of the future of suprapubic lithotomy, than had been taken either by the President or Mr. Thomson. As compared with the lateral operation, the suprapubic had many advantages. It was absolutely safe as regarded hæmorrhage, and nothing could be cut that would do harm. As Dr. Stoker observed, in children suprapubic lithotomy would become the recognised operation as not endangering the procreative

organs. The reason he himself performed the operation, the subject of his paper, was not because there were three stones present, but because there was great difficulty in sounding on account of an enormous prostate, and the perineum was so deep he could only get his finger half way up the prostate through the rectum. Moreover, the man being 65 years of age, he thought it was a case in which suprapubic lithotomy was indicated. The two great dangers of suprapubic lithotomy were also those of lateral lithotomy; namely, infiltration of urine and blood-poisoning; but, in suprapubic lithotomy, antiseptics could be adopted to a degree inadmissible in lateral lithotomy. Moreover, death from urinary infiltration was not a result very much to be feared. As regards Dr. Chance's question, the degree of distension would depend on the size of the rectum and the age of the patient.—MR. NIXON also replied. He had determined on the suprapubic operation from the condition of the urine, the condition of the bladder, and the large size of the stone, and also because he suspected there was a second stone, which turned out to be the case. He had no doubt that syncope was the cause of death. The patient had been afflicted with hæmorrhage of the bladder for over fifty-seven years. From an experience of one case he was not prepared to lay down a hard-and-fast rule as to the cases in which the suprapubic operation should, or should not, be performed.

REVIEWS AND NOTICES.

In Memoriam.—PHYSIOLOGICAL AND PATHOLOGICAL RESEARCHES. By the late T. R. LEWIS, M.B., F.R.S. Elect, Surgeon-Major A.M.S., Assistant Professor of Pathology in the Army Medical School. London: Published by the Lewis Memorial Committee. 1888.

THIS handsome volume, arranged and edited by Professor Sir William Aitken, F.R.S., and Surgeon-Major G. E. Dobson, F.R.S., and A. E. Brown, B.Sc., is published as a memorial of the late Dr. LEWIS, whose lamented death was due to fatal illness contracted in the active discharge of his scientific investigations at Netley. It consists of a reprint of his scientific reports and papers, with a biographical sketch and portrait of the author. The editors obtained the willing consent of Dr. D. D. Cunningham, of the Bengal Medical Service and Professor of Physiology in the University of Calcutta, for including in the volume papers and reports which were the joint production of Dr. Lewis and himself.

When Drs. Lewis and Cunningham were passing through the course of instruction in the Army Medical School in 1868, the attention of the scientific world was called to the fungoid theories of cholera, propounded by Hallier and De Bary. At the suggestion of the professors, the above-named gentlemen were sent to Germany to study this theory, not only under its expounders, but also under Pettenkofer and other eminent German physiologists. Thus prepared Drs. Lewis and Cunningham went to India, and were appointed by the Government to enter on a special investigation on the causation of cholera. The editors say: "Their first report was published as an appendix to the 'Sixth Annual Report of the Sanitary Commissioner with the Government of India, 1870,' and in the same way most of their subsequent work on this and kindred subjects from time to time appeared."

In March, 1870, Dr. Lewis first discovered nematoid worms in a living condition in a specimen of milky urine in Calcutta; an abstract of his report on this discovery was published in this JOURNAL, November 19th, 1870. It was in July, 1872, that he found the *filaria sanguinis hominis* in the blood of a Hindoo suffering from chyluria. The editors refer to the "full and masterly account" by Dr. Lewis of what is known of this disease in Quain's *Dictionary of Medicine* under the article Chyluria. We have only space to refer our readers to the work before us for the many valuable papers on physiological and pathological subjects on which Dr. Lewis wrote, and more particularly to the one in which he quietly extinguished Koch's comma-bacillus, which he showed to be "an old friend under a new name," a spirillum broken up by manipulation, even demonstrating the accuracy of his opinion by showing a "comma-bacillus" existing in the saliva of Professor Max von Pettenkofer himself.

The editors have paid an eloquent tribute to the value of Dr. Lewis's work, the nobleness of his character, and the loss science sustained by his untimely death; and the number of service sub-

scribers to this goodly and beautifully illustrated volume show how much the late Dr. Lewis's labours in the field of science were appreciated by his brother officers.

The Army Medical School has indeed been unfortunate in the too early deaths of Parkes, De Chaumont, and Lewis. Had the last-named survived to this day, the universal voice of the medical services of the British and Indian armies would have named him as a fitting successor to the late Professor of Hygiene. This chair his great chemical knowledge, and the whole scope and tendency of his researches, as demonstrated in this posthumous collection of his papers, show that he was eminently qualified, more perhaps than any of his contemporaries, to fill with distinction to himself, benefit to the State, and in full harmony with the traditions of a post made famous by the eminent men whose names will always be associated with it.

FIFTH REPORT OF THE STATE COMMITTEE ON LUNACY OF THE COMMONWEALTH OF PENNSYLVANIA. Harrisburg: 1888.

THIS Report bears marks of praiseworthy activity. The efforts made to rescue the insane poor of Pennsylvania from neglect and ill-treatment have been untiring, and the result has been an immense alleviation of human suffering. Much remains to be done, but there is every reason to believe that this energetic Board will continue its work until the dependent, helpless class now unprovided for, as well as those able to pay at least a part of the cost of their maintenance, will be able to secure prompt admission into the State hospitals.

It is needless to say that the fearful abuses which have crept into the management of the insane in the States are not peculiar to America. Probably no country can boast of having been free from them; certainly England cannot. The Legislature was slow to provide accommodation. It was left for philanthropists, as in our own country, to move in the matter, and it was only when public feeling was aroused, to a large extent by a lady, Miss Dix, that the Legislature was induced to provide State hospitals for the insane. There has, however, always been a large mass of lunacy outside the hospitals, and lunatics have suffered greatly from their miserable treatment in almshouses and human pig-styes. There are now five large hospitals for the insane provided, containing 4,222 inmates. In this special work, the above mentioned had an enormous and unique influence. Of this remarkable woman, we observe a biographical sketch in a recent number of the *Journal of Mental Science*, with a portrait, which conveys a striking impression of the force and dignity of her character.

It is satisfactory to learn that while in 1885, of the 65 almshouses in the State, 36 contained insane patients, in 1886 the number was reduced to 27, and in 1887 to 21. Again, in 1883, when the State Committee of Lunacy began its work, there were 1,610 insane in county poor-houses; in 1884, there were 1,161; in 1885, 1,057; in 1886, 875; and in 1887, 898, thus showing a decrease of 612 in county poor-houses. In private hospitals and licensed houses there are 567, in the Philadelphia hospital 509, and in prisons 63; making a total, with the 4,222 in hospitals, of 6,259.

A number of instances are given in which the Committee investigated the condition of patients stowed away in private houses or elsewhere, and, finding them in a very unsatisfactory and degraded state, had them removed to hospitals for the insane. No one can read this Report without seeing that the labours of the Committee are of the utmost value, and that they have vastly improved the condition of the insane in Pennsylvania.

Valuable Appendices succeed the Report, containing maps of the districts in which hospitals are placed, and plans of asylums. A remarkable feature of this section is the introduction of a series of such plans of asylums in other countries. Application was made by the Board to Dr. Hack Tuke for copies of plans of typical hospitals for the insane in Europe, with the result that these were procured from England, Scotland, Germany, and France. Such a collection renders the Report before us a document of permanent value for reference, not only for Americans, but for those who are interested in asylums for the insane in other lands. The English Commissioners in Lunacy might do worse than follow the example of the Pennsylvania State Committee on Lunacy in the preparation of their annual reports.

The Chairman, Dr. Morton, and the Secretary, Dr. Ourt, appear to be indefatigable in their labours, and deserve well of their State and country.

GENERAL COUNCIL

OF

MEDICAL EDUCATION AND REGISTRATION.

SESSION 1888.

Friday, May 25th.

JOHN MARSHALL, F.R.C.S., F.R.S., President, in the Chair.

THE minutes of the last meeting were read, amended, and, as amended, confirmed. The Council then resolved itself into a Committee to continue the consideration of the recommendations comprised in the report of the Education Committee.

Instruction in Fevers.—The REGISTRAR then read the Rev. Dr. HAUGHTON's motion (second recommendation):—

"That candidates for the final examination be required to produce evidence that they have, so far as local circumstances will permit, studied fevers for not less than three months under recognised clinical instructors."

Sir DYCE DYCKWORTH said that in London the recommendation would only apply to small-pox and scarlet fever. He urged that men could hardly be expected to devote themselves exclusively to the study of fever for the whole three months.

Dr. GLOVER repeated his question as to whether the instructor might be a private practitioner, and whether "fever" meant zymotic diseases.

Professor HUMPHRY expressed a hope that the Council would not pass this resolution, seeing that it was very doubtful whether, if passed, it could be carried into effect. He deprecated recommendations bearing on special subjects, as tending to specialisation. If they suggested devoting three months to fever, why not three months in a lunatic asylum or skin hospital? One advantage of studying in the London Hospitals was that no such specialisation had yet taken place.

Dr. KIDD said that their object should be to make good general practitioners, and not specialists, but he thought that to send young men out into the world who had not seen anything of fever was little less than a scandal. He suggested that the best plan would be to address a recommendation to the schools to devise a means.

Dr. WILKS protested against placing fever among the special diseases. It was a most useful and necessary part of the ordinary curriculum of medicine.

Dr. STRUTHERS said that in many places infectious diseases had been sent away to special hospitals, and, so far, they had not the authority from the civic authorities to visit these hospitals. Doubtless if the Council made the recommendation the authorities would pay attention to it.

Mr. MACNAMARA thought that a means might be found, and suggested that the authorities at fever hospitals should be induced to admit students. In Dublin they were not only permitted, but invited, to attend.

Rev. Dr. HAUGHTON said the resolution was not his own, but was proposed by him on behalf of the Committee. He disagreed with parts of the resolution. He was prepared to put "fevers" instead of "fever," but he protested energetically against the introduction of the word "zymotic," which was bad Greek, worse English, and false in theory. He said that Professor Humphry seemed to proceed on the assumption that what could not be taught in three months in the lecture room at Cambridge ought not to be taught elsewhere.

Dr. STRUTHERS then moved the following amendment, which was seconded by Mr. WHEELHOUSE:

"That it is desirable that candidates for the final examination should have availed themselves of the opportunities within their reach of acquiring a practical knowledge of fevers."

The amendment was negatived.

A second amendment was moved by Sir JOHN SIMON, and seconded by Dr. PETTIGREW:

"That this recommendation be remitted to the Education Committee for further consideration."

This amendment was also negatived.

The original motion was then read from the chair and carried, 12 being for and 9 against.

Attendance on Labours.—Dr. KIDD moved the adoption of the third recommendation (seconded by Dr. LEISHMAN):

"That every student should be required either to attend for three months the indoor practice of a lying-in hospital, or to have

been present at not less than twelve labours, at least three of which he should have conducted personally under the direct supervision of a registered practitioner."

He said that six months' attendance in a lying-in hospital would do a student more real good than any other way of attending midwifery. He said the admission of a "registered practitioner" was the result of a compromise, as was the number (12) embodied in the resolution.

Dr. LEISHMAN objected to the assumption that when a student had attended 20 cases all had been done that was required. The great thing was that the student should receive proper instruction. He said that, in one school at any rate, the qualification for recording attendance on a midwifery case was touching the bedpost, so that a man who had touched twenty bedposts would be held to have attended 20 cases. The four or five cases which a man attended in Edinburgh were much preferable, seeing that attendance on midwifery cases involved a very serious loss of time.

Dr. GLOVER proposed as an amendment—
"That in this resolution the number 20 be substituted for that of 12."

He said that, having regard to the extreme importance of this branch of study, he must take the opinion of the Council as to the number. He said that the number (6) of attendances required by the Scotch schools was a discredit to the Council and to the examining bodies. Not only were not more than six cases required, but no proof was insisted upon as to how they were attended. He had been told that as a matter of fact the men did not attend even the six cases. In the majority of cases labour was over before the student arrived. He said that twelve cases did not afford a good opportunity of seeing any abnormality. The English bodies required twenty, and the Irish thirty.

Sir WILLIAM TURNER said it was quite true that the University of Edinburgh at present only asked for attendance on six cases, but steps were now being taken to bring about a condition of things almost identical with that shadowed forth in the terms of the resolution. He said that three factors had to be considered, namely, the student, the examining body, and the gravid woman.

Dr. Glover's amendment were agreed to, he doubted whether they could find a sufficient number of gravid women for the purpose.

Dr. HERON WATSON pointed out that the number of pregnant women was often not sufficient to provide even the six cases. Whatever the advantage might be of several students attending together, it was certainly not to the advantage of the woman. He suggested that students in the vacation might be enabled to attend cases with a practitioner, but he thought it was a mistake to lay down any hard and fast rule.

Mr. BRUDENELL CARTER explained how matters were carried on in London, taking the maternity of St. George's Hospital as a model. While the Council should not impose conditions on the Scotch Universities which they might not be able to carry out, that would not justify their pulling down the level of the London schools.

Dr. Glover's amendment was then negatived by 19 votes to 7. Dr. KIDD, speaking to the original motion, said he had voted for the amendment because he thought twenty better than twelve, but a hundred would be better than twenty. He regarded it as an act of justice. He then warmly defended the lying-in hospitals as at present conducted.

The PRESIDENT said that the resolution did not prevent men attending twenty cases, or more if they wished to.

The motion was then agreed to *nem. con.*

Hospital Attendance.—It was moved by Dr. STRUTHERS and seconded by Mr. WHEELHOUSE, that the fourth recommendation be as follows:

"In regard to hospital attendance: That means be taken to ascertain the regularity of the attendance; that every student shall, as far as possible, have served as dresser and as medical clerk, and have availed himself of the opportunities of attending the ophthalmic and other wards or hospitals for special cases; that the designation 'clinical instruction' be substituted for the designation 'clinical lectures;' that there be regulated clinical instruction to limited numbers; and that the certificate entitling the attendance has been, during a stated number of months, on 'hospital attendance with clinical instruction.'"

Dr. STRUTHERS explained that the recommendation was the outcome of a deliberation as to how the system of practical education could best be improved.

On Mr. MACNAMARA's suggestion, it was agreed to discuss the clause paragraph by paragraph.

Mr. MACNAMARA then discussed the means of ascertaining the attendance of students at clinical instruction, pointing out the failings of the various systems employed, and asked for some practical suggestion in this direction.

Mr. TRALE pointed out that to obtain satisfactory results the same students must follow the teacher, with which object in view they at Leeds had adopted the plan of subdivision into classes, which, he said, worked very well.

Mr. BRUDENELL CARTER said that the recommendation, as addressed to examining boards, was unnecessary and absolutely impracticable, and he should therefore vote against it.

Sir WALTER FOSTER characterised the recommendation as an excellent example of grandmotherly legislation, of which they had had too much in the past. If the examinations were made more thorough and more practical, the teaching would follow suit. He proposed to omit the entire paragraph.

Sir JOHN SIMON said the Council should not go into details which they might safely leave to the bodies concerned. He asked how the University of London was to ascertain regularity of attendance?

Dr. LEISHMAN expressed his satisfaction at finding that the recommendation was not to the taste of the Council. He said it would be absurd to send this recommendation down to the examining boards which had no direct control over the schools.

Mr. MITCHELL BANKS advocated that the subject of clerkships and dresserships should, at any rate, receive attention, seeing that certain bodies only required attendance at hospitals and did not insist on either of these posts.

Rev. Dr. HAUGHTON desired to get rid of the resolution altogether. They had special reasons in Dublin for trusting to examination rather than to registers of attendance. He said that the competition between the various hospitals there was very keen, and it was to their interest to get hold of the fees from the students without troubling too much about their attendance.

After some further discussion, in which Sir W. TURNER, Dr. BRUCE, and others took part, Dr. STRUTHERS, after condemning the University of London as a failure for the very reason that it could exercise no effective supervision over its students, said that, in view of the terms of Clause 15 of the existing recommendations of the Council in regard to the Final Professional Examination, he would ask leave to withdraw his motion, and, with the permission of the Council in Committee, the clause was accordingly withdrawn.

Instruction in Pathological Anatomy.—It was moved by Dr. STRUTHERS, and seconded by Mr. MACNAMARA:

"That greater attention be given to instruction in pathological anatomy than is required in the curricula of some of the examining bodies, and, with this view, that a course of not less than three months' lectures on pathological anatomy with practical instruction should be included in the curriculum of all the examining bodies, and that it should be made a separate subject of examination."

Sir WALTER FOSTER suggested that this and the remaining recommendations should be all withdrawn.

Dr. STRUTHERS suggested ironically that they should go back and withdraw the whole of the recommendations. He said that the study of pathology in this country was very much behindhand, although a question of the utmost importance; and he dilated on the shortcomings of pathological instruction in England.

Dr. TUKE, as the representative of a body which did not include pathology in its course, hoped the Council would pass the resolution.

Dr. WILKS said it ought to be made clear that by practical instruction they did not mean *post-mortem* examinations. He observed that the ignorance of men in respect of *post-mortem* appearances was something colossal. He could supply abundant examples of such ignorance, many of them having occurred in cases in which a fellow-creature's life was involved. He maintained that proper facilities were not afforded at Edinburgh for such instruction.

Sir WM. TURNER defended Edinburgh from the aspersions cast upon its system of pathological instruction.

Dr. WILKS would have liked to ask Professor Humphry how much direct experience students obtained at Cambridge?

Dr. HERON WATSON hoped that the student would not be burdened with an additional course, for which he would have to pay extra.

After some further discussion the motion was put to the vote and carried.

The Council then adjourned.

Saturday, May 26th.

JOHN MARSHALL, F.R.C.S., F.R.S., President, in the Chair.

THE meeting having been formally opened, the Council resolved itself into committee to continue the discussion of the recommendations embodied in the report of the Education Committee.

The Study of Insanity.—It was moved by Dr. TUKE and seconded by Dr. BANKS that the sixth recommendation should be as follows:

"That it is desirable that candidates for examination be required to have availed themselves of the opportunities within their reach of studying insanity."

Dr. TUKE pointed out that the study of insanity did not receive the amount of attention to which its intrinsic importance entitled it—in fact, that it was to all intents and purposes neglected. He urged that, both in the interests of the public and of the profession, it was desirable to put an end to a condition of things which was simply disgraceful.

Sir JOHN SIMON objected to the clause on the same ground that he had objected to its predecessor, namely, that it tended to specialisation.

A discussion ensued as to the means of giving effect to the recommendation if passed, and the motion was then put to the vote and carried by a large majority.

Curtailment of Lectures.—Mr. WHEELHOUSE moved that the seventh recommendation be as follows:

"That, in order to afford due time for clinical work, it is desirable that the number of systematic lectures be diminished."

The motion was seconded by Sir DYCE DUCKWORTH, but after a brief discussion it was withdrawn, by permission of the Council in committee, and the following motion by Dr. LEISHMAN, seconded by Dr. BRUCE, was substituted:

"That, in order to afford due time for clinical work, it is desirable that the number of systematic lectures be restricted, and that it be referred to the Education Committee to consider in what cases and to what extent this restriction should be applied, and to report to a subsequent meeting of the Council."

The motion was agreed to.

Subdivision of Examinations.—Mr. MITCHELL BANKS moved that the eighth and last recommendation should be amended to read as follows:

"That extreme subdivision of examinations for admission to the *Medical Register*, by allowing candidates to present themselves for the various subjects of examination separately, is prejudicial to sound professional education, and should be discouraged; and that this resolution be referred to the Examination Committee for their consideration and report."

He said that, while it was not fair to the student to require him to keep up too many subjects at one time, he thought the system of subdivision encouraged "grinding" more than any other system. He believed that such a recommendation, emanating from the Council, would influence the examining bodies.

Dr. KIDD, in seconding the above amendment (which was substituted for the original motion), expressed his approval of the object in view.

Dr. STRUTHERS praised the system adopted in Dublin of sessional examinations. He urged that it was impolitic to separate certain subjects, such as anatomy and physiology, which went naturally together, though no useful object would be attained by compelling the student to go up for, say, anatomy and chemistry together. He strongly disapproved of what he called the "dot and go one" system of the London Colleges.

After some remarks by Mr. BRUDENELL CARTER, Dr. GLOVER, and Mr. BANKS, the motion was agreed to.

The Council having resumed, it was moved by Mr. WHEELHOUSE, seconded by Dr. STRUTHERS:

"That the recommendations passed by the Council in Committee be received and entered on the minutes."

Sir JOHN SIMON suggested that the discussion by the Council of the resolutions should be delayed until a future meeting. He said that at least one resolution (No. 2, as to fevers) did not express what was intended by its proposer as to obliging the student to attend a special hospital where the general hospital did not give the necessary instruction.

Rev. Dr. HAYDON said that it was only in cases where fever

was not taught in the general hospital that they wished to insist upon the three months' course in a special hospital.

The PRESIDENT then read the resolution moved by Sir John Simon:

"That the report be referred to a future meeting of the Council for further consideration."

Mr. MITCHELL BANKS characterised the motion as preposterous, seeing that it would involve going over the ground again on that future occasion.

Dr. LEISHMAN objected to Sir John Simon's remark that the terms of Clause 2 were by no means those of the framer of the motion. He said that he perfectly understood and agreed with the motion as expressed in the terms thereof, and he objected to any attempt to adjust it so as to acquire a signification different from that which the Council had intended should be given to it.

Sir WALTER FOSTER said that the motion would have for effect to stultify themselves. He would have preferred that the work had been got through in sufficient time to enable the Committee to devote an evening to its consolidation. He said he perfectly understood what was meant by the fever instruction clause, and the designation of the instructor had purposely been left open.

Dr. GLOVER hoped Sir Walter Foster would at once take the opinion of the Council, for if it came up in October the whole thing would have to be gone over again, which would be an unconscionable waste of time.

Sir JOHN SIMON said that an economy of time might be a waste of character. What they did ought to be well done. They had already referred back two of the resolutions, and he proposed to refer that one also.

Dr. LEISHMAN said that as regarded No. 2 Clause, Dr. Haughton had begun by saying that it was not his motion, but that of the Committee, so that whether or not the terms were those preferred by Dr. Haughton did not matter.

Dr. STRUTHERS, speaking as the unhappy chairman of the Education Committee, objected to their being referred back. He moved that the Council adopt the recommendations.

Sir JOHN SIMON, with the consent of the Council, then withdrew his resolution, and the motion of adoption was agreed to.

Examination in Common Diseases.—Dr. GLOVER moved:

"That it be a recommendation to the examining bodies to include in their final examinations of candidates tests of their knowledge of common diseases and their treatment."

He said that unless they could get additional attention to the study of common diseases, it was of very little avail to hope to improve the curriculum. He thought such a recommendation was the logical conclusion of what had already been done.

Dr. HERON WATSON asked what was meant by "common diseases?" Was it "common and unclean?"

Sir DYCE DUCKWORTH resented the motion, as an insult to the examining boards of London.

Sir WILLIAM TURNER moved that "the Council proceed with the next business," and this was carried. The motion therefore fell through.

Aconitine in the Pharmacopœia.—The PRESIDENT read a letter from Dr. Thudichum, which was printed in the programme for the day's proceedings, bearing on the variable strength of the substance described as aconitine in the *Pharmacopœia*.

Dr. QUAIN protested against such letters being put into the programme, otherwise they would have endless communications of that kind. With regard to the particular letter, the *Pharmacopœia* Committee had gone very carefully into the subject. He said there was no preparation of aconitine for internal use in the *Pharmacopœia*.

On Mr. MACNAMARA'S motion, the letter was referred to the *Pharmacopœia* Committee, the President being requested to inform Dr. Thudichum what had been done.

The reports of the Finance Committee and of the Income and Expenditure Committee were received and entered in the minutes.

Defective Information.—It was proposed by Dr. STRUTHERS and agreed to:

"That the table showing results of preliminary examination in 1887, entered in the minutes of May 22nd (pp. 28, 29), be referred to the Education Committee, together with the examination papers indicated in the last column of the table as 'sent,' and that the Registrar be requested to apply to the examining bodies for any further information the Committee may desire."

Inspectors' Reports.—It was moved by Sir WILLIAM TURNER, and seconded by Dr. STRUTHERS:

"That the reports of the inspectors of the final examinations in medicine, surgery, and midwifery, along with any observations on the reports which the bodies inspected may make, be remitted to the Examination Committee for consideration and report to a future meeting of the Council."

Sir WILLIAM TURNER discussed the proper course to be followed with these reports, which he said was defined by the Medical Act (1886).

Dr. GLOVER observed that some expressions in the President's address seemed to indicate an intention to modify the reports, a course he strongly objected to.

The PRESIDENT said that he had asked to be associated with a sub-committee in order to discuss what to do with the reports. All he proposed was that they should be made clear and consistent with the object of the report, redundancies being eliminated. His object was twofold: (1) that the reports should contain an explicit conclusion, explicitly expressed; and (2) to strike out redundancies. Such alterations as might be deemed necessary would only be considered in the presence of the inspectors themselves.

The motion was then agreed to.

Distribution of Registration Fees.—Mr. MACNAMARA proposed: "That the fee paid for registration of the qualification or qualifications which admit a practitioner to the *Medical Register* should in future be credited to the Branch Council of the division or divisions of the kingdom in which the qualification or qualifications were obtained."

He said that the subject had been broached for the first time ten years ago, when he was chairman of the Registration Committee. The General Medical Council had no money and no income of their own, beyond the profit on the sale of the *Pharmacopœia*, the principal source of its revenue being the percentage rate based on the receipts of the Branch Councils. He said the whole intention of the Acts would be frustrated if the Branch Councils collapsed. He then discussed the present financial condition of the Irish Branch Council, which had a balance of £194 7s. 10d. It might be said that the Irish Branch Council was extravagant, but that was a matter for the consideration of the Council. He urged that the English Branch Council was unduly favoured in being able to meet just prior to the meeting of the General Council, which the other Branch Councils could not do. He maintained that after educating and examining men in Ireland, they ought to be credited with the registration fees. He had calculated that under the present system some £17,000 had gone to swell the exchequer of the English Branch Council, which should properly have gone to the others.

Dr. QUAIN, in replying to the cry of "justice for Ireland," criticised the expenditure of the Irish Branch Council, and compared its financial condition with that of the Scotch Branch Council. The money had been spent in holding unnecessary and uncalled for meetings, and the remedy lay in a more economical administration. He observed, moreover, that the fees which were paid in to the English Branch Council legally accrued to that Council, and could not be alienated even with the consent of the Council.

Dr. BRUCE moved "the previous question," but this was promptly negatived.

Sir WILLIAM TURNER, in seconding the motion, said the matter had been considered by the Scotch Branch Council, and it was not exclusively an Irish question. He urged that the usefulness of the Branch Councils was curtailed by this diminution in the fees accruing to them. He thought that in future the fees should be credited to the Council of the division where the man took his qualifications. He said the proposal was a reasonable one, and no objection should be raised to it; but, in view of Dr. Quain's contention as to the competency of the Council to modify the present system, he would leave the matter until a future occasion to be followed up.

Mr. CARTER moved, seconded by Dr. BRUCE,

"That the subject of Mr. Macnamara's motion be referred to the President, with power to consult the legal advisers of the Council on it, and particularly as to the competency of the Council to make an order to the effect of that proposal."

Sir JOHN SIMON suggested that the fee ought rather to go to the Branch Council of the place in which the holder of a qualification intended to practise.

The Rev. Dr. HAUGHTON observed that the result of this resolution would only be to postpone the discussion pending an opinion as to the legality of the proposal.

Mr. Carter's motion was then agreed to.

A motion brought forward by the Rev. Dr. Haughton in reference to the commencement of medical study by dental students, was withdrawn, it being pointed out that the proposal was unnecessary.

The Council then proceeded to elect the various committees.

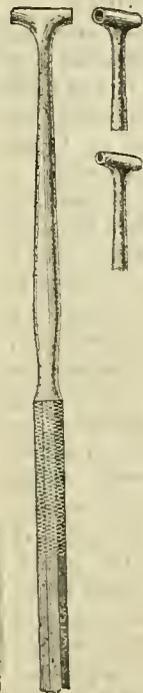

Mr. CARTER called attention to an advertisement issued by H. F. Partridge, and to the names of certain registered medical practitioners appended thereto.

The Council then adjourned.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS, IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

A NEW COMEDONES EXTRACTOR.

THE early and complete removal of comedones in the treatment of sebaceous acne is so important for the purpose of preventing the secondary consequences disfiguring to the patient, that I venture to draw attention to the accompanying illustrations of two simple steel instruments intended to supersede the use of the watchkey.

The smaller of the two, shaped like a pencil-case, I have found a valuable aid if held between the thumb and forefinger immediately above the pin of the spring stylette, the knob at the end resting in the palm of the hand.

The barrel being placed over the comedo, considerable and almost painless pressure can be applied with the surrounding flat and bevelled edge of the instrument, with the result of dislodging the accumulated sebaceous secretion.

The use of the spring stylette easily empties the barrel when filled.

The longer instrument, of simpler construction and attached to a handle, is better suited to the patient's own use before a mirror, as the hollow cross-piece placed at right angles to the shaft allows of unobstructed view.

The circular openings are of unequal diameter, to suit the varying size of the comedones.

The instruments have been made for me by Messrs. Weiss and Son, 287, Oxford Street, W.

J. HERBERT STOWERS, M.D., Physician to the Department for Skin Diseases at the North-West London Hospital.

SELF-DIGESTING WHOLE-MEAL BREAD.

(SAVORY AND MOORE.)

At the request of Dr. W. B. Cheadle, Messrs. Savory and Moore have produced a judicious variety of their malted food—namely, one made with whole-meal flour. It possesses all the advantages of whole meal, combined with those of diastatic foods. It is rich in albuminoids (12 per cent.) and phosphates. When mixed with milk, in the manner directed on the label, it forms an unexceptionable food, of excellent flavour. It is an improvement upon malted foods made with ordinary flour and malt meal only.

SEATREE'S CUMBERLAND BROWN BREAD MEAL.

(SEATREE AND SONS, LIVERPOOL.)

WE have received a sample of the above flour, and of a loaf of bread baked from it. Both are of the highest quality. The flour consists of whole meal, with 11.2 per cent. of albuminoids and 1.6 per cent. of fat. The loaf was exceedingly well baked and perfect in every way, free from excess of cellulose, which not infrequently, in coarsely-prepared whole meal, leads to irritation of the bowels and diarrhoea.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1888.

SUBSCRIPTIONS to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the West Central District Office, High Holborn.

 The British Medical Journal.

SATURDAY, JUNE 2ND, 1888.

 THE GENERAL MEDICAL COUNCIL.

THE forty-fourth session of the General Medical Council has been singularly uneventful, and it is easy to sympathise with the exclamation of an impatient member that if it had never been held the profession would not have been appreciably the worse. The greater part of the session was taken up by the customary academic discussions on suggested improvements in the existing arrangements for medical education, and especially for clinical instruction in certain subjects. Perhaps the most important piece of work was that done on Thursday, when a case in which a registered practitioner had acted as cover to an unqualified person, who was thereby enabled to carry on a medical practice as though he were a legally qualified practitioner, was heard. After a somewhat prolonged investigation, the practitioner in question admitted that he had inadvertently committed the offence, stated that he had discontinued the practice, and promised not to offend so again. The President administered to the erring practitioner a severe rebuke, which ought to be taken to heart by any who may have been tempted to commit a like indiscretion, for this plea of ignorance cannot be indefinitely repeated in the future. Though the Council in the two cases hitherto brought before it has wisely tempered justice with mercy, the time will assuredly come when the large penal powers which it possesses will be put in force. The practice of "covering" unqualified persons has no legal or moral justification, it inflicts a serious injury upon the public, and is a wrong to the profession. Upon this point the medical profession is, we believe, entirely at one with the Council. The employment of genuine pupils as assistants is an entirely different thing, and it may be authoritatively stated that so far from wishing to hamper this custom, it is the desire of the Council to favour the extension of the system. An attempt has been made to throw dust in the eyes of general practitioners by mixing up the two things, but they are essentially distinct, one being a useful part of the medical curriculum, the other a covert attempt to evade the law. The employment of an unqualified assistant is, however, only to be permitted under proper safeguards, and not either in complete substitution for the services of the principal or under circumstances in which due personal supervision and control are not or cannot be exercised by the principal.

The President stated that no less than seven cases of alleged "covering" had been brought to his notice, though in one

only had the evidence adduced justified the holding of an inquiry. The Council declines to take any share in the initiation of such inquiries, and assumes that it is only called upon to act in a judicial capacity; consequently, the labour of collecting evidence and sustaining the allegation before the Council, sitting in this judicial capacity, falls upon private individuals. This is much to be regretted, as it requires considerable moral courage to incur the possible odium which would attach to the failure to establish charges of "covering." The duty, it will seem to many, ought to be assumed by the corporations which have granted licences to practise to the accused persons. The corporations themselves possess certain disciplinary powers which could not be better employed than in sustaining or anticipating the action of the Council.

The greater part of the session was spent in the discussion of the report by the Education Committee. Its recommendations were in the end adopted with few alterations, and with only one important omission. By some one or other of the licensing bodies every one of these recommendations is already acted upon, though probably none are at present following all. The most important is that which states that, in order to afford due time for clinical work, it is desirable that the number of systematic lectures be diminished. This recommendation opens up a very important subject, for it will have to be recognised, sooner or later, by the corporations that the value of such lectures has been very much altered by the development of medical literature and by the increased complexity and extent of the subjects dealt with in the systematic courses. On the one hand, the lectures are rapidly falling in the estimation of students, who do not find them as indispensable as when textbooks were few and imperfect; and on the other, lecturers are compelled to deal in any single course with only a fraction of the whole subject, as when a lecturer on medicine limits himself to diseases of the chest or of the nervous system, which he finds afford more than sufficient material for one session. More will be heard of this matter, as it has been referred to the Education Committee to consider in what cases and to what extent the systematic lectures ought to be restricted; but it may be doubted whether any of the other recommendations will have much practical effect.

To tell students that they ought to avail themselves of the opportunities within their reach of studying fevers and insanity, is to give them very excellent advice, but as part of the requirements of examining bodies under existing conditions of keen competition among medical schools, the recommendation would, it is to be feared, be a dead letter. As to the third and fourth recommendations, it will be a surprise to many people that they should yet have to be made; that it should still be necessary to recommend that a course of pathological anatomy with practical instruction should be included in the curricula of all the examining bodies, and that every student ought to be required to be present at twelve and to conduct three labours is hardly creditable to the regulations now in force.

The first recommendation related, in the words of the President, to the "various substitutes for the beneficial purposes attained by the now extinct pupilage;" the main objection to the recommendation is that it would have the effect of prolonging the curriculum for six months, or of curtailing

the attendance in hospital. The last recommendation enters upon very debatable ground, although it was adopted without much discussion. The tendency of recent years has been towards the subdivision of examinations, and it may be doubted whether the University of Cambridge, for instance, would have adopted the practice if it were really so "prejudicial to sound professional education;" the recommendation may, however, do good by calling attention to the subject and preventing abuses.

It is worthy of note that the Council now consists of its contemplated number of thirty members, including the President; this has been brought about by the expiration of the term of office for which Dr. Matthews Duncan was nominated by the Crown. The vacancy thus created has not been filled up.

Sir John Simon having withdrawn from the Executive Committee, which he found too great a tax upon his health, his place was supplied by the election of Mr. T. P. Teale, who has been for twelve years a member of the Council.

DR. GASKELL AND THE MARSHALL HALL PRIZE.

SINCE the institution of the Marshall Hall prize ten years ago, it has very justly been looked upon as the blue ribbon of one division of the studies of medicine and physiology—that which deals with the nervous system. It is awarded only once in five years, and as yet there have been only three men who have received this very high compliment. The first two were men of not only English, but it might truly be said of European, reputation in their investigations of the nervous system by observation of disease and by the method of direct experiment—Dr. Hughlings Jackson and Dr. Ferrier; and now to these has been added a third, Dr. W. H. Gaskell, F.R.S. Though he graduated at Cambridge nearly twenty years ago, and became M.D. of that University in 1879, he has not turned his attention to the practice of his profession, but has kept it steadily fixed on some of the problems of physiology; and of those many problems he has chosen some of the most delicate and difficult, and has spared himself no trouble or expense to arrive at an accurate and complete solution. The magnificent opportunities which the University of Cambridge has been able to put at the disposal of its students in its great physiological laboratory, under the guidance of Professor Michael Foster, have never been more fully appreciated or put to worthier use.

The study of the influence of the nervous system on the heart and on all parts of the circulatory system is one of the most puzzling not only to the beginner, but to the advanced student. It is here first that he comes across the phenomena of inhibition of function by an efferent nervous impulse which everywhere else is an excitant; an inhibition, too, which does not seem when more closely analysed, and even after the arguments of Bernstein, to resolve itself into the withdrawal of a constant normal stimulus unconsciously supplied and conveyed by a nerve, but is the immediate and direct result of the application to the conveying nerve of anything that usually acts as a stimulus to the full excitement of the nervous action. Time may familiarise

us with such conceptions, but it does not render it more easy to realise them satisfactorily. In dealing with such questions in the spirit of accurate criticism, there is much difficulty in experiment owing to the extreme anatomical complexity of the course of the nerve fibres, both of the cerebro-spinal and the sympathetic system. There are some which both normally and under an artificial stimulus increase the rapidity of the rhythmical action of the heart, like the so-called *nervus accelerans*, which probably originates in the medulla.

Dr. Gaskell has done excellent work in showing, by most laborious and careful dissection and experiment, the points of origin, combination, and separation of the accelerator, sympathetic, and inhibitory fibres; and demonstrating by a comparative examination of the snail, the frog, the tortoise, the rabbit, the cat, the dog, and man, the gradual evolution and differentiation both of function and of structure, so that in man the same nerve fibre cannot be both inhibitory and motor, or accelerator. That is a considerable and valuable contribution to a very large question. As to the accelerating fibres, he has shown good cause why they had better be called "augmentor," as they not only increase rapidly, but strength of contraction of the auricles in cold-blooded vertebrates, and of the ventricles also in the warm-blooded. The process of inhibition might be supposed to be at the periphery, destructive or catabolic, constructive or anabolic (that is, leading to an ultimate increase of energy), or neutral and producing inhibitory effects by interference with some simultaneous process, just as two sets of motor vibrations on the same cord may interfere with one another so as to produce rest. Dr. Gaskell's view, which is based on researches dating from before the International Congress of 1881, is that the inhibitory action is anabolic, and that though the heart's action is stopped for the time, yet its subsequent action is so much the stronger as to more than balance the arrest. The "augmentor" influence, on the other hand, for the time quickens and strengthens, but ultimately exhausts.

"One fact," to quote his own words, "seems to be coming to the front, namely, that weak stimulation is most effective in the direction of inhibition, and strong stimulation in the direction of excitation;" weak stimulus of the sciatics slows the vaso-dilators; "the stimulus which produces by its inhibitory effects the condition of hypnotism is essentially a weak one." From the minute and prolonged consideration of a part of the nervous system, Dr. Gaskell is proceeding, by careful steps, to a more general survey of the largest and most fundamental divisions into what he calls "somatic" and "splanchnic" nerves, and the application of these divisions, even to the cranial nerves, in which he confirms and extends Van Wijhe's researches.

The conclusive way in which he has demonstrated the dropping of the investment of medullary sheath by some fibres at various points in the course of the nerve and its meaning was excellently illustrated by some magnified photographs thrown on the screen during his lecture at the Royal Medical and Chirurgical Society's rooms last week, and commanded the entire approval of his distinguished and numerous audience. The value of his strong independent individuality and concentration on his work was very widely felt.

THE SURGERY OF THE URETER.

SEVERAL bold surgeons have recently attempted or suggested different methods of closing, catheterising, or compressing the ureter. Dr. Tachmann, of the German Hospital, has constructed a hollow instrument, resembling a lithotrite. The blades are separated when this "ureter-forceps," as he terms it, is introduced into the bladder, and slipped along the base till it touches the posterior wall. On closing the blades, they will grasp the elevated ridge of mucous membrane, representing the very oblique course of the ureter through the vesical walls. By dint of practice on the cadaver, this delicate operation may be performed on the male as well as on female patients. Fifteen minutes are said to be sufficient for the purpose of keeping the ureter closed while the urine secreted by the opposite kidney runs from the hollow outer blade of the forceps, and is preserved for testing. In this manner, not without obvious precautions, the surgeon may discover if one or both kidneys be diseased. Mr. Hurry Fenwick has contrived a ureter-aspirator. In one case, at least, he succeeded in blocking the right ureter with clot by means of this ingenious instrument. The patient was a middle-aged man, suffering from severe hæmaturia due to traumatic malignant growth of the right kidney; when the "clottage," as Mr. Fenwick termed it, was performed, no distinct tumour could be felt. From the date of the "clottage," till the patient's death, six months afterwards, there was no recurrence of the hæmaturia, which for fourteen months previously had been violent and persistent. Dr. P. Müller has contrived a ureter-compressor, somewhat after the principle of Mr. Davy's now well-known lever. He took into consideration the anatomical relations of the ureter in its course along the pelvic walls. On introducing the finger into the rectum, feeling for the spine of the ischium, and then passing the finger about an inch and a half upwards towards the pelvic brim, the ureter can there be compressed against the bony wall of the pelvis. In women this compression may be effected through the vagina. Dr. Müller has constructed a special compressor. It forms an angle; the short arm is fixed by a bandage to the thigh after compression, and bears a hinge so that the instrument may be bent to a convenient angle, whilst the long arm bears a bag at its free extremity. The patient is placed on his side, and the long arm is passed about five inches into the rectum. The bag is left flaccid till it has been properly introduced, it is fitted with rubber tubing, which is placed in communication with a long glass pipe ending in a funnel. About four pounds of mercury are poured into the bag, the ureter is then compressed to the extent of at least four-fifths of an inch. Dr. Müller has effected compression in one instance only on the living subject. He further proposes to compress the ureter against the pelvic brim through the abdominal walls, by means of a pad.

Dr. Axel Iversen, of Copenhagen, has boldly opened the bladder by suprapubic section, so as to inspect the urine as it escaped from both ureters. The patient was a man aged 38; he suffered severely from discharge of purulent urine, which contained no tubercle bacilli, neither was there any swelling or any localised pain, to prove whether the disease were unilateral or bilateral. Calculous pyelitis was diagnosed. The bladder was opened,

and its cavity illuminated by the electric light. A continuous stream of pus issued from the orifice of the left ureter. From the right came an almost clear fluid. This was carefully examined and found to contain some red corpuscles, abundance of epithelium from the upper and middle part of the urinary tract, and a considerable quantity of hyaline and glandular casts. On that account Dr. Iversen gave up all intentions of removing the left, the evidently suppurating, kidney, nor did he deem it necessary to perform nephrectomy, seeing that the pus could be seen to flow as freely from the ureter as it would have escaped through a lumbar incision. The patient recovered from this remarkable exploratory operation. The above-named surgeons may partly be considered pioneers in a new and not unimportant branch of surgery. That there remains room for much improvement they would, we trust, be the last to deny.

A COURSE of lectures on bacteriology will be given by Professor Klein, F.R.S., for the College of State Medicine in the theatre of the Chemical Society, Burlington House. The first lecture will be given on June 4th at 4 P.M., and the course will be continued on succeeding Mondays at the same hour.

AID IN CONVALESCENCE.

THE convalescent work of the Charity Organisation Society is one deserving of public recognition and support, and we may express the hope that the sum of £1,500 required for the provision of the necessary summer beds may be shortly forthcoming. This appeal is signed by Dr. W. M. Ord, St. Thomas's Hospital; Dr. J. C. Steele, Guy's Hospital; Dr. Broadbent, St. Mary's Hospital, and others.

A FISH AND POULTRY JURY.

THE Sanitary Committee of the Corporation of Leeds have sanctioned, as an experiment for twelve months, the appointment of a "fish and poultry jury," to assist the sanitary officials in deciding as to food supposed to be unfit for human consumption. The committee will select three names from a list supplied by the dealers, to constitute the jury. This plan is said to work well in some other towns.

RICHMOND PARK.

THE Duke of Cambridge will probably receive a great deal more sympathy in the course which he is understood to be pursuing in opposing the proposal to hold the National Volunteer Rifle Meeting in Richmond Park than some of our daily contemporaries appear to expect. The park is one of the largest, as it is certainly the most beautiful, of London's lungs, and the establishment of extensive rifle ranges in it will very seriously curtail the privileges of the public. Wimbledon common is now for six weeks in the hands of the Rifle Association—a fortnight for preparation, a fortnight for the meeting, and a fortnight for removing, as far as possible, the traces it has left—and it is astonishing that anyone should regard with equanimity the subjection of Richmond Park to such an indignity.

ALCOHOLIC TRANCE.

THE first special study of alcoholic trance was embodied in a paper read by Dr. T. D. Crothers, to the Medico-Legal Society of New York, in 1881. In a second paper read to the American Medical Association, Dr. Crothers deduced the following conclusions from various clinical reports which have since been published:—I. Alcoholic trance is not an unusual condition in in-

tricity. The victim is generally an automaton, and acts without memory or consciousness of passing events. 2. This trance state is distinct from epilepsy, hysteria, or any known forms of mania, and is found associated with some unknown conditions following alcoholic poisoning, continuously or at intervals. 3. The condition is probably one of brain-exhaustion, followed by a lowering of consciousness, or a suspension of nerve force in certain directions. There is profound disturbance of the brain centres, with impaired and lessened sensibility. In some recorded cases the subject has gone about his daily work, the abnormal state being revealed only on an unexpected call for mental energy, producing confusion and stupor instead of adaptability to new conditions. In other cases the subjects had done unusual acts; for example, a city banker suddenly took to delivering tracts in the slums, but subsequently remembered nothing of the incident. In other cases some unusual line of conduct seemed to grow out of the surroundings or some old buried idea came to the surface, as in the instance of a merchant suddenly declaring aloud to all whom he met that he would kill an old schoolmaster who punished him in boyhood.

FIRE PREVENTION.

If there were any further proof needed of the lamentably inadequacy of our means of affording escape to the inmates of a burning building, it would be afforded by the calamitous fire which broke out soon after 6 o'clock on Wednesday morning last at a draper's shop in Edgware Road, by which five persons lost their lives. The absence, in the present case, of any fire escape was due to an extraordinary rule which provides for their removal at 3 A.M., when the greater part of Londoners are in their beds. But for this strange arrangement, the unfortunate persons who lost their lives by this disaster would have been saved. Great responsibilities rest upon the owners of large establishments where a large number of persons are housed; it is clearly their duty to provide adequate means of escape. The question ought to be considered whether all such establishments ought not to be placed under restrictive regulations by by-laws framed for the purpose by the local sanitary authority.

THE CENTENARY OF THE LINNEAN SOCIETY.

THE centenary of the Linnean Society was celebrated on May 24th by a meeting at which eulogiums of Linnæus, of Robert Brown, of Charles Darwin, and of George Bentham were pronounced. It is interesting to note that two of the eminent biologists to whom his honourable duty was intrusted, Sir Joseph Hooker and Professor Flower, are both members of the medical profession, and that, of the two recipients of the gold medal of the Society on this memorable occasion, one was Sir Joseph Hooker, and the other Sir Richard Owen, who became a Member of the Royal College of Surgeons in 1826, and a Fellow in 1843. On May 25th a *conversazione* was held in the rooms of the Society, at which all the memorials of Linnæus in the possession of the Society were exhibited, together with many other interesting objects.

A HARDWORKING WOMAN.

THE death is announced of Miss Martha Petrovna Grabovskana, the first female medical practitioner who has settled in the important Siberian city of Tobolsk, where she had entire charge of the female department of the city hospital and lunatic asylum. She lectured also at the School of Midwifery, and had a considerable private practice; in addition to her multifarious duties, she found time to pursue scientific investigations. One of her researches had reference to the hygienic effect of treating hospital walls with corrosive sublimate; for this purpose she is stated to have made fully 100 experiments in the laboratory. She was also much occupied in bacteriological research. Working sixteen hours a day, as this young lady is said to have done, tells, however, on the

strongest constitutions, and it is not much to be wondered at that she succumbed. Before going to Siberia, she was for a time chief of Professor Slavianski's clinic.

PROFESSOR DONDERS.

PROFESSOR DONDERS attained on Sunday last his seventy-first year, an age at which the Dutch law compels him to resign his professorship in the University of Utrecht. At the festivities by which the occasion was celebrated a large number of distinguished men, not only from all parts of Holland and the Dutch colonies, but from this and other countries, assembled. An address was presented to Professor Donders, recognising his forty years' services to science and humanity. The Professor announced that he desired the memorial fund to be appropriated to assisting young physiologists and ophthalmologists at the University. The King conferred the distinction of Commander of the Golden Lion on Professor Donders, and the Government was represented at the ceremony by the Home Minister. King Humbert sent him the Order of the Crown of Italy, and Sir Joseph Lister congratulated the Professor on behalf of the Royal Society of England. A medal was also struck commemorative of the day's ceremony. Professor Donders declared that, although he was leaving the University, he had not finished his task. A banquet was given to him in the evening.

THE RISKS OF A GENERAL HOSPITAL.

THE question whether a general hospital can be regarded as a nuisance to a residential neighbourhood has recently been raised in the law courts, and will probably be still further investigated. Whatever the final decision may be, it is clearly the duty of every hospital to take special precautions to prevent infectious persons found in the out-patient room, either from exposing to the risk of infection other patients in the institution, or the public who may chance to meet these persons on their return home. The actual requirements for such a hospital in London are (1) telephonic communication with the central offices of the Metropolitan Asylums Board; (2) rooms set apart for the isolation of infectious cases occurring either in the out-patient department or in the wards; (3) an ambulance for the removal of those persons who are unwilling or unable to obtain admission into hospitals for infectious diseases. Many institutions have already adopted these precautions, and it is well that the attention of others should be directed by the case to which we refer to the need for following their example.

A RISK OF TRAVEL.

THE reported indisposition of the Duke of Edinburgh from drinking impure water at a foreign station gives prominence to what is perhaps the most usual and frequent source of danger in foreign and Continental travel. Many of the sanitary authorities who have looked into the question have from time to time uttered warnings to Continental travellers as to the dangers of the ordinary drinking water to be found abroad. The pollution of table water at foreign hotels and houses is due to a great variety of causes. The water-supply of foreign cities is as a rule, to which there are only few exceptions, taken from sources lamentably liable to sewage pollution, either in open streams or uncovered reservoirs, or from defective sanitation in the house-supply. A large part of the domestic supply of drinking water is, moreover, from surface wells, which are constantly liable to sewage filtration. An examination made only a few years since, of syphons of sparkling "seltzer" in a great Continental city disclosed the fact that they were horribly polluted with sewage, and that the effervescent fixed air with which they were charged only served to conceal unutterable contaminations of a most dangerous kind. Sir Henry Thompson and Dr. Herman

Weber, who have both given attention to the subject, are very emphatic in their counsel to travellers to avoid ordinary drinking water abroad. The easiest and most agreeable means of avoiding the danger is the habitual use of a pure natural mineral water in lieu of the doubtful drinking water of the hotel or the private house. When the Prince of Wales went to India he took with him a large supply of the kind, and successfully avoided this risk. Another method in which safety is sought is by invariably boiling the water before drinking it. This, however, involves more trouble than many people are willing to take, and makes the table-water flat and insipid. This insipidity may be relieved by squeezing fresh lemons into the water. But for those who cannot always be bothered with the boiling-pot or troubled with performing this little domestic operation before taking a draught of drinking-water, it would be wise when travelling abroad to select as a table-water a natural mineral water of undoubted purity rather than run the risks of blood-poisoning, typhoid, and diarrhoea to which so considerable a number of travellers at present fall victims, finding death and disease where they are seeking health and pleasure. The instances of typhoid, blood-poisoning, diarrhoea, and dysentery, of which we hear this year from Italy and Egypt, are very lamentable, and for the most part avoidable.

MYXEDEMA.

THE usual scanty attendance of members at a "last night" meeting, when a massacre of the innocents is to be expected, did not obtain at the closing meeting of the session of the Clinical Society on Friday last, when a full house, which included Dr. Fordyce Barker, of New York, assembled to hear the conclusions arrived at by the Committee of the Society, which for years has been considering the whole question of myxœdema. These conclusions, which were read by Dr. Ord, the Chairman of the Committee, will be found in full at page 1162. It is nearly four years since this Committee was appointed, during the presidency of Sir Andrew Clark, and the labour has been enormous. The whole question has been investigated in every way that could tend to throw light on this complex subject, and the result has been the volume shortly to be published, which will be found a mine of information concerning myxœdema and its immediate congeners. The name of the Chairman of the Committee, Dr. Ord, will henceforth be indissolubly associated with the literature of myxœdema, in conjunction with that of Sir William Gull, who, some fifteen years ago, first accurately described the clinical features of the disease, though the name which he applied to it has since been altered. Altogether, the Society, and British medicine generally, are to be congratulated on the completion of this most important work. By it the relationship subsisting between myxœdema and disease, or absence of the thyroid gland, seems to be placed beyond all doubt, though the ultimate cause of the loss of function of the thyroid gland has not yet been determined.

THE MEDICAL DEFENCE UNION.

THIS useful union of medical men has been reconstituted, and is now entirely controlled and administered by medical men, whilst it seems calculated to be able to fulfil the defensive requirements of members of the profession. Mr. Lawson Tait is the President, and the Vice-Presidents and other members of the Council are well-known men, practising in various parts of the United Kingdom. One of the new articles of association states that:—"The Council may, after due investigation, undertake the conduct or defence of, or assist in conducting or defending any proceedings, whether of a strictly legal nature or otherwise, concerning or affecting any member of the union who may desire their assistance, providing that the cause of action, or of the proceeding, or

the action or the proceeding, have not arisen or been commenced prior to the date of the commencement of his membership of the union." Only those actions, therefore, which originate after the date of membership can be undertaken by the union. That some society of the kind has been needed seems to be generally admitted, though there is probably some diversity of opinion as to what sort of association it should be. There are now 449 members of the Medical Defence Union, to which large additions should be made, that the society may be the better able to pursue successfully its career. Besides conducting the defence of its members against any legal proceedings, the union will endeavour to suppress unauthorised practitioners by their prosecution. The subscription is fixed at ten shillings a year, and a call on the members to contribute funds for the purpose of the union, in proportion to the guarantee of each, is liable to be made. The name of the secretary is Dr. Leslie Phillips, 393, Moseley Road, Birmingham.

THE THYROID GLAND IN GRAVES'S DISEASE.

RECENT investigations have given probability to the hypothesis that some, if not all, of the symptoms of Graves's disease are to be traced to derangement of the functions of the thyroid gland. The enlargement of this gland is an early symptom, though not generally the earliest, being preceded by some acceleration of cardiac action, and it is, on the whole, doubtless more probable that both are dependent on some one cause than that either is the consequence of the other; the possibility that the anæmia and other symptoms of cachexia may be due to the thyroid lesion ought not to be overlooked. Cases have been recorded within the last eight or nine years in which the symptoms of Graves's disease have been observed to disappear after an operation on the gland; to this limited series Dr. Gauthier, of Charolles, has contributed a sixth (*Lyon Médical*, lviii, 22). In this case a cyst developed after four years and was tapped; the operation was followed by intense inflammation and suppuration, but the patient recovered freed from all the symptoms of exophthalmic goitre, except some cardiac palpitation. Though the cure was not permanent, the patient being as bad as ever seven years after the operation, the case is extremely interesting in the connection above referred to.

THE GERMAN EMPEROR.

WHILST the whole civilised world must rejoice at the relatively favourable turn which the malady of the German Emperor has recently taken, it is important from every point of view that the true significance of the facts should be clearly understood, and that hopes should not be excited which are doomed to disappointment. The illustrious patient has, no doubt, recovered to a considerable extent from the severe local inflammation which not long ago caused him so much suffering, and even placed his life in jeopardy; and this result is, of course, in itself highly satisfactory. It may be well, however, to remind the public that this distressing complication was after all only an accident of the disease, the essential nature of which remains unaffected by its disappearance. The negative result of Professor Virchow's last microscopic examination is of no clinical importance, as the eminent pathologist would no doubt be himself the first to admit; and we are sorry to have to say that hardly any greater weight can be attached to his reported failure to detect any glandular enlargement in the Emperor's neck. Apart altogether from the fact that in this, as in other cases, there may be secondary deposits in glands too deeply situated to be felt, it is not by any means the rule for malignant disease beginning within the larynx to affect the related lymphatic glands. The statement attributed to Professor Virchow by a lay contemporary that he could now say positively that the disease is not cancerous is simply incredible. Medical men, who are accustomed to have their clearest utter-

ances misinterpreted and distorted in the most grotesque way, even by exceptionally intelligent persons, will have no difficulty in understanding how such a misconception might arise without in the least impugning the good faith of the reporter. Such misstatements, however, obtaining as they do the widest currency on the authority of journals which, in all ordinary matters, are entitled to the highest respect, do harm; and in calling attention to a particularly flagrant example, we think it our duty to protest against the gross carelessness, or rather, utter recklessness, with which medical subjects are too often treated in the general press.

RECENT OBSERVATIONS ON TUBERCULOSIS.

THE stimulus given by Koch's discovery of the tubercle bacillus to a closer clinical observation of tubercular affections has resulted in a clearer understanding of some of the exceptional manifestations of tubercular disease. One of the most interesting additions to our knowledge in this respect is the proof, which is being continually strengthened by fresh observation, that the so-called dissection, anatomical, or *post-mortem* tubercle is really a manifestation of local tuberculosis, acquired by inoculation. Finger has lately published a case in which a man who had tubercular disease had suffered from five of these dissection warts, which preceded the development of general tuberculosis, and in which microscopical examination showed the tubercle bacillus. Steintal (*Monat. f. Prakt. Derm.*, 1888, p. 437) relates the case of a woman who was inoculated with tubercle on the skin of the hand through washing the clothes of her phthisical husband. Meyer (*Ibid.*, p. 283) has related a case in which a child was infected with local tuberculosis of the genital organs by the wound made in the rite of circumcision being sucked by the operator, who was the victim of tubercular disease; and at a recent meeting of the Medical Society at Copenhagen Dr. Salomon, sen., stated that he also had observed cases of tubercular infection produced in the same way by ritual circumcisers who practised suction. On account of the dangers of the transmission of syphilis and tubercle in circumcision, Dr. Salomon, sen., advocated that the rite should be performed under precautions laid down by the authorities.

THE CROONIAN LECTURE OF THE ROYAL SOCIETY.

THIS lecture was delivered in the Theatre of the Royal Institution on Monday, May 28th, by Dr. W. Kühne, Professor of Physiology in the University of Heidelberg, who selected for his subject The Causation of Vital Movements. After briefly reviewing the ideas usually held regarding the phenomena of life, he proceeded to show the functional as well as the morphological unity of all living matter. He showed that the cause of protoplasmic movements could only be internal, residing in the contractile substance itself, and could only consist of chemical processes taking place within the mass itself; and experimental researches had shown that there was a striking agreement between the irritability of protoplasm and that of muscle. The transition to the very highly-developed motor apparatus which distinguishes the animal kingdom from almost its lowest stages, namely, the bicellular apparatus consisting of separate cells united together for one purpose, one of which presents the exciting nerve, the other the obedient muscle, was traced. Some beautifully-prepared specimens were exhibited, showing that the termination of nerves in muscles was localised, and that the endings did not pervade the whole muscles. Portions of muscles free from nerves were demonstrated to twitch when stimulated. It appears that contact of the muscle-substance with the non-medullated nerve suffices to allow the transfer of excitation from the latter to the former. In order to answer the question whether one muscle can excite another, the lecturer gave a remarkable experimental proof that one muscle must have excited a second electrically.

ETHERISATION: AN UNRECOGNISED DANGER.

IT is not uncommon to read at the end of the description of some prolonged operation a statement to the effect that when the patient was put back into bed it was found necessary to use several hot water bottles to restore heat to the chilled surface; the fall of temperature which has impelled surgeons so constantly to resort to this expedient has been generally attributed to the combined effects of exposure during the operation and shock. Dr. H. A. Hare, of the University of Pennsylvania, has pointed out (*Therap. Gaz.*, May, 1888) that another factor must be taken into account. Observation on patients in the University Hospital showed that the difference in the rectal temperature before and after operation might amount to as much as three degrees, and a comparison of the effects observed after various operations appears to prove that the whole of the effect could not be attributed to shock and exposure, but that a large, possibly the greater, part was due to ether, which was the anæsthetic used. This view found confirmation in the result of some experiments on dogs: by continuous etherisation for an hour, giving five drachms of ether every five minutes after the animal had been brought thoroughly under the anæsthetic influence, the normal rectal temperature of the dog was reduced as much as from 8° to 10° F. Dr. Hare's inquiry suggests that it would sometimes be well for surgeons to combat this antipyretic action of ether by warm applications during the time that the patient is on the operating table.

SCOTLAND.

PROFESSOR WILLIAM STIRLING, of Victoria University, Manchester, formerly Professor of Physiology in Aberdeen University, has been appointed Thomson Lecturer in the Free Church College, Aberdeen, for the session 1888-89. The subject of his lectures will be The Physiology of Nutrition.

SUICIDE BY SWALLOWING SULPHURIC ACID.

A SECOND case of this form of suicide has happened in Glasgow. The attempt, however, has not as yet proved successful, as the patient, a man of about 40 years of age, was promptly submitted to treatment in the Royal Infirmary, and has now partially recovered from the immediate effects of the poison. It is altogether unprecedented that two cases of this uncommon form of suicide should have been admitted to the Royal Infirmary within one week.

HEALTH OF GLASGOW.

DR. J. B. RUSSELL's usual fortnightly report to the Health Committee of the Town Council notes as a remarkable fact that no death from fever had been recorded in the fortnight. In the preceding two weeks there had been three. Dr. Russell had gone back over his records as far as 1882 without discovering another example of a fortnight without a single fatal case of typhus, enteric, or undefined fever.

THE EDINBURGH UNIVERSITY UNION.

THE Edinburgh University Students' Union is fast approaching completion, and a further effort is on foot to present the building to the University free of debt, with which, in spite of the gallant efforts at the Fancy Fair, the undertaking is still encumbered. The latest move has proved a great success. The Theatre Royal was engaged for three nights of the week, and amateur theatrical performances of more than ordinary merit were given by the students and their friends. The pieces rendered were "Our Boys," "The Serious Family," and "Round the Corner." The audience was numerous and most enthusiastic.

THE EDINBURGH STUDENTS AND THE BOLOGNA OCTOCENTENARY.

THE Students' Representative Council of Edinburgh University recently approached the *Senatus Academicus*, with a view to obtain the countenance and assistance of that body in connection with the sending of a student representative to the commemoration festival at Bologna. The *Senatus* has cordially acceded to the students' request, and has granted a sum of twenty guineas towards the project. The Council has nominated Mr. Constable, one of their number, to be representative.

GLASGOW POOR CHILDREN'S FRESH AIR FORTNIGHT.

THIS scheme is now in full operation. On April 25th the first detachment of children left Glasgow for a fortnight's holiday, and on May 2nd a second party was despatched, the total number of children being 250. It has been decided to continue boarding out the children with respectable cottagers, as a preferable arrangement to building a home. The applications for the benefits of the scheme are already numerous.

GLASGOW CHARITY FOOTBALL CUP FUNDS.

THE Committee of the Glasgow Charity Cup met in Glasgow on May 21st, and distributed the funds raised by the season's matches. A total sum of £1,050 was divided among the various charities, of which the Royal and Western Infirmaries received each £100, Ophthalmic Institution £40, Eye Infirmary, Ear Hospital, and Sick Children's Hospital, each £20; Maternity Hospital, Blind Asylum, City Orphan Homes, and Broomhill Homes for Incurables, each £30; convalescent homes received £105, institutions for the deaf and dumb £45, Dispensary for Skin Diseases, Anderson's College Dispensary, Glasgow Medical Dispensary, Children's Fresh Air Fund, Society for Prevention of Cruelty to Animals, each £10; and similar sums were awarded to a large number of other institutions. The total sum now distributed by this Committee reaches nearly £8,000.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

AT the meeting of this Society on May 23rd, Dr. I. McIntyre showed an electric lamp that could be used with the vaginal speculum. A small, easily adjusted holder was fastened on the outer rim of the speculum, and the stem of the lamp inserted into it. The lamp could then be moved up the speculum as far as necessary. Dr. McIntyre also demonstrated, with the aid of an artificial bladder, Leiter's cystoscope for illuminating and examining the interior of the bladder. Dr. R. Pollock exhibited Allen's uterine dilators, and read notes of two cases in which they had been successfully used:—(1) removal of a dead child retained *in utero*; (2) a case of placenta prævia. The special advantage claimed for the dilators was that they could be introduced in the undilated condition of the os and cervix. The President (Dr. Wallace) then gave an interesting account of a recent visit he had made to the clinique of Dr. Apostoli, Paris.

ST. ANDREW AMBULANCE ASSOCIATION.

THE stall of this Association at the Glasgow Exhibition is one of very considerable interest both to the profession and the public. It is fitted up with the waggon, litters, stretchers, and apparatus used and provided by the Association for first aid to the injured. These are admirable alike in design and workmanship. Special notice may be made here of the hinged pit-stretcher with cover, lately designed to meet the provisions of the Coal Mines Regulation Act, 1837. On this stretcher the patient may be strapped down—the trunk, arms, and legs being strapped independently—and so conveyed up from the pit bottom in either a vertical, a

horizontal, or a sitting posture. The stretcher is also fitted with forked feet, so that it can be placed on ordinary lutch axles and wheeled along the underground rails. The Association has now been in existence for six years, and has earned a widespread reputation for usefulness. It has centres in nineteen towns and districts, chiefly in the West of Scotland, and by means of the classes taught around these centres it has given ambulance instruction to over 18,000 persons. It has also provided eighteen beautifully-equipped ambulance-waggons, and placed them at the call of any person by day or night, whenever an accident occurs, free of all cost and responsibility.

UNIVERSITIES (SCOTLAND) BILL.

THE Students' Representative Councils of the Universities of St. Andrews, Glasgow, Aberdeen, and Edinburgh have prepared a memorial for presentation to the Government respecting the Scottish Universities Bill. In this petition the memorialists pray that the Bill should be amended by providing for increased student representation in the University Court; by providing for student representation on standing committees; by defining the relations between the Commissioners on the one hand and the Students' Representative Council and the students generally on the other; by defining the relations between the Council and the Court and between the Council and the Senate; and by referring to the consideration of the Commissioners, the body by whom professorial appointments should be made.

GLASGOW UNIVERSITY.

THE new clock and bells erected in the tower of the University have now been completed. The clock is on the same principle as that of Westminster, and has been erected under the superintendence of Canon Cattley, of Worcester. The frame of the clock is of cast iron, 6½ feet long, 2 feet wide, and 1½ feet deep, and rests on beams built into the tower wall to prevent vibration. The whole of the wheels are of gun metal, and the pinions and arbors are of the best steel. The clock has three parts: the going portion, the striking, and the quarters. The hammer which strikes the hours weighs 120 pounds, and is lifted 10 inches. The main wheels of the striking gear are 20 inches in diameter. The pendulum is compensated for variations in temperature. It beats 1½ second, and the bob weighs 3 cwt. When it has been completely regulated the error should not exceed 2 seconds a month. An automatic apparatus stops the striking of the quarters during the night, and starts them again in the morning. The clock is not at present provided with dials, but provision has been made for their addition at any future time. They would be 11 feet in diameter. The total weight of the clock is 2½ tons.

IRELAND.

BELFAST SOCIETY FOR PROVIDING NURSES FOR THE SICK POOR.

THE annual meeting of this excellent Society was held on May 23rd, in the hall of the Young Men's Christian Association, under the presidency of Sir James Haaslett, Mayor of Belfast. The report showed a slight falling off in the ordinary subscriptions, but substantial amounts had been received from bequests and donations. The nurses had during the year attended 871 patients, of whom 19 were cases of cancer, 167 cases of ulcers, abscesses, burns, etc.; 171 cases of phthisis, 99 cases of pulmonary affections other than phthisis, and 138 cases of general debility. The object of the Society is to afford continuous and efficient aid to the sick poor who prefer to remain in their own houses rather than remove to a hospital; and it aims at preventing the improvidence and lack of self-respect which are apt to be fostered by indiscriminate alms-

ving. The report mentioned that some ladies had invited several of the nurses to spend their much needed holiday at their houses in the country, and commended this example to the attention of their friends of the institution.

THE GALWAY INFIRMARY.

LAST week in the Queen's Bench division, counsel applied on behalf of Dr. Kinkead, of Galway, that the conditional order for a *warranto*, granted in December last, be made absolute, notwithstanding the cause shown by Mr. Henry Pesse, J.P. The proceedings arose out of an election to the position of surgeon to the infirmary, when Dr. Colohan was elected. It appeared, however, that several of the electors who voted were not qualified, not having paid the amount to constitute them governors more than twelve months previously. Dr. Colohan however served notice admitting that he was not duly elected. The court made the conditional order absolute. A new election will now be necessary.

EPIDEMIC DISEASES.

AN epidemic of measles has prevailed in Skibbereen and the adjoining district for the past couple of weeks. In the commencement it appeared to be of a mild type, but last week some bad cases occurred and nine deaths took place. The schools of the parish have been closed to prevent the disease spreading. The outbreak of fever in Abbeyleix Union has not been so serious as was anticipated, and the disease so far has been of a mild type. The medical officer has complained of the great deficiency of sanitary accommodation in the hospital.

OVERCROWDING IN CORK WORKHOUSE.

AN inspector of the Local Government Board has drawn the attention of the guardians to the fact that there are many old persons in the hospital wards of the workhouse who would be in the infirm wards if proper accommodation existed in the latter. The Visiting Committee have accordingly recommended the guardians to provide such accommodation in these infirm wards as would obviate the necessity of retaining any inmate in the hospital excepting those who may require medical care. The medical officers have also pointed out that occasionally in the hospital two sick people have to be placed in one bed.

ROYAL COLLEGE OF SURGEONS IN IRELAND: ANNUAL MEETING.

THE annual meeting of the Royal College of Surgeons will be held on Saturday, June 2nd, and the election of President and Council will take place on the following Monday. Dr. Fitzgibbon, Vice-President, will go to the Presidency; and for the Vice-Presidency there are two candidates, Drs. Frazer and Meldon. For the Council there are several new candidates, namely, Messrs. E. Fitzmaurice (Tralee), J. B. Kelly (Drogheda), Conolly Norman, Theodore Stack, R. F. Tobin, J. Lentaigne, F. T. Heuston, J. B. Story. The subject of the biennial presidency will again be brought forward by Mr. Thomson, who has given notice that he will propose the following motion:

"That the Council of the College having failed to carry into effect the recommendation of the Fellows adopted at the annual meeting in June, 1887, namely: 'That it be recommended to the coming Council to take the opinion of the Fellows by letter on the question of biennial presidency, as suggested in the resolutions of Council of March 17th, 1887, and of June, 1883, and that a meeting of the College be then called to consider the matter;' it is hereby resolved that the declaration of the Fellows, that a President of the College may hold office for two successive years be re-affirmed; that this rule shall take effect from June, 1890; that the Fellow who may be selected as President at the annual election in that year may so hold his office for two years; and that it be a recommendation to the Council to take such steps as may be necessary to give effect to this resolution."

The necessity of some change which will make the office of President less "cheap" is forcing itself upon the Fellows at large, and the Council has been negligent in not carrying out previous recommendations on the subject. It is not unlikely, therefore, that the motion, or something in its spirit, will be adopted. From the report it appears that the College has a sum of £10,000 placed on mortgage at 4½ per cent. and £2,000 in New 2½ Stock. The total expenditure was £5,182 7s. 7d. A committee has considered the question of appointing a Professor of Pathology, and having reported in favour of that course, the Council has taken steps to obtain the necessary alteration of by-law.

ASSOCIATION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

At a meeting of the Central Committee of the Association of Members of the Royal College of Surgeons, held on Thursday afternoon, May 31st, the following petition was signed and transmitted to the Privy Council:—

TO HER MOST GRACIOUS MAJESTY THE QUEEN IN COUNCIL.

THE HUMBLE PETITION OF THE UNDERSIGNED MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND SHEWETH:

1. That your petitioners are Members of the said Royal College of Surgeons, and of the Association of Members thereof.

2. That on the 3rd day of May, in the year 1887, a petition signed by four thousand six hundred and sixty-five Members of the said College, including your petitioners, was presented to your Majesty's Privy Council, setting out the claims of the Members of the said College to a just share in the administration or control of the property and affairs of the said College upon grounds of public policy and of equity, having regard to the original constitution, history, and office of the said College.

3. That a deputation of delegates representing a large proportion of the Members of the said College, including also a large number of the Members thereof, attended before Your Majesty's Privy Council on the 11th day of November, 1887, in support of the said petition, and conveyed to the Right Honourable the Lord President their request to be heard by counsel in support of their said petition, if Your Majesty should not otherwise be advised that their claims ought to be permitted.

4. Your petitioners are informed and believe that no communication relative to the said petition has since been addressed either to the said Association of Members of the Royal College of Surgeons of England, or to the members of the said deputation, or to the signatories of the said petition.

5. Your petitioners are further informed and believe that although a copy of the statement made on the eleventh day of November, 1887, when the said deputation was received, has been submitted by Your Majesty's Privy Council to the President and Council of the Royal College of Surgeons, no answer to the said statement or to the contentions of the Members of the said College has been made by the President and Council of the College.

6. Your petitioners have heard with surprise that a proposal has nevertheless been made to the President and Council of the said College signifying an intention to grant a supplementary charter limited to certain points in which, so far as your petitioners are informed, the aforesaid claims and rights of your petitioners are not recognised in any way; but, on the contrary, the existing elements in the constitution and administration of the said College against which your petitioners and the Members generally protest will be further strengthened.

7. Your petitioners therefore humbly pray that Your Majesty will be graciously pleased to refer the matter in this present petition, together with the said petition signed by 4,665 Members of the said College hereinbefore referred to, and the statement submitted on the eleventh day of November, 1887, for the consideration of your Majesty's Privy Council, or some of the members thereof sitting in judicial capacity, with power to hear all parties interested in the matter of these said petitions by counsel and otherwise; and to receive evidence thereon, and humbly to advise Your Gracious Majesty in the premises as to Your Majesty may seem fit. And your petitioners, as in duty bound, will ever pray.

THE AMERICAN MEDICAL ASSOCIATION.

THE thirty-ninth annual meeting of the American Medical Association was held in Cincinnati, Ohio, on May 8th, 9th, 10th, and 11th, and was well attended. The Association was welcomed by the MAYOR, and also, in the name of the medical profession, by Dr. C. G. COMEGYS, who referred at length to the services rendered in the early part of the century by Dr. Daniel Drake, who had been instrumental in the creation of the Medical College of Ohio and of the Cincinnati Hospital.

President's Address.—The President, Dr. A. Y. P. GARNETT, of Washington, delivered an address in which he made certain proposals for improving the present standard of medical education in the United States; a radical and thorough reform was needed, for though facilities for education were excellent the systems of study were defective, and the preliminary education of students was insufficient. The ratio of practitioners of medicine to the population was 1 to 580, which was greater than in any other country in the civilised world. He suggested the formation of a committee, with members from every State, in order to bring pressure to bear on local legislatures, and to promote the establishment of a Board of Examiners in every State.

Address on Medicine.—Dr. ROBERTS BARTHOLOW, of Philadelphia, delivered an address, during the course of which he observed that the science of therapeutics was hindered by the unnecessary complexity and superfluity of pharmacopoeial preparations. He recommended more extensive use of the alkaloids as affording singleness and simplicity of action; jaborandi, for instance, contained two alkaloids, pilocarpine and jaborine, with dissimilar actions, and when the crude drug was prescribed there was not the same certainty of obtaining the desired result as when the alkaloid was prescribed; opium and nux vomica were also quoted as examples of this. In conclusion, he referred to the effect of the galvanic current on congestion and on the products of inflammation (as in stricture). He considered the electrolytic method full of therapeutic promise.

Address on Surgery.—Dr. E. M. MOORE, of Rochester, New York, who delivered the Address on Surgery, after some general remarks on the modern methods of treating wounds, the bloodless method of operating, and the application of the aseptic principle to abdominal surgery, quoted Volkmann's statistics of compound fracture of the leg, which showed 339 deaths in 885 cases in civil hospitals before the introduction of the antiseptic system, and 75 cases treated since its introduction without a death. He discussed the treatment of compound dislocation of the ankle, and expressed the opinion that amputation was seldom necessary. He recommended continuous irrigation with warm water as a most effective means of preserving the vitality of the contused soft parts; the malleoli and their attachments to the astragalus should be preserved if possible; the parts should be immobilised in plaster-of-Paris at first, but very delicate passive movements should be begun early and continued systematically; in this way the movements of the joint would in most cases be perfectly preserved. Referring to the treatment of caries, he strongly recommended the employment of hydrochloric acid (1 in 20), which he had been led to regard as one of the greatest advances in surgical therapeutics.

Address on State Medicine.—The address on State Medicine was delivered by Dr. H. P. WALCOTT, Chairman of the State Board of Health, who sketched the history of that Board since its establishment in 1869. During the period that the Board had been in existence the zymotic death-rate had declined from 25.6 to 19.0. Ovariectomy was justly regarded as one of the greatest triumphs of American surgery, but by comparing the annual death-rate of Massachusetts from ovarian dropsy with the reduction effected in a single town by an efficient Board of Health, he showed that the adoption of sanitary reforms in a community of 30,000 people had saved more lives annually than could have been saved by the operation of ovariectomy in the same period in a State containing two million people. He strongly urged the creation of a strong and efficient central health authority, the National Board of Health having been allowed by the neglect of Congress to fall into a state of hopeless lethargy.

Intestinal Surgery.—A series of interesting papers on intestinal surgery were read in the Section on Surgery and Anatomy.—Dr. L. S. McMURTRY reported a case of typhlitis in which laparotomy was performed; the cæcum was found to be gangrenous in spots, and laces had become extravasated. The edges of the perforations were trimmed, the openings were made elliptical in shape,

and then closed by suture. The patient, who was a member of the Association, made a good recovery, and was present at the meeting.—Dr. GROSS (Philadelphia) advocated early operation, and thought that in ambulatory typhoid with perforation operation afforded a fair chance of life.—Dr. SENN read a paper on rectal insufflation with hydrogen gas as a means of ascertaining the existence of injury of the gastro-intestinal canal by penetrating wounds of the abdomen. Hydrogen gas was perfectly innocuous and unirritating, and when injected into a serous cavity or connective tissue was rapidly absorbed. In man a pressure of from one-third to two pounds was sufficient to effect the passage of the ileo-cæcal valve, and the gas could be made to pass the entire length of the intestinal canal from the anus to the mouth. Wounds of the stomach could be diagnosed by inflation from the mouth. The gas was slowly injected from a rubber balloon holding 16 litres. A demonstration was given on a dog which was wounded in the abdomen with a pistol; the presence of the gas was recognised at its points of issue (mouth or wound) by ignition.

Apostoli's Method.—Dr. F. H. MARTIN read a paper in the Section on Obstetrics and Gynaecology on the value of galvanism in the treatment of fibroid tumours of the uterus according to Apostoli's method. He said that small tumours might be completely absorbed by the application of strong currents, and that hæmorrhage might be promptly cured by the local coagulating effect of the positive pole applied to the interior of the uterus; accompanying severe neuralgias were relieved by three or four applications. Except in cases where hæmorrhage or excessive leucorrhœa existed, he considered that the intra-uterine electrode should be in all cases negative. He governed the strength of the current by the area of the intra-uterine electrode, and recommended 23 milliampères for each square centimètre of active surface. Each sitting should last five minutes when the maximum current was employed, and the applications should be intermenstrual. Since the adoption of the flexible intra-uterine electrodes and Dr. Apostoli's vaginal galvano-puncture, extra-uterine puncture was only advisable, if at all, as a last resource. Where every effort to enter the cervical canal failed, it was justifiable to make a negative galvano-puncture in the presenting part of the obstructing mass so as to form an artificial canal, which took the place of the impermeable canal in the future treatment. He recommended that all instruments should be made thoroughly antiseptic, and that the vagina before a vaginal puncture was made should be thoroughly wiped out with bichloride solution (1 in 3,000). The method when carefully applied need not be, in his opinion, either painful or dangerous to life.—Dr. MARCY (Boston) considered the method most important, and had used it during the past winter with much, though not unqualified, success.—Dr. A. B. CARPENTER (Cleveland) advised that a small dosage should be used at first, and that patients should be required to rest for an hour at least after the application.¹

THE NATIONAL HEALTH SOCIETY.

A NUMEROUSLY-ATTENDED meeting of the National Health Society was held on Monday afternoon at Grosvenor House, under the presidency of the DUKE OF WESTMINSTER, for the purpose of distributing certificates of proficiency to the 250 successful candidates, principally ladies, in the ambulance and nursing classes. Among those present were the Duke and Duchess of Westminster, Sir T. Spencer Wells, Sir James and Lady Crichton Browne, Mr. Ernest Hart (the Chairman of the Society), Dr. Farquharson, M.P., and others, who filled both the great rooms.

The DUKE OF WESTMINSTER said the National Health Society could not be measured in its importance by the amount of pecuniary support it had received, for that was of a very slender nature. The Society had been of great use not only for the actual work in which it had been engaged, but also with regard to the way in which it had fostered the interest in the whole question, and had stimulated others to establish the Sanitary Aid Association and other associations of a similar sort. They were making, he said, a good start in connection with the Queen's Jubilee Fund. The amount of money was not very large, but he hoped they might effect a lodgment in St. Katharine's Hospital, which, though now a very useless institution, would, he trusted (and the Queen had expressed her willingness in this direction), eventually be a great centre, and that its funds would be devoted to establishing and training nurses for the sick poor. His Grace

¹ For most of these particulars we are indebted to the telegraphic report published in the *Medical Record* of New York.

cluded by expressing his willingness to place a site in Buckingham Palace Road at the disposal of the Society, which would be available for the purpose of a model sanitary building. The certificates were then distributed by the Duchess of Westminster.

Mr. ERNEST HART, the Chairman of the Society, in proposing a vote of thanks to the lecturers, among whom he mentioned Dr. Schofield, Mr. Owen Lankester, Mr. Edgar Willett, Dr. Gell, Miss Womersham, Miss Barnett, Dr. Parry Jones, Dr. Jessop, Dr. B. Connor, Mrs. Shiel; and, among those in the provinces, Dr. Lambly, Dr. Crossman, Dr. Dove, Dr. Roberts, and Dr. Prosser. He referred to a fear to which utterance had been given in a medical paper that those students who had passed through the courses of National Health Society lectures might, on the basis of such instruction, be tempted to regard themselves as fully trained nurses, or perhaps even as medical men or medical women. He wished it to be clearly understood that such was not their desire, and those who had attended to the teaching knew it was no part of their programme to attempt to give in that course anything like a technical professional education. There was no rivalry between their ambulance and that of the St. John Ambulance Association. They proceeded on parallel lines, but nowhere met. Mr. Hart referred to the absence of even a rudimentary knowledge of physiological science from school teaching, a defect which in Board schools this Society was doing something to remedy.—Sir SPENCER WELLS endorsed the resolution, with words of warm commendation of the scope of the Society's teaching and of its efficiency. He was well acquainted with the excellence and value of the lectures. Among the ladies who came up for certificates was Miss Wells.

Dr. SCHOFIELD, in replying for the lecturers, recommended the candidates to take up a course of lectures on domestic hygiene which, in view of the fact that it was believed that nearly 250,000 people died annually from preventable disease in this country, was of far greater importance than domestic surgery.—Dr. GELL spoke of the high standard they insisted should be maintained by the candidates.—Mr. OWEN LANKESTER said the thanks of the Society were due to those ladies on whom the success of the lectures so much depended. He stated that, so far from the ambulance work of their Society being regarded as being in rivalry with that of the St. John Ambulance Association, the latter society had expressed themselves delighted that the Society had taken up so good a work.

Sir CRICHTON BROWNE, in proposing a vote of thanks to the Duchess of Westminster, said there was no society to which they gave their generous aid more worthy of encouragement than the National Health Society. The best way to preserve health was to prepare for disease, and many of the ills that might be avoided by a little kindly foresight. It was the supreme duty of every man, woman, and child, to take the best of their opportunities. Our list of diseases increased as civilisation advanced.—Dr. FARQUHARSON, M.P., endorsed the motion.

The DUKE responded, observing that the Duchess was perhaps delighted for the distribution, inasmuch as she herself held a certificate.

A vote of thanks to the Secretary closed the proceedings.

THE RABBIT PEST IN AUSTRALASIA.

The idea that the only effectual means of checking the rapid increase of rabbits in Australia must be sought in some other form of life is an old one; at first it was proposed to introduce animals such as cats, ferrets, and stoats, which prey upon rabbits, but, as might have been foreseen, under the conditions of the problem, this scheme has proved quite inadequate. The predatory animals increased and multiplied, and preyed upon the rodents, the latter increased and multiplied still faster, and more than doubled their serried ranks. The idea that some form of infectious disease, capable of self-multiplication, might be utilised to decimate the rabbits on a large scale seems to have suggested itself to several persons independently. The first suggestion made, to the use of the virus of tuberculosis, was universally felt to be ineffective, because it failed to meet the primary condition that the disease virus used for the purpose must be incapable of injuring human beings or stock animals.

Legislative Action.—M. Pasteur's appearance as a competitor for the prize of £25,000 for the discovery of a means of exterminating the pest has somewhat precipitated matters, and the Legislative Assembly of New South Wales has found it necessary to

take action. The official papers printed by order of that Assembly show that three proposals have been formally made, and that the investigation of two had already been commenced before M. Pasteur's proposal was received.

Rabbit Scab.—The earliest seems to have been that made by Professor Watson, of the Adelaide University. He proposed to introduce a form of itch to which rabbits are liable; if untreated it is stated to be a serious disease, leading in time to glandular suppuration, and death from septicæmia and exhaustion. As, however, the disease runs a prolonged course, it causes much suffering to the animals, and the proposal is open to the charge of unnecessary cruelty; moreover, it is possible, if not probable, that sheep might become infected. On the whole, it is not surprising that the report of Mr. Edward Stanley, the Government veterinarian for New South Wales, who went to South Australia to observe the experiments which were in progress, was, on the whole, unfavourable to the proposal. Another scheme, proposed by Drs. Ellis and Butcher, is, as the report of the New South Wales Board of Health points out, wanting in precision, but the leading idea, to study any spontaneous outbreaks of disease among rabbits in crowded warrens, is sound; it might be comparatively easy to favour the spread of such a disease.

M. Pasteur's Scheme.—M. Pasteur's proposal, formally made in a letter dated from Paris on January 8th in this year, has already been fully detailed in these columns; it is founded upon the observation that rabbits are extremely susceptible to fowl-cholera, the virus of which can be easily cultivated. It was this microbe in which M. Pasteur first observed that diminution of virulence under special conditions of growth to which he applied the term "attenuation." The microbe has one advantage for the purpose in view, since it is easily destroyed by prolonged exposure to the air, or to moderate temperatures. The disease is easily communicated to rabbits by soaking their food in fluids in which the microbe has been grown, and it would seem that it rapidly spreads in the warrens. The New South Wales Board of Health, in reporting upon M. Pasteur's scheme, has taken the same view as was expressed in this JOURNAL when the proposal was first made public; recent researches in bacteriology, and especially those of M. Pasteur himself, show that clearer evidence than has yet been adduced is required to prove beyond doubt that the introduction of this virulent disease might not directly or indirectly produce, among human beings, disastrous results, as yet unsuspected; the Board truly observes that if it were to be found that such injurious results followed either to human beings or to stock animals, it would then almost certainly be beyond the power of any authority to remedy the mischief which had been done. If the scheme is to be tried, the plan proposed by Dr. Camac Wilkinson, of Sydney University, in an excellent letter (certain personal references apart) addressed to the Board of Health, ought certainly to be adopted. He suggests that a suitable island should be chosen, stocked with rabbits and every form of useful animal found in the colony, and that M. Pasteur's method should be applied to this isolated community; the method would then be tested with some approach to scientific precision, and the results of the experiment, which we have reason to believe will be made, will be awaited with great interest.

Intercolonial Commission.—An Intercolonial Rabbit Commission has been appointed; the members of the medical profession upon it constitute a majority; they are: for New South Wales, Dr. MacLaurin (President of the Board of Health), and Dr. C. Wilkinson, M.L.A.; for Victoria, Professor Allen; for South Australia, Drs. Stilling and Paterson; for Queensland, Dr. Baucroft. New Zealand is also represented on the Commission.

AMBULANCE INSTRUCTION TO POLICEMEN AND RAILWAY SERVANTS.—It is satisfactory to see, from the reports which so frequently reach us, that a knowledge of first-aid and ambulance work is fast spreading among railway servants and policemen. To no class of men probably is this knowledge likely to be of such advantage, and the St. John Ambulance Association is doing a good work in promoting and directing its extension. Last week about forty guards, porters, policemen, and platelayers, in the service of the London and South-Western Railway, went through a number of ambulance manoeuvres at Waterloo Station, and the manner in which they performed their drill reflected credit on Mr. S. Osborn, F.R.C.S., who directed the proceedings. Seventeen constables and two officers of the constabulary of Colchester, who had successfully passed the examination of the St. John Ambulance, were recently presented with certificates and badges.

ST. JOHN'S HOSPITAL.

At the annual General Board of Governors of the St. John's Hospital for Diseases of the Skin, held at the Criterion on Thursday, Lieut.-Colonel MERCIER, who, in the absence of a vice-president (the hospital being at the present moment without a president), took the chair, expressed himself very satisfied with the present condition of the affairs of the institution.

The SECRETARY read the report, which stated that there had been a reduction in the debt of the hospital of over £300, and an increase of patients. Reference was made to the three actions against newspapers now pending, on which Mr. Alderman GOULD stated as they were *sub judice* they were compelled to be silent. Reference was made to a circular signed by Messrs. W. J. Raymond and Samuel Hill, Honorary Secretaries of the Investigation Committee, and sent to the Governors, advising those who had the true interests of the hospital at heart to hold aloof until the inquiry instituted had been completed. Attention was called to the question asked in the House of Commons as to the "wilful misappropriation of funds" of the hospital.

Mr. GOULD observed that the only charges made against the hospital were those of discrepancies in the accounts. The Home Secretary had written to the authorities for an explanation, which he received, and having inquired into the matter, he replied that he could discover no reason which would justify any interference on his part.

The report was carried with two dissentients. The Duke of Teek was elected President of the Hospital, and a Board of Management, consisting of nine old members, eight new members, and a representative from the subscribing lodges of the Foresters and Odd Fellows was elected.

ASSOCIATION INTELLIGENCE.

BRANCH MEETINGS TO BE HELD.

SOUTH-WESTERN BRANCH.—The annual meeting of this Branch will be held at the Devon and Exeter Hospital, Exeter, on Tuesday, June 28th, under the presidency of Dr. John Woodman, F.R.C.S. Notices of motion or communications to be intimated to the Honorary Secretary without delay, and it will facilitate arrangements if members will inform the Honorary Secretary as soon as possible if they hope to be present at the meeting. The following motion was passed at the Council Meeting on May 2nd:—"That inasmuch as the annual meeting assumes more or less the character of a day of recreation, and with a view of encouraging the district meetings, the business of the annual meeting shall be confined to the President's address, the business of the Branch, the exhibition of cases or of specimens with notes, and the annual dinner."—P. MAURY DEAS, Wonford House, Exeter, Honorary Secretary.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH.—The annual meeting of this Branch will be held in the Birmingham Medical Institute, on Wednesday, June 14th, at 3.30 P.M.

METROPOLITAN COUNTIES BRANCH.—*Preliminary Notice.*—The annual meeting of this Branch will be held at the Holborn Restaurant on Wednesday, June 27th, at 5.30 P.M. President, Arthur E. Durham, Esq., F.R.C.S.; President-elect, C. Brodie Sewell, M.D. Dinner at 7 P.M.; tickets, 7s. 6d. each, exclusive of wine.—GEORGE EASTEN, M.B., E. NOBLE SMITH, F.R.C.S., Honorary Secretaries.

METROPOLITAN COUNTIES BRANCH: EAST LONDON AND SOUTH ESSEX DISTRICT.—The annual meeting for the election of officers will be held at the Forest Hotel, Chingford, on Thursday, June 7th, at 6 P.M. At 6.15 P.M. (sharp) the members and their friends will dine together. A. E. Durham, Esq., President of the Branch, will preside. Tickets, 8s. each, exclusive of wine. Members wishing to be present are requested to communicate with the Honorary Secretary not later than Saturday, June 2nd.—J. W. HUNT, Honorary Secretary, 101, Queen's Road, Dalston.

METROPOLITAN COUNTIES BRANCH: NORTH LONDON DISTRICT.—The annual meeting will be held at the Zoological Gardens, Regent's Park, on Thursday, June 14th, 1888. A. E. Durham, Esq., F.R.C.S., President of the Branch, will preside. Mr. Frank E. Boddard, Prosecutor to the Zoological Society and Davis Lecturer, will lecture at 5 P.M. on "Dinosauria," at which members are invited to attend. Election of Vice-President, Representative Member of Council, and Secretary for the ensuing year. All the present officers are eligible for re-election. Dinner at the Restaurant in the Gardens at 6.30; morning dress. Tickets, 6s. each, exclusive of wine. Members desirous of being present are asked to signify their intention before June 12th, to the Honorary Secretary, GEORGE HENTY, M.D., 302, Camden Road, N.

METROPOLITAN COUNTIES BRANCH: WESTERN DISTRICT.—The next meeting will be held on Tuesday, June 5th, at the St. Marylebone Infirmary, Ladbrooke

Grove Road, Notting Hill, W. The chair will be taken at 8.30 P.M. punctually, by H. Charlton Bastian, M.D., F.R.S., the Vice-President of the District. Business—1. Minutes of preceding meeting. 2. Election of Vice-President. Members of Council of the District, and Representative on Council of the Branch. The present officers of the district, not having served an entire year, will be proposed for re-election. 3. A paper will be read by Henry Power, Esq., M.B., F.R.C.S., Ophthalmic Surgeon to St. Bartholomew's and the Royal Westminster Ophthalmic Hospitals, on Certain Points in the Treatment of Injuries of the Eye. 4. A few cases of clinical interest will be introduced by John R. Lunn, Esq., F.R.C.S. Ed., Resident Medical Superintendent of the St. Marylebone Infirmary.—C. ARTHUR PATTEN, Honorary Secretary, Marpool House, Baling.

SOUTH MIDLAND BRANCH.—The annual meeting of the above Branch will be held at the Blechley Park Hotel, Blechley, on Thursday, June 14th, at 2.45 P.M. The new President, H. Veasey, Esq., invites the members to luncheon at the same place previously to the meeting, from 1.30 to 2.30 P.M., at which meeting and luncheon every qualified medical man will be a welcome visitor. Gentlemen accepting the invitation are requested to intimate the same to the Honorary Secretary not later than June 11th. The arrangements for a combined meeting this year of the Cambs and Hunts and South Midland Branches having fallen through, the informal reciprocal visits of members, to whom it may be convenient, at the respective meetings, would be most agreeable, and are hereby invited. Agenda—Usual business of annual meeting. Resolution on subject of "Fees to Medical Witnesses," etc. Communication from Chairman of Parliamentary Bills Committee on Subject of "Lunacy Acts Amendment Bill" (see JOURNAL, May 12th, p. 1025). The following gentlemen will be proposed as new members of the Association and Branch: John Henry Loyde, Esq., Bedford; J. Neil Whitfield, Esq., Northampton; A. E. Godfrey, Esq., and — Weatherley, Esq., Northampton Infirmary. Gentlemen wishing to read papers for discussion, cases, etc., are requested to send the titles of the same without delay to the undersigned. The following have been promised. Mr. Milligan: Case of Strangulated Umbilical Hernia: Operation for Radical Cure; Recovery. Dr. Jones: Physical Indications in Heart Affections. Dr. Goldsmith: A Question as to the Etiology of some Nervous Diseases of Children. Mr. Bull: Obscure Abdominal Tumour; Abdominal Section; Recovery. Mr. Evans: The Royal Colleges and the Society of Apothecaries.—C. J. EVANS, Honorary Secretary, Northampton.

MIDLAND BRANCH.—The annual meeting will be held at the Masonic Hall Nottingham, on Thursday, June 14th, at 2 P.M. After the transaction of the usual business a proposition to amend Rule 6 will be laid before the meeting. Papers, etc.: Mr. Edgar M. Crookshank: On the Alleged Origin of Certain Diseases from the Lower Animals. Mr. Frank Pope: A Case of Diabetes, probably of Traumatic Origin. Mr. R. C. Chicken: New Form of Bone Forceps for Sequestromy. Dr. George Elder: Remarks on Cases of Peritonitis treated by Abdominal Section. Dr. H. Handford: The Influence of Position on Cardiac Murmurs, and on the Treatment of Heart Disease. Mr. Frank Hodger will exhibit a patient on whom he has operated for Cataract of Each Eye by different Methods. Luncheon will be provided by the President-elect, at the place of meeting, at 1 o'clock. The dinner will also take place at the Masonic Hall, at 5 o'clock. Tickets, 7s., exclusive of wine.—W. A. CARLINE, M.D., Honorary Secretary and Treasurer.

CAMBRIDGESHIRE AND HUNTINGDONSHIRE BRANCH.—The annual meeting of this Branch is appointed to be held at Ely on Friday, July 6th. Members wishing to make communications, to exhibit specimens, or to propose new members are requested to signify their intention to Dr. Anningson, Cambridge for insertion in the order of proceedings.—BUSHELL ANNINGSON, Honorary Secretary.

SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT.—The next meeting will be held in the board-room of the hospital, at Hastings, on Tuesday, June 12th at 3.30 P.M. Dr. Bagshawe will preside. The following papers are promised: The Chairman: A Case of Chyluria. Mr. Titchhurst: A Case of Addison's Disease, with a Rare Form of Skin Eruption (Drawing to be shown). Dr. Penhall: A Case of Nephrotomy. Dr. Talford Jones: Mercury as a Diuretic. The dinner will take place at the Palace Hotel at 5.30 P.M.; charge, 6s., exclusive of wine.—T. JENNER VERRALL, Honorary Secretary, 97, Montpelier Road, Brighton.

SOUTH WALES AND MONMOUTH BRANCH.—The eighteenth annual meeting of this Branch will be held at the Infirmary, Cardiff, on Wednesday, June 27th. Further particulars in circulars. Members wishing to read papers, etc., are requested to send titles to Dr. Sheen before June 10th.—A. SHEEN, M.D., Cardiff, D. ARTHUR DAVIES, M.B., Swansea, Honorary Secretaries.

YORKSHIRE BRANCH.—The annual meeting of the Yorkshire Branch will be held in the Museum of the Yorkshire Philosophical Society at York on Wednesday, June 27th, when the representatives of the Branch on the General Council and the officers for the ensuing year will be elected. Members intending to read papers and show specimens, are requested to communicate in advance with ARTHUR JACKSON, Secretary, Sheffield.

SOUTHERN BRANCH.—The fifteenth annual meeting will take place at the Grosvenor Hotel, Queensgate, Southsea, on Thursday, June 14th. The general meeting will be held at 1 P.M. The President-Elect, H. B. Norman, Esq., has kindly undertaken to provide refreshments at the hotel. In accordance with the by-laws, two gentlemen will be elected at this meeting as Representative of the Branch on the Council of the Association for the ensuing year. The address will be delivered by the President-elect at 2 P.M. During the afternoon the members are invited to visit the Dockyard, the old Victory, H.M.S. Ternan and other places of interest. Dinner at 6 P.M.; charge, 5s., exclusive of wine, etc. The Committee request that those gentlemen who intend to be present at the dinner will send in their names on or before Wednesday, June 13th.—J. WARD COUSINS, Honorary Secretary and Treasurer.

LANCASHIRE AND CHESHIRE BRANCH.—The fifty-second annual meeting of this Branch will be held at the Medical Institution, Hope Street, Liverpool, on Wednesday, June 13th, 1888, at 2.30 P.M. Order of Business:—Introduction of

the new President. The new President's Address. The Report of Council. Election of Office-bearers: President-Elect, Vice-Presidents, Honorary Secretary. Election of Representative Members on the Council of the Association. Election of new Council. Choice of place for holding next annual meeting. Election of two members to serve on the Parliamentary Bills Committee. Grant to Epsom College; Notice of Motion: It will be proposed to make a donation of twenty-five guineas to the Epsom Medical Benevolent College out of the funds of the Branch. Miscellaneous Business. Medical and Surgical Communications.—Dr. Walter: Notes of a case of Total Extirpation of the Uterus per Vaginam. Dr. Glyn: A note on a New Method of Treating Chlorosis. Dr. Johnson Martin: How to prevent Small-pox, and how to spread it. Mr. R. Harrison will show the Electric Endoscope. Dr. Alexander: Hysterectomy for Uterine Cancer (patient). Mr. Shears: Xerosis of the Conjunctiva with Night Blindness. Dr. Imlach: The Use of Stimulants and Narcotics by Women. A small museum of drawings, photographs, and selected pathological specimens. Dinner.—The members will dine together at the Adelphi Hotel, Liverpool, at 5.30 P.M. Tickets, 7s. each (exclusive of wine).—CHARLES E. GLASCOTT, M.D., General Secretary, 23, Saint John Street, Manchester.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT.

THE annual meeting of the above District was held at Canterbury on Thursday, May 24th, Dr. PARSONS in the chair.

Honorary Secretary.—Dr. TYSON was re-elected Honorary Secretary for the ensuing year.

Next Meeting.—It was arranged that the next meeting be held at Hythe, and that Dr. LOVEGROVE be asked to take the chair.

Papers.—Mr. RAVEN read a paper on Tendon Reactions in Health and Disease. Mr. BRIAN RIGDEN read Notes of a Recent Epidemic of Measles, which gave rise to a good discussion, in which Mr. F. WACHER, Mr. JAMES REID, Mr. G. RIGDEN, Mr. PUGIN THORNTON, Dr. GOGARTY, Dr. BOSWELL, Mr. RAVEN, Mr. WHITEHEAD REID, Mr. GARRAWAY, and Mr. SIDNEY WACHER took part.

BRITISH MEDICAL ASSOCIATION.

FIFTY-SIXTH ANNUAL MEETING.

THE fifty-sixth Annual Meeting of the British Medical Association will be held at Glasgow, on Tuesday, Wednesday, Thursday, and Friday, August 7th, 8th, 9th, and 10th, 1888.

President: John T. Banks, M.D., D.Sc.(Hon.), F.R.Q.C.P.I., Regius Professor of Physic in the University of Dublin.

President-Elect: Professor W. T. Gairdner, M.D., LL.D., Professor of Medicine in the University of Glasgow.

President of the Council: Thomas Bridgwater, M.B., J.P., Harrow-on-the-Hill.

Treasurer: Constantine Holman, M.D., J.P., Reigate.

An Address in Medicine will be delivered by Thomas Clifford Allbutt, M.D., Consulting Physician, Leeds General Infirmary.

An Address in Surgery will be delivered by Sir George H. B. Macleod, M.D., Surgeon in Ordinary to Her Majesty in Scotland.

An Address on his "Recent Investigations in Surgery" will be given by William Macewen, M.D., Lecturer on Clinical Surgery, Glasgow Royal Infirmary.

An Address in Physiology will be delivered by John Gray McKendrick, M.D., LL.D., F.R.S., Professor of Institutes of Medicine, University of Glasgow.

All the rooms required for the purposes of the meeting will, by the kindness of the authorities, be provided in the University of Glasgow.

Humanity Class Room.

A. MEDICINE.—*President,* T. McCall Anderson, M.D. *Vice-Presidents,* R. L. Bowles, M.D.; George F. Duffey, M.D. *Honorary Secretaries,* J. McGregor Robertson, M.D., 400, Great Western Road, Glasgow; Robert M. Simon, M.D., 27, Newhall Street, Birmingham.

Chemistry Class Room.

B. SURGERY.—*President,* George Buchanan, M.D. *Vice-Presidents,* James Dunlop, M.D.; Charles Robert Bell Keetley, F.R.C.S. *Honorary Secretaries,* David Neilson Knox, M.B., 8, India Street, Glasgow; Walter Pye, F.R.C.S., 4, Sackville Street, Piccadilly, London, W.

Medical Jurisprudence Class Room.

C. OBSTETRIC MEDICINE.—*President,* Thomas More Madden, M.D. *Vice-Presidents,* William Leishman, M.D.; J. Halliday Croom, M.D. *Honorary Secretaries,* William Walter, M.D., 20, St. John Street, Manchester; W. L. Reid, M.D., 7, Royal Crescent, Glasgow.

Greek Class Room.

D. PUBLIC MEDICINE.—*President,* Henry Duncan Littlejohn, M.D. *Vice-Presidents,* James Christie, M.D.; D. Page, M.D. *Honorary Secretaries,* Ebenezer Duncan, M.D., 4, Royal Crescent, Crosshill, Glasgow; John C. McVail, M.D., Holmhead, Kilmarnock.

Hebrew Class Room.

E. PSYCHOLOGY.—*President,* James C. Howden, M.D. *Vice-Presidents,* James Rutherford, M.D.; Julius Mickle, M.D. *Honorary Secretaries,* A. R. Urquhart, M.D., Murray House, Perth; Alex. Newington, M.D., Ticehurst, Sussex.

Anatomy Class Room.

F. ANATOMY AND PHYSIOLOGY.—*President,* John Cleland, M.D., LL.D., F.R.S. *Vice-Presidents,* R. J. Anderson, M.D.; Henry Edward Clark, F.F.P.S.G. *Honorary Secretaries,* John Barlow, M.D., 27, Elmbank Crescent, Glasgow; Charles Barrett Lockwood, F.R.C.S., 19, Upper Berkeley Street, Portman Square, W.

Law Class Room.

G. PATHOLOGY.—*President,* Sir William Aitken, M.D., LL.D., F.R.S. *Vice-Presidents,* Alexander Davidson, M.D.; Joseph Coats, M.D.; Charles Roy, M.D., F.R.S. *Honorary Secretaries,* G. Sims Woodhead, M.D., 6, Marshall Crescent, Edinburgh; J. Lindsay Steven, M.D., 34, Berkeley Terrace, Glasgow.

Midwifery Class Room.

H. OPHTHALMOLOGY.—*President,* Thomas Reid, M.D. *Vice-Presidents,* J. R. Wolfe, M.D.; C. E. Glascoff, M.D. *Honorary Secretaries,* Henry Bendelack Hewetson, M.R.C.S., 11, Hanover Square, Leeds; A. Freeland Fergus, M.B., 41, Elmbank Street, Glasgow.

Biblical Criticism Class Room.

I. OTOTOLOGY.—*President,* Thomas Barr, M.D. *Vice-Presidents,* John Astley Bloxam, F.R.C.S.; J. J. K. Duncanson, M.D. *Honorary Secretaries,* Johnstone Macfie, M.D., 23, Ashton Terrace, Glasgow; James Black, F.R.C.S., 16, Wimpole Street, London.

English Literature Class Room.

J. DISEASES OF CHILDREN.—*President,* Walter Butler Cheadle, M.D. *Vice-Presidents,* James Finlayson, M.D.; Henry Ashby, M.D. *Honorary Secretaries,* George S. Middleton, M.D., 23, Sandford Place, Glasgow; W. Arbuthnot Lane, M.S., F.R.C.S., 14, St. Thomas's Street, S.E.

Conveyancing Class Room.

K. PHARMACOLOGY AND THERAPEUTICS.—*President,* James Morton, M.D. *Vice-Presidents,* John Dougall, M.D.; Theodore Cash, M.D., F.R.S. *Honorary Secretaries,* Alexander Napier, M.D., 3, Royal Terrace, Crosshill, Glasgow; Sidney Harris Cox Martin, M.D., 60, Gower Street, London, W.C.

Divinity Class Room.

L. LARYNGOLOGY AND RHINOLOGY.—*President,* Felix Semon, M.D. *Vice-Presidents,* George Hunter Mackenzie, M.D.; Peter McBride, M.D. *Honorary Secretaries,* D. Newman, M.D., 18, Woodside Place, Glasgow; A. E. Garrod, M.D., 9, Chandos Street, Cavendish Square.

PROGRAMME OF PROCEEDINGS.

TUESDAY, AUGUST 7TH, 1888.

9.30 A.M.—Meeting of 1887-1888 Council. Randolph Hall.

11.30 A.M.—First General Meeting. Report of Council. Reports of Committees. Bute Hall.

4 P.M.—Service in the Cathedral. Sermon by the Very Rev. John Caird, D.D., LL.D., Vice-Chancellor and Principal of the University of Glasgow.

8.30 P.M.—Adjourned General Meeting from 11.30 A.M. President's Address. Bute Hall.

WEDNESDAY, AUGUST 8TH, 1888.

9.30 A.M.—Meeting of 1888-89 Council. Randolph Hall.

10.30 A.M. to 2 P.M.—Sectional Meetings.

3 P.M.—Second General Meeting. Address in Medicine by Thomas Clifford Allbutt, M.D., F.R.S. Bute Hall.

THURSDAY, AUGUST 9TH, 1888.

9.30 A.M.—Address on his Recent Surgical Investigations by William Macewen, M.D. Bute Hall.

11 A.M.—Meeting of Council. Randolph Hall.

10.30 A.M. to 2 P.M.—Sectional Meetings.

3 P.M.—Third General Meeting. Address in Surgery by Sir George H. B. Macleod, M.D. Bute Hall.

7 P.M.—Public Dinner. St. Andrew's Hall.

FRIDAY, AUGUST 10TH, 1888.

10.30 A.M. to 1.30 P.M.—Sectional Meetings.

3 P.M.—Concluding General Meeting. Address in Physiology by John G. McKendrick, M.D., F.R.S. Bute Hall.

SATURDAY, AUGUST 11TH, 1888.

Excursions.

ANNUAL MUSEUM.

THE Annual Museum will be held on August 7th, 8th, 9th, and 10th, in the Examination Hall of the University of Glasgow, and will be arranged in the following six Sections:

SECTION A.—Food and Drugs, including Antiseptic Dressings, and other Chemical and Pharmaceutical Preparations. (Honorary Secretary, R. S. Thomson, B.Sc., M.B., C.M., 3, Melrose Street.)

SECTION B.—Pathology, comprising Casts, Models, Diagrams, Microscopical Preparations, and Micro-organisms. (Honorary Secretary, J. Lindsay Steven, M.D., 34, Berkeley Terrace.)

SECTION C.—Anatomy, comprising Special Dissections, Methods of Mounting, Abnormalities, Drawings, Medals, etc. (Honorary Secretary, J. Yule Mackay, M.D., 34, Elmbank Crescent.)

SECTION D.—Physiology, consisting of Apparatus, Microscopes, Microtomes, and Microscopical Preparations of Normal Histology. (Honorary Secretary, J. McGregor Robertson, M.A., M.B., C.M., 400, Great Western Road.)

SECTION E.—Instruments and Books, including Appliances—Medical, Surgical, and Electrical. (Honorary Secretary, J. Macintyre, M.B., C.M., 173, Bath Street.)

SECTION F.—Sanitation (1) Domestic Sanitary Appliances, embracing all Improvements applicable to the Treatment of the Sick in Private Dwellings. (2) Personal Hygiene, including Dress and Gymnastic Appliances. (3) Ambulances, Carriages, and all other Appliances used for the Conveyance and Treatment of the Sick and Wounded, either in Civil, Naval, or Military Practice. (4) Drawings, Models, and Apparatus illustrative of the Ventilation, Lighting, and Draining of Hospitals. (5) Hospital Furniture. (6) Sanitary Appliances in connection with Educational Institutions and Public Buildings. (Honorary Secretary, 1, 2, 3, Robert Pollok, M.B., C.M., Pollokshields; Honorary Secretary, 4, 5, and 6, A. W. Russell, M.A., M.B., C.M., Western Infirmary.)

Intending exhibitors should communicate as early as possible with the Secretary of the Section in which they propose to exhibit, as the Museum Catalogue must be complete one month before the date of meeting. Inquiries as to advertisements in the Catalogue should be sent without delay to Dr. Thomson, 3, Melrose Street, Glasgow.

Honorary General Secretaries of Museum Committee, A. Ernest Maylard, B.S., M.B., 54, Berkeley Terrace; R. S. Thomson, B.Sc., M.B., C.M., 3, Melrose Terrace.

Honorary Local Treasurers, Joseph Coats, M.D.; Jas. B. Russell, M.D.

Honorary Local Secretaries, John G. McKendrick, M.D., F.R.S., 45, Westbourne Gardens, Glasgow; James Christie, M.D., Hillhead, Glasgow; John Glaister, M.D., 4, Grafton Place, Glasgow.

FRANCIS FOWKE, *General Secretary.*

Treatment of Blepharospasmus.—Action of Antipyretics on the Liver.—Pseudo-tuberculosis.—Canadol as a Local Anæsthetic.—Concentrated Solution of Boric Acid.—Naphthol B as an Antiseptic.—Wasting of the Muscles of the Chest in Phthisis.—Contra-indications of Antipyrin.

At a meeting of the Société de Médecine de Paris on March 24th, M. A. Dehénne read a note upon the treatment of tonic blepharospasmus by section of the supra-orbital nerve. Tonic blepharospasmus, the only form of this affection which is really dangerous, is not common. The contractions, which are often painful, are incessant, and last from several seconds to several minutes. The patients are unable to walk out of doors unaccompanied, and can follow no occupation which requires the use of the eyesight. When the affection is of old standing, the attacks, which occur from twenty to forty times daily, are accompanied by the following phenomena: the space between the eyelids is contracted, the eyebrow falls down over the upper eyelid, there are incessant clonic spasms in the lids. Neurotomy is the only treatment which has proved effectual in checking the contractions. In most cases section of one supra-orbital nerve suffices. The operation is performed as follows. The course of the supra-orbital nerve is marked with ink as far as the junction of the inner and middle thirds of the eyebrow. The skin is pinched up between the thumb and finger; a vertical fold is thus formed, at the bottom of which a small bistoury is introduced, about one centimètre above the eyebrow, with the blade parallel to the sur-

face of the skin. The bistoury is then withdrawn, and the neurotome, which is merely a blunt-pointed bistoury, with a slightly convex blade, is introduced in the same way. On reaching the vasculo-nervous bundle, the instrument is turned round and rested against the frontal bone. A series of cuts are then made until the periosteum is reached. The neurotome is then placed in its former position, and is rapidly withdrawn. Strong pressure is made by means of a coin wrapped in cotton-wool in order to prevent any subcutaneous effusion of blood. A compress bandage is applied. Tonic contractions entirely cease immediately after the operation, but clonic contractions sometimes persist for a few days longer. The first patient operated on by M. Dehénne in 1879 was a woman of 52, who had suffered from the affection for three years. Both supra-orbital nerves were divided, and immediate recovery ensued. Six months later the spasms reappeared. Electric stimulation, with continuous currents, which had been ineffectually applied before the operation, were completely successful after it. M. Dehénne cited a recent example of the admirable results of neurotomy in tonic blepharospasmus. The patient, a woman of 58, had suffered from double blepharospasmus for five years. The tonic contractions had begun three years after the appearance of clonic blepharospasmus. M. Dehénne divided the left supra-orbital nerve, in which the tonic form of the affection was most pronounced, on February 25th, 1888. The tonic contractions immediately ceased, and the patient was able to open her eyes. Since the operation all spasms in the eyelids have disappeared. M. Dehénne has performed neurotomy in other cases with similar success.

L'Union Médicale of April 14th publishes some interesting observations on the action of antipyretics, especially antipyrin, upon the liver, by MM. R. Lépine and Porteret. One of these observers has already proved that under certain circumstances aniline helps the disintegration of nitrogenous substances, and decreases the production of heat. One naturally inquires whether pyretics might not therefore retard the formation of hepatic glycogen. To elucidate this point, experiments have been made on guinea-pigs. It was first ascertained that the ordinary quantity of glycogen contained in their liver varies not only with their size and nourishment, but is also unequal in the case of animals of the same weight and apparently subject to the same circumstances. A number of guinea-pigs having been placed under the influence of pyretics, MM. Lépine and Porteret found at least one-fifth more hepatic glycogen, and a slight diminution of hepatic sugar. Another experiment showed that the suspension of the transformation of glycogen into sugar is in part the result of a direct action upon the hepatic cells.

M. L. Dor has reported a case which is probably similar to those described to the Academy of Medicine by Messrs. Charrin and Roger, on March 19th, and it was in consequence of this case, which occurred between the months of April and July, 1887, that he undertook the researches the result of which he now publishes. This malady is infectious, and resembles tuberculosis. The symptoms are, first, a tumour, often resembling an abscess; when it appears spontaneously it is found in the tongue or in the inner walls of the mouth. Secondly, glandular swelling in the groin when the inoculation has taken place in a posterior part, and cerebral when the original abscess is in the mouth; numerous metastatic granulations of a cheesy nature, resembling either round tubercles or irregular nodules, cauliflower-like in form, varying from the size of a pin's head to that of a pea. Thirdly, microscopic examination has shown that the malady is not tubercle, nor leucæmia, nor pyæmia, nor generalised sarcoma, the pustules being composed of a peculiar fermented species of leucocytes.

Dr. Plouckhine, in the *Revue de Thérapeutique Médico-chirurgicale*, April 15th, recommends canadol, a hydrocarburet distilled from American naphtha, as a local anæsthetic. It is a transparent liquid, very volatile and smelling like benzine; it is insoluble in water and in alcohol, which renders it superior to ether. It causes rapid cold in the first minute, like ether, but does not, like this substance, continue to lower the temperature in the ensuing minutes. The anæsthesia produced by canadol is complete in sixty seconds, and employed as an anæsthetic in cases of minor operations completely subdues all pain.

According to M. A. Cabanès, in the *J. de Méd. de Paris*, April 15th, a new way has been discovered of dissolving a large quantity of boric acid in distilled water. It is known that it has hitherto been possible to dissolve more than 4 or 4.50 grammes of this antiseptic in 100 grammes of water, which is not strong enough completely to destroy all micrococci. The new solution

is as follows: boric acid, 120 grammes; calcined magnesia, 10 grammes; aquæ destill., 750 grammes. It is possible that bichloride of magnesia is formed; at any rate, there remains in solution a considerable excess of boric acid.

In a communication recently made by Professor Bouchard to the Académie des Sciences, he states that naphthol β is an excellent antiseptic for external use. But what is more important, it would appear to be the most efficient agent for intestinal antiseptics, particularly on account of its slight solubility, which prevents its absorption and allows it to remain a long time in the intestine without poisonous effects. A daily variable dose of 1 gramme of naphthol per kilogram of weight of the animal may be administered without danger.

Dr. F. Bompard has lately made an interesting communication to the Société de Médecine de Bordeaux on atrophy of the thorax in phthisis. The following is a summary of his conclusions;—1. Muscular atrophy is frequent in tuberculous subjects; 2, it is met with in the neighbourhood of pulmonary lesions, and specially at the apex of the thorax; 3, it presents the following characters: (a) diminution of volume; (b) subsidence of prominences; (c) exaggeration of hollows; (d) diminution of strength; (e) diminution of electrical contractility; 4, it may be an early symptom; 5, it is sometimes accompanied by sharp pains in the muscles which are undergoing atrophy; 6, it constitutes a complication of pulmonary phthisis in augmenting the difficulty of breathing, and in this manner contributes to hasten the progress of the disease. It is, therefore, most important to combat this form of muscular atrophy, which is common, particularly at the outset of the disease, when a cure may still be hoped for. For this purpose nothing can be better than chamber gymnastics, already so much recommended by M. Peter in 1879.

Some time ago, M. Huchard called attention at the meeting of the Société de Thérapeutique to the contra-indications of antipyrin. He said the drug should be used sparingly in diseases such as typhoid fever, in which the kidneys served as emunctories, as it diminished the secretion of urine. On the same principle he gave 8 grammes a day to a woman suffering from meningomyelitis, who passed from 24 to 28 litres of urine in 24 hours. This quantity was reduced to 5 litres under the influence of antipyrin. M. Huchard therefore suggested the use of antipyrin in analogous cases, such as diabetes, for instance. M. Dujardin-Beaumez expressed a similar opinion. Antipyrin should no more be given than opium or salicylate of soda when the kidneys were diseased. These substances being eliminated by these organs, might possibly be absorbed into the organism with toxic effects. M. Dujardin-Beaumez had tried antipyrin in two cases of polyuria, the amount of urine being diminished in both cases. M. Huchard added that arterio-sclerosis should not be treated by antipyrin, even when the kidneys were not affected.

[FROM OUR OWN CORRESPONDENT.]

Professor Haab on General Gonorrhæal Infection.—Transmissibility of Molluscum Contagiosum.—Transfusion of Blood in Carbonic Oxide Poisoning.—Electrolysis in Hypertrophy of the Prostate.—The Berne Cremation Society.—Septuple Labour at Castagnola; the Ruttigen Chapel in Memory of a Septuple Labour.

At a meeting of the Gesellschaft der Aerzte, in Zurich, Professor Haab read a paper on a generalised or constitutional gonorrhæal infection developing consecutively to specific urethritis. He often met cases of gonorrhæal iritis and irido-cyclitis, as well as of conjunctivitis originating without any direct transmission of the urethral discharge. In the cases of the latter kind no gonococci were present in the conjunctival secretion, the disease usually running a mild and favourable course. He further cites a striking case of general infection after urethral gonorrhœa, where death was threatening in consequence of extreme exhaustion caused by a continuous, uncontrollable fever of many weeks' duration. The man was suffering from effusions into his knee and elbow joints, abscesses in the left axilla, prolonged obstinate cystitis, and double ophthalmia of the severest kind, ending in complete destruction of one eye, and serious disorganisation of the other. No microbes were found in the articular exudation, but the axillary abscess was found to contain staphylococcus.

Professor Haab seems to think that this case is an instance of a mixed general infection with gonococcus plus staphylococcus.

Professor Haab also states that he has succeeded in inoculating molluscum contagiosum into his own forearm. Having rubbed into the part a portion of the contents of a freshly extirpated nodule (and nearly forgotten all about it), he found, about six months afterwards, a typical nodule at the site of the inoculation. When the growth had reached the size of a hemp-seed he extirpated it in order to examine its structure microscopically. The structure proved to be absolutely identical with that of the primary nodule which had served for the inoculation. As is known, the number of successful experiments of the kind is as yet very scanty (Retzius, etc.).

In the *Correspondenz-Blatt für Schweizer Aerzte*, No. 8, 1888, p. 258, Dr. Siegfried Stocker, of Lucerne, relates a case of poisoning by carbonic oxide, where transfusion of human blood was successfully employed after all other means of resuscitation had utterly failed. The patient, a senior engineer to the Gotthard Railway, a powerfully-built man aged 50, went to bed (at an hotel in Goeschenen) in the best health and spirits. The next morning he and a companion were found in an unconscious state, and apparently dying. The stove (closed in the night) contained half-consumed coal and wood. The patient's friend was brought to his senses in twenty hours by means of cutaneous stimulation, ether injections, artificial respiration, and electrification of the phrenic nerves. But the patient remained in a seemingly hopeless state even after persistent and energetic resuscitating efforts of the same kind carried out for 48 hours. As a last resource, transfusion was resorted to; 500 grammes of blood were drawn from the patient's median vein, and 110 grammes of defibrinated human blood injected into the same vein. In about two hours very gradual improvement set in. It was only on the third day after the transfusion that the temperature, respiration, and pulse became normal, while extreme prostration and mental weakness continued for a long time. In fact complete recovery took place only two months later. According to Heinecke (1885), international literature contains twenty-three cases of blood-transfusion in carbonic oxide poisoning. Of these, recovery ensued only in eight. The success, therefore, is certainly not very brilliant; still Dr. Stocker believes that the procedure is decidedly indicated in all such cases where no improvement follows in spite of persistent treatment by fresh air, rubbing and brushing the cutaneous surface, faradisation of the phrenic nerves, etc. The author lays stress on free venesection as an essential condition of success, since it is imperatively necessary (1) to relieve the intense congestion of the internal organs which is invariably present in the cases under consideration; and (2) to eliminate some portion of the poison and its injurious products (including disintegrated blood-corpuscles). On the other hand, the introduction of healthy blood is also thought necessary, though the quantity need not be considerable. A saline transfusion in the cases in question seems to be quite useless.

In the *Revue Médicale de la Suisse Romande*, May 20th, 1888, p. 282, Dr. Roux, house-surgeon to L'Hôpital Cantonal, in Lausanne, writes that since August, 1887, he has employed electrolysis in six cases of enlargement of the prostate. He places the positive electrode of an ordinary galvanic apparatus on the abdomen, while the negative one is brought in contact with long steel needles, which are plunged into the gland through the rectum as deeply as $1\frac{1}{2}$ or 2 centimètres. The circuit having been closed, a weak current is allowed to pass; its strength is then gradually increased to 70 milliampères in the course of one to three minutes, and maintained at this height for two and a half to five minutes, after which it is gradually diminished. Then the needles are thrust into another portion of the prostate, the procedure being repeated, as a rule, two or three times at a sitting. Pain (frequently about the abdomen, sometimes about the gland) is said to be intense. One of the patients, aged 70, did not come again after a sitting with five *piqures*. Another, aged 74, with an enormous prostate (about the size of an orange, according to the estimate of a "confère un peu enthousiaste"), left the hospital with the gland diminished to a third of its former volume. A third man, aged 72, returned several weeks after a single sitting with such a striking diminution of his prostate that no further treatment was found necessary. A fourth patient, aged 70, who had been admitted with very bad symptoms, left the hospital after three sittings in the course of six weeks, feeling perfectly satisfied with his state. On re-examination, on the eve of the author's present communication, the prostate was found to have

undergone a marked reduction in size. A fifth, aged 77, in whom electrolysis was repeated five times, at present shows "a general diminution of the gland, whose surface is now covered with nodules, ridges, and depressions, which were entirely absent before the treatment." The sixth case is still under treatment. The general conclusions drawn by Dr. Roux from this series are: (1) that electrolysis actually enables us to diminish the volume of a hypertrophied prostate; and (2) that this simple, easy, and harmless method most decidedly deserves a further and more extensive trial.

The Berne Society for Cremation (*Feuerbestattungsverein*) was opened on May 15th. M. Gobat, a member of the Cantonal Government (*Regierungsrath*) has been elected the first President of the new society. The administration of the latter includes Dr. Schwarzenbach, the well-known professor of chemistry at the local university. The number of members registered during the first sitting has reached 308. This is not a bad figure for a town inhabited only by 50,000 candidates for burial of all kinds. *Ceteris paribus*, a London Cremation Society should show something like 26,000 members.

According to the *Bund* of May 10th, at the village of Castagnola, near Lugano, the wife of the local Communal President, aged 38, has been recently delivered, at full term, of six living children, every one of which, however, died in the course of a few hours after their birth. This startling event has induced a correspondent of the *Berner Volkszeitung* of May 19th, p. 2, to publish the following statement, which, he says, can be very easily verified: Many years ago a woman, residing at the village of Fullenbach, near Olten, was safely delivered of seven living, though tiny, infants. Since the nearest church at the time was at Olten, the seven children had to be carried to that town to be baptised. It happened that one of the rustic godfathers somehow lost one of his future godchildren on the way, the accident being discovered only after the napkins and wrappings had been carefully examined at the church. The happy father of the seven, plunged now into the very depths of unhappiness, registered a solemn vow to the Holy Mother that if "the lost child was found alive he would erect on the self-same spot a chapel dedicated to Her Holy name." The infant was soon found safe and sound, lying at the left bank of the river Aar, about 500 steps from the Aarburg Bridge, close to Ruttigen, where there now stands the chapel as erected by the father, true to his solemn promise. An official document, relating in detail to all these obstetrical and other events, is said to be exhibited within the chapel for the public edification.

CORRESPONDENCE.

BIENNIAL ELECTION OF PRESIDENT, ROYAL COLLEGE OF SURGEONS IN IRELAND.

SIR,—I think the time has arrived when, in the interests of the Irish College of Surgeons, the Council and Fellows at large should definitely decide that the office of President should last for more than one year.

The present system of electing a new President every year, owing to the altered condition of the College, has disadvantages too numerous to mention, and by instituting biennial elections much unpleasantness would be avoided, besides saving the College to a great extent from the unseemly contests for the post of Vice-President, which have been so common for the last few years.

The London College of Surgeons, where it would be easy to select a suitable President annually, owing to the number of distinguished aspirants for the position, do not adopt the system, but allow the President to hold office for two and sometimes three years, as is the case this year, when Mr. Savory takes the presidential chair for the third time in succession. The matter will be brought before the Fellows of the College at their next annual meeting, and I sincerely trust this much needed reform will be no longer delayed.

In order not to affect the present candidates for office the system might commence from June, 1890.—I am, etc.,

L. H. ORMSBY, F.R.C.S.I., M.D.,

Surgeon to the Meath Hospital and Co. Dublin Infirmary.

Member of the Surgical Court of Examiners, R.C.S.I.

Dublin, May 26th.

THE TREATMENT OF AURAL EXOSTOSES.

SIR,—Sir William Dalby, in the *JOURNAL* of May 26th, is reported to have made some remarks before the Royal Medical and Chirurgical Society, on "the removal of bony growths from the external auditory canal," in which he claims to have operated with the dental drill since 1874.

I have hitherto been under the impression that I had the satisfaction, on October 4th, 1877, of performing the first operation in England for double aural exostosis by means of drilling. This was published by me shortly afterwards. Since that time I have put on record several series of such cases, the results of which, as Roosa¹ has been good enough to observe, "justify all that Matthewson claims for the operation." Reviewing these cases, I see no reason to doubt the correctness of my original statement as regards the genesis of bony excrescences in the ear, that is, that they are commonly the result of mechanical irritation, and that a frequent source of this irritation is sea-bathing. It has again lately been recommended to use the chisel in preference to the drill for the removal of aural exostoses; but, inasmuch as drilling carefully performed is pre-eminently a safe and effectual operation, it is by no means apparent why a far rougher if readier method of procedure should be held in favour.

Now that, chiefly, as I am given to understand, through my persistent advocacy and practice, operation by drilling has come to be very generally recognised as one of the legitimate and indeed most valuable of the resources of the aural surgeon, it is desirable, I think, that I should draw attention to certain points in connection therewith. As, however, I have at present in preparation a series of some twelve fresh cases, to which I hope to add three to be treated this week, I do not purpose here to deal with this subject generally. First, I may mention that I have found it desirable to discard the crossbar at the end of the drill-holder, the use of which I recommended in the *JOURNAL* for April 30th, 1887, inasmuch as it hinders the access of light to the meatus. The steel guard which I long since recommended is, in fact, all that one requires for the protection of the ear, and it serves also the purpose of acting as a guide for the drill.

I have next to mention that prolonged experience in the treatment of deafness due to aural exostoses has taught me that the drilling of their apices is all that is absolutely necessary, as good hearing is maintained through a very small opening. It would appear from a report in the *JOURNAL* for May 26th of a paper read on the 22nd before the Royal Medical and Chirurgical Society that Sir William Dalby has lost sight of the fact that what the surgeon has to aim at in dealing with aural exostoses is not so much the removal of a tumour in bulk from the ear as the obviation of any deafness that it may cause. "In some of these cases of exceedingly hard, bony tumours in the external auditory meatus," we read, "it was found sufficient to bore a hole through their base, for that damaged their nutrition, and led to their death and removal by easier means." As, however, on the admission of Sir William, the boring of this hole is "no easy matter," and as, moreover, it is unquestionably both tedious and fraught with risk, I fail to perceive the advantage of its performance. If, further, as I have abundantly proved, a single operation by drilling suffices for all practical purposes, the death and the subsequent removal of the tumour, by means however easy, even with the most long-suffering of patients, does not appear to be a desideratum.

Not the least surprising statement in the report in question is that "burrs made of the best steel in the world were sometimes destroyed to the number of twenty or thirty before any serious impression was made, when they were revolving at a rate of 3,000 times a minute."

It seems impossible to avoid the conclusion herefrom, that the instruments referred to, whatever their original quality, must have been improperly tempered, or were otherwise unadapted for their purpose at the high rate of velocity employed, for in all my cases of ivory exostosis (and the first I operated on more than ten years ago), I have successfully used identically the same burrs.—I am, etc.,

GEORGE P. FIELD.

34, Wimpole Street.

¹ See *Treatise on Diseases of the Ear*, 6th ed., p. 486, where, also, the author remarks that "Field, of London, seems to have had the most experience in the use of the dental engine for the removal of exostoses."

THE UNIVERSITY OF DURHAM AND THE M.D. FOR PRACTITIONERS.

SIR,—In your report of the proceedings at the General Medical Council on Tuesday, May 22nd, the following paragraph occurs: "Dr. Glover asked for information as to the examinations of the University of Durham of practitioners of over fifteen years' standing. He said there were no examinations of greater interest to the profession generally."

Taken as it stands, this does not explain the meaning or object of the inquiry. You will perhaps allow me to say, therefore, that Dr. Glover asked the Registrar, Mr. Miller, if the statement in the table of passes and rejections, that the University of Durham had rejected the whole of the candidates for the practitioners' degree of the year 1887 was correct? The Registrar replied that the statement was incorrect, and arose from a printer's error, the correct numbers having been received from the University, that is, 8 rejections, 8 passes.

On inquiry, the Registrar of the University of Durham College of Medicine, at Newcastle, sent a note stating the same facts.—I

GEORGE Y. HEATH, M.B.Lond.,

Representative of the University of Durham in the
General Medical Council.

St. George's Club, Hanover Square.

THE MEDICAL COUNCIL AND THE COVERING CASE.

SIR,—In regard to this case, one cannot help feeling that the powers of the Medical Council are too limited. So far as the person covering is concerned, the power they possess, namely, to strike the offender off the *Register*, is ample, but with regard to the person covered, I cannot help thinking that the Council ought to have power to punish both, immediately and prospectively. Most certainly no person convicted of having practised regularly, by the aid of a cover or otherwise, ought to ever be registered, no matter what qualifications he may eventually obtain. With regard to the case lately before the Medical Council, I have every reason to believe that the real offender will not cease to practise in one way or another. I should say more, that the Medical Council should, in the case of such offender holding any office under the Crown, lay the facts of such offence before the advisers of the Crown, leaving it to them to take such steps as are of gravity of the case may require.

Finally, I hope that medical men throughout the country will do as I have done, and so stamp out this kind of parasite.—I

B. LUMLEY, M.R.C.S.

Northallerton.

MARSHALL AND SHAW DEFENCE FUND.

SIR,—Allow me further to trespass on your courtesy, and through your columns thank those who have so kindly and liberally contributed to the above fund, thereby relieving Dr. Marshall and myself to a great extent of the heavy legal expenses incurred in defending the recent lunacy action brought against us. I have succeeded, while clearing my character of the gross charges brought against me, in obtaining the approval of my professional brethren in my endeavours to uphold the honour and interests of the profession was of itself a sufficient reward for the many worries and anxieties entailed by this lawsuit. I regard it as a practical proof of sympathy as given in support of a cause other than personal, but I recognise and appreciate the individual kindness thus shown by so many professional friends, and I desire to express my warm appreciation of this token of their approval of good will.—I am, etc.,

HENRY MARSHALL, M.D.

Clifton, Bristol, May 26th.

SIR,—Will you permit me in your columns to return my thanks to the many generous contributors to the above-mentioned fund? Of the amount subscribed, £221 have been handed to me by the treasurer, Dr. E. Long Fox, and my legal expenses, so far as they are at present known, amount to about £330.

It is much to receive so substantial a contribution towards defraying the expenses of the late legal proceedings against Dr. Marshall and myself; it is infinitely more to know that under a prosecution for the simple discharge of a professional duty we receive the sympathy and moral support of those whose opinions we most highly value.—I am, etc.,

J. E. SHAW, M.B., C.M.

11, Lansdown Place, Victoria Square, Clifton, Bristol,

May 30th.

THE HORSE TAX.

SIR,—I think no medical man will deny that, on rare occasions, he uses his horse for pleasure, just as does the butcher, baker, etc. The latter, however, will have no tax to pay, and herein is one of the hardships to medical men.

Could not the Government be petitioned to reduce the amount of the tax by, say, one-half—making a third classification—where a horse is kept partly for work and partly for pleasure?

I imagine that if some such suggestion as this is acted upon, it will remove much of the present opposition to a tax which will apply so unjustly to us.—I am, etc.,

JOHN J. LANGSTON, L.S.A.

Newington, Sittingbourne, Kent, May 28th.

DIPHTHONGS IN MEDICAL AND SCIENTIFIC TERMS.

SIR,—I wish to call attention to a circular from the editor of the *Philadelphia Medical World*, which contains the following statement: "Please notice the stand we have maintained for the past year in regard to the use of diphthongs, discarding them altogether except in the formation of the genitive singular and nominative plural of Latin nouns of the first declension." Although a wish has sometimes been expressed that "diarrhoea" should give place to "diarrhea," and so forth, this innovation is hardly popular amongst standard English medical writers. Scholars strongly object to the reduction of "æ," as well as "œ" to "e," there being no warrant for such a change. Should the diphthong be suppressed, "—rhea" would probably be correct; but judging from philological evidence too complicated for discussion, "hemorrhage" ought to be written "hamorrhage" (pronounced "hay-morrhage"), rather than "hemorrhage." Again, in a leader on "Technical Terms and Medical Study" in the *JOURNAL* for December 24th, 1887, p. 1393, in reference to the craze of purists for "pure Anglo-Saxon words," it was observed: "Strange to say, by the way, some of these purists often object to diphthongs, which abounded in Anglo-Saxon, and whilst historians, who have really studied that language, write about 'Ælfred the Great,' medical authors think that we might as well take to spelling 'hæmorrhage' 'hemorrhage.'" British and American writers and editors ought hardly to abolish the two diphthongs without duly consulting classical scholars, who are also authorities in English composition.—I am, etc.,

φιλόλογος.

INTERMITTENT HÆMATURIA.

SIR,—The case of this disease related by Mr. Berkeley Hill in his clinical lecture on hæmaturia is of great interest. In May of last year I read before the Clinical Society an account of a case of hæmaturia due to bilharzia (which is published in vol. xx of the *Transactions*), and up to about that time no instance of the origin of the disease in this country had, I believe, been recorded. It appeared, therefore, that the continued observation of cases in this country would throw some light either upon the natural duration of life of the adult parasite, or on the possibility of the embryo reaching maturity within the human body without the intervention of an intermediate host—a very unlikely proceeding. Should the two cases originating in this country, and recorded by Mr. Berkeley Hill and Mr. Reginald Harrison, be supported by the discovery of others, the results of this method of observation will lose much, though not all, of their value. The case that I have recorded, originating in Natal, has now been under observation in this country more than two years and a half. Ova of the bilharzia have been found on every occasion when sought for, and still continue to be passed. The patient was much depressed at first on learning the nature of his malady, but has otherwise been in good health, and now is quite robust, playing football in the season once or twice a week. The loss of blood in the case related by Mr. Berkeley Hill seems to have been very excessive.

With regard to the hatching of the ova in urine I am satisfied I have observed this occasionally, though usually they remain unaltered for several days until they are killed by an advanced state of decomposition of the urine. When placed on a slide, in urine, under a cover glass I have watched dozens of the embryos escape from the shell, which the weight of the cover glass appears to help to rupture. The embryos continue to swim about actively in the urine for several hours.

The ova are readily preserved in glycerine diluted with about one-third water. I have numerous specimens that have been preserved in that manner and that have remained in good condition already for two years and a half.—I am, etc.,

Nottingham, May 28th.

H. HANDFORD, M.D.

LONDON UNIVERSITY: PRELIMINARY SCIENTIFIC (M.B.) EXAMINATION.

SIR,—A Royal Commission having been appointed to take evidence with regard to the development of higher education in London, one hopes that the result will be the establishment of a teaching university worthy of the importance of the metropolis, with its huge population and great position in the civilised world. If a teaching university be established and the present University remain simply an examining body, as it is at present, could not the Senate and Convocation be induced to do something to improve the position of the medical undergraduates?

The Medical Faculty is the most heavily weighted in the University, and the greatest impediments and difficulties appear to be thrown in the way of candidates for its degrees. No student is regarded as a student in medicine until after he has passed the preliminary scientific examination, notwithstanding that possibly he might have completed a year or two of hospital work before that date; and then a considerable period must elapse in which hospital lectures, etc., must be attended, between the intermediate and final M.B. examinations.

The preliminary scientific is an extra examination, as it were, no corresponding one being required in any of the other curricula. It is not a mere preliminary science examination to medicine, but a severe test, requiring at least twelve months' residence at some college or institution where science is well taught in the classroom and laboratory, and also considerable application on the part of the student, who should be endowed with fair brain-power. The severity of this examination has been recognised by the Senate in allowing candidates to divide the subjects into two parts, to be taken at different times, so that a student, if he be successful, may have to undergo five examinations before he can take his degree of M.B., whereas in Arts, Science, and Law he can only three.

Does this appear to be equitable or fair? It seems to me that medical students, having to undergo a special scientific training after matriculation and before they can be allowed to commence their professional studies, ought to have some particular designation given them—such as "Licentiates in Science"—instead of merely describing themselves as having passed the preliminary scientific examination. The organic chemistry of the intermediate M.B. may be added to the subjects of the preliminary scientific, so that subsequent studies may be entirely professional, and all those who had passed the scientific examination should be termed "Licentiates in Science." The character of this and matriculation cannot be less, if it be not more, than the B.A. in some of the older universities.

If the Senate and Convocation would give some more distinctive mark to those who had passed this examination, it would be a great incentive to candidates, as well as improve their position very considerably in the eyes of the world. The University of St. Andrews confers the designation of LL.L. on ladies who pass in certain subjects laid down by the Senatus and professors of that University; and, as the University of London is merely an examining body, surely it may do something to sweeten the hard struggles of many of its undergraduates. Of course all Licentiates in Science would be in *in statu pupillari*, as at present, and have no voice whatever in university matters.—I am, etc.,

R. CLIFFORD.

NAVAL AND MILITARY MEDICAL SERVICES.

THE MEDICAL RESERVE.

A CORRESPONDENT, "Vigilant," asks the profession and all who may contemplate joining the Army Medical Reserve, to consider, while the warrants relating to the regular medical service are so easily set aside or played ducks and drakes with, what assurance would be reservists have that they may not be tripped up and befooled with equal disregard of terms? They may think they are safe under certain conditions, but the "exigencies of the service" under Mr. Stanhope's Bill for extended powers over the militia and volunteers will place them completely in the clutches of the War Office, and send them for general duty all over the country; they will have no hold over their corps, or their corps over them. Any of them who have private practices worth conserving will find them absorbed on their return home by rivals, who, not entrapped by vain military medical titles, have an eye to real business in civil life.

THE OLDEST VOLUNTEER.

Mr. JAMES WILLIAMS, F.R.C.S., J.P. (Mount Pleasant, Brecon), writes: In the JOURNAL of May 12th, under "Volunteers," I find: "Surgeon and Honorary Surgeon James Williams, of the 1st Volunteer Battalion South Wales Borderers, late 1st Brecknock, has also resigned, with permission to retain his rank and uniform; his appointment was dated April 15th, 1862."

I wish this inaccuracy corrected. My appointment bears date November 15th, 1859 (enclosed for your inspection). I was enrolled in August three months before, making me presumably "the oldest volunteer in the kingdom," having served continuously for twenty-nine years, and having accompanied my regiment twice to Aldershot, and notably last year, to show our beloved Queen the loyalty and nationality of Brecknock Welshmen, accompanied by the emblematic goat in the march past, and myself honoured by my townsmen as the "Jubilee" mayor. Taking these claims into consideration, I asked the "highest military authorities" permission to remain with the regiment a little longer, as we are to be brigaded this year in our own town with other county regiments. My appeal was refused in the usual stereotyped fashion, and the favour asked not granted. This kind of treatment to an old volunteer of nearly thirty years' standing requires some explanation.

INSPECTION OF A BATTALION OF VOLUNTEERS.

SURGEON-MAJOR writes: It is, I believe, becoming increasingly common for the regimental bearers to march past under command of a surgeon, taking their position in rear of the battalion. May I ask if there is any authority for this?

Does Section 355, Part III, Manual for Medical Staff Corps, apply; and, if so, how is it that stretchers are so frequently carried, as they are strictly forbidden by the last paragraph? If it be right to march past, what is the position of the surgeon in command; and should he salute as the combatant officers do? I shall be glad to receive information on the above points, as although my men have repeatedly marched past, and sometimes with stretchers, I have never felt quite sure that it was right; and one likes more authority than the commendation of the inspecting officer.

. "At annual inspections of volunteer corps, the corps stretcher bearers will parade and be inspected as such under the medical officer" (*vide* Volunteer Regulations, Part I, Sec. VI, para. 517). There is no authority (except general sanction) for the march past of regimental bearers under command of surgeon.

Sec. 355, Part III, Manual of Medical Staff Corps, applies as far as the duties of regimental bearers in giving first aids and conveying the wounded to an ambulance wagon or the collecting station.

Stretchers are carried by bearers, as regimental waggons are rarely provided. The position of the surgeon is in rear of the centre of his bearers; he salutes with the hand, not, as the combatant officers, with the sword.

ARMY MEDICAL STAFF.

REGIMENTAL M. O. writes: "Verbum Sap," is not yet tired of agitation. Is he aware of the contrast that has been wrought in the last few years between the old "regimental" officer and the present semi-civilian rankless "doctor"? It is possible the authorities may tire of agitation, especially now as they are strengthening their hands by daily filling up the reserve lists. I fear a doctor in the army must remain one. If things go on as at present, civilians, pure and simple, will have medical charge of our army in the distant future. Before agitation, let medical officers unite and pull together; had they done this in time, they would not be in the condition they are in at present.

THE NAVY.

THE following appointments have been made at the Admiralty: G. A. CAMPBELL, Fleet-Surgeon, to the *Impregnable*; C. W. MAGRANE, Staff-Surgeon, to the *Lion*; J. F. DONOVAN, Surgeon, to the *Thunderer*; M. H. ACOCK, Surgeon, to the *Orlando*, additional; ANTHONY GORHAM, Fleet-Surgeon, to the *Impregnable*; ROBERT GRANT, Fleet-Surgeon, to the *Téméraire*.

THE MEDICAL STAFF.

SURGEON G. D. HUNTER has been seconded for service with the Egyptian army.

Surgeon F. W. C. JONES, serving in the Bombay command, having returned from Burmah, is posted to general duty in the Bombay district, Northern Division, and Aden.

Surgeon-Major C. C. PIPER died at Guildford on May 21st, at the age of 63. He entered the service as Assistant-Surgeon September 12th, 1855, and was promoted to be Surgeon and Surgeon-Major successively, retiring on half pay February 7th, 1876. He had no war record.

ARMY MEDICAL RESERVE.

SURGEON AND HONORARY SURGEON-MAJOR BURFORD NORMAN, of the 1st Volunteer Brigade, Southern Division, Royal Artillery (late the 1st Hampshire Artillery) is appointed Surgeon-Major (ranking as Major).

THE INDIAN MEDICAL SERVICE.

BRIGADE-SURGEON H. COTTER, M.D., Bengal Establishment, is appointed Deputy Surgeon-General with temporary rank, *vice* Acting Deputy Surgeon-General A. H. Hilson, M.D., appointed Officiating Inspector-General of Civil Hospital, Bengal.

Surgeon-Major W. D. STEWART, Bengal Establishment, is granted furlough in and out of India, on private affairs, for 1 year and 243 days.

Surgeon A. W. ALCOCK, M.B., Bengal Establishment, is appointed to the medical charge of the 2nd Punjab Infantry, *vice* Surgeon W. A. Sykes.

Surgeon-Major J. M'CONAGHEY, Bengal Establishment, Civil Surgeon of Bari Bankee, is appointed to officiate as Civil Surgeon of Fyzabad, during the absence on deputation of Dr. O'Brien.

The services of Surgeon C. W. OWEN, C.M.G., O.I.E., Civil Surgeon of Nynee Tal, are placed at the disposal of the Government of India, Foreign Department.

Surgeons J. HOLT, T. H. GRIFFITH, J. L. T. JONES, and W. E. JENNINGS, are brought on the strength of the Bombay Establishment, from April 22nd, the date of their arrival at Bombay.

Surgeon J. GARVIE, Bengal Establishment, is appointed to the officiating medical charge of the 13th Bengal Lancers, *vice* Surgeon W. Cunry, M.B., granted leave out of India.

Surgeon A. COLEMAN, Bengal Establishment, is appointed to the officiating

medical charge of the 17th Bengal Lancers, vice Surgeon S. H. Henderson, recommended for leave in India.

Surgeon H. HENDLEY, Bengal Establishment, is appointed to the civil medical charge of Dalhousie.

Surgeon-Major B. O'BRIEN, Bengal Establishment, Civil Surgeon of Fyzabad, is appointed to officiate as Civil Surgeon of Cawnpore, during the absence on privilege leave of Brigade-Surgeon J. H. Condon.

Surgeon H. P. DIMMOCK, Bombay Establishment, is appointed Civil Surgeon of Sukkur, vice Surgeon-Major M. L. Bartholomewsz, M.B., C.B., transferred.

Brigade-Surgeon G. Y. HUNTER, Bombay Establishment, Presidency Surgeon Third District, is allowed furlough to Europe for six months, on medical certificate.

Surgeon-General M. C. FURNELL, M.D., C.I.E., late of the Madras Establishment, died at Monte Carlo on May 24th, aged 58. Entering the service as Assistant-Surgeon, February 7th, 1855; he attained the rank of Surgeon-General, April 5th, 1855. He served during the Indian Mutiny in 1858-59, and was present at the battle of Dowdapore, in Oudh, and in the pursuit of Beni Madho and Runmst Singh (medal). He was nominated Companion of the Order of the Indian Empire, May 29th, 1886.

THE VOLUNTEERS.

The resignation of Surgeon and Honorary Surgeon-Major H. MEADE, of the 2nd West Riding Artillery, announced in the *London Gazette* of May 4th, is cancelled.

Surgeon A. HAMILTON, of the 2nd Volunteer Battalion of the Cheshire Regiment (late the 2nd Cheshire), is granted the honorary rank of Surgeon-Major.

The undermentioned gentlemen are appointed Acting-Surgeons to the corps specified.—R. S. SMITH, M.B., 1st Volunteer Battalion Royal Highlanders (late the 1st Forfar); A. E. OBLING, 1st Volunteer Battalion Lincoln Regiment (late the 1st Lincoln); C. W. MACDOWELL, M.D., 22nd Middlesex (Central London Rangers).

THE PHYSICAL TRAINING OF SOLDIERS.

LORD WOLSELEY has consented to preside at a meeting to consider the physique of soldiers and their physical training, to be held at the Royal United Service Institution, next Wednesday, when the subject will be opened by Colonel Onslow, Inspector of Gymnasias at Aldershot.

MEDICO-LEGAL AND MEDICO-ETHICAL.

ATTENDANCE ON THE FAMILIES OF MEDICAL MEN.

B. N. asks whether it is according to professional custom for a doctor to make a charge for professional services to the child of another medical man, staying in a relative's house. The relative is charged with an account, but refers the doctor for payment to the child's father. Should the latter pay without demur?

** A clearly defined answer to our correspondent's question and its collateral hearing will be found in the following rule, extracted from the *Code of Medical Ethics*, page 53:

"All legitimate practitioners of medicine, their wives, and children, while under the paternal care, are entitled (not as a matter of right, but by professional courtesy) to the reasonable and gratuitous services—railway and like expenses excepted—of the faculty resident in their immediate or near neighbourhood, whose assistance may be desired. In the case, also, of near relatives who are more or less dependent upon a professional brother (other than wealthy), it will likewise be well, at his request, to forego or to modify the usual fee. On the other hand, a son or daughter altogether independent of the father, or the widow and children of a practitioner left in affluent or well-to-do circumstances, should be charged as ordinary patients, unless feelings of friendship, or other special reasons, render the attendant practitioner averse to professional remuneration; in such case the rule need not apply. Moreover, if a wealthy member of the faculty seeks professional advice, and courteously urges the acceptance of a fee, it should not be declined, for no pecuniary obligation ought to be imposed on the debtor which the debtee himself would not wish to incur."

SEALED TENDERS.

THE point involved in the question submitted by our Cape Town correspondent is apparently altogether so foreign to the general usage and custom, ancient and modern, of the profession, that, after careful research, we have failed to discover any ethical rule whatever bearing on the subject, thereby evidencing, to our mind, the belief that "tendering" for a paid medical appointment has hitherto been a thing unknown to the medical profession; otherwise, a rule in reference thereto would, we think, have been formulated with the view of guarding, as far as may be, against any apprehended abuse thereof. In the absence, therefore, of such a rule, we do not hesitate to express the opinion that, for any legitimate practitioner to send in a "sealed tender" for the medical appointment advertised in the *Cape Times* would be regrettable.

TOD HEATLEY AND ELLIOT AND FRY v. BENHAM.

THE SECRETARY OF THE QUEEN'S JUBILEE HOSPITAL writes: As an impression appears to prevail in some quarters that the "Queen's Jubilee" Hospital is to be closed in consequence of Mr. Justice Kekewich's judgment in this action (based on the decision of the late Master of the Rolls, that "some throat affections might be contagious," and so constitute a legal nuisance), and as such an impression is calculated to damage the hospital, will you kindly allow me to state that the injunction is not to take effect for six months from the date of the judgment, and in the meantime it will be appealed against, and, if necessary, to the highest tribunal, as the judgment affects all existing institutions; and, in the event of the judgment being upheld, the hospital will be carried on at other premises in the immediate neighbourhood?

UNIVERSITY INTELLIGENCE.

THE ROYAL UNIVERSITY OF IRELAND.

At the close of the Spring Examinations in the Faculty of Medicine, the Senate awarded the following honours and exhibitions.

Third Examination in Medicine.

First Class Honours.—J. M. Hall, Queen's College, Belfast; J. W. Wolfe, Queen's College, Cork.

Second Class Honours.—Eleanora L. Fleury, London School of Medicine for Women; J. Jackson, Queen's College, Cork.

Exhibitions.

First Class, £30.—J. M. Hall (disqualified by standing); J. W. Wolfe.

Second Class, £20.—E. L. Fleury.

At a public meeting of the University held on Friday, May 18th, the following degrees were conferred by the Vice-Chancellor.

The degree of Doctor of Medicine.

J. F. St. John Annesley, J. Clifford (*in absentia*), J. H. Corcoran, D. Crowley, J. Hunter, G. Love, J. J. Lynch (*in absentia*), D. McKee, M. Molony (*in absentia*), P. J. O'Brien, L. O'Clery, M. Semple, H. Smith (*in absentia*), J. W. Wilson.

The degree of Bachelor of Medicine.

T. E. Duane, W. R. Gore, J. J. Griffin, W. Kelleher, P. McKenna, A. E. Mahood.

The degree of Master of Surgery.

J. F. St. John Annesley, J. Clifford (*in absentia*), J. H. Corcoran, D. Crowley, R. B. Gorsuch, M.D., J. Hunter, J. J. Lynch (*in absentia*), D. McKee, P. McKenna, A. E. Mahood, C. W. Morgan, M.D. (*in absentia*), J. J. O'Brien, P. J. O'Brien, L. O'Clery, M. Semple, H. Smith (*in absentia*).

The degree of Master of Obstetrics.

J. H. Corcoran, D. Crowley, J. R. Davison, M.D., A. E. Mahood, H. Smith (*in absentia*), J. Tomb, M.D. (*in absentia*).

The degree of Bachelor of Surgery.

T. E. Duane, W. R. Gore, J. J. Griffin, G. Love, M. Molony (*in absentia*), J. W. Wilson.

The degree of Bachelor of Obstetrics.

T. E. Duane, W. R. Gore, J. J. Griffin, G. Love, M. Molony (*in absentia*), J. W. Wilson.

The diploma in Sanitary Science.

C. F. Knight, M.D.

The degree of Master of Arts.

M. Henry.

EIGHTH CENTENARY OF THE UNIVERSITY OF BOLOGNA.—The Senate has deputed Dr. Moffett, President of the Queen's College, Galway, and Dr. Dunne, one of the Secretaries, to represent the Royal University at the celebration of the eighth centenary of the University of Bologna.

RECOGNITION OF A CORK HOSPITAL.—The Senate resolved to add to the list of recognised medical institutions the Eye and Ear Hospital, Nile Street, Cork.

TRAVELLING MEDICAL SCHOLARSHIPS.—The Senate decided to modify the rules respecting the standing of candidates for the travelling medical scholarship, so that in and after the year 1889, any person who may have passed the examination for the primary medical degrees, either in the year in which the scholarship examination is held, or in the year immediately preceding, shall be eligible to compete for it.

REGULATIONS FOR B.Ch AND B.A.O. DEGREES.—The Senate decided to admit to the degree of B.Ch. all graduates who obtained medical degrees in this University in the years 1882 to 1887, inclusive, upon payment of the fee of £5, and upon passing an examination in operative surgery only, provided such graduates had obtained at least 50 per cent of the marks assigned to surgery at the medical degree examination. The Senate also decided to admit to the degree of B.A.O. all such graduates as above mentioned upon payment of the fee of £2, without further examination, provided such graduates had obtained at least 50 per cent of the marks assigned to midwifery at the medical degrees examination.

CAMBRIDGE.

ASSISTANT TO THE PROFESSOR OF SURGERY.—Joseph Griffiths, M.B., C.M. Edin., and D.P.H. Camb., has been appointed Assistant to the Professor of Surgery (Dr. Humphry).

EXAMINERS.—Dr. Donald MacAlister, Dr. Broadbent, and Professor Julius Dreschfeld have been nominated as Examiners in Medicine; Dr. Galabin and Dr. Gervis, Examiners in Midwifery; Mr. Wherry, Mr. Macnamara, and Mr. Willett, Examiners in Surgery.

EIGHTH CENTENARY OF THE UNIVERSITY OF BOLOGNA.—A congratulatory address has been prepared for presentation to the University of Bologna, upon the occasion of the eighth centenary of its foundation. Professor Adams, Professor Middleton, Dr.

Jebb, and Mr. Justice Denman, have been appointed to represent the University of Cambridge at the ceremony.

PRACTICAL COURSE IN HYGIENE.—A course of practical instruction in hygiene will be given by Dr. Anningson and Mr. Robinsen, M.A., at Cambridge during the long vacation. Short explanatory lectures will be given, but the greater part of the course will consist of practical laboratory work, including analysis, microscopy, and the cultivation and recognition of micro-organisms. Special attention will be given to the examination of air, water, and foods to meet the requirements of medical officers of health, and the principles of drainage and ventilation will be dealt with in lectures illustrated by diagrams and models. The course is not limited to persons who are members of the University. Further particulars will be found in our advertising columns.

VICTORIA UNIVERSITY.

In connection with the incorporation of the Yorkshire College with the Victoria University, the College Council has created two new professorships in place of the former lectureships in midwifery and pathology in the medical department. Mr. C. J. Wright has been appointed Professor of Midwifery, and Dr. E. H. Jacob Professor of Pathology and Morbid Histology. The Senate has elected Professors Eddison and Smithells its representatives in the Court of the University.

INDIA AND THE COLONIES.

AUSTRALASIA.

INTERCOLONIAL MEDICAL CONGRESS AT MELBOURNE.—The first Intercolonial (Australasian) Medical Congress was held in Adelaide last year; the next is to assemble at Melbourne, and it was originally intended that an interval of three years should be allowed to elapse, but as the Centennial Exhibition is to open during the next Australasian summer, it has now been determined to hold the Medical Congress in January, 1889, when the Exhibition will be in progress. The President is Mr. T. N. Fitzgerald, F.R.C.S.I.

INDIA.

THE Bombay European General Hospital is in a very unsatisfactory state, and the Government resolution imposing another delay of six months in carrying the extension scheme to completion is regarded as most disappointing. The Government years back admitted the urgent need of improved accommodation for the nurses, and the present shilly-shallying is causing great discontent.

KASHMIR MEDICAL MISSION.—The report of the Kashmir Medical Mission for 1887 shows that the area of the work is increasing; the number of patients exceeded all previous records, and there was a proportionate increase in the number of major operations. In addition to the patients seen at the base, nearly three months were spent in itineration, over 6,000 patients being treated in the various villages. The dispensary equipment on these journeys consisted of two coolie loads of concentrated mixtures, pills, or drugs in bulk, and surgical instruments. In one such journey of four days, 1,200 patients were seen, and 120 operations performed. A very large proportion of all the operations done were on the eye, and the majority of these for trichiasis. Mr. A. Neve and Dr. E. F. Neve, the medical missionaries, state that they now perform a modification of Stellwag's operation, the total number of eyes thus treated for trichiasis being about 900. Miss F. Butler, M.D., and Miss Hull, with probably other ladies, were expected to join the mission this year. Subscriptions are asked for, and may be paid to the Rev. J. Lowe, F.R.C.S., 56, George Street, Edinburgh.

OBITUARY.

WILLIAM A. RICHARDS, M.D. LOND.

WE deeply regret to have to record the death of Dr. William Alsept Richards, of Winchester, which took place on Tuesday, May 8th, at 16, Fitzroy Square, London, at the early age of 42, from hæmorrhage following an operation for fistula.

Dr. Richards, who was a native of Cornwall, had a very brilliant college career. He studied at King's College, London, where he

obtained an exhibition in Chemistry and Materia Medica, passing First M.B. in 1865, L.R.C.P. Lond., 1867, M.R.C.S. Eng., 1867, M.B. and Medallist in Medicine, 1868, M.D. Lond., 1871. He went to Winchester some seventeen years ago as house-surgeon to the County Hospital, and after remaining there about eighteen months went into partnership with the late Dr. Butler, with whom he remained until the death of the latter. Since then he enjoyed an extensive practice in the city and neighbourhood, being recently assisted by his brother, Mr. D. Richards, his pleasant and genial manners making a host of friends, to whom the news of his death came as a sad surprise, and by whom he is most sincerely mourned. He was one of the physicians to the County Hospital and medical officer to Winchester College, Hants County Constabulary, the City Police, and H.M. Prison.

MATTHEW BAILIE GAIRDNER, M.D. EDIN.

WE regret to announce the death of Dr. Matthew Bailie Gairdner, late of Crieff, which took place on May 18th. The deceased gentlemen, whose connection with the district as a medical practitioner extended over fifty years, was born in Glasgow in 1808. His family removing while he was a youth to Edinburgh, where his father held an appointment in the customs, he was brought up to the medical profession, and, as was the custom in those days, apprenticed to one of the leading city firms, Messrs. Bell, Russell, and Co. one of the partners being Russell, the professor of clinical surgery, and another, Ross, a well-known medical practitioner of Edinburgh. Two of his co-apprentices were Dr. Ormond, of Edinburgh, and Dr. Fraser Thomson, of Perth.

Commencing his medical studies at the age of 15, he obtained the licence of the Royal College of Surgeons at the early age of 19, and two years later (in 1830) he graduated M.D. at the University of Edinburgh. He held the appointment of house physician to the Fever Hospital in Edinburgh, and subsequently went to Comrië as private physician to Sir Robert Dundas, of Dunira. Here he soon acquired a large and lucrative practice. A few years later he removed to Crieff, and shortly after the passing of the Poor-law Act he was appointed medical officer of the Crieff Parochial Board, a post he held till three days before his death. He was also connected for some years with the local volunteer corps as assistant surgeon.

Dr. Gairdner was the intimate friend of the late Professors Simpson, Christison, and Symes. On the discovery of the operation for strabismus he operated extensively in the district. Among the minor operations, he was fond of hare-lip and club-foot cases. He was universally successful, and was able to boast that he never lost a case, even among his major operations. He was for many years a member of the British Medical Association.

SURGEON-MAJOR WILLIAM CAREY COLES, M.D. EDIN.

THIS distinguished administrative officer of the medical department of Bombay was the son of the Rev. Thomas Coles, of Bourton-on-the-Water, Gloucestershire, where he was born in 1817; he received his medical education at University College, the College of Surgeons, and Apothecaries' Hall, London, taking the Fellowes gold medal and his diplomas 1839-40. Between the latter year and 1843 he served on board the Honourable East India Company's troopship *Minerva* in the Eastern Seas, receiving two silver medals, one for the China war and the other for the taking of Canton. On his return to England he took the degree of M.D. at Edinburgh, in 1844. In the following year he obtained his commission as an assistant-surgeon in the Bombay army.

For several years he was employed in various appointments on general duty, serving at different times with the 78th Highlanders, the 20th Bombay Native Regiment, and the Madras Artillery; and as assistant civil surgeon and surgeon to the coroner and garrison surgeon at Bombay. In 1849 he was appointed Professor of Midwifery and Medical Jurisprudence in the Grant Medical College, and held these appointments until 1854, acting for some time in 1852-53 as principal of the College during the absence on furlough of the late Dr. Herbert Giraud. Having frequently acted from 1848 as secretary to the Bombay Medical Board, he was permanently appointed to that office in April, 1855, and continued to hold it to his retirement from the service in 1865.

It has been truly remarked that it was in this position that he made his reputation as an administrative officer of the highest efficiency and distinction. To great natural capacities for such duties as were now required of him he added habits of the most

indefatigable self-denying industry and of the exactest regularity in the distribution and despatch of his work. His benevolent character, genial and engaging manner, won for him many friends, and on his leaving India he was presented by his brother officers with a service of silver. Dr. Coles was in his 71st year.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

DIPHTHERIA AT ENFIELD.

DIPHTHERIA has for a long time maintained itself in Enfield, and since 1873 scarcely a year has passed without deaths from that disease being registered in one or another portion of the district. During the last three years the number of such deaths has increased, and this increase has been coincident with a general prevalence of diphtheria over a wide area of country north of London. During 1886, in the Enfield district twenty-four deaths from diphtheria and four others from "croup" were registered, and during the first three quarters of 1887 cases continued to occur in various parts of the district. Towards the end of September last diphtheria began to be epidemic, especially in central Enfield, and between that time and the end of January of the present year 213 cases, of which forty-eight were fatal, were reported in the district.

At this stage, in consequence partly of the local panic, an inquiry was undertaken by the Local Government Board, and was entrusted to Dr. Bruce Low. But owing to the circumstance that, antecedent to its extension last autumn, diphtheria had persisted for several years in Enfield, and to the lapse of time since the commencement of epidemicity of the disease, Dr. Low's report, just published, does little more than review the chief conditions, so far as they could be learned, under which epidemic diffusion of the disease has occurred. A "sewer-gas" theory had locally most acceptance as the probable cause of the diffusion; but it is discarded by Dr. Low, who points out that, as a matter of fact, objectionable sewer emanations were complained of over a very wide area, whereas epidemic diphtheria was restricted to certain definable limits. Moreover, the first outbreak of the disease in September and October last was not in localities whence the chief complaint of foul emanations from sewers has come, but in another part of the district which has not been specially troubled in this fashion. The water-supply was also accused, but Dr. Low easily shows that accusation to be unfounded.

On the other hand, the medical officer of health's suspicions as to contaminated milk were ridiculed in some quarters, and few appear to have agreed with him in suspecting elementary schools as having had large concern in the spread of the diphtheria. In reality school attendance was the strongest influence in the spread of the disease. In one school, having an average attendance of 110 scholars, 28 had diphtheria in the course of a few weeks, and 11 of these died of the disease. Another school, situated at some distance from that already referred to, and still further from the locality of chief epidemicity of diphtheria in December last, supplied evidence of the same sort. Among several hundred houses having like conditions of population and sanitary and other circumstances, diphtheria tended to pick out (so far as fatal diphtheria was concerned, it did so without exception) families which sent children to the schools in question. Thus, of 20 families in Central Enfield invaded during the first three weeks of this year, at least 14 got their diphtheria in the persons of children attending those schools. The milk-theory of the medical officer of health is also borne out by some very convincing figures, but cannot be positively proved at this distance of time.

Many other influences tended to foster diphtheria in Enfield. Not a few instances came to light in which parents, accompanied often by children, had visited at houses where diphtheria existed for the purpose of condolence, of gossip, or of idle curiosity; and very commonly children, regarded by their parents as practically well after diphtheria, were sent to school without trouble on the part of anyone to obtain certification as to freedom from infection. So, too, as regards what appear to have been mild cases of diphtheria, people have been content to take advice from "chemists," who in turn have given medicine for "colds," "teething," and the like, with the result that, in several instances,

children having decided diphtheria have mingled freely with their fellows.

Again, there is a custom among the working class in Enfield, as, indeed, elsewhere also, of assembling children of the family in the sickroom to take their last leave of the relative dead or dying from infectious disease, and Dr. Low gives some instances in which children have even been brought from other districts to take part in such formal leave-taking. Domestic animals have also fallen under suspicion in the Enfield epidemic, cats being observed to suffer in considerable numbers from illness. Though there were no known causes of diphtheria occurring in the practice of the veterinary surgeons of the locality, yet they saw many cases of "influenza" at this time among animals. Several curious illustrations are detailed by Dr. Low.

Diphtheria is a disease around which a great deal of obscurity still hovers, and every fresh link in the chain of evidence is welcome. Much has been elucidated from time to time by the medical staff of the Local Government Board, but it is unfortunate that such opportunities of studying a sustained epidemic as has recently been afforded at Enfield should so often be lost. This is mainly owing to the smallness of the staff of inspectors, but is none the less unfortunate.

DISEASES OF THE RESPIRATORY ORGANS AT MIDDLESBROUGH.

It has been reported that a rapidly fatal epidemic, supposed to be due to noxious fumes emanating from a factory in the neighbourhood, prevails at Middlesbrough-on-Tees. We have made inquiries into the matter, and are informed by Dr. Malcolmson, the medical officer of health for the district, that there is no epidemic there traceable to noxious fumes. In common with all towns on that coast, they have had a large fatality from diseases of the respiratory organs (pneumonia, bronchitis, and phthisis), during the months of March, April, and the early part of May. Pneumonia, always very prevalent at Middlesbrough in the spring months, has this year been exceptionally prevalent, and the people of this district have suffered greatly from the east and north winds, the atmosphere this year being for a long time charged with moisture. The population is an iron-working one, and the labour, which is hard, is carried on in a hot atmosphere, which causes free perspiration; resting on the way home the men are prone to get sudden chills, and these circumstances are, in Dr. Malcolmson's opinion, sufficient to account for the exceptional fatality experienced during this, as in previous springs.

HEALTH OF ENGLISH TOWNS.—During the week ending Saturday, May 26th, 4,911 births and 3,201 deaths were registered in the twenty-eight large English towns, including London, which have an estimated population of 9,398,273 persons. The annual rate of mortality, which had been 17.6 and 18.9 per 1,000 in the two preceding weeks, declined again to 17.8 during the week under notice. The rates in the several towns ranged from 10.9 in Birkenhead, 11.6 in Portsmouth, 13.3 in Nottingham, and 15.7 in Derby to 22.8 in Salford, 22.8 in Norwich, 24.8 in Manchester, and 27.8 in Preston. The mean death-rate in the twenty-seven provincial towns was 18.8 per 1,000, and was 2.2 above the rate recorded in London, which did not exceed 16.6 per 1,000. The 3,201 deaths registered during the week under notice in the twenty-eight towns included 285 which were referred to the principal zymotic diseases, against 287 and 330 in the two preceding weeks; of these, 113 resulted from whooping-cough, 38 from diarrhoea, 36 from scarlet fever, 36 from measles, 29 from diphtheria, 25 from "fever" (principally enteric), and 8 from small-pox. These 285 deaths were equal to an annual rate of 1.6 per 1,000; in London the zymotic death-rate was 1.8; while in the twenty-seven provincial towns it averaged 1.4 per 1,000, and ranged from 0.0 in Portsmouth, and 0.5 in Birkenhead to 2.3 in Salford, 2.5 in Nottingham and 2.6 in Wolverhampton. Measles caused the highest proportional fatality in Nottingham and Derby; scarlet fever in Blackburn and Halifax; whooping-cough in Leeds and Salford; and "fever" in Derby and Hull. The 29 deaths from diphtheria in the twenty-eight towns included 19 in London, 2 in Liverpool, and 2 in Norwich. Of the 8 fatal cases of small-pox recorded during the week under notice, 3 occurred in Sheffield, 2 in Preston, 1 in Bristol, 1 in Oldham, and 1 in Hull. The Metropolitan Asylums Hospitals contained only 4 small-pox patients on Saturday, May 26th, and no new cases were admitted during the week. These hospitals also contained 891 scarlet fever patients on the same date, against 91 and 82

at the end of the two preceding weeks; there were 66 admissions during the week. The death-rate from diseases of the respiratory organs in London was equal to 2.8 per 1,000, and was considerably below the average.

HEALTH OF SCOTCH TOWNS.—In the eight principal Scotch towns 860 births and 529 deaths were registered during the week ending Saturday, May 26th. The annual rate of mortality in these towns, which had been 21.1 and 19.3 per 1,000 in the two preceding weeks, rose again to 20.9 during the week under notice, and exceeded by 3.1 per 1,000 the mean rate during the same period in the twenty-eight large English towns. Among these Scotch towns the lowest rates were recorded in Leith and Dundee, and the highest in Glasgow and Perth. The 529 deaths in these towns during the week under notice included 51 which were referred to the principal zymotic diseases, equal to an annual rate of 2.0 per 1,000, which exceeded by 0.4 the mean zymotic death-rate during the same period in the large English towns. The highest zymotic death-rates were recorded in Paisley, Greenock, and Glasgow. The 257 deaths in Glasgow included 13 from measles and 9 from scarlet fever. The mortality from diseases of the respiratory organs in these towns was equal to 4.0 per 1,000, against 2.8 in London.

HEALTH OF IRISH TOWNS.—During the week ending Saturday, May 26th, the deaths registered in the sixteen principal town-districts of Ireland were equal to an annual rate of 23.3 per 1,000. The lowest rates were recorded in Galway and Sligo, and the highest in Lurgan and Drogheda. The death-rate from the principal zymotic diseases in these towns averaged 2.4 per 1,000, and was highest in Wexford, Lisburn, and Lurgan. The 165 deaths registered in Dublin during the week under notice were equal to an annual rate of 24.4 per 1,000, against 23.1 and 23.6 in the two preceding weeks, the rate for the same period being 16.6 in London, and 17.8 in Edinburgh. The 165 deaths included 17 which resulted from the principal zymotic diseases (equal to an annual rate of 2.5 per 1,000), of which 7 resulted from whooping-cough, 5 from scarlet fever, 2 from measles, 2 from diarrhoea, and 1 from "fever."

PENALTY FOR THE SALE OF UNSOUND MEAT.

At Dumbarton Police Court a sausage-maker and butcher was fined £10, with an alternative of 60 days' imprisonment, for having on his premises intended for sale or the manufacture of sausages a quantity of meat which the medical officer of health declared to be in a state of decomposition and unfit for food. When the meat was seized it was about to be cut up for sausages. The full penalty allowed was imposed, and was paid.

PAYMENT FOR ATTENDANCE ON A CASE OF ABORTION.

NOM. DE PLUME asks whether he is entitled to a fee under the following circumstances.

I attended a woman for abortion by an order from the overseer, and had to continue in attendance for about seven weeks, as she suffered from severe *post-partum* hemorrhage. I charged £2 in my half-yearly bill to the guardians, but they say I am not entitled to a fee, as it was an abortion. Of course I am aware that a case of abortion *per se* is not paid for, but I imagined that the long attendance afterwards entitled me to charge £2, as in a difficult labour.

*. "Nom de Plume" has no legal claim upon his guardians, but boards of guardians frequently entertain an application for remuneration under exceptional circumstances.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the first professional examinations in Anatomy and Physiology for the Diploma of Fellow at meetings of the Board of Examiners on May 23rd and 24th, namely:—

Balley, Robert Cozens, St. Bartholomew's Hospital.
 Box, Charles Richard, St. Thomas's Hospital.
 Caley, Henry Albert, St. Mary's Hospital.
 Corner, Albert, St. Bartholomew's Hospital.
 Fawcett, John, Guy's Hospital.
 Fox, Herbert, St. Bartholomew's Hospital.
 Moore, Joseph, St. Bartholomew's Hospital.
 Nall, John Frederick, St. Bartholomew's Hospital.
 Playfair, Hugh James Moore, King's College.
 Ronald, Arthur Edwin, Cambridge and St. Thomas's Hospital.
 Ross, Arthur MacLeod, Edinburgh University.
 Rouillard, Laurent Antoine John, St. Thomas's Hospital.
 Schorstein, Gustave Isidore, Oxford and London Hospital.
 Stevens, Cecil Robert, St. Bartholomew's Hospital.
 Waring, Holburt Jacob, St. Bartholomew's Hospital.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following gentleman has been admitted a Fellow of the College after examination.

H. M. Brabazon, M.B., B.S. Univ. Dub., L.K.Q.C.P.I., Indian Medical Department.

SOCIETY OF APOTHECARIES OF LONDON.—The following gentlemen having passed the Qualifying Examination in Medicine, Surgery, and Midwifery have received certificates entitling them to practise in the same, and have been admitted as Licentiates of the Society.

Ashe, Evelyn Oliver, of the London Hospital.
 Bour, Edouard François, of University College.
 Brett, William George, of Guy's Hospital.
 Gunton, George Andrew, of St. George's Hospital.
 Hughes, Samuel Henry, of St. Bartholomew's Hospital.
 McOscar, John, of the Middlesex Hospital.
 Part, John Shepley, of the Westminster Hospital.
 Williams, William Wilfred, of Guy's Hospital.

The following Licentiates passed the Qualifying Examination for the present Diploma.

Bately, Robert Godfrey, 169, High Street, Gorleston.
 Collier, William Henry, Brook House, Carbrook, Sheffield.
 Key, Augustus Cooper, 30, Wilton Place, Belgrave Square, S.W.
 Langston, John James, Newington, Sittingbourne.
 Smith, Ebenezer Thomas Aydon, 2, Alexandra Road, N.W.
 Stephens, William John, 41, Grand Parade, Brighton.
 Wordley, Alfred William, 8, Great Suffolk Street, S.E.

The following gentlemen passed the Surgical portion of the examination.

P. T. B. Beale, of King's College; W. H. Best, of the London Hospital; C. E. Dodd, of the Liverpool School of Medicine; W. G. Gray, of Belfast; F. Hues, of Queen's College, Birmingham; P. J. Le Riche, of University College; S. L. Melville, of the Liverpool School of Medicine; H. E. Owen, of the London Hospital; M. Tench, of the Middlesex Hospital.

The following gentlemen passed the Medical portion of the examination.

E. C. Masser, of Queen's College, Birmingham; W. G. Sargent, of the London Hospital.

MEDICAL VACANCIES.

The following Vacancies are announced:

BALTINGLASS UNION.—Medical Officer, Dunlavin Dispensary. Salary, £135 per annum, and fees. Applications to Captain Heighton, J.P., Honorary Secretary, Dooard House. Election on June 13th.

BERKS COUNTY ASYLUM, Wallingford.—Assistant Medical Officer as *Locum Tenens*. Two guineas per week, with board, etc. Applications to J. Harrington, Esq., Medical Superintendent.

BOARD OF WORKS FOR THE WANDSWORTH DISTRICT.—Medical Officer for the Parish of Clapham. Salary, £75 per annum, with increase. Applications by June 12th to the Clerk to the Board, East Hill, Wandsworth.

BRECON INFIRMARY.—Resident House-Surgeon. Salary, £100 per annum, with furnished apartments, etc. Applications by June 5th to the Secretary.

BRIGHTON, HOVE, AND PRESTON DISPENSARY.—House-Surgeon. Salary, £140, with apartments, etc. Applications by June 2nd to the Assistant Secretary.

BUCKS COUNTY LUNATIC ASYLUM, Stone, near Aylesbury.—Assistant Medical Officer. Salary, £100 per annum, with board and lodging. Applications by June 8th to the Clerk to the Committee of Visitors, County Hall, Aylesbury.

CARMARTHEN UNION (Conwil District).—Medical Officer. Salary, £80, and also Officer of Health, £18 10s., and vaccination fees. Applications by June 7th to R. Browne, Esq., 5, Hall Street, Carmarthen.

CHILDREN'S HOSPITAL, Birmingham.—Assistant Resident Medical Officer. Salary, £10, with board and lodging. Applications by June 6th to the Secretary.

CHILDREN'S HOSPITAL, Birmingham.—Resident Medical Officer. Salary, £80, with board and lodging. Applications by June 6th to the Secretary.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—Assistant Physician. Applications by June 7th to the Secretary.

DUFFUS PAROCHIAL BOARD.—Medical Officer. Salary, £35. Applications by June 23rd to John Nicoll, Esq., Inspector of Poor, Hopeman, N.B.

FOLKESTONE FRIENDLY SOCIETIES' MEDICAL ASSOCIATION.—Medical Officer. Salary, £150, with fees and unfurnished apartments. Applications by June 6th to the Secretary, 47, St. Michael's Street, Folkestone.

FULHAM UNION.—Resident Medical Superintendent of Infirmary, and Medical Officer of the Union Workhouse. Salary, £350, with residence, etc. Applications by June 5th to the Clerk to the Guardians.

KING'S COLLEGE HOSPITAL.—Assistant-Surgeon. Applications to the Secretary.

LONDON TEMPERANCE HOSPITAL, Hampstead Road.—Surgeon. Applications by June 16th to the Secretary.

METROPOLITAN ASYLUMS BOARD: WESTERN FEVER HOSPITAL, Fulham, S.W.—Clinical Assistant. Board and lodging. Applications to the Medical Superintendent at the Hospital.

MILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich Road, S.E.—Junior Resident Medical Officer. Salary, £30 per annum, apartments, board, etc. Applications by June 9th to the Honorary Secretary.

- NORTH LONDON CONSUMPTION HOSPITAL**, Hampstead and London.—Resident Medical Officer. Salary, £50 per annum, with board and lodging. Applications by June 2nd to the Secretary.
- NOTTINGHAM GENERAL HOSPITAL**.—Resident Surgical Assistant. Board and lodging, etc. Applications to the Secretary.
- OWENS COLLEGE**, Manchester.—Professor of Surgery. Applications by June 9th to the Registrar.
- PARISH OF LOCHS**, Stornoway.—Medical Officer. Salary, £140, house and rates free. Applications by June 23rd to H. McL. Ross, Inspector of the Poor, Lochs, Stornoway.
- PARISH OF ST. MARY ISLINGTON** (Third District, Lower Holloway).—Medical Officer. Salary, £100 per annum, with fees. Applications by June 6th to Edwin Davey, Esq., Clerk, Guardians' Offices, St. John's Road, Upper Holloway, N.
- QUEEN'S COLLEGE**, Birmingham.—Assistant Medical Tutor. Applications by June 20th to the Secretary.
- ROYAL LONDON OPHTHALMIC HOSPITAL**, Moorfields.—Curator and Librarian. Non-resident. Salary, £120. Applications by June 7th to the Secretary.
- ROYAL SOUTH HANTS INFIRMARY**, Southampton.—House-Surgeon. Salary, £100, board, lodging, etc. Applications by June 20th to the Secretary.
- SHEFFIELD GENERAL INFIRMARY**.—House-Surgeon. Salary, £120, with board, lodging, etc. Applications by June 15th to the Secretary.
- SHEFFIELD GENERAL INFIRMARY**.—Assistant House-Surgeon. Salary, £80 per annum, with board, lodging, etc. Applications by June 15th to the Secretary.
- SURREY DISPENSARY**, Great Dover Street, Southwark.—House-Surgeon. Salary, £120, and furnished apartments. Applications by June 19th to the Subcommittee.
- VICTORIA HOSPITAL FOR CHILDREN**, Chelsea.—House-Physician. Honorarium of £50, with board and lodging. Applications by June 2nd to the Secretary.
- VICTORIA HOSPITAL FOR CHILDREN**, Chelsea.—House-Surgeon. Honorarium of £50, with board and lodging. Applications by June 2nd to the Secretary.
- WELLINGBOROUGH AND DISTRICT MEDICAL INSTITUTE**.—Medical Officer. Salary, £280, and fees, with dwelling-house, etc. Applications to G. Bayes, Esq., Jackson's Lane, Wellingborough.
- WESTERN GENERAL DISPENSARY**, Marylebone Road, N.W.—Junior House-Surgeon. Salary, £75, with apartments, etc. Applications by June 4th to the Secretary.
- WESTPORT UNION**.—Medical Officer, Westport No. 2 and Louisburgh No. 2 Districts. Salary, £39 per annum, and fees. Election on June 24th.

MEDICAL APPOINTMENTS.

- ANDERSON**, Douglas H., M.B., C.M.Édin., appointed Assistant Medical Officer to the Hull Borough Asylum, *vice* W. V. M. Koch, resigned.
- BARNES**, W. S., M.D., appointed Supernumerary Surgeon to the Colony of British Guiana.
- BLAKENEY**, J. H., M.R.C.S., L.R.C.P., appointed Resident Surgeon to the Birmingham General Dispensary, *vice* J. H. North, M.R.C.S., L.R.C.P., resigned.
- BEAY**, G. A. T., M.R.C.S., L.R.C.P., appointed House-Surgeon to King's College Hospital.
- BUCKENHAM**, John, L.R.C.P., M.R.C.S., appointed Medical Officer to Her Majesty's Prison, Cambridge, *vice* T. Hyde Hills, Esq., M.R.C.S., resigned.
- CHEATLE**, G. L., M.R.C.S., L.S.A., appointed Assistant House-Physician to King's College Hospital.
- DREW**, H. W., M.R.C.S., L.R.C.P., appointed House-Surgeon to the Croydon General Hospital, *vice* A. Matthey, M.R.C.S., L.R.C.P., resigned.
- HENSLEY**, Arthur E., M.R.C.S., L.S.A., appointed House-Surgeon to King's College Hospital.
- HILL**, W. J., L.R.C.P., M.R.C.S., appointed House-Physician to the Bristol Royal Infirmary, *vice* P. Watson Williams, M.B., M.R.C.S., resigned.
- IRVING**, M. H. C., L.R.C.P. and L.R.C.S.Édin., appointed Supernumerary Surgeon to the Colony of British Guiana.
- JONES**, G. Carleton, M.R.C.S., appointed House-Accoucheur to King's College Hospital.
- ORD**, W. T., M.R.C.S., L.R.C.P., appointed Resident Surgeon to the Birmingham General Dispensary, *vice* S. C. Lawrence, M.R.C.S., L.R.C.P., resigned.
- PENNY**, J., M.R.C.S., L.R.C.P., appointed Assistant House-Accoucheur to King's College Hospital.
- THEOBALDS**, Owen L., M.R.C.S., L.R.C.P., L.S.A., appointed House-Surgeon to King's College Hospital.
- THOMPSON**, T. W., L.R.C.P.Éd. and L.M., M.R.C.S., appointed Medical Officer of Health to the Parish of Barnet, etc., *vice* C. E. Saunders, M.D., resigned.
- WARD**, Howard P., M.R.C.S., L.S.A., appointed House-Physician to King's College Hospital.

THE HOSPITALS ASSOCIATION.—The annual general meeting of the Hospitals Association was held recently at the Westminster Town Hall, under the presidency of Dr. Bristowe. In opening the proceedings, the chairman referred with regret to the resignation of Sir Andrew Clark, who was president of the association, and proceeded to deal at length with the questions of the registration of nurses and the Nurses' Pension Fund. In reference to the first subject, he said it had been found that it was neither feasible nor

acceptable to introduce that system at present. The Nurses' Pension Fund had been subjected to very considerable criticism, with which he dealt at length, and said that the success of the fund depended upon whether nurses could afford to make present sacrifices for the prospective benefits which it offered, and whether the friends of nurses would give adequate assistance in the matter. He based his hopes of its success upon the association of the eleemosynary element with the strictly commercial portion of the undertaking. The contributions of the public to the fund could not be regarded as charity, any more than pensions to those who had rendered public service. It would be disastrous if the fund were to fail. Mr. Henry Burdett, in seconding the motion for the adoption of the annual report, remarked that the question of failure had ceased to be a factor in the history of the National Pension Fund for Nurses, for arrangements had been made to issue 200 policies to nurses in this country, and many more forms of proposal were in process of preparation. One great difficulty they would have to meet in connection with the fund was, that they would have to provide for a number of people who had passed the age at which they could pay at the actuarial rate which would procure them the minimum pension they desired. That difficulty, however, had been met by its being decided to keep faith with the nurses who first registered themselves, and by guaranteeing to any nurse who would consent to give one-eighth of whatever her earnings were, that she should receive a minimum retiring allowance of 10s. a week. Mr. C. W. Sinclair Cox urged that the apathy of the public in reference to the deficiencies in hospital finances was due to the facts and figures not being freely published. Mr. Burdett denied this, and claimed that all the representative London hospitals were willing and anxious to encourage inquiry into all their affairs. The accounts were audited by professional auditors, and as the question affected £500,000 a year, it was desirable that that fact should not be ignored. Formal business was transacted, and the proceedings closed with thanks to the president.

WORSHIPFUL COMPANY OF PLUMBERS.—At the meeting of delegates terminated at Sheffield of the Operative Plumbers' Association of Great Britain and Ireland, ninety-seven of the chief towns of the kingdom being represented, the following resolution was moved by Mr. R. J. Lyne, delegate, Kensington Lodge, London, and seconded by Mr. T. Anderton, delegate, Liverpool:—"That this delegate meeting, having fully considered the system of registration of qualified plumbers established by the Worshipful Company of Plumbers, London, deem it worthy of adoption by the Association as a measure necessary in the interests of the trade and the public; and desire that the Executive Council do take steps to promote the extension of the system throughout Great Britain and Ireland, appointing representatives of the Association to act in the matter." It was supported by delegates from England, Ireland, Scotland, and Wales, and carried. The authoritative expression of opinion in favour of registration embodied in this resolution is the more satisfactory from the fact that the Company's registration system involves the technical training and examination of members of the craft. The decision must, therefore, tend both to the immediate extension of technical training classes for plumbers, and to that ultimate improvement of plumbers' craftsmanship for which there is obvious need in the interests of the public health.

The twelfth annual meeting of the British Medical Temperance Association was held on May 30th at 11, Chandos Street. The annual report showed a further increase in the number both of members and associates who are abstaining students, especially of the latter, who had increased 69 per cent., the total number being 387 members and 187 associates. A report of the result of the republication of the three medical declarations of 1839, 1847, 1871, stated that the first had been signed by 517 practitioners, the second by 526, the third by 537. One had signed the first only, 5 the second, and 22 the third. Names are still being added, and the list will be published when complete. Dr. H. W. Williams read a paper on "The Alcohol Habit and Medical Authority," in which he gave extracts from the published opinions of the two Cheynes, Dr. Beddoes, Dr. Hope, Sir B. Brodie, Dr. Grindrod, Dr. W. B. Carpenter, and Dr. Parkes.

BIRMINGHAM MEDICAL BENEVOLENT SOCIETY.—The report of the sixty-sixth annual meeting of this deserving charity shows the amount of invested funds to be £11,047 2s. 4d. During the year £502 10s. had been expended in grants among seventeen annuitants, the sums ranging between £10 and £40. The roll of

benefit members numbered 284. The financial statement read showed a balance at the disposal of the Society of £11,025 15s. 5d. Sir James Sawyer suggested that out of the Society's income of £600 about £50 should be devoted annually to the relief of distressed medical men not members of the Society. On the proposition of Mr. Lawson Tait, seconded by Mr. C. A. Newnham, it was resolved to request the directors to consider what proportion of the funds of the Society they would recommend as a fund for casual relief. Dr. Warden was elected president, and Dr. Marriott president-elect. Dr. Harvey and Mr. Foster (Knowle) were appointed vice-presidents, Mr. Bartleet and Sir James Sawyer being re-nominated treasurers, and Dr. Savage honorary secretary. Mr. W. P. Whitcombe and Dr. Kennedy were appointed scrutineers, and Mr. T. H. Ranchill auditor. Three directors were balloted for, the result being that Messrs. H. M. Morgan (Lichfield), Priestley Smith, and Lawson Tait were elected.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The report presented to the annual general meeting of the Society, held on May 18th (the President, Sir James Paget, in the chair) showed 330 members; 5 had been elected during the year, 7 had died, and 7 resigned. Sixty-five widows were receiving relief and 8 orphans; 2 widows were admitted in 1887, and 1 had died. The grants for the year had been £2,774, the expenses £225. A legacy of £5,000 had been received from the executors of Sir Erasmus Wilson. The following gentlemen were elected directors in the place of the six seniors, who retired: Dr. Maurice Davis, Dr. Glover, Mr. W. Spencer Watson, Mr. W. A. Brailey, Dr. Matthews Duncan, and Dr. Buzzard. A special grant was made to a widow. A short history of the Society from its foundation in 1788, drawn up by the Acting Treasurer, Mr. Fuller, was presented to the meeting. Some proposed alterations in the by-laws were considered, and a vote of thanks to the President brought the proceedings to a close.

THE HABITUAL DRUNKARDS ACT (1879) AMENDMENT BILL NO. 2 passed a second reading in the House of Commons last week. It may be remembered that No. 1 Bill was withdrawn, owing to the development of opposition from an unforeseen quarter. The second Bill is the practical issue of an understanding with the Home Secretary, and the prospect of its passage through Parliament during the current session is, therefore, hopeful. It provides for a permanent instead of a temporary measure, the original Act expiring next year. It also legalises the appointment of a deputy to the licence of a retreat, under certain time restrictions. If carried as at present drawn the original and the amending Acts will be known by the less objectionable title of "Inebriates Act," following the designation of the South Australian Act of 1874.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION.—The quarterly meeting of this Association was held at Bethlem Hospital on Wednesday, May 16th, at 4 P.M. The meeting, which was numerously attended, was presided over by Dr. Needham. Dr. Maudsley communicated "Some Remarks on Crime and Criminals," which was followed by a discussion, in which Drs. Hack Tuke, Rayner, Fletcher Beach, and Rogers, and Mr. Herbert Stephen took part. A special meeting of the association subsequently took place, at which the subject of Pensions was discussed, the matter being ultimately referred to the Parliamentary Committee.

NATIONAL PENSION FUND FOR NURSES.—The attention of the Council of the National Pension Fund for Nurses having been called to the fact that certain misleading statements have been reprinted from the *Lancet*, and circulated amongst the hospitals throughout the country, the Council announce that they are prepared to supply to the managers, officers, etc., of hospitals, copies of the reply, which has been prepared by Mr. King, the eminent actuary. Applications for copies (gratis) should be made to Mr. P. Grove, Secretary, 33, Old Jewry, London, E.C.

THE COLLEGE OF STATE MEDICINE.—The following gentlemen have been elected as associates of the College: William Henry Burke, M.B., Qual. Stat. Med. Dub. Surgeon Bombay Medical Department; Hugh Herbert Mason, Dip. Pub. Health Camb., Barking, Essex; Colin William McRury, M.D., Dip. Pub. Health Camb., Surgeon-Major Bombay Medical Department; R. R. Harvey Whitwell, M.B., B.Sc. Stat. Med. Edin., Bengal Medical Department; E. E. Stewart Davis, M.B., Qual. Stat. Med. Dub., Madras Medical Department; Allan Macfadyen, M.D., B.Sc. Stat. Med. Edin., Pinner.

HAMILTON AMBULANCE ASSOCIATION.—The annual meeting of the Hamilton centre of the St. Andrew Ambulance Association was held on April 19th, Dr. Loudon presiding. The report stated that, in accordance with the desire of the medical members of the executive, no new classes had been formed in Hamilton during the past session. Classes had, however, been formed in Larkhall, Blantyre, and at North Motherwell Colliery, and the constabulary class had been renewed under Dr. Lindsay, while last summer Dr. Beath conducted a military class. The ambulance waggon had been called out thirty-two times during the past fourteen months.

HOSPITAL SUNDAY FUND.—At the last meeting of the constituents of the fund, the attention of the Council was called to the contrast between the receipts from South London churches and chapels and the awards to South London hospitals and dispensaries, and they were invited to consider what changes, if any, were desirable in the rules for the administration of the fund. The Council had since had the matter under consideration, and had come to the conclusion that it was not desirable to make any departure from the present laws and constitution.

VACANT CORONERSHIP.—Dr. Macdonald, M.P., Dr. Henry Foster Burnes, Dalmaney House, Tufnell Park, and Mr. Eugene Yarrow, Old Street, City Road, are the candidates for the post of coroner for the newly-constituted district of North-East Middlesex.

THE Queen has been graciously pleased to accept a copy of Dr. Thorne Thorne's presidential address to the Epidemiological Society of London "On the Progress of Preventive Medicine during the Victorian Era."

THE Victoria Hospital, Southend, erected as a memorial of the Queen's Jubilee, was opened on Wednesday last by Mrs. Rasch, wife of Major Rasch, M.P.

MEDICAL MAGISTRATE.—Dr. Whitla has been appointed to the Commission of the Peace for Co. Antrim.

DIARY FOR NEXT WEEK.

MONDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 5 P.M.—Professor A. E. J. Barker: On the Operative Treatment of Tubercular Disease in Joints.

ODONTOLOGICAL SOCIETY, 8 P.M.—Mr. F. F. Burghard: On some cases of Epulis. Mr. W. Mitchell: On some Observations on Metal Cap Crowns. Mr. Van Praagh: Casual communications.

COLLEGE OF STATE MEDICINE, Burlington House, 4 P.M.—Professor Klein, F.R.S.: On Bacteriology.

WEDNESDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 5 P.M.—Professor A. E. J. Barker: On the Operative Treatment of Tubercular Disease in Joints.

OBSTETRICAL SOCIETY OF LONDON, 8 P.M.—Specimens will be shown. Dr. Stevenson: An Advocacy for the more Extensive Use of Electrolysis in Gynaecological Practice, with an Addendum by Dr. Lovell Drage. Dr. Gibbons: Electrolysis in some Chronic Uterine Affections, with Illustrative Cases. Dr. John Shaw: The Constant Current in the Therapeutics of Gynaecology.

FRIDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 5 P.M.—Professor A. E. J. Barker: On the Operative Treatment of Tubercular Disease in Joints.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 5s. 6d., which should be forwarded in stamps with the announcement.

BIRTHS.

ALLAN.—On the 24th instant, at 1, Dock Street, London, the wife of Francis J. Allan, M.D., of a son (stillborn).

MOUAT-BIGGS.—May 23th, at Abbey Row, Malmesbury, the wife of C. E. F. Mouat-Biggs, M.R.C.S., L.R.C.P. Lond., of a daughter.

WOOD.—May 29th, at Sunderland, the wife of John C. Wood, L.R.C.S., etc., of a son.

MARRIAGE.

GAILLEY-WARD.—On the 24th instant, at the Parish Church, Leek, by the Rev. Clement C. Ward (brother of the bride), assisted by the Rev. Evans Belcher, Rector of Heather, and the Rev. C. B. Maude, Vicar of the Parish, John Alexander Gailley, M.D., of Leek, to Frances Ann, only daughter of John Ward, Esq., J.P., Southbank, Leek.

DEATHS.

FORD.—On May 27th, at the residence of Dr. Roberts, Avenue Hotel, Peckham Rye, London, Edward M. Ford, L.R.C.P. and L.R.C.S. Edin., aged 87, eldest son of Mr. M. Ford, Nottingham, deeply regretted.

PEMBERTON.—May 25th, at Edgaston House, Birmingham, aged 34 years Harvey, the eldest son of Oliver Pemberton, F.R.C.S. Eng.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY.....10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's (Ophthalmic Department); and Royal Westminster Ophthalmic.—2 P.M.: Metropolitan Free; St. Mark's; Central London Ophthalmic; Royal Orthopaedic; and Hospital for Women.—2.30 P.M.: Chelsea Hospital for Women.

TUESDAY.....9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's; St. Bartholomew's (Ophthalmic Department); St. Mary's; Royal Westminster Ophthalmic.—2 P.M.: Westminster; St. Mark's; Central London Ophthalmic.—2.30 P.M.: West London; Cancer Hospital; Brompton.—4 P.M.: St. Thomas's (Ophthalmic Department); Brompton.—10.30 A.M.: Middlesex.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: St. Thomas's; University College; Westminster; Great Northern Central; Central London Ophthalmic.—2.30 P.M.: Samaritan Free Hospital for Women and Children; St. Peter's.—3 to 4 P.M.; King's College.

THURSDAY.....10.30 A.M.: Royal London Ophthalmic.—1 P.M.: St. George's.—1.30 P.M.: St. Bartholomew's (Ophthalmic Department); Guy's (Ophthalmic Department); Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Central London Ophthalmic; Hospital for Diseases of the Throat; Hospital for Women.—2.30 P.M.: North-West London; Chelsea Hospital for Women.

FRIDAY.....9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.15 P.M.: St. George's (Ophthalmic Department).—1.30 P.M.: Guy's; Royal Westminster Ophthalmic.—2 P.M.: King's College; St. Thomas's (Ophthalmic Department); Central London Ophthalmic; Royal South London Ophthalmic; East London Hospital for Children.—2.30 P.M.; West London.

SATURDAY.....9 A.M.: Royal Free.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: King's College.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Middlesex; Royal Free; Central London Ophthalmic.—2.30 P.M.: Cancer Hospital, Brompton.

HOURS OF ATTENDANCE AT THE LONDON HOSPITALS.

CHARING CROSS.—Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; Skin, M. Th., 1.30; Dental, M. W. F., 9.

GUY'S.—Medical and Surgical, daily, 1.30; Obstetric, M. Tu. F., 1.30; Eye, M. Tu. Th. F., 1.30; Ear, Tu. F., 12.30; Skin, Tu., 12.30; Dental, Tu. Th. F., 12.

KING'S COLLEGE.—Medical, daily, 2; Surgical, daily, 1.30; Obstetric, Tu. Th. S., 2; o.p., M. W. F., 12.30; Eye, M. Th., 1; Ophthalmic Department, W., 1; Ear, Th., 2; Skin, Th., Throat, Th., 3; Dental, Tu. F., 10.

LONDON.—Medical, daily, exc. S., 2; Surgical, daily, 1.30 and 2; Obstetric, M. Th., 1.30; o.p. W. S., 1.30; Eye, W. S., 9; Ear, S., 9.30; Skin, Th., 9; Dental, Tu., 9.

MIDDLESEX.—Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; o.p. W. S., 1.30; Eye, W. S., 3.30; Ear and Throat, Tu., 9; Skin, Tu., 4; Dental, daily, 9.

ST. BARTHOLOMEW'S.—Medical and Surgical daily, 1.30; Obstetric, Tu. Th. S., 2; o.p. W. S., 9; Eye, Tu. Th. S., 2.30; Ear, Tu. F., 2; Skin, F., 1.30; Larynx, F., 2.30; Orthopaedic, M., 2.30; Dental, Tu. F., 9.

ST. GEORGE'S.—Medical and Surgical, M. T. F. S., 1; Obstetric, Tu. S., 1; o.p. Tu., 2; Eye, W. S., 2; Ear, Tu., 2; Skin, W., 2; Throat, Th., 2; Orthopaedic, W., 2; Dental, Tu., S., 9, Th., 1.

ST. MARY'S.—Medical and Surgical, daily, 1.45; Obstetric, Tu. F., 1.45; o.p. M. Th., 1.30; Eye, Tu. F. S., 9; Ear, M. Th., 3; Throat, Tu. F., 1.30; Skin, M. Th., 9.30; Electrician, Tu. F., 2; Dental, W. S., 9.30; Consultations, M., 2.30; Operations, Tu., 1.30; Ophthalmic Operations, F., 9.

ST. THOMAS'S.—Medical and Surgical, daily, except Sat., 2; Obstetric, M. Th., 2; o.p. W., 1.30; Eye, M. Th., 2; o.p., daily, except Sat., 1.30; Ear, M., 12.30; Skin, W., 12.30; Throat, Tu. F., 1.30; Children, S., 12.30; Dental, Tu. F., 10.

UNIVERSITY COLLEGE.—Medical and Surgical, daily, 1 to 2; Obstetrics, M. Tu. Th., F., 1.30; Eye, M. Tu. Th. F., 2; Ear, S., 1.30; Skin, W., 1.45, S., 9.15; Throat, Th., 2.30; Dental, W., 10.30.

WESTMINSTER.—Medical and Surgical, daily, 1.30; Obstetric, Tu. F., 3; Eye, M. Th., 2.30; Ear, M., 9; Skin, Th., 1; Dental, W. S., 9.15.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS respecting editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

In order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the office of the JOURNAL, and not to his private house.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL, are requested to communicate beforehand with the Manager, 429, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication. CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

QUERIES.

M.D. asks what has been ascertained to be the effect of cascara sagrada upon the secretion of milk, as to quantity and quality.

ANSWERS.

INQUIRER.—It is certainly not unprofessional.

INUNCTION IN SCARLET FEVER.

In answer to "Micrococcus" as to the value of inunction in scarlet fever, Mr. FRANCIS W. CLARK (Croydon) writes that the preparations of olive oil and carbolic acid, known as "carbolic oil," have been proved to possess no germicidal action. Should "Micrococcus" wish to use a germicidal inunction during the desquamative stage of the disease, he suggests that a preparation of olive oil containing about one drachm of ol. menth. pip. to the twelve-ounce bottle, would probably prove efficacious in destroying any parasitic virus that might be contained in the epidermic scales.

MR. JNO. BROWN (Bacup) writes: In the JOURNAL for August 13th, 1887, there is a short article on The Prophylactic Advantages of the Early and Continued Inunction of Carbolic Oil in Scarlet Fever. If "Micrococcus" will refer to it, he will see the rationale given for the use of carbolic acid.

THE USE OF APERIENTS IN SCARLET FEVER.

MR. JNO. BROWN (Bacup) writes: In reply to Mr. Davis's query, "Am I right or wrong?" in giving aperients before or during the eruptive stage, I should say as a rule it is not safe. For years I have been convinced that to give aperients is, as Mr. Chavasse states in his book, "dangerous before and during the eruptive stage." Keep the bowels confined until the rash is well out. Cases in which diarrhoea is induced by aperients often die of convulsions due to suppression of the rash. In other cases the rash comes out tardily, and the recovery is longer than usual.

CHEMICAL CONSTITUTION OF MINERAL WATERS.

SURGEON asks where he can find the best information as to the chemical composition of the mineral waters most generally in use.

* * * The Mineral Waters of Europe, by Tiehborne and Prosser James, is probably the handiest work, giving more detailed analyses than more general works.

OCCIPITAL HEADACHE.

DR. JOHN IRVING (Leytonstone) writes: If "M.R.C.S., L.R.C.P." will give his patient a large dose of quinine every night at bedtime, and follow it in the morning by a saline tonic, as indicated in the subjoined prescriptions, relief may result in a few days.

R Quinine sulphatis ʒij; acid hydrobromici dil. ʒiij; aq. ad ʒvj. M. ʒij ex aqua nocte sumat. R Magnesie sulphatis ʒvj; acid. sulphurici dil. ʒj; liq. strychnin. mur. ʒxx. Aq. ad ʒvj. M. Capiat unciam ex aqua mane ante cibum.

MR. J. BRINDLEY JAMES (Brindley House, Jamaica Road, S.E.) writes that in the treatment of this form of headache he had vainly exhausted all the habitually recommended pharmacopoeial remedies, until the introduction into official rules of Bishop's effervescent hydrobromate of caffeine, the use of which in such cases he speedily learned to appreciate.

NOTES, LETTERS, ETC.

HIGH ALTITUDES IN CONSUMPTION.

DR. C. R. DRYSDALE (late Physician to the North London Consumption Hospital, etc.) writes: The question of the best climate for patients suffering from consumption is so extremely interesting, that I should feel obliged if allowed to take part in the debate upon it. After trying all sorts of climates, and being fully cognisant of the admirable results obtained either at the Riviera, at Algiers, or Egypt, or by sending patients to Australia, New Zealand, or the Cape and back, I must say that experience teaches me that the most rapid arrests of that dangerous disease have occurred in such persons as have been able to reside a considerable time in stations such as Davos or Colorado. It is out of the question to ask you to afford space for the narrative of cases. I would only say that I naturally, as physician for many years to the North London Consumption Hospital, took the greatest interest in following out the careers of the poor patients that came under my care there. Their fate was usually a sad one; and the very first case I remember which was sent to Colorado made such an impression on me as to the value of residence in high altitudes, that I have never forgotten it. Subsequent experience has corroborated that impression; and, for my part, I should, in all suitable cases, advise patients to try high altitudes in preference to other climates. On a visit I made to Davos two years ago, I interrogated the peasants in the adjacent valley at Langwies, and found that consumption was not a cause of death among the people who reside there.

A SIMPLE MEANS OF DIAGNOSIS IN CHEST-DISEASES.

MR. S. BINGHAM writes: I can fully endorse the remarks of Surgeon F. F. Nichols relative to the value of using a syringe to determine the existence of fluid in the chest. Only recently, by the aid of an ordinary hypodermic syringe, I demonstrated its presence in the pleura of a patient in whom it had been previously overlooked. The value of this method was shown to me many years ago, while assisting Dr. Robert Macnab, of Bury St. Edmunds; and Dr. Douglas Powell, in his work on Diseases of the Lungs, points out its utility.

TEA AND TEETH.

DR. JOHN IRVING (Leytonstone) writes: A. B., with whom the writer is intimately acquainted, subsisted, until he was 28 years of age, upon the plainest diet, and drank no beverage other than milk or water. Neither tea, coffee, cocoa, nor alcohol ever tempted him; nevertheless, from 17 to 28 he was a martyr to toothache, and during that period had no less than eight decayed teeth extracted. Since then he has employed tea in moderation (two cups per diem), for social reasons, and for six years, though dental decay continues to advance, actual toothache has been much diminished. His mother lost most of her teeth in early life, and almost in the same order as the son, the upper molars and bicuspids going first. The father, on the other hand, never knew what toothache was until he was 45 years of age, but within ten years nearly

THE CAVENDISH LECTURE ON THE ALTERED RELATIONS OF SURGERY TO MEDICINE.

Delivered before the West London Medico-Chirurgical Society,
Friday, June 1st, 1888.

By SIR WILLIAM STOKES, M.D., CH.M.UNIV.DUB., F.R.C.S.I.,
Professor of Surgery, Royal College of Surgeons in Ireland.

No one having even a limited acquaintance with surgical history can fail to realise the great change that has recently taken place in the status of the surgical branch of our profession, as well as the remarkable alteration that has occurred in the relations it now bears to medicine.

In considering the important question as to the causes that have led to these changes, we may glance briefly at the relations that formerly existed between surgery and medicine. The two branches of our common profession became united in the first half of the fifteenth century, and a conjoint examination for admission to the fellowship of physicians and surgeons was established.¹ Unhappily, however, the alliance appears to have been a short-lived one, and the causes that led to the rupture are not very clearly understood, but were, I believe, probably connected with the maintenance of alleged vested rights. The breach was still further widened by the subsequent fusion of the surgeons with the Barbers' Company. In this, however, as Sir James Paget has rightly observed, there was not any real fusion, but rather an official junction with a view to the settlement of disputes and the fixing of limitations to the duties and functions of each company.

In the interests not only of the social but also of the scientific position of the surgical profession, the junction, such as it was, of these two corporations was undoubtedly a calamity, and it helped to give the physicians the vantage ground which they occupied so long, and in which they were still further strengthened by an enactment made in Elizabeth's reign, prohibiting surgeons from prescribing internal medicines. As a proof that the inferior position, socially and scientifically, was maintained up to a comparatively recent period, I may mention a fact which I learned from Mr. Colles, who informed me that his father, Abraham Colles, had stated that at the commencement of his professional career in Dublin, when a consultation on any important case was held, the surgeon was not, as a rule, permitted to be in the room where the physicians held their deliberations, but, after the consultation was over, he was informed whether his services would be required or not.

The junction not only kept the professions of surgery and medicine separated, but also doubtless had much to say to the long exclusion, or, at all events, feeble recognition of surgery in the academic systems of the old universities. It had also another unfortunate result, which was, that when surgery emerged from the Cimmerian darkness in which it had been during the Middle Ages, and its teachers began to recognise the fact that in order to advance something more was to be relied on than the aphorisms of Hippocrates or the dogmas of Galen, there was little sympathy shown to them, and scientific methods of investigation were looked upon generally with suspicion, while the results of scientific research were received almost with contempt.

Although from time to time during the sixteenth and seventeenth centuries there were physicians of undoubted ability and scientific aptitude, still no serious effort apparently was made by the bulk of the profession to strike away the feeble props of the tottering and antiquated tripod on which it had so long rested—namely, empiricism, dogma, and aphorism. The result of this was that as time went on, medicine as a science lost instead of gaining ground in public estimation, and often became the object of satire and ridicule. Of this ample evidence may be found in the writings of many authors and philosophers of eminence, such as Voltaire, Molière, Locke, and many others in more recent times. It was doubtless from observing the faulty way in which medicine

was studied and practised that Locke was induced to make the following observation: "Were it my business to understand physic, would not the safer way be to consult Nature herself in the history of diseases and their cures than to espouse the doctrines of the dogmatists, the methodists, or the chemists?"

What was mainly relied on was clinical observation; and nothing is more remarkable in the whole history of medicine than the length of time it took before the fact dawned upon the medical mind that clinical observation, when not supplemented by other scientific methods of research, is a lamp that affords in truth but a faint and glimmering light, a shifting quicksand on which it is indeed perilous to build. They did not recognise the truth epitomised by Mill, who has well said, "Observation without experiment (supposing no aid from deduction) can ascertain sequences and coexistences, but cannot prove causation." (*Logic* vol. i, p. 423).

The consequences of too exclusive a reliance upon methods insufficient for purposes of real advancement have been for medicine in the past most unhappy. I allude more particularly to the foundation and advocacy of various systems which prevailed at different eras—of, for example, the dogmatists, eclectics, methodists, pneumatists, astrologers, and alchemists, and in later times to the schools of Cullen, Brown, Broussais, and Hahnemann. All these many outcomes of various phases of opinion have caused the history of medicine to be rather "a succession of cycles, barren hypotheses, and fanciful systems," than one characterised by a slow but sure scientific progress. At rare intervals in its history brilliant meteors, no doubt, have flashed across the sky, but their light only tended to make the darkness more visible. They were too far in advance of their time to make their influence felt, and any attempt to supersede the older unreliable methods—to ring out the old and ring in the new—only met with discouragement, often with contempt. My father has often related to me how, when he was a young man, and when he introduced into the Dublin school, along with Graves, the methods of physical diagnosis advocated by Laennec and Louis, he was ridiculed, satirised, and even caricatured by his contemporaries. I dare say a large proportion of those present here to-day recollect, as I do, hearing various instruments of precision, now in the hands of every educated practitioner, stigmatised as "toys;" and I can even call to mind that a late medical colleague of my own, who rose to considerable eminence in his profession, and who, for the time he lived in, was a skilful histologist, thought it desirable to publish, at the commencement of his professional career, a *brochure* which he entitled *An Apology for the Microscope*. But one of the most signal proofs of the low estimate that in former times physicians had of the employment of methods of research now universally used may be obtained from the views on pathological histology of Laennec. He observed: "If the causes of severe disease are sought for in mere microscopical alterations of structure, it is impossible to avoid running into consequences the most absurd, and, if ever cultivated in this spirit, pathological anatomy, as well as that of the body in a sound state, will soon fall from the rank which it holds among the physical sciences and become a mere tissue of hypotheses founded on optical illusions and fanciful speculations, without any real benefit to medicine." An unfortunate anticipation, Dr. Hudson observed, as time and progress have proved. When men of the intellectual grasp of Laennec held such views, it is hardly to be wondered at that the rank and file among physicians continued to look unfavourably and with doubt on all such novel methods of research, and under these circumstances it is not surprising that medical therapeutics in the past, and I fear to a certain extent also in the present, has been based too often on that flimsiest and most worthless of all foundations—fashion: a fact which doubtless suggested to the eminent French physician the sage advice he gave to his pupils, "Employez vite ce remède pendant qu'il guérit encore!"

In making these remarks I trust it will not be considered that I wish in any way to cast discredit on the labours of past physicians in the advancement of medicine, knowing as I do that the very men who were thus sceptical of new methods could always point with just pride to splendid results obtained by them from time to time.

My object is only to account for the fact that in the last century the relations between medicine and surgery were still deficient in cordiality. Old antagonistic traditions and feelings survived, and the breach was only widened for the time by the new departure of surgery into hitherto untried methods of advance, by the renunciation of the exclusive reliance on mere

¹ See *Memorials of the Craft of Surgery in England*. From Materials compiled by J. F. South. London, 1836.

clinical observation, and by a general widening of the area of research.

And to whom are we mainly indebted for such development? This is a question that will at once be asked. Who placed our science on the solid foundation on which it remains and will ever rest? Who was it that tore asunder the fetters with which it was bound by a blighting empiricism, and loudly sounded those clarion notes of scientific truth which have their echo still. He who occupies as a biologist a position above all rivalry, and who by the magic wand of an all-powerful intellect struck the rock from which came the living water, and evoked the dormant scientific spirit of his age—that beneficent, ever-living, and never-failing spirit which, when honestly appealed to, has ever generously responded. It has been said by Malgaigne that in the Middle Ages surgery was a mere craft, that it was made an art by A. Paré and J. L. Petit, but was elevated into one of the noblest of sciences by John Hunter. Animated by no unworthy craving for worldly honour or love of gain, he lit up the dark and rugged paths of that science he loved so well and to which he devoted his life with a lamp which shed no borrowed light—one fashioned by ceaseless toil and illuminated by untiring genius. His one aim, the goal he ever strove for, the ambition of his life, was, in the unexplored regions of physiology, surgery, pathology, and anatomy, to unfurl the banner of truth, and, by doing so, to elevate and dignify the profession of his choice, and to render it and its sister branch of medicine one and indivisible. He was in truth—

One of the few, Nature's interpreters,
The few whom Genius gives as lights to shine.

His immediate successors, many of whom were also his pupils—namely, Abernethy, Cooper, Cline, Dupuytren, Colles, and many lesser stars—all worked more or less on the same lines that he did, but not unnaturally with a bias rather towards the clinical and operative aspects of surgery and surgical pathology than in efforts to advance it by physiological research. But the splendid work of those great surgical leaders I have mentioned cleared and prepared the way for the more complete adoption of Hunter's great principle in advancing surgery, which was, in Sir James Paget's words, that "he brought the scientific method into the study of the practice, and welded scientific knowledge with the lessons of experience." It is the recognition and adoption of this principle in the age in which we live and work that will ever constitute one of its greatest glories. It is one which finds its embodiment in Von Langenbeck's watchword, "From physiology to surgery, and from the microscope to the resection knife." It has mainly been the cause of bringing about the altered relations of surgery to medicine, and happily shattered the barriers between them which in days gone by were such fruitful sources of mischief, and kept our profession divided, powerless, and weak.

The last and most brilliant outcome of the adoption of this principle has been the establishment of Listerian antisepticism, which has enabled the surgeon to bring about not only a degree of perfection and exactness in the comparatively limited field of operative surgery in which until recently he confined himself, but also to advance much further, and in abdominal and thoracic diseases, and, lastly, in those of the brain and spinal cord, to achieve results that until recently never could have been seriously contemplated. This signal advance into the domain of medicine has not been made in any hostile and intrusive spirit, but solely to render aid—an aid which it must be gratefully acknowledged has happily often been reciprocated.

It has been granted to but few men who have been pioneers in any of the paths of science to have during their lifetime a full recognition of their labours and discoveries, and to see the practical application to human requirements of the new knowledge they had given to the world. Harvey's great discovery met with but a limited acceptance during his lifetime, and the same might be said of other scientists, some of whom, instead of having their views accepted, were persecuted for promulgating them; but many of those who now constitute the scientific vanguard of our profession have been privileged to witness not alone the acceptance of their theories but also the almost universal recognition of the utility of the practice which has been based thereon; and operative procedures have been undertaken and carried to a successful issue that not very long ago could never have been seriously thought of; and, lastly, a distinct advance has been made towards that goal desired by all—unity in the science of medicine.

I have already indicated the regions in which operative surgery

has so largely supplemented medicine. Did time permit, I would gladly dwell more in detail on what it has effected in this direction, such as the surgical treatment of pulmonary abscess, antiseptic paracentesis in pleuritic effusions, empyema, and pericardial effusion. Also in abdominal surgery, including exploratory operations in and excision of the kidney, removal of renal calculi, operations on the gall-bladder, on the intestines for obstruction, excision of the pylorus and other portions of the intestinal tract for cancer, and the many operations connected with the female organs of generation.

In connection, however, with a region that until recently has been held to be the exclusive province of the physician, I should like to speak very briefly. I allude to certain lesions of the brain, and the means we have at our disposal for their localisation. It is a subject of absorbing interest, and exercises largely, as you all know, the professional mind at the present day. There is no wonder that it should do so, for our anticipations as to what may eventually be done in this direction are full of hope and confidence. Having regard to the results already obtained, these are not, I feel assured, misplaced; but still cases do occur, and one of them was recently in my own practice, which strikingly bring home to us the undoubted and unhappy fact that, notwithstanding the admirable work achieved by Professors Ferrier, Yeo, Schäfer, Victor Horsley, Munk, Goltz, and others, in reference to the localisation of brain function, we must admit that we are still only on the fringe of the inquiry, so to say, and that much, very much, has yet to be done before any definiteness can be said to exist in the means at our disposal for the accurate appreciation of many of these cases. This will not, I believe, be determined with sufficient accuracy until much more light than is at present available is thrown, not only on cranio-cerebral topography, but also on the localisation of cerebral function. We are undoubtedly much nearer finality in the former than the latter, although the difficulties in the path are still extreme. The relations between the lobes and convolutions of the brain and the enveloping bones vary in different periods of life, and up to a certain age the growth and development of both do not proceed *pari passu*. The frontal eminence, as Cunningham, Topinard, and Péré have shown, overlies a different portion of the frontal lobe of the brain in the adult and the child, and the relations between the Sylvian fissure and the squamo-parietal suture, as first noticed by Foulhouze, also vary in different periods of life. Remarkable changes in the temporo-sphenoidal lobe have also been observed, both as regards its position and form, as age advances from childhood to adolescence. For example—as may be seen in these preparations—in the adult the frontal eminence corresponds to the first frontal fissure; in childhood the frontal eminence is found at some point upon the second frontal convolution, and occasionally on the third. Again, the Sylvian fissure varies in relation to the squamo-parietal suture. In the adult it may correspond to it or be placed immediately above or slightly below it, but in childhood it is always found considerably above it. The high position of the fissure in childhood appears to be due to a twofold cause—one, to the low stature, if I might so express it, of the squamous portion of the temporal bone, which afterwards grows upwards towards the fissure; and secondly, that at the earlier period of life there is relatively a much greater area of the temporo-sphenoidal lobe in relation to the vault of the cranium. This is seen when compared with the outer surface of the parietal lobe. The method of topographical localisation when the relations are more fixed or constant, as in adult life, suggested by Hare, gives for practical purposes undoubtedly the best and most accurate results.

As regards the localisation of function, however, it is regrettable that even between very high authorities so much difference of opinion exists, and that the whole subject is consequently in such an unsettled state. Take, for example, the temporo-sphenoidal lobe. According to Professor Ferrier we have here the situations of tactile sensibility, hearing, and taste, whereas Professor Schäfer holds that none of these are so placed. Again, the centre of sight has been localised by Munk and Schäfer in the occipital lobe, but Goltz has shown that this lobe can be removed without impairing vision, and that removal of the frontal lobe is attended with loss of sight.

Our clinical experience, too, at times adds largely to the difficulties we have to contend with in our endeavours to accurately appreciate the situation of cerebral lesions. I allude to cases in which we have motor disturbance without appreciable lesion to account for it, and the reverse, cases in which morbid conditions,

profoundly involving the motor areas, exist without causing any motor or sensory trouble whatever. In illustration of this, I may mention the leading particulars of a few cases, and in doing so trust it will not be supposed for a moment that I wish to depreciate or detract in the slightest degree from the great value of recent investigations in reference to the localisation of cerebral function.

The first of them that I would mention was one which was quite recently under my care in the Richmond Hospital, and was of exceptional perplexity. J. O'D., aged 40, a law clerk by occupation, and for many years of intemperate habits, was recently under my care in the Richmond Hospital. Two days previous to his admission he had been drinking to excess in a neighbouring public-house, and, for making a disturbance on his way home, was arrested. In the encounter which ensued with the authorities, it was said he was struck with a baton on the forehead, over the left eye. He was stunned by the blow but soon recovered. On the second day after receiving the blow he suffered pain, which was chiefly referable to the forehead, and in the evening he became heavy and drowsy. The day following he was aphasic, and he was then brought to the hospital. On his admission, a contused wound was found over the left eyebrow, and much subconjunctival ecchymosis. When speaking he was unable to form a complete sentence, failing generally to find the required verb. When the word he wanted was suggested to him he at once recognised it, but was unable to repeat it. He conveyed that he could remember the word he wanted easily, but could not say it. When shown a watch he was able to tell the time accurately and without hesitation, but when asked to write a sentence he failed, and wrote some disjointed words, but was able to write his name. In the evening the aphasia was more pronounced. He could tell the name but not the address of his employer. He said it was the same as a Christian name. On going through a list of names, he at once recognised the one he wanted when "George's Street" was mentioned. There was no paralysis at this time of the upper or lower extremities. Next day it was found that speech was completely lost. There was rigidity of the muscles of the jaw, and he was quite unable to open his mouth. The left forearm and hand were paralysed, and fingers clenched. The scapulo-humeral muscles on the left side were only slightly affected. He could grasp firmly with his right hand. The left pupil was irregularly dilated, and did not react to light. Vision was lost in it, and there was slight ptosis. When given a pencil and paper he could write his name, but very indistinctly. Patellar and plantar reflexes were well marked. The day following his condition was worse. In the evening he had an alleged rigor, which probably was a convulsive seizure. Next day all the symptoms were still more pronounced. The patient was now in a semi-comatose state, jaws rigidly closed, his respiration blowing, accompanied by constant grinding of teeth. Throughout his condition was perfectly apyrexial.

With such a history and train of symptoms, the conclusion was unavoidable that they were produced by mechanical pressure. The patient, who had never before manifested symptoms of brain disease, had received a severe blow on the left side of the head. This was followed by progressive motor aphasia, an irregularly dilated pupil, loss of vision, subconjunctival ecchymosis, ptosis, blowing respiration, rigidity of the muscles of the jaw, paralysis of the left forearm and hand, a convulsive seizure, and, lastly, coma. These symptoms seemed to clearly point to mechanical surface-pressure over the left motor area, over or in the neighbourhood of Broca's convolution, followed by basic complication, as evidenced by the implication of the third and fifth pair of nerves, producing the symptoms referable to the eye and the muscles of the jaw; and lastly, there was paralysis of the forearm and hand, which latter was the great difficulty in the case. The pressure, either hemorrhagic or inflammatory, I believe primarily involved Broca's lobe, and the basic complications I considered were probably due to extension of the effusion.

Having regard to the fact that the patient was clearly *in extremis*, and that trephining gave him what might be termed the shadow of a chance, I operated and removed a disc of bone over Broca's lobe, and the result being negative, I removed another a little further back. Neither operation revealed a source of pressure. The patient died the next morning, and the result of the necropsy was as negative in its results as the operation had been. There was neither hæmorrhage nor abscess; the brain substance was whiter and harder than normal, the condition observed so often in alcoholism. The only tangible changes observed were evidence of arachnoid inflammation, which was all the more re-

markable, having regard to the apyrexial condition of the patient throughout, and also a thickening and adhesion of the meninges over the upper portion of the right motor area, which presented no signs of recent development, and under which was a small patch of softening about the size of a large pea. A careful examination of the cerebral vessels failed to give evidence of the existence of embolism.

In this most remarkable and exceptional case, in which so many of the symptoms of cerebral pressure supervened on the receipt of a severe injury, it was, indeed, as surprising as it was disappointing to find that they depended on some condition independent of mechanical pressure, and it proves how far we are still, even when the symptoms are signal and pronounced, from being able in many instances to correctly estimate the phenomena in cases of cerebral lesion, and especially in those having apparently a traumatic origin.

Dr. Bennett has drawn attention to a remarkable case of monocrural paralysis, which was under the care of a disciple of Professor Ferrier, and the site of the supposed central lesion was carefully indicated on the skull. Subsequently the patient was under Dr. Bennett's care for epileptic seizures, which ultimately proved fatal, and which were attributed to renal disease. Having regard to the monocrural paralysis, a careful *post-mortem* examination was made, but without discovering any evidence of a lesion either of the brain or its coverings.

We have, too, on the other hand, cases recorded in which there has been marked intracranial disease invading the motor zones, but without producing any motor disorder, as, for example, in the remarkable case of subarachnoid cyst recorded by Professor Cunningham (*Journal of Anatomy and Physiology*, vol. xiii, p. 508). In this case the cyst—one of exceptionally large dimensions—was limited in front by the Rolandic fissure, below by the parallel fissure, above by the intra-parietal fissure, and posteriorly it reached the occipital lobe—and yet in this case there was no evidence whatever of impairment of motor or sensory power. Another case illustrative of the fact that serious lesions, involving the motor area, may exist without producing paralysis, is one recorded by Dr. Byrom Bramwell. In this a large sarcoma, growing from the dura mater, "had apparently destroyed the greater part of the motor area on the right side. So far as one could judge with the naked eye, the whole of the motor centres in the face and upper extremity were destroyed, and on microscopical examination the grey matter in this region seemed to have completely disappeared; and yet there was absolutely no paralysis" (*JOURNAL*, April 21st, 1888).

From these interesting but somewhat dispiriting facts—which, unhappily, remind us of the dense mist in which we are still surrounded—let us glance at the brighter side of the picture, and consider some of the cases that give us encouragement and tend to restore confidence.

The first I would allude to are four cases of subcranial hæmorrhage, which have recently occurred in Dublin, and for which the operation of trephining was performed. In all four cases the condition was correctly diagnosed, and in three of them the hæmorrhagic effusion was reached and removed, and the treatment followed by immediate relief and ultimate recovery.

Two of these cases presented features of exceptional interest. In the first, which was under the care of my colleague, Mr. Thornley Stoker, the patient had sustained a fall off a cart nine days previous to the operation, and was, at the time of its performance, in a state of complete left hemiplegia, was comatose, and the respirations 12 per minute. The diagnosis which was made, and proved afterwards to be correct, was that hæmorrhage over the right motor area, due to laceration of the middle meningeal artery, and probably associated with fracture, had occurred and produced at first partial left paralysis, and that the increased hemiplegia which subsequently occurred was due to renewed hæmorrhage. Trephining was performed over the fissure of Rolando, and the hæmorrhagic effusion reached and successfully removed; this was promptly followed by relief, and an uninterruptedly good recovery was made. This case is of special interest in one particular, being signally illustrative of the doctrine of Ferrier, that the absence of anesthesia is, in such cases, indicative of the lesion being limited to the motor zone, and the brachial monoplegia also pointed to this alone being implicated.

The second case, which was under Mr. Ball's care, was one of motor aphasia, which came on after the patient had received a blow on the head with an open penknife ten days previous to his coming under observation. The cicatrix of the wound was

over the squamous portion of the temporal bone. There was an absence of any paralysis of the voluntary muscles, but the aphasia was distinct and progressive, both word-blindness and word-deafness being well marked. Trephining was performed, and the wound was found to be a penetrating one, involving both bone and dura mater, and a small subdural blood-clot was removed, which, it was believed, was situated in the Sylvian fissure. The recovery in this case was complete. In a third case of subcranial hæmorrhage, which Mr. Thomson has recorded, the operation of trephining and the removal of an epidural blood-clot was attended with an equally satisfactory result.

As a remote result of intracranial hæmorrhage another case, which was under the care of Mr. Kendal Franks, is noteworthy. The patient was a young man, aged 25, who commenced to suffer from severe epileptic seizures six years after he sustained a fall on the top of his head from a height of nine feet, and was treated by bromides continued without intermission for over a year, but without influencing the attacks, except occasionally to lengthen the interval between them. Trephining was performed, and a subdural blood-cyst, pressing on the left frontal lobe of the brain, was discovered. The cyst was then cleared out and drained. Immunity from the seizures for three months was the result; there was then a recurrence of them, but they were much slighter than before. A second trephining was then performed, and although the result of this was negative as regards disclosing anything further to cause cerebral disturbance, the condition of the patient since the operation has been most satisfactory, and he is now apparently free from the attacks which formerly were of such frequent occurrence.

In two cases of traumatic cerebral abscess—one epidural and the other subdural, and both of them illustrative of the pathological fact first noticed by Dease as to the late appearance of cerebral trouble after cranial traumatism—I trephined, and in one of them the result was very remarkable. The operation was performed seven weeks after the injury, which was a blow over the left temple. At the time the operation was performed the patient was clearly in *extremis*—motor and sensory paralysis complete, and coma, following convulsive seizures, profound. On raising a disc of bone at the situation where the injury was received no pus was to be seen, and on laying open the dura mater the result was equally negative. I then passed the needle of a hypodermic syringe into the brain substance as far as it would go, and to my great satisfaction found, on drawing up the piston of the instrument, that I had reached the abscess. I removed an ounce and a half of pus, and then washed out the cavity with a weak carbolic solution. The relief obtained by the evacuation of the abscess was immediate, and before the patient left the operating theatre he was able to articulate distinctly. His recovery was rapid and uninterrupted, and he returned to his usual avocation, which was that of a plasterer. As regards the situation of the trephine opening, I may mention that it was three quarters of an inch to the left of the mesial line, and an inch in front of the coronal suture. It corresponded to a point close to the junction of the supero- and meso-frontal convolution. After evacuating the contents of the abscess cavity, in order to ascertain the size and direction of the latter, I passed the little finger of my left hand cautiously into it. By doing so I was able to ascertain its limitation anteriorly, laterally, and inferiorly. Externally and inferiorly its limitation must have been formed by Broca's lobe, but posteriorly and inferiorly, although I passed my little finger in as far as possible, the limit of the cavity was not reached, and I believe the abscess possibly involved the lateral ventricle.

The final outcome of this remarkable case, if disappointing, is of much interest. For nearly nine months after the operation the patient remained perfectly well, and quite able to follow his usual avocation. It was then stated that he got a "fit," from which he recovered, and he returned the following day to his work. The morning after this he was found in bed in a state of complete insensibility, and he was then brought for the second time to hospital. Right hemiplegia was complete, and both plantar and patellar reflexes lost; his face was pale, but lips deeply cyanosed. Pulse 160; respirations 60; temperature 101.8°. He had frequent convulsive seizures after he came to hospital.

Thinking it possible that these symptoms might be due to the formation of a second abscess, I reflected the flap I made originally at the trephining operation and, on opening the dura mater, through some thickened cicatricial tissue gave exit to some bloody serum; I then passed a blunt-pointed director downwards and backwards to a distance of 5 centimètres, but did not reach any

pus or other fluid. A director was then passed downwards and slightly forwards, when a considerable quantity of serous fluid came gushing out. From this situation I removed six drachms of sero-sanguineous fluid dotted with white-coloured flakes. The effect of the operation was to reduce the pulse from 150 to 100, and the temperature from 105.1° to 104.6°. The patient, however, never rallied, and died the day following.

I might dwell on other cases of cerebral abscess illustrative of the beneficial results obtained by trephining and drainage, more particularly that published by Dr. Gowers and Mr. A. Barker, where the abscess occurred in the temporo-sphenoidal lobe, and depended on otitis media, and Dr. Greenfield's, which also depended on the same cause. Trephining and evacuation in both these cases were attended with the best results.

The operative efforts in cases of abscess, tumours, and epilepsy of Professor Victor Horsley, Mr. Alexander, Dr. Macewen, Mr. Godlee, and Dr. Roberts, of Philadelphia, are such as to give the greatest encouragement and hope that in the near future we may be able to undertake the operative treatment of such cases with a confidence we cannot yet possess.

There are many points of interest connected with these remarkable operative efforts that I have mentioned which, did time permit, I should like to dwell on. But in truth the discussion in any minute way of the technicalities of either the diagnosis or therapeutics of such cases seems, on an occasion like the present, hardly appropriate, such being more suitable for consideration at the ordinary meetings of your Society, where in the scientific crucible the golden ore of experience and research is tested, and the pure metal—that having the genuine ring of truth in it—is elicited and refined.

From what has been said it must be conceded that surgery can no longer hold in any sense the subordinate position to medicine which she occupied so long. So far, at all events, as physical conditions are concerned, surgery has undoubtedly advanced medicine in no small degree, and in doing so accomplished much in the direction of dispelling the factitious and unreasonable division of the two branches of the profession. It has also been its safeguard against irregular and unrecognised lines of practice, for no important surgical proceeding can be based upon such, at least in the public mind.

At the same time we must acknowledge that of late years, at all events, surgery is indebted to medicine. From Professor Ferrier's work, for example, brain surgery has to a large extent been the outcome, although without Listerian antisepticism little of what was done could have been accomplished. One of the best instances that could be mentioned of the good results that have been obtained by the combined work of a physician and surgeon is that of Dr. C. Allbutt and Mr. Teale, of Leeds, whose researches on scrofulous cervical glands, pulmonary abscess, and other conditions existing on the boundary line—one every day increasing in breadth—between medicine and surgery, are doubtless familiar to all present. In truth, the more investigation is pursued in this direction the more likely is it that surgical possibilities in many other medical cases than those I have mentioned will become recognised. One of the immediate and most salutary consequences of this overlapping or fusion of our work has been the gaining for the profession at large of a vast increase of influence and public confidence—more, it may be safely said, than has been gained by any of the other professions in the same time, and which has been obtained not because it has mastered so many of the secrets of disease or injury, but, as an eminent living statesman has observed, "Because the world was well aware that the very highest of human abilities were addressed in ample quantity to the business of the profession, and that their abilities were addressed to it with all the zeal and all the judgment which they could expect from human capacity and assiduity in any of the pursuits of life."

And now, what next? Are we on the threshold of unexplored regions of research, or have we arrived at the hopeless deadlock of finality that some maintain we have reached? We should reject so disheartening a suggestion, and fearlessly pursue our course, relying not alone on biological research, but also on improvement in surgical precision and of surgery, more particularly in its operative aspects.

As regards the future progress and development of medicine it has been said by an eminent scientist, but I think unphilosophically, that present research forces on us the conclusion that in order to appreciate the etiology and prevention of disease we must in future rely rather on chemical than on biological inves-

tigation; but considering, among other things, the results obtained by the recognition of parasiticism as an etiological factor in the production of disease, and the great probability of being able in the near future to recognise it as such in affections in which it has not yet been demonstrated, it is clear that we must not rely exclusively on either one or other of them, but rather to the outcome of researches in the many branches of natural science on which both medicine and surgery are based.

But there are other things we should do as well as not do. Among the latter, we should not yield to the tendency that exists in the present day to abandon the principle of unity of research, and to run into narrow specialistic grooves of work.

In certain branches of surgery and medicine, just as in law and other departments of human learning, specialism is doubtless not only inevitable but useful, but it is when there is undue extension of the principle that the harm is effected, leading as it doubtless does to what has been so well termed by Dr. Richardson a "centrifugal disintegration"—one which is tending to tear our science into shreds. It has been said by the apologists of specialism that what it loses in breadth it gains in depth; but it should be remembered that it is not always the deepest wells that furnish the clearest water; nor in mining operations is it the narrowest shafts that always lead to the purest metal.

Another error that is too often made, and which is fraught with peril to true advancement in surgery especially, is the premature publication of cases, and the danger that exists in consequence of drawing erroneous conclusions therefrom. In illustration of this I would allude, among many other examples that might be mentioned, to the records that have appeared so often of alleged successful results obtained after operations for lingual cancer. It must be admitted by all possessing operative experience that there are few surgical procedures that, as a rule, in their ultimate results are so disappointing as these. This disease seems, in truth, like an impregnable fortress, for ever proof against the sternest artillery of our art, an invulnerable enemy that apparently may be vanquished, but never conquered. To those who give unquestioning credence to the rosette statistics so frequently published of the treatment of cases of lingual cancer—cases in which permanent relief is too often triumphantly stated to have been obtained—this may, perhaps, appear too discouraging a picture, but these published results are as a rule so distinctly opposed to my clinical experience that on reading the records alluded to, in which success appears to be the rule and the want of it the exception, it is hard to avoid surprise and regret that so many have been found to prematurely publish records which, my belief is, are of necessity misleading. The custom of too early publication of such cases is the main factor in preventing a true estimate being formed of the value of such interference, and must tend to damage the worth of statistics as a means of establishing surgical truth.

In reference to this point Sir James Paget's words are very applicable. He observes, speaking of what good operative surgery may do when practised with prudence in the treatment of malignant disease: "It does not do all we want; the disease returns even after complete removal of the diseased parts. All that is locally wrong may be removed, the local portion of the disease may be deemed cured, but something remains or after a time is renewed, and similar disease reappears, and in some form or degree is usually worse than the first, and always tending towards death" (*On Cancer and Cancerous Diseases*, p. 25).

I hope I shall not, in making these observations, be understood as in any way depreciating operative surgery in such cases. Far from it. It sometimes cures, usually prolongs life, at all times gives relief; but in reference to cancer and its treatment it must I fear be confessed that as yet "we see through a glass darkly." We have only reached a sort of halfway house on the road, beyond which we are not likely to get until many of the problems connected with the disease are elucidated, such as the relations, if any, which exist between it and other specific diseases, notably syphilis; how far we are justified in regarding it as primarily a local disease; the nature of the *materies morbi* or microbe, or whatever is the agency that develops the phenomena of cancer; and, again, if a disease has a parasitic origin—and probabilities seem to point in that direction—to determine what are the circumstances which at one time render the organisms quiescent, dormant, and apparently harmless, and at another time which rouse them into dangerous activity? These, as well as many other problems, must be solved before the therapeutics of cancer can be placed on a sure and scientific basis.

In connection with the all-important question of the origin of cancer, it has often occurred to me as remarkable that the question as to what part syphilis takes in its development has not been more frequently a subject of consideration. I confess to a growing conviction, based on a tolerably long clinical experience, that in the early life-history of cancer it is not so much a direct etiological factor, so to say, but rather tends to promote a condition favourable to the development of the entity, whatever it may eventually prove to be, which plays so important a rôle in the first act of a drama which as a rule has so tragical a termination.

Recently Professor Lang, of Vienna, has drawn attention to this subject, and has given the particulars of a series of cases which illustrated the tendency to the development of carcinoma on a syphilitic base, and he alluded to similar cases recorded by Mr. J. Hutchinson and Professor von Langenbeck. My colleague, Professor Hamilton, has also detailed to me the history of two remarkable cases which were signally illustrative of the development of cancer occurring during the treatment for secondary syphilis, the disease appearing in the groin, and running a rapidly fatal course. Did time permit I could also adduce instances illustrating the close affinity between the two diseases. I allude more particularly to cases of ulcerated lingual gummata, which ultimately presented the characters, clinical as well as histological, of epithelioma. In reference to this subject Mr. Hutchinson observes: "The statistics are wholly wanting as yet which would enable us to give any confident opinion as to whether the damage the tissues receive from a syphilitic infection makes them more prone than before to take on the erratic modes of growth which constitute cancer. In the case of the tongue, the association of the two is so common that it is difficult to avoid an impression that syphilis must exercise some degree of predisposing influence." (*Syphilis*, By J. Hutchinson, 1887.) Mr. C. Heath also is of opinion that one of the causes of the increase of cancer of late years—a fact noted by the Registrar-General—is the greater spread of syphilis (*JOURNAL*, April, 1888). If these views be ultimately endorsed—and who in the present state of our knowledge can say they cannot?—how largely does it add to the imperative duty that devolves on us to make, with all the powers at our disposal, efforts to dissipate the public prejudice that exists to bringing about a re-enactment of, I trust, the temporarily laid aside Contagious Diseases Acts, and how greatly does it intensify the grave responsibilities of all who unhappily, under the baneful influence of that mischievous sentimentalism which has done so much to sap the judgment and good sense of so many men as well as women, thwart and hinder efforts which, when made, have been proved to all unprejudiced persons to be fraught with good to mankind, not merely now, but for untold ages to come.

The elimination of this dread scourge of the human race is not a national, it is a cosmopolitan question. It is one not so much for the therapist as for the statesman. "The time has come," said Marion Sims, "when we can no longer shut our eyes to its evil influences, and we must deal with it plainly, as we deal with other great evils that affect the general health of the people. If yellow fever threatens to invade our precincts, we take steps to arrest its progress at once. If cholera sounds the alarm we immediately prepare to defend ourselves against its ravages. If small-pox infects our borders we circumvent and extinguish it; but a greater scourge than yellow fever and cholera and small-pox combined is quietly installed in our midst, sapping the foundations of society, poisoning the sources of life, rendering existence miserable, and deteriorating the whole human family."

I might adduce much, and, to unprejudiced minds, conclusive evidence as to the beneficial effects of the Acts in protected districts, not only as regards the diminution of the disease, but also in reference to the good moral effects of them; but on the present occasion I will, in connection with the former, content myself with mentioning one fact. It is mentioned in an able paper on this subject by my colleague, Mr. W. Thomson (*Medical Press and Circular*, April 30th, 1879). In 1874 the 50th Regiment came to Dublin, an unprotected station. It was previously for seven months at Aldershot and Colchester, protected stations. The length of time was practically the same that the regiment spent in both the protected and unprotected stations, as was also the average strength of the regiment during the two periods. The admissions per 1,000 men, while protected, for syphilis was 11.97, and while unprotected 118.81, and it should also be stated that during the first period there was the adverse influence of 13 per cent. fresh recruits, while there were no enlistments in the second. Other facts equally striking could be mentioned, proving how

potent for good the Acts might be made; but the one I have adduced speaks, in my opinion, trumpet-tongued in their favour.

But encouraging as the results of the Acts have been, it is not from such partial legislation as that contained in them that we can look for any great or permanent improvement. This need not be expected until statesmen and philanthropists of all nationalities shall combine in endeavouring to crush the enemy in our midst, that every day brings in its train disease, destitution, and death, not alone to the guilty, but also to the guiltless, and transmits a bitter inheritance of sorrow and suffering to the innocent yet unborn. And yet to the efforts made to mitigate or stamp out the disease the strongest opposition is made by those "friends of humanity" whose perverted notions of right and religion make them give an insensate opposition to a movement which, if carried out effectually, would put such a check on immorality and diminish so largely diseases among all mankind. When we consider the suffering, blighted hopes, the loss of life that the disease unchecked carries in its wake, we cannot but realise the fact that although sentiment is a mercy, it may be one that for a nation is the most costly—and for humanity, the most cruel.

The task of dissipating many of these prejudices and errors of persons of doubtless good intention as a rule, but of weak intellectual fibre, and which, in more than one instance, have culminated into what has become a real calamity for mankind, is one that all can undertake, no matter what their abilities or mental powers may be. If it be not possible to have a position in the scientific vanguard of our profession, much may be done in supplementing the work of those whose strength and whose work have enabled them to get there. Men of much creative genius are, as they ever have been, rare in their generation. But those without this may not the less be "true sons of their century," for it is the men of order, the men who work with method, earnestness, and truth, that do the great mass of the world's work. If they have not strength to carry a votive tablet to the Temple of Truth, they can at all events assist in fixing and cementing it; and fortunate it is that such is the arrangement made by the One Perfect Workman, for it shows us the importance—nay, necessity—of mutual help which must exist so long as men's qualities, mental powers, and tastes are so diverse.

In future, the relations between surgery and medicine being now so happily altered, the physician and surgeon will work in unison, the labours of the one supplementing those of the other, their mutual jealousies and differences forgotten, or relegated to the hazy traditions of a past that has but little interest to anyone, save, perhaps, the historian or the antiquary. This union for the good purposes of mutual help will bring us increase of strength, of confidence, and hope, and assuredly prove that we are all, so to say, of the same guild, all animated by the same worthy ambition, by the same desire to "allow," as Lord Bacon said, "the spials and intelligencers of Nature to bring in their bills," and all animated by the same fair aspiration to discover, collect, and replace the scattered fragments of that precious crystal of truth, which, it has been said, fell from, and was given to us, from heaven.

THREE LECTURES

TUBERCULAR JOINT-DISEASE AND ITS TREATMENT BY OPERATION.

Delivered at the Royal College of Surgeons of England, June, 1888.

By ARTHUR E. J. BARKER, F.R.C.S.,

Hunterian Professor of Surgery and Pathology at the Royal College of Surgeons; Surgeon to University College Hospital; and Teacher of Practical Surgery at University College.

LECTURE I.

MR. PRESIDENT AND GENTLEMEN.—I shall doubtless best show my deep sense of the great honour you have done me in placing me in the position I occupy to-day by addressing myself at once to the task confided to me, with no more preface than a frank admission of my consciousness that the treatment of the subject chosen is worthy of far higher powers than I can hope to bring to bear upon it.

In selecting for the subject of these lectures some of the

questions involved in the operative treatment of tubercular disease of joints, I ventured to think that the time had come for a reconsideration of our position in this field of surgery. Within the last few years two great events have occurred, which may be said without exaggeration to have affected this subject to its very foundation. I allude to the general acceptance of the theory of antiseptic, or, as it may now be better styled aseptic, wound treatment, and the discovery of the true nature of what is known as tubercular disease. But, though the theories of a sepsis and of the parasitic nature of tubercle have already taken deep root in the surgical mind, reading and observation have convinced me that as yet they have not had that profound effect upon the daily operative treatment of scrofulous joint affections which they are destined to have when more thoroughly familiar to the profession at large. I have thought therefore, that to review this subject in the light of these two theories would not be a useless task, especially as the observations and researches bearing upon many of the questions involved are widely scattered, and more or less inaccessible to the ordinary reader; and, although it has been a labour of love to me to collect, study, and weigh these, and to test them in practice, I can easily believe that to many practitioners this might be a task demanding larger privileges than I have been fortunate enough to enjoy.

Step by step real and solid progress has been made in the operative treatment of joint affections in past years; but to those who look closely into the subject now in the light of these two events, it seems probable that these improvements will soon be left far in the distance by the achievements of the near future. The territory before us is large, and as yet its borders only have been cultivated. The object of these lectures will be to inquire whether, with our improved resources, we are not now better able to meet and overcome its hostile forces; and whether, with the increased light thrown upon some of its darkest spots, we have not already augmented its yield of fruit, and are not justified in looking for a still more abundant harvest.

In this survey, which must of necessity be brief, I cannot traverse all the ground already broken, but I do cherish the hope that I may be able, at all events, to make an outline sketch of our present position and of the ground before us, and thus perhaps assist in preparing the way for further steady advance.

If one were asked to furnish a good single illustration of the evolution of surgery from the condition of a mere handicraft to the dignity of a science, one could hardly do better than point to the change which has lately come over the surgeon's mode of regarding and dealing with what has hitherto been generally spoken of as scrofulous joint-disease.

In order to give this illustration its full force, it would be necessary, in the first place, to point out the various steps in the process of reasoning which had led to the substitution of the more exact term "tubercular" for the vague expression "scrofulous," and to trace the gradual crystallisation of the former term into its present more precise meaning. It would be necessary, further, to show how this gradual growth of knowledge had influenced not only the selection of cases, but also the actual mechanism of operation, and converted procedures which formerly seemed to demand little more than an acquaintance with the anatomy of a joint and the exercise of manipulative dexterity into a test of all those processes which go to make the success of a delicate experimenter in physics or chemistry. In this inquiry it would soon become abundantly evident that the old days of the showy *tour de maitre*, as applied to excision, had passed away, and had given place to a better era, in which the principles of physiology, chemistry, physics, and biology are applied to overcome difficulties and to repel forces either quite unknown or wholly misinterpreted in former times.

This, Sir, I am aware, is but hinting in homely phrase at what you have so eloquently and philosophically expressed on this spot in your Hunterian oration, the influence of which upon surgical thought cannot be overrated.

Remembering your words I am emboldened to pass on without apology to a review of the question on the lines indicated, and the consideration of those first principles which ought and actually do guide us now in excising diseased tissue from scrofulous joints; and though this review can only be brief, I fear, nevertheless, I shall have to claim the indulgence of many here to whom much that I have to say must be already familiar.

First in order among the numerous questions bearing upon the operative treatment of tubercular mischief in joints comes the

inquiry as to the nature of the disease so characterised; and before all things, we have to decide whether it is not the same as that hitherto spoken of as "scrofulous." To an audience such as I have the honour of addressing, I need hardly give all the reasons in detail for regarding them as identical; but I may be permitted, perhaps, *in order that my position may be defined*, to recall to your minds the leading facts which have been gradually accumulating in support of this view.

To some this may appear unnecessary, but I cannot forget that, up to a comparatively recent period, it was generally taught that scrofula and tuberculosis were two distinct diseases; also that many surgeons at home and abroad, who do not perhaps enjoy the privileges of closely following the rapid advances of pathological investigation, are still under the dominion of the same view. Further, the importance of settling this question is not only amply attested by the number of earnest workers who have devoted themselves to its study, but, as I hope to show, by the bearing it has upon the treatment of joint-disease, whether by or without operation.

The first great step towards a settlement of this matter was the gradual recognition of the fact that tuberculosis, as it presented itself in internal organs, was a well defined disease, producing definite tissue changes. That the result of the latter in their earlier stages was the formation of peculiar bodies having a well-defined structure recognisable in any tissue of the body, and liable, as they grew older, to certain secondary changes of a degenerative kind. These bodies, which received the closest attention in the lungs, soon came to be recognised in many other organs, both in the miliary form as well as in larger aggregations. Differences, to be sure, were noticed among them, but these were soon seen to be due to the stage of growth in which they were examined. The small miliary tubercle differed in its outward appearance from the larger caseating nodule; but, soon, intermediate forms were found, and it was observed that the larger body sprang originally from a focus identical with the smaller, and had only changed in so far as its more central portions had undergone fatty or caseous degeneration. It was observed further that when such a nodule broke down upon a surface exposed to the air it rapidly liquefied, the walls of the resulting space became more or less inflamed, and threw off not only its own proper necrotic fatty debris, but actual living leucocytes in the form of pus. We had, then, the tubercular cavity, say in the lung, secreting pus, and throwing off caseous detritus, and in the walls of which vessels of greater or less calibre were eroded, and often bled freely. Moreover, it was noticed that patients in whom these deposits could be demonstrated in the lungs frequently became affected similarly, and often fatally, in other parts, such as the joints, the brain, or intestines, and that the deposits in these parts underwent identical degenerative changes in the course of time.

Then came the recognition of the fact that the offspring of such patients appeared to be peculiarly prone to chronic joint-affections, besides enlargements of the lymphatic glands.

Further, it was noted that in these chronic affections of the joints and glands, characterised from time immemorial as "scrofulous," the ultimate result of the tissue changes was the production of caseous foci identical with those known as "tubercular" in the lungs.

Again, in innumerable cases of apparently primary scrofulous joint-disease, it was observed that, sooner or later, the lungs, brain, intestines, or kidneys became affected with typical tubercular disease. Ultimately, a careful microscopical study of the tissues of such joints revealed the fact that the initial lesion of joint scrofula was histologically the same as that of lung tuberculosis, and that typical tubercles could be demonstrated in them with the same ease as in the lung, and undergoing the same degenerative changes.

This would almost appear enough to establish the identity of the two diseases, but, in addition, there was a mass of clinical evidence accumulated, which pointed in the same direction. The age of the patients most commonly affected was in both cases usually the same; the conditions of life favourable to the development of scrofula and tubercle were shown to be closely allied. The general appearance of the patient was as nearly as possible alike in the two conditions; the variations of temperature, pulse, appetite, and body-weight, according as the disease was advancing or retrograding, were nearly parallel in the two affections.

But, though all these facts seemed to point very clearly to the identity of scrofula and tuberculosis, it was not until the disco-

very of the bacillus tuberculosis and its demonstration in the initial lesions of the two affections that positive proof was actually forthcoming. Almost at the same time Koch and Baumgarten pointed out that in typical tubercular and scrofulous nodules this organism could invariably be demonstrated by different methods of preparation, to which it is not necessary further to refer. Their researches were soon supported by a whole army of bacteriologists, both abroad and at home, and among our countrymen none has done more in this direction than Mr. Watson Cheyne. And it is a noteworthy fact that many of those who at first, on the strength of their own observations, had stood out most firmly against the theory of the specific or parasitic nature of tubercle have since become its most ardent supporters, and, moreover, have given in their adhesion to the view that this bacillus is the specific organism of tuberculosis. Among these may be mentioned Cohnheim, Klebs, and Schüller in Germany, and, I believe, the late Dr. Wilson Fox and Professor Burdon Sanderson in England.

But it was not alone on the constant discovery of the bacillus in tubercle, be it remembered, that the theory of its causal relation to tuberculosis was based. Experimental research soon showed that no substance not containing these organisms was capable of producing in healthy animals the disease in question; and, on the other hand, that substances in which they were present, if inoculated with due precautions, invariably produced the disease in certain animals, not only locally, but as a rule also generally throughout the system. It is true that experiments at first appeared to point in the opposite direction; but a repetition of them with proper precautions against error left no doubt on the subject. And not only was the inoculation of fresh tubercle shown to produce in all cases a definite tuberculosis, but it was also demonstrated that the organisms in question, cultivated for many generations in various media until all trace of contamination with matters from the original living tissue had been got rid of, were capable of producing this disease when introduced into the animal body, with as great certainty as deep sleep is produced by the hypodermic injection of morphine. Again, the bacillus could be obtained in any quantity from tubercles produced in internal organs by inoculation of these cultivations in distant parts, and could be multiplied *ad infinitum* by cultivation and propagated among some of the domestic animals with unerring certainty.

Now, it mattered little whether the tissue from which the inoculations were made was taken from a scrofulous joint or a typically tuberculous lung; the result was practically the same. And here we have, I think, the identity of the two diseases, tuberculosis and scrofula, proved to demonstration as clearly as anything is capable of proof by experiment.

The researches bearing upon these facts are far too numerous for detailed description. A mere enumeration of them would occupy more time than is placed at the disposal of a Hunterian lecturer. But to any candid mind they bear but one construction, namely, that tuberculosis and scrofula are diseases produced by the introduction into the animal body of a specific poison, and that this poison is always associated with the presence of the bacillus in question, if it be not actually the organism itself; and further, that without the presence of this organism typical tubercle does not exist.

But though we cannot follow here one tithe of the researches in support of this position, it will greatly promote the objects I have in view in discussing the nature and treatment of tubercle in joints if I am permitted briefly to sketch one typical inoculation experiment and its effects upon the tissues and organs. I will take, then, for illustration a well-known one as performed by Baumgarten, who is peculiarly qualified for such work by his profound histological research in other fields as well as this, an experiment which has been repeated by many other observers with the same results. The tissue changes here seen in the rabbit's eye have a close parallel in those demonstrable in tubercular disease in human organs, as is shown by Arnold's careful studies of the formation of tubercles in the lung. But as they can be followed in their various stages, and uncomplicated by ordinary inflammatory processes only in experimental inoculations on animals, the latter are taken for illustration.

In the experiment in question, a small fragment of caseating tissue is removed from a scrofulous joint or gland, with due precautions against contamination from without, and is inserted into the anterior chamber of a healthy rabbit's eye through an incision in the cornea (Fig. I, N.). The same operation is also performed at the same time on a large number of other rabbits' eyes. One or

more of these eyes is excised daily and placed in preserving fluid for histological examination.

Now, what is found?

In the first few days absolutely no change is observed, except the cicatrization of the corneal wound (Fig. I, N.) and the formation of a capsule of granulation tissue (Fig. I, Gr. K.) around the foreign body introduced. But from the second day on, a very evident increase of the bacilli is demonstrable within the inoculated fragment, until they are present in profusion. From this spot at which they first multiply they are now seen to spread rapidly. In the first place they permeate the granulation capsule (Fig. I, Gr. K.) around the caseous particle in enormous numbers, to which they communicate the blue colour seen in this enlarged drawing of Baumgarten's section. Subsequently they penetrate into the adjacent parts of the iris and cornea. In the latter they spread chiefly along the fresh scar tissue (Fig. I, N.), a fact of much significance to the operator, explaining as it does the occasional appearance of caseating foci in perfectly healed scars in the skin, perhaps weeks after an operation for deep-seated scrofulous disease.

On the fifth day scattered bacilli are seen in those portions of the cornea nearest to the point of inoculation, but without so far producing the slightest deviation from their normal histological texture. No traces of other species of organisms are to be seen with or near these immigrants, or throughout the whole iris or cornea.

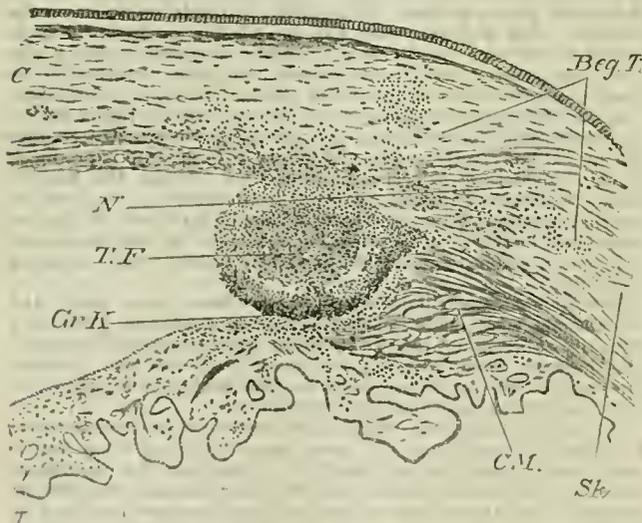

Fig. I.—Sk., sclerotic; C.M., ciliary muscle; I., iris; C., cornea; T.F., tubercular foreign body (the black dots represent bacilli); Gr.K., granulation capsule around latter packed with bacilli; N., new scar tissue in corneal wound with bacilli; Beg. T., beginning of tubercular hyperplasia around bacilli.

On the sixth day the bacilli are present in great numbers throughout the tissues of the cornea, which are still however practically unchanged. But at certain points, especially where the bacilli lie in dense groups, certain newly formed cells are to be seen, having the general appearance of endothelial or epitheloid elements, rather than of white blood or lymph corpuscles. Each day now adds to the hosts of invading parasites, which occupy an ever increasing tract of the tissues of the iris. The nearer to the point of inoculation, the more closely packed are they; the further off, the more scattered. Where the organisms are very sparse no histological changes are to be detected, but close to the point of inoculation young tubercles in the form of aggregations of epitheloid cells are now noticed, and a little later every intermediate form up to the perfect type of miliary tubercle with their lymphoid and epitheloid cells are to be seen, as in Fig. II, L.T. and E.T., which I have enlarged from Baumgarten's drawing of a microscopic section. These formations are constantly found associated with foci of bacillus proliferation, no organisms of any other kind being present. Moreover, in this experiment no tubercle, not even the smallest, is ever found at a spot free from the presence of bacilli, or having only a few of them. The amount of cell proliferation always corresponds to the richness in bacilli of the

nests of parasites. Thus developing and extending, the tubercular process advances further until on about the tenth or eleventh day a visible macroscopic iritis and keratitis is produced.

In the distant internal organs of the animals inoculated as above, an entirely analogous process of tubercularisation was observed by Baumgarten. This was best seen in the kidneys at about the fifth week after inoculation. Here the vessels of the

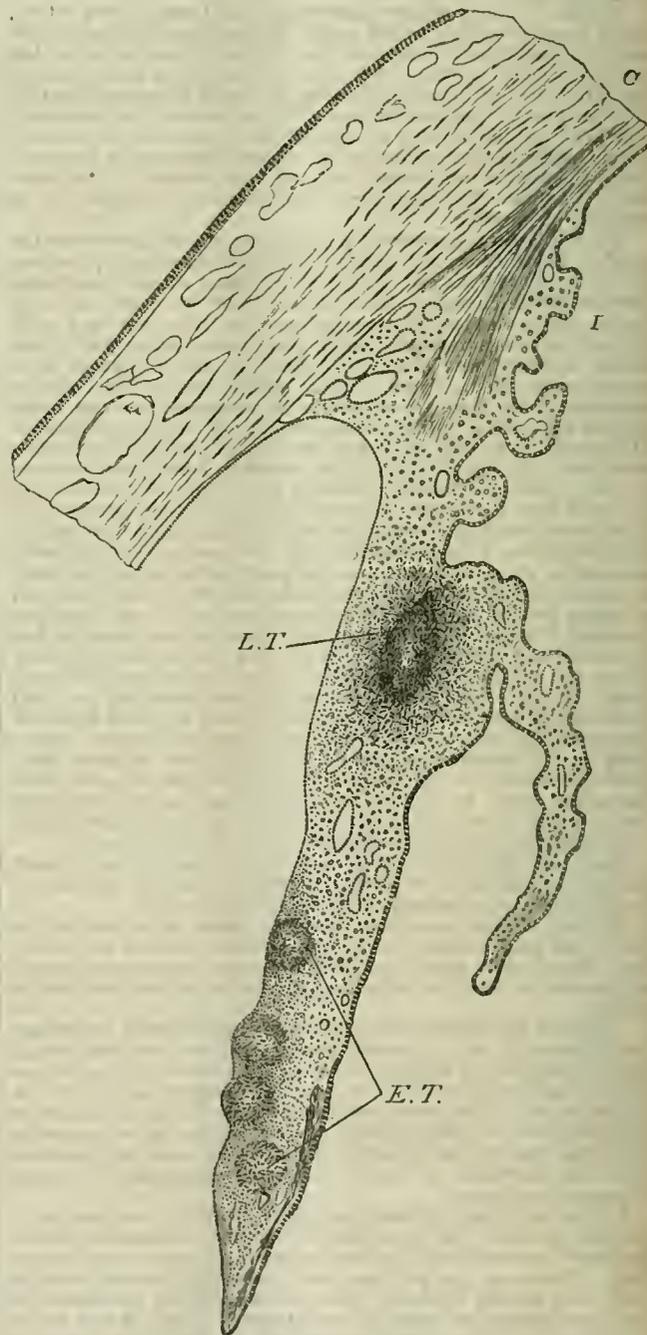

Fig. II.—C., the cornea; I., the iris; L.T., lymphoid tubercle of iris; E.T., earlier tubercles.

glomeruli were frequently found packed with bacilli, and, where the latter were spreading into the parenchyma around, typical tubercles were produced. Large numbers of bacilli were also excreted by the kidneys. Similar experiments have been repeated by many other observers with cultivated bacilli, and with exactly

the same results. The dosage of microbes was, however, shown by Mr. W. Cheyne materially to influence the rapidity of the development of the disease, a point of the utmost importance as bearing upon clinical experience.

The question now arises, Can we produce any clear evidence that anything similar to this direct inoculation of tubercle on the surface of the body ever takes place in the human subject? This question can, I venture to say, be answered distinctly in the affirmative, both as regards children and adults. Numerous cases have been put on record within the last few years which place the matter beyond doubt, and I cannot help thinking that other convincing cases must have come under the notice of some of those present here to-day. From the long list at our disposal allow me to select a few observations which are very striking, and which deserve to be familiar to all.

In a Continental town containing a Jewish community of some 9,000 souls, there were, during the months from February to May inclusive, nineteen children, all healthy, subjected to the rite of circumcision. Sixteen of the children were operated on by one man, the remaining three by others. In every case the bleeding was stopped, as was customary, by the application of the mouth to the prepuce and by sucking the latter. This part of the ritual is often carried out by different individuals, sometimes members of the family, sometimes by the operator. In the present instance the sucking was performed in ten cases by the functionary mentioned above as having circumcised sixteen of the children. In the remaining nine cases the application of the mouth to the prepuce was made by other members of the community. All these last nine cases recovered perfectly from the operation in the usual way; but the ten children in whom the bleeding was stopped by the application of the first operator's mouth all became affected with very serious disease between the eighth and twelfth day, and in precisely the same way. The wounds or scars in the prepuce first became the seat of nodules, then of unhealthy spreading ulcers, secreting but little. In about three weeks the inguinal glands became much enlarged in spite of vigorous anti-syphilitic treatment (the disease having at first been diagnosed as syphilis by Dr. Lehmann, under whose treatment the children were placed, and who records the outbreak with great care). In three cases these glands did not suppurate, but the patients died with all the symptoms of tubercular meningitis within a few months. In the remaining seven the glands suppurated, and four of these died, one of intercurrent diphtheria, three of "marasmus." Three of the ten children recovered, but only after years of suppuration in the inguinal glands and burrowing of sinuses under the skin. On looking into the matter Dr. Lehmann found that the operator on these ten children had been a patient of his own during the period of the outbreak, suffering from advanced phthisis of the lungs with cavities, characteristic sputa, night-sweating, etc., and who succumbed to this disease shortly after the last of these circumcisions in the month of May. He found that this patient had only applied his mouth to the prepuce in these ten infected cases, though he had circumcised sixteen, and that everyone of the ten were affected as above, while in the remaining six which he had circumcised, but in which the blood was sucked off by others, no evil result followed, nor in three other cases circumcised at the same period, though not by the same hand.

The careful way in which the details of this outbreak are given and the tables drawn up by Dr. Lehmann leave no room for doubt that the disease produced was local, and in several cases general, tuberculosis; and that it was inoculated into the prepuce from the mouth of the operator, who was dying of destructive tubercular lung disease at the time, and who became so weak at last that he had to be brought in a carriage from house to house for the performance of the rite in question.

I will not weary you by reciting all the cases of a similar kind which have recently been put on record, but will only mention that in many—notably those of Merkle, Holst, Elsenberg, and Pfeiffer—not only was the disease produced by the inoculation typically like tuberculosis, but the bacillus was fully demonstrated in the affected tissues. Pfeiffer's case, however, deserves a passing notice on account of its completeness.

The patient was a healthy veterinary surgeon, with a good family history, who, while dissecting a tubercular cow, punctured the joint of his left thumb. The wound soon healed, but was followed by induration of the scar, and later by swelling of the whole joint, which underwent the typical changes of a scrofulous synovitis, but without the formation of sinuses. Some

months later the patient began to show signs of pulmonary phthisis, which rapidly increased, and he died of this disease a year and a half after the wound of the thumb. The latter, which showed much swelling but an unbroken skin at death, was removed for special examination. The joint, on being laid open, showed all the destructive changes of scrofula both in the bones and synovial membrane; and in the latter, as well as in the broken-down material which filled the intervals between the bones, an unusually large number of bacilli tuberculosis were found. The microscopic appearance of the diseased tissues was also typically tubercular.

Such cases as those just described leave no room for doubt that tubercle can be inoculated in any part of the surface of the body, and may spread from the original point of entry throughout the whole system, until a fatal amount of general disease is produced.

Now, if the numerous facts of this kind already accumulated—of which those to which brief allusion has been made are only a sample—are capable of the interpretation put upon them, it is evident, in the first place, that a disease identical with human tuberculosis can be produced at will in animals by the inoculation from man of the products of strumous degeneration, and of the organisms obtained from them by repeated cultivation; also that the disease so induced may manifest itself locally before ultimately becoming general, and may remain localised for some time. It is also clear, from many experiments, that its tendency to become a general disease varies *ceteris paribus* directly with the number of the specific organisms present at the original point of inoculation, and that without these organisms no tuberculosis can be produced. Further, it is evident that the same disease can be produced in the human body in exactly the same way and subject to the same conditions.

But a number of other interesting and important facts have also been brought to the front in the extensive researches which have been made in this field—facts which have long been foreshadowed by clinical experience, and have only awaited proof by experiment. Among these, one of the most important is the influence of the condition of the soil upon the growth of the organism.

As of the pyogenic microbes so also of the bacilli tuberculosis. It may be said that they have to do battle in the animal economy with the vital forces of the tissue in which they are first deposited, and that these are in a large number of cases sufficient for their overthrow, or at all events sufficient to arrest their multiplication and dispersion throughout the body. In the case of the human being it has been shown, by accidental inoculation, that though they may be introduced in a thoroughly active form they may, if the body is healthy, be arrested in their development and kept at bay until finally eliminated or destroyed; but if the vitality of the individual or part be low, that they have a great tendency to multiply and spread. Schüller's long and admirable series of experiments, which must be familiar to many here, place this beyond all doubt as regards animals, and our clinical experience of scrofulous inflammations in man confirms the view. We know, for instance, that those who are weakly from inheritance or bad hygienic surroundings are most liable to these diseases, and also that those tissues and organs whose vitality has been lowered by injury or disease are specially prone to become the seat of tuberculous affections. Children again are more frequently a prey to scrofula than adults whose tissues are in their full vigour. Again, it has also been proved beyond cavil, that tubercular disease is auto-inoculable, that the introduction of the poison at one spot does not give immunity from inoculation at another, but further than this, that it is particularly liable to be grafted from one part of the body on to another. The importance of a full recognition of this last fact cannot be overrated in considering the operative treatment of tubercular joint-disease, and it will be necessary to refer to it over and over again.

We must now glance briefly at the ordinary modes of introduction of the tubercular poison into the human body before considering its behaviour towards the structures of the joints in particular.

Ever since the disease in question was first defined, the respiratory passages have been recognised as the point of attack at which the human body most frequently suffers. And clinical and pathological experience has shown that it is from this tract of mucous membrane that the infection most commonly spreads to the other parts of the system. The mode of this infection has been so often demonstrated by experiments on animals as to require only a passing notice here. Not only has it been shown that the injection of phthisical sputa or crude tubercular matter, or the bacillus tuberculosis derived pure by cultivation from it

into the air passages will produce typical tuberculosis of the lungs, but it has been observed that even healthy animals of certain species simply living with others thus affected speedily develop the same disease; and again, that healthy animals placed in an atmosphere contaminated by tuberculous dust are soon similarly affected. Not only has all this been proved by many independent observers, but the various stages of the disease from the first initial lesion of the catarrhal mucous membrane to the fully developed general tuberculosis have been traced step by step in animals thus dealt with.

And when we come to consider these experiments, and to compare their results with our clinical experience of phthisis in the human body and its minuter pathology we cannot doubt for a moment that its etiology is the same in both cases.

Next in the order of frequency comes the infection of the system through the alimentary tract. That disease was frequently propagated in the latter by direct inoculation due to the swallowing of phthisical sputa had long been suspected by clinical observers; but by others the presence of tubercular ulcers in the intestinal mucous membrane of patients suffering from pulmonary phthisis was regarded simply as evidence of the general infection of the blood with this poison, and that, once introduced, it could break out secondarily in almost any organ whose vitality was lowered by local diseases. Experimental researches have, however, proved that primary inoculation may take place in the intestinal mucous membrane without any lung disease through the medium of food contaminated with tubercular elements. Animals fed upon such food have developed the disease in the intestine readily, while other animals of the same species fed upon similar articles of diet but uncontaminated have remained healthy, though placed in exactly similar surroundings.

But perhaps the most striking illustration of this mode of infection through the medium of the alimentary tract is furnished by a series of the most interesting observations made by Bang on tubercular disease of the udders of cows. After describing this disease in detail, he goes on to show that it is associated with the presence in the diseased udders of countless bacilli tuberculosis, and ultimately with the characteristics of general bovine tuberculosis. And, further, he shows that the organisms can be demonstrated in the milk of such an udder, and that such milk will produce typical general tuberculosis when supplied as food to sucklings or rabbits, or when injected into their peritoneal cavity.

The special knowledge of this observer, and the care with which his investigations were conducted, leave no room to doubt the correctness of his conclusions, which are also confirmed by Bolinger's demonstrations of bacilli in the milk of tubercular cows and its infective properties. That this infection also frequently takes place by means of milk in the case of children there is every reason to suppose, and, moreover, there are cases on record in which even healthy adult individuals, living an isolated life amid the healthiest surroundings, away from other causes of infection, have become tubercular from a diet consisting largely of the milk of *perlsüchtige* cows. The most convincing instance of this is to be found in the case of certain shepherds in the Swiss hills mentioned by Klebs. Amongst these hardy men, living in the purest air and apart from other unhealthy individuals, acute tuberculosis has been shown to have been produced by a diet consisting almost exclusively of bread and the milk of cows suffering from the same disease. Klebs has also described the case of a healthy St. Bernard dog fed upon bread and the milk of a *perlsüchtiger* cow, with the result of producing general tuberculosis.

There is one other supposed mode of introduction of the tubercle virus into the human system to which I should like to direct your attention for a few moments, namely, that by inheritance. I am aware that here I am on disputed ground. But after a careful study of the evidence on this point *pro* and *con.*, I feel bound to express the opinion left in my mind, inasmuch as this opinion will influence considerably what I have to say later on in regard to the operative treatment of tubercular disease. Now, I must confess that the theory which I was always taught, and which I have hitherto held, that tubercular disease is directly inherited in the parasite form in a large proportion of cases, appears to me no longer tenable. There is a vast amount of evidence on this point, and the literature of the subject one can hardly even think of without a shudder. That the organism of tubercle may be transmitted from a diseased mother to the fetus *in utero* in animals has no doubt been shown by Johnne in one single case. But it is a significant fact that Johnne himself—with his special knowledge of the subject and his great oppor-

tunities amongst animals for study, and believing in the possibility of such transmission—writes in 1885 that the case he then described was the first certain one of fetal tubercle placed on record. It is also a remarkable fact that numerous other specially competent observers have failed to find evidence of tubercle in fetuses born of tubercular animals, or found *in utero* after death from the disease in question; and, so far as I can discover, typical tubercle has never been demonstrated beyond question in a human fetus at birth, or taken from the uterus after death, in spite of frequent search. But, even if it were occasionally found in the fetus, this would only show that such an infection was possible as an exception, but it would not account for the enormous amount of tubercular disease observed among very young children. We are, therefore, led to look for other possible methods of infection besides that from the mother *in utero*; and there are so many, as I have endeavoured to show above, that we are in no difficulty. Children born of parents debilitated with phthisis may inherit a low vital energy, but be without a trace of parasitic disease at birth. But, with inherited debility, they are peculiarly fitted to become a fruitful soil for the propagation of the tubercle bacilli if implanted on them; and in a household in which phthisical people live together there are countless ways in which an infant may acquire the disease from them. In the first place, the mother's milk may introduce the organism into the child; her breath may infect it; the dust of the house, contaminated by sputa, may carry the poison into its lungs or alimentary tract, or deposit it on an abrasion of the skin. Indeed, it seems almost difficult to explain how a child born weakly and brought up among consumptive people can escape more or less infection in one or other of these ways briefly alluded to. At all events, the prevalence of tuberculosis among the children of consumptives is easily accounted for without any resort to the theory of inheritance.

Without going further into this very interesting question of inheritance, I will venture to say that anyone who will carefully study the evidence bearing upon it, and especially Wahl's exhaustive paper, will come to the conclusion that, although tuberculosis can certainly be inherited, such an occurrence is excessively rare, and that, in the vast majority of cases met with, the disease has been acquired, most probably, from the surroundings of the patients or from the food supplied to them.

It is highly probable, however, that there is such a thing as hereditary predisposition to tubercular disease among the offspring of consumptive parents; in other words, that their tissues are a peculiarly fertile soil for the growth of the organism once introduced; but wherein this predisposition consists—whether in anatomical or physiological deviations from the normal, or simply in a general loss of that unknown quantity "vital energy"—is still a mystery.

When once engrafted upon one of the surfaces of the body, the bacillus tuberculosis is disseminated throughout the latter in a variety of ways. In the first place, though it has not been proved to possess the power of locomotion, its mode of spreading from a point of inoculation strongly suggests this. In Baumgarten's experiments on the eye mentioned above, the position of individual bacilli in the outskirts of the primarily infected spot can hardly be explained by their transport by any known tissue current. For instance, they spread by preference into the cornea along the fresh scar tissue of the recently healed incision (Fig. I, N.), in which, of course, there would be no vessels of any kind during the first few days; and, unless they travel by virtue of some power inherent in themselves, it is hard to account for their presence here at all. A few, of course, may be carried in the interior of wandering leucocytes, but this does not explain the movements of the majority, many of which are found apart from the leucocytes. They have also been shown to have the power of penetrating the walls of the venules and arterioles from without, and of so gaining access to the blood-stream.

But leaving this question as to their power of moving themselves from place to place to be settled by future observation, the other modes in which they are spread through the body demand brief notice. There can be little doubt that, in the vast majority of instances, they are primarily taken up by the lymphatics, and pass from these into the blood-current, to be carried by the latter secondarily into distant parts of the body. But, as a rule, the glands nearest to the point of inoculation arrest the progress of the organism more or less completely. It must not be forgotten, however, that the walls of a large lymphatic vessel such as the thoracic duct may be secondarily infected from proximity to an inde-

pendent focus of caseation. From a vessel so infected an abundant supply of bacilli may be furnished direct to the circulation, no glands intervening to offer a barrier. Through the coats of the pulmonary vessels they have also, as already stated, been observed to pass directly into the circulation; but they probably do so to a very small extent as long as the walls of the vessels are unbroken by inflammation. But it is quite otherwise when a vein, whether in the lung or elsewhere, lies in close apposition to a caseating focus of tubercular disease. In such a case the wall of the vessel may be eroded, and the contents of the caseous abscess may be poured directly into the venous, and from this into the general circulation. This has actually been demonstrated by Weigert, in an interesting series of cases, to have taken place, and to have been followed by rapid general tuberculosis. A knowledge of this fact ought to have an important bearing on the operative treatment of tubercular caseating foci. It is very easy to imagine how easily surgical interference may give rise to this mode of general infection when we remember the constant presence of dilated thin-walled veins around the walls of caseous abscesses, and the ease with which they may be torn. Again, the rough handling of a tubercular joint, even without any cutting operation, may complete the rupture of a vein already partly eroded by its proximity to a caseating process, and may regularly inundate the venous blood-stream with the products of the latter. We have all, I suppose, seen rapid general tuberculosis follow upon some disturbance of a scrofulous joint by injury or surgical interference, and such a sudden inroad of the products of the local disease into the venous circulation would best explain such an occurrence. The beneficial effect of absolute rest too in limiting tubercular processes may be no doubt explained in part by absence of this dispersion of bacilli through eroded vessels, rest giving the latter time to erect barriers against the encroachment of the organisms by means of ordinary plastic phlebitis.

But it is to the lymphatics that we must look as the ordinary carriers of the microbes from their first landing-place; and it is fortunate that this is so, for in a large proportion of cases the lymphatic glands appear to have the power of arresting their further progress until they either die or in some way their dangerous powers are curtailed. There is every reason to suppose that in many cases the bacilli are arrested completely in the glands and never get any further. But it is equally probable that in a large proportion of cases they or their spores pass quickly through them in greater or less number, and gain an entrance into the blood. It is also more than likely that they, or their spores, often pass on from the glands into the circulation after a long and comparatively quiet sojourn in the former, perhaps amounting to years, and only become dangerous on being disturbed and widely distributed through the circulation. The importance of this power of the lymph glands to arrest the organisms and prevent their contamination of the whole blood-stream is, of course, enormous; for, once they have entered the blood, they find a most fruitful soil for their propagation, and not only this, but they are carried to every part of the system, and can select among the organs and tissues one or more spots specially suited, either physiologically or pathologically, for their propagation. That certain organs and tissues are peculiarly liable to be attacked by this disease has been well known for a long time past; but the conditions determining the point of attack have not been so well understood. Undoubtedly the view that injury to a part predisposed it to tuberculosis is quite correct, whether this injury consist of disintegration of tissue, with extravasation of blood, or disturbance of its functions, or only amount to impairment of those forces which go to make up what is briefly termed its "vitality."

But besides the influence of external agencies in predisposing to tubercular growth, there appears to be in certain spots in the body some inherent suitability of soil for the cultivation of the bacillus tuberculosis depending upon their physiological conditions. In other words, with the organism in the blood of an individual not unfavourably influenced as regards one part or another by external agencies, the bacillus appears to prefer to make its home, as a rule, in certain tissues, and to leave others unaffected.

The pia mater of the child furnishes, perhaps, the best example of what I mean, the medulla of the bodies of the vertebrae the next best. Both of these tissues in the child are as far removed from the action of injury, or, indeed, of any external influence, as possible, and yet the frequency with which they become the seat of tubercular disease is proverbial.

It would be interesting to examine the various aspects of this

particular question at greater length, but I am obliged to content myself to-day with this very brief allusion to it. Enough has been said, I hope, to indicate the line of reasoning I have been led to adopt as regards the nature of tubercular or scrofulous disease, and which I shall venture to pursue in its direct application to joint-disease in my next lecture.

ON HYDROPHOBIA AND ITS "TREATMENT."

ESPECIALLY BY THE HOT-AIR BATH, COMMONLY TERMED

THE BOUISSON REMEDY.

BY VICTOR HORSLEY, F.R.S., ETC.,

Surgeon to the National Hospital for the Paralysed and Epileptic, Professor Superintendent of the Brown Institution, Professor of Pathology in University College, and Assistant-Surgeon to University College Hospital.

HYDROPHOBIA being a disease of which the true pathology was scarcely known until a few years ago, indeed almost until M. Pasteur began his remarkable investigations, has always been regarded by the quack and the impostor as a fair field of enterprise. The authoritative statements employed by such therapeutical pirates to foist their methods and nostrums upon the much beguiled public commonly include the prominent expression of some popular belief. Amongst such beliefs must be placed the ubiquitous confidence reposed by the laity in the active secretion of sweat as an efficient means in getting rid of the *materies morbi* of acute specific diseases. It is a very widespread notion that if there is such a poison in the body, it can be "sweated out," just as it used to be generally believed (though now only by a particular sect) that the exercise of religious faith would, if energetically resorted to, get rid of a malady. The application of this sweating treatment in the shape of hot baths to the relief of rabies is of very ancient origin: and, under the belief referred to, it has been largely employed and advocated by irresponsible persons of every degree.

The practice of subjecting hydrophobic patients to hot air baths, however, received support from a French physician of professional repute, Dr. Bouisson. This gentleman seems to have suffered from symptoms, most of which resembled those of hydrophobia; but, from the account he gives of his trouble, his diagnosis that he was really suffering from that disease may well be called in question. Acting on the belief that he was so stricken, he entered a hot-air bath with the idea of terminating his existence, but he gradually became calmer, and soon the symptoms totally disappeared. Struck by these circumstances, he strenuously advocated the use of the hot-air bath in hydrophobia, and published cases in which he thought he had successfully combated the disease. He stated that if the patient were placed in the bath on the first day that the symptoms manifested themselves, a cure would be infallibly obtained. If only on the second day, that the cure was possibly uncertain, and that the treatment was hopeless if begun as late as the third day. Since Dr. Bouisson's papers were published, many patients, actually or supposititiously suffering from hydrophobia, or in whom the occurrence of the disease seemed possible, have been treated on this plan. All those patients who have been reported by respectable practitioners to have been suffering from genuine hydrophobia have died in spite of the Bouisson treatment.

Instances of its employment by such practitioners will be referred to presently. In spite of the failure of this procedure an attempt was made in the recent epidemic of 1885, and subsequently, to secure its trial by the profession. As might be supposed, its adoption is principally urged by those who are, for obvious reasons, opposed to the progress of medical science, the paid antivivisectionist agitators. These persons spread broadcast glowing misrepresentations of the system, and raise, as I have myself seen, many false hopes, and so cause much pain in the minds of the patient and his friends. For instance, one of their agents, a Rev. J. P. Wright, made the assertion that "Eighty cases had been already cured by this method, and only one doubtful case was chronicled." (The *Zoophilist*, January, 1888, p. 152.) It is deeply to be regretted that certain medical practitioners—to wit, Dr. Bell Taylor, of Nottingham, and Dr. Clarke, of Clapham, have countenanced the statements of these people, and advocated the trial of such treatment on man. What the "antivivisectionists" clearly desire is that the profession at large should make a series of experiments on man to see whether this Bouisson treatment is worth going on with or not. Most of us,

however, believe that we can more fitly fulfil our duty towards our neighbour by testing new remedies, not upon his body, but upon that of one of the lower animals, and it was with the object of averting such wholesale human "vivisection" that I instituted a series of experiments (that is, carried out the Bouisson treatment) upon lower animals (rabbits) suffering from rabies or hydrophobia. I was careful to carry out this treatment, not only therapeutically, but also prophylactically, but I regret to say that it favoured rather than hindered the course of the disease, death being invariably the result in each case.

The experimental method adopted was as follows. I inoculated by the usual subdural method eleven animals with what M. Pasteur calls the *virus fixe*—that is to say, the pure virus of the

tion commenced prophylactic treatment with the hot-air bath, as will be seen in Table III. This treatment antedated by two days the onset of the symptoms, and so expedited the fatal result. There is, therefore, no question in my mind but that this measure exerts a very unfavourable therapeutical influence upon patients suffering from hydrophobia by diminishing their resistance to the disease.

I will now proceed to describe in detail the method of experimentation, and afterwards will discuss the effect which it appears to have had upon the human patient in those cases where it has been tried in indubitable cases of hydrophobia.

A. Bouisson Treatment of Rabbits.—The rabbit is an animal which is sensitive to the action of heat, and in which, conse-

disease, which, in the series that I possessed, produced its first symptom almost invariably upon the eighth day after inoculation, sometimes, but more rarely, as will be seen by Table I, on the ninth day. I also inoculated three rabbits with virus taken from the medulla of rabid dogs of the street, such virus usually producing, as is well known, its first symptom about the sixteenth day, but in certain rarer instances in the manner of the *virus fixe*—namely, from about the seventh to the ninth day. (See Table II.) These fourteen animals I placed in a hot-air bath, according to Dr. Bouisson's suggestion, directly they showed the first distinct symptoms of the disease. Finally, I inoculated two other animals with the *virus fixe*, and on the third day after inocula-

tion, the effects of the hot air can not only be readily observed but also seen to continue long after the animal has been removed from the bath. Bearing in mind the statements made by the advocates of the system as to the therapeutic advantage to be gained by employing a high temperature in a more or less continuous manner, the rabbit appeared to be an animal which specially lent itself to such a mode of treatment, for by keeping it at a high temperature for some hours and then removing it one was able as a rule to prevent the onset of heat paralysis, and at the same time to obtain the continuance of the effect of the bath, for example, in the elevated body-temperature, etc. The bath consisted of a roomy wooden chamber with glass front and window at the back,

there being at both ends a suitable aperture fitted outside with a ledge for the resting of the head of the animal in the fresh air surrounding the box. As the aperture was, of course, considerably larger than the neck of the rabbit, the interspace was blocked by soft cotton wool. My object in keeping the animal's head in the outer air while the body and limbs were subjected to the hot air was to provide against the possibility of its general vitality being depressed by the carbonic acid, etc., which was doubtless present in the heated air of the chamber, the said air being obtained from an iron funnel and pipe (this opening into the bottom of the chamber), heated by a large Bunsen burner. A thermometer passing through the roof of the chamber recorded the temperature.

conscious and dies comatose, usually in from three to four days after the appearance of the first symptom. In Table I it will be seen with what remarkable, indeed mathematical, regularity the symptoms ran their course, with a rapidity slightly (as in Table I) or markedly (as in Table III) accelerated by the treatment.

2. The effect of the bath. (a) On the normal animal. When a healthy rabbit is placed in a hot-air bath which is, to begin with, at the temperature of the room, and rapidly, that is within thirty minutes, raised to 75° C. = 147° F., the respirations of the animal steadily but quickly increase in number, the rate of the heart also being accelerated, and the temperature of the body rising to a variable height, usually one-half or more degrees

10	1/12																						WITH MARKED PARALYSIS OF HIND LIMBS

The animal's condition could thus be easily inspected during the treatment, and the exposure of so small a portion of the body surface as the head to the cooler air doubtless exerted none but a beneficial effect. In two instances, Experiments 6 and 8, Tables I and II, it will be seen that the animals succumbed to heat paralysis. These were cases in which the disease was extremely marked, Experiment 6 being one of those remarkable instances in which the virus from the rabid dog of the streets occasionally evokes the first symptom and causes death within the minimal period, namely, that of the *virus fixe*. In these cases I was endeavouring to counteract the obviously more intense action of the malady by more prolonged bathing, but of course the injurious effect of the bath found little resistance in the central nervous system already overwhelmed by the disease, and so produced the fatal result.

This leads me now to speak first of the appearance of the symptoms calling for the treatment by the bath, secondly, of the action of the bath upon the normal and upon the rabid animal.

Centigrade. Occasionally, however, the rise in the number of respirations is preceded by a slight fall. The elevation of the temperature and acceleration of the heart and respiratory rhythm are maintained for some hours after the animal is removed from the bath, and gradually return to normal. *b*. On the rabid animal. The diseased rabbit when placed in the hot chamber exhibits the same series of phenomena, but, as might be expected in a more violent, that is exaggerated, manner, and this in proportion as the disease has exerted its destructive influence upon the nerve centres. Thus, in Experiment 2 (see Table IV), on the third day of treatment the rise of temperature of the body (rectal) was most remarkable. The temperature of the animal at the moment of its being placed in the bath was excessively low, it being at the end of the disease, namely, 24.5° C. In two hours and a half it had shot up to 39° C., that is a gigantic rise of no less than 14.5° C. = 26° F.

I have 69 charts of the curves, indicating the temperature of the chamber, the rise of the temperature of the body from the be-

THE SIZE OF THE LETTER S INDICATES THE RELATIVE SEVERITY OF THE SYMPTOMS.

1. The initial symptoms. As is well-known, in the rabbit rabies is rarely (see Table I, Experiment 15) accompanied by the excitement so usually seen in other animals. Consequently the first symptoms observed in this animal is the paresis of the hind limbs, this occurring in all cases of rabies, furious or not. When this was distinctly present in the running or jumping movement of the animal it is expressed in Table I, under the term "marked paresis." It constituted an admirable means of detecting with certainty the onset of the characteristic symptoms of the malady. It will not be out of place to add that in the further progress of the disease the animal becomes more and more paralysed, and that from being apathetic at the commencement, it rapidly becomes un-

ginning to the end of the experiment and the variation in the respiratory rhythm. Analysis, however, of these numerous observations would take me beyond the scope of the present paper, and therefore I will content myself with simply exhibiting the chart, showing these phenomena in the instance just referred to (see Table IV).

I will now mention the general effect upon the rabic symptoms. These may almost be entirely summed up as being exacerbated. If the animal was taken out before the respiratory acceleration became excessive, it was occasionally noticed that, when previously apathetic, it might be more excitable, but, as a rule, that if the apathy were well marked to start with, the rabbit

was rendered more unconscious. In all cases it was much weakened by the heat, and this exhaustion and diminution in the vigour of the animal explains, I believe, the effect of the treatment in man in those cases where it reduced spasm.

The unsteady, shaky gait of the animal was always exaggerated, as also the paralysis.

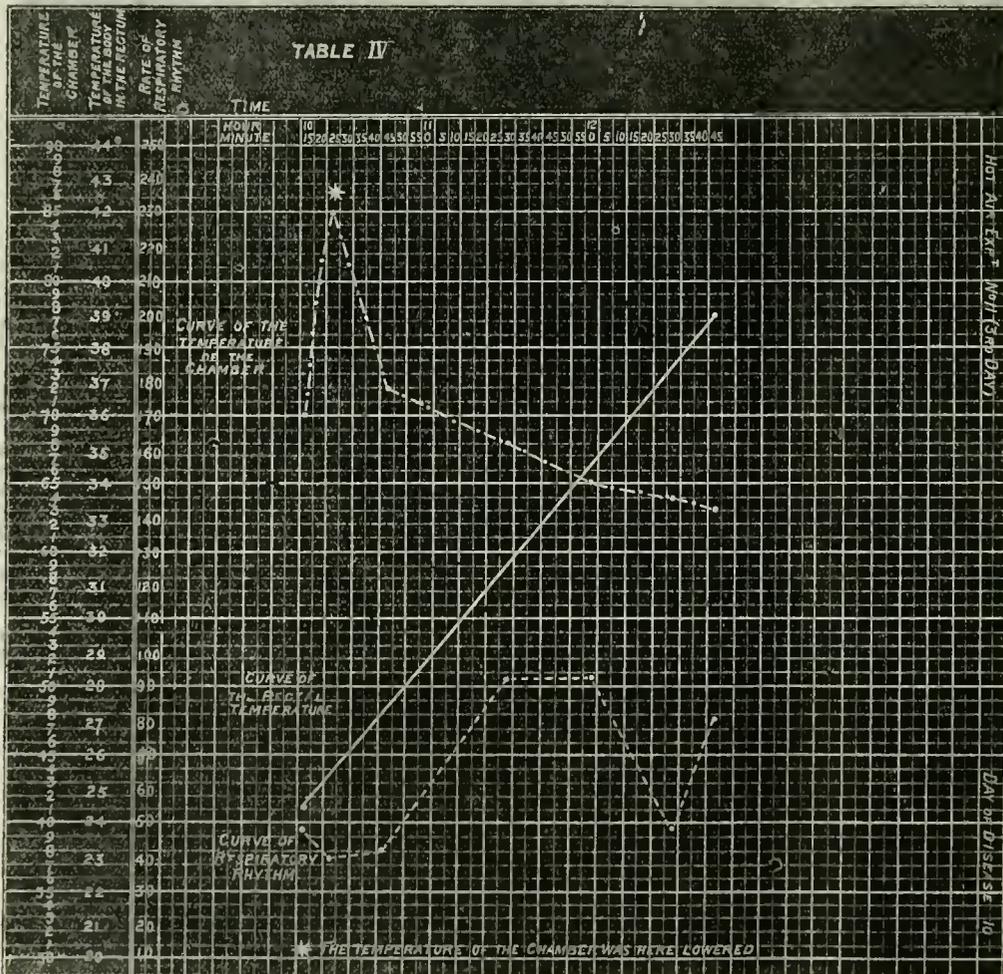

Apart from the effects described, the usual influence of heat upon secretion was made obvious. Ordinarily there was a free flow of saliva and urine, and the intestinal peristalsis was notably increased. The hypothetical excretion of the poison might thus be supposed to have been in full activity, but the only effect upon the animal was sedative—that is, that of further exhaustion.

B. Prophylactic Treatment by the Hot-air Bath.—With a view of giving the treatment a trial before the disease had shown itself, I employed it prophylactically in two cases, as shown in Table III. In each instance the bath was employed as already described, but

patient was much comforted, became drowsy, and ultimately slept for half an hour. This result can but be considered as a very gratifying one, if regarded in its true light, namely, as a palliative not curative effect. As Mr. Southam states it did not "prevent a fatal issue."

On the other hand, instances are recorded in which the hot-air bath caused distress. Thus in a case published by Dr. Southey (*Medical Press and Circular*, 1887, p. 72) the bath was administered on the evening of the first day of the spasm; "he now had a vapour bath, during which he complained greatly of the heat, and he perspired freely." The next day "he absolutely refused the vapour bath." This patient, being a genuine case, of course died.

If an efficient palliative, the hot-air bath would be an adjunct to a sedative course of treatment; for in Mr. Southam's case it clearly exhausted the nerve centres, so that they no longer painfully reacted to reflex stimulation. The exact counterpart of this exhausting effect we have seen in the rabbit similarly treated

in each case, also, as shown in the table, the symptoms commenced on the sixth day, that is, two days prematurely, and one animal actually died at the end of the eighth day, instead of as usual at the end of the eleventh. The others died at the end of the ninth day. This indicated so unmistakably the general injurious effect of the treatment, that it was unnecessary to pursue the investigation.

I will now give two instances in which the bath has been described to have produced an effect upon the hydrophobic human patient. The only genuine case I am aware of in which distinct "benefit" can be attributed to the bath alone is that reported by Mr. Southam, of Manchester. In Case v (? Case VI) *BRITISH MEDICAL JOURNAL*, 1881, p. 815, it is expressly stated that after exposure to the hot air the spasms became much less marked, the

The consideration of this point suggests that this is the time to ask ourselves upon what definite plan we ought to treat this disease. Are we to go on attempting to cure it by experimenting upon human beings with substances like curare, or, as suggested by the antivivisectionists, with the hot-air bath; or shall we adopt what seems to me to be the only justifiable course, namely, assuage with all the narcotics at our disposal the sufferings of the patient, until we shall have found out the real antidote by experiment upon the lower animals, especially upon that one (the rabbit) in which the disease takes its painless form, paralysis, a form of which that remarkable veterinarian, Mr. Youatt, said with prophetic force thirty-seven years ago; "I very much regret that I never instituted a course of experiments on the production and treatment of rabies in this animal. It would have been attended

with little expense or danger, and some important discoveries might have been made" (*The Dog*, by William Youatt, 1851). Surely the public, at any rate, who place themselves in our hands, under these the worst of circumstances, would unhesitatingly choose to be helped to die painlessly. And in following such a course no practitioner would be violating, by neglect, the great ethical principle of his profession, that he should endeavour as far as lies in his power to preserve life as well as alleviate pain. For there is no single case of reputed cure of developed hydrophobia by drugs or other means that will bear close investigation. Neither has anyone succeeded in arresting by these methods the march of the symptoms when once distinct in an experimental animal, although an enormous series of drugs have been tried, notably by Mr. Dowdeawell (*Proceedings of the Royal Society*). Nor have workers in this direction been able, by the use of drugs, to imitate in the slightest the protection afforded by M. Pasteur's system of inoculation. Of the ability of that system to overtake and check the development of disease, if applied within a reasonable time after inoculation, and under the ordinary circumstances, there is no longer any doubt, but it is powerless against the developed symptoms. There remains for us, therefore, the determination of our action in those cases where M. Pasteur's system has failed, or where it has not been applied. I hope I have shown sufficient reason that that action should, in the present state of knowledge, be simply palliative (by the employment of the most powerful narcotic drugs), and that all tentative treatment by drugs or the hot-air bath, being quite powerless to cure, and, consequently, cruel, should be abandoned.

A NOTE ON METHYLENE AND OTHER ANÆSTHETICS.

By SIR SPENCER WELLS, BART., F.R.C.S.
Surgeon to the Queen's Household.

EARLY in May I received from Berlin a sample of "methylene-chloride," manufactured by Riedel, of that city, with a paper on some of the different specimens of that anæsthetic by five other chemists, from a recent number of the *Pharmaceutische Zeitung*. I was informed that Professor Bardeleben had tried, and had been quite satisfied with, Riedel's methylene. Inhaling a little myself, it appeared to me very much like the methylene most used here, but rather stronger; so I asked Dr. Day to make some comparisons of it with that to which we have been accustomed for many years past. And having to operate at Manchester on May 13th, and at Liverpool on the 14th, I took some with me. At Manchester I had to do splenectomy; and Dr. Scott, who had administered ether in Edinburgh for Dr. Keith for two years, preferred ether to anything he had not used before. So he gave ether, with most satisfactory result. I never saw more quiet or complete anæsthesia, and I am glad to say that the patient has done well; but for two or three hours after the operation she had a flushed face, hot forehead, and excessively rapid pulse. I could scarcely count it, but it was certainly over 150. I supposed that this might be due to the altered circulation following removal of the large spleen; but Dr. Scott said that Dr. Keith had remarked to him upon the occasional occurrence of very rapid pulse after his operations. As I could not remember such rapidity after methylene, I was somewhat confirmed in my dislike to ether. I have seen it used alone, or after nitrous oxide, and I have never been quite pleased with the effects. Once Dr. Matthews Duncan and I simply examined a lady after the use of gas and ether, and for twenty-four hours afterwards she was in a state of hysterical, almost maniacal, excitement, which would have been alarming after any severe surgical operation; and more than once I have had to deal with troublesome bronchial irritation after the use of ether. At Liverpool, on May 14th, I performed ovariectomy assisted by Dr. Grimsdale and his son, and Dr. Rawdon (who had been accustomed to the use of methylene) used the sample of Riedel's preparation which I had with me. At first the action seemed rather quicker than usual, but towards the end of the operation, although it was unusually short, it was difficult to send the vapour through the tube of Junker's apparatus, and Dr. Rawdon noticed that the rapid evaporation had led to the partial closing of the tube by a sort of snow, or frozen vapour. This I had never noticed with the London methylene. The patient went

on remarkably well after the operation, so on May 16th Dr. Day used the new methylene for a lady in London for whom I performed ovariectomy. This was also a very short operation, but the patient's face was flushed and her head hot for several hours afterwards, though neither pulse nor temperature was much raised. On the 22nd I did a laparotomy at Gloucester with Mr. Edis, and Mr. Cuthbert preferred to administer chloroform, as being more accustomed to it. It answered admirably, and the patient, like the others, went on quite well. This I have often observed when chloroform has been given for me. The reasons I gave up the use of chloroform as a rule were not only the reports of the deaths to which it had led, but my own observation. I have only once seen a death from chloroform; that was in Paris, when Dr. Waters of Chester and I stood beside Malgaigne while he amputated at the shoulder-joint. But I nearly lost a patient in the Samaritan Hospital while I was removing a breast, Dr. Snow Beck giving chloroform; and twice in private practice, while Mr. Clover was giving chloroform vapour from his bag, I have had to suspend the operation for a time, and resort to artificial respiration during ovariectomy.

It was these cases which led me, at first with the help of Dr. Richardson, and afterwards of Dr. Junker (who devised the admirably simple inhaler which is called after him) to use methylene as a rule, and other anæsthetics only exceptionally. Once in Pomerania, when about to remove an enormous ovarian tumour, none of my German colleagues would give anything but chloroform, to which they were accustomed. The patient was very weak, and I very much preferred methylene; so I showed an intelligent nurse how to administer it, and she did it quite effectually and safely. I mention this to show that any supposed difficulty in the administration of methylene by Junker's apparatus is a mistake. Since 1872 I have preferred methylene to any other anæsthetic.

In the Address on Surgery at Manchester in 1877, I said: "Given properly diluted with air, the vapour of chloromethyl has, in my experience of more than ten years with more than 1,000 operations of a nature unusually severe as tests of an anæsthetic, proved without a single exception applicable to every patient, perfectly certain to produce complete anæsthesia, relieving the surgeon from all alarm or even anxiety; and its use has never been followed by any dangerous symptom which could be fairly attributed to it." And I went on to say: "I wish I could speak as confidently of the chemical composition of the fluid sold as bichloride of methylene as I can of its anæsthetic properties; but whatever may be its chemical composition, whether it is or is not chloroform mixed with some spirit or ether, or whether it really is bichloride of methylene, I am still content with the effects of the liquid sold under that name, when properly administered." And more than ten years' additional experience has confirmed me in the opinions so expressed. Professor Tyndall told me that no chemist could make pure bichloride of methylene under ten shillings an ounce, and that when made, it would not keep a week. Others said a mixture of chloroform and methylic alcohol would act as well, but on trial it did not; neither did the A.C.E. mixture of the Committee of the Royal Medical and Chirurgical Society; neither does this new preparation of Riedel's. Last week Dr. Day gave it for me in a case of amputation of a breast. The tube became so choked with snow before I began the operation that the patient could not be made unconscious, and we had to give chloroform, neither of us very willingly, as we had just heard of a patient having become so near death under chloroform that the surgeon had to do tracheotomy with a pocket-knife before animation could be restored.

Surprised at the obstruction of the tube by the new preparation, I wrote to Professor Bardeleben, and he replied on May 29th as follows: "We have made the same observation on artificial snow, and the obstruction of the tubes in using Riedel's methylene-chloride with Junker's apparatus. No doubt it is dependent on the cold produced by the rapid evaporation. We have another objection to make to this new anæsthetic substance. The anæsthesia is effected very slowly, and is not of long duration; and the nausea and vomiting begin often before complete anæsthesia has been attained."

Accordingly, until some better anæsthetic is brought forward, I shall remain content with the bichloride of methylene, made as first proposed by Dr. Richardson. I have never known it to fail, and I have never once been alarmed, or even made uneasy, by its effects in any one of more than 2,000 operations, many of them of unusual severity or duration.

ON RARE DISEASES AND EXCEPTIONAL SYMPTOMS.

BY JONATHAN HUTCHINSON, F.R.C.S., F.R.S., LL.D.,
Emeritus Professor of Surgery at the London Hospital.

(Continued from page 1150, Vol. 4, 1887.)

XXX.—FRACTURE OF THE TEMPORAL BONE CAUSED BY A BLOW ON THE CHIN.

A FOOTMAN looking on at a cricket match received the ball as he says "deliberately" on the tip of his chin. He was almost knocked down by the blow, but did not actually fall. He felt somewhat stunned, and immediately afterwards recognised that he was deaf in the left ear. When he got home his fellow-servants "laughed at him because his face was all on one side." After this he had complete facial paralysis and almost complete deafness, but both gradually improved. When I saw him four months later the facial paralysis was not perceptible unless his muscles were thrown into action. He could use most of them fairly well, but could not frown on the left side of his forehead at all (occipito-frontalis), nor could he whistle, as the left half of his mouth remained flabby. He could close the left eye well; he could hear a watch two inches from the ear. There was nothing amiss with the membrana tympani, and he had never had bleeding either from nose or ear.

It seemed certain that in this case there must have been a fracture of the petrous bone caused by the condyle being violently driven against it. In no other way could the simultaneous paralysis of the auditory and facial nerves be accounted for.

XXXI.—CASE OF PSEUDO-HYPERTROPHY OF THE MUSCLES OF ONE LOWER EXTREMITY FOLLOWING ŒDEMA FROM VENOUS OBSTRUCTION.

The case which follows seems worthy of record as an example of overgrowth of muscles as the result simply of retarded blood-current.

A gentleman who consulted me about a skin-disease of no great moment told me that he had one weak leg, and that it was larger than the other. In this I was much interested, and at once got him to let me examine the limb. He had, as he had said, on the left side a splendid calf, whilst that on the right was decidedly poor. The contrast to the eye was very marked, and it was confirmed by measurement, for the girth of the left calf was nearly 14½ inches, whilst the right measured less than 13 inches. There was a difference also in the thighs, but it was not so conspicuous; there was no œdema of the limb excepting a very little just where the edge of the boot touched. Over the whole calf the contour of the muscle was well marked, and I could not detect the slightest evidence of thickening of the skin or of effusion into the cellular tissue. A curious point was that the patient said that although the muscles of his left limb looked in such excellent condition, yet they were more easily tired than those of the right. If he walked far he always found his left leg tire first. There were no varicose veins in the limb until the ham was reached, where a few were present, but of no great size.

The history of the case pointed to venous obstruction by pressure, with possibly implication of the lymphatics. Mr. M. had lived in India, and whilst there, twelve months before I saw him, he went through an attack of typhoid fever. He brought to me his medical report, which described a severe illness with profuse hæmorrhage from the bowels and a painful swelling in the left iliac fossa, which caused venous obstruction. The obstruction lasted some months, and was attended by considerable general swelling of the limb. It was when at length this swelling cleared away, that the muscles were found to be hypertrophied. In reference to the possible suggestion that it may have been that the muscles of the other limb had wasted, and thus caused a relative disproportion, I may say that although Mr. M. was thin and out of health, he was not so in any extreme degree, and that the size of the larger calf was obviously out of proportion to his general build. Even if it were preferred to say that the venous obstruction simply prevented waste rather than caused overgrowth, we should still have an illustration of the same law.

I am well aware that instances of overgrowth from retarded blood-supply are well known, as, for example, in cases of elephantiasis and its ally, "one leg œdema." In all those, however, that I have seen, something of the nature of permanent œdema was present, and the overgrowth was rather of cellular tissue

and skin than of muscles, or, at any rate, the muscles were concealed in the general thickening. In this instance there was no thickening whatever of skin, but the muscles resembled those of pseudo-hypertrophy.

XXXII.—TUMOURS OF THE NECK, ILLUSTRATING THE LAW OF INCREASING RATIO OF GROWTH IN PROPORTION TO SIZE ATTAINED (POPULATION INCREASE).

I adduce the two woodcuts here given in order to illustrate

several points in reference to the pathology of tumours. One is from a photograph given me by the late Sir W. Fergusson, and the other from a patient under the care of Mr. Edwards, of Keston. In each instance, the tumour had been growing for upwards of a quarter of a century before it attained the encumbering dimen-

sions exhibited. In neither case had it caused any pain or other inconvenience to the patient excepting from its bulk, but in both it was at last the cause of death. In Sir W. Fergusson's case the patient, wearied by the distress caused by the increasing mass, at length took courage to have it removed, and came home from India for that purpose. He sank after the operation. In the

other case the tumour eventually inflamed and sloughed in parts, and caused death by exhaustion.

The cases are of interest as showing to what enormous size tumours developed in connection with the side of the face or neck may eventually attain. Presumably they were originally formed over the parotid (or, perhaps, the submaxillary), and were in part cartilaginous and in part fibro-cellular. I cannot in either give any details as to their nature or precise relations to the glands.¹

Some years ago, in a communication to this JOURNAL, I drew attention to the important clinical fact that the growth of tumours, innocent as well as malignant, often illustrates the law of increase of population. It is rapid in ratio with size attained, or, in other words, in ratio with the number of the cell elements. Thus a tumour which for many years may have grown so slowly that the patient was led to hope that it might never much incommode him, increases its rate of growth every year, and finally develops with dangerous rapidity. This had been remarkably the fact in these two patients. The knowledge of this law may often induce us to urge the timely removal of innocent tumours which as yet cause no inconvenience.

ON THE USE OF CODEINE TO RELIEVE PAIN IN ABDOMINAL DISEASE.

By T. LAUDER BRUNTON, M.D., F.R.S.

Lecturer on Materia Medica and Therapeutics, and Assistant Physician, St. Bartholomew's Hospital.

I HAD intended to bring the subject of this paper before the British Medical Association at its last meeting, but I was unfortunately prevented from attending, and delayed publication of this paper for several reasons, one of which was the desire to obtain a larger experience of the utility of the drug. The relief of pain may be classed next to the saving of life, and must perhaps sometimes be even put before it as the chief duty of the physician. As yet no drug has taken the place of opium as a general analgesic, though the use of crude opium is now frequently replaced by the subcutaneous injection of morphine, the most active of the alkaloids it contains. In abdominal pain many practitioners still have a preference for the use of opium, as compared with that of morphine, and this very preference is sufficient to make one ask whether it may not have some foundation in the presence of other active principles along with morphine in opium, and if so, to inquire which active principle it is that helps to allay pain.

Thanks to its recommendation by Dr. Pavy, codeine is largely used in the treatment of cases of diabetes, but at present its use is almost confined to this disease, and it is rarely employed for other purposes, excepting perhaps that of soothing cough or irritation in the throat.

Codeine was discovered by Robiquet in 1832, and two years afterwards its action was tested upon himself by Gregory,² who found that instead of causing sleep, it rather caused excitement, and had also a slight laxative tendency. It was applied therapeutically by Barbier³ in 1834, who noticed that it seemed to have a special action upon the sympathetic system, and found that it was of great use in lessening pain in persons presenting symptoms of irritation in the solar plexus. Such symptoms are pain in the epigastrium, spreading to the sides and back, and associated with a feeling of burning, anxiety, depression, more or less tenderness of the epigastrium, with sighing, lack of energy and tendency to faint. Occasionally the pain may cause symptoms of collapse, palpitation, and vomiting. In such cases Barbier gave a grain of codeine in a tablespoonful of syrup, and repeated it if necessary in one or two hours with the best results. From his observations he came to the conclusion that codeine acts chiefly upon the sympathetic nervous system, and especially upon that part of it which is in the region of the stomach; that it is a most useful remedy in abdominal neuroses depending upon disordered condition of the nervous plexus in the abdomen, and

especially those in the gastric region; that it does not disorder the digestion, and rather aids than interferes with the action of the bowels. He found also that it produced sleep with tolerable certainty, and that this sleep was never followed by heaviness in the head or stupidity, but, on the contrary, persons who had taken it felt happy, and were disposed to be cheerful on awaking. About twenty years later, in 1856, Robiquet's⁴ son undertook some observations on the action of the drug which his father had discovered. The results he obtained, however, did not quite accord with those of Gregory or of Barbier, and it is possible that the discrepancies may have been due to more or less impurity in the drug employed. In large doses he found that it caused an unrefreshing sleep, followed by a period of confusion of thought; occasionally nausea and vomiting were produced. In small doses he found it of great service in hypochondriasis, relieving nervousness, irritability, and all the discomforts from which patients affected with this disorder are apt to suffer.

Shortly afterwards Berthé⁵ made a much more full and complete investigation of the physiological action of the alkaloid. Amongst other things he confirmed Barbier's observation that it had a specific action upon the sympathetic, and found that it lessened the irritability of the intestine to such an extent that a dog which had received 15 grains of arsenic along with $7\frac{1}{2}$ grains of codeine exhibited neither vomiting nor purging, nor any other symptom excepting drowsiness, while another dog which had received a similar dose of arsenic without the codeine began to suffer in the course of an hour from severe pain, vomiting, and bloody diarrhoea, and indeed presented well-marked symptoms of arsenical poisoning, although it ultimately recovered. These experiments suggested the idea to me that codeine was likely to be of service in abdominal pain, and I proceeded to try it, with very satisfactory results. The class of cases in which I have used it is, I think, somewhat different from those in which it has previously been recommended, because while Barbier, Aran and others have chiefly employed it in gastralgia and painful disorders of the stomach, I have used it chiefly in pain affecting the intestine and lower part of the abdomen. The kinds of cases in which I have used it have been very varied. As examples I may shortly describe one or two. In one case which I saw with Dr. Eccles, there was high temperature, intense pain in the right iliac fossa, with considerable swelling, so that there could be little doubt that there was inflammation around the cæcum, although examination after the acute symptoms had subsided showed that there was also pelvic cellulitis. In this case one grain of codeine, given in the form of a pill, relieved the pain at once, and repetition of the dose whenever the pain began to return prevented its becoming at all severe.

In another case, seen with Dr. Philpot, of Croydon, a lady, aged 50, had pneumonia of the right base, a greatly dilated heart with very irregular action, pulse so rapid and weak that it could hardly be counted, and pain over the epigastrium and spreading out from it. She was slightly jaundiced, and a tumour was felt in the right lateral abdominal region, which descended with respiration, but was partly covered by intestine, and could be moved from side to side, so that it seemed to be renal rather than hepatic. As no *post-mortem* examination was obtained the exact diagnosis could not be established, but the administration of codeine in half-grain doses relieved the pain, as Dr. Philpot said, "as if by magic."

In another case, seen with Dr. Pardington at Tunbridge Wells, there was pain in the abdomen depending upon a mass of impacted fæces in the transverse colon. In this case codeine seemed to be especially indicated, as one wished to relieve the pain without interfering with the action of the bowels. In grain doses codeine relieved the pain, and the use of copious enemata, aided by washing out the stomach, cleared away the impacted mass which had given rise to the disturbance. I have tried codeine in cases of long-continued abdominal pain for which no definite cause could be assigned, as no tumour could be felt, and the functional disturbance did not seem sufficient to warrant a diagnosis of malignant disease. I have tried it in cancer of the liver and pancreas with success in relieving pain, and also in numerous cases where the age of the patient, the presence of diarrhoea, tenderness on pressure, and visible peristaltic movements, and thickening of the gut, easily perceptible on palpation, led to the diagnosis of malignant disease in the intestine, although inability to obtain a *post-mortem* examination prevented the confirmation of the diagnosis. In such cases I generally begin with half a grain, in the form of a pill made up with extract of gentian, three times a day; and if this

¹ Sir W. Fergusson's case is probably published, but after some search I am unable to find a reference. In the other there was no *post-mortem* examination. A photograph of a case almost precisely similar to Mr. Edwards's patient was shown to me during a recent visit to Glasgow by Dr. Paterson. In the museum of the Richmond Street Hospital, Dublin, is the portrait of a man, aged 54, from whom Mr. Hutton removed a tumour of somewhat similar kind and size. It weighed six pounds, and contained cysts. Hunter successfully removed one which weighed ten pounds, and had been sixteen years growing (College of Surgeons' Museum, Ag 62). See Paget's Lectures, vol. II.

is insufficient to control the pain I increase the dose to a grain, and give it as frequently as seems necessary. As a rule, I find that it does not produce drowsiness, nor has it interfered with the digestive functions.

To sum up, the results I have obtained from the administration of codeine have satisfied me that it has a powerful action in allaying abdominal pain, and it can be pushed to a much greater extent than morphine without causing drowsiness or interfering with the respiration or with the action of the bowels. It is, therefore, specially indicated in such a case as Dr. Philpot's, which I have already mentioned, where the dilated heart and consolidated lung tended to make one afraid of morphine. Codeine is also specially indicated in a case like Dr. Pardington's, where one wished to relieve the pain without interfering with the action of the bowels. On the other hand, in cases where there has been much diarrhoea, as in some cases of malignant disease of the colon or rectum, the absence of any tendency to lessen peristaltic movement is rather a disadvantage to codeine as compared with morphine or opium.

I have found that in cases of long-continued enteralgia without organic disease, it has continued to relieve pain for months together, without the dose being increased beyond one grain three times a day, and I found the same to be the case where the presence of a tumour, in addition to other symptoms, had led to the diagnoses of malignant disease.

It is interesting to follow the vicissitudes of a drug, and to notice how its use extends or diminishes until at last it finds its right place and maintains it. Thus digitalis, while mentioned in the London *Pharmacopœia* of 1721, was excluded from that of 1746. It again appeared in 1788, and since then it has held its place.

Possibly codeine, after falling into almost complete disuse as an analgesic for many years may again regain a more or less important place amongst the remedies which enable us to relieve pain.

ON THE TREATMENT OF TUBERCULAR LEPROSY BY EXCISION.

By BEAVEN RAKE, M.D.LOND.,

Medical Superintendent of the Leper Asylum, Trinidad.

MODERN pathology tends to show that leprosy is a parasitic disease. However that may be, I have for some time been of opinion that a good deal may be done in the way of local palliative treatment by excision of tubercles. Having lately had an opportunity of testing the truth of my conviction, I will first briefly describe two cases, and afterwards make a few remarks.

CASE I.—J. J., aged 14, a negress born in Trinidad, was admitted to the Leper Asylum on November 5th, 1884, with one year's history. She was a well-developed, healthy-looking girl. The forearms, hands, and fingers were covered with large tuberculated masses, and there were similar isolated masses on the forehead, cheeks, nose, and chin. As she wished to have something done to improve her appearance, I determined to try the effect of free excision.

On January 1st, 1885, she was put under chloroform, and tubercles were ligatured and excised from the *alæ nasi* and above the eyebrows.

On January 22nd more tubercles were removed from the end and side of the nose.

On January 29th a large mass of tubercles about two inches long was removed from the chin without chloroform, as she took the anæsthetic very badly.

On February 7th she was given chloroform, and a flat mass of tubercle about an inch and a half square and half an inch in height was removed from the right cheek; the edges of the wound were rubbed over with strong nitric acid.

On March 5th about two square inches were removed from the left cheek without chloroform. The edges of the wound were trimmed with scissors so as to bring them level with the surrounding skin. She made but little complaint of pain.

On March 31st some small tubercles, which had sprouted from the *alæ nasi* since the operation of January 1st, were removed. A slight recurrence at the upper margin of the cicatrix on the right cheek was also removed with scissors, also a tubercle about three-eighths of an inch in diameter from the bridge of the nose.

On April 14th the following was the condition of the cicatrices: Right cheek: cicatrix $2 \times 1\frac{1}{2}$ in.; small scab in centre; small

patches of tubercle at lower and inner margin. Left cheek: cicatrix $2\frac{1}{4} \times 2$ in.; small scab remaining; a few small islands of tubercular tissue scattered about in cicatrix. Over right eyebrow: cicatrix $1\frac{1}{4} \times 1$ in.; small growth of tubercles at upper and inner margins. Over left eyebrow: cicatrix $\frac{1}{4}$ in. diameter; growth at edges. Chin: crescentic patch $2 \times 1\frac{1}{4}$ in.; lower part occupied by cicatrix, upper part by rather exuberant tubercles encroaching on the lip. Right side of nose: cicatrix $1 \times \frac{1}{2}$ in.; growth of small tubercles all down outer side. Left side of nose: triangular patch; cicatrix in centre; tubercles at edges. There was a recurrence of small tubercles round the nostrils and tip of the nose, at the edges of the cicatrices. There were a few untouched tubercles on the forehead and over the glabella.

On April 23rd a small tubercle was removed from the lower lip.

On September 29th the tubercles over the eyebrows and nose were found to be sprouting more, and at her own request the tubercle over the right eyebrow was further removed on October

6th. A superficial incision was made all round at the junction of healthy with infiltrated skin. The tubercle was then lifted up and snipped off with scissors. Strong glacial carbolic acid was rubbed over, and then tannin powder sprinkled over so as to form a crust. No chloroform was given, and she made no complaint of pain.

The more thorough cauterisation on this occasion was suggested by the recurrence of small tubercles on the margins of the old cicatrices. This recurrence appeared to be due to escape of some of the tuberculous tissue, and it was hoped, by freer excision, and cauterisation with such a powerful bactericide as glacial carbolic acid, to prevent lateral extension. It will be seen that this method was more fully carried out in the next case.

Magenta showed swarms of the bacillus lepræ in the excised tubercles. She was put on four minims of liquor arsenicalis three

times a day on January 26th, and this was increased to six minims on March 31st.

The accompanying woodcuts are from photographs taken before and after operation. It must be noted that some tubercles had been already removed from above the eyebrows, and from the *alæ nasi* before the first photograph was taken, but this does not materially affect the comparison.

CASE II.—R. G., aged 12, negro, born in Venezuela, was admitted to the Leper Asylum on September 16th, 1881, with a three

years' history. Large tuberculated masses involved the trunk and extremities, but these were especially exuberant on the face and ears, producing a degree of disfigurement which I have never yet seen equalled in tubercular leprosy. On April 11th, 1885, he was given chloroform, which he took remarkably well. A large mass of tubercles, about 3 by 2 inches, was excised from the forehead. There was a good deal of hæmorrhage. The raw surface was treated as above described, with carbolic acid and tannin. This method was adopted in all subsequent operations. The cicatrix was complete by April 25th.

On April 18th numerous tubercles were excised from the left cheek, over an area of about four square inches.

On April 25th more tubercles were removed from the left cheek, over an area of about two square inches, also from the left side of the chin.

On May 5th, about one ounce of tubercles was removed from the right ear and *alæ nasi*.

On May 12th tubercles were removed with scissors from the left ear, also from the right side of the chin and lips, also a few from the bridge of the nose.

On May 28th nearly all the scabs had fallen, and his appearance was so much changed that he was not recognisable.

The areas of cicatricial tissue were roughly calculated as follows: Forehead: $3 \times 1\frac{1}{2}$ in. Each cheek: $4 \times 3\frac{1}{2}$ in. Chin: $2\frac{1}{2} \times 2\frac{1}{2}$ in. Each ear: $2 \times \frac{1}{2}$ in. Total area about 27 square inches.

Most of the tubercles were preserved in spirit and weighed, and their total weight was calculated at about four ounces.

On June 20th he was found to have an attack of yaws, which, however, had passed by September 22nd.

On December 4th it was noted that there was practically no return of tubercles in the ears. There were firm, smooth cicatrices on the face. Those pieces of tubercle which had escaped removal by knife or scissors had grown a little, but not more than $\frac{1}{4}$ to $\frac{1}{2}$ inch; where the knife or scissors had gone more deeply there was no return. On the *alæ* of the nose the tubercles had grown rather more—about $\frac{1}{2}$ inch—but here it was not practicable to remove them without more or less destroying the nose. Over the forehead and eyebrows the tubercles were stationary.

In this case, also, magenta showed swarms of bacilli in the excised tubercles. On April 21st he was ordered four minims of liquor arsenicalis three times a day, but there was some difficulty in getting him to take the medicine regularly.

The accompanying illustrations, showing the face before and after operation, will serve to give some idea of the relief afforded.

I have at present in the asylum two milder cases which are undergoing similar treatment. Though the result can be at the best but palliative, it seems worthy of consideration in such a disfiguring disease as tubercular leprosy. It may be objected that this treatment is practically the same as that pursued by the late Dr. Beauperthuy. An all-important distinction lies in the use of the knife or scissors—a detail which I believe was not adopted by him. Free excision combined with caustics gives a more rapid, clean, and effectual cicatrix than the use of caustics alone. Assuming, as a working hypothesis, that leprosy is a parasitic disease, it is hoped that the use of two powerful germicides—one, arsenic, internally; the other, strong carbolic acid, externally—may kill, at any rate, some of the bacilli, and thus hinder if not prevent recurrence. In point of fact, on examining tubercles after the use of arsenic, I found in some cases fewer bacilli, but this may have been a mere error of experiment, and of course a large number of comparative observations will be necessary. The tannin powder is used with the idea of forming crusts to protect the granulating surfaces and so prolonging the local action of the carbolic acid.

Another important effect of this treatment is to lessen the amount of ulceration. Tuberculated tissue ulcerates much more readily than sound skin, and thus often works its own cure to a certain extent. This was very marked in the second case. Before operation the large masses on the ears were constantly raw and ulcerated. After operation a small firm cicatrix formed, and one could scarcely recognise the site of the former tubercles.

A SECOND SUCCESSFUL CASE OF EXTRACTION OF GLASS FROM AN EYE,

AFTER A LODGMENT OF SEVEN YEARS AND A DAY

By T. H. BICKERTON, M.R.C.S.,

Oculist, Liverpool Royal Infirmary.

IN the JOURNAL for April 28th I recorded the case of a gentleman, from whose left eye a piece of glass, which had lodged there for a little more than ten years, was successfully extracted, and it is curious that, within a few weeks, another similar case should have come under my care. The history given to me by the patient is as follows.

W. C., aged 33, received at midnight on January 12th, 1881, a severe wound of the right eye, owing to the bursting of the glass water gauge of a boiler, and was, in consequence, admitted into hospital. About three months later the eye was "needled," and the patient eventually returned home, with fair vision (C+ 3" 23, C + 2½ J 8), and with all inflammation gone. In 1883 the eye was hit with a piece of rope; it inflamed, was very irritable, and watered much, and opinions were divided as to the necessity of its removal. Eventually sedative treatment was selected, and after some months the eye again settled down. In May, 1885, inflammation recurred, this time without apparent cause, and it disappeared in about a fortnight. In the autumn of 1885 the eye again received a trifling knock, the inflammation being again allayed by hospital treatment, and after a short time he was able to return to work. In the beginning of July, 1887, the eye was slightly flicked with a piece of bagging. A fortnight later, the irritation not subsiding, an adhesion between the iris and the cornea was successfully divided (September 17th, 1887), and after

nine days he left hospital. On October 3rd, 1887, he started work, and whilst bending down to lift a sack, he was struck by a lightning shock of pain, which, starting at the supra-orbital notch, passed along the right side of the head as far as the occiput, and this acute pain occurred almost every time he bent his head down, and often on moving it from side to side. He therefore did his work holding the head in the erect posture, but in spite of this the pain now and again attacked him, and the eye becoming greatly irritable, he was again compelled to seek hospital treatment. This time a large iridectomy was performed upwards (October 15th, 1887), but the redness and irritability not subsiding, and the pain continuing, the removal of the eye was determined on. In this decision the patient acquiesced, but his employer objecting, he now came under my notice, November 8th, 1887. The right eye was very red, irritable, and watering much on exposure to light; V C + 12 D $\frac{1}{2}$: C + 14 D a few words of Ja +. Just below the centre of the cornea there was a small cicatrix, and it was easy to see that an adhesion to the iris had existed here. A large upward iridectomy pupillary space was occupied by capsular remains. The iris was attached firmly to these remains below and on the outer side, but it was free on the inner side. By means of careful oblique

Line of Incision | Glass, actual Size. | Glass in Situ.

illumination, and when the eye was turned in certain directions, there could be seen lying in the anterior chamber, in the sinus between the cornea and iris, and not imbedded in the latter, a piece of glass, which appeared to be quite a quarter of an inch long, and was of considerable breadth. The position of the glass was not quite horizontal, its inner end being slightly tilted upwards. The treatment adopted was rest, in the hope that the eye might again settle down, and allow the extraction to be performed under the best possible conditions.

The redness and irritability did slowly subside until January 11th, 1888, but on that morning the patient awoke with much pain in the eye, and, as an examination of it showed that the glass had moved, its inner end being still more tilted up, and that the vascularity of the eye had greatly increased, further delay was considered inadvisable. Therefore, on January 13th, 1888, the eye having been put thoroughly under the influence of cocaine, the method of operation which had been practised in the former case was again resorted to. An oblique corneal incision was made by puncture and counter-puncture with a Graefe's knife across the front of the cornea, at the junction of the lower third with the upper two thirds. A curette was introduced between the lips of the wound, and passed on in front of the iris, to a position behind the glass, in order to fix it, and a fine pair of forceps being now put in, the glass was seized at the fourth attempt, and removed entire.

By the next day the anterior chamber had re-formed, there was no iritic adhesion, and the eye was absolutely free from pain. Recovery was uninterrupted, and on February 10th the patient was able to return to his work with the eye in a perfectly quiet condition, and up to the present day (May 18th) the eye has remained absolutely free from all pain and irritation. The weight of the glass, kindly taken by Mr. Rawson, Professor Campbell Brown's assistant, was .01331 grammes; its dimensions, taken by Mr. Chattock, Professor Oliver Lodge's assistant, were, greatest length 6.4 millimètres; greatest breadth, 2.7 millimètres, and it may be mentioned that the actual breadth was much greater than had been expected from the appearance which the glass presented when in the eye.

THOMAS'S OPERATION FOR REMOVAL OF BENIGN TUMOUR OF THE FEMALE BREAST.

By ALEXANDER JAMIESON, M.A., M.D., M.R.C.P.,
Consulting Surgeon to the Imperial Maritime Customs in China,
Shanghai.

THE recognised risk of adenomata of the female breast developing into recurrent fibro-cystomata has always prompted me to urge early extirpation of these tumours, and most surgeons follow, I imagine, the same practice. A seriously deformed breast is, how-

ever, in the estimation of the majority of young women, a disproportionate price to pay for the avoidance of a danger which at worst is only probable. Therefore when in 1882 Dr. Gaillard Thomas, of New York, brought forward an operation for the removal of benign mammary tumours without visible mutilation, I felt confident that the new method would be extensively tried. Whether this has been the case or not I cannot say. It is at least certain that few cases, if any, have been reported in European journals. The ratio of benign tumours of the breast to malignant is everywhere small; and in semi-civilised countries it is smaller than in Europe and America, for the simple reason that in such countries a tumour in any locality and in either sex is invariably disregarded until by its size, by the pain it excites, or by its factor, it renders life intolerable to the patient or his neighbours. Accordingly, putting together four cases operated on by me since the publication of Dr. Thomas's paper, and one by Dr. Boone, my colleague at St. Luke's Hospital for Chinese, out of the five two were European women, one an American, one a half-caste living under foreign conditions, and only one was pure Chinese.

The operation is begun by an incision exactly following the fold between the skin of the thorax and that covering the breast in its lower semi-circumference. The length and precise position of the incision depend on the size and situation of the growth, but at all events when the breast is allowed to fall, the line followed by the knife must be invisible, except perhaps at one or other extremity. On reaching the muscles the gland is dissected from the chest sufficiently to enable it to be turned upwards, exposing its posterior surface. This is incised along a radial line over the tumour, and the latter removed. The gland is then replaced, its cutaneous surface remaining completely uninjured. In all the five cases to which I have referred, healing was immediate under antiseptic dressing.

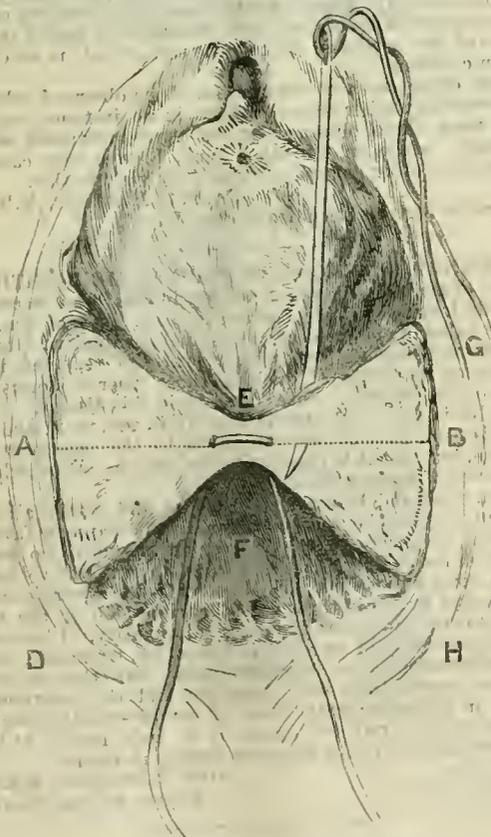

The accompanying woodcut from a photograph taken two months after operation well represents what, so far, has been the invariable result. In this instance the patient was an American,

aged 26, who had received a blow on the left breast five years before. A tumour the size of a small orange had formed in the substance of the gland midway between the nipple and the axillary periphery, taking about six months for its development. It varied in size under excitement and menstruation, but was never smaller than as described above. It gave rise to severe spontaneous pain and was extremely sensitive to pressure. With its removal all these symptoms disappeared. Histologically it was a tubular adenoma with no cyst formation.

ON CATGUT SUTURES IN THE OPERATION FOR RUPTURED PERINEUM.

By G. ERNEST HERMAN, M.B.LOND., F.R.C.P.,
Obstetric Physician to the London Hospital, etc.

DURING the last few years I have done the operation for ruptured perineum in a manner somewhat different from that usually described. The method I now follow depends essentially upon the use of fine catgut for the sutures. I describe the operation as in a case of complete rupture through the rectal sphincter. I make the raw surface by splitting the recto-vaginal septum.¹ The raw surface so produced may be described as forming two triangles, a right and a left (C D E and G H E), the base of each (C D and G H) being the skin of the perineum, the sides being formed by the mucous membrane of the rectum and that of the vagina, the apices being truncated and meeting in the middle line. A line

Drawn by Dr. W. Ambrosé Kibbler (diagrammatic).

(A B) may be imagined drawn through the middle of each triangle, so as to bisect its base; this line I shall mean when I speak of the middle of the raw surface. The first suture is entered at the junction of rectal mucous membrane and raw surface, close to the apex of the triangle, and brought out in the middle of the raw surface; entered again at the middle of the raw surface on the opposite side, and brought out as close as possible to the junction

¹ I learned this method of making the raw surface fourteen years ago, from my colleague, Mr. W. Warren Tay.

of raw surface and rectal mucous membrane. This suture is then tied, and the ends held out of the way with forceps. (The diagram shows the first suture passed, but not tied, and the second suture being put in. This is for the sake of pictorial clearness, but it is better to tie each suture before putting in the next, and it is convenient at this stage not to cut off the ends, because by them the parts can be pulled upon if it be wished.) The second suture is put in at the junction of vaginal mucous membrane and raw surface, brought out at the middle of the raw surface, a little nearer the base of the triangle than the first suture, entered at a corresponding point in the middle of the raw surface on the opposite side, and brought out as close as possible to the junction of vaginal mucous membrane and raw surface; this is then tied. The third suture is entered at the junction of rectal mucous membrane and raw surface, still nearer the base of the triangle, and so on, sutures being entered alternately from the rectal and vaginal aspect until the two triangles of raw surface have been completely brought into apposition. When all except a strip of raw surface parallel with the base of each triangle (C D, G H) has been brought together, the apposition of the bases is completed by transverse sutures, through the skin of the perineum. It is well not to tie the last pair of sutures (vaginal and rectal) until these transverse stitches have been put in. When the stitching is complete, the ends of all the sutures are cut short. The rectum is washed out twice a day for the next fortnight. The stitches are not removed. At the end of a fortnight usually all trace of them has disappeared.

For the majority of cases of complete perineal rupture, this mode of stitching, with fine catgut alone, is quite enough. But in some cases the laceration has been in the beginning attended with sloughing, and then there may be much cicatricial tissue about the parts which have to be brought together, so that they cannot be approximated without much strain on the stitches. In that case it is well, before sewing up with catgut, to pass a single deep stitch of silkworm gut through the recto-vaginal septum in the usual way, so that this may relieve the strain on the fine catgut.

The chief advantage of this method of operating is that no sutures have to be removed; and in the bad cases last described, only one suture. The removal of wire sutures, and even of silkworm gut, causes a good deal of pain to the patient. By the use of a large number of stitches there is a larger surface brought into contact, there is less strain on each stitch, and little, if any, suppurative in the suture tracks. The perineum produced is thicker and larger than that which results from the puckering effect of the ordinary method of suture. The only disadvantage of this method is that the operation takes rather longer in performance.

A continuous catgut suture has been recommended for recent rupture of the perineum: and it might also be used for the secondary operation. But it has this disadvantage, that if the catgut breaks, then the whole suturing has to be done over again; or if the knot slip, then the whole gets loose. With an interrupted suture as here described, if one stitch break, it is only that stitch which needs replacement; and if one or two knots should slip, the others hold the parts together, and it makes little difference.

For a rupture which does not go through the sphincter, only one set of stitches is required. Here the advantage of catgut is decided, for, the operation once done, all the after-treatment wanted is to keep the parts clean: no sutures have to be removed.

OBSTETRIC MEMORANDA.

ABORTION IN DOUBLE UTERUS.

CASES of double uteris are comparatively rare, but it is very probable that many of them are overlooked. The following is a brief record of a case which came under my observation lately, and which presents several points of interest.

Mrs. E., aged 28, consulted me on February 27th last, on account of severe metrorrhagia and pain in the lower part of the abdomen. Menstruation, which commenced at 14, was regular and painless until Christmas, 1887. At that time she had been married for four months and, although there had been no cessation of menstruation, she fancied, from a feeling of weight in the pelvis and a slight increase in size, that she was pregnant. On December 26th she was attacked with severe pelvic pain and

flooding. She states that amongst the clots expelled there was a large firmer body, and that soon after this came away the flooding ceased. Six weeks later menorrhagia and pain returned, and continued until the day before I saw her.

Dr. Cullingworth very kindly examined the patient with me, and together we made out the following points. Ostium vaginae wide, admitting two fingers. Vagina normal in lower part; at upper third a loose fleshy septum was found, dividing the upper part of the vagina into two equal lateral portions. Each compartment contained a cervix, resembling the normal nulliparous cervix, each os externum being closed. The bimanual examination was unsatisfactory on account of the tension of the abdominal muscles. Two uterine sounds were introduced, one into each cervix. In the first part of their course they ran parallel, but were separated by a septum; higher up they diverged, each tip running outwards from the middle line. No enlargement of either uterine cavity was made out. With the sounds still in position the abdomen was now examined, and two distinct uterine fundi were felt, separated by an interval of about two inches, the tip of each sound being plainly felt through the abdominal wall. *Per rectum*, the lower part of the uterus could be felt, but the point of divergence could not be made out.

It was thought advisable, before proceeding to more active treatment, to try the effect of rest for a few days, and accordingly the patient was ordered to remain in bed, and the pain was relieved by opiates. On March 2nd the hæmorrhage returned, and she expelled a solid substance about two inches long and one inch broad, which, on examination, proved to be a piece of placenta. After this her recovery was rapid; the discharge ceased, all pain disappeared, and a fortnight later she was going about as usual.

REMARKS.—The malformation in this case was that known as uterus duplex bicornis. An important point is the fact that the vagina was double at its upper part but single below. In the majority of cases of uterus duplex bicornis the septum extends the whole length of the vagina, so that there are two external orifices.¹ It is not difficult to understand how the abnormality should have been unsuspected both by the patient and by her husband; even on vaginal examination the case was one which might have passed as normal, for the septum was so lax that it was easily flattened against either side of the vagina, and in this way one cervix was covered up and concealed. A very similar case is described by Lumpe,² who believed that the lower part of the septum had been detached by coitus. The cause of the hæmorrhage was not quite clear at first, but, from the history, it seemed probable that it was due to some retained products of conception, and this view was confirmed later when the portion of placenta came away. At the time of examination, however, there was no hæmorrhage, both uterine orifices were closed, and there was no appreciable difference in the size of the two uterine cavities. The continuance of menstruation during pregnancy in a double or partially double uterus is uncommon; it is noted only in two out of seventy cases collected by Kussmaul. From the patient's description of the expelled ovum I believe the abortion occurred at the third month. Statistics tend to show that abortion is not more likely to occur in a double uterus than in a normal one, but I am inclined to think that the abnormality in this case was alone the cause of the abortion, as I was unable to assign any other reason why it should have occurred. Possibly the continuance of menstruation may have had something to do with it.

ARCHIBALD DONALD, M.A., M.D.,
Surgeon to St. Mary's Hospital, Manchester.

OBSTRUCTION DURING LABOUR FROM MALFORMATION OF VAGINA.

On February 9th I was called to attend a primipara, aged 24. She had been ten hours in labour. The os was fully dilated; the head presenting, and found to be prevented from descending by a broad band of tissue stretching antero-posteriorly across the vagina. With each pain this band became taut, and encircled the head, arresting its progress. Its exact relations could not now be ascertained. After waiting some hours delivery was effected with difficulty by forceps, without any tearing of the tissues.

On careful examination of the parts ten days after delivery, I found that the vagina was double, being divided into two compartments by a septum, attached in the middle line along the

anterior and posterior walls of the vagina, and extending from the cervix uteri to about an inch from the vaginal orifice. At its cervical end the septum was attached in front of and behind the cervix, but was free opposite the os, forming a crescent in which the cervix lodged. It was possible to pass the finger from one side of the vagina to the other through this opening. This septum was so stretched and displaced during labour as to appear as the fleshy band above described. The child was small, otherwise division of the septum would probably have been necessary. The uterus was apparently normal. The patient was not aware that she was in any way malformed.

This case may with advantage be compared with that described by Dr. Fleischmann, in the *Prager Medicinische Wochenschrift*, and quoted in the *JOURNAL* of March 10th.

HERBERT C. MALE, M.D., M.R.C.S.

THERAPEUTIC MEMORANDA.

TREATMENT OF ECZEMA.

DURING the last two years I have been treating all cases of eczema which have come under my care, whether acute or chronic, in the following way:

The part or parts affected with eczema are first bathed with warm water, so as to clear the surface. A soft cloth is then lightly placed over the surface thus bathed, in order to dry it, and then the following ointment is smeared over the part thus prepared: R Zinci oxidi, ℥j; bismuthi subnitratris, ℥j; vaseline, q.s.

This method of treatment has been especially useful in cases of eczema of the head and behind the ears, which is so often met with in children.

While other cases of eczema have been observed which have been treated by other means, I have in no instance seen results better than those obtained by the above-mentioned method of treatment; while, on the other hand, I have seen cases which have resisted other methods of treatment yield to this.

ANTIPYRIN IN CEREBRO-SPINAL MENINGITIS.

The list of maladies for which antipyrin has been recommended is already long, but I have one to add to it. It is of the greatest possible value in epidemic cerebro-spinal meningitis. Its success in this disease depends less on its property of reducing temperature than on its power of quelling those "nerve storms" which are one of the principal causes of death in this disease.

Its value is all the greater in that it is not, as in the case of other diseases, only a mere addition to the armament of the physician, but that it is practically the only medicine which is a real "remedy" against the disease.

Opium, ergot and belladonna, bromides, and aconite all do good service in allaying the terrible pains, and perhaps in favourably influencing the course of the disease, but they have no power of warding off impending death, while antipyrin I have found to fulfil all three indications. The necessary doses vary somewhat, but forty-five grains in three doses distributed over the evening and night is the most usually successful quantity. I have not yet had an opportunity of trying it in idiopathic, traumatic, or tubercular inflammations of the meninges, but the pathological conditions, apart from the causation and the symptoms, are so allied in character with those of cerebro-spinal fever that I would suggest a trial and expect it to yield results at least as favourable as those of the remedies already in vogue.

SURGICAL MEMORANDA.

NATURE'S SURGERY.

SURGEON-MAJOR MARK ROBINSON, I.M.S., has forwarded to us the account of a curious deformity observed in a prisoner at the gaol, Thyetmyo, Burmah.

The man is 65 years of age, named Nape; he was lately admitted into gaol for dacoity. He is a leader of dacoits, and has been concerned in a hundred dacoities or more, the distortion of his left arm giving him great value in the eyes of these men. They be-

¹ Von dem Mangel, der Verkümmerng und Verdopplung der Gebärmutter. A. Kussmaul. Würzburg, 1850.

² Wiener Wochenbl., 1856; No. 22.

June 9, 1888.]

ieve that such things render a man bullet-proof, and therefore a desirable leader.

The man states that up to fifteen years ago the left arm was as good as his right; that then an abscess formed at his elbow from, he says, no particular cause; the abscess burst, and a large wound was formed. Through this wound all the bones of the arm came

away, one whole, but he was not clear which. At the present time there is not a vestige of the humerus, ulna, or radius to be felt in the arm. The hand is quite useless; the only movement that he can give the limb is by the motion of the scapula, which moves freely.

TUMOUR OF THE BLADDER RECURRING AFTER REMOVAL BY SUPRAPUBIC CYSTOTOMY.

In the JOURNAL (October 16th, 1886) I published an account of a case of multiple papillomata of the bladder, removed the previous May by suprapubic cystotomy; in the last note, four months after operation, the patient's condition was described as very favourable, as he was then free from bladder symptoms, with the exception that slight traces of blood occasionally appeared in the urine, especially after any active exercise.

The subsequent history of the case is worthy of record. The following December blood was from time to time present in the urine in considerable quantity. In January, 1887, micturition began to be painful, and attended by considerable difficulty; the symptoms of obstruction gradually became more marked, until at length almost complete retention of urine was produced. On February 5th, after straining violently in futile attempts to pass water, the suprapubic cicatrix, which hitherto had been firmly closed, suddenly gave way, and a fistulous opening formed, through which the urine found an exit. Four days later he was admitted into the hospital in an extremely exhausted state, all the masses of growth also protruded. Death took place on the fourth day after admission from suppression of urine and anæmia.

At the necropsy the bladder was found full of soft villous growth, of considerable size, springing from the base, lower part of the anterior and posterior, and both lateral walls. The summit was free, except that here and there several small tufts the size of peas were scattered over it. Both kidneys were in a condition of hydronephrosis, and the ureters were dilated. The lower portion of the sacrum was infiltrated with a new growth of a pale, greyish-red colour, of firm consistence, but sufficiently soft to be readily cut with a knife; there was no connection between it and the bladder, the intervening tissues being quite free from any deposit. The other parts of the body were healthy.

Microscopical examination of the recurrent tumours (sections of which have been kindly made for me by my friend, Dr. Raiton) showed them to be papillomata apparently taking on sarcomatous action, for the fibrous stroma of their deeper parts was extensively infiltrated with groups of small round cells; the deposit in the sacrum consisted of a similar small, round-celled growth infiltrating and causing destruction of the osseous tissue.

The case is interesting for several reasons.

1. It shows that papillomata, when sessile and multiple, as the primary growths were, are apt to rapidly recur.
2. It illustrates the fact that the recurrent tumours, under these circumstances, may take on malignant (sarcomatous) action, and be accompanied by secondary deposits in other parts.
3. The reopening of the suprapubic wound, after it had been firmly healed for a period of eight months, in consequence of the recurrent tumours blocking the vesical orifice of the urethra, and interfering with the escape of the urine, is, I believe, unique.

F. A. SOUTHAM, M.B.Oxon., F.R.C.S.
Manchester.

CASE OF PUNCTURED WOUND OF THE PERITONEUM, WITH PROTRUSION OF THE INTESTINE: RECOVERY AFTER OPERATION.

SHORTLY after midnight on August 31st, 1886, A. M., aged 9 years, fell through the drawing-room window at a dancing party on the spike of an iron railing, causing a piece of small intestine, about the size of a clenched fist, to protrude. The spike entered about two inches above the middle of Poupart's ligament on the right side.

Whilst the boy was being chloroformed I covered the intestine with a large piece of lint, squeezed out of hot water, to protect it from dust and retain natural warmth. Reduction by gentle taxis being impossible, I enlarged the opening about half an inch, and then cautiously returned the bowel completely within the abdominal cavity. One suture was inserted through the deep structures, including the peritoneum, and four superficial ones then applied. Some clear fluid escaped from the abdominal cavity, but very little hæmorrhage occurred. The wound was dressed with a compress of lint and a spica bandage. The boy was then carried to bed, and a pillow placed under his knees to keep the thighs flexed on the abdomen. Nothing but water and small doses of liq. opii sed. was given for two days, after which liquid food only was allowed during the ensuing week. On the third day after the accident the wound had almost completely healed by primary union, so that I removed the superficial sutures and dressed the wound with strips of strong rubber plaster to prevent risk of the edges gaping. The deep suture did not come away until the tenth day. The intestine was exposed and constricted for nearly two hours.

The boy made a complete recovery, his temperature at no time rising higher than 100.4° F., so that on the seventeenth day after the accident he was able to move about with a pad over the seat of injury, and without the slightest tendency to hernia.

No antiseptic precautions other than extreme care and cleanli-

ness were possible, as I was obliged to operate in the drawing-room about 2 A.M. He is now, more than a year and a half after the accident, strong and healthy, without any tendency to ventral hernia.

REPORTS

OF

HOSPITAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN, IRELAND, AND THE COLONIES.

ST. MARY'S HOSPITAL.

CASES OF EAR DISEASE.

(Under the care of Mr. FIELD.)

CASE I.—*Suppurative Meningitis Caused by a Bead in the Ear.*
—Mary C., aged 3 years, came under Mr. Field's care on February 9th, 1888, for purulent discharge from the right ear, into the middle meatus of which, owing to attempts at removal from the external meatus, a round blue bead had been thrust some five weeks previously. The patient had already for some time been in a highly feverish condition.

Mr. Field passed a fine hook into the hole of the bead, and so was able, though with difficulty, to extract it. The otorrhoea, which by the time of the operation had become slight, on the following day ceased. There was then some tenderness, but no redness or œdema, over the mastoid process; the temperature ranged from 98.5° to 101° F., and the pulse from 140 to 160. Great restlessness, intractable vomiting, and constant screaming supervened on the evening of the 10th, and persisted till the 14th.

On the 11th the bowels were opened by castor-oil. The morning temperature was 103.8°, the evening 98°. Slight retraction of the head was now observable. With increase of this last symptom there was next day distinct *tache cérébrale*; retraction of the abdominal wall was, however, absent. By Politzerisation air, but not pus, could be forced through the rent membrana. The supra-mastoid region was still somewhat tender, though normal in appearance. Three leeches were applied behind the ear, and a grain of calomel was given.

On the 14th coma set in, the pupils beginning to dilate and becoming insensible to light, but there was no optic neuritis. The temperature, 101° in the morning, rose to 103° at night. Another leech was applied. During the two following days the coma grew profounder, but the retraction of the head and the *tache cérébrale* were less distinct.

On the 16th, as the existence of a localised collection of pus in or about the cerebellum appeared probable, a small aperture was trephined, after consultation with Mr. Page, Mr. Pepper, and Dr. Phillips, who were in hospital, in the squamous portion of the temporal bone, three-quarters of an inch above and behind the right mastoid foramen. The dura mater, which bulged considerably into the aperture, was punctured, and a director inserted into the brain substance, with the effect of setting free, not pus, but a large quantity of cerebro-spinal fluid, presumably from the lateral ventricle. The temperature and pulse now improved for a time. The occipital bone was next trephined below the level of the right lateral sinus, and two inches behind the external auditory meatus. No pus, however, was obtained by the use of a director. The patient survived the operation only about six hours, dying comatose.

Post-mortem examination of the brain and membranes revealed flattening of the convolutions and partial obliteration of the sulci of the convexity. There was much greenish puro-lymph in the meshes of the pia mater, in largest amount over the right temporo-sphenoidal lobe, and the convolutions bounding the posterior limb of the fissure of Sylvius, and at the base, chiefly about the anterior extremity of the fissure. It was in considerable quantity over the parts corresponding to the floor of the third ventricle, and over the pons, and the under surface of the cerebellum, and to a less extent, over the medulla. The brain substance in general was sticky, and its vessels were engorged. The ventricles were dilated with turbid cerebro-spinal fluid. No focus of suppuration could be found in the brain, nor was there any discoloration or per-

ceptible abnormality of the dura mater covering the roof of the tympanum. The right seventh nerve was, however, soft and pulpy where it emerged from the internal auditory meatus, also the right tympanic membrane had disappeared, and the middle ear was full of pus.

The moral of such histories as the above cannot be too often enforced. Instead of conveying the child at once to a hospital for treatment by one accustomed to deal with aural affections, the mother, first with a hairpin, and four doctors subsequently with all sorts and conditions of forceps, made frantic and ineffectual efforts to remove the errant bead, and succeeded only in pushing it through the tympanic membrane, and fatal meningitis was set up. Nearly all the deaths that have been occasioned by foreign bodies in the ear might have been avoided by the adoption of proper modes of treatment. In the particular case just related, the use of a syringe and warm water would probably have sufficed in the first instance. Had there been swelling in the meatus, this could have been relieved by applying a leech behind the ear, after which the extraction might have been easily accomplished. Furthermore, when the bead was actually in the middle ear, its timely removal might have been effected by the use of a suitable instrument.

CASE II.—This case affords a striking example of the extensive ravages that may be wrought by neglected ear disease. A. P., an anæmic-looking girl, aged 14, with a family history of phthisis, was admitted November 24th, 1887. When quite young she had suffered from scarlet fever, which had left her with a large perforation in the left membrana tympani. She had three years before been under the care of Mr. Field for mastoid abscess, and this had been successfully treated by an incision down to the bone to release pus. Now, on her readmission to hospital, pus was flowing from the ear, and over the left mastoid there was again a large swelling, which, it transpired, had for weeks been poulticed at home. Much pus was evacuated by a free opening reaching through the periosteum, but some was found to have burrowed a passage alongside the sheath of the sterno-mastoid.

The patient was subsequently placed under chloroform and ether, and Mr. Page, at Mr. Field's request, explored the sinus in the neck, discovering that it communicated with the anterior mediastinum, and pus followed when an incision was made one inch and a half above the clavicle at the inner edge of the left sterno-mastoid. The patient took the anæsthetics very badly, and it was abundantly manifest that nothing could be done for her. She died December 15th, 1887. The necropsy proved her to have been the subject at once of empyema, pyæmia, pericarditis, pleurisy, and suppuration in the left lateral sinus. She had, in fact, come under treatment too late for any chance of recovery.

The salient *post-mortem* features may be briefly stated as follows: Rigor mortis marked; dorsal hypostasis. Excess of sub-arachnoid fluid, chiefly in the cerebellar fossa. Pus and broken-down blood-clot in the left lateral sinus, the pus proceeding from a carious and discoloured portion of its bony wall over the mastoid cells. Suppuration through the mastoid foramen to the tissues beneath the insertion of the left sterno-mastoid. No trace of suppuration immediately outside the skull, but a probe passed through the incision in the neck reached to within an inch of the mastoid process. Brain substance wet; active congestion of the vessels of the pia mater; and excess of ventricular fluid. A large quantity of puro-lymph in the right, and of serum in the left pleural cavity. Right lung collapsed and slate-coloured, but mottled; the pleural surfaces covered with lymph; scattered abscesses in the parenchyma seen on section. Left lung partly collapsed, with substance throughout congested; buttery lymph over part of diaphragmatic surface and lower edges; an abscess pointing beneath the pleural surface of the outer part of upper lobe, and other abscesses here and there. Excess of serous fluid in the pericardium. Sub-pericardial and sub-endocardial petechiæ both absent. The kidneys both congested, and exhibiting cloudy swelling.

CASE III.—S. P., omnibus conductor, aged 31, came to the hospital as out-patient January 2nd, 1888. Six weeks previously he had suffered pain in the left ear, which grew worse until, after a fortnight, it was relieved by offensive otorrhœa. This ceased two weeks later; the earache then increased, and the tissues over the mastoid swelled, causing the helix to stand out prominently from the head. First three, and two days later five, leeches were applied over the mastoid. On the 9th Mr. Field incised the swelling deeply, letting out a considerable quantity of pus. By the 16th the patient, having passed a week in hospital, was completely restored to health.

CASE IV.—M. J., a nurse, aged 28, admitted January 2nd, 1888, had lost both parents by consumption, and one of her two sisters had abscesses in the neck. Five years before coming to hospital the patient had a discharge from the right ear, an abscess having burst into it. Since then there had been a little otorrhœa at intervals of about a month. Near the middle of November, 1887, she experienced much general headache, which after a fortnight became localised in the right ear. This discharged freely, and was poulticed. The patient was recommended by her medical man to use hot chamomile flowers and to drop a mixture of oil and laudanum into the ear. Otorrhœa, however, persisted, and after a week a swelling formed over the mastoid, which gradually implicated the face. The patient was then sent to Mr. Field, in the out-patient department, who, on December 31st, extracted a polypus and ordered the application of eight leeches to the swelling. This he incised two days later precisely as in the last-mentioned case, setting free a large accumulation of pus. It was found that water syringed into the abscess escaped through the external meatus. On January 9th the first incision had closed up, and a small abscess lower down was opened by the house-surgeon, Mr. Norton. On the 22nd both the swelling and the discharge had disappeared, and the patient left the hospital in all respects well except for a large perforation in the membrana tympani.

Both the last two cases of mastoid abscess are of the type most commonly met with, dangerous in the extreme if neglected, but in almost every instance yielding readily to treatment, the important factor in which is an early, and deep, and long incision over the mastoid down to and through the periosteum, so as to afford the freest possible exit for pus.

GENERAL INFIRMARY AT LEEDS.

CASE OF OPTIC NEURITIS ASSOCIATED WITH CHLOROSIS.

(Under the care of Dr. EDDISON and Mr. TEALE.)

[Reported, with remarks, by T. WARDROP GRIFFITH, M.B., Professor of Anatomy, Yorkshire College; late Resident Medical Officer to the Infirmary.]

This patient, a kitchenmaid, aged 26, was admitted on June 3rd, 1887, complaining of dimness of vision. She stated she had had but poor health for some time, but that the failure of sight dated back only three weeks. It commenced with pain and lachrymation in the right eye, and in two days she was almost totally blind in that eye. The left eye was not affected, she said.

On admission the patient, who was rather a delicate-looking young woman, with bad teeth and slight enlargement of one gland at the angle of the jaw, was seen to be markedly anæmic. Menstruation was said to be normal in point of frequency, but the flow was scanty. There was a loud venous hum at the root of the neck, and a systolic *bruit* in the pulmonary area. The vision was R. = shadows; L. = $\frac{1}{2}$, and Jäger 1 at 8 inches. Pupils—right, active; left, rather sluggish. There was very well marked optic neuritis in the right eye, with much swelling of the papilla, extending into the surrounding retina a short distance, slight obscuring of the vessels, and a few small hæmorrhages. No glistening spots of exudation were seen. The left eye presented similar appearances, but they were much less marked.

A full examination of the patient failed to elicit evidence of disease of any of the organs of the body. Repeated examination of the urine failed to detect albumen. No history of injury could be made out, nor any history or evidence of syphilis.

On June 6th, the patient was put on a mixture containing in each dose liq. arsenic hydrochl. \mathfrak{v} , and tinct. ferri perchl. \mathfrak{xv} , and on a pill containing ferri sulph. grs. \mathfrak{ij} , ext. aloës soc. gr. \mathfrak{j} , and ext. nucis vom. grain $\frac{1}{2}$, each to be taken three times daily. The pills were increased to two, three times daily, on June 19th.

About June 10th it was noted that her sight had begun to improve. On the 23rd the neuritis was unquestionably less than on admission, and on July 9th the vision was Jäger 20 with the right eye.

On examination now, the edge of the disc was much more distinct. She was then sent to the seaside, and continued the medicine and pills without interruption.

On November 16th, 1887, she sent me a specimen of writing corresponding to Jäger 3, which she could easily read with her right eye.

REMARKS BY DR. T. WARDROP GRIFFITH.—In the JOURNAL of May, 1881, Dr. Gowers has a valuable paper, giving full details of three cases in which optic neuritis, associated with chlorosis,

cleared up under treatment with iron. In one of the cases stellate spots were observed round the macula, but in none does the vision seem to have been so profoundly affected as in the case now recorded.

Dr. Gowers comments on the resemblance of the optic neuritis in those cases to that found in cerebral tumour, and, as bearing on this point, I append brief notes of two cases that I had the opportunity of observing in the clinics of Drs. Churton and Barrs, to whom I am indebted for permission to refer to them.

1. A girl, aged 19, attended the out-patient department for many months with the usual symptoms of chlorosis. She had well marked neuro-retinitis, strongly resembling that found in Bright's disease, but beyond this no evidence was made out of gross intracranial lesion. One day she fell on the ice, striking her head. Three weeks afterwards she was admitted into the infirmary, having been wildly delirious for two days. Her pupils were dilated; her temperature varied from 99° to 102°, and she died on the third day after admission, apparently from syncope. On *post-mortem* examination we found a tumour, with the naked-eye appearances of a tubercular mass, occupying the inner aspect of the right occipital lobe. The membranes at the base of the brain were thickened and opaque. There was some effusion, but no grey granulations could be made out.

2. A servant girl, aged 22, fairly healthy-looking, but rather anæmic, was admitted complaining of general weakness and pain in the head of two years' duration. The pain, which was sometimes in front and sometimes behind, varied in severity, but was always on the right side. There was occasional vomiting, but always after food. There was no aural discharge. Menstruation was generally regular, but the discharge was scanty, and then there was slight œdema of the feet towards night.

On examination, the scalp was found tender on the right side, the hair markedly grey behind, this being of recent date. Lungs normal; faint systolic *bruit* all over cardiac area; urine varied in amount from 76 to 86 ounces; no albumen; specific gravity, low; sight slightly impaired; Hm = 1 D. Distinct swelling of optic discs, with blurring of margins and very distinct curving of vessels. She was put on sulphate of iron pills, which she continued pretty regularly. The neuritis steadily diminished, and, when I saw her a year subsequently, the discs were absolutely clear, and the sight normal.

CIVIL HOSPITAL, CALCUT, MADRAS PRESIDENCY.

PUNCTURED WOUND OF CHEST INFLICTED BY AN ELEPHANT.

(Under the care of Surgeon-Major H. D. COOK, M.B., Civil Surgeon, Calcut.)¹

R. N., aged 55, was admitted on January 15th, 1888. On admission his condition was as follows. He was unable to sit up; decubitus on left side, with body inclined well over to the right, head resting on left hand, right arm approximated to side, with hand close to face. There was a penetrating wound (fleshy) of the right side of the chest. The wound of entrance was four by three inches, irregular in shape, and situated six inches from the spine, opposite the fourth dorsal vertebra, and an inch and a half below the middle third of the spine of scapula. The wound of exit was four and a half inches long, clean cut, and extended downwards and outwards, from a point three inches above and to the inner side of the right nipple, but was in no part of its course lower than two inches above the horizontal nipple line. The wound of entrance was offensive and sloughy with sero-purulent discharge. Two lacerated bits of muscles were exposed, evidently portions of the deltoid and infra-spinatus muscles. The whole of the integument over the shoulder was swollen and œdematous, and had an erysipelatous blush. The parts were too swollen and painful to be thoroughly examined.

He stated that on the day previous to his admission, while he was employed with his elephant (he is a mahout) drawing timber, a Mopilla crossed in front of the animal, who suddenly became excited, and chased the man about a hundred yards; that he then struck the animal by way of punishment with a small stick he had, who promptly resented his punishment by throwing him to the ground, and striking him with one of his tusks over the right shoulder, penetrating the muscles of the chest, and emerging in front below his armpit. After inflicting this injury the man states that he turned over on his back, when the elephant placed one foot on his chest with the intention of crushing him; but

¹ Communicated to the South Indian Branch of the British Medical Association.

this he prevented by suddenly drawing his knife and stabbing the elephant in the trunk, when the animal turned and fled. The accident occurred at Cuttady, a small place on the backwater some twenty miles from Calicut. The wound was syringed and dressed with perchloride of mercury lotion 1 in 2,000. Charcoal poultices were also applied to the wound of entrance.

The case is still under treatment. At first there was a great deal of constitutional disturbance and abundant discharge from the anterior wound. The parts are now, however, looking healthy, and there is every prospect of a speedy recovery.

ROYAL PRINCE ALFRED HOSPITAL, SYDNEY.

ANEURYSM OF AXILLARY ARTERY: ELECTROLYSIS: LIGATURE OF SUBCLAVIAN: CURE.

(Under the care of Mr. G. T. HANKINS.)

[Reported by J. McALISTER, M.B., B.S., and E. G. BLAXLAND, M.R.C.S.E., L.R.C.P.]

J. C., aged 64, widower, no history of alcoholism or syphilis, had met with frequent severe accidents during a long life in the bush, but was not aware that the left shoulder or arm had ever suffered any special injury; he was quite well up to some months ago, when he first felt aching in the left arm and numbness of the fingers.

Admitted September 23rd. Five weeks ago he first detected a lump in front of the shoulder, from which time the pains in the arm became worse; there was no pain over the swelling itself, which, when first detected, seemed about the size of a goose's egg, and had not increased much since.

The tumour was situated below the outer third of the clavicle, which was slightly displaced upwards; it filled up the hollow in front of the shoulder, and could be felt from the axilla; it was distinctly pulsating, and over it a loud systolic murmur was audible. Pulse at left wrist more feeble than at right; heart's action intermittent; urine normal. The patient was first admitted into the medical ward under Dr. Shewen, and placed under appropriate medical treatment for a week—rest, low diet, and iodide of potassium in full doses; but as the pain in the arm increased, and the tumour appeared to be getting larger, surgical treatment was decided on. It was very difficult to compress the subclavian artery sufficiently to stop pulsation, and Esmarch's bandage could not be borne on account of severe pain. Before resorting to ligature, it was determined to try the effect of electrolysis.

On September 30th four insulated steel needles were passed into the tumour and connected with the positive pole, the negative pole of the battery being connected with a large wet clay electrode on the chest after the manner of Apostoli. A current of 140 milliampères, produced by a battery of 47 bichromate cells arranged in series, was passed through the aneurysm. At the commencement of the operation an elastic bandage was placed on the arm, and attempt was made at the same time to compress the subclavian, but both had to be given up on account of the pain produced. Chloroform was then administered, but the patient became so unmanageable that it was discontinued.

On withdrawing the needles after the current had been passing for thirty minutes, the uninsulated portions, about one-third of an inch, were found to be nearly eaten away. The aneurysm then appeared to be more solid and the expansion less marked, although still very perceptible.

On the following day some further improvement was noticed; but on the third day from the operation the pulsations became stronger, and the tumour began to increase in size, though still more solid than before treatment. Ligature of the subclavian was then decided on, and performed by Mr. Hankins on October 4th.

The operation was in this case very easy, the artery being found rather high in the neck, and apparently quite healthy, the tense cord of the brachial plexus proving the best guide to it, as the scalene tubercle could not be easily reached. The external jugular vein was divided between two ligatures, also a smaller vein just over the artery; no other vessels were seen, and no blood to speak of was lost. The artery was tied with carbolised catgut, when all pulsation in the tumour immediately ceased. The wound was closed with horsehair sutures, a small drainage-tube inserted at the outer angle, and dressed with dry sublimate gauze. The arm was then wrapped in cotton-wool and a flannel bandage. Feeble pulsation in the radial was first noticed twenty-six hours after the operation, but the pulse could not be counted until thirty-two hours had elapsed, when it was very soft and faint. There was no pain and no pulsation in the tumour.

The wound healed by first intention, and the patient had no bad symptom. Thirty-one days after the operation the tumour, compared with a cast taken by Mr. McAlister, the house-physician, before treatment, showed a considerable diminution in size, but it did not feel very hard, although quite free from tenderness or pulsation.

The patient was now anxious to leave the hospital, but was cautioned against using his arm until the swelling had become absorbed.

REPORTS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

FRIDAY, APRIL 20TH, 1888.

JAMES LITTLE, M.D., President, in the Chair.

Migrainous Headache.—The PRESIDENT read a paper on the value of a combination of salicylate of sodium and effervescent citrate of caffeine in migrainous headache. He said he was in the habit of directing the patient, when he awoke with any feeling of headache, to take twenty grains of the salicylate in a wineglassful of water, made effervescent by the addition of a dessertspoonful of the granular citrate of caffeine, and, if necessary, to take a second or even a third dose at intervals of two hours. The effervescent caffeine made the dose a very palatable one, which the salicylate alone was not, and probably rendered it more useful; but that the good effect was not due to the caffeine was proved by the fact that the author had seen it relieve persons who had previously used the caffeine alone without benefit. It did not appear to lose its effect, as a patient, to whom Dr. Little gave it more than two years ago, said she found it as valuable as when she first began its use.—Dr. WALLACE BEATTY, testified to the value of the treatment suggested by Dr. Little.—Mr. COX had himself found that the active principle of tea and coffee had a powerful beneficial effect.—Dr. ATTHILL, speaking from a large practice, exclusively among females, said Dr. Little had suggested the combination to him two years ago, and, having prescribed it since in twenty or thirty cases, he had always found some benefit, and, in the majority of cases, the benefit was considerable. This form of headache, especially near the menstrual period, was accompanied by ovarian pain, and in such cases he administered twenty-grain doses of bromide of sodium.—Mr. JOHN J. BURGESS, in the case of a lady, aged 44, found that the most efficacious remedy was a full hypodermic injection of morphine. He also found fifteen-grain doses of antipyrin useful in relieving the headache.—Dr. J. W. MOORE felt justified in mentioning other remedies, having regard to the probable state of tension of the arteries about the head, as indicated by the rigid appearance of the temporal artery, and also the weak pulse. These remedies were nitroglycerine, the tabloids of the *Pharmacopœia*, and nitrate of amyl. He also gave one to two grains of butyl chloral every half hour until relief was obtained. As regards Dr. Little's combination, the good effect of the effervescent draught of salicylate of sodium and caffeine was probably due to the action of the salicylate of sodium on the liver. Once the bowels were freed, and the tendency to nausea was relieved, the headache disappeared almost like magic.—Mr. R. MONTGOMERY said he found that a combination of sulphate of magnesium, bicarbonate of potassium, and bromide of potassium, a wineglassful in the morning with a wineglassful of hot water, gave great relief.—Mr. W. F. WEST observed that he found thirty-grain doses of guarana every four hours gave marked relief.—Dr. FINNY said he had never used the President's combination, but felt satisfied that the profession would have reason to feel indebted for it. He had tried to anticipate the attack or nerve storm by a course of arsenic. Hence caffeine, as supporting the nervous system, was one of the best drugs, and would be most efficacious when the treatment was carried out by arsenic or some nerve tonic. The bromides were also most useful; and if the attacks were preceded by nerve symptoms, as deranged vision or perversion of the senses, such as hallucinations, he considered a full dose of bromide of potassium would be of great use.—The PRESIDENT, in reply, said the attacks were quite as common in men as in women—certainly among neurotic persons. He did not know that the combination would prove efficacious if the bowels were entirely neglected; but, on the other hand, no amount of purgation would keep off the attack. Those nerve storms were

more likely to occur at the menstrual period when they attacked women. Gastric pains were liable to make themselves felt at the menstrual period, but he did not attach much importance to these symptoms. When the combination he had recommended was not successful, a rather free hypodermic injection of morphine was the only thing to give relief. The advantages of salicylate of sodium were of wider application than those of antipyrin. No doubt, as Dr. J. W. Moore observed, the salicylate of sodium was a hepatic stimulant; for he had noticed the relief which it gave persons who upset the liver by too free living.

Saccharin in Chronic Cystitis.—The PRESIDENT read a note on the use of saccharin in chronic cystitis for rectifying the ammoniacal effluvia of the urine.—Dr. A. W. Foor asked whether the saccharin was more beneficial in the tubercular cystitis, or in the rheumatic, or in the gonorrhoeal, or simply in the mucous cystitis?—Sir WILLIAM STOKES inquired what was the *modus operandi* as regards the action of saccharin. He endorsed the President's view as to the great importance of thoroughly evacuating the bladder in all the forms of cystitis, especially in that associated with enlargement of the prostate in aged individuals. Advantage followed the exhibition internally, as well as the local application, of boric acid in five-grain doses, perfectly plain in water three times a day, and washing out the bladder with a weaker solution.—After some remarks by Mr. DOYLE, the PRESIDENT, replying, said the proper heading of his paper would have been "The Value of Saccharin in Ammoniacal Urine." The cases he had seen were not those of the ordinary cystitis at all, but where the urine had become ammoniacal in consequence of paralytic affection, or prostatic disease, or stricture. Saccharin had no effect on the cystitis, except so far as the cystitis was kept up by the ammoniacal condition of the urine. Tubercular cystitis was a rare affection. A little boy whom he saw in hospital with it was treated with saccharin, but it did him no good. His urine, however, was not ammoniacal.

Rare Form of Mental Disease.—Mr. CONOLLY NORMAN read a paper on a rare form of mental affection, first described by Griesinger under the name of *Grübelnsucht*. Since Griesinger's time, four or five cases had been recorded. The essential condition of the affection was the obsession of the mind by an impulsive concept taking the form of perpetual interrogation. The entire mental energy was occupied with constant questionings about indifferent matters. The patient described by Mr. Norman was tortured with a desire to read every scrap of written paper which she saw, and was unable to attend to her domestic duties through a constant impulse to investigate every detail of the most familiar things and most familiar operations. The illness began when she was about five months pregnant. She had borne children in very quick succession, and had been exhausted by lactation. There was also a moral factor in domestic troubles, and worry about money matters. The patient recovered under tonic treatment. Mr. Norman referred to the rarity of this affection, particularly among asylum patients; to the question of its causation; to its analogies to *folie du doute* and other forms of mental disease; and to the presence in the case which he described of nervous proxyms, such as had been recorded only by Berger among previous observers.—A discussion followed, in which Dr. A. W. FOOT, Mr. R. MONTGOMERY, Mr. S. M. THOMPSON, and Mr. JOHN MOLONEY took part.—The PRESIDENT had no doubt the form of insanity described by Mr. Norman was rare in asylum practice; but in ordinary general practice cases were met with from time to time in which the same train of symptoms was presented. Some years ago, a business gentleman consulted him, whose duty it was in his department to take the invoices and mark on the pieces of cloth the proportionate price to allow the regulation profit. He had been many years at this, and was so expert that, no matter what the fractions to which the invoice price descended, he could go on without making a mistake; yet he got into such a state of doubt that, even if the invoice price were only a shilling, he could not convince himself that he was right, though the man inside told him he was. Another case came under his observation in which a pharmaceutical chemist, failing to convince himself of the accuracy of weight or measure, could not carry on business, and life became almost intolerable. Thus, there were many similar cases in which there appeared to be a letting-go of common sense—a seeking for evidence of self-evident propositions. This occurred less frequently among persons of humble means than persons who had not the necessity of providing food and drink, and were able to indulge the vagaries of fancy. Such persons should try and cultivate what Sir Benjamin Brodie called "a happy recklessness

as to results," or seek the overpowering control of a masterful mind, which would not discuss the evidence of those things, but dogmatically assert them.—Mr. CONOLLY NORMAN replied.

NEW SOUTH WALES BRANCH: ADJOURNED ANNUAL MEETING.

FRIDAY, APRIL 6TH, 1888.

The Hon. Dr. J. MILDRED CREED, President, in the Chair.

PRESIDENT'S ADDRESS.

Progress of Medicine in Australia.—After some preliminary remarks on the business of the Branch the President said that the year in the life of the Association which had just terminated had been an eventful one in the history of medicine in Australia. The graduating as M.B. Sydney of the first students, six in number, who had obtained their medical education in the local medical school, was a memorable event. The first intercolonial medical congress had been held, and had been attended by medical men from all the Australasian colonies.

Regulation of the Practice of Medicine.—The Select Committee appointed by the Legislative Council to inquire into the state and operation of the laws for the regulation of the practice of medicine and surgery in New South Wales had led to some startling revelations (already mentioned in the JOURNAL), and had presented a report which had been unanimously adopted by the Legislative Council. Action had been pressed upon the Premier by a letter signed by Lieutenant-Governor Sir Alfred Stephens, the Chief Justice, Cardinal Moran, the Primate (Dr. Barry), the heads of all other religious denominations, the Mayor of Sydney, and the President of the Chamber of Commerce.

Registration of Births, Deaths, and Marriages.—The report of another Select Committee, pointing out the defective state of the law in the colony for the registration of births, marriages, and deaths, had also been unanimously adopted by the Legislative Council. Dr. Creed, as chairman of that Committee, had introduced a Bill into the House providing for the better registration of births, and enacting that, before disposal of a dead body by burial or cremation, the district registrar shall issue a permit; and that, before issuing such permit, he must be satisfied either by the certificate as to the cause of death from a legally-qualified medical practitioner, if one had been in attendance, or, if not, by police inquiry, that the death had occurred from natural causes.

Neglect of Vaccination.—Dr. Creed next referred to the constant peril in which the colony stood, owing to the terrible neglect of vaccination, which was optional, the result being that a very small proportion of children were vaccinated. The present rapidity of transit had immeasurably increased the risk of the introduction of the disease. It was true that the admirable health authorities had so far been able to completely isolate all cases; but this good fortune it would be absurd to expect always to continue; already the quarantine station was seldom free, and it sometimes happened that a fresh ship arrived with the disease on board before the crew and passengers of previous ones had been released. Sooner or later the type of the disease introduced would be of so virulent a character that it would spread like wildfire. He recommended the establishment of a commission to investigate every case in which evil effects were alleged to have followed vaccination.

Federal Quarantine.—The question of federal quarantine was still in abeyance, though the scheme formulated by the Hon. Dr. Mackellar had been adopted by the Australasian Sanitary Conference, which met in Sydney in 1884. The varying action of the colonies hampered commerce and increased the risk of the introduction of disease. There could be no doubt that infected persons should be removed, and the ship disinfected at the first port of call, instead of these measures being delayed until the ship reached its destination.

Cremation.—Cremation was legal in the Colony, and the recently formed Cremation Society, would shortly be able to undertake cremations. The proposal to cremate the bodies of persons dying in quarantine from infectious diseases, which was first made by the principal medical officer, Dr. MacLaurin, when an outbreak of cholera occurred on board the mailship *Dorunda*, in Queensland waters, had as yet no practical result.

Rabbit Pest.—Dr. Creed detailed the various proposals made for dealing with the rapid increase of rabbits (see JOURNAL of June 2nd, p. 1181), and observed that neither the Government nor the people of Australia would have any choice as to whether disease should be used for their extermination; pastoralists, threatened by ruin, would take the matter into their own hands. The only

choice the Government had was whether the use of disease should be supervised and the results recorded, or whether it should be left to rash and ignorant hands.

Concluding Remarks.—Dr. Creed referred to Mr. W. H. Paling's generous gift of an estate containing 450 acres, and an endowment of £10,000 for the establishment of a convalescent station. He uttered a word of warning as to the disproportionate number of medical practitioners who were coming from all parts of the world to practise in Australia. In conclusion, Dr. Creed referred to the success of the *Australasian Medical Gazette*, of which he is the editor, and thanked the Branch for the unvarying kindness displayed towards him during his term of office as President.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.

WEDNESDAY, MAY 16TH, 1888.

JOHN URQUHART, M.D., President, in the Chair.

Intubation of the Larynx.—Professor OGSTON gave an account of the method of intubation of the larynx, showed O'Dwyer's instruments for that purpose, and gave details of a case in which he had successfully employed intubation for the relief of croupous laryngitis.

Left Ophthalmoplegia Interna.—Dr. MCKENZIE DAVIDSON showed a female patient suffering from paralysis of the ciliary muscle and iris of the left eye. Otherwise the eye was normal, and the cause of the palsy exceedingly obscure.

Hyperæmia after Trauma.—Dr. MACKENZIE BOOTH read notes of a case of this nature where marked hyperæmia came on after a rupture of the drumhead from blowing the nose, and lasted nearly three weeks.

Recovery from Catarrh of Tympanum.—Dr. MACKENZIE BOOTH also detailed the case of an elderly gentleman who had suffered from advancing tympanic catarrh and its attendant deafness for many months, and who was relieved after the removal of a nasal polypus which had existed for many years.

Composite Photograph.—Professor OGSTON showed a composite photograph of the medical students forming the class of 1887-1888, taken by Messrs. G. W. Wilson and Co., Aberdeen.

Abscess of Liver.—Dr. GORDON showed specimen of abscess of liver, with glycerogelatin cast of the same. The case was that of a lad in whom the appearance was of doubtful import, and rendered the diagnosis exceedingly difficult.

Refraction Ophthalmoscope.—Dr. MCKENZIE DAVIDSON exhibited and explained the mode of use of Jessop's Refraction Ophthalmoscope

SOUTH INDIAN BRANCH.

ANNUAL MEETING.

FRIDAY, MARCH 2ND, 1888.

Surgeon-General G. BIDIE, M.B., C.I.E., President, in the Chair.

PRESIDENT'S ADDRESS.

Position of the Branch.—THE PRESIDENT, in beginning his address, showed that the Branch was in a flourishing condition; it now numbered 71 members, and had held eleven meetings during the year 1887. He referred to the bond of union which membership of the Association afforded, and dwelt on the great educational work which, directly and indirectly, the members of the medical services in India were doing.

The Educational Work of the Medical Services.—In thirty-two years, the period of the President's service, the number of civil hospitals in the Madras Presidency had increased from 38 to 349, and these institutions, small as some of them were, were yet the advanced posts of the movement to put skilled medical aid within reach of the entire population. Many lives were yearly sacrificed to the ignorance of native quacks, who still largely relied on incantations and charms. Even the better class of them clung to a system which was a feeble echo of the doctrines of Galen, while their anatomical knowledge was comprised in the doctrine that the navel is the principal seat of life, and the origin of all the vessels. The native population would not consent, even if it could afford, to pay fees which would remunerate educated men and women, and the only course which could be recommended was to render the native practitioners less dangerous to their patients; more could not be hoped. This might be done perhaps by disseminating cheap and simple literature, suited to the comprehension of the native practitioners, and by encouraging them to visit the hospitals.

Vaccination.—Though vaccination had been introduced into Madras in 1802 it was still in a backward state; not more than 17 per cent. of the children born were protected, and during the

twenty years ending 1885 the average annual mortality from small-pox in Southern India was 33,000. Vaccination from the calf had now been introduced, and the most bigoted and superstitious were thus left without the least excuse for continued opposition.

Sanitation in Southern India.—The annual average mortality from cholera, small-pox, fevers, and bowel complaints in the Madras Presidency was 330,000, and the task of stirring the natives to remedy evils traceable to the neglect of centuries was almost, but not quite, hopeless. The natives required to be taught to help themselves; India absorbed one-fourth of the gold and one-third of the silver produced throughout the world, and the country contained an enormous amount of dormant capital secreted in the bowels of the earth or locked up in useless jewelry; the people ought to be encouraged to invest their savings in loans for municipal and local improvements. Already town and village communities were beginning to recognise the extreme importance of pure water and removal of sewage as preventives of sickness. Future progress would largely depend on the energy, knowledge, tact, and sagacity of the officers of the medical service. The efforts made in India to exterminate cholera would be critically watched by the whole civilised world, which had grown to resent the devastating epidemics which moved westward from India, to devastate the cities, to restrict the intercourse, and to interrupt the trade and commerce of Europe. He did not shrink from the ordeal, feeling confident that his medical brethren of all grades would in this contest, as on the battlefields of former days, show that they could and would do all that men could do.

Surgical Cases.—A series of surgical cases were communicated by Surgeon-Major COOK, M.B., Civil Surgeon, Calicut. (1.) A case of severe compound and comminuted fracture of the thigh, involving the knee, in a native, aged 25. Amputation was refused, but the patient eventually did well, and left the hospital in ten weeks, though with a short leg and stiff knee. (2.) A case of comminuted fracture of the femur complicated by an extensive lacerated wound, in a native, aged 40. The patient did well, and recovered in two months, with little shortening. (3.) A case of gangrene of the left forearm due to improper treatment of a fracture of the bones by a native practitioner; the radius had entirely disappeared, and the upper half of the ulna, which was exposed and banging down, was removed. Symptoms of tetanus set in, but passed away under treatment by bromide of potassium and chloral hydrate. (4.) Another case of gangrene of the arm after native treatment of a fracture. The arm was amputated, but tetanus set in on the fifth day, and the patient died on the tenth day. (5.) A case of obliterative arteritis leading to spontaneous gangrene of the foot, in a woman, aged 39. Amputation was performed in the lower third of the leg. The patient recovered, and was discharged on the twenty-fourth day. (6.) A case of penetrating wound of the right lung in a native, aged 25. Air passed in and out of the wound, from which bright frothy blood also escaped. The sputum was blood-stained. The wound measured 4 inches by 2 inches, and extended through both pectoral muscles and the third rib. The patient had an attack of pneumonia, but was discharged well on the twenty-seventh day. (7.) A second case of penetrating wound of the lung, in a native woman, aged 25. The wound, an inch long, was situated just below the inferior angle of the right scapula; air passed in and out, and the immediate neighbourhood was emphysematous; there was also a wound of the mamma, from which milk flowed (the woman was suckling). She was discharged well on the thirty-fourth day. (8.) A case of wound of the abdomen with protrusion of omentum, in a native, aged 30. The omentum was washed and returned; the patient recovered without fever, and was discharged in a fortnight. (9.) Abdominal wound in a boy, aged 9, dividing the ensiform cartilage and exposing the anterior surface and border of the left lobe of the liver, which protruded from the wound, but was uninjured. The liver was pushed back, and the wound closed by sutures and strapping. (10.) Another case of penetrating wound of abdomen, in a boy, aged 12. The transverse colon could be seen through an aperture which admitted the forefinger. The boy recovered. And other cases, some of which will be published in full.

Specimens.—Brigade-Surgeon SIBTHORPE: Comminuted Extracapsular Fracture of Left Femur.—Surgeon J. SMYTH, M.D.: (1) Thrombosis of Veins; (2) Rheumatic Endocarditis affecting Mitral Valve; (3) Cyst Worm from Subperitoneal Tissue of Sheep; (4) Dislocated Testicle; (5) Glioma of Cerebellum and Medulla Oblongata, and Cyst of Cerebellum.

REVIEWS AND NOTICES.

NOUVELLE ICONOGRAPHIE DE LA SALPÊTRIÈRE: CLINIQUE DES MALADIES DU SYSTÈME NERVEUX. Publiée sous la direction du Professeur CHARCOT, par PAUL RICHER, GILLES DE LA TOURETTE, ALBERT LONDE. Janvier et Février. No. 1. Paris: A. Delahaye and E. Lecrosnier. 1888.

SOME years have elapsed since the publication of *L'Iconographie Photographique de la Salpêtrière*, an album of photographs and text, treating chiefly on the phenomena of hysteria in women, and published, under the direction of Professor Charcot, by Bourneville and Regnard. Since then, Professor Charcot's *clinique* has undergone many and important changes, both as regards materials, appliances, and the *personnel* of the department. To the original infirmerie, containing only female patients suffering from chronic diseases, there have been added new wards for the treatment of male patients and acute cases, and a *poli-clinique* corresponding to our out-patient department. The organisation and subdivision of the work was as complete as possible, and in the hands of assistants who have already become distinguished workers themselves. M. Richer still figures as the *chef de laboratoire*; the clinical and pathological work is done by the *chef de clinique*, assisted by a number of *internes*; and, amongst former *chefs*, we have a whole series of distinguished names, such as Cornil, Bouchard, Pierret, Pitres, Brissaud, Féré, Marie, and others. An excellent museum and a clinical laboratory supplement this branch of the *clinique*; the electrical apparatus, of the most elaborate description, both for physiological investigation and therapeutic application, is entrusted to M. Vigoureux; the ophthalmic department is under the direction of M. Parinaud; whilst M. Londe acts as photographer, and, presiding over the whole, like the chief of a military "general staff," we have Professor Charcot himself. Whilst every facility is given for the study of nervous diseases, in their physiological and pathological relations, therapeutics is not forgotten; and amongst the latest additions, we notice a complete system of baths, which will stand comparison with any of the best hydropathic establishments.

With such material and appliances, and so perfect an organisation, we can well imagine that each case is worked out in its fullest details; and the *Nouvelle Iconographie* will be welcomed by many besides those more especially interested in nervous diseases.

The work is edited by Messrs. Richer, Gilles de la Tourette, and Londe, under the direction of Professor Charcot, and published in two-monthly fasciculi, the first of which has just appeared. Though the authors modestly state, in the preface, that their intention is to make accessible to "others the numerous figured documents which accumulate day by day in the albums of the Salpêtrière," a glance at the first number shows that the scope of the work covers a much larger ground; and that, in the *Iconographie*, we have not simply a photographic representation of interesting cases, but rather a series of able articles, on new or little recognised points in aid of diagnosis and treatment of nervous diseases. Thus, in the first article, M. Gilles de la Tourette gives an exact description of the attitude and walk in hysterical hemiplegia, studied with the help of the graphic method, and illustrated by two excellent photographs. The second article is by Paul Richer, on the Morphological Anatomy of the Lumbar Region. The relation of the external configuration of the human body to disease has occupied the attention of several observers, and has lately been taken up again by Charcot and his pupils. In a recent number of the *Archives de Neurologie*, Babinski draws attention to the deformity of the hip produced by a hysterical affection; in the article before us, Richer speaks of the median prominence in the lumbar region of the spine which occurs normally, but which may be so exaggerated as to simulate a spinal deformity. That this is not generally known is shown by the history of a patient, who suffered from syphilis and hysteria, but in whom the spinal projection and the obscure nervous symptoms were held to be due to some organic spinal disease. On this hypothesis the actual cautery was applied, the indelible marks of which, together with the spinal lumbar protuberance, are well depicted in the photograph accompanying the article. The third article (the first part of which only appears in this number), by Paul Bloek, treats of Fibro-tendinous Retractions. This peculiar affection, the true nature of which has been recognised by Charcot, occurs in the course of spasmodic contrac-

tures, especially hysterical contractures, and is characterised by the persistence of the deformity during the chloroform narcosis. It is amenable to treatment by surgical interference—that is, cutting through the contracted and altered tendons—a treatment which, in the cases figured in this article, has given most satisfactory results.

The part concludes with a prototype of a picture by Albert Dürer, illustrating the passage in the Acts of the Apostles (chapter iii, 1 to 9) where St. Peter says to the crippled beggar, "Rise up and walk." This photograph is taken from a work, shortly to be published by M. Charcot, on the artistic representation of deformities, and of diseases in general. Charcot ingeniously shows that, in the picture before us, Albert Dürer had for his subject a person affected with leprosy, the characteristic features being given with such exactness that we can recognise that the leprosy, at the beginning of the sixteenth century, was of the same type and nature as the affection seen at the present day; the face, and especially the lips, show the nodular variety, the forearm and hand the atrophic form, with the characteristic atrophy of the interossei, and the flexed position of the forearm depicted with wonderfully correct anatomical details.

The foregoing brief account of the contents of the first part of the new *Iconographie* abundantly shows that, besides the collected *Leçons sur le système nerveux*, besides the numerous publications in the various journals, and the many important theses written by his inspiration, the indefatigable founder of the "Salpêtrière School" has enough material left for the publication of a great work, full of important and original matter, which is destined materially to advance our knowledge of those obscure and complex diseases, in the study and recognition of which M. Charcot has for a long time taken and kept the lead.

The work is got up in an excellent way. The style is easy, clear, accurate, and concise, and the illustrations numerous and of truly artistic merit.

A STUDENTS' MANUAL OF PSYCHOLOGY. Adapted from the *Katechismus* of F. Kerehner by DROUGHT. London: Swan Sonnenschein and Co.

THE publishers deserve credit for the series of educational books which they are translating and publishing. This manual is neatly got up, well printed, and handy. The medical student who is aiming at the higher degrees is expected to have some knowledge of mental pathology, and it is better for him if he have been trained to classify and define nervous processes. Psychology, though one of the most venerable and interesting of studies, has till recently been founded solely on introspection, and not on any really scientific basis.

Workers nowadays are eagerly rushing in to till the neglected fields of study, and already there are many followers of Herbert Spencer. The future of psychology will rest with careful observation of the development of the various mental faculties, and later the recording the variations in health and disease of the various sensory and other nervous reactions, and then studying the aberrant types and the effects of dissolution. This prospect is yet a distant one, and the workers must not suppose that they can discard all past knowledge which was gained by subjective study, and they must be as careful of the use of terms as their predecessors. The manual under notice is eminently well suited for the student who is preparing for the study of mental functions in health and disease. It is brightly and clearly written, and has nothing repellant to the "intelligent student." The author not only gives clearly the opinions of others, but quotes authorities freely. His point of view is neither one-sided, empirical, nor purely spiritualistic; and he devotes particular attention to consciousness, imagination, the feelings, emotions, and passions.

The book consists of an introduction and two parts. In the introduction a very useful and complete history of psychology is given. Naturally it is only an epitome, but it is a satisfactory and trustworthy one. In summing this up he says: "It is evident that no dualistic view, in accordance with which man consists of two contrasted substances, can solve the psychological problem." Strict idealism is just as untenable; and, when speaking against materialism, he says: "Facts permit us to conclude that there is reciprocity between these factors (soul and body), but not that they are identical. But experience teaches that body and soul rather lead a common life, with inseparable common developments." As to the method followed by our author, he says

that both the analytic and the synthetic have proved one-sided, and he prefers what he calls the "genetic." This method collects observations, but from established metaphysical standpoints. It proceeds, in the first place, like the investigation of Nature. It seeks to establish facts to find out a claim for them to mount to the universal cause of phenomena. But this genetic method then joins to this the speculative element, the inquiry into the nature of the soul, in order thence to comprehend phenomena. The observations include (1) the observation of one's own self, (2) one's own observation of others, (3) the self-observation of others, (4) the observation of others by others. On starting each fresh subject, an interrogatory is made, and the answer is clearly supplied, and any specially important words, or phrases are printed in italics, so that the salient points are readily recalled by the student.

In Part I the nature of the soul is considered, and consciousness is taken as the fundamental fact which is allowed by both idealist and materialist. The nature of consciousness is first studied, then the results of psychological research, and, finally, the metaphysical conception of the soul is developed. The questions are plainly stated, and the answers given are clear and concise; throughout the book there runs a pleasant humour, unusual for such a subject. Part II discusses the mental faculties, for though the author considers the soul to be substance which, as personality, animates the body and is a unity, yet it is not a mere homogeneity. In answer to the question, "What course will our discussion follow?" our author says: "Our Ego first becomes conscious of itself in ideation; we will, therefore, in the first place, treat of this. But since ideation is brought about by some perception, we have first to examine sensation; to this succeeds the discussion of feelings and of the phenomena of desire."

To discuss all this would be beyond the scope of a medical review, but we would recommend our readers to compare this work with that of Dr. Mercier on the *Nervous System and Mind*, recently published; for though the methods and the objects differ, yet both point to the more practical study of mental functions, which is the boast of the present time.

ESSAYS IN PREVENTIVE MEDICINE: Infection and Disinfection, the Health of Children, and the Period of Infection in Epidemic Diseases. By WILLIAM SQUIRE, M.D., F.R.C.P. London: J. and A. Churchill. 1887.

THE course of conduct to be pursued when an infectious disorder breaks out in a family ought to be determined from an intimate acquaintance with the natural history of the disease. There are few circumstances under which the opinion of the physician is more eagerly sought, and few under which the young practitioner appears to less advantage; the decision must be made on the moment and must be grounded mainly on the period during which infectivity is active. Measles, for instance, is infective before the rash appears, and is very frequently propagated at this early stage, so that it is hopeless to attempt to prevent its spread among those who have been in close contact with the patient up to the time of eruption; whereas scarlet fever is much less infective during the first day or two of sore throat than it afterwards becomes, so that an early separation gives good hopes of immunity. No man has contributed more to our knowledge of questions of this class than Dr. WILLIAM SQUIRE, and his essays here brought together contain much valuable information not only on average but also on exceptional periods.

The arrangement of the volume, which consists of detached essays written at various times, is somewhat defective, and the information on each disease is scattered, so that the labour of reading is needlessly increased, but no fault can be found with the matter of the book. The two essays "On Infection and Disinfection" and on "The Period of Infection in Epidemic Disease," read together, give a fairly complete account of the subject. Dr. Squire gives not only the results of his inquiries but also the cases upon which they are based, so that all the elements for forming an independent judgment are provided. He has some very judicious observations upon the nature of the processes which are going on during the period of incubation, and establishes that the variations in this period are to be traced to variations in the duration of the earlier of the two stages, of latency and of invasion, into which this period may be divided.

Dr. Squire makes one generalisation which will undoubtedly be found of considerable value, if only as affording a convenient help to remembering the facts; it has, however, a deeper significance,

being based on the natural characters of the diseases. He points out that the zymotic diseases, with regard to their behaviour in this respect, may be divided into two classes: (1) Diseases having a long incubation period, namely, variola, vaccinia, measles, "rubella" (rötheln), mumps, varicella, typhoid, and typhus; (2) diseases having a short incubation period, namely, scarlet fever, diphtheria, plague, cholera, yellow fever, diarrhoea, influenza, dengue, and erysipelas. Relapsing fever occupies an intermediate position; and whooping-cough, which would generally be reckoned in Class 1, in reality belongs to Class 2. The generalisation to which we refer is that infection is generally spread during the early or invasion stage of Class 1 and during the later stages of Class 2; the long period of invasion increases the chances of infection during that stage, while, as a rule, diseases of the class terminate suddenly, infection ceasing at a comparatively early period of convalescence; in the case of measles, for instance, the duration of personal infection probably never exceeds three weeks. The diseases in Class 2 present a marked contrast, for the short period of incubation minimises the dangers of infection during the onset of the disease, while the liability to relapses and to prolonged definite sequelæ extends the period during which infection is possible far into convalescence: in consequence, these diseases are most commonly spread at the end, during the period of convalescence, so-called. The use of the one term "convalescence" to express the stages which follow the subsidence of the pyrexial period of zymotic diseases is a little unfortunate; for, as Dr. Squire has well brought out by his classification, the virus of the disease may continue to be present during this time in an active state; though the patient has conquered the disease, it must not be forgotten that virus is still being eliminated.

A large number of problems which are constantly arising in practice are ably discussed by Dr. Squire; for instance, if children have visited at a house where scarlet fever subsequently breaks out, how long they must be kept from school, the proper time to send children who have had scarlet fever for change of air, and the infectivity of catarrh and of tonsillitis, to mention only a few. These and many cognate questions are dealt with in a second essay "On the Period of Infection in Epidemic Disease." The volume contains also a valuable practical essay on Infection and Disinfection, especially in its relation to domestic hygiene.

NOTES ON BOOKS.

Studies in Pathological Anatomy (especially in Relation to Laryngeal Neoplasms). (1) Papilloma. By R. NORRIS WOLFENDEN, M.D. Cantab., Senior Physician to the Throat Hospital, Golden Square, and SIDNEY MARTIN, M.D. Lond., Pathologist to the City of London Hospital for Diseases of the Chest, Victoria Park. (London: J. and A. Churchill. 1888.)—This pamphlet, which we understand is the first fasciculus of a projected systematic work, affords evidence of the great strides by which laryngology is advancing, and is, at the same time, an excellent example of the way in which a speciality ought to be studied. The conflicting opinions which have been expressed as to the prognosis in the case of the Emperor Frederick of Germany have shown the need for a thorough overhauling of the pathological facts with regard to laryngeal neoplasms. To this task Drs. Wolfenden and Sidney Martin have set themselves, calling in the aid of the most recent histological processes and the best art of the lithographer. Next to an examination of the specimens themselves, nothing can be more instructive than a study of the excellent coloured plates executed by Messrs. Danielsen. Each plate has a key plan, which is a useful guide to its comprehension. The authors detail the process used in preparing the microscopic specimens, and leave nothing to the imagination except the naked-eye appearances of the growth, an omission which they may be recommended to repair in future fasciculi. They express in very decided terms the opinion that the nature of a growth can be determined only by microscopical examination of a portion removed, but reserve for future discussion the diagnosis between papilloma and epithelioma, and the all important question whether papilloma degenerates into epithelioma. We understand that the fasciculus has already been translated into German, and will shortly be published in that language.

RETURNS just issued show that the death-rate in St. Petersburg has been unusually high this spring, namely, 40.9.

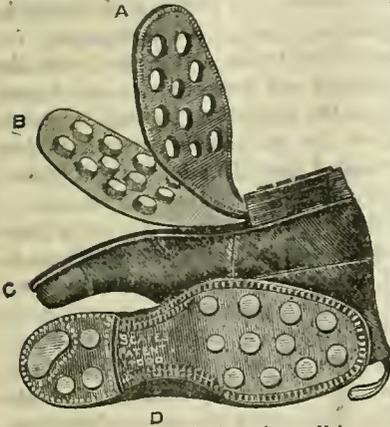

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS, IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

SCAFE'S WATERPROOF BOOTS.

A BOOT with a sole of a novel and ingenious construction, in which leather and india-rubber are combined, has been submitted to us.

A thin india-rubber sole (B) is inserted between the inside sole (C) and outside sole (A). The outside sole of leather is pierced by holes through which studs attached to the india-rubber sole are passed, and form slightly raised projections or cushions of india-rubber, which are said to wear equally with the sole. The boot as completed is represented at D. The boots are considered specially adapted to the use of the medical profession, as they are waterproof at the sole without being unduly

heavy; they are noiseless in walking, and the india-rubber studs prevent slipping and render them more durable. The boots it is thought would also be well adapted for Alpine work. They are the invention of Mr. Scafe, of the Leather and Rubber Boot Company, 20, Albion Street, Leeds.

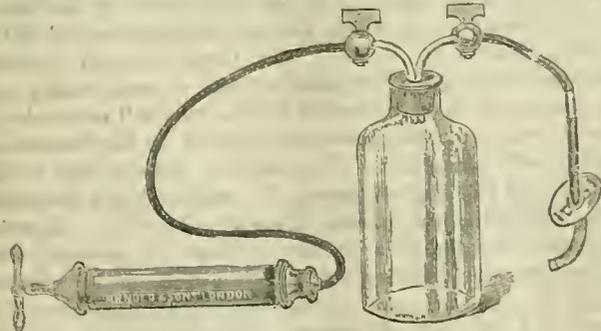

SCOTCH OATEN.

(CARR AND Co., CARLISLE.)

THIS preparation consists of the finest Scotch oats, carefully deprived of all husk, and so crushed that the form of the grain is still distinctly discernible. The cellulose amounts to only 1.2 per cent. Scotch oaten makes excellent porridge.

"MEMBRANE" ASPIRATOR FOR CASES OF DIPHTHERIA AFTER TRACHEOTOMY.

THIS instrument is intended to obviate the necessity of applying the mouth in order to suck out an obstruction from a tracheotomy tube in cases of diphtheria. It consists of a bottle in which more or less of a vacuum is produced by an exhausting syringe, and to which is appended a tube having a tapering nozzle of rubber or vulcanite which will fit into any tracheotomy tube. A pint bottle is of sufficient size, and the tapering rubber cork will adapt itself to many different bottles. The instrument has been so well made that a sufficient vacuum can be maintained for at least twenty-four hours. The bottle being kept exhausted (or it

can be rapidly exhausted), the nozzle only requires to be placed in the tracheotomy tube, the tap turned, and any fluid or membranous obstruction will be sucked up through the rubber tube into the vacuum bottle. In practice it will be found advisable to

exhaust the bottle night and morning, and to keep it by the bedside. It will then be ready for use at a moment's notice.

Although it may not be possible to have the above for every private case, its use in hospitals after tracheotomy for diphtheria will, it is hoped, be the means of saving valuable lives. At any rate, there should be no necessity for any surgeon to risk his own life by sucking at a tracheotomy tube to remove obstructions. The instrument has been made for me by Messrs. Arnold and Sons, of West Smithfield.

T. FREDERICK PEARSE, M.D., F.R.C.S.

THE SWISS MILK COMPANY'S PREPARATIONS.

THE Swiss Milk Company have added to their Pure Compressed Milk Extract (previously noticed in our columns), consisting of skim milk completely deprived of water, three very good and useful milk preparations; the most important is Pure Compressed Cream Milk, which represents the solid matter of whole milk, including all the fat of the original milk. The preparation is distinguished by being perfectly free from all rancidity; it is quite sweet, mixes readily with warm water, and thus yields good, palatable milk. The preparation represents the highest possible degree of concentration which can be attained, and is sure to be appreciated.

The same company manufacture a Sweetened Compressed Milk Extract, consisting of milk solids, with a moderate amount of cane-sugar, and Chocolate and Milk in Powder. Both are well made, sound, and of good quality.

PERFECT FOOD BISCUITS: WHEATENA BISCUITS.

(Messrs. S. HENDERSON AND SONS, Edinburgh.)

THE use of whole-meal flour as such, and in the manifold application in food preparations, is evidently becoming very general, judging by the numerous articles containing whole meal which are brought under our notice. The above biscuits are excellent whole-meal preparations. The "perfect food biscuits" are particularly rich in albuminoids, while the lighter wheatena are most palatable and nutritious. They form creditable additions to the list of high class biscuits made by Messrs. Henderson and Sons.

RIZINE.

RIZINE consists of whole rice grains completely deprived of husk and indigestible cellulose, cooked and crushed into very thin laminae, which readily swell up in warm water, and with very little further preparation form a food ready for the table. Rizine makes very good milk puddings, and is particularly well adapted, in conjunction with milk, for nursery use.

SALT'S "RUBY-BACKED" CLINICAL THERMOMETER.

MR. SALT (69, Corporation Street, Birmingham) has designed (in co-operation with Mr. Hlicks) and patented what he describes as a "new ruby-backed clinical thermometer." This is an elegant little instrument in a metal case, the novelty of which consists in the background of the index being of a ruby tint, whereby the mercury is rendered much more easily visible. It appears to be clearly and carefully scaled, and to be very accurate.

THE PNEUMATIKON.

MR. EDMUND F. T. PRICE, M.B., C.M. Edin., writes: In the JOURNAL of May 26th Mr. J. Brindley James describes, under the name of the "Pneumatikon," a respirator, which he has registered, and of which he gives a drawing.

I think it right to mention that a respirator similar in principle and construction, devised by Dr. Andrew Smart, of Edinburgh, has been in use here for some years.

Dr. Smart, in a lecture delivered to the Edinburgh Health Society, on the harmful effects of dusty occupations, and published in his book, *Germs, Dust, and Disease*, in 1883, showed and described this instrument as a "respirator designed to warm, filter, and medicate the air in its passage to the pulmonary organs."

The above facts are well known to me, as I assisted Dr. Smart in the out-patient department of the infirmary here, and consulted him before bringing the matter under your notice.

IODIFORM ERUPTIONS.—In the *Annales de Derm. et de Syph.*, 1888 (p. 190) two cases are related in which an eruption was produced by the application of iodoform. In one case the face was the seat of violent erythema, with the formation of small bullae; and in the other the lesions were not unlike those produced by a burn in the second degree. In each case, by the substitution of boracic dressings for iodoform dressings, the symptoms rapidly subsided.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1888.

SUBSCRIPTIONS to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the West Central District Office, High Holborn.

The British Medical Journal.

SATURDAY, JUNE 9TH, 1888.

THE FORTHCOMING GLASGOW MEETING OF THE BRITISH MEDICAL ASSOCIATION.

WE publish in another column the programme of the forthcoming meeting of the British Medical Association in Glasgow, being its fifty-sixth annual meeting. These preliminary particulars will make it sufficiently evident that the arrangements, scientific and social, are on a scale adequate to fill the frame of what will undoubtedly be one of the largest gatherings which this great Association has ever yet held in its long, prosperous, and brilliant course. Glasgow could not fail to be a great centre of attraction on many grounds. Its rank among the first cities of the Empire, and among the greatest seats of academic learning, scientific research, and practical medical teaching; its situation at the gate of the most picturesque scenery within the limits of the three kingdoms; the public spirit and hospitality of its municipality and its citizens; the numbers, energy, ability, and spirit of the medical profession of Glasgow and throughout Scotland, are all earnest of the brilliant reception which awaits the Association on this great occasion, and of the wide range, completeness, and attractiveness of the arrangements for ensuring success in all the departments of the work of such a meeting. The Association will meet in the newly completed and magnificent buildings of the University. The authorities have generously placed all the resources of this monumental building at the disposal of the Association, and have thus secured for its meetings halls and chambers fully adequate to the requirements of even so great a gathering as this, with all its numerous sections and committees.

To add to the attractiveness of the meeting and the admirable qualifications of the site, it is only necessary to mention that the University buildings looks down on the picturesque grounds on which is placed the great Exhibition which is now being carried on at Glasgow with such signal success. It is only to be feared that the immediate proximity of this unrivalled industrial and art show, which is now attracting hundreds of thousands of visitors weekly, may prove somewhat distracting to the members of the Association. As against such attractions, however, it will be noted that there will be provided scientific and practical material of extreme value.

A Committee has been appointed to compile a Handbook of the Medical Institutions of Glasgow, a copy of which will be presented to every member attending the meeting. The articles are written by gentlemen connected with the various

institutions described. The editorship of the volume has been entrusted to Dr. James Christie. Among the entertainments it may be mentioned that a *conversazione* will be given by the Professors of the University, at the University, on the Wednesday evening of the meeting, and a further *conversazione* by the Corporation of Glasgow, on Friday evening.

The meeting will be presided over by Professor Gairdner, and the addresses will be delivered by Dr. Clifford Allbutt, Sir George Macleod, Dr. Macewen, and Professor McKendrick. In all the Sections the practice is maintained of arranging for discussions on the leading clinical topics of the day, with the aid of those eminent physicians and surgeons who are known to be especial authorities on the subjects to be treated, and it is only necessary to inspect the preliminary programme (see page 1241 *et seq.*) to be assured that the scientific and clinical proceedings of the meeting will be of very marked interest.

The general affairs of the Association have singularly prospered throughout the year; its material progress continues to be most satisfactory, and its work is progressing in every direction. Of the number of new Branches which are seeking to affiliate themselves with the Association, or which are already in useful activity throughout the world, we speak elsewhere. It is impossible to regard this continued extension of the British Medical Association throughout the great dominions, colonies, and dependencies of the empire without feeling that such extension is full of promise for the social and scientific future of the profession. Through the medium of the JOURNAL the members of our common profession throughout Greater Britain are thus enabled individually and collectively to keep touch and to grasp hands. We on our side are strengthened and enriched by the new experiences of our brethren in the distant regions and various climates of this great empire. The great social problems as well as the scientific researches which occupy us become simultaneously the common possession of all our colonial and distant colleagues, and on our side we learn what are the new questions, the new goals, and the new solutions on which they are intent.

In other respects, also, the progress of the Association and its continually extending usefulness are plainly evident. The work of the Scientific Grants Committee and of its Research Scholars, and the work of the Collective Investigation Committee, afford solid evidence of the success with which scientific interests are being promoted. Progress will also be announced in a new direction in the draft report of the Therapeutic Committee, of which the foundations were laid at the recent meeting at Dublin. This Committee will probably arrange to secure the assistance of fifty or more leading men in different parts of the British Islands, who will undertake to investigate therapeutic questions suggested by the Committee, and record their results. The records of cases of busy practitioners will be obtained through the medium of the Branches, who will, in the first instance, discuss local results. Especial attention will be paid to the opinions of members who differ from the majority, and efforts will be made to distinguish the special causes or conditions of experience which may lead to such difference. This inquiry is in the hands of a most competent and highly skilled committee, and after examining the proposals now in hand for carrying out this scheme, we entertain no doubt that the future work of

the Therapeutic Committee is likely to be among the most valuable results of the associated action of the members of our society. The formation of the library, which is now being commenced under favourable auspices, will be an additional topic of congratulation, and generally it may, we believe, be said that rarely, if ever, has any meeting of the Association come into view under more agreeable, prosperous, and promising conditions than the great meeting which is to be held at Glasgow in August.

The Association has met only twice before on Scottish ground, and each time in Edinburgh. Its first meeting in Edinburgh was under the presidency of the philosophic Alison, and its second meeting under the distinguished chairmanship of Sir Robert Christison.

The first meeting was coincident with the great political success of the Association in obtaining from Parliament the Medical Reform Act, which was the Magna Charta of registered practitioners, which swept away territorial limitations to corporate influence, which enabled for the first time Scottish practitioners to practise freely in England as well as on their own soil, while it established an equal supervision over medical education. The announcement of the passing of the Act arrived in Edinburgh at the moment of the meeting, and was welcomed throughout the country with great enthusiasm. The influence of the Association has but yesterday been exercised with equal advantage in obtaining for the medical profession and for practitioners throughout the three divisions of the kingdom direct representatives on the Council; and the political influence of the Association, which has always been exercised for the benefit of the profession at large, apart from any individual corporate interests, grows day by day, under conditions which ensure that it will always have equally popular aims and equitable uses.

We publish elsewhere an account of what will undoubtedly prove very attractive to the great mass of our members attending the meeting, and that is the excursions already planned to the unrivalled scenery of the Highlands, and the innumerable attractions of the meeting in the land of Burns and Scott. Few members, probably, will leave Scotland without becoming more intimately acquainted with the rare beauties of its mountains, glens, and lochs, and without visiting some, at least, of the historic spots glorified by the genius of Scott and consecrated by association with Burns. It is but reasonable to anticipate that such a meeting will not only serve the purpose of scientific progress and intellectual recreation, but that it will also tend to widen the basis of fraternal union, and strengthen the bond of friendly intercommunication.

OUR DISTANT BRANCHES.

"*OPIFERQUE PER ORBEM DICOR*" might be a very appropriate motto for the British Medical Association, as it is indeed a suitable badge for the whole of our profession. The distant Branches of the British Medical Association in the Empire of India, and in the great Australian Continent, take to their work in a vigorous and able manner, which plainly testifies to their vital energy, and to the wide sphere of usefulness which they successfully occupy. Inspiring themselves with the traditions of professional unity and public effort which are the

watchwords of our work in Great Britain, and availing themselves of the free autonomous constitution which all our Branches enjoy, the most distant Branches of the Association, whether in Jamaica, British Guiana, or in the great dependencies, are addressing themselves vigorously not only to the cultivation of medical science and good fellowship, but also to the solution of the larger questions of social and sanitary administration, in which medical men when united—but only when organised and acting in concord—are able to exercise so powerful and valuable an influence.

Branches of the Association are now flourishing in Adelaide and South Australia, Melbourne and Victoria, Sydney and New South Wales; in the North-West Provinces of India, and in South India and Madras (to which will shortly be added a Branch in the Punjab); in Canada (Halifax); Bermuda, British Guiana, Jamaica, and Ceylon. Branches are in course of self-formation in the Mauritius, Tasmania, Kimberly (South Africa), and Malta. The circumstances of such Branches, the particular needs of the members for their mutual professional and social advantage and for the public good, necessarily vary very widely in countries so differently placed as to the surrounding population, administration, climate, and social organisation. We publish in another column abstracts of two addresses by the Presidents of distant Branches of our Association, which will be read with great interest. Our pages frequently bear evidence of the valuable clinical and scientific work which is being done in these Branches.

The address of the Hon. Dr. J. M. Creed to the Sydney and New South Wales Branch (formed in 1880) was chiefly concerned with administrative matters, which he discussed in a spirit at once practical and scientific. A scanty population engaged in pastoral pursuits does not miss laws providing for the registration of births and deaths, or restricting the practice of medicine by imperfectly trained persons, and finds in quarantine the readiest defence against the importation of infectious diseases, which at the worst can spread but slowly among a scattered people.

But in Australia these days are over, and nowhere, evidently, is this more keenly felt than in Sydney, which, according to the most recent information at our disposal, contains, with its suburbs, a population of 300,000. Dr. Creed, who, as a member of the Legislative Council, is intimately acquainted with the temper of the politicians of New South Wales, afforded in his address several illustrations of the difficulties which a young and growing community has to face when its urban population begins to assume large proportions.

One of the first and most pressing demands of sanitary reformers is an efficient system of registration of births and deaths, for upon a knowledge of the prevailing forms of fatal disease sanitary enactments must, so far as they are not drawn from the codes of other countries, be based, and by it the success of sanitary administration must be tested. The registration at present in force in New South Wales is very imperfect, but there seems to be some prospect that the Legislature may sanction the establishment of a more efficient system. The whole of Australia appears to stand at the present moment in a peculiarly dangerous condition as regards small-pox; vaccination is much neglected, chiefly it would seem owing to the absurd prejudices aroused by the clamour of the people called

"antivaccinationists." There seems to be no prospect that a law making vaccination compulsory could be passed in the present state of knowledge and political development in the colony, and the only remedy which can be suggested is the appointment of a special standing Commission to investigate every case of alleged injury following vaccination in the colony, and to report for the information of the public; in this way it is hoped that a healthier public opinion might grow up, and that in time it might become the rule rather than the exception for parents to have their children vaccinated. At present the whole country lives in a state of constant dread of the importation of the disease; the expenditure in quarantine stations, isolation, and inspection—the latter sometimes, it would seem, involving the use of a special train—must be considerable, but would of course be hardly worthy of consideration were there any good hope that such measures would be permanently effectual. People, however, who entertain such hopes deliberately take risks which they would not dream of incurring in ordinary matters of business; sooner or later the disease, as Dr. Creed said, will reach the country in a virulent type, will override the barriers raised by quarantine and isolation, and then it is to be feared that we shall witness such an epidemic as that which devastated Montreal.

One other point of great local, and of some general, interest was touched upon by Dr. Creed, who sketched the progress of the movement on foot to place the practice of medicine under proper regulations. At present the Australasian colonies appear to be overrun by untrained and incompetent practitioners who constitute a real danger to the general public, who are not able always to distinguish between knowledge and self-assurance. We published last autumn some excerpts from the evidence given before a Select Committee, appointed to inquire in New South Wales into the matter, but the title was not told, and the first effect of the publication of this evidence in the colony has been to convince leading men of all professions that some restrictions must be imposed which shall enable the public to draw accurate inferences. An important letter, signed by Sir Alfred Stephen (Lieutenant Governor), the Chief Justice, the Bishop of Sydney, Cardinal Moran, the heads of the other religious denominations, the Mayor of Sydney, and the President of the Chamber of Commerce, has been addressed to the Government, urging the necessity for immediate legislative action.

The topics which occupied Surgeon-General Bidie, C.I.E., in his presidential address to the South Indian Branch meeting in Madras, were also questions of sanitary legislation and administration, but the problems to be solved in India are, if possible, of greater complexity. The Indian Medical Service, which supplies the sanitary advisers of the Government of India, has to deal with a teeming population, steeped in ignorance and superstition, and ready to attribute the terrible devastation wrought by cholera, fever, and other zymotic plagues to the inscrutable decrees of fate. Dr. Bidie chose a striking comparison to bring home to us the enormous mortality caused every year in the Madras Presidency by cholera, small-pox, fever, and bowel complaints. He showed that the actual deaths produced by that pastime of princes, called war, were but a trifle numerically when compared with the mortality caused in Southern India by these four classes of dis-

ease. He stated that, in the fifty years ending 1886, the total losses to England, France, Germany, and Austria on battle-fields amounted to 368,000, whereas the annual mortality from the above mentioned preventable diseases in the Madras Presidency alone was 339,000. Dr. Bidie gives a deplorable account of the sanitary condition of the towns and villages studded through the country; by the filth and neglect of centuries they have been rendered terribly foul, and the people are only slowly being aroused to a consciousness of the consequences of their sanitary surroundings.

The statesmanlike character of Dr. Bidie's main proposal for remedying these defects will be generally appreciated. The first step must be to make the people themselves realise that the improvements must be carried out speedily, and that they must find the money; so far they have been treated too much as though they were paupers, and the habit of self-help has not been formed. India, it is said, absorbs about one-fourth of the gold and one-third of the silver produced throughout the world, and there is reason to believe that there is an enormous amount of dormant capital throughout the country buried in secret hiding-places, or locked up in useless jewellery. Dr. Bidie believes that if the people could be made to see the advantages of municipal and local improvements, this dormant capital might be utilised. He thinks that the capital necessary for carrying out such improvements might be borrowed at 3 or 4 per cent. if the loan were issued in small bonds (Rs. 10). It is certain that such a scheme would have to be worked by very judicious officials if it is ever to be successful; but there can be little doubt that if it could be floated, it would confer great benefits on the people, not only by the good effects produced by the public works undertaken, but also by facilitating loans to individuals and other financial and commercial transactions.

Dr. Bidie truly said that the efforts of the sanitary advisers of the Indian Government to exterminate cholera will be critically watched by the whole civilised world. How difficult the task is perhaps few of the critics understand, but Dr. Bidie is confident that his comrades will not shrink from the ordeal, and will do all that men can do. Still, men cannot work miracles, and the evils which exist can only be remedied by a judicious expenditure of capital, and by a plentiful stock of patience; the accumulated sanitary evils of centuries and the habits of scores of generations cannot be set right by legislative enactments. Unless the people can be won over to the side of the enactments, but little amelioration can be hoped for.

THE annual *conversazione* at the Royal College of Physicians of London will be held on Wednesday evening, June 27th.

THE second *conversazione* at the Royal Society, held on Wednesday evening last, was largely attended, and the ladies, for whose benefit it is mainly intended, were delighted by the exhibition of numerous scientific curiosities.

THE discussion on the papers on "Electrolysis in the Treatment of Diseases of Women," which were read at the Obstetrical Society of London on Wednesday night, June 6th, was adjourned to a special meeting of the Society to be held at 8 p.m. on Thursday, June 21st.

We regret to announce the death of Mr. De Bardt Howell, on June 5th. Mr. Howell had left his home near Elstree to walk a short distance to the station, when he felt indisposed, returned home, and in a few minutes expired. In consequence of this sad event Mr. Mark Howell, who has been in attendance upon the Emperor Frederick continuously since August last, has left Potsdam. His place will be supplied by Dr. Krause.

THE QUEEN'S BIRTHDAY.

The medical officers to the Queen and her Household were well represented last Saturday at the ministerial and official banquets, Sir William Gull, Sir Prescott Hewett, and Dr. Laking dined with the Lord Chamberlain; Sir Edward Sieveking with the Lord Steward; Sir William Jenner with the Master of the Horse; and Sir Spencer Wells with the Duke and Duchess of Buccleuch (Mistress of the Robes). The Marchioness of Salisbury's reception at the Foreign Office was attended by Sir James Paget, Dr. Laking, Sir Edward Sieveking, and Sir Spencer Wells.

THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS.

The election of three Fellows to fill the vacancy caused by the retirement, in due course of time, of Sir Joseph Lister, Mr. Cadge, and Mr. Bryant, will be held at the College on Thursday, July 5th, the ballot to commence at 2 o'clock. Sir Joseph Lister has positively decided not to offer himself for re-election; Mr. Bryant and Mr. Cadge will, we understand, appear in the field. It is probable that Mr. Pick (date of Fellowship 1866), Surgeon and Lecturer on Surgery, St. George's Hospital, will contest the vacancy. No provincial Fellow has as yet offered himself as a candidate. We may observe that all applications must be sent in to the Secretary of the College not later than Monday next.

MR. BRYANT.

On Thursday, May 31st, in the Anatomical Theatre of Guy's Hospital, a testimonial from the past and present students was presented to Mr. Bryant. The testimonial took the form of a handsome silver punch-bowl, with an illuminated book containing photographs of various parts of the hospital, and the names of the subscribers. Mr. Drew, the senior house-surgeon, in a few well-chosen words, presented these to Mr. Bryant, in the presence of the sisters and a large number of the students. Mr. Bryant then returned thanks for the handsome gift, and for the kind manner in which it had been given; he remarked that he had not severed his connection with Guy's; that he had been a student there for forty years, and hoped to remain a student still. One of his chief causes of regret at leaving was that he would no longer mix with young men. He then gave a few words of advice to those present, telling them not to rely too much upon their teachers, but to work for themselves. He concluded by expressing the hope that all would become successful members of the profession.

A SOURCE OF INFECTION.

To obstetricians, who need to be constantly on the look out for possible sources of puerperal septicæmic infection, the following case, revealing a somewhat unusual, or at least unexpected, source of danger, sent us by a correspondent, will have some interest:—"A few months ago," he states, "I confined a woman of her seventh child. Immediately after birth she developed unmistakable signs of so-called puerperal fever, which rapidly terminated in death. During and after the confinement I carried out the strictest antiseptic treatment. Part of the *post-partum* treatment consisted in washing out the uterus with an antiseptic twice daily; for this purpose I used an ordinary Higginson's syringe, with large catheter attached. The catheter I provided myself, taking care to use one which had never been used for any purpose before. The syringe

my patient provided me with was a new one. At the termination of the case I advised my patient's friends to burn the syringe and the catheter, this being, I thought, the surest way to prevent the possibility of subsequent infection from their being given out on loan. Quite recently I learned upon inquiry that the catheter had been burned, but the syringe had been "returned to the chemist" from whom it had been borrowed at a moderate charge per diem. The poorer classes are, it appears, in the habit of borrowing syringes in this way, and one at least of my professional neighbours sends his patients to the chemist to hire one when he finds they cannot afford to purchase. It is not difficult to see how, under these circumstances, puerperal septicæmia may be spread. I bought from the chemist one of the two syringes he keeps on hire; the other he told me had not been returned. 'Indeed,' he added, 'I lose on an average one in five months.' Although I put the one I secured beyond the possibility of future harm, unfortunately it is impossible to identify it as the one I used some months ago, which means that the stolen one is at large, possibly carrying with it puerperal septicæmic influences."

EXPERIMENTAL RESEARCH.

A PARLIAMENTARY paper just issued by the Home Office contains a report showing the number of experiments performed on living animals during the year 1887 under licence, distinguishing painless from painful experiments. The total number of persons licensed to perform such operations in England and Scotland was 82, all (save one foreign graduate) graduates of a British university, or Fellows or Members of royal colleges. Of these, 64 exercised their right. The buildings where such experiments are allowed to be made are 26 in number—9 in London, 9 in the provinces, 8 in Scotland. The number of experiments was 1,220, of which 582 were performed without anaesthetics. These were, with very few exceptions, simple inoculation experiments, and were consequently painless. The experiments were—physiological 237, pathological, 703, and therapeutical 280. The number of cases in which pain has been unavoidably inflicted during experiments conducted under certificates dispensing with anaesthetics, or with the killing of the animal on recovery, was 71—2 being physiological, 21 pathological, and 48 therapeutical. Comparatively few vivisections properly so called—that is, involving a distinct surgical operation on a living animal—were practised during the year. In all cases in which such experiments have been performed under the certificate dispensing with the slaughter of the animal before recovering consciousness, it has been made a condition that the wound should be rendered painless by antiseptic treatment, and, that failing, the animal should be destroyed. This condition has, the inspector believes, been faithfully fulfilled. The animals on whom pain was inflicted were 2 cows, 12 calves, 1 cat, 32 rabbits, and 24 frogs. In Ireland there are only four persons licensed, and the experiments, 11 in number, were all painless.

A REMARKABLE CASE OF NARCOLEPSY.

DR. CATON has recently had a remarkable case of narcolepsy in the Liverpool Royal Infirmary. The patient was a man, aged 37. He would fall asleep while standing, when selling articles in his shop, or even when walking in the streets. If he attempted to read or to sit in a chair he invariably fell asleep in a moment. During sleep a spasmodic closure of the glottis always took place, lasting nearly a minute. Violent contraction of the diaphragm and other respiratory muscles would come on, increasing in force, and the patient would get more and more cyanosed, until at length the violence of the inspiratory efforts partially roused him, and the spasm of the glottis yielded. Loud noisy respirations would now come on, and the cyanosis would disappear, to be followed by deep sleep and the same round of symptoms. This con-

dition has existed for six years, and constantly occurs by day and by night. When awake the patient is perfectly intelligent, and there is no evidence of organic disease. The kidneys are healthy, and secrete abundance of urea. Dr. Caton supposed that the symptoms were due to the formation of some narcotic alkaloid in the alimentary canal or the blood, and this view was strikingly confirmed by the results of treatment, most benefit being derived from a limitation of diet and the administration of charcoal and naphthalin thrée or four times daily. Under this treatment the drowsiness diminished considerably, and the spasm of the glottis disappeared altogether, but when the treatment was suspended for some time the symptoms returned.

MR. CHAMBERLAIN ON EDUCATION.

IN his recent speech at Birmingham, on the occasion of the opening of a new board school, Mr. Chamberlain made some remarks worthy of attention. As is well known, Mr. Chamberlain has long advocated free compulsory education under school boards, and in the speech to which we refer he dealt largely with this question, as well as with the present position of national and denominational schools. As a result of the analysis of statistics, accumulated since the passing of the great Education Act, some very unexpected results appear. In 1871 the accommodation in denominational schools was a little over 2,000,000; it is now 3,452,000, an increase of about 70 per cent. The average attendance was then 1,231,000; it is now 2,187,000, an increase of about 75 per cent. The grant in aid on the average attendance was then 10s.; it is now 17s., an increase of 70 per cent. It is thus seen that the national and denominational schools have not only continued to exist, but have grown enormously. This growth of the schools not under school boards is doubtless largely due to compulsory school attendance, and also in part to the existence of board schools, whose duty it is to receive all applicants, thus freeing the voluntary schools of many poor and troublesome children, who previously encumbered the educational work of the teachers and lowered the standard of results. In many cases the creation of a board school in a parish, by receiving the poorer children of the neighbourhood, has enabled the managers of the voluntary schools to raise their fees, and give better educational advantages. This competition may have its advantages, but it has certainly tended to crowd into many board schools a high percentage of poor, neglected, and ill-developed children. This is one of the reasons why we have often taken occasion to urge the public duty of inspection of board schools by some authority capable of examining the children as to their physical condition, reporting to the Board as to the number of defective and feeble children who exist in every large school, and who are unfit to work in the ordinary curriculum under the Educational Code. As Mr. Chamberlain says, there is no worse economy than stunting the education of the children. It is ignorant children that grow into criminals and paupers; and I wisely, therefore, he would rather spend £10 on the schools than £1 on the gaols and workhouses. The argument might be extended to the policy of sorting out the children of feeble and defective brain power, and making due provision for their education in auxiliary classes or schools, that they may not become paupers or criminals.

THE ELECTRIC LIGHTING OF THE PARKS.

IN connection with the public feeling which has been aroused by the recent outrage in Regent's Park, it may be hoped that official attention will be effectually directed to the question of rescuing the public parks from their present anomalous condition as unlighted and unguarded spaces, which at night are scenes of obstruction, danger, and demoralisation, instead of being areas of light and much-needed recreation. To aid this result it may not be inopportune to republish the following extract from the address

delivered in 1884 by Mr. Ernest Hart before the Society of Arts on the International Health Exhibition, its Influence and Possible Sequels:—"The practical demonstration which this exhibition, afforded of the eagerness of the English people to resort to healthful means of outdoor amusement was in itself a valuable result, and an important experience. The gardens, illuminated by the electric light and enlivened by music, were undoubtedly a great attraction.....I look upon this not merely as a means, but itself an end. It is no small thing to have acquired the conviction that our open spaces may be, and should be, much more largely devoted to the open-air recreation of the people than they are at the present moment. I say this now, without any intention of entering upon that large question, but with the specific desire to repeat (for it is only by repeating often that one can gain access to the minds of the majority who are all powerful in such questions) that it appears to me to be no small disgrace to this great metropolis that, in the very centre of its crowded districts, within an arrow's flight of the houses probably of most of us who are here, there lie great open spaces, such as Hyde Park (but what I say refers also to Victoria Park) which at night are dreary desolate areas of darkness, which are unlighted, which are dangerous to cross, which are unused in the evenings for any wholesome or moral purpose, which are often scenes for the display of some of the worst vices incidental to the lowest dregs of the population of the great City. Why should we not learn from the success of the music and the lighting of the gardens of the Health Exhibition, that our great parks should all be lighted by the electric light at night, and that throughout the spring and summer months the military bands should play there, and should make those places, which are now not only useless but scandals to the metropolis, the sites of healthful and innocent recreation? I have inquired from a good source what would be the cost of lighting Hyde Park by the electric light; and I am not speaking without data when I say that I believe that Hyde Park could be adequately lighted with the electric light, so that it might add to the resources of health and enjoyment for the teeming population surrounding it, at an annual expenditure of about £5,000. Nor is it likely that the example once set, it would end here. Our Eastern population have a right to the enjoyment of their parks in the evenings that could be conceded to the West."

THE CAVENDISH LECTURE.

THE earlier part of Sir William Stokes's Cavendish Lecture, which we publish this week, deals with a point in the history of medicine which has already attracted the attention of more than one writer both in this country and abroad, but there was still plenty of room for the view which Sir William Stokes, as a surgeon who has observed advances of his department during the present generation, has taken. Surgery has always been the handmaid of medicine, and however much individual practitioners may find it necessary to combine in practice the two departments of the one art, medicine may still, in one sense—that is, in order of time—claim precedence of surgery. The invasion by the surgeon of organs long believed to be beyond his reach is largely due to increased precision in diagnosis. Without the work of Ferriér and of Hughlings Jackson the surgeon would not know where and when to apply his trephine, and until the physician's powers of diagnosis have been still more increased and refined, obscure cases such as those so well described by Sir William Stokes must occur to disappoint the surgeon. It hardly seems necessary for surgery at this time of day to be sensitive about old social slights, for not even the greatest sticklers for an antiquated etiquette could claim more for medicine than that it is *primus inter pares*. The real phenomenon of the present age is the elevation of the apothecary, and his evolution into the general practitioner; the whole complexion of the profession has, indeed,

changed since a Court physician used to meet apothecaries at a certain hour at his coffee-house, and, after having symptoms described, advise as to the treatment of patients he had never seen, charging half a guinea for his opinion. It is only by extreme subdivision of the field of practice, and minute study of some chosen subject, that the so-called pure physician can now maintain his position.

OLYMPIAN WRATH.

THE customary placid calm of the Athenæum Club has been rudely disturbed by events arising out of a proposal made at the annual meeting to put an extra storey on the building at a cost of £20,000. The proposal was almost unanimously rejected, though it was urged that this was the only means of checking the annual deficiency in the income of the club. Had it been carried it was proposed to elect 250 new members, but being lost a committee was appointed to investigate the causes which led to an excess of expenditure over income, and [at the suggestion of several members who thought that an able and business-like medical man would strengthen the Committee, the name of Surgeon-General Balfour, F.R.S., was substituted in the balloting list for that of an eminent Queen's Counsel. This selection has been cancelled by the Committee, on the ground that no notice of the nomination had been given; but as no such notice was required, and the election took place in strict accordance with the by-laws, we hear the case will be brought before the law courts.

LECTURES AT THE ROYAL COLLEGE OF SURGEONS.

WE may remind our readers that Mr. Bryant's two lectures at the Royal College of Surgeons on the causes, effects, and treatment of tension as met with in surgical practice, will be given on Monday and Wednesday next at 5 P.M., and the third lecture, on surgical interference in cranial injuries, on Friday at the same hour. Mr. Marcus Gunn's Arris and Gale lectures on light percipient organs will be given on corresponding days in the week following (June 18th, 20th, and 22nd), at the same hour. The customary syllabuses have been issued.

ENGLISH PRACTITIONERS PERMITTED TO PRACTISE IN SWITZERLAND.

AN eminent London physician forwards us the following telegram, received to-day from Switzerland (St. Moritz):—"A law permitting a limited number of English doctors to practise has been carried by an enormous majority." Our correspondent adds: "I forward this telegram to show you the successful result of the efforts of the BRITISH MEDICAL JOURNAL and its articles in favour of the English physicians. The law was carried in the Grosserrath of the Grisons, the Sanitatsrath having recommended that a commission should be appointed to consider the conditions and the proposals for practice. So the English doctors are much indebted to the BRITISH MEDICAL JOURNAL."

THE ROYAL COMMISSION ON UNIVERSITY EDUCATION.

THE various bodies concerned in University education in London appear to be all busily engaged in giving or preparing evidence for the Royal Commission on the Higher Education in London. On Saturday last, Sir George Young and Mr. Erichsen attended on behalf of University College, and it is understood that representatives of King's College will attend the next meeting on this day (Saturday). A committee appointed by the Senate of the University of London has met, and has selected witnesses to give evidence before a future meeting of the Royal Commission. The Committee of Convocation has also named representatives. The two Royal Colleges are not idle, for a meeting of the delegates was sum-

moned, at thirty-six hours' notice, to meet at the somewhat unusual hour of 9 P.M. on Friday evening, to consider a communication from the Royal Commission.

THE CASE OF SEXTUPLE PREGNANCY.

IT may be remembered that our Swiss correspondent last week mentioned an extraordinary case of multiple pregnancy which recently occurred at Castagnola, near Lugano, in Switzerland. A woman, aged 36, wife of the local *sindaco*, was delivered on May 4th of six children—four boys and two girls—at a birth. They were born alive, though prematurely, but they all died in a few seconds. Their united weight was only three pounds thirteen ounces, and the length of their bodies, which were perfectly well-formed, varied from $8\frac{3}{4}$ to $10\frac{1}{4}$ inches. The case, which is said to beat all previous *authentic* records of human fecundity, is vouched for by Dr. Francesco Vassalli, of Lugano, who attended professionally on the occasion, assisted by Drs. Bianchi, Reali and Solari, of the same place. Dr. Vassalli has reported the case in detail in the *Gazzetta Medica Italiana-Lombardia* of June 2nd, and an abstract of his account may be interesting. It has been stated that the woman had previously borne seven children in two batches of four and three respectively, but this is inaccurate. She was married only two years ago to a widower, aged 41, who had ten children by his first wife. There were no twins among these, but it appears that he has five cousins—brothers—each of whom is the father of twins. A sister of the patient has also borne twins on one occasion. The patient herself in the first year of her marriage had a boy who is now fifteen months old and in perfect health; she suckled him for eleven months, when she became aware that she was again pregnant. The catamenia had reappeared in the seventh month of her nursing, and the last period began on December 4th, and lasted six or seven days; conception must therefore have taken place in the early part of January. The patient suffered severely almost from the first from weakness of the legs and vomiting, and in the fourth month the abdomen was as large as it usually is at full term. On the morning of May 4th (being about the 115th day of pregnancy) whilst doing some light outdoor work, she felt a sudden desire to empty her bowels, and, on squatting down for the purpose, there was a gush of hot liquid from the vagina, which she recognised as amniotic fluid. She immediately went home, walking with much difficulty, on account of something which she felt protruding from the vulva. A neighbour was called in, who found a tiny fœtus hanging by the foot, which was speedily delivered. All this occurred within a few minutes. Dr. Vassalli was then summoned, and found the os only partially dilated, whilst an unruptured sac could be felt through it. There being no urgent symptoms, the patient was kept quiet, and, after passing a fairly good night, she got up the next morning to attend to her household duties, feeling quite well. Towards mid-day, pains came on with increasing violence, and she lost a good deal of blood. Seeing that abortion was inevitable, Dr. Vassalli thought it advisable to hasten delivery. He therefore punctured the membranes, and extracted a small fœtus by the foot. After tying the cord, he followed up the placental end with his right hand, till he came to another sac of fluid; this he also punctured, and delivered a third fœtus. Two more were extracted in the same way, the whole procedure occupying two hours. Fresh hæmorrhage now occurred, and the uterus did not contract. Dr. Vassalli therefore tied all the cords together, and made gentle traction, at the same time applying pressure to the womb. This failing, he introduced his hand into the uterus, and tried to bring away the placenta, which, however, he only succeeded in tearing, with the result of making the bleeding more alarming. Having no hæmostatics at hand, he sent for assistance, keeping his hand in the uterus meanwhile as a plug. It was four hours before help arrived; the

after-birth was then got away with some difficulty, a sixth fœtus enveloped in its own membranes being found attached to it. The patient bore the trying ordeal very well, and made a good recovery. The heads of the fœtuses were rather large relatively to the bodies, and the eyes were covered with the pupillary membrane. The genital organs were completely differentiated. There was only one placenta. The specimen has been placed in the museum of the R. Scuola Ostetrica, at Milan. Dr. Vassalli calls attention to the curious fact that Castagnola is rather remarkable for multiple births. From the official registers it appears that in a population of 585, from January 1st, 1876, to May 10th, 1888—that is, 13 years and 4 months—there was a total of 247 births. Of these 228 were single, and 19 multiple, the latter consisting of 5 cases of twins, 1 of triplets, and the present one of *sixtuplets*. The proportion of twin births, therefore, was 1 in 45, instead of Schröder's estimate of 1 in 89; and of triplets 1 in 228, instead of 1 in 7,910.

ANTHRAROBIN, A SUBSTITUTE FOR CHRYSAROBIN.

Dr. BEHREND (*Tierl. f. Derm. u. Syph.*, 1888, 2 IIeft, p. 261) has made experiments with a substance discovered by Professor Liebermann, of Berlin, named anthrarobin, which has an analogous action to that of chrysarobin and pyrogallic acid, being less active than the former and more active than the latter. It produces less inflammatory irritation than chrysarobin, and does not present the dangers of absorption which attach to pyrogallic acid. In dispensing it requires to be rubbed up with olive oil before being mixed up with the ointment basis. Ten and 20 per cent. ointments are used. Although it is insoluble in water, it becomes soluble by the addition of borax, and is also very soluble in alcohol and glycerine. Anthrarobin 10, borax 8, distilled water 80, is one formula; anthrarobin 20, borax 35, alcohol and glycerine each 90, is another formula. Anthrarobin stains the skin and linen, although not so intensely as chrysarobin, and so little irritation does it produce that it may be applied to the head and face, and even to the eyelids. The alcoholic tincture is preferred to ointment, and the action of this substance is much increased if the part is washed with soap, particularly potash soap, before it is used. It acted successfully in cases of psoriasis and erythrasma. It cures psoriasis less quickly than chrysarobin, but more quickly than pyrogallic acid.

SCOTLAND.

EDINBURGH PATHOLOGICAL CLUB.

THE Edinburgh Pathological Club, one of the most recent developments of scientific activity in Edinburgh, has increased its membership from twenty-five to thirty. The increase was made in consideration of the long list of applications for admission. Members are selected by ballot.

FAITH-HEALING AT DUNOON.

THE committee of the Dunoon Parochial Board, appointed to investigate this case, has presented its report, and fully corroborates the statements formerly made. The patient was prayed over and anointed with oil to cure her of paralysis, but became mad through religious excitement, and had to be removed to the asylum at Lochgilphead, where she still remains.

GLASGOW SOUTHERN MEDICAL SOCIETY.

THE last meeting of the session took place on May 31st. The President (Dr. McMillan) described a case of chronic cystitis in a young man, caused by the introduction of paraffin wax into the bladder. Lithotomy was performed, and paraffin and phosphatic calculi removed. Assisted by Dr. McIntyre he had illuminated

and examined the interior of the bladder with Leiter's cystoscope. This instrument was then shown to the Society by Dr. McIntyre. Dr. McIntyre also showed a ruptured popliteal aneurysm, for which amputation of the thigh had been performed by Dr. W. J. Fleming. The limb was much swollen by effused blood. The popliteal vein was completely occluded, and was adherent to the wall of the aneurysm. The patient had valvular heart disease, and a large aneurysm of the abdominal aorta. Dr. Erskine showed a sequestrum from the ear, consisting of the complete cochlea and some small fragments of the adjacent bone.

SANITATION OF THE MILK SUPPLY.

THE Glasgow Dairy Company, Limited, appears to be carrying on a well-organised effort to open throughout the city of Glasgow branches for the supply of milk and its products of guaranteed purity and excellence. The arrangements are under strict medical and sanitary supervision. A few years ago the milkshops in populous districts were in keeping with the insanitary surroundings of the farmyards and byres whence the supply came. These, it is said, are now giving place to shops where the trade is carried on not only with the requisite degree of cleanliness, but with surroundings which are pleasant to the eye and of primary necessity when dealing with dairy products. The arrangements for safeguarding the supply adopted by the Glasgow Dairy Company provide for the collecting of the milk in pitches, which are then strained and subjected to a course of refrigeration before delivery. All vessels are washed and cleansed by hot water and steam. The medical officer is Dr. Robert Bell.

WORKMEN AND THE VICTORIA INFIRMARY, GLASGOW.

At a meeting of workmen employed in the ironworks on the south side of Glasgow, a movement was set on foot for obtaining for working men some voice in the management of the Infirmary. Dr. Wallace, of Cardross, who addressed the men, explained the arrangement prevailing in Sunderland, where a penny per week or fortnight is given up out of their wages by the men. A fund is thus formed, under the control of a committee of the men, and payments are made out of the fund to the various charities, the men having also the privilege of electing representatives to the Infirmary Board of Management. The meeting approved of the proposal. Similar meetings are about to be held in connection with other works, and the scheme will shortly be put into operation.

GLASGOW SICK CHILDREN'S HOSPITAL.

THE dispensary in connection with this hospital is now rapidly approaching completion, and will soon be ready for the admission of patients. It is a handsome stone building, and will be admirably adapted for its purpose. In planning the internal arrangement, the architect has been very successful in his endeavours to simplify the work of the attendants and prevent confusion of patients. The central part of the building is a large octagonal hall or waiting room, and around this hall the various other departments are arranged. Patients will be admitted at one end of the building and pass out at the other. In a small entrance hall the cases will be registered and classified as medical or surgical, and will then be admitted to the waiting room, the medical on one side, the surgical on the other. The physicians' and surgeons' rooms are at opposite sides of the hall, and patients after having been attended to will not return to the hall, but will pass on to the apothecary's department. There the two streams of patients will again meet, and having received their medicine, pass out of the building. All the rooms are large and well lighted, and will be fitted up regardless of expense. The angles of the rooms, at ceilings and floors, are rounded off to prevent the lodgment of

June 9, 1888.]

dust, and facilitate cleaning. As little wood-work is used as possible, free use being made of glazed enamelled bricks. The front part of the building consists of two storeys, and on the upper floor there is a committee room, sewing room, and other apartments. Outside of the main building there is a caretaker's house. In view of the early opening of the dispensary the directors of the hospital are now advertising for three physicians and three surgeons for this department, and numerous candidates are already in the field.

THE CHURCH OF SCOTLAND AND THE CONDITION OF THE POOR.

DR. J. B. RUSSELL'S lecture on *The City in which we Live*, published under the title of *Life in One Room*, some of the striking facts of which we quoted in our issue of March 10th, last, has attracted marked attention in high ecclesiastical circles. The General Assembly of the Church of Scotland, which has been holding its usual convocation in Edinburgh, has been invited by the Presbytery of Glasgow to give more attention to the condition of the people. The Glasgow Presbytery asked the Assembly to consider the misery and degradation in which a large percentage of the population of large cities lived, and declared that it was specially the duty of the Church of Scotland to care for the whole population, and to labour for their physical as well as their moral and spiritual well-being. They went on to urge the duty of the Church to devise new methods to aid in obtaining, for the poor, improved sanitary conditions and better dwellings, and in providing reading-rooms and other counter-attractions to intemperance. Dr. Donald Macleod, brother of the eminent Glasgow surgeon, referred directly to Dr. Russell's lecture, and noted that the number of people living in one-roomed houses, 126,000, was very close to the estimated numbers of non-churchgoers, 120,000. He considered it the duty of the Church to take up the question of the dwellings of the poor, and to create a public opinion on the subject which might issue in action of some kind. The Assembly enjoined Presbyteries to take what practical steps seemed to them possible and desirable, and resolved to issue a pastoral letter to the people, setting forth the duty incumbent upon all classes of society of co-operating in a united effort to amend a condition of things most injurious to the interests of morality and religion. If this be not a mere spasm of emotion which has passed over the Assembly, it may be the beginning of a movement destined to operate most beneficially in the interests of the physical well-being of the poor classes of the community, especially in large cities.

THE RECENT EPIDEMIC OF SORE THROAT IN EDINBURGH AND ITS RELATION TO THE MILK-SUPPLY.

At the meeting of the Edinburgh Medico-Chirurgical Society on Wednesday last (June 6th), Dr. G. Sims Woodhead and Mr. J. M. Cotterill read a paper of much interest on a curiously limited epidemic of sore throat, and suggested a relationship with the milk-supply. Mr. Cotterill was called to attend successively a large number of cases of sore-throat, occurring in an educational institution in the city. The grouping of the cases raised the suspicion of infection from a common source, and, after careful exclusion, Mr. Cotterill came to the conclusion that the mischievous factor was to be found in the milk-supply. This was accordingly suspended, when the sore-throat epidemic quickly disappeared. When the milk was recommenced sore-throats of a similar character appeared again. Then all the milk was boiled before use, when the epidemic similarly yielded. Dr. Woodhead's attention was accordingly called, and he instituted a careful examination into the condition of the cows from which the milk-supply in question was obtained. Most of the animals showed unmistakable signs of cow-pox in the scab stage. One cow, which had been

separated from the rest as specially healthy, and whose milk was devoted to the use of a hand-fed child, showed similar appearances. On inquiry it was discovered that the child, too, as well as other persons who had partaken of the special milk, suffered likewise from sore-throat of similar character. The clinical evidence thus appeared strongly to support the view that the milk was the medium of infection from the diseased animals. Dr. Woodhead then undertook a series of cultivations and inoculation experiments. He examined the matter from the teats of three of the diseased cows, and found streptococcus pyogenes in all; further, a very small bacillus in the discharge from two, and several other organisms in that from one. In the matter from the tonsils he discovered the streptococcus pyogenes, the slender bacillus, and a very small micrococcus. In two instances there was found, in addition, the short thick bacillus. By cultivation from these, and from the milk, no less than fourteen distinct organisms were separated. Of these, four were common to the milk, to the discharge from the sores, and to the tonsils, while seven were found common to the milk and the sores. It is possible that some of the others may be found common to the three sources, but so far they have not yet been obtained pure. Inoculation experiments were conducted on rabbits with the several pure cultivations whose derivation has been detailed. The results so far obtained have been entirely negative, the staphylococcus pyogenes amongst others not producing any effect, except a very slight amount of swelling and transient redness at the seat of inoculation. Inoculation was made by means of subcutaneous injection into the rabbit's ear.

IRELAND.

DEATH FROM HYDROPHOBIA.

A MAN named Harman died last Saturday, June 2nd, in Barrington's Hospital, Limerick, from hydrophobia. About three months ago, deceased was bitten in the hand by a stray cat, but no symptoms of the dread malady supervened until the evening of May 30th.

BELFAST ROYAL HOSPITAL: QUARTERLY MEETING.

THE usual quarterly meeting was held at the hospital upon May 28th, Mr. T. McClelland, J.P., presiding. The staff reported that during the quarter 532 intern patients had been treated, 88 operations had been performed, and the extern patients numbered 3,124. The financial report showed that the balance against the hospital, which was £823 at the end of the last quarter, was now £869. Two bequests, amounting to £1,000, had been received and invested on behalf of the hospital. Dr. Mackisack had during the quarter succeeded Dr. Dunlop as house-physician.

CORK DISTRICT LUNATIC ASYLUM.

A SPECIAL meeting of the governors was held recently for the purpose of taking into consideration the inadequate accommodation in the asylum at present. From the report of Dr. Dwyer, Resident Medical Superintendent, it appears that they had 103 inmates in the asylum over the certificated accommodation which included the hospitals. Should the latter be excluded, which contains 100 patients, there would be close on 200 patients over the certificated accommodation. Dr. Dwyer suggests that, when the additional building is constructed, it might be worth trying, in a small way, to copy the admirable institutions, the Royal Scotch Asylums, by converting a portion of it into accommodation for a better class of patients, whose friends would be prepared to pay according to the comforts bestowed on them. This would be a boon to people who object to private asylums, and the rates would not suffer, as they would more than defray their annual expenses.

After discussing the matter, and inspecting the sites proposed, the governors directed plans to be prepared for the erection of the building, to contain 300 persons, with one side for males and one for females.

THE GALWAY INFIRMARY.

WE are informed that the legal position with regard to the Surgeoncy to the Galway Infirmary was misrepresented in a paragraph published in the *JOURNAL* of June 2nd, page 1179, in so far as it was stated that the decision of the Court of Queen's Bench had rendered a new election necessary. Dr. Kinkead contends that the effect of the order is to validate his election, and has instituted proceedings to obtain a mandamus to place him *de facto* as well as *de jure* in possession of the appointment.

OUTBREAK OF RABIES.

PROMPT and vigorous action is now being taken by the police to check the spread of rabies which broke out some time ago in Tuam, and has lately spread with alarming rapidity. Many persons are said to have been bitten. On May 21st, a man who was fearfully lacerated by a rabid dog, which was ultimately destroyed, was with commendable activity on the part of the guardians despatched to M. Pasteur for treatment. The magistrates, on being made acquainted with the serious nature of the outbreak, issued special instructions to the police at the Belclare Barracks, who forthwith proceeded to every farm in the division, and shot all the dogs they could find. Another outbreak of rabies is reported from co. Armagh.

ROYAL MEDICAL BENEVOLENT FUND OF IRELAND.

THE forty-sixth annual meeting of the Royal Medical Benevolent Fund Society of Ireland was held on Monday, June 4th, in the King and Queen's College of Physicians, Dublin; Dr. Little, President of the College, in the chair. From the report it appeared that the fund had suffered from the general depression, while the claims for relief had risen from 91 to 97. The grants amounted to £1,284, making a sum of £34,715 which had been distributed by the Society. A special "Jubilee" fund of £129 2s. had also been distributed. Mr. Thomson, Honorary Treasurer, submitted the statement of accounts, from which it appeared that the income was £1,608 5s. 11d., and the amount in bank stock £6,235 0s. 6d., which at present rates represents £18,586. The usual resolutions were passed, and the officers were elected for the ensuing year.

ROYAL COLLEGE OF SURGEONS, IRELAND.

THE annual election took place on Monday, when the following were chosen for the ensuing year:—*President*: Henry Fitzgibbon. *Vice-President*: Austin Meldon. *Secretary*: William Colles. *Council*: William Colles, Sir George Porter, George H. Kidd, Rawdon Macnamara, Edward Hamilton, Robert McDonnell, J. Kellock Barton, Philip Crampton Smyly, Edward H. Bennett, Anthony Hagarty Corley, Sir William Stokes, William Stoker, William I. Wheeler, J. Bellew Kelly, William Carte, Sir Charles A. Cameron, R. Theodore Stack, Kendal Franks, John Benjamin Story, Richard Francis Tobin. There were two candidates for the Vice-Presidency, Dr. Meldon and Dr. Frazer, the former being successful. Mr. Stack, Mr. Story, Mr. Kelly, and Mr. Tobin are new men. Mr. Corley, the outgoing President, headed the list for the Council, and it was felt that the vote of thanks to him for his conduct during his year of office was very well merited.

TREATMENT OF ECZEMA BY COLD POWDERS.—Dr. Veiel, in a paper on the treatment of eczema (*Monat. f. Prakt. Derm.*, 1888, p. 181), speaks highly of the soothing effects to be obtained in acute cases without exudation by the application of cold dry starch powder. Gauze bags filled with the powder are applied to the part, and kept cold by being covered with india-rubber bottles filled with ice and salt, which were frequently refilled.

ROYAL COLLEGE OF SURGEONS, IRELAND.

THE annual meeting of the Royal College of Surgeons, Ireland, was held on Saturday, June 2nd. Dr. A. H. CORLEY, President, occupied the chair.

The report from the Council, an abstract of which has already been published (No. 1431, p. 1179) was read.

Dr. CARTE bore testimony to the laborious duties of the Council during the past year.

Mr. THOMSON hoped that the Council would again try to divert the Carmichael prize fund into some more useful channel. The essays on Medical Education, which were periodically printed at great expense, were never read by anyone.

The PRESIDENT explained that at least one of the trustees offered strong opposition to the diversion of the fund to any other purpose. When the prizes were not awarded, and there was any balance on hand as a result, a sum had been handed to the Medical Benevolent Fund.

The report then passed.

Mr. WM. THOMSON then brought forward the motion of which he had given notice, namely:—

"That the Council of the College having failed to carry into effect the recommendation of the Fellows adopted at the annual meeting in June, 1887, namely: 'That it be recommended to the incoming Council to take the opinion of the Fellows by letter on the question of biennial presidency, as suggested in the resolutions of Council of March 17th, 1887, and of June, 1883, and that a meeting of the College be then called to consider the matter,' it is hereby resolved that the declaration of the Fellows, that a President of the College may hold office for two successive years be re-affirmed; that this rule shall take effect from June, 1890; that the Fellow who may be selected as President at the annual election in that year may so hold his office for two years; and that it be a recommendation to the Council to take such steps as may be necessary to give effect to this resolution."

He said the Council had failed in its duty to the College in not obeying its recommendation. Everyone admitted that change was necessary, but from the inaction of the Council a further period must elapse, during which the present bad arrangement must continue. He was prepared to accept any plan which would enable them to get the best men for the dignified position of the chair. That honour ought to be the reward of a life of professional activity and eminence; but there seemed to be a desire with some to reverse the natural order of events; sometimes the chair was taken by men who were not out of their professional teens, who had made no name by their works, and who rather sought success through the presidency. In saying this he only repeated what the Fellows said individually, and it was due to themselves to put an end to the system. In London, where there were plenty of men fitted to fill the office of President, the chair was occupied by the same person for more than one year, and it was absurd that in a city like Dublin they should have a change every year. An Ex-President should be raised above the rank and file; but at present he really went back to the ranks as soon as he left his office. He urged upon the Fellows to pass a resolution which would be effective in diminishing in some degree the evil of which they all complained.

Dr. MARTIN (Portlaw) seconded the motion. He said he had on a former occasion strongly opposed it, but he had since been converted to the necessity of such a change.

Dr. THORNLEY STOKER supported the motion.

Dr. CARTE and Dr. KIDD suggested that a motion should be passed referring the subject to the Council, asking them to submit a scheme to the College at an early date.

Mr. THOMSON accepted this suggestion, and a motion to this effect was unanimously passed.

The PRESIDENT expressed his cordial approval of the principle set out in the resolution. He had brought it before the College himself in 1874, when he was in a minority of three. He was glad to see that the Fellows were now in favour of a principle which he had then unsuccessfully brought forward.

Dr. E. HAMILTON submitted a motion rescinding the resolution of the special meeting of the Fellows in favour of the amalgamation of medical schools.

Mr. THOMSON rose to order. He submitted that no notice had been given of an intention to propose this motion, which was now sprung upon them.

The PRESIDENT pointed out that if a precedent were established now by allowing the motion to be discussed, it would be

a most inconvenient one, and he hoped Dr. Hamilton would withdraw it.

Dr. KIDD protested against a motion of this sort being sprung upon the meeting.

Dr. HAMILTON said the special meeting was not a legal one. The Fellows had not been sufficiently informed of it.

The PRESIDENT said he would not have summoned an illegal meeting.

Dr. HAMILTON said he had achieved his purpose in the discussion, and he would withdraw the motion.

The proceedings then terminated.

IRISH MEDICAL ASSOCIATION.

THE 49th annual meeting of the Irish Medical Association was held in the Royal College of Surgeons, Dublin, on Monday, June 4th, Mr. H. G. CROLY in the chair.

Dr. CHAPMAN, Honorary Secretary, read the report, which stated that the Council were full of hope that the Government would next session introduce a Bill providing retiring allowances as a matter of right to worn out and disabled union officers. On the subject of medical witnesses at inquests the report states:—

“Dr. Whyte, Coroner for Dublin City, kindly attended a meeting of the Committee of Council, when the subject was discussed at much length, when the following suggestions were agreed to. Some one or more medical gentlemen specially skilled as pathologists, and accustomed to make *post-mortem* examinations, who are good witnesses and thoroughly enjoy the professional as well as the public confidence, should be appointed by the State in cities and large towns, to be called on by the coroner when required. A medical gentleman who saw the deceased person at or shortly before death, or who was in attendance on deceased, ought to be called upon by the coroner, provided he can give evidence of any value or in any way material to the case; but in order that the ends of justice should be met, an expert should be always available to make a *post-mortem* examination in the event of the other medical witnesses not being such. Your Council consider that the State should be memorialised to empower a joint committee, equally represented by the Irish medical authorities, to appoint for Dublin city and the other cities and large towns of Ireland a medical gentleman in each, qualified to act as expert medical witness at coroners' inquests; and that the coroner or the jury should have power to require his services when deemed necessary or desirable.”

“In the annual report, adopted on June 7th, 1886, is to be found (at p. 159 *et seq.*) a copy of a letter addressed by the Council of this Association to the Local Government Board, remonstrating at the restrictions with regard to revaccination which a short time previously had been imposed by that Board in their new issue of regulations, which, notwithstanding, remain unaltered. The difficulties forecasted in that remonstrance have occurred in those neighbourhoods since visited by small-pox, and several dispensary medical officers, unaware of those restrictions, but actuated by a commendable desire to check the spread of that loathsome disease, at some inconvenience and expenditure of time revaccinated all persons who applied to them for that purpose, irrespective of their ages. Amongst the persons revaccinated were a small proportion of children under 12 years of age who did not bear evidence of sufficient protection against susceptibility to small-pox, judging by the cicatrices which resulted from primary vaccination. Your Council consider it advisable that the limit of age, or rather of youthfulness, for revaccination under ordinary circumstances, should be fixed at ten years, and at seven years when there is immediate danger of small-pox. With reference to the recent appointments of medical gentlemen to high official positions in public departments, your Council have received many letters from members of the Association protesting against the selection by Government of gentlemen not actually holding office in those departments. They trust that in future a preference may be given by Government to gentlemen of unquestionable ability and fitness still in the service, who are applicants for the office, instead of to others who, no matter how fit or able they may be, either have never held office in the department, or have, on promotion to some other more lucrative position, ceased to belong to the particular branch of the public service in which an important office becomes vacant.”

The report was adopted.

On the motion of Dr. THORNLEY STOKER, seconded by Dr. POLLOCK, a motion was carried condemning the present system of

supplying dispensaries with drugs by contract, and suggesting that there should be a central depot for supply.

The result of the ballot was then declared as follows:—

President: Andrew K. Young, Esq., Monaghan. *Vice-Presidents:* Leinster, Dr. Z. Johnson, Kilkenny; Ulster, Dr. F. Carre, Letterkenny; Munster, Dr. F. G. Mayberry, Kenmare; Connaught, Dr. J. O'Kelly, Ballinasloe; Drs. St. George Ashe, J. W. Boyce, R. Browne, William Carte, J.P.; A. H. Corley, H. G. Croly, Albert Croly, F. J. Davys, Edward Hamilton, W. J. Hepburn, A. H. Jacob, David Jacob, J. B. Kelly, J. Dillon Kelly, G. H. Kidd, R. J. Kinkead, G. J. Mackesy, James Martin, A. Meldon, R. McDonnell, F. V. McDowell, G. Morrogh, J. Molony, A. O'K. Nolan, T. Purcell, J. Ridley, W. Thornley Stoker, Tagert, William Thompson, Usher, William Wheeler. *Honorary Secretary:* Dr. Chapman. *Honorary Treasurer:* Dr. Minchin. *Auditors:* Dr. Henry W. Oulton and Dr. Arthur H. Benson.

The new PRESIDENT then took the chair, and expressed his sense of the honour conferred on him.

Dr. DELAHOYD moved:

“That the restriction imposed by the Local Government Board with regard to age for revaccination is unsatisfactory, from a public health point of view, and is opposed to the requirements of some Government departments, factories, and schools. That in the opinion of the Irish Medical Association the age for revaccination under ordinary circumstances ought to be ten years, whilst in the presence of an epidemic of small-pox the age ought to be fixed at seven years.

Dr. GREEN seconded the resolution, which was agreed to.

In the evening the annual banquet was held.

PROVISION FOR MEDICAL MEN AGAINST SICKNESS, ACCIDENT, ETC.

At the monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Society, held on Wednesday June 6th—present, Mr. ERNEST HART, in the Chair, Dr. de Havilland Hall, Mr. S. W. Sibley (Treasurer), Mr. F. Wallace, Dr. M. Greenwood, jun.—after the transaction of the usual business and the passing of payments to sick members of £170 for the past month and an insurance claim of £200, the Chairman made a short statement as to the affairs of the Society. Although the financial year of the Society would not close until the end of the current month, sufficient was already known to prove it had been one of a very prosperous nature, whether tested by the numerical increase of members, the accumulation and investment of funds, or the important work of payment of sums during the illness of the members. It would be found that about 130 new members had joined during the year—a number above recent averages. This indicated the continuous and steady growth of confidence in the work of the Society. Though, of course, there had been some lapses, and, unfortunately, several deaths among the members, they could already look forward to a time in the near future when they might confidently count on having an effective membership of over 1,000. With reference to the reserves, they might anticipate an addition to the investment of at least £7,000 on the year, and might count on a total by the end of the current month and close of the financial year of £25,000, which had been and was being invested in the most remunerative manner consistent with principles of the highest financial security. The importance and great professional value of the distribution of sickness pay made by the Society would be at once apparent from the fact that the year's work would probably show disbursements under this head of about £1,800, paid to considerably more than 100 claimants, while the claims still remain below the ratio of sickness provided for in the tables. They were of a character which abundantly proved the urgent need for the Society, and were very interesting from their diversified character and the proof they afforded of the liability of medical men to certain risks impossible to foresee or to avert. Thus, payments to members had been made during the year in fifteen cases of accident, totally disabling from practice, some of them of a very severe nature. One was a particularly striking case, the accident having happened to a member during the first six months of his membership, and forming the foundation of a claim under which he had received over 100 guineas, having sustained a compound fracture which disabled him for several months. Then there had been payments made in respect to nine cases of fever, some of them of a severe character. There had also been a number of cases of affections arising from chill and exposure to which, particularly in the

winter, the practitioner was necessarily peculiarly liable. While the great majority of cases were, happily, of temporary disablement the Society had already experience of that severe class of illness which developed into practically incurable maladies, and in those cases had been able to do good and useful work by the payment of what was really a permanent allowance during the remainder of the life of the afflicted members. It was an essential and useful part of the work to be able to deal effectively with such cases. Several insurance claims had been met by immediate payment in full and without any deductions such as insurance societies sometimes made in such cases. Thus it would be seen that the work of the Society on behalf of the profession was progressing most successfully and beneficently, and that the good sense and self-respect of the members of the profession were leading them, in increasing numbers, to provide against the calamities of illness, accident, or permanent disablement, against which, till now, they had no means of effectually providing, and which had reduced so many to great straits, and had caused others so much severe anxiety during periods of illness, when above all times their minds should be free from such pain and pre-occupation.

Prospectuses of this Society, proposal forms, and all particulars may be obtained, free of cost, from the Secretary, Mr. C. J. Radley, 26, Wynne Road, Brixton, London, S.W.

THE VOLUNTEER MEDICAL SERVICE.

ON Tuesday last an influential deputation of medical men connected with the Volunteer Service had an interview with Mr. Stanhope at the War Office, in order to draw his attention to the insufficiency of the medical organisation of the force, and to the anomalous position in which the medical officers at present stood. Mr. Stanhope was accompanied by Surgeon-General Sir Thomas Crawford, Director-General of the Army Medical Department. Colonel Howard Vincent, C.B., M.P., introduced the deputation.

Surgeon-Commandant NORRIS, of the London Volunteer Medical Staff Corps, stated that the Volunteer Medical Service was really without any organisation, though several attempts had been made to bring the medical officers together. It was to be hoped the Volunteers might never be called upon to go into action, but, if there was any just reason for organising the force, there must be equal reason for organising its medical staff. He would not suggest any scheme to the right hon. gentleman, but would ask him to allow the appointment of a committee, with some Volunteer medical officers, who should formulate a system of organisation.

Dr. W. R. SMITH, 3rd Volunteer Battalion West Kent Regiment, pointed out many defects in the present arrangements.

Mr. STANHOPE, in reply, said he recognised the extreme importance of the matter which had been brought before him. The deputation had pointed out various anomalies and deficiencies which existed, and he would say at once that he had been discussing the matter with his adviser, Sir Thomas Crawford, and thought it would be best to appoint a committee to consider all the points connected with the Volunteer medical organisation.

Mr. Norton and his colleagues will, no doubt, take care that their good-will is not used to force the hands of their colleagues in the Regular Army Medical Department—a rather serious consideration, seeing the way in which the War Office is now dealing with that Department.

DR. MEADOWS MEMORIAL FUND.

A MEETING of subscribers of this fund was held at 38, Portman Square on Saturday afternoon, May 26th, when the following were present:—Mr. Joseph Anderson, Mr. George Baird, Rev. F. Parry Burnett, Rev. R. C. F. Griffith, Rev. J. H. Hindson, Mrs. Leith, Mr. J. M. Macdonald, Miss Palmer, Sir Edward Sieveking, and Mr. W. J. Spratling; Mr. James Watson was in the chair. It was announced that the amount of subscriptions was £219 16s. 6d., which, after deducting £3 16s. 8d. for printing and incidental expenses, left £215 19s. 10d. at their disposal. Mr. WATSON referred to the objects which had been put forward in the circular as being suitable as a memorial, and for which subscriptions had been invited, namely, a carved wooden lectern, a carved wooden pulpit, or (if funds sufficed) a peal of bells. These, it was observed, were all objects which Dr. Meadows (who had done much for Colnbrook and the Parish Church during his residence at Poyle) had greatly at heart, and wished to see introduced had his life been spared, and therefore objects very agreeable to his family. A resolution, proposed by Sir EDWARD SIEVEKING to the effect that a carved

wooden pulpit be presented to the Parish Church at Colnbrook, was carried unanimously, and a committee was appointed to carry out the work at a cost not exceeding £120. It was proposed by Sir EDWARD SIEVEKING, and seconded by the Rev. F. PARRY, that the residue of the money subscribed for a memorial to Dr. Meadows be invested in the names of three trustees, namely, the Dean of St. Mary's Hospital School for the time being, Mr. J. Macdonald, and Mr. Spratling, with a view of founding biennial or triennial prizes in midwifery, bearing the name of the "Dr. Alfred Meadows Prize," to be awarded after competition to past or present students of St. Mary's Hospital under such conditions as the School Committee of that hospital may lay down with the sanction of the trustees. Sir E. Sieveking remarked that such a prize would promote the interests of the schools with which Dr. Meadows had been so intimately connected, and would serve to keep his name in remembrance through succeeding generations.—The proposal on being put to the vote was unanimously carried. The hope was expressed that whilst the pulpit was in course of erection other contributions would come in to augment the value of the "Dr. Alfred Meadows Prize" to students at St. Mary's Hospital, and subscriptions will continue to be received for this object by Mr. James Watson, 38, Portman Square.

THE UNIVERSITIES (SCOTLAND) BILL.

THE widespread interest taken in the most recent measure for the reform of the Scotch Universities was further evidenced last week by the appearance at the Lord Advocate's Chambers of a deputation, representative of students of the four Universities. In the memorial which the students submitted, the chief contention was that more direct representation in the University Court should be granted to the undergraduate element. The claim was based on the ground that only thus would it be possible for the students' wishes to obtain effective recognition. More especially, representation was asked on the Standing Committees on museums and libraries, because information on matters of detail connected with them could be furnished only by those who used them. Their claim was no innovation, as the students already had direct representation through their Lord Rector and his assessor. They merely asked for a proportional increase, in view of the increased number of the court. The Lord Advocate, after complimenting the members of the several representative councils on the very extraordinary strides which had been made by the students themselves within the last few years, assured them that the interests of the councils would be carefully guarded by the Commission, by whom, doubtless, a proper constitution would be given. But he reminded them that no sharp line could be drawn between the graduate student and the undergraduate student; and that through the assessors appointed by the University Council itself they would have a large and powerful representation. He further counselled them to select as Lord Rector a man who was conversant with the affairs of the University, and who would give them attention. If their Rector was to be a dummy, then he should not be in the Court at all.

The General Assemblies of the Presbyterian Churches in Scotland have had this Bill before them, and have most heartily and unambiguously accepted its main provisions as modified by the amendments of the Secretary for Scotland. Professor Miligan, of Aberdeen, introduced the subject at the Established Assembly, and in the course of his remarks said the teaching power of the universities at present was totally inadequate to the multitude of young men seeking instruction. Moreover, in this country, as compared with Germany, we went upon the altogether false impression that the only business of the professor was to teach, and forgot that even a greater part of his duty was the charge of a particular department of work, and that it was his business to the utmost of his power to advance that department. In these and other points the present system required complete revision; and it seemed to him that, taking the Bill as a whole, it would open up a new field and era of progress for our Scottish Universities. The Free Church Assembly held it to be unjust, as well as unfavourable to the best interests of the universities, that the occupancy of any chair should be limited to a particular religious denomination, and declared their opinion that provision should be made in the Bill for terminating the existing connection between the theological chairs and one of the Scottish Churches. Both Assemblies agreed to petition Parliament in favour of the Bill.

The Bill passed through the Committee stage *pro forma* on June 5th.

ASSOCIATION INTELLIGENCE.

NOTICE OF QUARTERLY MEETINGS FOR 1888.
ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Meetings of the Council will be held on July 18th, and October 17th, 1888. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before each meeting, namely, June 27th, September 26th, and December 28th, 1888.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No member can be elected by a Branch Council unless his name has been inserted in the circular summoning the meeting at which he seeks election.

FRANCIS FOWKE, *General Secretary.*

COLLECTIVE INVESTIGATION OF DISEASE.

THE Report upon the CONNECTION OF DISEASE WITH HABITS OF INTEMPERANCE, which was presented to the Section of Medicine in the Annual Meeting of 1887, will shortly be published in the JOURNAL.

Reports upon the two remaining inquiries, namely, that into DIPHTHERIA, and that into the GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES, are in preparation, and will be published as soon as ready.

The following inquiry only of the first series remains open, namely, that on the ETIOLOGY OF PHTHISIS.

A fresh inquiry into the ORIGIN AND MODE OF PROPAGATION OF EPIDEMICS OF DIPHTHERIA has been issued.

Memoranda upon these subjects, and forms for recording observations, may be had on application to the Secretary of the Collective Investigation Committee, 429, Strand, W.C.

BRANCH MEETINGS TO BE HELD.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.—The next meeting of this Branch will be held at the Braes of Gight on Wednesday, June 20th, at 1.45 P.M., the President, Dr. Smith, of Kinnairdy, in the chair. Business: 1. Minutes, nomination of new members. 2. Ballot for the admission of Dr. Jeekyns, Belize, British Honduras; Dr. W. L. Mackenzie, Royal Infirmary; Dr. W. R. C. Middleton, Royal Infirmary; Dr. Rannie, Peterculter; Dr. J. Scott Riddell, 7, Ferryhill Place; Dr. A. M. Will, Royal Infirmary. 3. Notes on Gight and its Castle, by Dr. Alexander Cruikshank, Aberdeen. An omnibus excursion to the Braes of Gight, through the grounds of Haddon House, has been arranged for those who can meet at Old Meldrum at 11.30 A.M. A train leaves Aberdeen at 10.20 A.M. and arrives at Old Meldrum at 11.30 A.M., where carriages will be in waiting. Dinner (inclusive of attendance but exclusive of wine) in a marquee at the Braes of Gight at 5s. per head. Arrangements have been made for members from Buchan to drive from Maud Junction (11.15 A.M.), and for those from Banff from Fyvie (1.15 P.M.) to the Braes of Gight, in time for the meeting and dinner, and returning to catch later down trains. Members from the north will meet the party at Inverurie at 10.50, those from the south and Deeside at Aberdeen at 10.20. A train leaves Old Meldrum at 5.25 P.M., arriving in Aberdeen at 6.40 P.M. Members are invited to bring medical friends.—ROBERT JOHN GARDEN and J. MACKENZIE BOOTH, *Honorary Secretaries.*

BIRMINGHAM AND MIDLAND COUNTIES BRANCH.—The annual general meeting of the Branch will be held in the Birmingham Medical Institute, Edmund Street, on Thursday, June 14th. The chair will be taken by the ex-President, Mr. Lawson Tait, at 3 P.M., who will introduce his successor, Dr. T. W. Thurstfield. Business:—The following members of the Association will be proposed as members of the Branch: James A. B. Thompson, M.D. Glasg., Brawles, Warwickshire; Frank J. Allen, M.A., M.B. Cantab., Mason College; Joseph Henry Patrick, M.R.C.S., 212, Balsall Heath Road; John Angell James, M.R.C.S., L.R.C.P., Queen's Hospital. Alteration of Rules:—Mr. Lawson Tait will move that Rule 9 be amended so as to read as follows: "That in the case of a vacancy occurring in any office other than that of President or President-elect, such vacancy shall be filled up by the Council. In the case of a vacancy in the office of President or President-elect, the vacancy shall be filled up at a general meeting, due notice having been given by the Secretary in each case." Presentation of the reports of the Council, the Treasurer, Pathological and Clinical Section, and Local Collective Investigation Committee. Election of office-bearers, and other formal business. An address will be delivered by the President, Dr. T. W. Thurstfield. The annual dinner will take place at the Grand Hotel, Colmore Row, at 6 P.M. Tickets, 5s. each, exclusive of wine. Each member has the privilege of introducing a friend to the dinner on giving notice of his intention to do so.—ROBERT SAUNDY, M.D., 43A, Edmund Street, and JORDAN LLOYD, F.R.C.S., 22, Broad Street, *Honorary Secretaries.*

CAMBRIDGESHIRE AND HUNTINGDONSHIRE BRANCH.—The annual meeting of this Branch is appointed to be held at Ely on Friday, July 6th. Members wishing to make communications, to exhibit specimens, or to propose new

members are requested to signify their intention to Dr. Anningson, Cambridge, for insertion in the order of proceedings.—BUSHELL ANNINGSON, *Honorary Secretary.*

LANCASHIRE AND CHESHIRE BRANCH.—The fifty-second annual meeting of this Branch will be held at the Medical Institution, Hope Street, Liverpool, on Wednesday, June 13th, 1888, at 2.30 P.M. Order of Business:—Introduction of the new President. The new President's Address. The Report of Council. Election of Office-bearers: President-Elect, Vice-Presidents, Honorary Secretary. Election of Representative Members on the Council of the Association. Election of new Council. Choice of place for holding next annual meeting. Election of two members to serve on the Parliamentary Bills Committee. Grant to Epsom College: Notice of Motion: It will be proposed to make a donation of twenty-five guineas to the Epsom Medical Benevolent College out of the funds of the Branch. Miscellaneous Business. Medical and Surgical Communications.—Dr. Walter: Notes of a case of Total Extirpation of the Uterus per Vaginam. Dr. Glynn: A note on a New Method of Treating Chlorosis. Dr. Johnson Martin: How to prevent Small-pox, and how to spread it. Mr. R. Harrison will show the Electric Endoscope. Dr. Alexander: Hysterectomy for Uterine Cancer (patient). Mr. Shears: Xerosis of the Conjunctiva with Night Blindness. Dr. Imlach: The Use of Stimulants and Narcotics by Women. A small museum of drawings, photographs, and selected pathological specimens. Diner.—The members will dine together at the Adelphi Hotel, Liverpool, at 5.30 P.M. Tickets, 7s. each (exclusive of wine).—CHARLES E. GLASCOTT, M.D., *General Secretary*, 23, Saint John Street, Manchester.

METROPOLITAN COUNTIES BRANCH.—*Preliminary Notice.*—The annual meeting of this Branch will be held at the Holborn Restaurant on Wednesday, June 27th, at 5.30 P.M. President, Arthur E. Durham, Esq., F.R.C.S.; President-elect, C. Brodie Sewell, M.D. Dinner at 7 P.M.; tickets, 7s. 6d. each, exclusive of wine.—GEORGE EASTES, M.B., E. NOBLE SMITH, F.R.C.S., *Honorary Secretaries.*

METROPOLITAN COUNTIES BRANCH: NORTH LONDON DISTRICT.—The annual meeting will be held at the Zoological Gardens, Regent's Park, on Thursday, June 14th, 1888. A. E. Durham, Esq., F.R.C.S., President of the Branch, will preside. Mr. Frank E. Beddard, Prosecutor to the Zoological Society and Davis Lecturer, will lecture at 5 P.M. on "Deinosauria," at which members are invited to attend. Election of Vice-President, Representative Member of Council, and Secretary for the ensuing year. All the present officers are eligible for re-election. Dinner at the Restaurant in the Gardens at 6.30; morning dress. Tickets, 6s. each, exclusive of wine. Members desirous of being present are asked to signify their intention before June 12th, to the Honorary Secretary, GEORGE HENTY, M.D., 302, Camden Road, N.

MIDLAND BRANCH.—The annual meeting will be held at the Masonic Hall Nottingham, on Thursday, June 14th, at 2 P.M. After the transaction of the usual business a proposition to amend Rule 6 will be laid before the meeting. Papers, etc.: Mr. Edgar M. Crookshank: On the Alleged Origin of Certain Diseases from the Lower Animals. Mr. Frank Pope: A Case of Diabetes, probably of Traumatic Origin. Mr. R. C. Chiokea: New Form of Bone Forceps for Sequestromy. Dr. George Elder: Remarks on Cases of Peritonitis treated by Abdominal Section. Dr. H. Handford: The Influence of Position on Cardiac Murmurs, and on the Treatment of Heart Disease. Mr. Frank Hodges will exhibit a patient on whom he has operated for Cataract of Each Eye by different Methods. Luncheon will be provided by the President-elect, at the place of meeting, at 1 o'clock. The dinner will also take place at the Masonic Hall, at 5 o'clock. Tickets, 7s., exclusive of wine.—W. A. CARLINE, M.D., *Honorary Secretary and Treasurer.*

NORTH OF IRELAND BRANCH.—The annual meeting of this Branch will be held in the Belfast Royal Hospital, on Wednesday, July 11th, at 4 P.M. Gentlemen who desire to read papers or to bring any other business before the meeting will kindly communicate as early as possible with the Secretary, JOHN W. BYERS, M.D., Lower Crescent, Belfast.

READING AND UPPER THAMES BRANCH.—The annual meeting of this Branch will be held in the Library of the Royal Berkshire Hospital, Reading, on Wednesday, July 11th, at 4.15 P.M. The chair will be taken by the President (Dr. C. H. Tench), who will introduce the President for the coming year (W. B. Holderness, Esq., of Windsor), who will then take the chair. Members willing to read short papers or bring forward cases of clinical interest are requested to communicate with the Honorary Secretary without delay. The annual dinner will take place on the same evening at 8.15 P.M., at the Queen's Hotel, Reading. Dinner tickets (5s. without wine, or 10s. including wine) should be obtained from the Honorary Secretary on or before Saturday, July 7th.—H. HEYGATE PHILLIPS, 43A, London Road, Reading, *Honorary Secretary.*

SOUTH MIDLAND BRANCH.—The annual meeting of the above Branch will be held at the Blechley Park Hotel, Blechley, on Thursday, June 14th, at 2.45 P.M. The new President, H. Veasey, Esq., invites the members to luncheon at the same place previously to the meeting, from 1.30 to 2.30 P.M., at which meeting and luncheon every qualified medical man will be a welcome visitor. Gentlemen accepting the invitation are requested to intimate the same to the Honorary Secretary not later than June 11th. The arrangements for a combined meeting this year of the Cambs and Hunts and South Midland Branches having fallen through, the informal reciprocal visits of members, to whom it may be convenient, at the respective meetings, would be most agreeable, and are hereby invited. Agenda:—Usual business of annual meeting. Resolution on subject of "Fees to Medical Witnesses," etc. Communication from Chairmen of Parliamentary Bills Committee on Subject of "Lunacy Acts Amendment Bill" (see JOURNAL, May 12th, p. 1026). The following gentlemen will be proposed as new members of the Association and Branch: John Henry Lloyd, Esq., Bedford; J. Neil Whitfield, Esq., Northampton; A. B. Godfrey, Esq., and Weatherley, Esq., Northampton Library. Gentlemen wishing to read papers for discussion, cases, etc., are requested to send the titles of the same without delay to the undersigned. The following have been promised: Mr. Milligan: Case of Straugulated Umbilical Hernia: Operation for Radical Cure: Recovery. Dr. Jones: Physical Indications in Heart Affections. Dr. Geldsmith: A Question as to the Etiology of some Nervous Diseases of Child-

dren. Mr. Bull: Obscure Abdominal Tumour; Abdominal Section: Recovery. Mr. Evals: The Royal Colleges and the Society of Apothecaries.—C. J. EVANS, Honorary Secretary, Northampton.

SOUTH-WESTERN BRANCH.—The annual meeting of this Branch will be held at the Devon and Exeter Hospital, Exeter, on Tuesday, June 26th, under the presidency of Dr. John Woodman, F.R.C.S. Notices of motion or communications to be intimated to the Honorary Secretary without delay, and it will facilitate arrangements if members will inform the Honorary Secretary as soon as possible if they hope to be present at the meeting. The following motion was passed at the Council Meeting on May 2nd:—"That inasmuch as the annual meeting assumes more or less the character of a day of recreation, and with a view of encouraging the district meetings, the business of the annual meeting shall be confined to the President's address, the business of the Branch, the exhibition of cases or of specimens with notes, and the annual dinner."—P. MAURY DEAS, Winton House, Exeter, Honorary Secretary.

SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT.—The next meeting will be held in the board-room of the hospital, at Hastings, on Tuesday, June 12th, at 3.30 P.M. Dr. Bagshawe will preside. The following papers are promised: The Chairman: A Case of Chyluria. Mr. Titchurst: A Case of Addison's Disease, with a Rare Form of Skin Eruption (Drawing to be shown). Dr. Penhall: A Case of Nephrotomy. Dr. Taloufer Jones: Mercury as a Diuretic. The dinner will take place at the Palace Hotel at 5.30 P.M.; charge, 6s., exclusive of wine.—T. JENNER VERRALL, Honorary Secretary, 97, Montpellier Road, Brighton.

SOUTH WALES AND MONMOUTH BRANCH.—The eighteenth annual meeting of this Branch will be held at the Infirmary, Cardiff, on Wednesday, June 27th. Further particulars in circulars. Members wishing to read papers, etc., are requested to send titles to Dr. Sheen before June 10th.—A. SHEEN, M.D., Cardiff, D. ARTHUR DAVIES, M.B., Swansea, Honorary Secretaries.

SOUTHERN BRANCH.—The fifteenth annual meeting will take place at the Grosvenor Hotel, Queensgate, Southsea, on Thursday, June 14th. The general meeting will be held at 1 P.M. The President-Elect, H. B. Norman, Esq., has kindly undertaken to provide refreshments at the hotel. In accordance with the by-laws, two gentlemen will be elected at this meeting as Representatives of the Branch on the Council of the Association for the ensuing year. The address will be delivered by the President-elect at 2 P.M. During the afternoon the members are invited to visit the Dockyard, the old *Victory*, H.M.S. *Vernon*, and other places of interest. Dinner at 6 P.M.; charge, 5s., exclusive of wine, etc. The Committee request that those gentlemen who intend to be present at the dinner will send in their names on or before Wednesday, June 13th.—J. WARD COUSINS, Honorary Secretary and Treasurer.

YORKSHIRE BRANCH.—The annual meeting of the Yorkshire Branch will be held in the Museum of the Yorkshire Philosophical Society at York on Wednesday, June 27th, when the representatives of the Branch on the General Council and the officers for the ensuing year will be elected. Members intending to read papers and show specimens, are requested to communicate at once with ARTHUR JACKSON, Secretary, Sheffield.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.

A MEETING of this Branch was held at 198, Union Street, Aberdeen, on Wednesday, May 16th, at 8 o'clock P.M. Dr. URQUHART in the chair.

Nominations and Ballot.—Six new members were nominated for election at next meeting, and Dr. Ligertwood Methlick was balloted for and admitted an ordinary member.

Summer Meeting.—After some discussion, it was decided that the summer meeting should be held at Gight, on Wednesday, June 20th, and it was remitted to Professor Ogston and Dr. Mackenzie Booth to make the necessary arrangements.

Representative to Council.—Dr. Wight was proposed as the representative of the Board on the Council of the Association for the ensuing year, and was elected unanimously.

CEYLON BRANCH.

An ordinary meeting of this Branch was held at the Colonial Medical Library, on March 3rd, Dr. VAN DORT, Vice-President, in the chair. The following gentlemen were present: Drs. Asserappa, Attygalle, Loos, Rockwood, Messrs. Van Geyzel, Eleyatambi, Nell, Brito, Schokman, Fernando, and Keegel (Honorary Secretary).

The minutes of the previous meeting were read and confirmed.

Proposed Amendment of By-law.—Dr. ROCKWOOD, on behalf of Mr. THORNHILL, moved in pursuance of notice that the following alteration or amendment of By-law 4 be made: After the words "Colombo" to insert "Kandy, Galle, Jaffna, and Badulla." To omit the words "and the following," and also the whole of the third, fourth, and fifth lines, and the word "Colombo" in the sixth line, and insert "these towns."—Mr. NELL seconded.

Dr. ATTYGALLE moved as an amendment: "That the consideration of Mr. Thornhill's resolution be postponed till the next annual meeting of the Branch in December next."—Mr. ELEYATAMBI seconded.

Dr. LOOS moved as another amendment: "That Messrs. Thornhill, Craib, and Griffin be still considered members of the Council,

although the three superintending medical officers cease to hold their office from the circumstances of those offices being abolished."—Dr. ASSERAPPA seconded.

Dr. ATTYGALLE's amendment being put to the vote, was negatived by 6 against 4.

Dr. LOOS having withdrawn his amendment, in view of the necessity of previous notice, as the amendment amounted to a substantive motion necessitating a material change in the constitution of the Council,

Mr. THORNHILL's motion was put to the vote and lost, the proposer and seconder alone voting for it.

Paper.—A paper on Anchylostomiasis was read by Mr. FERNANDO, on behalf of Mr. GRATIAEN.

DORSET AND WEST HANTS BRANCH: SPRING MEETING The spring meeting of this Branch was held at the Yeatman Hospital, Sherborne, on Wednesday, May 30th, JOHN COMYNS LEACH, M.D., President, in the chair. There were also present thirty members and visitors.

Branch Council.—Mr. G. W. Daniell, of Blandford; Dr. W. E. Humble, of Corfe Castle; Dr. J. C. Leach, of Sturminster Newton; Dr. P. W. Macdonald, of the Dorset County Asylum; Dr. R. P. Simpson, of Weymouth; Dr. W. V. Snow, of Bournemouth; and Dr. W. H. Williams, of Sherborne, were elected as members for the ensuing year.

Representative of the Branch on the Council of the Association.—Dr. W. G. Vawdrey Lush, of Weymouth, was re-elected as representative of this Branch on the Council of the Association for the ensuing year.

Representative on the Parliamentary Bills Committee.—Mr. C. H. Watts Parkinson, of Wimborne, was elected for the ensuing year.

New Members.—The following gentlemen were elected:—Mr. James Charles Clark, of Wimborne; and Dr. John Lyon, of the Royal Naval Sick Quarters, Portland.

Next Meeting.—It was resolved that the summer meeting be held at Swanage.

Vote of Sympathy.—It was resolved unanimously that the members of the Dorset and West Hants Branch of the British Medical Association express their hearty sympathy with Dr. Lush and Mr. Good in the anxiety caused them by the controversy with the majority of the committee of the Dorset County Hospital.

Communications.—Mr. MARSH: Short Notes of a Case of Lawson Tait's Operation for Extension of Perineum, with an Uncommon and Unfortunate Termination. Dr. GREVES: Case of Cerebral Tumours (specimen), with Remarks on the Diagnosis of Intracranial Tumours Implicating the Cortex of the Brain. Dr. DAVISON: A Case of Infantile Scurvy. Dr. MACDONALD: On Epilepsy, with notes of a case and pathological specimens.

Dinner.—The members and friends dined together at the Digby Hotel.

HALIFAX, NOVA SCOTIA BRANCH.

THE fourth ordinary meeting of this Branch was held at Halifax on March 20th. Deputy Surgeon-General McDOWELL in the chair. The following gentlemen were present:—Hon. Dr. Parker, Drs. Slayter, Morrow, Milsom, Goodwin, Black, De Witt, Cowie, Farrell, Trenaman, and Curry; Surgeons Weston and Fowler, A.M.S.

Amendment of the Health Act.—The PRESIDENT and Dr. PARKER explained the steps that had been taken by the Committee of the Branch and the Local Government to amend the present Health Act.

Cases, Etc.—The Hon. Dr. PARKER showed a new stomach pump for washing out the stomach, and explained its use and the cases for which he considered it appropriate. He also gave the history of a fatal case of leucocythemia with abnormally enlarged spleen.—Dr. SLAYTER brought forward an interesting case of excessive lactation, giving the treatment pursued and inviting suggestions.—Drs. COWIE and PARKER related similar cases.

THE fifth ordinary meeting was held at Halifax on March 8th, the Hon. Dr. PARKER in the chair. The following gentlemen were present:—Drs. Black, Chisholm, Milsom, Wickwire, Farrell, Morrow, Goodwin and Tobin; Surgeon-Major Bolster, A.M.S.; Surgeons Grier, Weston, Fowler, and Deebie, A.M.S.

Communications.—Surgeon FOWLER, A.M.S., described a case simulating locomotor ataxy now under his care in hospital.—Dr. BLACK exhibited a specimen showing a fistulous opening be-

tween the vermiform appendix, bladder, and rectum. The patient had suffered from perityphilitis, and had passed fecal matter and flatus by the urethra for some months before death.—Dr. CAMPBELL showed two specimens removed from the body of a man who had died of Bright's disease; one was a contraction, without thickening or signs of previous ulceration of the pylorus; the second consisted of the apex of the right lung which had undergone "grey induration."—Remarks were made by Drs. BLACK, FOWLER, CHISHOLM and others.

NEW SOUTH WALES BRANCH.

THE annual meeting of this Branch was held at Sydney on March 2nd, Dr. KNAGGS in the chair.

Report of Council.—Mr. G. T. HANKINS, the Honorary Treasurer, read the Council's report and balance-sheet, showing a balance to the credit of the Branch of £143 2s.

Officers of Council.—The following gentlemen were elected *Councillors* for the ensuing year: Drs. Creed, Knaggs, Hankins, Chambers, Fiaschi, O'Reilly, Quaife, McCormick, MacLaurin, and Scot Skirving. *President*: Dr. Chambers. *Vice-President*: Dr. Fiaschi. *Honorary Treasurer*: G. T. Hankins, M.R.C.S.; *Honorary Secretary*: Dr. Scot Skirving. *Auditors*: Drs. Crago and Ellis.

Medical Defence Association.—Dr. ELLIS's letter relating to the Medical Defence Association was read and received.

Vote of Thanks.—Dr. ELLIS proposed, and Dr. ROSS seconded, that a hearty vote of thanks be accorded to the retiring office-bearers.—Carried.

The adjourned annual meeting was held at the Royal Society's Room, Sydney, on Friday, April 6th, 1888. Present: the Hon. Dr. CREED, M.L.C., in the chair: Drs. Knaggs, O'Reilly, Chambers, Roth, Garrett, Twynam West, Kendall, Wm. Chisholm, Crago, Hankins, Worrall, Fiaschi, Faithful, Martin, Foreman, Clubbe, and Scot Skirving.

President's Address.—The Hon. Dr. J. MILDRED CREED, the retiring President, delivered an address. The very satisfactory monetary position of the Branch was, he said, the result in a great measure of the time and care devoted by the Honorary Treasurer, Mr. Hankins, to the duties of his office; and gratitude was also due to the Honorary Secretary, Dr. Scot Skirving, and to the Assistant Secretary, Mr. Green, for the devotion and exactitude which they had shown in the conduct of business. He mentioned the papers which had been read during the year, and said that the Branch had to deplore the deaths of five members—namely, Drs. Hoff, Halket, Lentaigne, Markey, and Leacock. The sympathy of the Association had been conveyed to their representatives. He then passed in review a variety of topics of special interest to the profession in New South Wales. An abstract of his remarks will be found at page 1213. He said they were entering upon a year of new work; and, besides, it was the centenary year of the colony, an occasion which the Branch should do something to mark.

Leacock Fund.—The Hon. Secretary (Dr. SKIRVING) stated that he had received £102 8s. towards the fund in aid of the family of the late Dr. Leacock, the Newcastle Committee wished to send in their contribution at the same time as this Branch.

An Amateur Surgical Instrument Maker.—Dr. SCOT SKIRVING exhibited a curious specimen of surgical instrument made and used by an amateur.

New Members.—The PRESIDENT announced the election of the following gentlemen:—Dr. Lloyd, Hunter's Hill; Dr. Robertson, Auckland. Dr. Creed then gave up the chair to the President-elect, Dr. Chambers.

Vote of Thanks to President.—Dr. KNAGGS said he had much pleasure in proposing a vote of thanks to Dr. Creed for his able address, and for the general interest displayed by him in the work of the Branch. He (Dr. Knaggs) felt sure that as mover for the committee which reported on the registration of births and deaths, Dr. Creed deserved the thanks of the whole community, for if the Bill was properly administered, many existing evils would be remedied. With regard to the report of the committee on the law and practice of medicine, Dr. Creed's action was to be commended by every right thinking person.—Dr. CLUBBE seconded the resolution.—The Hon. Dr. CREED returned thanks.

The New President.—Dr. CHAMBERS then thanked the members for the honour they had done him by electing him to the position of president, and would ask members to lend a helping hand.

BRITISH MEDICAL ASSOCIATION.

FIFTY-SIXTH ANNUAL MEETING.

THE fifty-sixth Annual Meeting of the British Medical Association will be held at Glasgow, on Tuesday, Wednesday, Thursday, and Friday, August 7th, 8th, 9th, and 10th, 1888.

President: John T. Banks, M.D., D.Sc.(Hon.), F.K.Q.C.P.I., Regius Professor of Physic in the University of Dublin.

President-Elect: Professor W. T. Gairdner, M.D., LL.D., Professor of Medicine in the University of Glasgow.

President of the Council: Thomas Bridgwater, M.B., J.P., Harrow-on-the-Hill.

Treasurer: Constantine Holman, M.D., J.P., Reigate. An Address in Medicine will be delivered by Thomas Clifford Allbutt, M.D., Consulting Physician, Leeds General Infirmary.

An Address in Surgery will be delivered by Sir George H. B. Macleod, M.D., Surgeon in Ordinary to Her Majesty in Scotland.

An Address on his "Recent Investigations in Surgery" will be given by William Macewen, M.D., Lecturer on Clinical Surgery, Glasgow Royal Infirmary.

An Address in Physiology will be delivered by John Gray McKendrick, M.D., LL.D., F.R.S., Professor of Institutes of Medicine, University of Glasgow.

All the rooms required for the purposes of the meeting will, by the kindness of the authorities, be provided in the University of Glasgow.

PROGRAMME OF PROCEEDINGS.

TUESDAY, AUGUST 7TH, 1888.

9.30 A.M.—Meeting of 1887-1888 Council. Randolph Hall.

11.30 A.M.—First General Meeting. Report of Council. Reports of Committees. Bute Hall.

4 P.M.—Service in the Cathedral. Sermon by the Very Rev. John Caird, D.D., LL.D., Principal and Vice-Chancellor of the University of Glasgow.

8.30 P.M.—Adjourned General Meeting from 11.30 A.M. President's Address. Bute Hall.

WEDNESDAY, AUGUST 8TH, 1888.

9.30 A.M.—Meeting of 1888-89 Council. Randolph Hall.

10.30 A.M. to 2 P.M.—Sectional Meetings.

3 P.M.—Second General Meeting. Address in Medicine by Thomas Clifford Allbutt, M.D., F.R.S. Bute Hall.

9 P.M.—*Conversazione* given by the Professors of the University.

THURSDAY, AUGUST 9TH, 1888.

9.30 A.M.—Address on his Recent Surgical Investigations by William Macewen, M.D. Bute Hall.

11 A.M.—Meeting of Council. Randolph Hall.

10.30 A.M. to 2 P.M.—Sectional Meetings.

3 P.M.—Third General Meeting. Address in Surgery by Sir George H. B. Macleod, M.D. Bute Hall.

7 P.M.—Public Dinner. St. Andrew's Hall.

FRIDAY, AUGUST 10TH, 1888.

10.30 A.M. to 1.30 P.M.—Sectional Meetings.

3 P.M.—Concluding General Meeting. Address in Physiology by John G. McKendrick, M.D., F.R.S. Philosophy Class-room.

9 P.M.—*Conversazione* given by the Corporation of Glasgow at St. Andrew's Hall.

Garden Party given by the Faculty of Physicians and Surgeons at the Botanic Gardens.

SATURDAY, AUGUST 11TH, 1888.

Excursions.

The following discussions and papers are promised up to the present time.

SECTION A.—MEDICINE.

Humanity Class Room.

A. MEDICINE.—*President*, Professor T. McCall Anderson, M.D. *Vice-Presidents*, R. L. Bowles, M.D.; George F. Duffey, M.D. *Honorary Secretaries*, J. McGregor Robertson, M.A., M.B., 400, Great Western Road, Glasgow; Robert M. Simon, M.D., 27, Newhall Street, Birmingham.

The President will open the proceedings by introducing a discussion on the Diagnosis and Treatment of Syphilitic Disease of the Nervous System. Dr. Thomas Buzzard, Dr. T. S. Clouston, Dr. William Moore, Dr. Ross, Professor Grainger Stewart, and Dr. C. W. Suckling will take part in the discussion.

On the third day of the sectional proceedings, the Value of Inhalations in the Treatment of Lung Disease is set down for discussion, to be opened by Dr. C. Theodore Williams. The following gentlemen have already indicated their intention to engage in this discussion: Dr. Burney Yeo, Dr. W. W. Ireland, Dr. C. F. Knight, Dr. J. A. Lindsay, and Dr. E. Markham Skerritt.

Drs. Byrom Bramwell and Milne Murray will give a demonstration of their Method of Graphically Recording the Exact Time Relations of Cardiac Sounds and Murmurs.

The following papers have been promised.

FINLAY, David W., B.A., M.D. Bronchiectasis treated by Incision and Drainage.

FREW, W., M.D., Kilmarnock. Prevalence of Cerebro-spinal Fever in Scotland.

GREENE, G. E. F., L.K.Q.C.P. A Note on a Recent Epidemic of Erysipelas.

MYRTLE, A. S., M.D., Harrogate. Neurasthenia, True and False; Diagnosis and Management.

TONORY, J. K., M.B. East African Fever, with special reference to Climatic Conditions.

WARNER, Francis, M.D. Methods of Studying and Examining the Nerve System.

Sir W. Roberts, Dr. Lauder Brunton, Dr. Russell Reynolds, Dr. F. W. Pavy have also intimated their intention to take part in the proceedings of the Section.

SECTION B.—SURGERY.

Chemistry Class Room.

B. SURGERY.—*President*, George Buchanan, M.D. *Vice-Presidents*, James Dunlop, M.D.; Charles Robert Bell Keetley, F.R.C.S. *Honorary Secretaries*, David Neilson Knox, M.B., 8, India Street, Glasgow; Walter Pye, F.R.C.S., 4, Sackville Street, Piccadilly, London, W.

As already announced, in this Section discussions have been arranged for on the following subjects:

1. The Surgical Treatment of Abscess of the Lung and of Empyema. To be introduced and supported by Mr. T. Pridgin Teale (Leeds), Sir Spencer Wells (London), Mr. A. Pearce Gould (London), Mr. R. J. Godlee (London), and Mr. W. Thomas (Birmingham).

2. The Operative Treatment of Club-Foot. To be introduced and supported by Sir William Stokes (Dublin), Mr. E. Lund (Manchester), Dr. Alexander Ogston (Aberdeen), Mr. R. W. Parker (London), Mr. E. M. Little (London), Mr. John Chiene (Edinburgh), Mr. W. J. Walsham (London), and others.

The following papers have also been promised.

BESTON, Samuel, Esq., London. On the Treatment of Stricture of the Rectum by Electrolysis.

CLARK, Sir Andrew, London. The History of a Case of Catheter Fever.

CLARKE, W. Bruce, Esq., London. On the Vesical Endoscope.

FENWICK, E. Hurry, Esq., London. Notes from the Experience of 450 Cases of Organic Stricture of the Urethra.

FLEMING, W. J., M.D., Glasgow. 1. On Continuous Extension in Spinal Curvature. 2. On the Treatment of Perineal Fistula.

HARRISON, Reginald, Esq., Liverpool. On an Improvement in the Construction of Ships' Berths, relative to the Treatment of some Surgical Injuries and Diseases at Sea (with models).

KEETLEY, C. B., Esq., London. Plastic Amputations of the Foot.

MCINTYRE, John, Esq., Glasgow. The Electric Illumination of the Cavities of the Body.

OWEN, Edmund, Esq., London. A Case of Trephining for Intracranial Hæmorrhage (Subdural); Localisation; Recovery.

RAKE, Bevan, M.D., Trinidad. The Value of Nerve Stretching in Leprosy, based on One Hundred Cases.

ROTH, Bernard, Esq., London. On Scoliometry, or an Accurate Method of Recording Cases of Lateral Curvature of the Spine.

SILCOCK, A. Quarry, Esq., London. On Excision of Enlarged Bursæ in the Popliteal Space.

STOKES, Sir William, Dublin. Modification of Gritti's Amputation; and will show Casts of Stumps.

SECTION C.—OBSTETRIC MEDICINE.

Medical Jurisprudence Class Room.

C. OBSTETRIC MEDICINE.—*President*, Thomas More Madden, M.D. *Vice-Presidents*, William Leishman, M.D.; J. Halliday Croom, M.D. *Honorary Secretaries*, William Walter, M.D., 20, St. John Street, Manchester; W. L. Reid, M.D., 7, Royal Crescent, Glasgow.

Professor Stephenson (Aberdeen) will take part in the discussion on Obstructive Dysmenorrhœa.

Dr. Samuel Sloan (Glasgow) will show his Antero-posterior Compression Forceps, and will explain their use in Flat Pelves.

The following papers are promised.

CAMERON, Murdoch, M.D., Glasgow. 1. On Cæsarean Section, with Notes of a Successful Case. 2. On the Thermostatic Nurse, with Cases.

HART, D. Berry, M.D., Edlburgh. Successful Case of Cæsarean Section (Porro's modification).

INLACH, Francis, M.D., Liverpool. The Function of Anæmia in Gynæcology.

STEPHENSON, William, M.D., Aberdeen. On the Influence of Permanganate of Potass on Menstruation.

SECTION D.—PUBLIC MEDICINE.

Greek Class Room.

D. PUBLIC MEDICINE.—*President*, Henry Duncan Littlejohn, M.D. *Vice-Presidents*, James Christie, M.D.; D. Page, M.D. *Honorary Secretaries*, Ebenezer Duncan, M.D., 4, Royal Crescent, Crosshill, Glasgow; John C. McVail, M.D., Holmhead, Kilmarnock.

1. Sanitary Legislation. This discussion will be introduced by the Opening Address of the President of the Section.

2. The Communicable Diseases Common to Man and Animals, and their Relationships. Discussion to be opened on the second

day of the sectional meetings by George Fleming, LL.D., F.R.C.V.S., Chief of the Veterinary Department of the Army.

3. The Disposal of Sewage (a) in Large Towns; (b) in Small Towns and Country Districts. Discussion will be opened on the third day by Dr. James B. Russell, Medical Officer of Health, Glasgow.

The following papers are promised.

DRYSDALE, Charles R., M.D. 1. On Indigence as a Main Cause of High Death-rates. 2. The Berlin and Parisian Sewage Farms.

HIME, T. W., M.B. Milk Scarlet Fever.

KERR, Norman, M.D. Some Risks of Sanitation.

SIMPSON, —, M.D., Medical Officer of Health, Calcutta. On Cholera and its Fostering Conditions in the Endemic Area.

SUTHERLAND, J. Francis, M.D. National Sanatoria.

SECTION E.—PSYCHOLOGY.

Hebrew Class Room.

E. PSYCHOLOGY.—*President*, James C. Howden, M.D. *Vice-Presidents*, James Rutherford, M.D.; Julius Mickle, M.D. *Honorary Secretaries*, A. R. Uqhart, M.D., Murray House, Perth; Alex. Newington, M.D., Ticehurst, Sussex.

Dr. J. C. Howden, the President of the Section, will deliver an Address.

Dr. C. M. Campbell will introduce a discussion on the Uniform Recording of *Post-Mortem* Examinations in Asylum Reports.

Drs. A. Yellowlees and A. Campbell Clark will introduce the following subject: The Sexual and Reproductive Functions—Normal and Perverted—in Relation to Insanity. 1. Menstruation: its Commencement, Irregularities, and Cessation; 2. The Sexual Instinct and its Abuse; 3. Pregnancy, Parturition, the Puerperal Period, and Lactation.

Dr. Clouston will initiate a discussion on the Principle of Construction and Arrangement of an Asylum for Private Patients of the Richer Classes.

The following have promised papers: Drs. Savage, Mack Tuke, Fletcher Beach, Charles Mercier, W. J. Mickle, and Turnbull.

SECTION F.—ANATOMY AND PHYSIOLOGY.

Anatomy Class Room.

F. ANATOMY AND PHYSIOLOGY.—*President*, John Cleland, M.D., LL.D., F.R.S. *Vice-Presidents*, R. J. Anderson, M.D.; Henry Edward Clark, F.F.P.S.G. *Honorary Secretaries*, John Barlow, M.D., 27, Elmbank Crescent, Glasgow; Charles Barrett Lockwood, F.R.C.S., 19, Upper Berkeley Street, Portman Square, W.

C. B. Lockwood, F.R.C.S., will introduce a discussion on the Teaching of Anatomy; and will show sections illustrating the Development of the Organs of Circulation and Respiration.

The following papers are promised.

BROOKS, Henry St. John, M.D. On the Morphology of the Epitrochleo-anconeus or Anconeus Sextus (Gruber).

BROWN, J. Macdonald, M.B., F.R.C.S. The Construction of the Cardiac Ventricles in the Mammalia.

CLELAND, Professor, M.D., F.R.S. On the Nature of Certain Forms of Double Monstrosity.

COLLIER, Mark P. Mayo, M.B., F.R.C.S. On the Mechanism of the Heart and Pulse.

LANE, W. Arbuthnot, M.B., F.R.C.S. The Influence Produced by Excessive Strain upon Muscles and Ligaments (to be illustrated by specimens).

PATERSON, A. M., M.D. On the Position of the Vertebrate Limb, considered in the Light of its Innervation and Development.

SECTION G.—PATHOLOGY.

Law Class Room.

G. PATHOLOGY.—*President*, Sir William Aitken, M.D., LL.D., F.R.S. *Vice-Presidents*, Alexander Davidson, M.D.; Joseph Coats, M.D.; Charles Roy, M.D., F.R.S. *Honorary Secretaries*, G. Sims Woodhead, M.D., 6, Marehall Crescent, Edinburgh; J. Lindsay Steven, M.D., 34, Berkeley Terrace, Glasgow.

Arrangements are being made to hold a discussion on Cancer originating apart from Epithelial Structures, in which Mr. Lawson Tait (Birmingham), Dr. Joseph Coats, Dr. John Carlyle (Greenock), and others are expected to take part.

The following papers have been promised.

BRUCE, Alex., M.B., F.R.C.P. Edin. On Disseminated Sclerosis.

COATS, Joseph, M.D. On a Case of Lipæmia in Diabetis, with Suggestions as to the Source of the Fat.

KENNEDY, —, On Case of Cystic Kidneys and Liver.

MAPOTHER, E. D., M.D., Dublin. An Anomalous Form of Eczema.

MAYLARD, A. E., M.B., B.S. Lond. The Results of some Bacteriological Cultivation Experiments with Iodoform.

RAKE, Bevan, M.D. Lond., Medical Superintendent of the Trinidad Leper Asylum. The Percentage of Fibrin in the Blood of Lepers.

RUSSELL, William, M.D. The Pathology of Pernicious Anæmia.

The following gentlemen have also intimated their intention of contributing to the business of the Section by reading papers or otherwise: Professor Greenfield, Professor Roy, Professor D. J.

Hamilton, Dr. William Hunter, Dr. Barrett (Edinburgh), Dr. McFadyean (Edinburgh), Alex. Edington, M.B. (Edinburgh), etc.

Demonstrations.—Dr. Alexander Bruce (Edinburgh) will give a Magic Lantern Demonstration on Diseases of the Spinal Cord; and Alexander Edington, M.B. (Edinburgh), a Bacteriological Demonstration. Arrangements are also being made for a series of Microscopical Demonstrations illustrative of Tumours, Tuberculosis, etc.

Pathological Section of the Annual Museum.—Intimation has been received of the following exhibits for this Section of the Annual Museum: 1. Calculi removed by Lithotomy, by Professor George Buchanan. 2. Calculi removed by Lithotripsy or by Scoop, by Professor George Buchanan. 3. Miscellaneous Objects removed from the Body, by Professor George Buchanan, namely: Bullets; Needles, Cases of Teeth, Impacted Pessaries, etc.; also Isolated Bones of the Tarsus Excised. 4. Rhinoplasty; Wax Cast, by Professor George Buchanan. 5. Bladder and Urethra showing False Passages. 6. Selected Specimens from the Private Collection of Professor W. T. Gairdner. 7. A Series of Specimens of Tumours of the Brain, by Dr. Joseph Coats. 8. A Series of Specimens illustrative of Diseases of the Kidneys, by Dr. David Newman. 9. A Series of Specimens illustrative of Leprosy, by Dr. Beaven Rake (Trinidad). 10. A Series of Large Sections illustrating Malignant Tumours of the Lung; and a Series of Specimens illustrating Deformities of the Liver, by Drs. Woodhead and Bruce. 11. Drawings and Sections to illustrate Diseases of Bone and Joints, by Mr. F. M. Caird (Edinburgh). 12. A Series of Specimens illustrative of Diseases of the Heart, by Dr. John Lindsay Steven.

As space for the Museum is somewhat limited, gentlemen intending to send specimens should intimate their intention without delay to John Lindsay Steven, M.D., 34, Berkeley Terrace, Glasgow, Honorary Secretary of the Section of Pathology of the Annual Museum.

SECTION H.—OPHTHALMOLOGY.

Midwifery Class Room.

H. OPHTHALMOLOGY.—*President*, Thomas Reid, M.D. *Vice-Presidents*, J. R. Wolfe, M.D.; C. E. Glascock, M.D. *Honorary Secretaries*, Henry Bendelack Hewetson, M.R.C.S., 11, Hanover Square, Leeds; A. Freeland Fergus, M.B., 41, Elmbank Street, Glasgow.

Mr. Brudenell Carter will open a discussion on the Treatment of Senile Cataract. Drs. Prichard, Meighan, Mason, Teale, and others have promised to take part in the discussion.

The President of the Section intends to give a Demonstration of several Instruments of Use in Ophthalmic Diagnosis.

The following papers are promised.

BICKERTON, T. H., M.D., Liverpool. Sailors and their Eyesight.
 MACKAY, George, M.D., Edinburgh. A Contribution to the Study of Hemianopsia of Central Origin, with special reference to Acquired Colour Blindness.
 MEIGHAN, T. S., M.D., Glasgow. On the Treatment of Symbblepharon by Transplantation of Mucous Membrane from the Lip.
 RENTON, J. C., M.D., Glasgow. The Value of the Caustery in the Treatment of Ulceration of the Cornea.
 WOLFE, J. R., M.D., Glasgow. Detachment of the Retina.

SECTION I.—OTOLOGY.

Biblical Criticism Class Room.

I. OTOLOGY.—*President*, Thomas Barr, M.D. *Vice-Presidents*, John Astley Bloxam, F.R.C.S.; J. J. K. Duncanson, M.D. *Honorary Secretaries*, Johnstone Macfie, M.D., 23, Ashton Terrace, Glasgow; James Black, F.R.C.S., 16, Wimpole Street, London.

The following special subjects have been proposed for formal discussion:

1. The Conditions calling for Perforation of the Mastoid Portion of the Temporal Bone, and the Best Methods of Operating. Mr. Peter McBride has promised a paper on this subject.

2. The True Value of those Aids to Hearing usually termed "Artificial Tympanic Membranes." Dr. W. L. Purves has promised a paper on this subject.

3. Adenoid Growths in the Naso-Pharynx; their Influence on the Middle Ear, and their Treatment.

The following have promised papers.

BROWNE, Lennox, Esq. (Title not received.)
 TORRANCE, R., Esq. On Syphilitic Cochleitis.
 WARDEN, Charles, M.D. (Title not received.)

SECTION J.—DISEASES OF CHILDREN.

English Literature Class Room.

J. DISEASES OF CHILDREN.—*President*, Walter Butler Cheadle, M.D. *Vice-Presidents*, James Finlayson, M.D.; Henry Ashby, M.D. *Honorary Secretaries*, George S. Middleton, M.D., 23, Sandy-

ford Place, Glasgow; W. Arbuthnot Lane, M.S., F.R.C.S., 14, St. Thomas's Street, S.E.

The following two discussions will take place:

1. Diphtheria: (a) Etiology. (b) Relationship to other Infectious Diseases, and to other Forms of Sore Throat; Occurrence on Open Wounds and on Mucous Membranes other than those of the Throat. (c) Diagnosis. What are the Distinctive Features, especially those Distinguishing the Lesion in the Throat from other Forms of Sore Throat? Does Membranous Croup occur apart from Diphtheria? (d) Pathology and Sequelæ. (e) Medical Treatment. (f) Surgical Treatment; Tracheotomy; Tubage. This will be opened by Dr. A. Jacobi (New York). Drs. E. Owen, H. R. Hutton, W. T. Gairdner, James Finlayson, D. Newman, George Buchanan, H. C. Cameron, and John Macintyre will take part in the discussion.

2. Rickets: (a) Etiology and Prevention: (b) Its Connection with Syphilis and Scurvy. Is Enlargement of the Liver and the Spleen always present, more or less, in Rickets; or only in Cases of Syphilitic Origin? (c) Medical Treatment. (d) Surgical Treatment; at what Stage, and in what Way? Drs. Macewen, R. W. Parker, H. R. Hutton, R. Haggard, L. W. Marshall, E. L. Freer, and John Gordon will take part in the discussion.

Drs. Jacobi (New York), Keating (Philadelphia), Ranke (Munich), and Sanné (Paris), and other members of the profession on the Continent have been invited.

SECTION K.—PHARMACOLOGY AND THERAPEUTICS.

Conveyancing Class Room.

K. PHARMACOLOGY AND THERAPEUTICS.—*President*, James Morton, M.D. *Vice-Presidents*, John Dougall, M.D.; Theodore Cash, M.D., F.R.S. *Honorary Secretaries*, Alexander Napier, M.D., 3, Royal Terrace, Crosshill, Glasgow; Sidney Harris Cox Martin, M.D., 60, Gower Street, London, W.C.

A special discussion will be opened by Professor Theodore Cash, M.D., F.R.S., on Carbolic Acid, Antipyrin, Antifebrin, and their Allies; especially as regards their Antipyretic, Analgesic, and Antiseptic Actions. Dr. Walter G. Smith (Dublin) will take part in the discussion.

Dr. W. Allan Jamieson (Edinburgh) will show two cases of Xeroderma Pigmentosum.

The following have promised papers.

DOUGALL, J., M.D., Glasgow. (Title not received.)
 DRYSDALE, C. R., M.D. 1. On the Therapeutic Value of Alcohol. 2. The so-called Abortive Treatment of Syphilis.

SECTION L.—LARYNGOLOGY AND RHINOLOGY.

Divinity Class Room.

L. LARYNGOLOGY AND RHINOLOGY.—*President*, Felix Semon, M.D. *Vice-Presidents*, George Hunter Mackenzie, M.D.; Peter McBride, M.D. *Honorary Secretaries*, D. Newman, M.D., 18, Woodside Place, Glasgow; A. E. Garrod, M.D., 9, Chandos Street, Cavendish Square.

The following subjects are proposed for special discussion:

1. The Use and Abuse of Local Treatment in Diseases of the Upper Air Passages. To be opened by Dr. de Havilland Hall (London) and Mr. Stoker (London).

2. The Causes, Effects, and Treatment of Nasal Stenosis. To be opened by Dr. Macintyre (Glasgow) and Mr. Creswell Baber (Brighton).

3. Hemorrhages from the Pharynx and Larynx, and other Hemorrhages which simulate these. To be opened by Dr. Percy Kidd (London) and Dr. Hodgkinson (Manchester) (probably).

The following gentlemen hope to take part in the discussions: Dr. Prosser James (London), Dr. McBride (Edinburgh), Dr. Charles Warden (Birmingham), Dr. Cartaz (Paris), and Mr. Richard Ellis (Newcastle-on-Tyne).

The following papers have been promised.

JOHNSTONE, R. Mackenzie, M.D. Account of a Case of Tumour of the Naso-Pharynx.
 MCBRIDE, P., M.D., Edinburgh. On Hay-Fever and Allied Conditions.
 MACINTYRE, J., M.D. Anatomical Demonstration of the Larynx.
 NEWMAN, D., M.D. Two Cases of Complete Laryngeal Stenosis produced by Wounds of the Larynx in Attempted Suicides.
 WARDEN, C., M.D. (Title of paper not yet received.)

Members desirous of reading papers, or joining in the discussions, are earnestly requested to communicate without delay with the Secretaries of the respective Sections.

ANNUAL MUSEUM.

THE Annual Museum will be held on August 7th, 8th, 9th, and 10th, in the Examination Hall of the University of Glasgow, and will be arranged in the following six Sections:

SECTION A.—Food and Drugs, including Antiseptic Dressings, and other Chemical and Pharmaceutical Preparations. (Honorary Secretary, R. S. Thomson, B.Sc., M.B., C.M., 3, Melrose Street.)

SECTION B.—Pathology, comprising Casts, Models, Diagrams, Microscopical Preparations, and Micro-organisms. (Honorary Secretary, J. Lindsay Steven, M.D., 34, Berkeley Terrace.)

SECTION C.—Anatomy, comprising Special Dissections, Methods of Mounting, Abnormalities, Drawings, Medals, etc. (Honorary Secretary, J. Yule Mackay, M.D., 34, Elmbank Crescent.)

SECTION D.—Physiology, consisting of Apparatus, Microscopes, Microtomes, and Microscopical Preparations of Normal Histology. (Honorary Secretary, J. McGregor Robertson, M.A., M.B., C.M., 400, Great Western Road.)

SECTION E.—Instruments and Books, including Appliances—Medical, Surgical, and Electrical. (Honorary Secretary, J. Macintyre, M.B., C.M., 173, Bath Street.)

SECTION F.—Sanitation (1) Domestic Sanitary Appliances, embracing all Improvements applicable to the Treatment of the Sick in Private Dwellings. (2) Personal Hygiene, including Dress and Gymnastic Appliances. (3) Ambulances, Carriages, and all other Appliances used for the Conveyance and Treatment of the Sick and Wounded, either in Civil, Naval, or Military Practice. (4) Drawings, Models, and Apparatus illustrative of the Ventilation, Lighting, and Draining of Hospitals. (5) Hospital Furniture. (6) Sanitary Appliances in connection with Educational Institutions and Public Buildings. (Honorary Secretary, 1, 2, 3, Robert Pollok, M.B., C.M., Pollokshields; Honorary Secretary, 4, 5, and 6, A. W. Russell, M.A., M.B., C.M., Western Infirmary.)

Intending exhibitors should communicate as early as possible with the Secretary of the Section in which they propose to exhibit, as the Museum Catalogue must be complete one month before the date of meeting. Inquiries as to advertisements in the Catalogue should be sent without delay to Dr. Thomson, 3, Melrose Street, Glasgow.

Honorary General Secretaries of Museum Committee, A. Ernest Maynard, B.S., M.B., 4, Berkeley Terrace; R. S. Thomson, B.Sc., M.B., C.M., 3, Melrose Terrace.

Honorary Local Treasurers, Joseph Coats, M.D.; Jas. B. Russell, M.D.

Honorary Local Secretaries, John G. McKendrick, M.D., F.R.S., 45, Westbourne Gardens, Glasgow; James Christie, M.D., Hillhead, Glasgow; John Glaister, M.D., 4, Grafton Place, Glasgow.

EXCURSIONS.

THE following eight excursions will take place on Saturday, August 11th.

1. *Lanark and Falls of Clyde.*—The party, limited to 100, will leave the Central Station by special train about 10 A.M., for Tillietudlem, where, by the kind permission of the Earl of Home, an opportunity will be given to visit the ruins of Craignethan Castle, the scene of Sir Walter Scott's *Old Mortality*; proceeding on foot to the picturesque ravine of the River Nethan for about a mile; the party will then be conveyed by coach through some of the most charming Clydesdale scenery to the Falls, visiting Stonebyres, and then, by the kindness of the proprietor, will enter the Corehouse estate, to see Cora and Bonnington Linn. Returning by coach to Lanark, dinner will be served about 2.30 P.M., in the Clydesdale Hotel. After dinner the party will be shown the library of Dr. William Smellie, the famous obstetrician, which was bequeathed by him to the Grammar School of that town. It is a very interesting collection of books, containing two or three black letter volumes. It is also expected that the Lee talisman, or "Lee Penny," will be shown to the visitors. This charm was taken from the Saracens by Sir Simon Lockhart, of Lee, after a battle, as part ransom of a captive. It was deemed a charm of great medicinal virtue in the end of the last century. It gives the title to *The Talisman*, another of the novels of Sir Walter Scott. Afterwards short excursions may be made on foot to Cartland Crags, Roman Bridge, Old Abbey, and Smellie's grave. The party will return from Lanark by special train to Glasgow, arriving not later than 8 P.M.

2. *Ayr and the Land of Burns.*—The party, fixed at 100, will leave Glasgow about 9.30 A.M., by special train to Ayr. Thence by conveyances it will proceed, *via* Maybole, to Crossraguet Abbey (one of the finest Gothic remains in Great Britain), thence to Cutzean Castle, where it is expected the party will be received by his Grace the Marquis of Ailsa, and returning to Ayr by the sea-shore to Burns's Monument, Alloway Kirk, Burns's

Cottage, and "Twa Brigs." Dinner will be served at the Station Hotel, after which, by special train, the party will return to town.

3. *The Perthshire Highlands, Lochearnhead and Crieff.*—The party, numbering 100, will leave Buchanan Street Station about 9.15 A.M., in special saloon carriages, for Lochearnhead, and during the journey will see some of the finest Highland scenery, thence by coaches *via* Loch Earn, to St. Tillans, where a halt will be made for refreshments, at the Drummond Arms Hotel: then to Cannie, where a second halt will take place to visit the Devil's Cauldron, and thence to Crieff, where the party will be entertained to dinner by Dr. Meikle, at his Hydropathic Establishment. After dinner, short walks to places of interest in the neighbourhood may be made, and the party will leave Crieff in the same saloon carriages for Glasgow, where it will arrive about 8 P.M.

4. *Callander and the Trossachs (Loch Katrine).*—The party, 100 in number, will leave the same station as last at the same hour, in special saloon carriages, for Callander, where coaches will be in readiness to convey them to Loch Katrine. Dinner will be served about 2 P.M., in the Trossachs Hotel, after which visitors may enjoy a sail on the loch to the Silver Strand, mentioned by Sir Walter Scott in the *Lady of the Lake*. The party will return by the same route to Glasgow, where it will arrive about the same time as the former excursion.

5. *Arran.*—The party, numbering 100, will leave Bridge Street Station in saloon carriages about 9 A.M., for Wemyss Bay, where, it will join the famous Clyde steamer *Ivanhoe*, which *en route* to Arran calls at Rothesay, and passes through the Kyles of Bute. Dinner will be served on board during the passage. On landing on the island the party will be enabled to visit Broderick Castle, by the kind permission of his Grace the Duke of Hamilton. The party will return to Glasgow by the same route, arriving there about 7.30 P.M.

6. *Stirling, Bridge of Allan, and Dunblane Cathedral.*—The party, limited to 100, will leave Buchanan Street Station about 9.15 A.M. by special train for Stirling. On arrival visits will be paid to the Castle of historic renown, the Royal Infirmary, High Church, etc., under the conduct of Provost Yellowlees of that town, and Dr. Haldane, of Bridge of Allan, returning to the Smith Institute, where cake and wine will be served. Thence the party will proceed by conveyances to the Wallace Monument, *via* the King's Park, where an unrivalled view is to be obtained, then through the demesne of Airthrey, the seat of the Right Honourable Lord Abercromby, to Bridge of Allan, where dinner will be served in the new Museum Halls. After dinner seats in the conveyances will again be taken, and the party will then drive through the grounds of Keir, the seat of the late Sir W. Stirling Maxwell of bibliophilic fame, and Kippenross, to Dunblane, where the Cathedral and Library of Archbishop Leighton will be visited. The party will then return by the famous Wharry Glen to the Spa at Bridge of Allan, where tea will be provided for the visitors at the Hydropathic Establishment. The party will leave Bridge of Allan for town, arriving there about 8 P.M.

7. *Rothesay and the Kyles of Bute.*—The party, fixed at 250, will leave Central Station about 9 A.M., by special train from Greenock, where it will join the new steamer *Victoria*, specially chartered for the trip. The steamer will then sail down the Firth of Clyde to Rothesay, and thence will proceed through the Kyles of Bute, *via* Loch Ridden, and then round the Island of Bute to Kilchattan Bay pier, where those of the party who choose may land to walk to Mount Stuart, the seat of his Grace the Marquis of Bute, visiting on the way the beaver colony, now an almost unique sight. The remainder of the party will return to Rothesay by the steamer, where conveyances will be in readiness to convey them to Mount Stuart; on returning, the party will alight at the Glenburn Hydropathic Establishment, where, by the kindness of Dr. Philp, the proprietor, tea will be served to the party at 5 P.M. Dinner will be served on board the *Victoria en route*. After tea a visit may be paid to Rothesay Castle. The return journey to Glasgow will be made by the same steamer, either to Greenock or Wemyss Bay (not yet decided), and thence by special train, arriving in town about 8 P.M.

8. *Loch Lomond.*—The party, numbering 150, will leave the North British Railway Station, Dundas Street, at 10 A.M., by special train for Balloch Pier, where it will be waited for by a special steamer; during its passage to the head of the loch all the places of historic interest will be pointed out. Facilities will be given, by arrangement made before or in the early part of the

meeting, for an ascent of Ben Lomond by a small party. On arriving at the head of the loch fifty of the party (to be fixed by ballot or choice) will land, the remainder returning by the same steamer to Tarbet, where dinner will be served about 2.30 P.M. in the hotel. From here parties may visit Loch Long by a very picturesque road. For the party of fifty left at the head of the loch a special dinner will be provided on board the steamer, arriving there about 2 P.M. The return journey will be made by steamer to Balloch, and by special train to town, arriving about 7 P.M. As this is the busiest time of the tourist season, intending visitors to this place should apply early, in order that completely comfortable arrangements may be made.

Short descriptive sketches of the different excursions will be given in the JOURNAL from week to week, in order to enable visitors to determine their choice, and also that early applications may be made during the meeting for tickets.

FRANCIS FOWKE, *General Secretary.*

SPECIAL CORRESPONDENCE.

VIENNA.

[FROM OUR OWN CORRESPONDENT.]

The Question of Trephining in Cerebral Lesions.—Resection of Vermiform Appendix in Perityphlitis.

PROFESSOR NOTHNAGEL recently showed the following case to the Imperial Royal Society of Physicians of Vienna. The patient, a girl, aged 18, had been struck on the head with a sabre. She instantly fell down, lost consciousness, and came to herself after half an hour with paralysis of the right arm and the right leg. The paralysis disappeared after some days, but some impairment of sensibility remained behind. Since then she constantly suffered from headache. About fourteen days after the healing of the wound, convulsions, lasting from one to two minutes, supervened in the right leg. At present the patient did not suffer from convulsions, and both upper extremities showed a fairly equal degree of power. The right lower extremity was somewhat paretic, and was still subject to convulsive attacks, consisting in frequent and rapid contractions; consciousness and sensibility were unimpaired. The scar on the vertex of the skull exactly corresponded to the spot in the brain which must have been injured. The central convolutions, and especially the centre governing the lower extremity, had their seat there. The only doubt was as to whether the neighbouring convolutions were not equally affected. There must be a lesion in the brain causing two conditions, namely: (1) debility and inhibition of function; and (2) irritation, as spasms used to occur occasionally. Both these conditions could be explained by the supposition of a vegetation of bone, having the periosteum as its point of departure. The important question now arises as to what should be done in a case like this. There was scarcely any doubt that the treatment with bromide of potassium and galvanisation, etc., would be quite useless. We had to ask the surgeons whether trephining was indicated in such a case. If no changes were to be found in the bone, the dura mater would have to be opened. The lecturer had a patient of his trephined last year, but without success, probably because the dura mater had not been opened. It was, moreover, a question whether the inconveniences from which the patient now suffered would justify such an operation, or whether the complete development of Jacksonian epilepsy should be waited for before any surgical intervention. The lecturer holds that this will probably not be the case. Docens Dr. Maydl remarked that about ten cases of this kind had been reported in the JOURNAL of 1887; in two of these cases tuberculosis and sarcoma were present. In all these cases except that of sarcoma, the operation was attended with good results; in the case of sarcoma, recurrence took place, and the patient died. There was no doubt about the success of the operation, though there was an eleventh case on record (that of Bergmann) in which the operation ended fatally. As to the therapeutic effect, the results were not in all cases the same. In the majority of cases the attacks disappeared after operation, returned after a certain time, and completely disappeared after an interval of some weeks. Professor von Dittel also spoke in favour of the operation.

Dr. Brenner, Assistant to Professor von Dittel, showed a patient, aged 19, who had been admitted into Professor von Dittel's clinic in March last, with symptoms of severe intestinal obstruction. The history of the case and the intense pain in the cæcal region

led them to conclude, with a certain degree of probability, that they had to deal with perityphlitis and consecutive suppurating peritonitis. Laparotomy was performed on the day of admission. After opening the abdomen, a great quantity of pus escaped; the intestines were washed with a solution of salicylic acid; and on close examination it was found that there was an abscess in the region of the cæcum around the vermiform appendix, which was perforated. The vermiform appendix was ligatured and removed. The part of the cæcum which had become affected by the suppurating process was drawn forwards and fixed to the abdominal wound by means of sutures, as resection of the intestine could not be done, owing to the collapsed state of the patient during the operation. The abdominal wound was closed, and healing took place by first intention. Three other cases of suppurating peritonitis following perityphlitis were treated in the wards of Professor von Dittel by laparotomy, but all ended fatally. Dr. Brenner remarked that the recent advance in the surgical treatment of these cases consisted in the fact that operation was resorted to at an early date, and that the affected part of the intestine was removed from the abdominal cavity. This was the first case of healing after resection of the vermiform appendix when general peritonitis was already present.

BERLIN.

[FROM OUR OWN CORRESPONDENT.]

Health of the Emperor.

The improvement in the health of the Emperor, which I mentioned in my last letter, still continues. The journals every day report increase of strength and appetite on the part of the illustrious patient. This agrees with what I am now able to state on the best authority; namely, that the physicians in attendance on His Majesty are no longer certain about the diagnosis. The pathological character of the swelling and the clinical course of the affection are so entirely different from all that is known generally to occur in laryngeal cancer, that to state the fact bluntly, the physicians do not know the nature of the disease with which they have to deal. This uncertainty of course is in itself an immense improvement on the terrible diagnosis which was arrived at in November. This change of opinion has not yet been officially made known to the public, for fear of exciting hopes which might afterwards be disappointed.

It seems to me that a more hopeful opinion has prevailed since Professor Rudolf Virchow, who returned from Egypt not long ago, had the opportunity of examining the affected parts. You are acquainted with Virchow's opinion that alveolar structure is to be considered as cancer only if the nested cells are found in the mucous tissue itself, and that alveolar structure in the epithelium—that is, above the mucosa—has no malignant character. This, however, is not the opinion of our greatest anatomist, Professor Waldeyer, whose researches on carcinoma, as you know, are classical. Waldeyer believes that nests of epithelial cells arranged like an onion constitute cancer wherever they are found. Therefore where Virchow finds only "pachydermia laryngis," Waldeyer sees cancer. The future will show which of these eminent pathologists is right. The fact, however, remains that the Emperor himself must be more hopeful as to his prospects of life than he was some time ago. This is proved by certain acts of political importance. When His Majesty returned from San Remo after the death of his illustrious father, the continuity of the Government was not interrupted in any manner. The ministers remained in their places, and no liberal measures were brought forward, though it was well known to the whole German people that the new Emperor was far more liberally inclined than his predecessor. The conviction, therefore, was universal, that the sick monarch did not mean to begin what he was sure not to finish. Since about a fortnight a change is to be observed. Eminent deputies of the Liberal party, like Virchow and Forckenbeck, have been honoured with high decorations, and the position of the Minister of the Interior, Herr von Puttkamer, an extreme Conservative, seems to be considerably weakened.

All this proves that the Emperor has taken the reins of Government into his own hands, and that his physicians must have given him hopes of a longer life. Even Professor Senator, who was absolutely convinced of the malignant nature of the disease, is now, as I have just heard, not without hope that the Emperor's life may be prolonged for several years.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

Sudden Deaths from Wound of Larynx.—Uterine Tetanus.

At a meeting of the Société de Chirurgie, April 4th, 1888, M. Chauvel read notes of a case which had come under the notice of M. du Cazal of sudden death from a wound in the larynx. A quartermaster swallowed a bit of glass, which wounded the larynx. After violent attacks of pain the patient suddenly died. The necropsy revealed ulceration of the lower part of the left vocal cord. The patient might have been saved by tracheotomy, but neither suffocation nor any other symptom indicated the operation. According to M. du Cazal's opinion, the patient died of reflex syncope. M. Chauvel was surprised that the subglottic surface of the vocal cord should be wounded without hæmorrhage ensuing. He believed that death was caused not by the wound, but by subglottic œdema. It is to be regretted that a laryngoscopic examination was not made. In such cases it is fatal to temporise. To support this assertion, M. Chauvel related the case of an Arab suffering from laryngeal syphilis, who obstinately refused to allow him to perform tracheotomy. The latter remained near the patient with the intention of operating on the first signs of urgency, but the Arab died suddenly in one of the attacks.

Dr. Duriez has lately published an interesting paper on a very rare accident of confinement—namely, uterine tetanus. The womb may be affected during labour in various pathological ways bearing some analogy to uterine tetanus. These are (1) uterine rheumatism, the symptoms of which are fever, with sudden pains, possibly extending beyond the womb, increased by pressure and movement; (2) puerperal tetanus, the result of infection; this resembles surgical tetanus, and is consequently accompanied by trismus, opisthotonos, etc. It is followed, after the delivery of the child, by spasms of the inner orifice of the womb, which closes, preventing the issue of the after-birth, or affecting the womb itself, produces complete or partial hardening of the placenta. Spasm of the womb may occur in connection with confinement, and is characterised by its sudden contraction, or of its neck, when the latter becomes rigid. If the spasm be continuous, then it is caused by uterine tetanus, which is simply a permanent contraction of the womb lasting from eighteen to thirty-six hours. It may be caused by the early rupture of the membranes, by any obstacle to delivery, and by a wrong presentation of the child, especially when the shoulders present. The prognosis is absolutely fatal to the child, and is doubtful for the mother, whose safety is endangered by the long labour, and the measures necessary to assist delivery. Preventive treatment consists chiefly in rectifying a faulty presentation. In a case of tetanus, the means of allaying the spasm being uncertain and at times dangerous, if, after several attempts at version, attempted under chloroform, the delivery is not effected, it is better to have recourse at once to embryotomy. The average of deaths from this operation is about 8 in 53.

SWITZERLAND.

[FROM OUR OWN CORRESPONDENT.]

Bacteriological Test for Surgical Tuberculosis.

At a recent meeting of the Medicinisch-Pharmaceutischer Bezirksverein von Bern, Dr. Tavel read an important paper on a novel method of differential diagnosis between tuberculosis and other affections, by inoculation experiments on guinea-pigs. The method is at present systematically practised by Dr. Tavel, in Professor Kocher's surgical clinic, in all cases where it is necessary to differentiate a tuberculous affection from syphilis, traumatic granuloma, non-tuberculous ulcers, polyarthritis deformans, lymphoma malignum, gonorrhœa, acute abscesses, malignant tumours, glanders, and actinomycosis. Guinea-pigs are selected for the purpose, because these animals are peculiarly susceptible both with regard to scrofula and true tuberculosis, which is not the case with rabbits. Moreover, the course of the disease in the former is by far more rapid than in the latter. In guinea-pigs, a positive diagnosis becomes possible from two to four weeks after inoculation. From the results obtained in 120 cases where this diagnostic inoculation was practised, from one to five animals being used in each case, Dr. Tavel lays down the following propositions: 1. If the case is of tuberculous nature, inoculation invariably gives rise to the development of tuberculosis in the animal experimented upon. 2. The method requires far less time and

trouble, and gives more trustworthy results, than microscopic examination. 3. The method is certain, even where anatomical examination is practically impossible. The single inconvenience attending it is that the diagnosis cannot be made till after the lapse of a couple of weeks. In the discussion which followed Dr. Tavel's communication, Professor Kocher said that the bacteriological differential diagnosis in cases of surgical tuberculosis was an important advance, because, to use his own words, "the clinician who seeks support from the anatomist is always forsaken by the latter just at the critical moment when he more than ever stands in need of learning something sure and certain. Now at last we have at our disposal a method which can be relied upon."

EGYPT.

[FROM OUR OWN CORRESPONDENT.]

Annual Exodus.—Recurrent Sarcoma of Neck.

EVERY year there is an exodus from Egypt of people who try to make out that they cannot support the terrible summer heats. The necessity for this is entirely fictitious, for, compared with India and other Oriental places, there is absolutely no reason why Europeans should not remain and thrive in this wonderful country for years together without a break. When I say no reason, I pass over the fact that they must, of course, take some slight trouble to sacrifice to sanitation; must bear some expense to have their homes put into a moderately hygienic condition. If they choose to live over a festering cesspool, they must, of course, expect to suffer; but, in common fairness, our admirable climate should not be blamed for the results of their own crass carelessness. I repeat, with every confidence, that there is nothing in the climate of Egypt to injure Europeans. If they take the trouble to make their houses wholesome, they should enjoy better health in this much maligned country than in their own foggy and damp native land.

Notwithstanding the exodus, the sick still keep coming in to Kas-el-Aini Hospital. The following notes of a recent case may prove interesting. Nebowna, aged 6, daughter of Egyptian parents, was first admitted in 1884 with a small tumour below the right ramus of the jaw. She was operated on by the native professor of surgery, but in 1886 had to be re-admitted. She had then an enormous tumour, extending from the left angle of the jaw to within half an inch of the symphysis menti. It was adherent to the skin and deep parts, and had a thickness of about three inches and a half. As the tumour involved the common carotid artery and the internal jugular vein, it was removed with great difficulty; about three-quarters of an inch of the artery being included with the ablated part, as well as a portion of the parotid gland, and about half a square inch of the periosteum of the lower jaw with the subjacent bone. The facial nerve was also at the same time divided. On the fourth day the dressing was renewed, but, during the process, a sudden burst of hæmorrhage took place from the common carotid artery, which was with difficulty controlled with the finger till the necessary instruments could be brought to ligature the vessel. The wound healed in thirty-five days by granulation, and the child was soon afterwards discharged. In April this year, however, she was readmitted with a tumour in the old position, extending from the parotid gland to the symphysis, and consisting of two distinct masses; the larger and superior being the size of a small cocoa-nut, and the smaller, lying below the inner third of the maxilla, being about as big as a chestnut, and separated from the larger mass by a deep groove. This smaller mass was diagnosed by Professor Virchow, who was passing through Cairo, as an enlarged gland. The tumour was removed on this occasion more easily than at first; the blood-supply being found to come from the facial and inferior thyroid arteries; there being no trace whatever of any carotid artery or internal jugular vein. In the groove between the two portions of the sarcoma there was found a small exostosis, about one inch long, half an inch broad, and one line in thickness, arising from the lower jaw at the place where it had been scraped during the previous operation. The tumour had evidently, in its growth from the deeper parts, come across this exostosis, and, being unable to displace it, a portion had passed behind, and, bulging out on the other side, had simulated the appearance of a swollen gland to such an extent, that the great professor—who is called by the Egyptians Abou Awram, the Father of Tumours—was deceived. The wound is now all but healed, and the little patient relieved temporarily of her disease.

LIVERPOOL.

[FROM OUR OWN CORRESPONDENT.]

New Royal Infirmary.—The Teaching of Anatomy.—Hodgkin's Disease.—Low Death-rate.

THE new Royal Infirmary, the foundation stone of which was laid last October, is making rapid progress, and already a fair idea may be obtained of the appearance and arrangement which it will present when finished. It is being erected of local grey brick, with dressings of red terra-cotta, and glazed bricks will be largely used in the interior. The wards will be arranged in six blocks, and will contain altogether 280 beds. There is a special set of rooms for the out-patients, and a separate block is to be devoted to the administrative department. The contract price for the building is £105,000, but at the time of commencing the operations the amount subscribed fell short of that sum by £15,000, and accordingly the Committee decided to defer the erection of one of the wings until the necessary funds were provided. Since then, however, additional subscriptions have nearly made up the deficiency, and the entire building will be proceeded with according to the original designs. The architect is Mr. A. Waterhouse, R.A., of London. During the construction of the new building the work of the Infirmary is carried on in commodious temporary premises which have been erected at considerable outlay, supplemented by the building that was formerly the Lock Hospital, and has now been converted into two medical wards.

In the School of Medicine some improvements have recently been introduced in the arrangements of the anatomical department. The dissecting room has been surrounded by a dado of glazed tiles, and the so-called "boneroom" has been enriched by numerous preparations of great utility and beauty. No device has been spared to make the intricacies of anatomy plain to the student, and Mr. W. Mitchell Banks, the Professor of Anatomy, is to be congratulated on the completeness of his arrangements.

Two cases of Hodgkin's disease have lately been in the Royal Southern Hospital under the care of Dr. Carter. The first was a man, aged 50, in whom the disease had existed five years, and when treatment was commenced about five months ago there was extreme glandular enlargement all over the body, the inguinal glands on one side forming a lump as large as an infant's head. The blood corpuscles were in normal amount, and anæmia was not marked. The medicinal treatment adopted was arsenic, continued for three months, and supplemented during the greater part of the time by iron and quinine. At the present time the glands can scarcely be felt, and the patient is practically well. The second case is still under treatment. It is remarkable that in both patients effusion took place into the left pleura, apparently from the pressure of the enlarged glands. The first case was tapped three times.

The number of deaths registered in this city during the week ending May 26th was 191, being at the rate of 16.6 per 1,000 in the year. This is the lowest death-rate ever recorded in Liverpool. The temperature during the week was unusually high for the time of year, reaching a maximum of 71°.

SHEFFIELD.

[FROM OUR OWN CORRESPONDENT.]

Cessation of Small-pox Epidemic.—Cost of Vaccination.—Physiology and Education.—Heavy Damages against a Railway Company.

THE small-pox outbreak has now so much subsided that it can hardly be regarded as epidemic. Scattered cases still occur, but the last weekly return showed only three deaths attributable to that cause. The Manchester and Sheffield Railway Company commenced now their excursions for Whitsun week, and it is expected now the Midland will follow with their cheap seaside and other trips. The cloud which has so long hung over the town, and so seriously interfered with its trade, has now it is hoped disappeared. Every well-wisher to "Steelopolis" will fervently pray that it may be very long before the health of its inhabitants and its commerce are again affected by such a scourge.

At a meeting of the Ecclesall Board of Guardians recently, it was announced that the cost of public vaccination for the year ending Lady day last was £921 4s. 2d., as compared with £284 19s. 10d. for the previous year. No doubt the increased expenditure would be found to apply particularly to the months of December, January, and February, when revaccination was so much encouraged.

Dr. Dyson recently read before the Literary and Philosophical Society a valuable paper entitled "Some Physiological Aspects of a Modern Education." By request it was repeated before the Sheffield Teachers' Guild. From the standpoint of a physician and physiologist he pointed out the errors in the systems of the day and the dangers accruing therefrom. The audience consisted of teachers of all grades, and their willingness to learn and the spirit in which the lecturer's remarks were received were very gratifying.

Two claims for damages in consequence of injuries received at the Hexthorpe (Doncaster) railway disaster were decided before the Under-Sheriff on June 1st. In one case, that of a solicitor, aged 28, who had undergone amputation of one leg and sustained severe injuries to the other, £4,000 was awarded; whilst in the other, a clerk obtained £950, having had fracture of a leg.

Dr. W. R. Thomas has resigned his office as Physician to the Public Hospital and Dispensary, intending to practise in Bourne-mouth.

The following institutions have received legacies from the executors of the late Mr. Joseph Nicholson: General Infirmary, £525; Jessop Hospital for Women, £105.

MANCHESTER.

[FROM OUR OWN CORRESPONDENT.]

Whitsun Week.—Conversazione in Owens College.—Chair of Surgery.—Proposed Gift by Whitworth Trustees.

IT is the custom in the Medical School of Owens College that no lectures are delivered during Whitsun Week, when all Manchester holds high holiday. The lectures were resumed on Monday, May 28th.

The Council of the Owens College has issued a large number—several thousands—of invitations for a grand *conversazione*, which is to be held on June 8th, on the occasion of the opening of the magnificent Biological and Geological Laboratories and Museum. These buildings were used by the members of the British Association at its Manchester meeting; but on the day mentioned they will be formally opened, though they have been in use for some time.

Very little has so far been heard as to the vacancy in the Chair of Surgery, but so much is certain that several local gentlemen are likely to be candidates, and it is said that perhaps others may apply; but as the time for receiving applications does not expire until June 9th, the names of the actual candidates are not likely to be known until that date. The Council, in its statement of the duties of the new professor, intimate that the duties of the chair may be rearranged.

Some time ago, the Whitworth Trustees intimated that they were willing to present a large piece of land for use as a public park and as a site for a museum and other buildings. The trustees now propose to increase their gifts; and it is probable that, within a short time, Manchester—through the generosity of the Whitworth Trustees, combined with the Exhibition surplus—will be possessed of technical schools and an enlarged art-school.

CORRESPONDENCE.

DR. NITZE AND ELECTRIC ILLUMINATION OF THE BLADDER.

SIR,—Dr. Nitze writes me, stating that the original idea of introducing a light into the cavity of the bladder belongs solely to him, and suggests that I have not made this appear distinctly in my late lectures on the subject.

When I showed the instrument in London, in the year 1880, soon after its invention, I said: "The idea of carrying an electric light into the bladder and other cavities appears to have originated with Dr. Nitze, now of Vienna; but its realisation is due to the patience and perseverance of Leiter, the surgical instrument maker, of that city." I quote from a lecture given at that date, and since widely circulated in my "Clinical Lectures." I had just come from Vienna; that was the impression I received there, and the statement has not been called in question hitherto. I am quite unable to enter into any discussion as to the relative shares of merit due respectively to the originator of the idea, which I fully believe Dr. Nitze to be, and the clever mechanic who rendered it practicable, and who has subsequently improved it, as, with technical knowledge, he might naturally be expected to do. In

general terms, the chief merit is unquestionably due to "the thinker," and I regret that I did not give more prominence to that fact in my recent lecture. Had I but repeated the words quoted above, I should only have done simple justice to Dr. Nitze, whose name the instrument ought certainly always to bear. But I regarded the matter as already known, and merely mentioned incidentally Dr. Nitze's association with Leiter, without, on that occasion insisting on the Doctor's claim as the original inventor. I trust this statement will be satisfactory to Dr. Nitze, as I unfeignedly desire it should be.—I am, etc.,

Wimpole Street.

H. THOMPSON.

THE TREATMENT OF AURAL EXOSTOSES.

SIR,—If Mr. Field had heard at the Royal Medical and Chirurgical Society the paper which he criticises in the *JOURNAL* of June 2nd, he would have observed that references were made to the account (published in 1876) of my operation in 1874; also to his first operation in 1877, and his further published cases.

I am sure that (had he heard or seen the paper) his comments would have been valued and received with attention. I am equally sure that the impressions he now has of the contents of the paper would have been in many respects quite different, in others the exact opposite of what he appears to have at present.

If Mr. Field will bring the cases he proposes to publish before one of the Societies in London, I shall be happy to discuss all the points to which he refers in his letter.—I am, etc.,

London, June 3rd.

W. B. DALBY.

URTICARIA DIFFUSA OCCURRING AFTER OVARIOTOMY.

SIR,—Mr. Butler-Smythe's communication is interesting, and confirms an experience which has been to me quite a common one. After almost all kinds of abdominal section, acute attacks of urticaria occur in at least six or seven per cent. of the cases. It seems sometimes to come in outbreaks, for I have quite lately had the appearance he describes come over eight or nine cases, one after the other, within two or three weeks; and this is by no means the only incident of the kind which I have witnessed. The symptoms are occasionally somewhat severe, but they never give any reason for anxiety, and the administration of a saline purgative generally causes them to disappear.—I am, etc.,

Birmingham, June 2nd.

LAWSON TAIT.

ETHERISATION: AN UNRECOGNISED DANGER.

SIR,—Having noticed more than once the collapse subsequent on prolonged ether-anæsthesia, I have often thought how simple it would be to have an operating table made of zinc or tin, hollow, which could be filled with hot water before operation, and which, when covered with blanket, would contribute immensely to the patient's comfort, as well as tend to prevent the chance of collapse.

A table like those seen in restaurants for keeping roast joints hot all day will explain what I suggest. The interesting paragraph in the *JOURNAL* of June 2nd on Etherisation, etc., has prompted me to publish this suggestion; and I fancy, if carried into effect, it would be useful at least in hospitals, where prolonged operations are the rule.—I am, etc.,

Dublin, June 3rd.

ALEXANDER DUKE, F.R.C.S.P.

MEDICAL OFFICERS OF HEALTH AND COUNTY BOARDS.

SIR,—I have received a copy of a circular signed by some medical officers of health chiefly in the south-west of England, in which they refer to the question of compensation which they propose to claim in case the Government decide to attach medical officers of health to County Councils, and to discontinue the services of some medical officers of health holding annual appointments of minor districts. The cry for compensation is a very natural cry, and one which will always find very numerous adherents among the persons interested. In the first place, however, I would remind those who may be addressed on this subject, or who may feel interested in it, that the proposal to create adequate districts for sanitary purposes, and to officer them by medical officers of health of full qualification with adequate salaries, and not in private practice, is one which has been uniformly aimed at by the best professional authorities and endorsed by the British Medical Association for a long series of years. It was the plan which the Association expressly adopted after the most elaborate consideration of the whole sub-

ject at the instance of Rumsey, Stokes, A. P. Stewart, W. H. Michael, Farr, Sibson, and of all the recognised leaders of the Association. This plan they, at the request and with the concurrence of the Association, urged upon the Government year by year, and their evidence before the Royal Sanitary Commission, earnestly pressed it upon that Commission. Further, in the very able and detailed report presented to the annual meeting of the British Medical Association at Plymouth in August, 1871, and unanimously adopted without one dissentient voice, the joint Committees of the British Medical and Social Science Associations severely criticised the report of the Royal Sanitary Commission on the ground that it did not adequately provide for the extension of administrative areas as health districts.

"It is well known," says this report, which was unanimously adopted by the Association, "that petty elective authorities in small separate districts are apt to obstruct rather than forward sanitary improvement, and that for the most part they render any uniform and efficient system of administration almost impossible."

Again they say, referring to the proposed creation of about a thousand limited and isolated areas for sanitary purposes, against such a project of Local Government, "we strongly and earnestly protest," and they especially complain that "while the Committee propose to facilitate the combination of districts for limited purposes, its adoption is to be merely permissive," and they protest against the distinction between urban and rural authorities.

Further on in the report they urge, as an important reason for wider administrative areas, that they would supply a superior machinery for the appointment of scientific medical officers of health.

And again they say that it is almost impossible to overrate the importance, or to question the practical wisdom, of the recommendations for, as far as possible, providing such areas and making such appointments as will ensure the employment of a medical officer of health who, not being in practice, will not be the rival of his brethren, so that he may secure their goodwill and co-operation, and that opportunities of admonitory intercourse with sick families should not even be liable to abuse for the purpose of professional competition.

This memorandum, which is the *locus classicus* of sanitary principles of administration, laid down after the most earnest and continuous study of the subject by the very ablest sanitary authorities in the profession, who were also the leaders of the medical profession, establishes indisputably the principles of sound administration in respect to medical officers of health, their areas and their qualifications, whether in the interest of the public or of the profession.

The main difficulty of the Government was then, and is up to this moment, that the boundaries had not yet been fixed, county boards had not yet been established, and the requisite authority for the larger area had not yet been brought into existence. It is, therefore, a matter of course that either now, or at a very early date after the creation of the county boards, the sanitary administration should be constituted under suitable medical officers of health over a suitable area thus arranged; and the Government have recognised the necessity for this by providing that the County Councils should have cognisance of public health questions.

The Bill as drafted falls short of providing suitable medical officers to advise the Councils, and to enable them to carry out the functions so imposed upon them. Without such officers it is obvious that the Act must in this respect be a dead letter, and the cause of public health retarded and obstructed. In calling the attention of the Government to this defect in providing adequate machinery, the Society of Medical Officers of Health is true to the best and noblest traditions of the profession; while the Parliamentary Bills Committee of the British Medical Association has only followed in the course absolutely laid down for it, and defined by the Association in past years when dealing with this subject.

I have read, therefore, with some surprise the very narrow-minded doctrine of the circular letter referred to, which appears to be based upon purely selfish and personal considerations. There is reason, however, to suppose that the probable fear which some of its signatories entertained, that their own individual functions in respect to public health may be determined, and that their own appointments may come to an end, is exaggerated and without foundation. It is obvious that a considerable proportion of the appointments, and all those which are most valuable, whether in respect to the services performed or the salaries earned, are far

more likely to be continued, strengthened, and extended, than to be in any way diminished. It is notorious that a considerable number of medical officers of health of small districts only hold those appointments reluctantly, and to keep out intruders in practice, and would very willingly resign them if a county officer not in practice were appointed over a large district, to which he should give his whole time and care. But, however this may be, it would be an evil day for the profession if it was supposed that at a given moment, and in order to obtain the continuance of annual salaries on a small scale for a given number of its members, it should sacrifice the principles for which it has contended, and turn its back upon its deliberate and declared conclusions of what is best for the profession and the public as a whole, in order to satisfy small and purely selfish objects. On the question of compensation which the circular raises, it is clear that these gentlemen are not willing to face the position. They refer to the compensation claimed by publicans as a precedent for compensation to be awarded to themselves in case their functions should cease.

Now there is a great division of public opinion on the question of compensation to publicans, but the two cases stand on a wholly different footing. The publican claims to be recouped for the large sums which he has expended on the purchasing of a goodwill of a business for which he has given many thousands of pounds, on the faith of public Acts of Parliament which have created a precedent for the carrying on of his business. What he bought he bought on the faith of Acts of Parliament; that, at least, is his contention, and on the justice or injustice of it will depend his claim. The medical officer of health stands, and always has stood, upon an absolutely different footing. He is a salaried annual officer, who receives an annual salary for work done, and is constantly subject either to the suppression of his office altogether, under the existing law, if at any time the local authorities choose to combine and form a larger district, or to dismissal at any time without compensation. Any medical officer belonging to a conjoint district, and who is paid by contributions from separate districts, is liable at any moment to the cessation of that portion of his salary paid by any authority within the combined district. Whenever any one of these authorities chooses to withdraw, his salary ceases, and no question of compensation ever has or can be raised. As well might the qualified assistant of the general practitioner claim compensation if his employer ceases to practise, or enters into a new partnership, or chooses to alter his arrangements for any other purpose. Thus to attempt to create a demand on the ground of vested interest, with a view to opposing a salutary reform which the whole profession long since endorsed, and which every sanitary authority without exception has approved for a long course of years, is, in the name of professional interest and duty, to prostitute every other consideration to that of imaginary personal profit. Such a course of action is more damaging than anything else could be to the reputation of the profession and to the advancement of the cause of public health.—I am, etc.,

M. O. H.

SIR,—Like many other medical officers of health, the other morning I received a circular from a committee of gentlemen who have issued it, presumably in the interests of those who hold public health appointments under "small" authorities, and who work their appointments in conjunction with their private practices. This circular I enclose you.

In this circular, if I may be allowed to criticise it, I think there is much that is unreasonable and much that is reasonable in the principles it circulates. In the first place, it is notorious how many appointments are made and held in which there is no pretence to sanitary work. These sinecure appointments may well be disestablished. Then there are a goodly number of able, active, and conscientious officers who are much hampered in the good they might do by local interests, which might reflect upon their practices. These officers have mostly and proportionately got good results to show for their work, and such a change in appointment, as by combination under the County Board, might bring with it some hardship such as the circular indicates. But in public health administration the welfare of the community is the first consideration; and, as it appears to me, there is no reason why these interests and those of the cited conscientious medical officers of health should be conflicting. The prospect is that, by the division of the country into "combined sanitary districts," there will be appointments in sufficient numbers, and open to these officers, or, at any rate, for such as are sufficiently enthu-

siastic, or who might find it worth their while to accept such appointments.

In the second place, the qualification test, if applied, as the circular says, "to the exclusion of the older medical officers at present in office, in favour of younger men fresh from school and armed with a brand new diploma in sanitary science," might, and probably would act—and very unnecessarily so—to the prejudice of the existing race of health officers, who have made sanitation what it is. Fully recognising the advantages and the desirability of some standard of qualification such as a diploma would testify to, I would suggest that the licensing bodies granting such diplomas might with very good reason so modify their public health examinations to practitioners of some years' standing (for, say a year or two) that the grounds of complaint above quoted, and the unequal facilities for preparation for examination enjoyed by men established in practice (without very considerable sacrifice), might be removed. The credit of the public health service would in no way suffer by such a proceeding.—I am, etc.,

A RURAL M. O. H.

NAVAL AND MILITARY MEDICAL SERVICES.

ARMY MEDICAL DEFENCE FUND.

MEDICAL STAFF writes: The Government and its medical advisers having clearly shown their intention to take no steps to redress the existing grievances of the medical staff, it only remains for action to be taken on the lines laid down by Surgeon-General Irving in the *JOURNAL* of May 6th.

Let a comprehensive scheme be proposed for the establishment of a Medical Staff Defence Fund, and the proposers will find that subscriptions will at once be forthcoming. An annual subscription of £1 per annum will probably produce £1,000 a year as a current income, and with such a sum much can be done. It is obviously impossible for officers on the active list to initiate the movement, but it is equally certain that they will warmly support it.

It only remains for Surgeon-General Irving to lay the details of his scheme before the medical officers of the army through the columns of the *JOURNAL*, calling for the names of those willing to subscribe, and the necessary financial support will be at once assured him.

THE NAVY.

The following appointments have been made at the Admiralty:—**THOMAS C. HICKEY**, Fleet Surgeon, to the *Benbow*; **CHRISTOPHER HARVEY**, Staff-Surgeon, to the *Neptune*; **THOMAS M. SIBBALD**, Staff-Surgeon, to the *President*, additional, temporarily; **GRAHAM E. KENNEDY**, Surgeon, to the *Benbow*; **GEORGE T. BROATCH**, Surgeon, to the *Orwell*; and **ROBERT F. BOWIE**, Surgeon, to the *Excellent*.

JOHN SOUTER to be Surgeon and Agent at Buryhead; **JAMES LITTLE** to be Surgeon and Agent at Maryport.

ARMY MEDICAL RESERVE.

SURGEON-COMMANDANT A. T. NORTON, London Division Medical Staff Corps, to be Surgeon-Major (ranking as Lieut.-Colonel).

Surgeon and Honorary Surgeon-Major THOMAS PARTRIDGE, 2nd Volunteer Battalion Gloucester Regiment (late the 2nd Gloucester), and **SURGEON R. P. FRAZER**, 1st Volunteer Battalion Royal Fusiliers (late the 10th Middlesex), to be Surgeon-Major (ranking as Majors).

SURGEON J. E. SQUIRE, M.D., London Division Medical Staff Corps; **Acting-Surgeon II. W. ROBERTS**, 2nd Volunteer Battalion Royal West Kent Regiment (late the 3rd Kent); **Acting-Surgeon D. V. REES**, 1st Volunteer Battalion South Wales Borderers (late the 1st Brecknock); and **SURGEON J. H. HAAS, M.D.**, 7th Volunteer Battalion Argyll and Sutherland Highlanders (late the 1st Clackmannan and Kinross), to be Surgeons (ranking as Captains).

THE INDIAN MEDICAL SERVICE.

DEPUTY SURGEON-GENERAL W. WALKER, M.D., Bengal Establishment, is appointed to officiate as Surgeon-General and Sanitary Commissioner with the Government of India during the absence on leave of Surgeon-General Sir B. Simpson, K.C.I.E.

Surgeon-Major C. H. JOUBERT, M.B., Bengal Establishment, Officiating Civil Surgeon of the 24th Pergunnahs, is appointed to officiate as Professor of Midwifery at the Medical College, and Obstetric Physician at the Eden Hospital, Calcutta, during the absence on furlough of Surgeon-Major R. Harvey, M.D.

SURGEON C. W. OWEN, C.M.G., C.I.E., Bengal Establishment, is appointed to officiate as Agency Surgeon in Beloochistan during the absence on furlough of Surgeon-Major J. C. Fullerton, M.B.

SURGEON-MAJOR G. GRIFFITH, Bengal Establishment, whose services have been temporarily placed at the disposal of the Government of the North-West Provinces and Oude, is appointed to the civil medical charge of the Etawah District.

Brigade-Surgeon D. J. MCCARTHY, M.D., Madras Establishment, Medical Officer to the Queen's Own Sappers and Miners, has leave of absence for one year on medical certificate.

DEPUTY SURGEON-GENERAL T. G. HEWLETT, C.I.E., Bombay Establishment, has retired on a pension of £950 per annum, payable in England. He entered the service as Assistant-Surgeon, January 20th, 1854, and attained the rank of Deputy Surgeon-General, November 1st, 1879. He was present at the attack on Arab tribes at Hodeida, in the Red Sea, in 1856, and during the Indian Mutiny in 1858-59. He was at the destruction of the fortified village of Rowa, siege and destruction of Awah, operations before Kofah and pursuit of Gwalior rebels (medal with clasp, C.I.E.).

The services of **SURGEON-MAJOR K. A. DALAL, M.B.**, and **SURGEON A. W. F. STREET, D.P.O.**, both of the Bombay Establishment, are placed at the disposal of Government for employment in the Civil Department.

SURGEON C. J. SARKIS, Bombay Establishment, is appointed to officiate in

medical charge of the 16th Native Infantry during the absence of Surgeon-Major W. C. Kiermunder.

Brigade-Surgeon W. H. ROBERTS, M.D., Madras Establishment, doing duty in the Eastern District, is directed to do duty with the Hyderabad Subsidiary Force.

The undermentioned Surgeons, appointed to the Bengal Establishment, reported their arrival at Bombay on the dates specified: A. COLEMAN, April 9th; A. E. ROBERTS, D. M. DAVIDSON, J. C. LAMONT, A. H. NOTT, W. W. WHITE, D. T. LANE, M.D., R. C. MACWATT, W. H. E. WOODWRIGHT, J. K. CLOSE, M.D., and J. M. MACNAMARA, M.D., April 22nd.

Brigade-Surgeon J. E. T. AITCHISON, M.D., C.I.E., Bengal Establishment, has retired from the service, which he entered as Assistant-Surgeon, January 27th, 1853. He was engaged in the war in Afghanistan in 1878, and was at the capture of the Pelwar Kotal, for which he received the medal with clasp.

In the JOURNAL of May 18th it is stated, in the paragraph announcing the retirement of Brigade-Surgeon A. GARDEN, that he has no war record. We are asked to say that this is not correct, as Brigade-Surgeon Garden was present during the Indian Mutiny campaign in 1857-59, including the siege of Lucknow, and received the medal with clasp granted for the campaign.

FOREIGN SERVICE.

REGULATIONS have been issued from the War Office notifying that in future the period of service abroad for medical and veterinary officers, chaplains, and officers of the Commissariat and Transport Corps, Ordnance Store Corps, and Army Pay Department, will be four years for station in the West Indies, Bermuda, China, Ceylon, and Mauritius, and six years for all others, except the West Coast of Africa, where each month's service will be reckoned as three months.

ARMY MEDICAL DEPARTMENT.—The annual dinner was held in the Holborn Restaurant, on Tuesday, June 5th; Sir Thomas Crawford, K.C.B., in the chair. There were also present: Sir William Aitken; Surgeons-General Balfour, C.B.; Ekin, C.B.; Fraser; C. A. Gordon, C.B.; Irvine; Massy, C.B.; Muschamp; O'Nial, C.B.; Reade, C.B.; Webb. Deputy Surgeons-General Den; Jeffcoat; Laing; McGrath; Marston, C.B.; Sly; Veale; Watts. Brigade-Surgeons Anderson, C.I.E.; Candy, Clarke, Corban, Gribbon, Hector, Jagoe, Jameson, Leask, Mackenzie, Mackinnon, Maunsell, Myers, Nash, O'Dwyer, Owen, Wilson, Wright. Surgeons-Major Allin, Beattie, Boileau, Faris, Harvey, Johnston, Le Motté, Ligertwood, McNamara, Maturin, O'Farrell, Pratt, Rae, Roe, Shaw, Slaughter. Surgeons Clark, Falvey, Harris, Harwood, Kirkpatrick, Morris, Treherne, Trewhman. The guests were Sir Andrew Clark, Bart.; Sir William MacCormac; Director-General Dick, C.B., R.N.; Mr. Ernest Hart, Mr. Wakley, Mr. Clarke, and Mr. Norton.

MEDICO-LEGAL AND MEDICO-ETHICAL.

CERTIFICATES OF SICKNESS IN SCHOOL ATTENDANCE CASES.

T. S. II. asks whether it is legal to receive the certificate of a chemist in a school attendance case?

"* By Section 74 of the Elementary Education Act 1870, the fact that a child has been prevented from attending school by sickness or any other unavoidable cause is defined to be a "reasonable excuse" for his failure to attend school. When a parent is summoned, this, like any other material fact, must, if disputed, be proved by proper evidence. The certificate of a chemist is just as good for this purpose as the certificate of a qualified medical practitioner or of any other else—that is, it is legally no good at all. The evidence on which the court acts is the statement of some person who knows the child to be ill; but the production of a certificate is often accepted as a corroboration of that evidence. If objected to, a certificate ought in strictness not to be received at all.

THE APOTHECARIES' HALL AND THE TITLE OF ITS NEW LICENCE.

LIC. MED. writes: In Mr. Carpenter's letter in the JOURNAL of May 26th is the following passage: "To the profession and to lawyers L.M. Lond. would imply 'Licentiate in Midwifery of the Royal College of Surgeons,' which would render any apothecary taking that title, unless he possessed it, liable to criminal proceedings." May I ask how it is that the majority of Scotch licentiates are allowed to call themselves L.M. Glasgow or Edinburgh, when there is no such registrable qualification given by any university or corporation in Scotland? Is it only an apothecary who is liable to prosecution?

"* It is precisely because the universities and colleges of Glasgow and Edinburgh do not confer a separate Licentiatehip in Midwifery, as does the College of Surgeons (Eng.), that persons calling themselves "L.M. Glasg." or "L.M. Edin." would not by so doing be liable to prosecution, as would a person representing he was a L.M. of the College of Surgeons, for falsely pretending they possessed a legally recognised diploma.

"A HYPOTHETICAL CASE."

A.—If our correspondent, instead of vague, general imputations, will submit a specific charge in reference to the alleged misdoings of B. and C. in the hypothetical case briefly alluded to in the JOURNAL of May 26th, we will carefully consider it, in connection with any statement from the other side, and, if expedient, comment thereon. As the case at present stands, A. cannot fail to recognise the fact that no overt acts have been adduced on which we can comment, or arraignment made on which to adjudicate.

ASSISTANTS AND LEGAL FEES.

JUSTITIA asks whether it is the custom for a qualified assistant to retain any part or the whole of fees received by him for giving evidence in a police court on a case which has been under his care; also the same concerning evidence given in a coroner's court.

"* A qualified assistant can legally claim the fee for giving evidence at a police court or inquest, unless debarred by terms of his agreement, but such claim is rarely made by any assistant who wishes to retain the confidence and friendship of the principal. In some cases the division of fees is made a matter of agreement."

UNIVERSITY INTELLIGENCE.

LONDON.

EXPENDITURE OF THE UNIVERSITY.—Now that a strong endeavour is being made to found a new university in London, considerable interest attaches to the following extract from the Educational Estimates, 1888-89. For the London University the sums set apart are as follows:—Salaries and wages, £3,503; examiners, £7,252; exhibitions, scholarships, etc., £1,997; incidental expenses, £900; total, £13,652. The exhibitions include two at matriculation of the value of £30 each, two of £20, and two of £15, with eleven others at different stages of graduation. The scholarships are fourteen in number, and vary in value from £50 to £150. The prizes are eight in number, and the medals twenty-one.

The sums set apart for other universities and colleges in England and Wales are as follows:—

A.—In aid of the expenses of the University College			
	for North Wales	...	£4,000
B.—	"	South Wales	4,000
C.—	"	Aberystwith	4,000
D.—	"	Victoria University	2,000
Total			£14,000

CAMBRIDGE.

At the Congregation held on Thursday, June 7th, the Rev. W. E. Smyth, M.A., of King's College, was admitted to the degree of M.B., and Reginald R. Whishaw, M.B., B.A., of Cavendish College, to the degree of B.C.

OBITUARY.

PROFESSOR L. M. POLITZER, M.D., Vienna.

DR. POLITZER, the eminent Professor of Pediatrics in the University of Vienna, and one of the most distinguished physicians in Austria, died at Vienna on May 23rd. He was the first to introduce the critical methods of modern medicine and natural science into the study of children's diseases, and to sweep away the dogmatic and arbitrary doctrines, especially with respect to their etiology and treatment, which had prevailed up to that time. He showed that the causes of disease were the same in the child as in the adult, and the differences in the symptoms were not solely due to the frequent occurrence of ascaris lumbricoides in the intestinal tract, or to the universal morbid influence ascribed to dentition, but they were due to the anatomical and physiological peculiarities of the newborn and rapidly developing organism. His influence on therapeutics was most important, and he energetically protested against the general use of certain medicaments in all possible cases of disease, in particular against the abuse of laxatives and emetics, and the too frequent prescription of ipecacuanha, antimony, and calomel.

Politzer was born at Arad, in Hungary, in 1814, and after completing his preparatory studies in his native town, he studied medicine at Buda-Pesth and Vienna where he obtained his M.D. degree in 1839. Later on, he became the assistant of Professor Mauthner in the "St. Anna Kinderspital," where he acquired a great reputation throughout Austria and abroad by his literary activity. In 1875 he received the title of Professor, and in 1880 he was intrusted with the management of the first public institution for the diseases of children in Vienna. In June, 1853, he started, together with Mayer and Schiller, the well-known *Jahrbuch für Kinderheilkunde*. Among his writings may be mentioned: "Prejudices and Errors in the Pathology and Therapeutics of Children's Diseases," 1874; "Principles of

June 9, 1888.]

Scientific Dietetics and Physical Education of the Child," 1858; "Treatment of the most important Diseases of the Infantile Age," 1859; "Diagnosis and Treatment of Diseases of the Brain and the Meninges," 1861; "On the Special Nosology, Diagnosis, and Treatment of the Cerebral Diseases of the Child," 1863; "Therapeutic Experiments on the most important Drugs in the Practice of Children's Diseases," 1863 and 1864; "Several Cases of Noma," 1864; "Bronchial Asthma and Bronchial Spasm in the Infantile Age," 1870; "On the Diseases ascribed to Dentition and their Admission into Pathology," 1874; "Criticism and Reform of Therapeutics," 1875; "The Origin of Danger in the Course of Disease," 1881; "On the Value of Certain Single Symptoms for the Diagnosis of the Diseases of the Infantile Age," 1887, etc. Most of these papers appeared in the *Jahrbuch für Kinderheilkunde*.

Politzer was also the first to recognise the occurrence of bronchial asthma with the characteristic type of respiration in sucklings, and he was one of the first to point out that the disease which was called "pseudo-paralysis syphilitica" in newborn children was not to be looked upon as a cerebral paralysis, but only as an osteo-chondritic inflammatory process.

INDIA AND THE COLONIES.

INDIA.

THE new Walter Hospital at Oodeypore was opened by the Resident in state on the Queen's birthday.

BOMBAY GENERAL HOSPITAL.—The same apathy that the Bombay Government has shown in the matter of the provision of suitable quarters for the English nurses at the European General Hospital is said to prevail in regard to the residence of the house-surgeon, from the insanitary condition of which both he and his family have suffered in health. This state of things was reported to the authorities more than a year ago; and the Public Works Department, recognising the urgent need, undertook that a new building should be erected at the earliest possible date. This has not been done.

CONTAGIOUS DISEASES IN INDIA.—A Parliamentary paper, just published, contains a despatch dated May 17th, 1888, from the Secretary of State for India in Council to the Indian Government, with respect to the Contagious Diseases Act and the Cantonment Acts and Regulations of that country. The former Act, as far as it related to India, was only in operation in Madras, Bombay, and Bassein (Lower Burmah), and the Indian Government had determined to suspend it in these places. To this Viscount Cross gives his consent, but requests that the result of the suspension may be carefully watched. With regard to the Cantonment Acts, he says that the health and efficiency of the British garrison have been steadily kept in view since the measure was brought into operation. The maintenance of the cantonments in a proper sanitary condition and the prevention and cure of disease are equally matters of the highest importance, and all infectious disease ought to be dealt with as a question of police. No examination should be imposed upon women compulsorily, but no person likely to spread disease ought to be allowed within the cantonments except in hospital, and no one who objects to medical treatment ought to be in the cantonment at all. The result of the latest inquiries has shown the necessity for the regulation of prostitution in cantonments. Viscount Cross thinks that the rules framed under Clauses 7-31 of Section 27 of Act 111 (1850) require revision, and the principle to be borne in mind is, that the efforts to control prostitution and to mitigate its attendant evils should not be developed into anything that can assume the appearance of an encouragement of vice or a legalisation of prostitution by the Government and its officers.

SOUTH AFRICA.

IRREGULAR PRACTITIONERS.—The state of the law for the suppression of irregular practice in South Africa can hardly be considered satisfactory. In recently sentencing a Hindoo to a fine of £10 for practising as a physician in Capetown without a licence, Mr. Justice Buchanan said it was utterly useless instituting prosecutions of the kind unless the accused had property. He had had a similar case at Grahamstown, and reserved for the Court of Appeal the question whether the convicted person could not be imprisoned on failure to pay the fine. The Court of Appeal held that no alternative punishment could be imposed.

"PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

DRAINAGE AND DIPHThERIA.

AN important case has just been decided in the Glasgow Sheriff Court. The pursuer was a tenant of a house in Glasgow, and on June 3rd, 1887, his only child died from diphtheria. It was proved at the trial that for several months previously the house had been in an insanitary condition, through faulty condition of drains, and that the defenders, though frequently applied to by the pursuer to have them put in order, and eventually directed by the sanitary authorities to do so, did not put them in order till after the death of the child. The sheriff therefore found that the death of the pursuer's child was due to the fault of the defenders, and awarded pursuer £100 as compensation. In a note the sheriff says: "An argument for the defenders was founded on the ground that the introduction of traps on drains outside of houses is comparatively modern, and that it was not recognised as necessary at the time when this house was erected, about 1864. It is now, however, recognised by sanitary authorities as a necessary condition for safety, that a drain should be provided with a trap to prevent the escape of sewer gas from the drain, and it would be impossible at the present day to relieve a landlord of liability for the consequence of a drain being left untrapped, on the ground that when he built his house a trap was not thought necessary, and that he declined to comply with the recognised requirements of modern science."

It is deeply to be regretted that all builders of houses and drains have not as clear an idea of the necessity of traps and ventilators as the learned sheriff.

THE ALLOTMENTS ACT.

THE Local Government Board have issued, under date May 30th, a series of model clauses for the assistance of local sanitary authorities in framing regulations under Section 6 of the Allotments Act, 1887, "for regulating the letting of allotments under the Act, for preventing any undue preference in the letting thereof, and generally for carrying the provisions of the Act into effect." This series is prepared on the lines adopted in the model by-laws issued by the Board under the Public Health Act, and should prove to be very useful to local authorities. The Board have taken the opportunity thus afforded of again urging sanitary authorities to endeavour to give full effect to the intentions of the Legislature in passing the Allotments Act. It is to be feared that, with a few exceptions, little has hitherto been done by local authorities in this direction.

HEALTH OF ENGLISH TOWNS.—In the twenty-eight large English towns, including London, which have an estimated population of 9,398,273 persons, 5,794 births and 3,172 deaths were registered during the week ending Saturday, June 2nd. The annual rate of mortality, which had been 18.9 and 17.8 per 1,000 in the two preceding weeks, further declined during the week under notice to 17.6. The rates in the several towns ranged from 13.0 in Derby, 14.3 in Bradford and in Brighton, and 14.6 in Birkenhead to 22.4 in Blackburn, 23.7 in Preston, 24.9 in Wolverhampton, and 25.7 in Manchester. In the twenty-seven provincial towns the mean death-rate was 18.9 per 1,000, and exceeded by as much as 2.8 the rate recorded in London, which was only 16.1 per 1,000. The 3,172 deaths registered during the week under notice in the twenty-eight towns included 101 which were referred to whooping-cough, 46 to diarrhoea, 39 to diphtheria, 34 to measles, 31 to scarlet fever, 21 to "fever" (principally enteric), and 10 to small-pox; in all, 282 deaths resulted from these principal zymotic diseases, against 330 and 285 in the two preceding weeks. These 282 deaths were equal to an annual rate of 1.6 per 1,000; in London the zymotic death-rate was 1.6; while it averaged 1.5 per 1,000 in the twenty-seven provincial towns, and ranged from 0.0 in Birkenhead and in Huddersfield, and 0.4 in Sunderland to 2.8 in Norwich, 3.0 in Preston, and 3.3 in Manchester. Measles caused the highest proportional fatality in Wolverhampton and Bradford; scarlet fever in Blackburn; whooping-cough in Sheffield, Salford, Wolverhampton, and Manchester; and "fever" in Plymouth. Of the 39 deaths from diphtheria recorded during the week under notice in the twenty-eight towns, 26 occurred

in London, 3 in Hull, and 2 in Norwich. The 10 fatal cases of small-pox included 4 in Sheffield, 1 in Bristol, 1 in Nottingham, 1 in Derby, 1 in Preston, and 1 in Hull. The number of small-pox patients in the Metropolitan Asylums Hospitals on Saturday, June 2nd, was only 3, and no new cases were admitted during the week. These hospitals also contained 873 scarlet fever patients on the same date, showing a slight further decline from recent weekly numbers; 78 cases were admitted during the week, against 91, 82, and 66 in the three preceding weeks. The death-rate from diseases of the respiratory organs in London was equal to 2.9 per 1,000, and was slightly below the average.

HEALTH OF SCOTCH TOWNS.—During the week ending Saturday, June 2nd, 869 births and 489 deaths were registered in the eight principal Scotch towns. The annual rate of mortality, which had been 19.3 and 20.9 per 1,000 in the two preceding weeks, declined again to 19.3 during the week under notice, but exceeded by 1.7 per 1,000 the mean rate during the same period in the twenty-eight large English towns. Among these Scotch towns the lowest rates were recorded in Greenock and Leith, and the highest in Glasgow and Paisley. The 419 deaths in these towns during the week under notice included 52 which were referred to the principal zymotic diseases, equal to an annual rate of 2.1 per 1,000, which exceeded by 0.5 the mean zymotic death-rate during the same period in the large English towns. The highest zymotic death-rates were recorded in Paisley and Glasgow. Of the 225 deaths registered in Glasgow, 10 resulted from measles, 6 from scarlet fever, 14 from whooping-cough, and 4 from "fever;" 2 fatal cases of scarlet fever occurred in Dundee, and 2 of diphtheria in Edinburgh. The mortality from diseases of the respiratory organs in these Scotch towns during the week under notice was equal to 3.2 per 1,000, against 2.9 in London.

HEALTH OF IRISH TOWNS.—In the sixteen principal town-districts of Ireland the deaths registered during the week ending Saturday, June 2nd, were equal to an annual rate of 21.5 per 1,000. The lowest rates were recorded in Armagh and Galway, and the highest in Lurgan and Wexford. The 159 deaths registered in Dublin during the week under notice were equal to an annual rate of 23.5 per 1,000, against 23.6 and 24.4 in the two preceding weeks, the rate for the same period being only 16.1 in London, and 18.4 in Edinburgh. The 159 deaths included 20 which resulted from the principal zymotic diseases (equal to an annual rate of 3.0 per 1,000), of which 9 resulted from whooping-cough, 4 from scarlet fever, 4 from different forms of "fever," 2 from diarrhoea, and 1 from measles.

DISINFECTATION BY HEAT.

M. O. H. asks for experience in rural districts of disinfection by heat in cases of infectious disease—what contrivances can be used? and, if a disinfecting chamber, whose? what is the cost, and whose is the cheapest to employ?

"* We may mention in part reply to the above that Messrs. Frazer, of London, have a fixed disinfecting chamber, where, in a close chamber subjected to about 300° F., any materials can be properly treated. They have also a perambulating apparatus. Messrs. Nelson, of Leeds, have an apparatus in use in London and the provinces, which takes the form of a wrought iron chest. The heat is regulated to 200°, and this cannot be exceeded if wished. Dr. Rogers, of East Retford, has a portable apparatus, which consists of an iron outer case and a wooden box within. Messrs. Stobbs and Seagrave, of London, have also a perambulating disinfecting apparatus which applies superheated air or steam. Dr. Scott, of Dalkey, co. Dublin, has several systems of disinfecting by hot air. We believe they are engineered by Messrs. Maguire and Son, sanitary engineers, Dublin. Mr. Washington Lyon, of Cornhill, London, has a valuable but costly movable apparatus on wheels, which disinfects, dries, and heats as well by the action of steam. Mr. Arthur Jennings, of Cross Street, Lambeth, S.E., has lately brought out an excellent apparatus, which disinfects by the heat produced by gas, and which is highly spoken of.

We would recommend M. O. H. to write to the above firms for descriptions, prices, and testimonials, so as to judge for himself.

INSANITARY DWELLINGS.—The report of the Mansion House Council on the Dwellings of the People, presented at its last meeting, stated the action that had been taken in regard to numerous cases of insanitation in the districts of St. Olave's Southwark, Shoreditch, Westminster, Clapton, and the City. Instructions were given to bring to the notice of the Government particulars of prolonged neglect on the part of the authorities for Plumstead and Woolwich.

MEDICO-PARLIAMENTARY.

HOUSE OF COMMONS.—Friday, June 1st.

Lunacy Acts Amendment Bill.—Mr. W. H. SMITH, in reply to Dr. FARQUHARSON, stated that it was the intention of the Government to pass the Bill in the course of the present session.

The Vaccination Laws.—Mr. PICTON submitted the following motion: "That a Select Committee be appointed to inquire into the circumstances of the epidemic of small-pox in Sheffield and the surrounding district, and especially to ascertain whether its origin can be traced to defective vaccination, or to insufficient sanitary precautions, or to any other causes; also to inquire how far the rapid spread of infection has been owing to the absence of any system of compulsory notification of contagious disease; likewise, whether the notorious diminution of vaccination in Leicester, Keighley, Dewsbury, and other towns, has been attended by any evil consequences, or whether preventive measures other than vaccination have been found effectual; and, if so, whether they are capable of wider application."—This was seconded by Mr. COLMAN.—Dr. FARQUHARSON said if the Government would agree to hold an inquiry into the two specific cases of Norwich and Leicester, it would, he thought, supply a great deal of scientific information, and would satisfy, to a great extent, the public mind.—Dr. CAMERON said there were three different systems which he thought might be inquired into with advantage: the system which prevailed in Leicester, where there was defective vaccination but strict attention to segregation; the system which prevailed in London, where vaccination was carefully carried out, but there was no attempt at segregation; the system prevailing in Glasgow where there was great attention to vaccination and revaccination, and the most strict attention to segregation.—Mr. RITCHIE said whatever inquiry might be made, a Select Committee of the House of Commons was not the proper body to make it. He said it was impossible to dissociate the inquiry which the hon. member for Leicester asked for from the cause which the hon. gentleman represented in the House in speaking for the large masses of people who were opposed to vaccination; and therefore, if an inquiry were granted, the hon. member would insist upon certain gentlemen with strongly adverse opinions to vaccination being placed on the Committee of Inquiry. No such tribunal could ever hope to come to a unanimous report, and matters would remain very much as they now were. With regard to the Sheffield outbreak, a house-to-house visitation had been made, and all the circumstances connected with every single case of attack would be specifically reported upon. There never was a more complete case in favour of vaccination than the Sheffield case. The number of vaccinated children under 10 years in Sheffield was given at 82,958. Out of that number 207, or 1 in 400, were attacked, and out of the 207 attacked only 2 died. The number of deaths of vaccinated children was, therefore, only 1 per cent. The number of unvaccinated children under 10 years of age was 4,366. Of these 146, or 1 in 30, were attacked, and 7 died. Some remarkable facts had been brought to light with regard to small-pox in Montreal. Prior to 1885, there had been for many years no case of small-pox in Montreal, a large proportion of people, like those at Leicester, being unvaccinated. In February, 1885, a man was admitted to the hospital with small-pox. He was cured and left the hospital. But the disease spread so rapidly, that in six months, among a population of under 200,000, as many as 3,164 deaths occurred from small-pox. Vaccination and revaccination were then rigorously enforced, the stations being literally besieged with persons clamouring for vaccination, and in three months 80,000 were vaccinated. He must decline to grant any further investigation whilst the present one at Sheffield was pending.—Dr. MACDONALD maintained that there was no foundation for the arguments and statistics of the anti-vaccinationists. The subject then dropped.

Tuesday, June 5th.

The Contagious Diseases Acts in India.—Sir J. GORST, in reply to Sir R. TEMPLE, said, of the thirteen members of the Council of India present on the occasion of the despatch of the Secretary of State to the Government of India on the subject of the Contagious Diseases Acts, nine voted against it.—Mr. McLAREN moved, and Sir R. N. FOWLER seconded, the following resolution: "That, in the opinion of this House, any mere suspension of measures for the compulsory examination of women, and for licensing and regulating prostitution in India, is insufficient, and the legislation

which enjoins, authorises, or permits such measures ought to be repealed."—Mr. G. C. BENTINCK had on the paper the following amendment: "That, considering the large and alarming increase of disease in the army and navy, and the sufferings of the unfortunate women on the home stations since the repeal of the Contagious Diseases Acts, this House is of opinion that it is inexpedient to repeal the Acts now in force in India;" but he did not intend to propose it, as he preferred the amendment which stood in the name of Sir R. Temple, for which he should vote.—Sir J. GORST said he was instructed to say that, if the Council of the Governor-General thought fit to repeal the Contagious Diseases Acts altogether, the Secretary of State would assent to that repeal. The Indian Government, recognising the general feeling in England, had on its own initiative suspended their operation, and, although the Secretary of State possessed the technical power to direct legislation, it would be most unconstitutional for him and inexpedient of Parliament to interfere with the independence of the Indian Legislature. The regulations under the Cantonment Acts were now under revision, and the Secretary of State had distinctly declared against rules being framed or continued which might appear to legalise vice.—Sir R. LETHBRIDGE, while strongly condemning the regimental system, thought that, as the Government of India had suspended the Acts, further action might be left to them.—Mr. J. E. ELLIS, Mr. H. WILSON, and Sir J. SIMON spoke in support of the resolution.—Sir R. TEMPLE disputed the assertion that the Acts had not been successful in maintaining the health of the troops.—Sir W. FOSTER argued that the administration of the Acts in India had failed; and Mr. STANSFELD thanked the Government or the spirit in which they had received the resolution.—The motion was carried.

MEDICAL NEWS.

MEDICAL VACANCIES.

The following Vacancies are announced:

ANDERSON'S COLLEGE DISPENSARY, Glasgow.—Physician. Applications to David Wilson, Esq., Honorary Secretary, 42, Bath Street, Glasgow.

ANDERSON'S COLLEGE DISPENSARY, Glasgow.—Surgeon. Applications to David Wilson, Esq., Honorary Secretary, 42, Bath Street, Glasgow.

MALTINGLASS UNION.—Medical Officer, Dunlavin Dispensary. Salary, £135 per annum, and fees. Applications to Captain Heighton, J.P., Honorary Secretary, Donard House. Election on June 13th.

BOARD OF WORKS FOR THE WANDSWORTH DISTRICT.—Medical Officer for the Parish of Clapham. Salary, £75 per annum, with increase. Applications by June 12th to the Clerk to the Board, East Hill, Wandsworth.

LETHBRIDGE UNION.—Medical Officer for the Workhouse. Salary, £100 per annum; also £15 per annum as Medical Superintendent Officer of Health. Applications by June 15th to Mr. Samuel Manning, Clerk of the Union.

UFFUS PAROCHIAL BOARD.—Medical Officer. Salary, £35. Applications by June 23rd to John Nicoll, Esq., Inspector of Poor, Hopeman, N.B.

WEST LONDON HOSPITAL FOR CHILDREN, Shadwell, E.—Resident Clinical Assistant. Board and lodging. Applications by June 25th to the Secretary.

WELMINGTON HOSPITAL FOR SICK CHILDREN, Southwark Bridge Road.—Surgeon to Out-patients. Applications by June 25th to the Committee of Management.

WEST HOSPITAL, Dudley.—Resident Medical Officer. Salary, £110 per annum, with board and residence, etc. Applications by June 21st to the Secretary.

WINDSOR COLLEGE HOSPITAL.—Assistant-Surgeon. Applications to the Secretary.

WINDSOR TEMPERANCE HOSPITAL, Hampstead Road.—Surgeon. Applications by June 16th to the Secretary.

METROPOLITAN ASYLUMS BOARD: WESTERN FEVER HOSPITAL, Fulham, S.W.—Clinical Assistant. Board and lodging. Applications to the Medical Superintendent at the Hospital.

HILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich Road, S.E.—Junior Resident Medical Officer. Salary, £30 per annum, apartments, board, etc. Applications by June 9th to the Honorary Secretary.

NEWTON HEATH (MANCHESTER) DISTRICT.—Medical Officer of Health. Salary, £50 per annum. Applications by June 18th to the Chairman of the Local Board of Health, Town Hall, Newton Heath, Manchester.

OTTINGHAM GENERAL HOSPITAL.—Resident Medical Assistant. Board and lodging, etc. Applications by June 13th to the Secretary.

OTTINGHAM GENERAL HOSPITAL.—Resident Surgical Assistant. Board and lodging, etc. Applications by June 13th to the Secretary.

ORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney Road, E.—Junior House-Surgeon. Salary, £30 for six months. Applications by June 19th to A. Nixon, Esq., Secretary, 27, Clement's Lane, E.C.

QUEEN'S COLLEGE, Manchester.—Professor of Surgery. Applications by June 9th to the Registrar.

PARISH OF LOCHS, Stornoway.—Medical Officer. Salary, £140, house and rates free. Applications by June 23rd to H. McL. Ross, Inspector of the Poor, Lochs, Stornoway.

PARISHES OF PENNYGOWN AND TOROSAY.—Medical Officer. Salary, £100 per annum. Applications by July 3rd to Mr. A. McDougall, Inspector of Poor, Auchnacraig, Oban, N.B.

QUEEN'S COLLEGE, Birmingham.—Assistant Medical Tutor. Applications by June 20th to the Secretary.

RAMSGATE AND ST. LAWRENCE ROYAL DISPENSARY AND SEAMEN'S INFIRMARY.—Resident Medical Officer. Salary, £120 per annum, with furnished apartments, etc. Applications by June 23rd to the Secretary.

ROYAL ALBERT HOSPITAL, Devonport.—Assistant House-Surgeon. Board and lodging. Applications by June 18th to the Chairman of the Managing Committee.

ROYAL SOUTH HANTS INFIRMARY, Southampton.—House-Surgeon. Salary, £100, board, lodging, etc. Applications by June 20th to the Secretary.

SHEFFIELD GENERAL INFIRMARY.—House-Surgeon. Salary, £120, with board, lodging, etc. Applications by June 18th to the Secretary.

SHEFFIELD GENERAL INFIRMARY.—Assistant House-Surgeon. Salary, £80 per annum, with board, lodging, etc. Applications by June 18th to the Secretary.

SURREY DISPENSARY, Great Dover Street, Southwark.—House-Surgeon. Salary, £120, and furnished apartments. Applications by June 19th to the Subcommittee.

WELLINGBOROUGH AND DISTRICT MEDICAL INSTITUTE.—Medical Officer. Salary, £250, and fees, with dwelling-house, etc. Applications to G. Bayes, Esq., Jackson's Lane, Wellingborough.

WEST LONDON HOSPITAL, Hammersmith Road, W.—Physician. Applications by June 21st to the Secretary Superintendent.

WEST LONDON HOSPITAL, Hammersmith Road, W.—Assistant Physician. Applications by June 21st to the Secretary Superintendent.

WEST LONDON HOSPITAL, Hammersmith Road, W.—House-Physician. Board and lodging. Applications by June 21st to the Secretary Superintendent.

WEST LONDON HOSPITAL, Hammersmith Road, W.—House-Surgeon. Board and lodging. Applications by June 21st to the Secretary Superintendent.

WESTPORT UNION.—Medical Officer, Westport No. 2 and Louisburgh No. 2 Districts. Salary, £39 per annum, and fees. Election on June 24th.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Resident Assistant. Board and lodging, etc. Applications by June 25th to the Chairman of the Medical Committee.

MEDICAL APPOINTMENTS.

BANNISTER, Marmaduke, M.R.C.S., L.R.C.P., late House-Surgeon to the Manchester Royal Infirmary, appointed Resident Surgeon at the Hospital of No. 7 Section of the Manchester Ship Canal.

BATTLE, W. H., F.R.C.S., appointed Assistant Surgeon to the East London Hospital for Children, vice L. A. Dunn, M.B., F.R.C.S.

CAMPBELL, T. Kenneth, M.B., F.R.C.S., appointed Assistant Surgeon to the Gordon Hospital for Fistula, etc.

CHAMBERLAIN, W. W., M.B., C.M. Edin., appointed Senior House-Surgeon to the Halifax Infirmary and Dispensary, vice J. P. Gray, M.R.C.S., L.S.A., resigned.

CLARK, Francis William, L.R.C.P. Lond., M.R.C.S., appointed Assistant Medical Officer to the Metropolitan District Asylums Schools, Darent, vice W. T. Maddison, M.D. Lond., resigned.

COX, D. Charles, M.D., L.R.C.P. Edin., appointed Parochial Medical Officer and Public Vaccinator, Annav, vice D. Mackenzie, M.B. and C.M., resigned.

DUNN, L. A., M.B., F.R.C.S., appointed Surgeon to the East London Hospital for Children, vice A. Caesar, resigned.

FROST, W. Adams, F.R.C.S. Eng., appointed Surgeon to the Royal Westminster Ophthalmic Hospital.

HARRIDGE, G., F.R.C.S. Eng., appointed Surgeon to the Royal Westminster Ophthalmic Hospital.

LOVEGROVE, C., M.D., L.R.C.P., late Surgeon to the Liverpool Corporation Waterworks, Llanwddyn, appointed Surgeon to No. 7 Section of the Manchester Ship Canal; and Consulting Surgeon from Lymm to Salford.

LUCAS, Albert, M.R.C.S., L.R.C.P., appointed Assistant House-Surgeon to the Metropolitan Hospital, vice H. L. Harrison, M.B., resigned.

ORB, W. Theophilus, M.R.C.S. Eng., L.R.C.P. Lond., appointed Resident Surgeon to the Birmingham General Dispensary.

PAGET, S., F.R.C.S. Eng., appointed Assistant Surgeon to the West London Hospital, vice B. Wainwright, M.B. Edin., F.R.C.S. Eng., resigned.

PAUL, E. W., M.R.C.S., L.S.A., appointed House-Surgeon to St. Peter's Hospital for Stone, etc., vice F. H. Norvill, M.B., resigned.

POWELL, John Allan, M.D. Dub., appointed Locum Tenens Assistant Medical Officer to the Berks County Asylum, Moulsoford.

PRETSELL, W. G., M.B., C.M., appointed Assistant Medical Officer to Govan Poorhouse and Asylum, vice George Davidson, M.B., resigned.

SINCLAIR, F. Howard, M.D., M.Ch. (R.U.I.), L.K.Q.C.P.I., L.R.C.S.I., L.M., etc., appointed Visiting Physician to the Hospital for Consumption, Belfast, vice Samuel Dickey, M.D., M.Ch., L.M. (Q.U.I.), resigned.

VICKERY, W. H., M.R.C.S., L.R.C.P., appointed House-Surgeon to the Mid-diesex Hospital.

PROFESSOR VIRCHOW.—The German Emperor has conferred on Professor Rudolf Virchow the Order of the Red Eagle, Second Class. In the bestowal of this honour, medical men will probably

see nothing but a graceful recognition of the great pathologist's scientific eminence, and of services rendered by him to the person of the Emperor. Public opinion in Germany, however, appears to attach some political significance to it, as an additional proof of His Imperial Majesty's sympathy with Liberal ideas. Professor Virchow is one of the leaders of the Liberal party in Germany, and one of the most determined opponents of Prince Bismarck, with whom he fought a duel many years ago.

GLASGOW DEAF AND DUMB INSTITUTION.—The annual meeting of this institution was held on May 31st. The report stated that, at the beginning of the new session, 109 pupils returned, and, during this session, 24 new pupils joined, making a total of 133, 10 less than that of the preceding year. Employment of various kinds had been readily procured for those who left. The fire which occurred at the end of March had not stopped the work of the institution, and, while the repairs were being executed, the opportunity was being taken to make some structural improvements which experience had shown to be necessary.

PORTSMOUTH HOSPITAL.—The Bishop of Winchester on May 29th reopened the Portsmouth Hospital. It was decided last year to raise a fund to be spent on the building as a local celebration of the Jubilee, it being hoped that sufficient money would be collected to enable the committee to erect an entirely new structure. The fund, however, reached only a little over £3,000, and with this sum the interior of the hospital has been entirely reconstructed on modern principles, and the number of beds increased from 70 to 104.

BOURNEMOUTH AMBULANCE CORPS.—Mr. Embleton, M.R.C.S., of Bournemouth, who has been engaged in instructing members of the local fire brigade and others in the principles and practice of first aid, has been presented by his class with a silver pencil case as a token of their appreciation of his services. It has been decided to form an ambulance corps in Bournemouth consisting of certificated members.

ADULTERATED CHEESE.—At Glasgow Sheriff Court, recently, a case was brought up in which a provision merchant was charged with selling cheese consisting essentially of oleomargarine or foreign fat. The cheese was one of the kind known as "lard cheese," sold in America as "imitation cheese." A fine of £3 was imposed and paid.

PORT GLASGOW AMBULANCE CENTRE.—At a meeting of this centre very satisfactory reports were read, the treasurer's statement showing a balance of £6 10s. The executive for next year was appointed, of which Drs. Crawford, McBride, and Taylor are members. Dr. Crawford was afterwards presented by his class with a marble timepiece, in recognition of his services in their instruction.

EPIDEMIC OF MEASLES AT NEILSTON.—There is at present a serious outbreak of measles among the children attending the public schools at Neilston. In one school 105 children, belonging to 59 different families, have been attacked; and in another there are 61 cases out of 30 families. In consequence of the epidemic it has been deemed advisable to close the schools.

FAVERSHAM COTTAGE HOSPITAL.—A cottage hospital, the gift of Mrs. Rose to the town of Faversham in memory of her late husband, was formally opened on May 26th in the presence of the mayor, the vicar, Lady Harris, and a number of other influential residents of the vicinity. The site was presented by Mr. T. Townend Hall, J.P., and Mr. Rigden, and the furniture, costing £400, by Mr. Rose.

TREATMENT OF WARTS.—Dr. Roosen (*Monat. f. Prakt. Derm.*, 1888, p. 325) states that he has treated callosities and warts successfully by the application of pure crystallised salicylic acid. The acid is kept in position by moistened boracic lint, and over all there is fastened a piece of gutta-percha tissue. The application is removed after five days, when the hardened epidermis usually falls off.

A LAD has died in the Derby Infirmary under peculiar circumstances. He was running away from a cow, when the animal overtook him in a narrow passage and crushed him so severely against the wall that he succumbed to his injuries.

MEDICAL MAGISTRATES.—Dr. MacRae-Laggon has been appointed to the Commission of the Peace for the county of Inverness.—Mr. Charles Brook, M.R.C.S.Eng., has been placed on the commission of the peace for Lincolnshire.

MR. JAFFRAY, of Birmingham, whose name is well-known in connection with princely gifts to local hospitals, has generously offered to defray the whole expenses incurred by the Birmingham Hospital Saturday Committee during the current year.

DR. GEORGE FREDERICK PHILPOT, practising at Hemel Hempstead, has been found not guilty of the charge of conspiring with his brother to defraud the Mutual Accident Insurance Company.

The Hygiene and Life-saving Apparatus Exhibition at Ostend will be opened on June 30th. About 400 exhibitors have, it is stated, already sent in their names.

In consequence of the increase of hydrophobia in Paris, dogs are not allowed in the streets except in the leash.

THE Princess Christian paid a visit to Brompton Hospital on Monday last, and took part in a concert given to the inmates.

THE Duke of Devonshire has granted land between Eastbourne and Beachy Head for a new convalescent home for children.

DIARY FOR NEXT WEEK.

MONDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 5 P.M.—Professor T. Bryant: On the Causes, Effects, and Treatment of Tension as met with in Surgical Practice.

TUESDAY.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8.30 P.M.—Dr. A. Sangster and Dr. F. W. Mott: On Pemphigoid Eruption, with Changes in Peripheral Nerves. Dr. W. R. Gowers and Professor V. Horsley: Case of Tumour of the Spinal Cord: Removal: Recovery.

WEDNESDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 5 P.M.—Professor T. Bryant: On the Causes, Effects, and Treatment of Tension, as met with in Surgical Practice.

COLLEGE OF STATE MEDICINE, Burlington House, 4 P.M.—Dr. G. Fleming: On Some of the More Important Diseases common to Man and Animals.

BRITISH GYNECOLOGICAL SOCIETY, 8.30 P.M.—Specimens will be exhibited by Dr. G. Granville Bantock, Dr. Richard Smith, Dr. Bedford Fenwick, and the President, Mr. Lawson Tait: The Influence of Removal of the Uterus and its Appendages on the Sexual Appetite. Dr. Henry T. Rutherford: Notes of a case of Uterine Fibroid successfully treated by Electricity.

ROYAL MICROSCOPICAL SOCIETY, 8 P.M.—Rev. W. Howchin: Additions to the Knowledge of the Carboniferous Foraminifera.

EPIDEMIOLOGICAL SOCIETY OF LONDON, 8 P.M.—Annual General Meeting. Arthur H. Downes, M.D.: Notes on Diphtheria. Robert Cory, M.D.: The Condition as to Vaccination of One Hundred and Fifty Persons Scarcely by Small-pox.

THURSDAY.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, 5 P.M.—Dr. Donald MacAlister: The Croonian Lecture on Antipyretics.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM, 8.30 P.M.—Living and Card Specimens at 8 P.M. Mr. Silecock: (1) Sarcoma of Frontal Bone; (2) Sarcoma of both Orbits. Mr. Jessop: Case of Symmetrical Ring of Pigment on Anterior Capsule of Lens. Mr. J. Hutchinson, jun.: Two cases of Cicatrices in Vitreous and Retina. Papers:—Mr. Emrys-Jones: On a case of Large Orbital and Intracranial Ivory Exostosis, associated with Cerebral Tumour. Mr. Edgar Browne: Optic Atrophy in Three Brothers. Mr. Rockliffe: Notes on (1) Secondary Hemorrhage after Iridectomy for Glaucoma; (2) Ophthalmoplegia.

FRIDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 5 P.M.—Professor T. Bryant: On Surgical Interference in Cranial Injuries.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d. which should be forwarded in stamps with the announcement.

BIRTHS.

GODFREY.—On May 30th, at Brookbank House, Malton, the wife of Frank W. A. Godfrey, M.B. Edin., of Scarborough, of a daughter.

SPENCE.—At St. Ninians, Burntisland, on June 4th, the wife of Robert Spence, M.B., C.M., of a daughter.

MARRIAGES.

ORD—HAWKINGS.—On June 5th, at All Saints, Clapham Park, by the Rev. F. S. Coleman, M.A., brother-in-law of the bride, assisted by the Rev. A. G. Girdleston, M.A., Vicar, and the Rev. Wadehouse Raven, M.A., Vicar of Christ Church, Streatham, George William Ord, M.R.C.S., of Mildenhall, Suffolk, eldest son of George Rice Ord, of Streatham Hill, Surrey, to Edith Emily Lucy, third daughter of Charles F. Hawkins, of Belmont, Clapham Park.

WILSON—WALTON.—On June 6th, at Edgbaston Parish Church, by the Rev. G. H. Cameron, B.A., William Wilson, M.B., C.M. Ed., of Forest Hill, to Jane Alice (Jennie) Walton, only daughter of Frederick Walton, Edgbaston.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY.....10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's (Ophthalmic Department); and Royal Westminster Ophthalmic.—2 P.M.: Metropolitan Free; St. Mark's; Central London Ophthalmic; Royal Orthopaedic; and Hospital for Women.—2.30 P.M.: Chelsea Hospital for Women.

TUESDAY.....9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's; St. Bartholomew's (Ophthalmic Department); St. Mary's; Royal Westminster Ophthalmic.—2 P.M.: Westminster; St. Mark's; Central London Ophthalmic.—2.30 P.M.: West London; Cancer Hospital, Brompton.—4 P.M.: St. Thomas's (Ophthalmic Department);

WEDNESDAY.....10 A.M.: National Orthopaedic.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: Middlesex.—1.30 P.M. St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: London; University College; Westminster; Great Northern Central; Central London Ophthalmic.—2.30 P.M.: Samaritan Free Hospital for Women and Children; St. Peter's.—3 to 4 P.M.: King's College.

THURSDAY.....10.30 A.M.: Royal London Ophthalmic.—1 P.M.: St. George's.—1.30 P.M.: St. Bartholomew's (Ophthalmic Department); Guy's (Ophthalmic Department); Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; St. Thomas's (Obstetric Department); Central London Ophthalmic; Hospital for Diseases of the Throat; Hospital for Women.—2.30 P.M.: North-West London; Chelsea Hospital for Women.

FRIDAY.....9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.15 P.M.: St. George's (Ophthalmic Department).—1.30 P.M.: Guy's; Royal Westminster Ophthalmic.—2 P.M.: King's College; St. Thomas's (Ophthalmic Department); Central London Ophthalmic; Royal South London Ophthalmic; East London Hospital for Children.—2.30 P.M.: West London.

SATURDAY.....9 A.M.: Royal Free.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: King's College.—1.30 P.M.: St. Bartholomew's; St. Thomas's Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Middlesex; Royal Free; Central London Ophthalmic.—2.30 P.M.: Cancer Hospital, Brompton.

HOURS OF ATTENDANCE AT THE LONDON HOSPITALS.

CHARING CROSS.—Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; Skin, M. Th., 1.30; Dental, M. W. F., 9.

GUY'S.—Medical and Surgical, daily, 1.30; Obstetric, M. Tu. F., 1.30; Eye, M. Tu. Th. F., 1.30; Ear, Tu. F., 12.30; Skin, Tu., 12.30; Dental, Tu. Th. F., 12.

KING'S COLLEGE.—Medical, daily, 2; Surgical, daily, 1.30; Obstetric, Tu. Th. S., 2; o.p., M. W. F., 12.30; Eye, M. Th., 1; Ophthalmic Department, W., 1; Ear, Th., 2; Skin, Th., Throat, Th., 3; Dental, Tu. F., 10.

LONDON.—Medical, daily, exc. S., 2; Surgical, daily, 1.30 and 2; Obstetric, M. Th., 1.30; o.p. W. S., 1.30; Eye, W. S., 9; Ear, S., 9.30; Skin, Th., 9; Dental, Tu., 9.

MIDDLESEX.—Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; o.p. W. S., 1.30; Eye, W. S., 8.30; Ear and Throat, Tu., 9; Skin, Tu., 4; Dental, daily, 9.

ST. BARTHOLOMEW'S.—Medical and Surgical daily, 1.30; Obstetric, Tu. Th. S., 2; o.p. W. S., 9; Eye, Tu. Th. S., 2.30; Ear, Tu. F., 2; Skin, F., 1.30; Larynx, F., 2.30; Orthopaedic, M., 2.30; Dental, Tu. F., 9.

ST. GEORGE'S.—Medical and Surgical, M. T. F. S., 1; Obstetric, Tu. S., 1; o.p., Tu., 2; Eye, W. S., 2; Ear, Tu., 2; Skin, W., 2; Throat, Th., 2; Orthopaedic, W., 2; Dental, Tu., S., 9, Th., 1.

ST. MARY'S.—Medical and Surgical, daily, 1.45; Obstetric, Tu. F., 1.45; o.p., M. Th., 1.30; Eye, Tu. F., 9; Ear, M. Th., 3; Throat, Tu. F., 1.30; Skin, M. Th., 9.30; Electrician, Tu. F., 2; Dental, W. S., 9.30; Consultations, M., 2.30; Operations, Tu., 1.30; Ophthalmic Operations, F., 9.

ST. THOMAS'S.—Medical and Surgical, daily, except Sat., 2; Obstetric, Tu. F., 2; o.p. W., 1.30; Eye, M. Th., 2; o.p., daily, except Sat., 1.30; Ear, M., 12.30; Skin, W., 12.30; Throat, Tu. F., 1.30; Children, S., 12.30; Dental, Tu. F., 10.

UNIVERSITY COLLEGE.—Medical and Surgical, daily, 1 to 2; Obstetrics, M. Tu. Th., F., 1.30; Eye, M. Tu. Th. F., 2; Ear, S., 1.30; Skin, W., 1.45, S., 9.15; Throat, Th., 2.30; Dental, W., 10.30.

WESTMINSTER.—Medical and Surgical, daily, 1.30; Obstetric, Tu. F., 3; Eye, M. Th., 2.30; Ear, M., 9; Skin, Th., 1; Dental, W. S., 9.15.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS FOR THE CURRENT WEEK'S JOURNAL SHOULD REACH THE OFFICE NOT LATER THAN THE FIRST POST ON WEDNESDAY.

COMMUNICATIONS respecting editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

IN order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the office of the JOURNAL, and not to his private house.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate beforehand with the Manager, 429, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication. CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

QUERIES.

HIGH TEMPERATURE IN A CHILD AGED 16 MONTHS.

DR. JOSEPH SMITH (Streatham Hill, S.W.) writes: I was called to see a male child, aged 16 months, at 10 A.M., and found my little patient with swollen gums, which I lanced. I prescribed calomel gr. ij, as the Lowels were constipated, and a little salicæ mixture. The temperature was 101.6°. There was a little cough; but on carefully examining the lungs the physical signs were almost nil. At 6 P.M. I was informed that the calomel had acted twice; but as the child looked worse I again examined its lungs, and found the physical signs in the same condition as on my first visit.

Upon taking the temperature, my thermometer recorded 110°. Thinking the thermometer was at fault, I compared it with the others, and found the record correct. Upon visiting the child again at 10 P.M., the thermometer registered 102°. In two days the child was comparatively well and the temperature normal. What was the cause of such an abnormally high temperature in the absence of any signs to account for it?

ADMIRALTY EXAMINATION.

W. E. M. writes: Having been asked to examine the mouth of a youth who is preparing for the entrance examination as an engineer student in Her Majesty's dockyards, but naturally does not wish to present himself if liable to be rejected afterwards owing to the condition of his teeth, I shall be obliged for any information as to condition or number of teeth required which will aid me in giving an opinion.

ANSWERS.

THE DUTY OF THE MEDICAL ATTENDANT IN CASES OF DEATH FROM CHLOROFORM.

A MEMBER writes: I shall feel obliged by your kindly informing me if the medical attendant is obliged to report to the coroner the occurrence of death under chloroform administered during parturition?

** Yes; without doubt. The case should also be medically recorded as one of great interest to the profession.

MEDICAL BOOKKEEPING.

DR. H. F. LANCASTER (Lewisham High Road, S.E.) writes: In the JOURNAL of May 5th "M.B. and C.M." asks for an easy method of medical bookkeeping. Having well considered the several systems that are published, I have come to the conclusion that for a day-book that of the "Handy" system, published by Lewis of Cardiff, is the best, and I have used this for some time. One important point in its favour is the proximity of patient's name and monthly amount on the page, which avoids an error one might possibly fall into of attributing a sum to the wrong patient when these two items are a good way apart in the open pages, as is the case with the other day-books. Another advantage is the different-coloured ruling, which assists in the same way.

As to the ledger, I have for some years used the "Expedite," published by Sang and Barony; but, as this is arranged for yearly and not half-yearly accounts, and in two or three other matters I found I could improve on it, I have had one made for me to my liking, which I consider superior. It is alphabetical, very compact, and will last each patient three years with one entry. I think each of the ledgers—"A. B. C.," "Handy," "Expedite," "Carlyle's"—is faulty in some particulars, specially in the easy treatment and rendering of arrears, and I believe that in this I have combined their virtues. If "M.B. and C.M." will communicate with me I shall be most pleased to let him see a specimen sheet and to give further particulars.

DR. NEALE'S "MEDICAL DIGEST."

DR. RICHARD NEALE writes: In answer to "Disappointed," at page 1147 of the JOURNAL, who states that the *Digest*, without the journals referred to, is a delusion and snare, pure and simple, I must ask you to insert a few of the remarks made by different reviewers who are supposed to have studied the work before criticising it.

"It is at once an index and an abstract. Not infrequently the mere reference is in itself a suggestion, and further search is unnecessary. This is especially the case in the domain of practical therapeutics. The busy practitioner is anxious about a case which proves obstinate, and resists all ordinary modes of treatment; by turning to the *Digest* he finds hints and suggestions as to the methods to be pursued, and the necessity for a consultation may be avoided. It is often said that the *Digest* is difficult to understand; but we do not think that is the case. We have often referred to it, not infrequently when much pressed for time, and have rarely failed to find what was required."—BRITISH MEDICAL JOURNAL, August 7th, 1886.

"Not merely to practitioners who have access to great libraries, but to everyone, this book, in and for itself, has a value for what it suggests. Without looking up single reference, one may in perplexity obtain a suggestion when a suggestion is all that is needed."—PRACTITIONER, 1882.

"The range of inquiry suggested and of information conveyed is incalculable..... The mere reading of the *Digest* will thus impart an incredible amount of knowledge."—MIDLAND MISCELLANY, 1882.

"An erroneous impression exists that the *Digest* is a mere index, and that it is therefore of little or no value to medical men who have not a medical library at hand in which they can turn up the references given. It is surprising how much information may be obtained on any subject by merely a reference to the work."—ALABAMA REVIEW, September, 1882.

Is the book to be condemned by those who fail to grasp its merits? Is it not rather an illustration of the folly of offering gems to those who know not their value?

NOTES, LETTERS, ETC.

FUGITIVE OEDEMA OF THE EYELIDS.

MR. T. L. KENRICK DAVIES writes: I was interested in Dr. Illingworth's note of fugitive oedema of the lower lids, to which Dr. Tom Robinson has directed attention. From observation of a case lately in which the patient consulted me for "stiffness and aching of the lower eyelids," I concluded the oedema was due to the same cause as Dr. Illingworth attributed it to, namely, passive venous congestion in the infra-orbital region. The condition was most marked

REMARKS ON PAROXYSMAL SNEEZING.

By SYDNEY RINGER, M.D., F.R.S.,
Holme Professor of Clinical Medicine, University College, London.

AND

WILLIAM MURRELL, M.D., F.R.C.P.,
Lecturer on Materia Medica and Therapeutics, Westminster Hospital, London.

PART I.

THE frequency with which of late years cases have been recorded under the title of "Hay Fever," and similar terms, has attracted attention to a curious and interesting complaint, the very existence of which was not definitely recognised until the publication in 1819 of Dr. John Bostock's account of his own symptoms and sufferings. It is true that Heberden, in his *Commentarii de Morborum Historiâ et Curatione*, speaks of an annually recurring attack of catarrh in certain individuals, but he probably regarded it much in the same light as did Dr. Elliotson, who, in his *Præctice of Medicine*, speaking of this complaint says:—"I could not tell what to make of it, and I disregarded it entirely, supposing it to be a sort of aguish or hypochondriacal affection, of which those who had little or nothing to do became the subject." The disorder is of great interest, not only from the mystery which surrounds its earlier history, but from its prevalence in all countries, and the tenacity with which, once having attacked its victim, it clings to the unhappy sufferer during the best years of his life.

The names "hay fever" and "hay asthma," it must be admitted are unfortunately chosen, for the existence is now very generally recognised of a complaint presenting identically the same symptoms, but excited by causes other than the presence of pollen in the atmosphere. Bostock, in his second communication, published in 1828, called it the "catarrhus æstivus;" whilst Dr. Phebus, in 1862, in his well known monograph on the subject, speaks of it as the "Frühsummer Katarrh," or early summer catarrh. The names "summer asthma" and "summer bronchitis" are also used, but all these cases may be more appropriately classified under the general term, "paroxysmal sneezing," the unfortunate sufferers being appropriately called "sneezers." The attacks, whatever may be their exciting cause, may affect only the upper part of the respiratory tract, or they may involve the lungs, or both may suffer. The sneezing paroxysms usually alternate with or replace the asthmatic troubles, or one of them may preponderate. In both varieties we meet with cases in which there is itching or irritation of a part or even of the whole of the interior of the nares, or possibly the feeling of discomfort may involve the inner canthus of the eyes or the whole of the eyeball, being accompanied by repeated and violent attacks of sneezing and profuse watery discharge from the nose or from the nose and eyes. Again in both forms the irritation may attack the soft palate and pharynx, there being experienced in these parts a feeling of roughness, or as patients often call it, "scraping." The lungs too may be attacked, not only with asthmatic troubles, but by symptoms of bronchial catarrh more or less severe.

The subject of hay fever proper has been ably investigated by Dr. Blackley, whose experimental researches are generally recognised as being of the highest value, but it may be as well to point out that in those cases in which the paroxysms are indubitably excited by the emanations from plants all kinds of pollen are not equally virulent, their activity depending on the variety of grass from which they are derived. The grasses most productive of hay fever are the sweet-scented vernal grass (*Anthoxanthum odoratum*), the rye grass (*Lolium perenne*), and the sweet-scented soft grass (*Holcus odoratus*), and it is found that the fresh plant is less potent in its effect than the hay made from these grasses. Many years ago M. Vogel discovered that some grasses owe their odoriferous properties to the presence of benzoic acid, and it is a well-known fact that the vapour of this substance is capable of producing violent paroxysms of cough and sneezing, accompanied by irritation of the fauces. It is a curious circumstance, too,

that amongst the English branch of the Anglo-Saxon race grasses are the most frequent causes of attacks of paroxysmal sneezing, whilst with Americans the pollen of the rose and some other plants is regarded as being more potent. The frequency with which "rose fever," "rose cold," or "rose catarrh" prevails in the United States is well known, whilst in India the affection is often attributed to the blossom of the mango, which flowers in February or March, and exhales an odour not unlike that of pure terebene. In Great Britain, too, it is by no means rare to meet with people who are affected by other pollen than that of grasses. In a case which recently came under our notice the pollen of the common daisy (*Bellis perennis*) gave rise to more inconvenience than that of any other plant. We are told of a lady who could never remain in a room with even a single stalk of Indian corn without being seized with shortness of breath, and on one occasion when abroad she suffered from a severe attack of asthma from going accidentally into a room where a mattress stuffed with the leaves of Indian corn was being shaken. In another instance it is recorded of a man that he could never pass the shop of a certain rope-maker in his native town without suffering from dyspnoea, excited presumably by the dust from the flax. Cullen refers to the case of a man who was seized with fits of sneezing whenever rice was threshed in the neighbourhood of the house, whilst Trouseau tells us that he himself always had asthma if he remained for even a few minutes in a room with a bouquet of violets. The power of ipecacuanha dust to produce in certain susceptible persons attacks of shortness of breath has long been recognised. Cullen relates that the wife of an apothecary was seized with asthma whenever ipecacuanha root was powdered in her husband's surgery even if she happened at the time to be in another part of the house.

Sir Thomas Watson says: "I recollect a servant employed in the laboratory at St. Bartholomew's Hospital, when I was a pupil there, who had the peculiar ill-luck to be liable to this affection. Whenever that drug was under preparation he was obliged to fly the place. This idiosyncrasy is not very uncommon. A very small quantity of ipecacuanha dust is sufficient in such persons to bring on a paroxysm of extreme dyspnoea, wheezing, and cough, with singular anxiety and great weakness. The distress usually terminates by a copious expectoration of mucus."

Some people, although insusceptible to the action of ipecacuanha, suffer severely from exposure to linseed or scammony. Dr. William Smith, of Preston, records the case of a patient in whom a linseed-meal poultice provoked the symptoms, whilst in another instance the smell of mustard was the exciting cause. Powdered colocynth may have a similar effect, and an epidemic of sneezing which occurred in a house was traced by us to the use of bitter apple, which was powdered over the carpets and other articles as a preventive of moth. A medical student under our care assured us that the dust from a clean pocket-handkerchief always excited in him paroxysms of sneezing, to which he was subject, and he was so assured of this that he gave orders that his handkerchiefs should never be starched. The coryza induced by preparations of iodine made with methylated spirit is well known. Poyer mentions the case of a lady in whom asthmatic attacks were induced by scents of all kinds, and we are told of a sea captain engaged in the guano trade, who was so severely affected by the emanations from this substance that he had to relinquish his occupation.

Most writers include under the term "hay fever" similar attacks induced by the exhalations from cats, dogs, horses, and other animals. Hyde Salter, in his interesting work on Asthma, gives detailed notes of several cases in which the shortness of breath was induced by exposure to the effluvia of various animals, his list including not only cats, dogs, and horses, but wild beasts, cattle, guinea-pigs, rabbits, and hares. A patient, the proprietor of a well-known equestrian establishment always had his asthma brought on by the presence of horses, so that he was continually asthmatic. He had no suspicion of the real cause of his suffering till he made his fortune and retired from business, when his symptoms departed, only to return if by chance he visited his old haunts. Salter tells the story of a country clergyman who was always rendered asthmatic by the neighbourhood of a hare or a hareskin. If by chance he met a man who had been poaching, he at once detected him. When this gentleman was a boy studying with a private tutor, a fellow student, as a practical joke, put a dead hare under a sofa on which he was sitting, and he immediately had a severe attack of his complaint.

Bastian, in the *Philosophical Transactions* (vol. clvi. p. 583), relates some remarkable effects invariably produced on himself

whilst working at the anatomy of the *Ascaris megaloccephala* from the horse. These were a greatly increased secretion from the Schneiderian membrane, with irritation of it, causing continuous sneezing, also irritation of the conjunctiva, with such a sense of itching about the eyelids and caruncle lacrymales as to make it extremely difficult to abstain from rubbing them. When they were rubbed this immediately gave rise to a swollen and puffed condition of the eyelids, swelling of the caruncle, and extreme vascular injection of the conjunctiva, and if the rubbing were at all persisted in, actual effusion of fluid would take place under the conjunctiva, raising it from the subjacent sclerotic and cornea. At the same time that these effects were produced upon the mucous membranes, the skin of the face and neck was affected so as to cause a sensation of itching somewhat similar to that which exists in mild attacks of nettle-rash.

Several cases of paroxysmal sneezing produced by emanations from animals have been under our care, and many of them serve to illustrate points of interest. The first is a typical case of sneezing produced by emanations from horses.

A gentleman, aged 24, had two cousins who suffered from asthma, and a sister who was a cat-asthmatic. His father's cousin suffered from hay fever. He himself, when 23 years old, had bronchitis, and from that time until the age of 9 had attacks of sneezing and asthma. He then went to live at the seaside, and for four years was perfectly well. Little by little, however, after leaving the seaside both forms of attack recurred, sneezing first, then the asthma. For the last two years his sneezing has been growing better and his asthma worse, but he suffers more or less all the year round. He finds that either or both forms of attack may be brought on by coming near a horse, and this is the only exciting cause he can discover. One night at the theatre he felt oppressed and commenced sneezing, without being able to account for it. In a few minutes, in the course of the performance, a horse galloped on the stage, and his attack then became so bad that he had to get up and leave. He found that going into a stable would at any time immediately excite a paroxysm, and that the clothes of people who had been racing had a similar effect. One day at Malton some betting men got into the same railway carriage with him, and an attack was at once induced. The emanations from horses would sometimes bring on asthma and sometimes an attack of sneezing, and not infrequently both. The asthma was more likely to come on in a carriage or close space, the sneezing in the open air, the attacks always lasting as long as he was exposed to the exciting cause. Flowers and grasses did not affect him in the slightest degree, but he occasionally had peptic asthma as the result of an indigestible meal. During the sneezing attacks the conjunctivæ and the eyeballs itched, the conjunctivæ becoming red and congested. The itching was also felt over the whole of the inside of the nose, and was frequently accompanied by irritation of the throat. The nasal cavities were examined, but nothing abnormal could be detected. The sister's attacks, which sometimes assumed the form of sneezing and sometimes of asthma, were never excited by horses, but only by cats.

The following case of asthma and sneezing produced by contact with a caterpillar is, we believe, unique. Some years ago we had under our care a gentleman of neurotic temperament, who, about the age of 50, suffered severely from acute pleurisy the result of exposure to cold and wet whilst out shooting. He recovered, but from that time was subject to what he called "hairy caterpillars asthma." If by any chance he touched a caterpillar, especially a very hairy one, he was immediately seized with an attack of shortness of breath, often lasting an hour or more. Sometimes the paroxysms commenced with an attack of sneezing, accompanied by itching and irritation of the eyes and nose, with profuse watery discharge from both. He was not in the slightest degree affected by pollen, and he could pass hours in and about the stables without experiencing the slightest inconvenience. One of his daughters, who shared his temperament, was a cat-asthmatic, her attacks of sneezing and coryza being always induced by contact with cats, or even by the presence of one in the room. She was not subject to hay asthma, and ridiculed her father's objection to caterpillars.

The close connection existing between hay fever and intermittent sneezing is well shown in those cases where not only pollen but other excitants induce an attack.

The following is a case in point: The widow of a clergyman has suffered for many years from this complaint. She sneezes a good deal, but the running from the nose

and eyes is very profuse, and out of all proportion to the sneezing. During the attack she has itching of the whole of the nose and of the eyeballs and throat. The attacks occur all the year round, but are most severe in the summer. They often occur the first thing in the morning, as soon as she begins to move in bed. They are excited at any time by grasses, roses, privet, and, in a less degree, by other flowers. Driving in the face of a strong wind will always bring on an attack. Any dust, especially the dust of a bedroom, brings on a violent paroxysm, and sunlight is also a frequent exciting cause. Food at once affords relief, even when no stimulant is taken, the symptoms subsiding before the meal is finished. She never catches cold in the head, and the chest is not usually affected. The attacks last from one to two hours, and are followed by great exhaustion. She finds that she can at once obtain relief by going into a dark room. It is worth mentioning that her daughters suffer from the same complaint.

This case is of interest as showing the influence of light as an exciting cause. It is a good example, too, of what may be called a mixed case, the attacks being induced not only by pollen, but by other causes. It may, of course, be argued that all dust is liable to contain pollen, but in this particular instance bedroom dust was found to be more likely to provoke an attack than dust from other sources. The influence of sunlight in causing the attacks is one of the striking features of her complaint, and this is the case with many people who suffer from hay fever due to pollen. In some patients sunlight is insufficient to induce an attack unless the disease is aroused, so to speak, by the action of pollen, and then the rays of the sun will induce a paroxysm of sneezing, or increase its severity. In this particular hay fever is comparable with other neuroses, such as migraine and neuralgia. The complaint may be excited by a carious tooth, and as long as this irritation persists other minor causes, such as a puff of wind on the face, will bring on a paroxysm; but when the predisposing cause, the decayed tooth, or whatever it may be, is removed, the minor exciting causes fail to arouse the attack. In some instances, as we all know, strong sunlight alone is sufficient to excite a paroxysm of sneezing, and it is by no means uncommon to meet with people who cannot look at the sun without sneezing violently. We have a patient, for example who, whenever he leaves the house in the morning, if it be a fine bright day, sneezes for five or ten minutes, the attacks being so violent that they often cause him to lose his train. The frequency and violence of the sneezing vary greatly in different cases, but are not uncommonly sufficiently severe to justify the patient being classed with intermittent sneezers.

The following case illustrates the influence of strong sunlight in people not affected by pollen: A boy, aged 12, suffers from attacks of cough every morning between six and eight, accompanied by wheezing and tightness of the chest. He has suffered in this way for two years, and during that time has been liable to colds in the head and transitory attacks of bronchitis. Strong sunlight always makes him sneeze, and causes his eyes to be "full and red," so that the tears run down his cheeks. The sneezing is not excited by dust or pollen or by any other cause. His mother is a sneezer but not to any marked extent. Her mother suffered in the same way, and she had two sisters who were hay-asthmatics.

Dust, as we have seen, is a common exciting cause, its influence being attributed by Blackley to the very general distribution of pollen. We are not able experimentally to disprove this, but we have seen so many cases where this explanation seems to us highly improbable, that we have some hesitation in accepting it. Our difficulty is illustrated by the following case. A lady, aged 35, or thereabouts, suffers from severe attacks of sneezing, which will nigh shake her to pieces. During a paroxysm she is literally bent double, and suffers agonies of pain. They begin the first thing in the morning, but may attack her at other times during the day. The attacks may last only a few minutes or perhaps an hour or two; sometimes, however, they persist for twenty-four hours, or even three or four days. The sneezing is accompanied by profuse watery running from the eyes and nose, and the eyes become red and swollen. She soaks her pocket-handkerchiefs through and through, and her washing bill is a heavy one. The attack is always preceded by "pins and needles" over both nasal bones, the frontal sinus and the upper eyelid, with itching of the tip of the nose, but without any itching of the nostrils or irritation of the throat. The itching not uncommonly occurs without the sneezing, but the sneezing never

without the itching and the sensations of "pins and needles." House dust will bring on an attack, bedroom dust and the dust from shaking a bed being most potent. The dust of the street, curiously enough, does not affect her; indeed, she often experiences relief during a paroxysm from going out of doors. Flowers do not bring on the attacks, which cannot be due to hay, for she resides in a large city; they occur at all times of the year. Sunlight will not excite the attack, although she complains that it hurts her eyes. She obtains some relief from taking food, hot tea, or port wine. Her mother has been a sneezer all her life.

A middle-aged man, an ironmonger, has suffered from paroxysmal coryza and asthma for two years, the attacks being induced only by the dust of his shop. Other kinds of dust, for example that of a road, fail to affect him, and flowers, grasses, and bright sunlight are innocuous. The case is peculiar in this respect, that whilst coryza and asthma are excited only by the dust of his shop, he in certain localities suffers at night from simple asthma without coryza.

Sneezing may sometimes be induced by violent exercise. A patient, who has been a sneezer for twelve years, assures us that in his case this is the most powerful exciting cause, and he always suffers severely if he takes a long ride on his bicycle. The sneezing generally lasts half an hour or more, and is accompanied by profuse watery nasal discharge. When the exercise taken is unusually violent, the nose swells about the bridge, and the conjunctivæ become red and irritable. He does not suffer from itching of the nose or any part of the face. The attacks are never excited by dust, and he is not affected in any way by smoke, hay, or the smell of flowers. He has occasionally had an attack in the middle of the night, for which he can assign no cause. These night attacks, however, have ceased since he has worn a nightcap. Two years ago he became the subject of peptic asthma, and more recently caught cold, which brought on an attack of bronchitic asthma. The asthmatic attacks usually commence about two or three o'clock in the morning, and terminate with a sharp paroxysm of sneezing. His father was asthmatic, but has outgrown it.

Food is sometimes assigned as the exciting cause of attacks of sneezing. A nervous man subject to attacks of neuralgia stated that for nearly two years he had suffered from sneezing after meals, and especially after breakfast and dinner. The occurrence of these attacks was favoured by excitement, nervous fatigue, or brain work. He often wakes up with a migrainous headache over the left brow or at the back of the head, and then immediately after breakfast sneezes violently twenty or thirty times, the attack being accompanied by cough and expectoration, and running at the nose and eyes. He has never been able to discover any other cause for the attacks except food. It is probable that in this case the affection is central in origin. We assume that an impression conveyed from the stomach through the vagus and reaching its centre would, through diminished resistance in this part of the central nervous system, spread thence to that part of the fifth nucleus in connection with the nerves proceeding from the mucous membrane of the nose, inducing in this part of the nervous centre those molecular changes which impress on the sensorium the sensation of tingling or pricking, and this condition of the nervous centre of the fifth excites violent sneezing.

From these cases it will be seen that the exciting causes of attacks of sneezing are various, the chief being pollen, the emanations from various animals, and bright sunlight. In some instances it is difficult or impossible to discover any exciting cause, as is often the case in the allied affections—asthma, neuralgia, and migraine. In these cases the mucous membranes may be perfectly healthy, or there may be slight chronic catarrh of the nose.

The following case illustrates the power of this nasal irritation to intensify the attacks: The patient, a gentleman aged 45, has been subject to neuralgia for many years. He has had attacks of persistent sneezing for three months. They may occur at any time of the day, but are usually worse after dinner. He has constant tingling in the left nostril posteriorly, and in the region of the septum. At times this pain becomes much worse, and radiates over a large area, reaching the ala of the left nostril. This "sharp pang," as he terms it, excites the attacks of sneezing. There is a constant watery discharge, but this is intensified during the sneezing attacks. The discharge is worse from the nostril which itches. He is quite unable to discover any exciting cause, but is satisfied that it is not dust or pollen or bright light.

A lady, aged 70, has almost every night for years had attacks,

lasting from twenty minutes to an hour, beginning with itching behind the sternum, and leading to a severe paroxysmal cough, accompanied by profuse running from the eyes and nose without itching of the nostrils or eyes, and with only an occasional paroxysm of sneezing. This case is of interest from its affinity with asthma.

Asthma, as we know, often changes its character, and may be replaced by paroxysmal cough or dyspnoea. Many patients suffer from itching over the sternum, which precedes the attack. We know, too, that many diseases in their transmission from parent to child change their type; an epileptic parent, for example, begetting a neuralgic, migrainous, or rheumatic child, or several members of the family may have different neuroses. In other words, these same changes in the nervous system in transmission affect probably a different part of the central nervous system, and so induce a different set of symptoms. We know too that in the same individual one neurosis may replace another, and this interchange may occur not once but many times. In other cases two or more neuroses not only affect the same person, but the attacks may occur simultaneously, a fact well illustrated by the following case.

A little girl, aged 6, has had chronic Bright's disease for some years, but she is now nearly well, although a little cystitis remains. Every week, or sometimes oftener, she has attacks of running from the eyes, the lids becoming swollen, the upper especially, and the conjunctivæ suffused and bloodshot. The right eye is always more affected than the left, the difference being well marked. There is great intolerance of light, so that the room has to be darkened, and usually she keeps her eyes covered with a shade. The nose runs, but she seldom sneezes. The bowels invariably act at the onset of the attack, the motions being light in colour. She always vomits about half an hour after the commencement of the attack, and ejects a large quantity of bilious matter. The tongue is red and spotty, and frequently covered with circular patches like raw beef-steak. There is no shortness of breath, but the attack is followed by drowsiness. The only cause that can be discovered is excitement, but often enough the attacks come on when the patient has been kept quiet. It is thought that inattention to diet will intensify them and prolong their duration, but on this point the evidence is not clear.

THREE LECTURES

ON

TUBERCULAR JOINT-DISEASE AND ITS TREATMENT BY OPERATION.

Delivered at the Royal College of Surgeons of England, June, 1888

By ARTHUR E. J. BARKER, F.R.C.S.

Hunterian Professor of Surgery and Pathology at the Royal College of Surgeons; Surgeon to University College Hospital; and Teacher of Practical Surgery at University College.

LECTURE II.

In the light of the researches and deductions briefly alluded to in my last lecture, we have now to consider the behaviour of tubercular disease in the joints. That this is identically the same affection as that known under the same name in the lungs and other organs, there can, as I have shown, be no manner of doubt; and that the presence of the bacillus tuberculosis is associated with analogous tissue changes in the joints to those found in the internal organs, is also, I think, beyond dispute. But why the structures entering into the composition of the articulations are so liable to be infected, as appears to be the case, is one aspect of the question which claims a short notice.

In the first place, it is almost certain that here we are dealing with a secondary infection in the vast majority of cases; in other words, that the organism introduced into the system elsewhere and present in the blood has found, in its wanderings, a home peculiarly fitted for its growth in the tissues of the joint. That direct infection of the latter may take place through a wound has been shown more than once, notably by such cases as those recorded by Pfeiffer and Middeldorpf; but this must be such an exceptional occurrence as hardly to need consideration.

In speaking of infection of the joints it will, of course, be understood that only the synovial structures and the cancellous tissue of the bones are referred to. In these alone does the dis-

case take its origin, however deeply it may ultimately involve the other components of the articulation. Studied in its earliest stages, articular tuberculosis is seen to consist in the deposit of the characteristic granulations either in the synovial tissues, or the medulla of the ends of the bones, or in both together. In these tubercles, made up of the typical lymphoid, epithelioid, and giant-cell elements; the bacilli are often scantily represented, and require care and patience for their demonstration. That the avascular cartilage, the highly-differentiated, compact bone-tissue, and the fibrous material of the ligaments and capsule are primarily exempt, is clear even from the most casual examination.

The reasons for this must be sought for in several directions. In the first place, adopting the view alluded to above that the disease is only a local expression of a general infection, and that the specific is circulating in the blood, it is only to be expected that the characteristic foci of hyperplasia produced by the organism should be most frequently, if not exclusively, found wherever vascularity is greatest. Or, to put it conversely, as the blood is the distributor of the organism throughout the body, those tissues with a small vascular supply ought to have the greatest immunity from infection. And this is just what we find everywhere in studying tuberculosis. But looking further into the matter we can, I think, trace the operation of other factors, for it is certain that tubercular disease does not commonly develop in every part to which the organism is carried by the blood. We have seen elsewhere how predisposition of individuals plays an important part in the spread of this disease. Given, then, an individual predisposed by hereditary debility to tuberculosis, we might expect tubercle to manifest itself first at those spots in the system where the vital energy was at its lowest from one cause or another. Setting aside for the present the question of traumatic or other lesions, are there any special reasons why joints should be so frequently selected by the organism as a point of attack? Undoubtedly there are. It is well known that the disease generally finds its most fertile soil among the very young, probably because, among other reasons, the vitality of the young cells is unequal to cope with the invading organism. And, if this be true, we should expect to find that, with the bacillus once in the blood, those tissues which are youngest, or, in other words, approach most nearly to the embryonic type, should be most liable to suffer from its attacks. Now, such embryonic tissue is abundant in childhood, and most so at those spots where growth and physiological activity are greatest. In adults such tissue has become scanty, although we may find its analogue in the cellular products of plastic exudations. But the medulla of the ends of growing bones and the synovial structures both abound in embryonic tissue hardly yet differentiated, and are in active growth. And that this tissue all over the body is peculiarly liable to inflammatory disease of every kind, experience, whether of purely traumatic conditions or infective influences, abundantly proves. This fact may be noticed, for instance, in the so-called general septic affections.

But the matter may be put in another light. It may be suggested that young growing tissues being necessarily very vascular, the physiological hyperemia requires but a slight stimulus to convert it into a pathological congestion. Be this as it may, it is important to note that throughout the body highly differentiated tissues—such, for instance, as muscle or tendon—are not liable to inflammatory changes in anything like the same degree as the areolar tissues or the soft vascular material forming the basis of the synovial fringes of joints. And in the case of bones, we may observe that all inflammatory changes, whether purely traumatic or infective—as, for instance, after measles and scarlet fever—have their starting point, not in the cartilage or the compact tessel, but in the growing material underlying the periosteum and between the epiphyses and diaphyses, or in the medulla itself. That great physiological activity predisposes in some way to inflammatory disease could not be more simply or better illustrated than by reference to the frequency of suppuration in the breast during lactation and the rarity of this condition at other periods. Now, the physiological activity in the neighbourhood of joints in children is, of course, very great. We find here the most rapid bone growth, and a correspondingly active development of the synovial membrane. And it is in these structures that inflammatory troubles start so readily in children. Moreover, after the structures in question have attained maturity, inflammatory disease (apart from injury) becomes rarer and rarer in them. If one were asked, then, to suggest the most potent factors in the predisposition of joints to tubercular disease, one would be inclined

to say, in the first place, the inherent low vitality of the youngest tissues; and, in the second, high physiological activity—unless, indeed, we regard these two factors as one and the same thing. But this would, I think, be an improper view to take, for there does seem to be a difference between low vitality due to the age of a tissue and that susceptibility to give way before opposing forces found in the conditions produced by great physiological unrest. In this very case of the joints, we find that, after maturity has been reached, and the bones, having attained their full size, have lost their epiphyseal and periosteal embryonic tissue, they cease to be a prey to primary tubercle, while the synovial membrane is still liable to the disease, its functional activity being called into play as much or more than ever under the increased stimulus of the vigorous adult movements of the articulation. It is extremely difficult—nay, almost impossible—to accurately determine the relative frequency of tubercular disease starting in the synovial membrane and that starting in bone, and, after carefully examining numerous tables compiled with a view to elucidate this point, I cannot say that they come even near definitively settling the matter. But one point, I think, may be accepted as almost certain, namely, that tubercular disease starts more frequently in the bone alone in childhood, and in the synovial structures alone in adult life. If this preponderance of primary synovial disease in

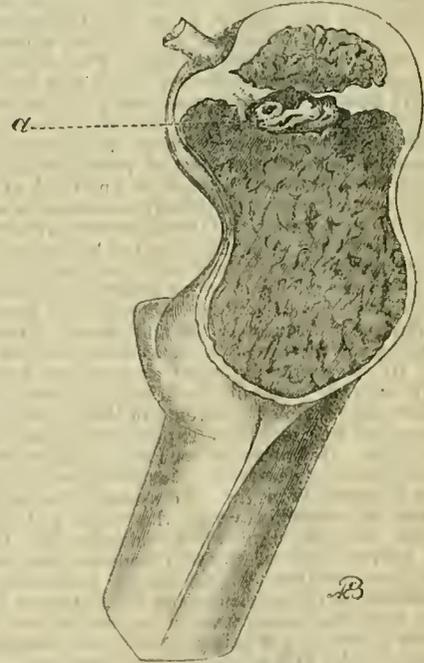

Fig. III.—Upper end of young femur, showing a focus of tubercular disease (a) at the usual starting point in the epiphyseal line of growth (from a specimen in University College Museum).

the adult be a fact, as I think it is, it would be best explained by the cessation of physiological activity in the bones while it continued in the synovial tissues, the other factors in the production of the disease remaining unaltered.

From the above considerations it would appear that there are several kinds of predisposition to tubercular disease of joints. In the first place, a peculiar debility may be inherited from phthisical or otherwise unhealthy parents, rendering the tissues of the child generally less capable of repelling the attacks of the parasites than had it come of a robust stock. Next there is the general predisposition of early age, the tissues of the young having less resisting force than those of the mature. Thirdly, certain localities in the body appear to be particularly open to the attacks of the organism, owing probably to the hurried physiological changes involved in rapid growth which are going on in them—changes which are associated with the presence of abundance of almost embryonic tissue and great vascularity.

In support of this view let me point to what is usually, if not invariably, found when the ends of the long bones, for instance,

are examined in the *earliest* stages of scrofulous disease. Take the upper end of the femur as represented in these drawings from specimens in our museum at University College (Figs. III and IV), or the lower end of the femur and upper end of the tibia, which I have copied from Koenig's plates (Figs. V, VI, VII). In every one of these specimens the initial lesion is found

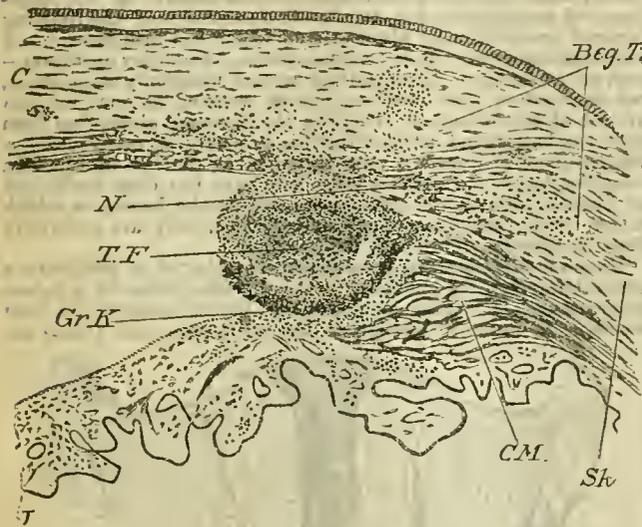

Fig. I.—Sk., sclerotic; C.M., ciliary muscle; I., iris; C., cornea; T.F., tubercular foreign body (the black dots represent bacilli); Gr.K., granulation capsule around latter packed with bacilli; N., new scar tissue in corneal wound with bacilli; Beg. T., beginning of tubercular hyperplasia around bacilli.

as a focus of hyperplasia, with caseation at the lines of most active growth between the epiphyses and diaphyses. And I could produce specimens showing that this is the rule for all the long bones and most of the short ones.

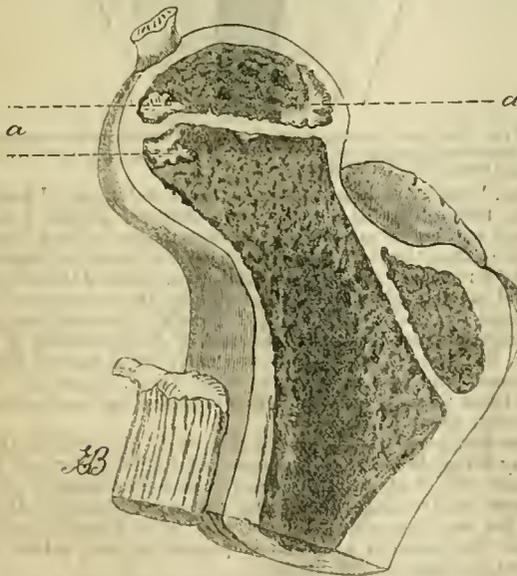

Fig. IV.—Section of the upper end of a young femur showing centres (a a) of tubercular disease at either side of the epiphysary fluid of cartilage. The surfaces of the bone have not yet been reached.

The bearing of this fact upon the question of early conservative operations on the ends of bones, *versus* later and more complete excisions of entire joints, is obvious, and needs no further emphasis here. Its practical importance I hope to refer to again later on.

Finally, there is the predisposition of external injury, using the term in its widest sense. In the case of the joints, injury may

render their tissues more open to the attacks of the bacillus tuberculosis circulating in the blood, in several ways acting singly or together. In the first place the violence may cause more or less active inflammation, with exudation of plastic material into the tissues around. Such exudation material resembles embryonic connective tissue, and seems to have very little power to resist the attacks of the organisms; in other words, it offers a favourable soil for its growth. This we have seen in the case of inoculation of the rabbit's eye with tubercle by Banmgarten (Fig. 1), where the bacilli spread most rapidly into the granulation capsule (Gr. K) and along the cicatricial tissue of the corneal wound (N) than in any other direction.

Further, the increased blood-flow to an inflamed part would also, *ceteris paribus*, involve a greater supply of bacilli to it than if the vascularity were normal. Again, without any active inflammation, or, following upon it, vascular atony may result from violence to a joint, and passive congestion of its tissues be the result, as is so often seen clinically. In this condition not only is the general nutrition of the part damaged, but the slowing of the blood-stream in the smaller vessels, amounting often almost to stasis, offers a better opportunity for the deposit of the bacillus in the parts around than is afforded with a normal circulation. And here, too, the greater amount of blood entering the congested area would bring a larger army of organisms to the attack. Finally, injury to a joint will often produce more or less extravasation of blood into its tissues, which remains for a time unabsorbed. With this blood the bacilli, too, escape from the vessels, and in

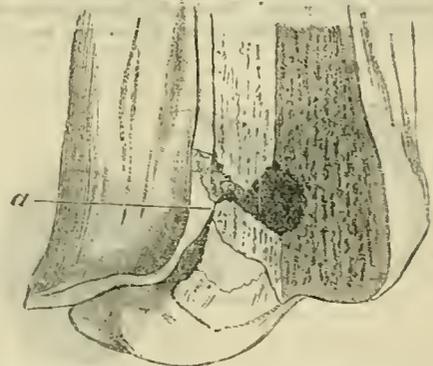

Fig. V.—Lower end of young femur, showing a focus of tubercular disease (a) close to the epiphysary line, and bursting on posterior aspect of bone outside the capsule (after Koenig).

their new position withdrawn from the current of the circulation, and in a state of rest they meet with the most favourable conditions for further growth, and soon form large colonies. This last-mentioned effect of injury is probably a most potent factor in the determination of the points at which tubercular disease shall start throughout the body, and will best explain its appearance in many unusual situations. Those who are not familiar with Schüller's experiments bearing upon this point will do well to give them their careful attention.

The parasitic nature of tubercular or scrofulous disease of joints has now, I hope, been sufficiently indicated, and its great power of extending locally and generally. In its modes of spreading by contiguous infection, through the lymphatics, and by entrance of its virus into veins, it offers, as we have seen, a close parallel to the modes of generalisation of the so-called malignant neoplasms. Indeed, there is much to justify our regarding tubercle itself in the light of a malignant growth, and our dealing with it accordingly. But that in spite of its capacity for wide dissemination it may remain for a long time localised in a joint, the rest of the system continuing unaffected, I need not undertake to prove; every clinical observer is thoroughly familiar with the fact. On the other hand, we must all have been impressed with the experience that in many cases after a long period of quiescence as a purely local affection, tuberculosis has rapidly become general. We must have noticed that this has usually followed upon some injury to a fully developed caseating focus, or the bursting of some caseous abscess, or, what is perhaps of greater importance for us as surgeons to remember, it has followed soon after a surgical operation upon a tuberculised part. From Wartmann's statistics, embracing the results of 837 resections, it would

appear that in at least 10 per cent. of the total number of deaths following operation, rapid, general, miliary tuberculosis supervened in such a way as to suggest strongly, if not to prove, that the surgical interference was the exciting cause of the generalisation of the disease. And I cannot help feeling, after a careful study of large masses of statistics, that if it were possible to analyse them more accurately, this percentage would be still higher.

This is a very grave consideration for the operating surgeon. But if, instead of closing our eyes to the fact, we set to work to determine the actual causal relation of operation to this general dissemination of tuberculosis, we shall in the future be able to eliminate one more risk in such cases, and shall escape the pain of seeing every now and then a patient relieved of his local disease only to succumb to rapid general tuberculosis set agoing by our operative interference. The explanation of this occasional generalisation of tuberculosis as the result of disturbance of a localised caseous form is to be found in what we have already considered. It will be remembered that the first effect of the introduction of a portion of tubercular tissue into the living rabbit's eye was the encapsulating of the same within a layer of granulation tissue. Now, beyond this latter (Fig. I, Gr. K.) the bacilli undoubtedly spread to some relatively small extent, as we have seen, but the fact remains that it is within this granulation capsule that they most rapidly multiply and accumulate, and that they appear to be imprisoned in a measure within it. In the same way, when inoculated in certain quantities in the human body, there is good reason to suppose that as a rule a similar capsule of granulation tissue is thrown out around the bacilli in sufficient quantity to limit their further extension, or at all events to prevent their

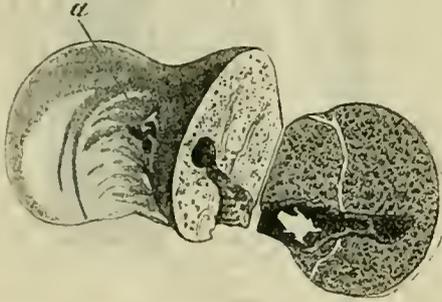

Fig. VI.—Section of young femur to show a focus of tubercular disease (a), starting at the line of epiphysary growth, and eating its way into the growth secondarily (after Koenig).

escape into the body generally in greater quantity than can be dealt with by the eliminatory powers of the various organs. That they can be got rid of from the system by excretion has been proved beyond doubt, for they have been found in several of the secretions; and it is also probable that to a certain extent, when the dosage is small and the individual vigorous, they can be totally destroyed within the body before they find a suitable soil for their growth.

Now, as long as this limiting layer of plastic exudation remains undisturbed and unbroken, whether it still preserve the form of granulation tissue or have undergone that organisation into fibrous tissue often found around caseous foci in various parts of the body, we are justified in believing that a very considerable obstacle is offered to the dissemination of the organisms within it, and that the disease remains in many cases almost or altogether localised. But if in any way this barrier is dissolved by suppuration or broken through by violence, a means of escape for the bacilli is provided, and more or less generalisation of the disease takes place. The organism may be distributed over a wider local area, may be carried along the lymphatics to be arrested partially or completely in the glands, or may gain access to an eroded or torn vein, and thus be carried in overwhelming numbers into the general circulation, as shown by Weigert. We are all familiar with the rapid swelling of the neighbouring glands which often takes place when a scrofulous joint has received a fresh injury or has been over-exerted; and here, too, it is probably a question of the disturbance of a latent tubercular focus.

Again when a caseating centre, say in the knee or hip, has burst through the skin, and the resulting sinus has become inflamed, how often do we see the inguinal or pelvic lymphatic

glands enlarge and in many cases soften, whereas they had been little or not at all affected during the months or years the tubercular forms may have remained in an unbroken and inflamed state. This can best be explained either by the increased stimulate given to absorption, by the access of pyogenic organisms previously excluded by the unbroken skin, and the taking up of the bacilli tuberculosis together with the newcomers; or the occurrence of suppuration has resulted in destruction of the limiting layer of granulation or fibrous tissue which had hitherto shut off the organisms from the rest of the system. And after operation—say, an excision—if the resulting wound unhappily suppurates, we have often both of these factors working at once for the spread of the infection. There is the increased absorption from the lymphatics, and besides there is probably in many cases a taking-up of the specific virus through the radicles of the vein wounded by the operation. These may have run close to the foci of disease, both in the soft tissues and in the bones, in which latter, from their anatomical arrangement, they are peculiarly fitted to take up all kinds of fluid matter.

From all this there ought to be considerable risk of producing a general infection by operating on local joint-disease of a tubercular nature. It would be possible to invoke further aid from statistics in order to strengthen the conclusion that this is so:

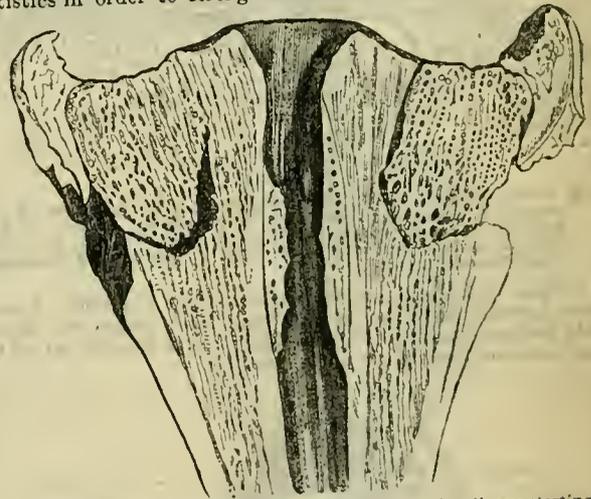

Fig. VII.—Section of young tibia, showing tubercular disease starting at line of epiphysary growth, and producing a sequestrum involving the joint secondarily (after Koenig).

but from lengthy and elaborate statistical statements I purposely abstain throughout these lectures, trusting rather that my audience will credit me with an earnest desire to give them fair deductions from the statistical evidence before me rather than weary them by a recital of the figures themselves. Some of these data may be found in such tables as those containing the experiences of Mr. Marsh and Mr. Croft in the *Clinical Society's Transactions*, and in the admirable monographs of Koenig, of Willemer and of Wartmann. But if such risks exist, we may, by a careful study of their causes and effects, learn to avoid them, or, at all events, reduce them to such an extent that they are far outweighed by the benefits of operation.

In the first place the improved powers of diagnosis at the present day bring the scrofulous diseases of joints under our notice at a much earlier stage than formerly, and consequently we have the option of treating them by operation or otherwise from the first. We are also able to determine with tolerable accuracy whether the articular affection is primary or only a local manifestation of a general condition.

How often joint tubercle is really a local affection it is difficult to prove by figures; but from Koenig's analysis of his own long series of cases, which is the most accurate guide that I know of, it would appear that in over 21 per cent. no evidence of any other tubercular affection could be found; and, as he remarks, this percentage will probably be found in the future to be much under the mark. We are speaking here of palpable evidence of infection elsewhere than in the joint only; for of course, in one sense, tubercular disease in the latter is always secondary—that is to say, the organisms have been imported into the tissues of

the articulation from some spot of primary inoculation. But there is ample evidence to show that, so introduced, it may localise itself in one part only of the body, such as a joint, and remain limited to that part for a long time.

Now by the mere fact of an early diagnosis one of the risks above alluded to may be reduced considerably, whether we operate or not. By attention to general hygiene in every way known to us the vitality of the tissues may be increased, and their power of resistance to the spread of the infection throughout the system be greatly enhanced. Again, by rest of the tubercular joint, and by protecting it from external influences, whether of varying temperature or of violence, the tendency of the local infection to spread may be restrained. The mere staying off of suppuration by these measures will also tend largely in the same direction, as may be seen from any of the carefully-recorded series of cases referred to, but in none better than in those of Marsh, Croft, Willemer, and Wartmann.

The general ill-effects of suppuration upon the *ultimate* results of tubercular joint-disease cannot be better illustrated than by an allusion to Willemer's tables, in which the knee is specially referred to. In these the results are recorded after the lapse of several years, the shortest time being two and a half, the longest nine years since the reception of the patients into hospital.

KNEE TUBERCLE (WILLEMER).

	Non-suppurating, 65.	Suppurating, 102.
Resected	51.0 per cent.,	against 60.0 per cent.
Amputated primarily	0.0 " "	16.0 "
Treated conservatively	49.0 " "	24.0 "
Of the last group treated conservatively there were, after a lapse of years:		
Complete cures	54.0 per cent.,	against 34.0 per cent.
Incomplete cures	18.0 " "	19.0 "
Ultimate cure by amputation	6.0 " "	13.0 "
Deaths	22.0 " "	34.0 "

In speaking of suppuration I do not mean that we should always aim at anticipating liquefaction of the tubercular material by operation. This softening is not of course suppuration, but is due to a fatty necrotic change in the infected tissues. When suppuration is referred to something quite different is meant, namely, that inflammatory exudation which sometimes is associated with caseation when a tubercular focus is subjected to injurious external influences.

It is most important to draw the clearest distinction between the liquefaction of caseation and true suppuration, not only as an abstract pathological axiom, but also for practical purposes. Of course the necrotic changes and fatty degeneration which take place in a caseating nodule are as different from the exudative and proliferative processes at an inflamed and excited spot as death is from life. But the matter has its practical bearing on treatment. If a surgeon adopts the view that no operation is proper until suppuration has taken place in the tissues of a joint, he will always operate in very advanced disease. Tubercular affections are not associated with true suppuration, except at what may be called an advanced stage; so that, if the surgeon waits until it is present, much valuable time will have been irrevocably lost. But if the rule is made to operate as soon as there is evidence of the commencement of caseation, the conditions of operation are totally different. We shall be interfering in such a case relatively early, and with all the consequent advantages. We must, therefore, in the future watch for and endeavour to recognise early the doughiness of commencing caseation rather than wait for the distinct fluctuation of suppuration.

Again, if the increased risk of generalisation of the tubercular infection associated with the access of pyogenic organisms through the formation of sinuses be recognised, we shall be more careful to step in early, and, before the latter have formed, will remove the whole of the locally infected tissues as thoroughly as possible, and secure union of the resulting wound by first intention.

Moreover, in undertaking any operation, we shall be careful not only to go wide of the disease, whether osseous or synovial, but also to do so with as little violence to the surrounding healthy tissues as may be possible. This last point is of the utmost importance; for, if we believe in the infective nature of the disease at all, we must believe in the possibility of re-infecting our own wound from the tubercular material we are engaged in extirpating; and this danger will be greatly enhanced if by vio-

lence in handling the tissues around we open up the small veins, or tear pockets from which the dangerous *débris* cannot be washed away so easily as from a clean-cut wound. Moreover, by rough handling during operation the likelihood of subsequent reaction and suppuration in the track of the wound is much increased, and the dangers of this in adding to the probability of general infection we have already seen. Finally, when we operate early before suppuration has taken place, we can ensure the rapid healing of the wound we have made. All subsequent disturbance of the freshly-injured joint can, in the case of such a clean, non-suppurating wound, be avoided by the use of permanent dressings and immovable apparatus. Vascular and lymphatic excitement will thus be speedily allayed, and with this the probability of the spread of the disease locally or generally from small quantities of the tubercular virus, perhaps left accidentally behind in the operation wound, be diminished. The sooner a wound is healed and the quieter it is kept for a long time after, the less likelihood will there be of a rekindling of the original process or the general dissemination of the virus from it. And not only this, but if suppuration is anticipated and prevented, we need have no fear as regards amyloid disease or exhaustion carrying off the patient. One has only to glance at any of the older lists of excisions to be impressed with the perils which lie in this direction, and to be convinced of how much might have been done to ward them off by forestalling suppuration by excision or getting rid of it by amputation.

I purposely abstain here from going into the question of the better prospect of a useful limb after an early excision than after extensive disease has necessitated free removal of bone. This may require consideration later on, but I am anxious now, in the first place, to emphasise the need there is of attending to the reduction of the mortality from tubercular disease of joints before we have anything to say as to the preservation of their functions. There is but little use of course in preserving to a patient the functions of his joint if the prospect of his being delivered from what may be called almost a malignant disease is not improved by our operation, still less if his chance of this is diminished. I need only remind you here that more than half of the total mortality after resections for tubercular disease is due to extension of the tubercular process, either locally or generally. Glance for a moment at Sack's analysis of 144 excisions of the knee with 25 deaths. In 13 of these the cause was tuberculosis. Or Mr. Croft's list of 45 excisions of the hip with 18 deaths, at least 6 of which were due to tuberculosis. Grosch's table of 120 cases of antiseptic excisions of the hip show the same thing. Here, with a mortality of 36.7 per cent., more than half the deaths were due to tubercular affections. These results have certainly not been due in every case to the steady advance of general tubercular disease which existed before the operation. And anyone who will carefully weigh the evidence which is now accumulating from all sides, and especially Weigert's researches on extension of the process through the veins, and Arnold's observations in the same field, can come to but one conclusion, namely, that the general affection has been set up in very many cases by extension from the local joint-disease, just as sarcoma and carcinoma become generalised from a primary source.

I have now briefly alluded to the chief risks which surround patients afflicted with tubercular joint-disease, and have hinted that one of them may be enhanced to a certain extent by operative interference, if undertaken without due caution. And we have seen in a measure the direction this caution against local re-inoculation of the disease should take. But there are other risks more especially connected with operation (though they may appear in the course of cases never submitted to the knife) to which attention must be directed for a moment; I allude of course to the septic infections of various kinds which may follow operation. In former years these risks were so imminent as to produce considerable hesitation about operating at all on a large scale in this class of cases. But, nowadays, with all the improvements of aseptic treatment, surgical infective diseases have become so rare that we are relieved of our chief anxiety in considering the propriety of interference by operation.

A comparison of any of the older statistics of the pre-antiseptic period with any of those of recent years will convince us of the stride that has been made in this direction. No better illustration could be given than Willemer's analysis of 195 cases of tubercular disease of the knee operated on in Koenig's clinic. Out of these only thirteen died as the direct effect of the operation, that is, of erysipelas, pneumonia, sepsis, tetanus, carbolic in-

toxication, and hæmorrhage—a mortality of only 13.6 per cent.

Now the vast improvement which has already taken place is but the first step in what is to come, and I venture to think that the time is not far distant when operations on tubercular joints will be performed with as little fear of accidental septic wound diseases as are our osteotomies and tenotomies, in which we do not expect even 1 per cent. of mortality from these causes. The only remaining risks then in connection with tubercular joint-disease will be on the one hand the acute infective tuberculosis connected with operation alluded to already, and the mortality from which at the present time may probably be estimated at about 10 per cent. of the deaths from all causes (Wartmann), and on the other, the chronic tubercular affections which arise in those cases independently of operation, and within the first few years after the latter, the death-rate from which is still higher. Recent statistics, however, especially those of Willemer, give us good ground for hope that here too a great improvement in the mortality may be effected by early operation and an intelligent recognition of the way to avoid reinoculation during the latter, so that on the whole the prospect for the operator is daily growing brighter in this region of surgery. At all events we now know two at least of our great enemies in this field, and we have also learned the tactics necessary to defeat them. And suppose for a moment we are able to wipe out completely the mortality from pyæmia, erysipelas, etc., due to operation, and also that from acute tubercular meningitis, etc., set up in all probability by the latter, we should see such a table, for instance, as that of Mr. Croft's hip incisions, altered marvellously for the better. We should see 39 per cent. of the total number of deaths due to the first set of causes, and 11 per cent. due to the second swept away with one stroke; in short, 50 per cent. of the total mortality would be done away with for this terrible class of affections. Moreover, this probably does not represent anything like the gain which would indirectly follow, and which will follow I believe firmly in the near future now that we are recognising the true nature of the risks to be combated.

Leaving this brief, and I am conscious necessarily imperfect, sketch of the nature of tubercular joint-disease to serve as an indication of the line of action we should pursue in dealing with it by operation, I pass on now to consider the methods which I venture to consider can most be relied on in effecting our object. And here let me say at once that I think in the case of most of the joints of the extremities the choice, when we can make a choice, should only lie, as far as operation is concerned, between early excision, partial or complete, and amputation. The practice of excising in advanced disease cannot be too strongly deprecated. After what has been said above regarding the dangers of producing a wider local infection and a general tubercular disease by imperfect interference with a local focus in a debilitated patient, and about the other risks bound up with late operation, this need not be further insisted on here. When tubercular disease is far advanced we shall find better ultimate results from the simple cleansing of sinuses and opening of abscesses than from excision, and better still from amputation. If we examine any long list of accurately recorded excisions we must be struck with the fact that it is the operations on late cases that have so fearfully swelled the mortality hitherto, and made them compare so much less favourably than we would wish with series of cases treated entirely without any severe operation. I do not think that the service which Mr. Marsh has done in emphasising this point by his tables recording the result of hip-joint disease treated without excision has been sufficiently appreciated.

But we cannot conceal from ourselves that operative interference with tubercular joint-disease without actual excision, that is, by the opening up of abscesses and the scraping out of sinuses, has also many dangers connected with it, and should be resorted to with the utmost caution for the reasons given above. Every surgeon of any experience must have regretted often having persisted in opening abscesses and scraping out sinuses in the hope of saving an extremity, only to see his patient succumb to general tuberculosis or septic infection where an amputation would have saved life. I cannot help feeling that conservative surgery has gone too far in this direction at the present day, and that with our newer views as to the true nature and tendencies of tubercular joint-disease we must aim at bringing about a reaction in favour of amputation well above the diseased area in many advanced cases. The direction which the conservative surgery of the future should take is to try to recognise the disease as early as possible, and, if it is distinctly on the increase in spite of the

best hygienic measures, to attack it by early and free operation, so that, on the one hand, only sound tissues are left behind, and, on the other, the resulting wound shall not be so severe as it would have to be later on, and may heal by first intention.

What, then, are we to consider as proper cases for early interference? It is quite plain that a considerable number of tubercular joint-diseases may run their course without any appurpuration either to arrest of the local condition or to death from general tuberculosis. If we turn to Mr. Marsh's invaluable tables of 401 cases of hip-disease, for instance, treated *without* operation, we find that 124, or 31 per cent., did not suppurate; by which I suppose is meant that no caseous abscesses in and about the joint could be detected. Now, of these 69.3 per cent. were cured or convalesced, 20.2 were incompleated cases, and 10.5 died. This is striking contrast to the results in suppurating cases not operated on given in the parallel column of the accompanying table.

HIP-DISEASE. (MARSH).

	Non-suppurating.	Suppurating.
Cures or Convalescents ...	69.3 per cent.	against 42.5 per cent.
Incomplete cures ...	20.2 "	" 24.3 "
Deaths ...	10.5 "	" 33.2 "

Taking the most hopeful view of the middle group, we may perhaps assume that about 89 per cent. of these non-suppurating cases recovered with more or less useful limbs, and between 10 and 11 per cent. died. And although at least 9 per cent. of the deaths were due to tuberculosis of internal organs, which might have been prevented by early operation, I think we must admit that the results in these cases were very good, and such as might justify our abstaining from all operation in non-caseating cases. And if this is true of the hip, it is more so of other less important joints.

I think, then, that for the present at all events, we might make it a rule that, as long as there is no distinct evidence of the presence of caseation in tubercular joints, so long may we be content to wait while treating them by other means. But does the converse of this hold good? Ought we to operate early so soon as we are satisfied that caseation is commencing and advancing? This question, I think, it is quite safe to answer in the affirmative, except in very exceptional cases, as, for instance, where internal organs are also affected with tuberculosis. And I venture to think it is much to be regretted that this is not accepted yet as an established rule.

Taking Mr. Marsh's table of hip cases again for illustration, we find that suppuration was observed in 69.3 per cent. of the group not treated by operation of any kind. Here the mortality was high, namely, 33.2 per cent., as against 10.5 of the non-suppurating cases. Of the total of deaths, 25 per cent. at least died of general tuberculosis, probably many more; for, in another 25 per cent., the cause of death was unknown. Again, 31 per cent. at least succumbed to albuminuria and exhaustion. Now, it is fair, I think, to assume that an early excision in these cases before caseation had commenced would have almost or entirely wiped out the latter group; and, if so, it would have reduced the total mortality. And although there would be the set-off of the risks of operation had excision been practised, these would not at the present day go near to raise the mortality again to its original figure. But besides preventing albuminuria and dropsy, early excision would probably greatly reduce the mortality from general tubercular disease, although late interference might run some risk of increasing it.

In view of these and other considerations, I venture to think that it would be a wholesome rule that in cases where general tubercular disease does not contraindicate it, the infected tissue of a joint should be thoroughly removed so soon as it is suspected that caseation is advancing in it. Further, I believe that until some such rule is adopted as a general guide, improvement in the results of operations on tubercular disease of the joints will be very slow. Too often we see cases allowed to run on to the formation of large abscesses, with sinuses burrowing in all directions, which are only treated by excision when the patient is brought very low indeed, and where the prospect of thoroughly eradicating all the tissues infected with tubercle is very slender, while the risk of producing further infection is great. Moreover, the severity of such an extensive operation as is necessary in such a case often most seriously influences the general nutrition of the patient, and, if it does not actually destroy life at once, it goes far to render the system less able to fight against the inroads of pyogenic organisms, and against the development and spread of the tubercular bacilli already present in its tissues. In such cases of advanced

suppuration the proper treatment will either be to let them run their course without operation, but with every care as to general hygiene, or, in the case of the extremities (excluding the hip), to subject them to amputation, which, though it maim them, nevertheless preserves them in many cases from the risks of septic or tubercular infection, local or general, and from amyloid disease and exhaustion. They certainly are unfitted, in the vast majority of cases, for conservative operations of the nature of excisions.

Having now considered some of the main questions which, I venture to think, ought to influence us in treating this disease by operation, we turn to the consideration of the operative measures themselves by which we may hope to attain our object. In doing so I will for the present exclude the non-caseating group of tubercular joint-disease from consideration, and propose that we should limit ourselves to the operative treatment of those cases only in which definite caseation can be diagnosed in one or more tubercular foci about a joint. It is assumed, of course, that everything possible is done by rest and other appropriate general treatment to limit this degenerative change as much as may be; nevertheless, it is advancing. Can anything be done by operation short of actual extirpation of the diseased tissue to hinder the local disease? I fear not much. A great deal has been tried in the way of injection of various germicides into the diseased area with the object of killing the organisms which are producing the complaint, but so far the results have been very unsatisfactory. Injections of carbolic acid and bichloride of mercury have been employed in this way but without avail, and are now with one consent abandoned. In iodoform, however, there seems to be a growing belief that we possess a powerful agent for the destruction of the bacillus tuberculosis, and this may be brought to bear upon the latter in various ways. In the first place it ought to be noted that those who have employed iodoform largely in the dressing of wounds made in and about tubercular joints are almost all agreed that their results have been immensely improved, and, from what they have observed, are inclined to attribute this to the use of the drug. My own experience entirely confirms this view, and I am inclined to regard the free use of iodoform as one of the most important advances which have been made of late in the dressing of excision wounds for tubercular disease; but whether we can effectually employ it before the latter has reached the point requiring excision or not is another and an important question. I think, however, that we have now enough evidence of its usefulness in dealing with caseous tubercular foci elsewhere to encourage us to try its influence on the joints. Strumous abscesses have been shown over and over again to dry up and heal after repeated aspiration and injection with iodoform and glycerine emulsion, and I have myself had several cases of the kind. I think, then, that when there is evidence that a tuberculous deposit in or around a joint is softening into a cold abscess, we will do well first to aspirate all the contents of the latter through a large needle if we can, and replace the removed liquid by the now well-known glycerine emulsion, just as we do with a cervical or lumbar abscess. Besides its germicidal properties, which have been proved by experiment in such cases to be very great, this emulsion has, by virtue of its high specific gravity, the property of gravitating into the deepest parts of tubercular cavities, and even through thick deposits of caseous debris, which rise gradually through it until they float upon its surface. This can easily be demonstrated by half filling a test-tube with the contents of a strumous abscess, and then gently pouring in some of the emulsion on to the top. In a few minutes the position of the two fluids is reversed; the emulsion fills the lower half of the tube, the caseous debris has floated to the top. Now if this takes place in the body, and if the iodoform be a germicide, we have it brought into the most intimate contact with all the deeper parts of a tubercular cavity, and not only this, but as fast as liquefaction or suppuration takes place, the products of the process float up through the emulsion, and the iodoform remains below undisturbed. But while suggesting a trial of this method of treatment for early caseous abscesses, I should be very sorry to persist in it if there were evidence that the disease was steadily advancing in spite of it. I should in every case endeavour to forestall the bursting of an abscess and would operate.

This brings me to the consideration of the methods of actually extirpating tubercular tissues. A joint has, we will suppose, been infected. There has been relatively slight injury; the first decided reaction has passed off, leaving the part swollen more or less, but with comparatively little pain. At this time there is probably no rise of body-temperature. The joint cannot be made

to execute all its movements to their full extent, except under an anæsthetic, but it is still used by the patient in a guarded way. Presently pain increases, and swelling becomes very evident. There is more decided fixation of the joint, and even under chloroform its movements are not free. A little later there is a slight rise of temperature in the evening, which recurs with regularity. A careful examination of the swollen part may now detect a certain amount of doughiness or deep fluctuation, or, at all events, a softness suggesting liquefaction of tissue at one spot or another. There seems to be good reason to believe that in a large proportion of cases uncomplicated by other disease elsewhere these two last symptoms commonly go together; that is to say, that there is usually no regular rise of temperature due to strumous disease of a joint, unless the process of caseation has begun and is progressing. Again, there is nearly always a regular evening rise when liquefaction is well advanced, and almost certainly when actual suppuration has been grafted on to the process of caseation.

Now in a case with the general outlines just given, in which we suspect that liquefaction has taken place, and where the ordinary treatment, including, perhaps, the injection of iodoform, has been tried, there may still be considerable room for doubt as to how far the disease has affected the ends of the bones or the synovial membranes—whether, therefore, an excision or a more limited arthrectomy may be required. Are we then still to wait and watch such cases until unmistakable evidence is at hand of extensive destruction of the tissues of the joint? Most decidedly not. Surely we are fully justified in making an exploratory incision into the articulation, in order to investigate the actual condition of things. Guarded by antiseptics we now make exploratory incisions in doubtful cases into the peritoneal cavity, the pleura, the bladder, and even into the brain, and we are certainly justified in extending this invaluable aid to diagnosis to the joints also. The risks are infinitesimal, with rigid asepsis and the use of Esmarch's tourniquet; the gain is immense, whether we suspect bone or synovial disease. Moreover, such incisions should be free, seeing that with the elastic bandage we need not fear bleeding. We know now from experience accumulated in the treatment of fractured patella and of loose bodies, that joints may be freely opened without the slightest damage to their functions, and where far graver issues are involved than in these last-named conditions, we should not hesitate to incise them widely for the sake of accurate diagnosis. We have furthermore the encouraging prospect, in a considerable proportion of cases, of being able to reach and eradicate a more or less local form of extra-articular tubercular disease, either in the synovial membrane or bone, without materially impairing the functions of the joint. Everyone who has read the record of them must have been greatly impressed by those cases occurring, for instance, in Koenig's clinic, and I believe paralleled elsewhere, in which joints have been opened for examination, and large wedges of redundant tubercularised synovial tissue been removed and the wound stitched up again, with the result that not only have the functions of the part been restored completely, but also that the disease has been arrested permanently, although probably all the tubercular tissue had not been eradicated. This experience is most remarkable, and would be almost incredible did we not know that a parallel is found in the case of general tubercular peritonitis. Many cases, you will remember, of the latter disease have been treated by abdominal section and cleansing of those parts of the cavity accessible to the operator, with the result of complete arrest of the disease, although there was no pretence that all the tubercular material had been removed.

We may therefore, I think, encourage one another to much freer exploration of joints by incision than we have hitherto practised, assured that, with care, there is little or no risk, and that much of the difficulty of diagnosis of tubercular conditions in an early stage will thus be overcome. This difficulty in determining the exact stage of the disease and its primary seat in a joint is, of course, one of the chief obstacles to our successful treatment of it by operation. If we could in all cases localise the primary focus early, we should be able in a very large proportion of them to extirpate it before it had infected the surrounding tissues, or had poured its virus into the circulation either through the lymphatic system or through eroded veins. Not only should this be possible, but it has been shown to be feasible without seriously impairing the functions of the articulation by many cases recently placed upon record by several surgeons, and notably by Koenig and Sandler, in the case of the knee. But unless formal exploratory operations are frequently resorted to at an early stage of the disease, such results will be few and far between.

A LECTURE ON CHRONIC RHINITIS AND ITS SEQUELÆ.

Delivered at the Eye, Ear, and Throat Hospital, Edinburgh.

By G. HUNTER MACKENZIE, M.D.,

Laryngologist to the Hospital; Vice-President, Section of Laryngology and Rhinology, British Medical Association, 1885.

SINCE Vololini first demonstrated the causal relationship between nasal polypi and asthma, the study of nasal diseases has become of increased importance, not only from their direct effects, but also from their secondary or reflex results upon the organs of respiration.

In discussing the symptoms and results of nasal disease, not only have we to bear in mind the various functions and sensitiveness of the general nasal mucous membrane, but also its intimate relationship to certain passages, cavities, and spaces, such as the nasal duct, the antrum, the frontal sinuses, and the Eustachian tubes, as also the peculiarity in structure of that portion of the membrane covering the inferior turbinated bone in its whole extent. This possesses the character of "erectile tissue," is consequently liable to sudden congestion and swelling, and appears frequently to be the source of reflex phenomena. The connection between the nose and the passages and spaces now referred to may, in nasal disease, lead to their being similarly affected, with characteristic symptoms in each instance.

The more common affections of the nose and its mucous membrane are of the simple inflammatory type, acute or chronic. As a result of chronic inflammation there occur, in the first place, a swelling and thickening of the nasal mucous membrane, more particularly of that covering the inferior turbinated bone, which itself also may be thickened from participation in the inflammatory process. This thickening may extend over the whole of the erectile area, or may be more or less localised, in the latter instance forming tumours of a soft or firm consistence. After this chronic inflammation has lasted for some years, it is said occasionally to undergo atrophy and thinning, and now the atrophic form of rhinitis supervenes. This atrophy may even affect the bones. There are thus two forms of chronic inflammation of the nasal mucous membrane, the hypertrophic and the atrophic, the latter of which is supposed to be consecutive to the former, though some authorities, with whom I agree, believe that the atrophic may exist from the first. It is frequently associated with *ozæna*, and may extend to the pharyngeal mucous membrane (pharyngitis sicca), or along the Eustachian tube to the tympanic cavity and drum (sclerosis). Acute rhinitis is usually bilateral; the chronic form may be mainly confined to one nostril, or, at any rate, may effect more marked changes in the nasal mucous membrane of one side than the other.

Chronic rhinitis has such an important influence, not only upon the nasal mucous membrane and its functions, but also upon the sense of hearing and upon the integrity of the whole respiratory system, that it is necessary to dilate upon it to some extent. I am the more anxious to do this as this causal relationship is frequently overlooked by the practitioner, with therapeutic failures as the result. I propose, therefore, to consider in some detail certain of the results which are liable to be induced by its occurrence.

1. *The Effect of Chronic Inflammation upon the Nasal Mucous Membrane and its Functions.*—The effects of this structural change of the nasal mucous membrane are seen in the blunting or abrogation of the senses of smell and taste, the partial or complete cessation of its respiratory functions, and, from augmented irritability, a decided tendency to evoke reflex phenomena.

The loss of the sense of smell (*anosmia*) may be owing to either central or peripheral causes. The former may be disease of or injury to the olfactory nerves or bulbs or the olfactory centre, the latter, certain conditions existent inside the nasal cavities. The degree of *anosmia* depends upon the amount of blocking of the nasal fossæ, as also upon the condition of the mucous membrane in regard to nutrition, secretion, moisture, and dryness. Thus, according to Morell Mackenzie, long-continued paralysis of the

fifth nerve destroys smell by interfering with the proper nutrition of the mucous membrane. It may also happen that, as a result of chronic rhinitis, the internal structure of the nose is such as to unfit it to direct the air over the olfactory area. In atrophic rhinitis, with wasting of the inferior turbinated bone and its mucous membrane, the air on deep inspiration has not the advantage of impinging upon and being deflected into the olfactory area by the anterior end of the inferior turbinate bone. A similar state of affairs arises when, owing to destruction of the nasal cartilages, the openings of the nose become vertical instead of horizontal. In both these instances the air, despite the act of deep inspiration or sniffing, cannot be drawn over the olfactory area, but invariably passes along the inferior meatus towards the lungs. In degree corresponding to the amount of *anosmia* present is the loss of the power of appreciating flavours, which also depends upon the olfactory nerve. The sense of taste is consequently correspondingly blunted.

The respiratory functions of the nose are necessarily impaired in chronic inflammation and thickening of its membrane, especially when, as frequently happens, the inferior turbinated bone is the area most affected. The open mouth and vacant look which characterise these cases of nasal obstruction and oral breathing must be well known to you all. Sleep is also restless and noisy; the mouth and throat are dry and uncomfortable; and the general nutrition, especially in children, is impaired.

Any description of chronic rhinitis and its effects upon the nasal mucous membrane would be incomplete without reference to the subjects of *ozæna* and of neoplasm. *Ozæna*, as already stated, is usually associated with chronic atrophic rhinitis with a purulent secretion, which dries and forms a crusty coating with an offensive odour. Woakes proposes to restrict the term to cases of disease of the ethmoidal frontal, or sphenoidal cells. It appears to be doubtful whether the odour encountered in this complaint is not met with in cases of ordinary chronic catarrh of the nose. This much can be said about *ozæna*—that it is always associated with more or less chronic atrophic rhinitis, and that, whilst its radical cure is hopeless, it can be greatly benefited by the treatment appropriate to this complaint. *Ozæna* is usually bilateral; when unilateral, it is supposed to be characteristic of abscess of the antrum.

The thickening resulting from chronic rhinitis, instead of extending uniformly over the nasal mucous membrane, may become localised, and so form mucous, bony, or cartilaginous tumours. It is important in this connection to distinguish those tumours, when situated over the region of the inferior turbinated bone, from the vascular swellings which occasionally arise in connection with the erectile tissue of this region. This can be done by the local application of cocaine, which causes the latter to disappear by contraction of the vessels, but has no effect upon the former. As results of long continued chronic inflammation in the superior nasal region, we occasionally find mucous growths or polypi, whose favourite seat is the middle turbinated bone, whence they protrude into the general cavity of the nose. They are always associated with a condition of chronic inflammation of the nasal mucous membrane, and sometimes with necrosis of the nasal bones.

2. *The Direct and Reflex Effects of Chronic Rhinitis upon Contiguous Structures.*—From direct extension of the inflammation of the nasal mucous membrane, adjoining cavities and their communicating canals may participate in the inflammatory process. Thus the ethmoidal and sphenoidal cells and sinuses may become affected, and become filled with purulent secretion. When the frontal sinuses are implicated, frontal pain and headache become troublesome symptoms of the complaint. In addition to direct extension by continuity of tissue, it is possible that, as suggested by Woakes, catarrhal symptoms develop in contiguous structures from the identity of the vasomotor nervous supply, an example of which is seen in the occurrence of herpes labialis in nasal catarrh. From the irritation of the filaments of the second division of the fifth nerve supplying ordinary sensation to the nasal mucous membrane, and the free distribution of this nerve to the face, it is not unusual to have facial neuralgia associated with, and probably dependent upon, chronic rhinitis. Headache (different from that due to direct extension of the inflammation to the frontal sinuses) vertigo, and even epileptic attacks have been clearly traced as owing their origin to intra-nasal inflammation. It is interesting to note that, as recently pointed out by Lauder Brunton, similar symptoms may spring from carious teeth with complete absence of toothache.

3. The Effects of Chronic Rhinitis upon the Ear and the Sense of Hearing.—In chronic rhinitis the sense of hearing may be affected in three ways: (a) By direct extension of the inflammation backwards through the posterior nares to the naso-pharyngeal space. According to Woakes, affections of hearing are a most important and frequent complication of post-nasal catarrh, occurring in 95 per cent. of the cases. Blocking of the Eustachian orifices may be aided by the participation of the pharyngeal tonsil in the chronic catarrh, which may enlarge to such an amount as to press directly upon the openings of the tube. (b) Defects of hearing may also be produced by the nasal stenosis in this way. Nasal breathing having been partially or completely arrested, the current of air in mouth-breathing no longer bathes the Eustachian orifices, and a condition analogous to that occurring in direct obstruction of the Eustachian tubes is brought about. In both instances the amount of air necessary to equalise the external pressure upon the drum is insufficient, and this is also liable to be withdrawn during the acts of swallowing. (c) Another factor in producing deafness is seen in the condition of the palato-tubal muscles which, from the long continued irritation of the catarrh, are liable to become more or less paralytic, and so incapable of discharging their function in connection with the opening of the tubal orifice to the admission of air.

4. The Direct and Reflex Effects of Chronic Rhinitis upon the Vocal and Respiratory Organs.—These are amongst the most important results of chronic inflammation of the nasal mucous membrane. Everyone is aware of the important modifications of the voice which ensue from partial or complete blocking of the nose—modifications varying from loss of timbre and harshness to complete inability to utter the nasal vowels and consonants. The voice may further become husky or hoarse on account of the supervention of chronic laryngitis from the action of the cold and impure air during oral respiration. Nasal obstruction, in short, seems to me to be one of the most important and generally overlooked causes of chronic laryngitis. I am desirous to direct your attention to the close and intimate relationship which frequently subsists between chronic nasal inflammation and certain respiratory disorders, such as simple cough and asthma. It seems that, owing to reflex dilatation of the vessels of the bronchial mucous membrane, simple bronchitis may also thus be produced.

Voltoolini's discovery—that in certain instances nasal polypi had a clear causal relationship to asthma—has received such ample confirmation from the observations of other practitioners that its truth may now be considered as indubitably established. More prolific even than polypi as sources of local and reflex disturbances are the erectile-tissue tumours, to whose occasional presence I have already referred. The area over the inferior turbinated bone is said to be particularly irritable, probably owing to its containing so much erectile tissue. Some observers (John Mackenzie), however, say that the posterior part of this area and the corresponding part of the septum are the most liable to induce reflex phenomena. My experience has been that irritation of any part of the mucous membrane may, under certain circumstances, induce reflex phenomena.

Nasal asthma and cough, then, are induced by mechanical irritation of a hyperæsthetic mucous membrane. This may be induced by the action of polypi, particularly when the position of the head is such as to fill the cavernous sinuses and cause turgescence of the mucous membrane. This is most apt to occur in the lateral recumbent posture, and explains why these attacks, as well as stuffiness of the undermost nostril, occur so frequently during sleep. Preceding or accompanying these attacks of asthma and coughing are usually sneezing and a copious flow of mucus from the nose. Sneezing is a reflex act, due to irritation of the fifth nerve, and, whilst it may be induced by irritation of nerves in other parts, is usually of value as indicating the presence of irritation of the nasal mucous membrane.

The fact of the simultaneous occurrence of nasal polypi or hyperæsthesia of the nasal mucous membrane, such as frequently results from chronic rhinitis, with cough, asthma, or bronchitis, points to the necessity of making a careful examination of the nasal cavities in all cases of respiratory disorders. It is not always possible to say whether this causal relationship obtains in a given case characterised by the presence of both pulmonary and nasal disorders. It is in favour of its existence, however, if the nasal symptoms now alluded to precede the respiratory attacks, or if mechanical irritation of the nasal mucous membrane by means of a probe indicates hyperæsthesia, and more so if it is the means of evoking a reflex act, such as cough. A neurotic basis is probably an important element in most of these cases.

Chronic rhinitis appears under other forms than those we have just been considering. It is a prominent condition in the malady known as hay fever, a latent or recurrent complaint in which there exists a hyperæsthesia of the nasal mucous membrane to the influence of the pollen of certain grasses. In newly-born children a condition of rhinitis analogous to the ophthalmia neonatorum is sometimes present, and is apparently due to a specific inflammation of the nasal mucous membrane by the vaginal secretion during parturition. It may become chronic. This rhinitis neonatorum is productive of serious inconvenience and trouble to the child, not only by preventing sleep, but by obstructing nasal respiration, and so rendering impossible the act of sucking.

Rhinitis, in a more or less chronic form, may complicate other diseases. Attention has, for example, been recently directed to the co-existence of whooping-cough and nasal catarrh, and it is stated that this disease has been cut short by treatment directed to the nose—insufflations of dried coffee and boric acid in equal parts, or of pulverised benzoïn.

Amongst the results or sequelæ of chronic rhinitis may be mentioned certain connected with glands. The lymphatics of the nose open, some into a gland in front of the vertebral column, others into a gland situated in the parotid region, whilst a third set discharge into certain of the deep cervical glands lying in front of and beneath the sterno-mastoid muscle. Chronic inflammation of the nasal mucous membrane may consequently cause enlargement and even suppuration of these glands, and thus we may come to have a retro-pharyngeal abscess dependent upon intra-nasal inflammation.

I ought not to finish my remarks on chronic rhinitis without directing your attention to the subject of post-nasal or naso-pharyngeal catarrh. Accompanying this condition may be enlargement of the pharyngeal tonsil and naso-pharyngeal vegetations. This variety of catarrh is characterised by a troublesome morning cough and sanguineous expectoration, frequently accompanied by vomiting. As already remarked, it is a frequent cause of deafness, and by direct extension to the larynx and pharynx, undoubtedly induces secondary inflammation of these regions and of the tonsils, and so aggravates the symptoms of nasal obstruction. Stoerk has, under the title of "Blenorrhœa of the Respiratory Mucous Membrane," described a form of inflammation which, commencing in the nasal mucous membrane, spreads slowly to the pharynx, larynx, and sometimes as far as the bronchi, causing in its course serious stenosis of these passages. These post-nasal and naso-pharyngeal inflammations and growths are extremely liable to evoke reflex phenomena after the manner of chronic rhinitis, a fact which points to the necessity of posterior as well as of anterior nasal examination and exploration in all cases of spasmodic respiratory disorders.

Chronic rhinitis may extend anteriorly to the face, as well as posteriorly towards the pharynx. I have witnessed the production of facial erysipelas in this way, an occurrence which has also been noted by other observers. It is also important to bear in mind that the outside of the nose may become red and swollen from reflex dilatation of the blood-vessels by long-continued irritation of its mucous membrane, and may be cured by treatment of the rhinitis.

In considering the treatment appropriate to this complaint, regard must be had to whether the rhinitis exists in a simple form, or whether it is complicated by one or other of the sequelæ already mentioned. In all cases, however, it is necessary in the first instance to adopt measures to ensure cleanliness of the nasal mucous membrane, and the removal of all muco-purulent or purulent secretion. Solutions of the alkaline carbonates or bicarbonates are the best for this purpose, applied by sniffing up from the palm of the hand, by spraying, douching, or syringing. These ought always to be used tepid, so as not to excite the flow of mucus. The spray is probably the best means, as the mild method in which it impinges against the pharynx is less liable to cause inflammation of the Eustachian orifices than either the douche or the syringe.

After the nares have been thoroughly cleaned and freed from secretion, measures ought to be adopted with the view of restoring the mucous membrane to its normal condition. The nature of these measures depends to a large extent upon the degree of affection of the mucous membrane, and the presence or absence of sequelæ and complications. Powders, sprays, pigments, gossypia, and instrumentation may be so employed, singly or in combination.

Hypertrophies, growths, and polypi are as a rule quite uninflu-

enced by medical remedies. They are best treated by means of the galvano-cautery snare, puncture, or simple furrowing, the mucous membrane having previously been rendered insensitive by the application of a 5 to 10 per cent. solution of cocaine hydrochlorate. The sensitive areas within the nose, upon whose irritation cough or asthma seems to depend, are also best treated by the application of the galvano-cautery. With regard to polypi, the great advantage of the galvano-cautery is, that not only can we remove the larger polypi, but by passing the cautery freely over and through the rootlets of those which cannot be removed, we have a greater chance of preventing their growth and assumption of the place of the larger polypi. In the cases of necrosis with polypi, the diseased bone ought also to be removed. It ought to be remembered that the inferior turbinate, being a separate bone, is much more tolerant of interference than the superior or middle turbinates, which are parts of the ethmoid.

I have not attempted to enumerate to you the various therapeutical agencies which may be adopted for the treatment of chronic rhinitis, as these will subsequently, in my lecture on "Respiratory Therapeutics," be considered in greater detail. I am more anxious that you should grasp the principles upon which this treatment should be founded, and recognise the necessity of examining not only the chest and throat, but also the nose, in all cases of recurrent or spasmodic laryngeal or pulmonary affections.

THERAPEUTICS OF HAY FEVER.

By CARL GENTH, M.D.,
Langen Schwabach.

THE approach of the time at which hay fever usually appears induces me to offer you the following notes and observations.

For the past ten years, a young medical man of my acquaintance has suffered, from the beginning of May to the end of June, so severely from hay fever that his practice has been seriously interfered with. It will be understood, as a matter of course, that he had in succession tried all the many and much-lauded remedies without any good result. Quinine, in large quantities, alone produced favourable results, and not before symptoms of poisoning presented themselves. It may not be without interest to mention that urticaria broke out, beginning on each side of the spine, following the course of the chief nerve-branches down the arms and legs, and finally covering the whole body. This painful state lasted for three days, at the end of which the hay fever disappeared—leaving, however, in the patient no desire to repeat the experiment with quinine.

In a comparatively large number of cases of hay fever, I found that the primary indication of the disease was a slight twitching sensation at the inner corner of the eye. This sensation becomes more intense day by day; next follows a swelling of the conjunctiva, with all the accompanying symptoms of acute conjunctivitis, and the symptoms referable to the mucous membrane of the nose, asthma, etc., set in later. These slight premonitory symptoms, which sometimes precede the final outbreak by a fortnight, and perhaps disappear with a change of weather, may easily be forgotten. But even assuming that, now and again, the disease does not begin in the eyes, but in the nose or the bronchial tubes—a possibility which in principle cannot be rejected—the exception would not by any means invalidate the assertion that hay fever usually begins with the symptoms of conjunctivitis.

Upon these facts I build my therapeutic plan. Since the first symptoms of hay fever manifest themselves in the eye, it is probable that the agent which is to be regarded as the cause of the hay fever (I do not here refer to the pollen grains which are everywhere present during the season in which the fever prevails, and are consequently to be found in the secretion of the conjunctiva and in the mucus of the respiratory tracts) first attacks the conjunctiva; under favourable circumstances (heat) it multiplies there, and then diffuses itself over the mucous membrane of the respiratory organs, perhaps through the medium of the laryngeal canal. To be effective the condition must be attacked by local treatment, directed to the eyes at the earliest possible date.

I will pass over the details of the experiments that were ineffectual. On the advice of my learned friend Dr. Pagenstecher, of Wiesbaden, I chose instillation and bathing of the conjunctiva with sublimate solution, of the strength of 1 in 3,000. The bathing began perhaps fourteen days before the appearance of the hay fever, whenever the patient returned home after open-air exercise. The patient was besides required to keep as cool as possible, and

to wear pale blue spectacles. The result of the treatment was that he remained free from his trouble for a length of time. Not before the end of June did slight irritation of the conjunctiva reappear, which, however, could not be compared in intensity to former attacks, and involved no complication. Relying probably upon his generally healthy condition, the bathing had not been performed with sufficient energy. Although the sublimate solution came in contact with the mucous membranes of the nose or throat only slightly, or perhaps not at all, neither of these organs was affected, which must have happened if the virus of the hay fever passed into the body through the nose and mouth. In such an exceptional case, it would be simple enough to apply the solution by a nose douche, by garglings, or perhaps even by cautious inhalation.

THE VALUE OF INSPECTING THE ORIFICES OF THE URETERS BY ELECTRIC LIGHT IN THE DIAGNOSIS OF "SYMPTOMLESS" HÆMATURIA AND PYURIA.¹

By E. HURRY FENWICK, F.R.C.S.,

Surgeon (Out-patients) to St. Peter's Hospital for Urinary Diseases; Assistant-Surgeon to the London Hospital.

IN the endoscopic examination of the eye, the ear, or larynx, the operator first directs the light upon the most important structure—the optic disc, the drum, or vocal cords, and having satisfied himself as to their condition, he turns his scrutiny to their surroundings. The need for it in exploration becomes more pressing as the field we have to search enlarges, and in the wider areas the rule of starting from some fixed important point is often no mean factor of success. Thus, in abdominal section for obstruction the hand first feels the cæcum to ascertain if it be full or empty, and from thence the fingers trace the coils of large or small intestine according to the clue which cæcal distension or contraction may afford.

In the exploration of the bladder with the electric light it is necessary to have some such starting point in order that the examination may be systematic, rapid and effective. The most important section of the bladder, speaking cystoscopically, is the inferior zone, and the cardinal points in this area are the orifices of the ureters. Upon them the operator should first direct the light,² and from them the search should radiate. There are several reasons for this choice. From the orifices of the ureters may be seen to issue fine jets of renal blood in kidney bleeding, the semi-vididness of which may prove fallacious (without the cystoscope) in the diagnosis of the source of symptomless hæmaturia. Upon their lips or in their immediate neighbourhood are most often to be found those tumours which can baffle diagnosis.³ Moreover, their appearance, their clean-cut, slit-like openings, or their tumid, gaping mouths—that is, their healthy or unhealthy aspect—is an index to the soundness or unsoundness of the remainder of the mucous membrane, which cannot be neglected in the treatment or prognosis of disease.

In hæmaturia I generally first satisfy myself that the ureters are free from tumours, and then make a rapid survey of the rest of the bladder, proceeding from below upwards (that is, inversely to the tendency the zones evince to growth).⁴ If I can find no cause for hæmorrhage I return to the orifice of each ureter, and watch the colour and amount of its efflux. In three cases lately I have thus been able to detect the renal source of symptomless hæmaturia, which otherwise I might have overlooked.

CASE I.—Mr. B. consulted me in January, 1888, in reference to a hæmaturia. He brought with him a specimen of bloody urine

¹ Excerpt from a demonstration of the value of the electric light in the diagnosis and treatment of obscure vesico-urothelial diseases given before the Staffordshire Branch of the British Medical Association, May 31st, 1888. This subject is an appropriate addition to an editorial on "The Surgery of the Ureter," in the JOURNAL, June 2nd, 1888.

² Vide author: A Description of the Electric Cystoscope, JOURNAL, February 4th, 1888.

³ Single villous papillomata are found at the right ureteral orifice in 43 per cent., and at the left in 26 per cent. of the cases. Fibromata and small single myxomatous in 90 per cent. of the cases are situated at the ureteral orifices. Author, *Lancet*, March 10th, 1885.

⁴ The liability of the three zones to become affected by single cancerous growths may be expressed thus:—The upper: middle: lower zone: : 1: 2: 6. Author, *Pathological Transactions*, Carcinoma of the Bladder, 1885.

containing much clot. His history was as follows: In January, 1886, he had been out riding for two hours, and came home completely chilled. He passed blood the same evening. He suffered no pain or inconvenience, except a slight urethral tingling when the clots were passing. The hæmorrhage stopped in the summer, but recurred in the winter of 1887, to cease once more upon the advent of the warmer weather.

Present Condition.—“A well-built, anæmic man, aged 30. The urine is voided thrice a day. No pain attends the act. He suffers ‘agony’ after coition, in the neck of the bladder. In micturating he has noticed that the urine often becomes more bloody towards the finish.”

I expected to find a vesical growth with the electric light, but nothing abnormal could be discovered. The entire bladder was healthy. I was just giving up the examination in despair, when I saw a stream of brightish blood shoot right across the prism. Keeping the instrument fixed, I waited until the medium became clear again, and then I found that I was watching the orifice of the right ureter (Fig. 1). In another second a jet of bloody urine

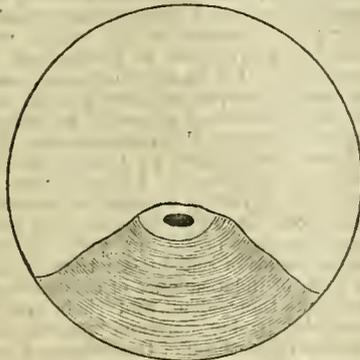

Fig. 1.—Ureteral projection, much magnified by proximity of the prism.

burst from the tiny opening, and, after forming many rings, paled by diffusion and disappeared, but only to be replaced by a successor (Fig. 2). The phenomenon of efflux suggested to my mind

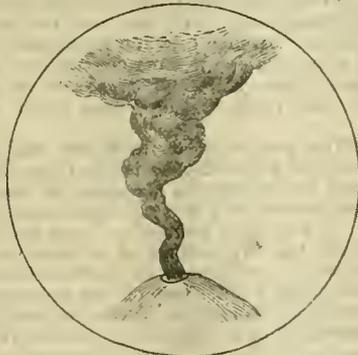

Fig. 2.

a miniature cuttle-fish, squirting out its coloured fluid into the water around. The right renal source of the hæmorrhage was at once indicated.

CASE II.—Mr. C. (under the care of Drs. Underwood and Harvey), a well-built man, aged 52. Since May, 1887, he had suffered from hæmaturia, which was painless and intermittent in its character, and seemed more dependent upon exercise than anything else. The urine was passed thrice a day. He was disturbed only once at night. Some specimens of hæmaturia contained cylindrical clots. I passed the electric cystoscope under cocaine, and found a low collarette of prostatic growth, but it was obviously not the cause of the hæmorrhage. The bladder was healthy. I could see jets of blood issuing from the right ureter, and the diagnosis of the site of the trouble was at once established.

CASE III.—A lady, under the care of Dr. Hepworth, of Manchester, and Dr. Battersby, of Cannes. For eighteen months the patient had suffered from hæmaturia. The urine varied much in colour, but there were no symptoms whatever to afford a clue as

to the exact source of the bleeding. The electric cystoscope (No. 30 French gauge) showed the bladder to be perfectly healthy, but, on turning the instrument towards the left ureteral orifice, a spurt of bloody urine flowed over the prism. I allowed the ureter to play upon the prism, in order to judge of the rhythm of the flow, but it never varied, although Drs. Hewitt, Lys, and I watched it for some little time. It was rather like an artery severed under water. I could detect no renal tumour in any of these cases.

These three cases are sufficient to illustrate the value of inspecting the orifices of the ureters by means of electric light, and of excluding the kidneys as a source of the hæmaturia; moreover, the same advantage can be gained in pyuria, and the many methods and instruments advised and devised for obtaining urine direct from either kidney must now be partially superseded by the electric light. The ureteral orifices are not difficult to find. They are very rarely displaced, and still more rarely are they absent. A little tact in manipulation and knowledge of the cystoscope will bring them into view, and amply repay the operator for examining them.

ABSTRACT OF PRESIDENTIAL ADDRESS ON THE SOCIAL POSITION OF THE MEDICAL PROFESSION.

Read before the Birmingham and Midland Counties Branch of the British Medical Association,

By THOMAS WILLIAM THURSFIELD, M.D., M.R.C.P. LOND.,
Physician to the Warneford Hospital, Leamington.

I HAVE taken for the subject of my address one which has interested me for a considerable time. It is “The Social Position of the Medical Profession in this Country at the Present Time.” In contrasting the position which is held by the medical profession, in social estimation, with that of the other learned professions, I think it will be admitted that we do not stand so high as either the Bar or the Church; and yet the attainments of the members of our profession, their character, their self-denial, and their public services, are acknowledged on all hands, and should command for them a respect as high as that in which any other profession is held.

Dr. Thursfield indicated that this low estimate was in part due to the ignorance or jealousy of the public, but in part to certain faults in the profession which he classified as follows:

Imperfect Preliminary Education.—The fact that anybody can become a registered medical student merely on having passed a second grade examination of the College of Preceptors, and that anyone between the ages of 16 and 17 years can if he chooses drop for ever all learning except that which is specially set apart for the acquisition of professional knowledge, leads to the introduction into this profession of a very large number of men who, I do not hesitate to say, are more imperfectly educated in a general sense than the aspirants to any one of the other learned professions. And here I may say that I think the entire abolition of the apprenticeship or pupilage system has been a mistake; for I cannot think it wise that a boy should go straight from school into a life so full of manifold temptations as is that of a medical student. A year passed in the family of a medical man in large practice would greatly widen the student's ideas, and add largely to his obtaining a truer conception of the duties he is about to undertake. Narrow though his education may be as compared to that of a medical man, it cannot be denied that the young curate has a much better social position at the outset of his career than the young physician or surgeon, while it is quite certain that the position of the young physician or surgeon is not comparable with that of the most junior member of the Bar. This I believe to be largely due to the more prolonged and complete preliminary education necessary for the Church and the Bar.

Imperfect Professional Education.—The second reason of the low estimation of our profession is, I think, the imperfect professional education which so large a proportion of our number receive, though I must admit that this is improving day by day. And yet, when one looks at the vast domain of medicine, one is lost in wonder as to how it is possible, in the short space of four

years or less, to get anything like a concise knowledge of the subject into a young fellow's head.

Professional Quackery and Dishonesty.—Those of us who have been any time in practice must be well aware that quackery is not to be found wholly outside the profession. If the art of the quack is to pretend to a knowledge which he does not possess, to be constantly disparaging the art of others, and to be using remedies whose utility is not proven or is at least mysterious, then we must admit that there is plenty of quackery within our ranks. And do you think for one moment that an intelligent public does not see through this dishonesty?

Professional Jealousy.—This is one of the most potent causes for the low estimation in which our profession is held. I need go no further than the daily papers for the last six months "to point the moral and adorn the tale." Does a man acquire an illustrious patient, his neglected rivals make little hesitation about disparaging him in public. Does a man make a great success in professional life, it is seldom but that whispers are heard among his own compeers that it is to luck and chance, and not to merit, that he owes his advancement. Our quarrels in law courts are such that any leading counsel will tell you that medical testimony is of little or no avail when anything like disputed points arise. Is it possible that we can blind ourselves so far as to believe that these things are not supremely damaging to our social estimation?

Professional Etiquette.—If we could once realise that the only basis of true professional etiquette is always, and on all occasions, to do towards our professional brother what we should like him to do towards us were he in our place, we should then, I think, escape from this reproach of having amongst ourselves a code of laws which is "not understood of the people," and which is believed by them to be made entirely for the benefit of the members of the medical profession at the expense of the public. It is short-sighted policy on our part, I am sure, to surround with difficulties the natural wishes of our patients to resort to consultations and further advice; and the difficulties which we so often place in their way are a constant source of distrust and dislike by them of us.

Deficient Public Spirit.—Another cause is one which five years ago was so well, so eloquently, and so wisely pointed out by Sir Walter Foster in the chair from which I now speak. In that splendid address he gave on the "Political Powerlessness of the Medical Profession" he pointed out, better than I can ever do, how the want of public spirit outside of our own immediate professional avocations has largely influenced the public estimation of us, and he counselled in more eloquent words than I possess, and he has, in his own person, more illustriously set the better example, and has shown how devotion to public duty does secure public esteem.

"Provident" Dispensaries and Out-patients.—The multiplication in our midst of certain provident dispensaries and amalgamated clubs, and of private penny dispensaries of all kinds, together with the abuse of the out-patient departments of hospitals which is permitted wherever a hospital is found, have tended, and are tending, largely to reduce the legitimate rewards of our labours. It cannot be right that such vast masses of the population, who, many of them, are raised by their wages, or salaries, or earnings greatly above the level of necessity, or even of penury, should by combination be enabled to obtain skilled medical attendance and medicine at an average rate per person of 3s. or 4s. per annum. The principle of co-operation and association, whether applied to medicine or to any other profession which secures to the public the supply of a daily need, is obviously a good one, and is one which the medical profession at large should countenance and further, but certainly under conditions. The application of the principle of unlimited competition in such matters as these cannot but lead to the degradation of the profession and to disaster to the public.

Suggestions.—First, is it not possible to largely improve the preliminary education of the young members of our profession? Are we not making them to some extent one-sided by the almost exclusive devotion which is given to the scientific side of their education, to the exclusion of the more general and literary? I am one of those who still believe that a good classical education is a priceless possession, and that it in no way interferes with the subsequent development of the power of scientific observation, which necessarily lies at the root of all success in the difficult art of medicine. With

regard to professional education, so far as it goes it is a vast improvement on anything which has ever yet been done, but I hope that it may be still further improved, and this can only be done by materially lengthening the ordinary curriculum. Several of the countries of Europe, inhabited by people who are supposed to be not so progressive or intelligent as those who inhabit this island, have determined by law that five years is the shortest possible time in which to manufacture an intelligent and safe medical practitioner. If the standard of professional education is to be maintained at its present level, or is to be by imperceptible degrees raised still higher than it is at the present time, it is quite certain that the ordinary human being who has the misfortune to become a medical student will in most cases be made by repeated rejections to increase his term of preparation to five years; and should this be the case, as it seems likely to be, I hope that before long that five years will be the rule and not the exception. I think too, that there is opportunity for improving the clinical education of medical students, for when one sees the vast mass of clinical material which is running to waste in our county hospitals, and in our union workhouses, one is tempted to exclaim against the criminal extravagance which permits it. If we are to recover public esteem to the extent we undoubtedly deserve, we must cast away from us professional quackery, and professional dishonesty. Let us also cultivate more friendly intercourse, more *esprit de corps*, and more general cohesion among ourselves. Let our professional etiquette be simplified, and let its main principles be always the consideration of our duty towards our neighbour, and, above all things, let us avoid public quarrelling and public differences. I do hold most strongly with Sir Walter Foster, who says that though the excuse given to explain our absence from the duties of public life is our absorbing interest in a most laborious profession, yet it is, though a good one, more or less a species of selfishness; that in many instances it arises from a want of independence of character; and that until medical men will take their share, and their fair share, in that which is becoming day by day more and more the duty of all good citizens, they must expect those of the citizens who do submit to the heat and burden of the work, to estimate lowly, and even to despise those who shirk it. Our colleges may largely help to enhance the public estimation of the profession at large, and they will do so when they admit the principle that they owe a duty to every member of their body which they can never fulfil so long as they remain the close conservative bodies they now are. A large infusion of the democratic spirit into our medical corporations, and free admission of all members and licentiates to the governing body, will alone enable these corporations to take up and to use those duties of *discipline* and *censorship* in the exercise of which, up to the present, they have been so lamentably deficient.

Conclusion.—The profession of medicine may not be appreciated as it should be politically, socially, or commercially; it may not be recognised by the State in the shape of State rewards, and this may be some reason why it is not appreciated as it should be by the public. It has been pointed out over and over again that there is no item in the expenditure of a household more grudgingly bestowed, and more liable to be questioned and more tardily settled, than the doctor's bill. One of our greatest statesmen has said: "Your profession has a great future before it, and I believe that in one generation, or at most two, it will be far in advance of the other learned professions." Lord Bacon said of the pursuit of knowledge that "it is not a couch whereon to rest a searching and a restless spirit," or "a terrace for a wandering and a fiery mind to walk up and down with a fair prospect," or "a tower of State for a proud mind to raise itself up," or "a fort and commanding ground for strife and contention," or "a shop for profit or sale," but it is a rich storehouse for the glory of the Creator and for the relief of man's estate. Thomas Carlyle has said: "I have often said, what profession is there equal in true nobleness to medicine? He that can abolish pain and relieve his fellow mortal from sickness, he is indisputably the usefulest of men. Him savage and civilised will honour; he is in the right, be in the wrong who may. As a Lord Chancellor, under one's horsehair wig there must be misgivings; atill more, as a Lord Primate, under one's cauliflower; but, if I could heal disease, I would say to all men and to angels 'en, ecce.'" Another living celebrity has said: "When we regard the rapid and marked progress which our art and science has made during little more than half a century, I feel that we are fully justified in believing that progress in the future will be even more remarkable, and that, with materials for inves-

tigation in abundance, with willing and able workers, there can be neither fear nor doubt for the continued advance of the healing art."

CLINICAL MEMORANDA.

THE TREATMENT OF CHRONIC DYSENTERY AND ITS ALLIES.

It has appeared to me, from observation of a good many cases of the above diseases, that a considerable number of patients, presenting a close uniformity of symptoms, gain marked benefit from a treatment differing in some respects from that usually adopted. The class of cases I refer to generally admit long-standing constipation, followed, on arrival, or after living some years in India, by what they call "diarrhoea and dysentery." They complain of frequent passage of small bloody stools, inability to hold their motions, with more or less abdominal discomfort and dyspeptic symptoms. On careful examination it is found that there is no proper diarrhoea; the motions are lumpy, often consisting of half-digested materials, with a large quantity of blood-stained mucus, and though frequent, but little true fecal matter passes. In these cases a prolonged course of saline aperients has a remarkable effect, the disease being to a large extent mechanical, the result of hardened feces passing over an irritable mucous membrane. As a rule these patients have never had an acute attack of dysentery, and the above simple treatment, combined with an easily-digested, nutritious diet, often suffices to cure them. In cases where the chronic is a sequel to a more or less recent acute attack, the disease is more obstinate and the treatment requires to be persevered in long after apparent recovery. I make no claim to originality either for the observation or treatment of this condition; I merely wish to record that as regards treatment I have found great advantage in drawing a sharp line between "constipatory" and "diarrhoeic" dysentery.

F. P. NICHOLS, B.A., M.B. Cantab., Surgeon, Medical Staff.
Hounslow.

MIMETIC PARALYSIS: SPEEDY RECOVERY.

C.C., aged 19, was brought in from the country to my out-patient room by her mother, on April 11th. To the casual observer she was indeed a pitiable object, as she hobbled across the room with a right crutch. I noticed the following appearances: Young, fresh-coloured, and good-looking; ptosis (?) of the left eyelid; left forearm swathed and bandaged; left hand with claw-like contraction; the long overgrown nails embedded in the fleshy palm; contracture of the left leg upon the thigh. The mother informed me that the girl had been sent to service in Leicester eight months ago; that after being in her place a fortnight she had had a "fit," for which she was treated by a local doctor, and sent home invalided; that she became a hopeless paralytic, and had ever since been in receipt of charitable and medical aid.

The diagnosis was easy; the ptosis was spurious, there being marked effort to keep the eyelids closed. She was told to put out her tongue, and protruded that organ, clear and healthy-looking, in the middle line, there being no alteration in the facial muscles of expression. All this did not correspond with the late paralysis (contractures) of the left extremities.

The treatment was summary. Telling the patient to listen attentively to what I was going to say, I told the mother that her daughter was a "fraud," and in the past eight months had been practising an accomplished deception on all about her, and that I would soon effect a speedy cure.

I noticed the girl's face flush deeply and then pale as I said this, proving that her mental faculties were by no means in abeyance, and placing my left hand on her left thigh, and seizing the foot with my right, I soon extended the limb, the patient squealing a good deal, and at once returning it to its former position.

I sent her up to the operating theatre, and, seeing her there later on, I appealed to her good sense. I opened her left eyelids, and they remained opened. My assistant extended the fingers, and they so remained, the stench from the decomposing sweat being intolerable; but she would not resign her leg, so I had one pole of a strong faradic current placed on the triceps extensor, and the other on the front aspect of the tibia. She again screamed lustily, and I told her the entertainment would last until her foot (also swathed in bandages) was placed on the ground. It soon

reached the required position with a thump, and I left her. I was told that her mother appropriated the crutch, and that, with the loan of a shoe, she walked out of the infirmary. On April 18th she walked into my room the picture of health, and I have not seen her since. I learned afterwards that she had twice been an inmate of one County Lunatic Asylum, each time being discharged at the month's end. Lunacy failing, she tried paralysis. It will be interesting to note what her next "move" will be.

The rector of the parish wrote to me on the 18th: "She walked down here (a mile) to-day, apparently quite well; what is to be done with such a case? Is the shamming really a disease?" I replied "that it is hard to say where badness ends and madness begins; and he had propounded a social problem very difficult of solution; but that in my opinion, in the present case, the malady should be spelt with a "b," and not with an "m," and that laziness was at the bottom of it."

J. HEADLEY NEALE, M.B., M.R.C.P. Lond.,
Honorary Assistant-Physician to the Leicester Infirmary.

OPHTHALMOLOGICAL MEMORANDA.

FRACTURE OF THE CORNEA FROM THE KICK-BACK OF A FRAGMENT OF A WHIP-TAIL.

IN the summer of 1882, the first whip (J. Press) of the North Warwickshire hounds, while walking the pack on the public road, struck at one of the hounds with his whip, and almost immediately felt his right eye to be injured, as he conjectured from a piece of glass being flicked up by the whip. When he presented himself to me there was a linear longitudinal fracture of the nasal side of the cornea, through which the aqueous had escaped. No foreign body presented. He made a good recovery, and regained his sight. That the injury was produced by the kick-back of a detached fragment of whipcord, Mr. Dunn's case conclusively proves (JOURNAL, April 14th). In both cases the patient imagined his eye had been cut by a bit of glass or stone.

In commenting on Mr. Percy Dunn's case, Dr. Sanctuary (JOURNAL, May 5th, p. 994) says: "The knot flew off on account of the lash being sharply curved, in order to produce the 'crack' of the whip," and adduces in illustration certain accidents which sometimes occur in fly-fishing, also giving a very interesting example.

J. VOSE SOLOMON, F.R.C.S.
Birmingham.

FORENSIC MEMORANDA.

SUICIDAL WOUND OF THE HEART.

H. C., aged 33, was found lying dead in the corner of a small room. The right hand was tightly clenched, and a small knife was on the floor just in front of him. His wife was found also in the room with a large wound on her head. The greater part of the frontal bone had been completely taken off with a bill-hook, and also a great part of the front of the brain. Two of her fingers had been cut off with the knife, and there was also a small stab in the left breast. Portions of brain substance were scattered on the floor and walls. The crime was committed, according to the woman's statement, at 6 o'clock on May 24th. The room was broken into, and the woman brought alive to the General Hospital, Bristol, at 7.30 on May 27th.

On making the *post-mortem* examination of the man, I found a large quantity of dried blood on his feet (on the soles), as though he had been walking about in blood. On the front of the chest, about one inch to the inner side, and three-quarters of an inch above the left nipple, were five small wounds, transverse in direction, and each about three-quarters of an inch long by a quarter of an inch wide. Just to the inner side of the nipple was another wound, about half-an-inch in length. About one inch below the nipple was a small wound, also about half-an-inch in length. On passing a probe into these, the first six mentioned wounds were found to pass deeply, the probe taking a direction downwards and slightly inwards. The last wound was little more than skin-deep. Apparently there had been very little hæmorrhage from these wounds.

On dissecting back the skin and muscles from the front of the thorax an extravasation of blood was found around the course of the uppermost wounds, which all corresponded externally to the third intercostal space, and perforated the thorax through the

fourth interspace. The fifth wound corresponded externally to the fourth interspace, and entered the thorax through the lower part of the fifth.

On removing the sternum the left pleural cavity was filled with blood, and the pericardium contained about three ounces of clotted blood. On the left side of the pericardium was a transverse wound a little over an inch in length. On the wall of the heart, corresponding to the wound in the pericardium, were two transverse wounds about three-quarters of an inch long, and separated by a narrow bridge of muscle about one-eighth of an inch wide; both of these perforated the left ventricle. A little above these were two small irregular wounds, not more than one-third of an inch long, and near the apex was another about the same size. These only perforated the superficial layers of muscle. All the cavities of the heart were quite empty, also the large blood-vessels. The sixth wound had penetrated the thorax, but had failed to wound any of the viscera. There was no wound of the lungs to be found. All the organs were healthy. The stomach was quite empty.

REMARKS.—This case appears very interesting on account of the number of times that the knife had touched the heart. I presume the man must have stabbed himself in the six places very rapidly, giving one blow after the other, or possibly he may have only partly withdrawn the knife, and then plunged it in again, as there was only one wound of the pericardium.¹

GUY'S HOSPITAL.

EPITHELIOMA OF THE MOUTH: REMOVAL OF THE TONSIL, PARTS OF THE SOFT PALATE, PHARYNX, AND TONGUE: PRELIMINARY LARYNGOTOMY: SUBSEQUENT RECURRENCE, WITH RESECTION OF HALF THE LOWER JAW.

(Under the care of Mr. CHARTERS SYMONDS.)

J. P., aged 45, was sent in by Dr. Hooper on October 29th, 1886, with an epithelioma of the mucous membrane behind the last molar. There was extensive ichthyosis of the tongue and mucous membrane of the mouth of syphilitic origin.

When first seen, there was a hard, irregular surface behind the last molar, extending downwards in the groove between the tongue and the jaw, and backwards involving the anterior part of the tonsil; forwards the mucous membrane of the cheek was slightly involved. He could protrude the tongue half an inch beyond the teeth. Under remedies he improved a little; the mouth became a little wider open, there being three-quarters of an inch between the teeth. The man had much pain in swallowing, and suffered the most intense mental distress. There was one gland below the jaw.

Under chloroform an incision was made from the angle of the mouth through the cheek to the masseter, and the extent of the growth was defined. Ascertaining that it could be removed, laryngotomy was performed, and a sponge to which a stout piece of silk was attached pushed into the pharynx. The mucous membrane over the jaw was then detached, and by means of scissors the anterior faucial pillar, a portion of the soft palate and of the side of the tongue, and the tonsil with a piece of the pharynx and part of the mucous membrane of the cheek, were removed. The separation was effected largely by a raspatory. The bone was left exposed for a good inch in its alveolar margin; the teeth having been extracted some years before left the region in front of the last molar free. Then through a submaxillary incision the gland was removed and an opening made into the mouth. The bleeding was arrested by pressure, no vessel in the palate or pharynx requiring ligature. The wound in the cheek was brought together and a drainage-tube put in the mouth through the opening

below the jaw. The tube was retained in the trachea for two days.

The man soon recovered from the shock of the operation, which had lasted nearly two hours. He was fed by a nasal tube for four days. The tracheotomy tube was removed in forty-eight hours and the wound filled with iodoform. It healed in forty-eight hours. Steady recovery followed; he lost all his pain in swallowing, and was very much relieved.

The facility secured by the laryngotomy was most marked. The operation was never arrested for a moment; no blood passed into the air-passages, and the anæsthetic was easily administered. The man was placed in a tent with a steam-kettle for two days. Again, it was quite possible to remove the entire tonsil and part of the soft palate through the opening made without resorting to the incision behind the lower jaw. The bleeding was controlled in the same way and with as much ease as in the operation for removal of the tongue by scissors.

The man returned on February 12th, 1887, unable to open his mouth, and was readmitted on the 14th. A small nodule could be felt in the centre of the old cicatrix, and the little finger could just detect a hard edge inside the cheek; no glands in the neck. As it was impossible to ascertain the true state of affairs, he was, on February 16th, placed under chloroform, and the mouth opened by Gowan's gag. It was then found that the inability to open the mouth was due to the cicatrix stretching from the palate to the lower jaw and not to a growth. A nodule of growth, however, was found attached to the inner surface of the bone, and ran further along the floor of the mouth as far as the canine tooth. An elliptical incision was made downwards and backwards, so as to include the nodule and the cicatrix, and carried by careful dissection to the mucous membrane; the first molar and second bicuspid teeth were extracted, the second and third molars having been long absent. The mucous membrane was then divided and the nodule removed. A portion of the masseter was cut away; and then, finding that, in order to give a movable jaw, it would be well to resect a portion of the bone, this was done so as to include the nodule of growth. The piece was wedge-shaped, with its base downwards, as recommended by Esmairel.

This exposed the side of the tongue freely, and now the epithelial growth was found running along the inner surface of the bone and the side of the tongue. A further inch of bone was removed, and with it the mucous membrane over the floor of the mouth and the side of the tongue. By keeping the tongue forward the blood ran out of the wound, which now extended well into the submaxillary region. The lingual was tied, and all bleeding arrested. The edges were united with two button sutures, and a drainage-tube passed into the mouth. He was fed by enemata for two days, and then, as he was able to swallow, took milk by the mouth; on the third day the button sutures were removed, and the drainage-tube on the second day. The odour from the mouth was unpleasant for four days. Saliva and mucus escaped through the tube, and relieved the pain consequent on swallowing.

February 19th. By the 28th the wounds were all healed, and he was discharged on March 1st, able to open his mouth to a fair extent.

On May 14th the man returned, with recurrence in the floor of the mouth, but without any glandular enlargement. I was unwilling to operate further; but, in the absence of glandular implication, yielded to his earnest pleadings, and made a further attempt to extirpate the disease on May 15th. It was necessary to remove the half of the lower jaw.

An incision was made along the bone and up the median line through the lip. The submaxillary tissues were next separated to the median line. The tongue was next drawn forward by two silk ligatures and split after Baker's method. Next the symphysis was sawn through, and all the structures, from the median line of tongue down to the hyoid bone, together with that part of the body of the bone in front of the former site of resection, removed. This formed a large mass, and the line of separation was everywhere free from growth. The epiglottis was exposed, and the mucous membrane connecting it with the tongue, together with the pharyngeal mucous membrane, was held up by forceps, and prevented the blood entering the larynx.

On examining the hard palate behind the last molar, a patch of growth was discovered, and from this a sinus leading to the ramus, which was rough and bare. This was found just as the operation was thought to have been completed, and, had I noticed it earlier, I certainly would have decided against operation altogether. But his inability to open his mouth prevented its being

¹ An inquest was held by the city coroner for Bristol, and after hearing the evidence the jury returned a verdict of *felo-de-se*. The woman is still (June 14th) living, and doing well.

detected. I was obliged to extend the incision upwards and turn out the entire ramus. In doing this the internal maxillary artery was wounded and gave a great deal of trouble.

I felt that the removal had been complete so far as the floor of the mouth was concerned; it was not satisfactory by any means as regarded the growth extending along the coronoid process. The wound was closed, the mucous membrane of the glosso-epiglottic fold and the pharynx being stitched to the cheek. A large tube was passed into the mouth, and the suture left in the right side of the tongue. Iodoform was freely used.

The patient was fed by a tube passed through the mouth. He was able in a few days to swallow fluids freely. At the end of the week he was walking in the park, all the wounds being healed except where the drainage-tube was placed. On the fifteenth day, though looking feeble, he at his own desire, returned to Ports-mouth.

The rapid recovery after such a severe operation—which lasted two hours, and during which a good deal of blood was lost—was due to the indomitable spirit of the man and his anxiety to get home. Unfortunately the growth again returned, and writing on July 18th, he says that it has recurred in the floor of the mouth and neck, and that he suffers great pain, more especially in front of the ear. He died in October, 1887, one year from the first operation.

I hoped by this last operation to eradicate the disease from the floor of the mouth at least. The operation cut wide of the disease in this direction, and went down to the hyoid bone, but even here it recurred.

I was only induced to attempt removal on the first occasion at the earnest solicitation of the patient, who begged that something might be done to prolong his life even a little time, so as to continue his Government pay for the benefit of his family. When recurrence took place the first time, it was impossible, owing to the cicatricial closure of the mouth, to determine its extent; the absence of glandular implication, however, induced me to undertake a further operation; the same reason justified the third operation, though I never would have proposed this last undertaking. When begged to do it, I felt that in the absence of gland implication I ought to yield to the man's entreaties.

The case illustrates the possibility of removing the tonsil and adjacent parts by dividing the cheek only, and the value of preliminary laryngotomy. The difficulty of expressing an opinion as to the distribution of the disease when the mouth is closed is also noticeable. Extensive glandular enlargement only occurred during the last stage of the disease.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JUNE 12TH, 1888.

Sir E. H. STEVENING, M.D., President, in the Chair.

Pemphigoid Eruption with Changes in Peripheral Nerves.—Drs. A. SANGSTER and F. W. MOTT read this paper. E. M. R., aged 78, was admitted to Charing Cross Hospital November 5th, 1886, in a very prostrate condition, a large extent of the surface of the trunk and limbs being covered with a bullous pemphigoid eruption of fairly symmetrical distribution. She was evidently suffering from renal disease, as the urine was scanty, and contained one sixth of albumen. The temperature was 102°. She died after nineteen days in hospital, having been unconscious the last three days, with uræmic symptoms. Necropsy within twelve hours of death exhibited granular contracted kidneys, the organs weighing 2½ and 3 ounces. Portions of the external cutaneous nerve were examined, also spinal ganglia and posterior roots. Sections after hardening exhibited a parenchymatous degeneration of the nerve fibres. This case corresponded very closely, both in clinical symptoms and pathological conditions, with a case reported by Leloir.—Dr. W. B. CHEADLE begged to thank the authors for their paper, which he thought had helped to throw light on an obscure subject. Fatal cases of pemphigus were not common; he had himself seen but one, and he inquired if in the case which had been described that evening there was any lesion of the intestine found, for he had found uncontrollable diarrhoea to be associated with all the fatal cases he had heard of, and death had been occasioned immediately by lesions of the mucous membrane of the intestine, similar in character to those

of the skin. His own case was in a man aged 52, in whom the eruption, which had been growing steadily worse, was for a short time arrested by arsenic; extremely severe diarrhoea then set in, which could not be restrained by opium, and ended in death in a week. The kidneys were found to be in an early state of granular degeneration. There was very extensive ulceration of the large intestine from the cæcum to the sigmoid flexure, in some large and some small patches.—Dr. SANGSTER said he had hesitated to use so definite a term as pemphigus in a case in which they had an unusual bullous eruption, which the very distressing condition of the patient made it impossible to examine very minutely. It seemed to him to resemble the pemphigus diutinus malignus. The point to which they had wished to direct attention was the condition of the peripheral nerves. There was an association of nervous lesion with bullous eruptions in leprosy and paralysis. As to the condition of the intestines in the present case he had no further evidence than that no abnormality was noticed in the careful report of Mr. Boyd. In fatal cases of such generalised eruptions as urticaria hæmorrhagica, he had seen a good deal of ulceration of the bowel, and a group of such cases had been published by Dr. Goodhart.—Dr. MOTT said he had only been able to find four cases at all accurately corresponding to the present one, which he thought might be described as pemphigus neuriticus. Leloir's case was almost identical. The specimens on the table had been prepared by a microtome from tissues embedded in paraffin, and the results shown could not be attributed to *post-mortem* change.

A Case of Tumour of the Spinal Cord: Removal: Recovery.—(Medical history of the case by Dr. GOWERS.)—The patient was a man, aged 42, who had suffered for three years from localised pain beneath the lower part of the left scapula. The pain varied much; at times it was scarcely felt, at other times it was most intense, and then was increased by movement to such a degree as to render it impossible for the patient to walk. Many medical men were consulted, and the diagnosis varied between aneurysm and neuralgia. Hypochondriacal insanity was even suggested, on account of the irritability of the patient, whose mind almost gave way under the continued suffering. Four months before the operation, first the left and then the right leg became weak, and the loss of power gradually increased to complete paraplegia. The patient was first seen by Dr. Gowers (with Dr. Percy Kidd) on June 4th, 1887. There was then motor and sensory paralysis up to the level of the sixth or seventh dorsal nerves, with intense spasm in the legs, foot clonus, and rectus clonus. The urine was retained, and there was some cystitis. At the level of the sixth dorsal nerves there was severe pain around the trunk, greater on the left side, and increased to agony by any movement. The symptoms pointed clearly to compression of the cord by a morbid process outside it. Caries of the spine could be practically excluded; aneurysm was improbable, although not impossible. The diagnosis lay chiefly between a tumour of the spinal bones and a tumour of the membrane. The indications (described in the paper) made a meningeal tumour rather the more probable. Syphilitic disease could be excluded. An operation afforded the only chance of escape from certain death after intense suffering. Sir William Jenner saw the patient, and concurred in the diagnosis, and sanctioned an operation. The patient was aware of the uncertainty of the result, but was extremely anxious that something should be done.—(Surgical history of the case by Mr. HORSLEY.) The diagnosis of intradural tumour pressing on the cord appearing to be well founded, an operation was performed for its removal on June 9th. After some difficulty, the growth was discovered, and removed under strict antiseptic precautions. The wound healed by the first intention, and the patient gradually lost the agonising pain, and at the same time gradually recovered motor and sensory power, as well as the control over the bladder and rectum. He remains in perfect health. Appended to the surgical history of the case was a table and analysis, in which the chief clinical facts relating to fifty-seven other cases were recorded; and from which it appears that operation is the only treatment to be adopted in such cases, and that, if it had been resorted to, 80 per cent. should have recovered, whereas all died.—Mr. HAWARD observed that a case so unique had little in common with the experience of many of them, and it was specially difficult therefore to discuss. One point had struck him forcibly, and that was the great mental change, the change as some had thought to insanity, that had been produced by long and severe pain. From another point of view it taught them that their ideas of the possibilities of interference with spinal cases must be entirely remodelled.—Dr. A. T.

MYERS inquired the nature of the tumour, of which they had heard nothing.—The HONORARY SECRETARY stated that in the part of the paper which time had not allowed him to read it was fully described as a myxoma.—Dr. PERCY KIDD remarked that the mental affection had been a very serious feature of the case, for, though he agreed with the author of the paper that it had only been a disturbance arising from acute and prolonged pain, yet several advisers had at the time considered it as genuine madness. The patient, he was glad to say, was in perfect health now, able to enjoy a dance, to walk at least three miles with a natural gait, and he begged to be allowed to express through him publicly his most heartfelt gratitude to Dr. Gowers and Mr. Horsley.—Mr. GODLEE thought that a specially interesting point had been the very large amount of cerebro-spinal fluid which had been discharged. He was anxious to know if Mr. Horsley had considered it dangerous. In a case under his own care he had removed a large sacral tumour, and found in its centre a small spina bifida, which he had cut and ligatured. The discharge of cerebro-spinal fluid, though through a very fine hole, had been exhausting, and ultimately fatal to the child.—Mr. HERNERT PAGE asked to say a word as having been the author of the statement in a surgical dictionary that trephining of the spinal cord could be of no advantage. He had limited that statement to the cases of fractures and dislocations. He desired not to be the last to congratulate Mr. Horsley on his brilliant success, and agreed with Mr. Haward that they would now have to reconsider much of the surgical treatment of the spinal column.—Dr. GOWERS was called on to reply, but remarked that he had not noticed any questions or objections which it would fall to his lot to answer.—Mr. VICTOR HORSLEY at once admitted to Mr. Page that when he quoted his words he was only discussing questions of treatment of fractures of the spinal vertebrae, as would have been plain if he had succeeded in further compressing his paper so that it could all have been read to the Society that evening. In answer to Mr. Godlee he said that cases of escape of cerebro-spinal fluid generally did badly, because, he thought, of the septicity of the fluid. He had long been struck with the fact that the skin was not irritated when boracic acid an inch deep was heaped upon it, and it was by this means that he thought he had been able to keep the wound aseptic. The exact amount of the discharge of cerebro-spinal fluid he had not been able to determine, but he found it enough to completely soak a pad of wool two inches thick in twenty-four hours. He had noticed almost the same result with cerebro-spinal fluid in a head case. The large discharge in the present case he considered due to his having not been bold enough to take out the drainage-tubes after the first twenty-four hours, and so allowing a sinus to form.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, JUNE 6TH, 1888.

JOHN WILLIAMS, M.D., President, in the Chair.

Specimens.—Dr. HERMAN: Uterus Inverted by a Gangrenous Fibroid.—Dr. W. DUNCAN: Male Infant Secreting Milk from Right Breast.—Dr. AUGUST LAWRENCE: Vesical Calculi Removed from a Woman who for eighteen years suffered from complete Prolapse of the Uterus.—Dr. BRAXTON HICKS: Form of Hodge's Pessary made on Watch-spring Pessary Principle.

Inverted Uterus Removed by Operation.—A report was read on Dr. HARRIS's specimen of inverted uterus, exhibited at the May meeting.

Note on the Use of Electrolysis in Gynecological Practice.—This memoir was read by Dr. W. E. STEAVENSON. The author in this paper drew attention to the numerous cauterising agents used in gynecological practice, with the object of raising a discussion on their relative merits and values. Reference was also made to the use of the actual cautery, Paquelin's cautery, and the galvanocautery; but the paper was chiefly devoted to advocating a more extensive use of electrolysis. It was pointed out that this property of electricity was especially useful in the treatment of affections in parts difficult of access, and perhaps found its widest field for usefulness in the treatment of those diseases of women in which local applications were necessary. It was a more efficient and elegant way of applying caustic than any other that we possessed; it could be most accurately localised at the part it was wished to affect; the amount used and the extent of tissue to be destroyed could be regulated to a nicety, and its action could be commenced and arrested at

any moment at the will of the operator. A brief account was given of the action and theory of electrolysis, and of the batteries and instruments to be employed. Its action and the method of employing it in the following affections were then given, namely, stricture of the female urethra; stenosis of the os uteri or cervical canal; dysmenorrhœa and sterility, in the place of the tents, dilators, or incisions that were often employed; abrasions of the cervix uteri; extra-uterine foetation; fibroid tumours of the uterus; and cancer. The author then again invited discussion on the relative merits of other caustics and modes of treatment employed in the affections mentioned, as compared with their treatment by electrolysis.

Cases of Chronic Cervical Catarrh Treated by Electrolysis.—These cases, read by Dr. LOVELL DRAGE, formed an addendum to Dr. Steavenson's paper. In all, the healing of the abraded area was promoted. In one instance, where the chronic condition of the cervix was complicated by a Hunterian chancre on that part of the uterus, the beneficial effect of the treatment was well-marked. No untoward effects were produced by the electrolysis; menstruation was not interfered with, nor was pain caused, either at the time when the current was passing or subsequently. All the cases were of long standing, and other treatment had failed to give relief. Dr. L. Drage, therefore, contended that a claim could fairly be made for the recognition of electrolysis as a useful treatment in such cases.

Electrolysis in some Chronic Uterine Affections, with Illustrative Cases. By Dr. R. A. GIBBONS.—The author related cases, which had been under his care as in-patients at the hospital, of chronic metritis, endocervicitis, lupus minimus, caruncle of the urethra, and cancer of the uterus. The latter were accompanied by profuse hæmorrhage, and were mentioned in order to call attention to the efficacy of the positive pole in arresting bleeding. After explaining the action of each pole on the tissues, the author dwelt upon the advantages derived from the use of the negative pole as a caustic in chronic inflammatory conditions of the body and neck of the uterus. The glairy discharge, so common in this class of affections, became electrolysed, and thus the lining membrane could be acted upon directly and thoroughly. The accuracy with which the application of electrolysis could be made was greater than that of any caustic. During manipulation the operator had no difficulty in keeping the electrolytic power under his perfect control. After giving technical details Dr. Gibbons dwelt on the necessity of a reliable galvanometer. This method of employing electrolysis had never been described in any English work.

The Constant Current in the Therapeutics of Gynecology.—This communication was read by Dr. J. SHAW, Obstetric Physician to the North-West London Hospital. The paper described the appearances presented by a myofibroma when subjected, about twelve hours after its removal, to the prolonged action of a constant current, and treated of the chemical and microscopical results observed in a subsequent experiment; also of certain attendant electrical phenomena. The different action on granulations of the positive and negative poles respectively was described, and the effects of the constant current in intra-uterine applications and punctures, on the circulation, temperature, sensibility to pain, and urinary excretion, were in turn detailed. The author, from these observations, concluded that the constant current acted on a fibroid in a threefold manner: (1) to but a small degree by electrolytic action, the positive pole most affecting the cellular, and the negative the formed, elements; (2) by the hæmostatic action of the positive pole and the derivative influence of the negative; (3) by increased arterial tension and so diminished nutrition accompanied by some alteration of the mutual relation of the fluid and solid elements.—In the discussion which followed the reading of the above papers, Dr. HARRIS noted the important admission of Dr. Steavenson that electricity possessed no specific virtues, but acted as a stimulant, caustic, or cautery. A powerful battery was expensive, ponderous, and hard to work and to keep in order, hence in general practice it would hardly be preferred to acids, alkalis, the knife, or the thermo-cautery. In hospital practice he had found the battery to be of certain value, but he agreed to Dr. Steavenson's admission. Even in the treatment of paralysis, careful friction of the affected muscles proved as beneficial as electricity. Statements about the number of cells which were used in a given case were unreliable, for newly charged cells were stronger than the same cells charged for some time or not in perfect working order. A means of measurement was absolutely necessary; for this purpose a galvanometer answered best, but that appliance introduced another complication and

expense.—Dr. AUST LAWRENCE said that allowance must be made for rest in bed, purgation, and the other altered conditions to which a patient under treatment by electrolysis was subjected. A highly-trained electrician was not indispensable, as, with a little help and study, anybody could master the details sufficiently to be able to employ electrolysis; but, on the other hand, a sound knowledge of gynaecology was necessary.—Dr. HERMAN insisted on clinical observation. The utility of electricity could not be ascertained by *a priori* argument. He therefore considered that the most instructive parts of the communications read that evening were the cases reported by Drs. Lovell Drage and Gibbons. Dr. Matthews Duncan taught that, if a cervical erosion could not be cured within two months, treatment had better be discontinued. Yet Dr. Drage's cases had been under treatment for three or four months. In the case of Dr. Gibbons's patients the improvement might have been simply due to the complete rest and appropriate diet which patients enjoyed in a hospital. Women subject to the minor diseases of their sex could not rest at home, if poor; in hospitals they could rest and be cared for. To this fact was largely due the great benefit which followed treatment in hospital. The course of Dr. Gibbons's cases after leaving hospital had not been stated; in some, at least, all the symptoms might have returned within a few weeks. In one case a urethral caruncle had been destroyed by two applications of electricity. By the older methods one was usually sufficient. Dr. Herman admired the candour with which the results of the cases had been reported, but he did not think that the prognosis of such cases would be much modified by the introduction of this method of treatment by electricity.—Dr. WILLIAM DUNCAN said that much more carefully recorded clinical evidence was needed. He had employed electrolysis in several cases of myoma, with marked benefit in those where the chief symptom was metrorrhagia; and in one instance, at least, the tumour was markedly diminished in size, which proved that the electricity was something more than a mere cauterising agent.—The discussion was adjourned till Thursday, June 21st, at 8 P.M.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

FRIDAY, MAY 4TH, 1888.

C. B. BALL, M.D., President, in the Chair.

Unreduced Dislocation Backwards of the Bones of the Forearm.

—Dr. E. H. BENNETT exhibited a specimen of unreduced dislocation backwards of the bones of the forearm, preserved in spirit, and with it six similar specimens, preserved after maceration. He said his object was to draw attention to the fact that, although the varieties and conditions of elbow-joint dislocation had been very fully described, yet still, as regarded the point with which he was about to deal, the descriptions of this commonest of dislocations were calculated to mislead. They tended to errors of diagnosis. Dr. Bennett then quoted the opinions on the subject expressed by Malgaigne, Erichsen, Hamilton, South, and Tredof. Incomplete dislocations had been allowed to go unreduced because they had not been recognised. Such error arose in great measure from reliance on the test given by the authorities quoted—the displacement of the olecranon above the line connecting the condyles of the humerus. This displacement was present in complete dislocations, but absent in the incomplete. To ignore the existence of the incomplete dislocations, or to teach that they were recognised by displacement of the olecranon "half an inch or more above the condyle," was to insure that they should remain unreduced. It was admitted that backward dislocations of the elbow were the most common variety of displacement of the joint, and of these the incomplete were the more common. In museums, at all events, the latter were the more common, perhaps because they were those most frequently left unreduced. Dr. Bennett's attention having been directed to the subject by obtaining this recent specimen, he thought it well to reiterate the statement of Malgaigne that the incomplete form of dislocation, backwards at the elbow did occur; that it was the more common form of dislocation of both bones; and that it probably remained unrecognised because the test of the elevation of the olecranon, relied on in the descriptions of complete dislocation was applied to it. It was very easy for an incomplete dislocation to be overlooked when a certain amount of swelling concealed the various features, including the existence of the tumour formed by the displaced humerus in front, and the abnormal projection of the head of the radius backwards. The specimen before them

exhibited these peculiar characteristics of partial dislocation; in fact, looking at the back of the elbow, one would say that there was no dislocation at all of the ulna. But the radial dislocation caught the eye, and in front the humerus projected as an unmistakable tumour.—The PRESIDENT said there had been no more important communication recently in the Section than that with which they had been just favoured. He would ask whether Dr. Bennett had satisfied himself of its existence in the case of any living subject.—Sir WILLIAM STOKES asked what were the signs that would enable them to diagnose this injury during life.—Dr. BENNETT, in reply, said he desired first to refer to one point in which the complete dislocation, when unreduced, differed very markedly from the incomplete. In the latter form, when it was unreduced, the displaced bones assumed at their ends a quadrilateral shape, whereas in the complete dislocation there was nothing of the kind; the bones lay all free of each other, and there was no unusual modification of shape. The appearance of the olecranon beneath the level of the two condyles marked the incomplete dislocation. Again, the incomplete dislocation was a very fixed lesion; hardly any movement of the dislocated bones was possible. In complete dislocation, on the other hand, the bones could be moved laterally with great freedom; particularly as the coronoid process was broken away. The ligaments were untorn to a great extent in the incomplete dislocation, and the bones were retained in a state of unstable equilibrium. There was a great difference in practice only as regarded the two lesions. As Malgaigne had pointed out, the incomplete dislocation was reduced with great ease—although it was so fixed, and could be reduced long after the occurrence of the injury, even so long as two years. On the other hand, the lapse of even a month after a complete dislocation was sufficient to render it absolutely irreducible. This was a fact of immense importance in estimating the force to be applied to an unreduced dislocation. The experience of all surgeons was that irreducibility occurred very early in the complete lesion, although it was very movable, while the incomplete dislocation could be reduced many months after the injury, although with difficulty. He could add nothing to the facts which were published concerning the injury in question by Malgaigne and De Musset so long ago as 1854 and 1855.

Acute Lobar Pneumonia and Chronic Bright's Disease.—Dr. JAMES LITTLE communicated a case of acute lobar pneumonia and chronic Bright's disease in a boy, aged 4 years, seen first on March 31st. According to his mother's account, he was in perfectly good health until two days previously, and on the day before his admission was playing about the house. The only thing she noticed—and it was what led her to bring him to the hospital, was that he had become swollen all over the body; the swelling first appeared in his face. When admitted he presented the typical appearances of a case of acute Bright's disease. His temperature was rather high, exceeding 104°. He had a little cough, not much, and no special hurry of breathing, save that on one occasion, when put into a warm bath, his breathing rose to 76. He was recognised as a child that had been in the hospital ten months before under the care of Dr. Beatty for acute Bright's disease, and the record showed that before he left the hospital at that time his urine was entirely free from albumen. He only lived three days after his admission. On the thorax being opened it was found that he had suffered from acute croupous pneumonia, which was not discovered during life. When the specimen was recent it was an exceedingly beautiful specimen of what Dr. Wilkes had described as a curious inflammation which was capable in a few days of converting the spongy texture of the lungs into a structure like cheese. Even now the upper lobe of the right lung presented the typical appearances of true croupous pneumonia; but they found what did not so frequently exist in such cases, namely, three islets of pneumonic process, one in the middle lobe and two in the lower lobe of the same lung. The kidneys were microscopically examined by Dr. Bewley, who found the convoluted tubules almost completely choked by swollen epithelium and albuminous material. It was difficult even in the light of the *post-mortem* examination to read the case. The impression on his mind was that it was acute pneumonia occurring in a patient who had previously been the subject of chronic Bright's disease, because it had been his experience that when pneumonia attacked a person who had previously been the subject of chronic Bright's disease, it was rapidly fatal. The microscopic appearances found by Dr. Bewley hardly accorded with the existence of chronic Bright's disease. On the other hand, it was very difficult to understand why a child could become so extremely

anasarcous as this child was from acute Bright's disease, and have kidneys which, instead of being bloody and dripping, were much paler than kidneys usually were after death in cases of acute Bright's disease. While the boy was alive he examined his chest on two or three occasions in search of pleural effusion; but, finding no sign of it in the lower part of the lung, he did not examine the upper portion. The boy's decubitus was invariably on the back, with a slight turn towards the right side.

Unreduced Dislocation of the Elbow.—Mr. J. LENTAIGNE submitted a case of unreduced dislocation of the elbow, with fracture of the lower end of the humerus. The two casts before them were taken from a patient who came under his care in the Mater Misericordiam Hospital some time ago. The case was one of those dislocations which were so commonly seen, but in which they could rarely prove whether the diagnosis was correct or not. The two casts represented the extremes of extension and flexion of which the limb was capable. The powers of pronation and supination were completely lost; the patient could not bend his forearm to within half-a-foot of his mouth, and the functions of the limb were in every way exceedingly impaired. The patient was a boy, aged 15. About a year ago he was violently pushed against by a horse, and the palm of his hand, held out in a semi-extended position, was struck by the horse's flank. He went to a bone-setter, who twisted his arm backwards and forwards, causing him frightful pain, and his arm then became utterly helpless. When the joint was excised last November, Mr. Lentaigne found a dislocation of the forearm backwards, with a fracture of the lower end of the humerus through the epiphysis. The lower epiphysis was broken into three portions. The line of the fracture could be seen clearly through the lower end of the bone. The olecranon fossa was reduced to a groove so narrow that his finger barely went into it.—Dr. BENNETT said he did not quite admit the diagnosis of an unreduced dislocation, and he saw no necessity for assuming the existence of a fracture as the explanation of such a condition. The idea of an epiphysary lesion should be put aside. In the casts the tumours formed respectively by the olecranon and the head of the radius were normally distant.—Mr. LENTAIGNE, in reply, said that though he had the greatest respect for Dr. Bennett's opinion, he could not help holding to his own in this instance. The patient had now got a joint perfect in all respects.

Intestinal Obstruction.—The PRESIDENT gave an account of three cases of intestinal obstruction, the viscera of which were on the table. The first case was that of a man, aged 27, who stated that he was quite well until February 12th in the present year. On March 7th he came under his (Dr. Ball's) care in the hospital, and stated that since February 17th he had had no fecal motions, save a little mucus, and that only after great straining. An examination of the rectum discovered a tumour pressing back the sacrum, which was as large as a foetal head. There was no fluctuation in any part of the swelling. All attempts to procure evacuation having failed, an exploration was made, and the interior of the peritoneum was found to be studded with small tumours, while in the iliac fossa was a large soft tumour, to which the small intestines were adherent. Colotomy gave temporary relief, but the man died with symptoms of obstruction higher up. On *post-mortem* examination an enormous mass of brawn-like tumour was found filling up the greater part of the abdomen. When freed from the intestines and surrounding parts it weighed ten pounds, and yet it had grown in less than six weeks. A portion of it surrounded the rectum and pressed it so completely that nothing could pass through. The portion of the sigmoid flexure, which was drawn out to make the artificial anus, could be seen in the specimen. The immediate cause of death was not obstruction of the large intestine, but a secondary obstruction of the small intestine, caused by the pressure of the tumour against the parietes of the abdomen. That this pressure produced complete obstruction was evident from the appearance of the intestine both above and below the seat of pressure. Dr. Purser had examined the tumour and pronounced it to be a sarcoma.—The second case was that of a woman, aged 36, who was admitted into the hospital on March 29th. For a week previously she had been constipated, and vomited every day. A marked feature of the case was that there was no evidence of distension of the intestines by gas. That led to the diagnosis of an obstruction high up, and on the same day laparotomy was performed. After searching for obstruction at the usual hernial point, they were guided by a portion of inflamed intestine to the left hypochondrium, and there found a large mass of intestine, several feet in length, much congested, roughened on

the surface, and tightly constricted by a ring formed in this way. The operation relieved the symptoms; but the wound opened six days afterwards; a portion of the omentum prolapsed; the case became septic, and she died. On *post-mortem* examination they were just able to find out where the obstruction existed. There was no general peritonitis about the seat of the obstruction. There was some inflammation of the omentum, and also in the pelvic cavity. Although the case was septic it was also afebrile, the woman's temperature never having risen above 99° during the ten days that she lived.—The third case was that of a man, aged 69, who was quite well until about three weeks before his admission to the hospital, when he began to suffer from loss of appetite, constipation, and distension of the abdomen. When he came in the distension was so excessive that no examination could be made. An examination by the rectum revealed nothing. A localised tympanitic distension of the abdomen was at first thought to be due to a dilated stomach, but that was negated by the passing of a tube. On *post-mortem* examination the surface of the intestine was covered with little masses of secondary cancer, like boiled sage. In the liver were found several little depressed umbilicated patches, such as they were familiar with in cases of secondary cancer. On searching for the focus of obstruction it was found to be in the tissues surrounding the caecum, where there was a large hard mass, the gut itself being considerably constricted. A section of the growth made by Dr. Weir showed it to be an ordinary cylinder-celled carcinoma, such as was commonly met with in the intestinal tract. A point which he was at a loss to understand was, that they were unable to find any portion of the intestine in which the mucous membrane was implicated.—A discussion followed, in which Dr. BENNETT, Mr. LENTAIGNE, Dr. T. E. LITTLE, and Dr. FINNEY took part.—The PRESIDENT replied.

Secondary Cancer of the Lung.—Dr. G. P. L'E. NUGENT communicated a case of secondary cancer of the lung in a metropolitan policeman, aged 26. On *post-mortem* examination both lungs were covered with innumerable nodular masses, varying in size from that of a walnut to that of a pin's head, more or less round in shape, projecting externally and into the lung, covered over with a perfectly smooth layer of pleura. The nodules were yellowish-white on section, and of rather soft consistence. The lungs internally were congested and oedematous. The mediastinal glands were much enlarged, and the weight of the lungs, heart, and glands collectively was 177 ounces. The glands on the left side of the neck were enlarged and softened in the centre. The liver was enlarged, 84 ounces, and pale in colour. The right kidney was 6 ounces in weight and pale; the left was normal. The abdominal glands were greatly enlarged, particularly along the course of the aorta. The right testicle was hard and heavy, slightly nodular, but little increased in size.

Pulmonary Artery with Two Valves.—Dr. A. W. FOOT exhibited a specimen of a pulmonary artery with two valves of equal size, and presenting no abnormal appearance other than unusual size. The heart exhibited was taken from a man, aged 69, who had long been subject to aortic regurgitation. Alluding to the rarity of this defect in the pulmonary valves, Dr. Foot observed that the only other example he knew of in Dublin had been found by Dr. Graves in a man, aged 66, who died of pneumonia and pericarditis. In five museums in London Dr. Peacock had been able to obtain only nine specimens of two-valved pulmonary artery. Numerical irregularities in the semilunar valves were much more often observed in the aorta than in the pulmonary artery.—Dr. BEWLEY said he once saw a similar form of aortic valve. It was taken from a man who had suffered from a nervous affection of the heart. There were two large flaps, each a good deal larger than the aortic flap, and between these a very small third flap, measuring between a third and a fifth of an inch across. They were all perfectly healthy. During life the aortic sounds of the heart had been perfectly healthy.—Dr. FOOT, in reply, said the formation of two ordinary-sized flaps, with a small one between them, was a well-known one. In the museum there was a pulmonary artery with four valves.

SECTION OF SURGERY.

FRIDAY, MAY 11TH, 1888.

A. H. CORLEY, M.D., President, in the Chair.

Punctured Wound of the Peritoneum, with Protrusion of the Intestine: Recovery after Operation.—Mr. F. DONNELLY related this case (which was published in the JOURNAL of June 9th, page 1219).—Dr. FRASER mentioned the case of a

boy, aged 7, who, while jumping over pointed sticks, was spiked behind the upper part of the testicle, sustaining a severe wound. An abscess formed, and in a few days out came a piece of the boy's breeches. He thoroughly believed in the benefit of opium in abdominal attacks, but small doses were of little use.—Dr. A. W. Foor also expressed himself in favour of the opium treatment, and related a case in which a wild cow gored a man, ripping open his abdomen. The intestines protruded, and without help the man struggled home, treading on his own intestines. The intestines were sponged to remove chopped straw, bits of hay, leaves, and dirt, and then put back, and the wound was stitched up. The patient was kept under the influence of opium as much as possible, and made a good recovery.—Dr. MOLONEY referred to a case in his own practice in which a man sustained eighteen or nineteen wounds of the body, abdomen, penis, legs, and arms in a fight with another man, who slashed him with a butcher's knife. Although the man did not tread on his intestines, they protruded, and were covered with dirt. He washed the intestines carefully and put them back, the wounds requiring forty-six or fifty-six stitches. Having treated him freely with opium, the patient recovered in four weeks without inflammatory symptoms beyond slight tympanites.—The PRESIDENT considered that large doses of opium were best.—Mr. NINIAN FALKNER also spoke.—Mr. DONNELLY, in reply, said the small doses of opium were given, having regard to the age of the child, while he was ready to increase the dose if required.

Enterectomy and Enteropathy.—Mr. M'ARDLE read a paper on enterectomy and enteropathy.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

PATHOLOGICAL AND CLINICAL SECTION.

FRIDAY, APRIL 27TH, 1888.

A. S. UNDERHILL, M.D., in the Chair.

Syphilis modifying Phthisis.—Dr. FOXWELL showed a case of phthisis in a man aged 21. It was interesting for these reasons: 1. When 17 years old the patient suffered from an attack of inflammation of the lungs, which confined him to bed for nine weeks, but from which he completely recovered. The physical signs now were almost confined to the base of the right lung. 2. Though he had had expectoration with his cough for 2½ years, and had been exposed to great hardship, yet the physical signs were decidedly those of early phthisis, and his general bodily condition was good. This Dr. Foxwell considered to be due in great measure to his being the subject of congenital syphilis, as he believed syphilis strongly militated against rapid destruction of lung tissue. Bacilli were present in moderate numbers.

Secondary Syphilis in an Old Woman.—Mr. MORRISON showed a case of secondary syphilis in an aged woman. The patient was a woman aged 68, who first presented herself on March 2nd, with a shallow suppurating sore, without induration, on the right labium majus. It was at first thought to be an ulcer caused by chafing. It quickly healed under the local application of iodoform powder. On March 29th a copious general papulo-squamous eruption was noticed, unmistakably syphilitic in character. At the present time there were characteristic spots on the nape of the neck and also enlarged cervical glands and sore throat. During the child-bearing period, she had borne eleven healthy children and had never had a miscarriage.

Subungual Exostosis.—Mr. MORRISON also showed the last phalanx of a thumb he had removed on account of a sub-ungual exostosis in a man aged 39. It was exhibited as an illustration of the homology between the hallux and the pollex: such growths being common on the great toe, but rare on the thumb.

Obstetrical Paralysis.—Dr. SUCKLING showed a case of obstetrical paralysis in an infant. The child's birth had been difficult, and turning had been performed. The left arm was noticed to be useless soon after birth. There was paralysis of the deltoid, supra- and infra-spinatus, biceps, brachialis anticus, and supinator muscles; the limb being extended and forcibly pronated. The paralysed muscles were wasted and flaccid, and presented the reaction of degeneration. The infant could move the fingers and hand. Dr. Suckling frequently met with the affection at the Children's Hospital, and he found that the paralysis was usually severe and more or less permanent.

Dilated Stomach.—Dr. SUCKLING also showed a man, aged 40, a puddler, who had complained for twelve months of pain and

heaviness after food, with excessive flatulence and vomiting. From the nature of his work he had been obliged to drink large quantities of liquid, and he had consumed enormous quantities of ginger beer, barley and oatmeal water. Dr. Suckling found that on palpation of the abdomen a well-marked succussion splash could be easily obtained; fluctuation could be elicited through the abdomen, and the stomach percussion-note extended almost to the pubes. The vomit contained sarcine. No peristalsis was observed at any time. The man was admitted into the Queen's Hospital on April 16th, and was treated as follows: Every morning the stomach was washed out with a solution of hyposulphite of soda. Only one pint of milk was given daily by the stomach, and this was peptonised; the patient was otherwise fed by enemata. A mixture containing strychnine and sulphocarbolate of soda was also given. The patient had not vomited since the commencement of treatment; he now felt quite well; the stomach area, though still large, had receded to the umbilicus, and the succussion splash was not so readily elicited. The patient had not lost much flesh.

Cirrhosis of the Liver in a Child.—Dr. HOBGEN exhibited the liver of a child aged 6 years, who died at the Children's Hospital. The liver was not much diminished in bulk as compared with the weight of the child's body, and the surface did not exhibit the "hobnailed" appearance to a very marked degree. The organ was extremely tough, the spleen much enlarged, and ascites with jaundice present before death. Microscopic examination revealed a very extensive new growth of fibrous connective tissue, taking the form of ordinary atrophic cirrhosis. The parents of the child had been in the habit of giving it beer and rum.

Spina Bifida Occulta.—Mr. BARLING showed, for Mr. MCCARTHY, a specimen of spina bifida occulta in the upper lumbar region. Associated with the condition were the following: a fusion of the laminae of the eleventh and twelfth dorsal vertebrae on the left side, and partial fusion of the bodies of the same vertebrae, dilatation of the central canal of the spinal cord, and inclusion of a process of dura mater in the anterior fissure of the cord. The skin over the bifid spine was covered with a patch of dark hair of considerable length, whilst deeper there was a sebaceous cyst an inch in its largest diameter. The specimen was taken from the body of a child aged 2 years, who died of broncho-pneumonia, and who had no idea of walking, although there was no condition of talipes present.

Alveolar Sarcoma of Breast.—Mr. HASLAM showed a breast he had recently removed from a woman aged 45. Six months before admission she noticed a small lump in the left breast; this gradually increased to the size of a large orange. There was no pain. The skin for an inch round the nipple was reddened, slightly swollen, and could not be freely moved over the growth; the nipple was not markedly retracted. The axillary glands were enlarged; the supra-clavicular glands could also be felt. On February 7th the breast, with the unhealthy skin and axillary glands, were removed. On making a section of the breast the growth was seen to have a distinct limit, being surrounded by apparently healthy breast-tissue; the cut surface was slightly convex, did not yield any juice, and felt and looked like fibrous tissue. On microscopic examination it was found to be an alveolar sarcoma. The patient recovered from the operation, but by the beginning of April there were obvious signs of recurrence in the tissue round the cicatrix and in the supra-clavicular glands. At the end of the month several fresh nodules had arisen in the skin at a distance of an inch and a half from the cicatrix. Attention was drawn to the rarity and extreme malignity of this form of sarcoma of the breast.

Air in Abdominal Abscesses.—Dr. MALINS read a paper on the presence of air in suppurative swellings of the abdomen, and related four instances in which it had come under his notice. He attributed it to decomposition of the contents of such collections—first, from the contiguity to the intestinal canal; and, secondly, from the presence of bacilli, which probably acted as carriers of the necessary elements. He thought it interesting, and exceptional from a clinical view, since in each instance the air occupied the uppermost surface of the interior swelling, and gave a resonant note on percussion, though fluid was present in quantity. The cases referred to were a suppurating hæmatocele, a remote parametric abscess, and two peritoneal cases. They were washed out and drained, all recovering.

Cases.—Dr. SIMON showed a patient with pseudo-muscular hypertrophy.—Mr. HAWKINS showed, for Mr. LENNETT MAY, a boy on whom he had performed amputation of the upper ex-

tremity in the contiguity of the trunk, by Berger's method, for sarcoma of the head of the humerus.

CAMBRIDGE MEDICAL SOCIETY.

FRIDAY, APRIL 6TH, 1888.

H. STEAR, M.R.C.S., President, in the Chair.

Urethral Calculus.—Mr. BALDING exhibited a calculus which he had removed by perineal section from the urethra of a man, aged 24, who came under the notice of Mr. F. Davey in consequence of a fistulous opening in the scrotum, about one inch from its perineal margin, discharging pus and urine. This had existed for about ten days, and the patient then attributed all his symptoms to bruising his perineum when getting over a stile about three weeks previously. The calculus, which caused induration and swelling of the whole perineal region, was easily reached through the sinus, and removed by enlarging it sufficiently backwards. The wound healed favourably. The calculus when dry weighed 624 grains, was 2½ inches in length, and 1½ in breadth. No satisfactory history could be obtained from the patient himself, but that procured from others established the fact that from about two to four years of age he had constant urinary troubles, and was considered to suffer from "gravel." Neither the man himself, nor any of his friends, knew of any subsequent symptoms till quite recently. It would, therefore, appear that a calculus existed in the bladder during childhood, and that it then passed into the urethra, where it remained for twenty years without producing any serious trouble till the perineum was injured, and suppuration followed. Mr. Balding referred to the other recorded cases, a somewhat similar one of which was by Mr. Christopher Heath, the calculus described by him bearing a curious resemblance to the one now shown.

Foreign Body in Rectum.—The PRESIDENT related a case in which he had removed a rib bone of a rabbit from the rectum of a man who had eaten some rabbit the day before.

Hydatid Cyst of the Liver.—Mr. C. LUCAS related a case of this affection.

Cerebellar Hemorrhage—Mr. A. INGLE (Shelford) read the notes of a case which occurred in a widow, aged 63. Ten years before she had an attack of paralysis on the left side, from which she recovered, the only remaining defect being a slight lisp. She had been subject to bilious attacks, and had often complained of giddiness in the head. On February 12th, 1888, she walked a mile to chapel, sat the service out, and afterwards it was noticed she was looking unwell. She walked into the vestry, thinking one of her bilious attacks was coming on, but feeling much worse in the course of an hour, she was helped to a neighbour's house, and soon afterwards vomited. She was put to bed, and became very drowsy. Several attacks of vomiting occurred during the day. She would mutter replies to questions, but one could get but very little information from her. She complained of no pain but headache. There was some retraction of the head; pulse 88, regular, fair volume and strength; arteries somewhat atheromatous; the first sound of the heart was not quite clear, but there was no definite murmur; the pupils were equal and active to light; no arcus senilis, no loss of power or sensation. Next day her condition was unchanged, but there was no further vomiting. On the 17th there was some loss of power in the left arm, and the urine occasionally dribbled away; the patient lay in a drowsy condition, but seemed to hear whatever was said in the room, and would occasionally interpose a remark. By the 20th the left arm was entirely paralysed, also some muscles on the left side of the face. Two or three days later the tongue was protruded to the right. She lingered till the 27th—fifteen days from the commencement—occasionally passing for several hours into a comatose state (once for forty hours), when she would be perfectly still, taking nothing, and not being able to be roused. For the last forty-eight hours she was in this condition. There was no evidence of loss of co-ordination. The following were the notes of the *post-mortem* examination: Very thin and soft skull. Much senile atrophy of convolutions and accumulation of subarachnoid fluid. No softening or lesion on exterior. Occupying position of right claustrum was a small cyst three-quarters of an inch deep by one-sixth inch broad, containing clear, serous-looking fluid. In left cerebellar hemisphere was large hæmorrhage, chiefly in region of convolutions, involving only posterior part of whole cortex. This extended a little to the right of the middle line. There was, besides, a small hæmorrhagic softening in posterior wall of posterior cornu of right lateral ventricle, but no blood in ventricles. Much atheroma of cerebral arteries.

MANCHESTER MEDICAL SOCIETY.

WEDNESDAY, JUNE 6TH, 1888.

J. DRESCHFELD, M.D., F.R.C.P., President, in the Chair

CLINICAL MEETING.

Cases.—Dr. DRESCHFELD showed a case of fibroid phthisis of the left lung, in which a pulmonary murmur was heard and the left vocal cord was paralysed.—Dr. LEECH showed a woman suffering from diabetes, who presented paralysis of the third, fifth, and sixth nerves.—Mr. WRIGHT exhibited a case of lupus erythematosus, and also one of rupture of the larynx.—Mr. JONES showed a case of ruptured urethra.—Mr. RICHMOND showed a case of congenital angioma.—Mr. MUSSON showed a case of multiple fibromata.—Mr. MORGAN showed a man presenting a peculiar rigidity of muscles throughout the body.—Dr. EMRYS-JONES showed a girl suffering from right hysterical hemianesthesia, with achromatopsia, and contraction of the field of vision on the same side.—Dr. WILSON exhibited different forms of apparatus for the administration of anaesthetics.

REVIEWS AND NOTICES.

SCIENTIFIC MEMOIRS BY MEDICAL OFFICERS OF THE ARMY OF INDIA. 1. Note on some Aspects and Relations of the Blood-Organisms in Ague. 2. Note on the Occurrence of a Minute Blood-Spirillum in an Indian Rat. 3. On the lately-demonstrated Blood-Contamination and Infective Disease of the Rat and of Equines in India. By Brigade-Surgeon VANDYKE CARTER, M.D.Lond., Bombay Army, Principal and Professor of Medicine, Grant College, Bombay.

In the first of Dr. VANDYKE CARTER'S papers the headings of which we have given, the author refers to Professor Maclean's observations on the researches of Tommasi Crudeli, Klebs, and Marchiafava, in which that author dwells on the significant fact that the bacillus malarie had eluded the search of competent observers in all parts of India where malarial fevers prevail. Among the unsuccessful searchers for the bacillus malarie was Dr. Vandyke Carter himself. Stimulated by the account given in this JOURNAL of March 12th, 1887, of Dr. Laveran's researches by Professor Osler, Dr. Carter renewed his examination of the blood of men affected with ague, and quickly detected at fever-periods many pigmented spherules, and subsequently the equally characteristic "crescentic bodies." The cases were taken as admitted, and before the administration of quinine. In the first case, one of quartan ague, the blood was examined on twenty-six days, about dates of every relapse, also during the intervals, and often subsequent to the latest paroxysm seen. With the onset of the fever, "pigmented spheroids, both sessile and free," were observed, and at apyretic periods only some pigmented leucocytes were seen in the blood. At no time in this case were crescentic bodies found, but on the third day after the last paroxysm of fever (quinine previously given) active flagellated spherules in the blood were detected with a temperature of 98° at 9 A.M.; at 1.45 P.M., only a few bare spheroids; and again at 2.15 A.M. and 1 P.M., after which date the blood remained free from visible contamination. We have not space for the details of the blood examination of the six other cases studied, restricting ourselves to the author's summary of the whole data.

"I consider there is proof enough that the genuine 'ague state'—the 'malaria process' in older term, and in the new the 'malaria infection'—is pathologically distinguished by a visible living blood-contamination (a) having hæmatozoic rather than hæmatophytal affinities, (b), and displaying a relationship to clinical symptoms which, if often less precise than obtains with pathogenic bacterial infections, may none the less be real. (c) Further, it has been shown that, in arresting malarial pyrexia, the drug quinine does not with equal promptitude annihilate the blood parasite; (d) this datum also indicating a probable different relationship of phenomena in the nomadic as compared with bacteric infection. That the hæmatozoa undoubtedly present in ague hold a close, if not causal, relation to the disease, may be inferred from, first, their constituting an adequate pathogenic influence, and, next, their exclusive limitation to this one morbid affection; nor need such influence be annulled by seemingly conflicting evidence regarding the details of

association. According to my observations, the visible blood-contamination may be more constant and uniform than concurrent pyrexial phenomena; and hence the inference that it is fundamental, whilst 'fever' is rather a contingent event. Certainly not all fever in malarious subjects is necessarily monad-pyrexia; and by experience I have been led to recognise at least three forms of such 'fever,' namely, first, the genuine specific form, with its positive blood-aspects; next, and oftener in old cases, the consecutive residual or quasi-reaction form, with its negative blood-state, which may have simulated the genuine type in a clinical sense; and, lastly, the pyrexia pertaining to a superadded infection, which for a time supersedes the monadic—as, for example, was demonstrated for enteric fever by Dr. Laveran. As to nature and causation, I would add that present results serve to explain the paroxysmal and periodic character of paludal fever, through the corresponding definite duration and reproduction of a living contagium. That such pathogenic agent should be zoöic rather than phytal, is a dictum of physiological import; because infusorial life is known to prevail under different and more restricted conditions than the bacterial, and hereby a clue may be gained as to the sources of ague-infection. The foreign and nondescript term of 'malaria' adopted in Britain since 1827 may soon have to be abandoned, if not in favour of the prior indigenous name of 'marsh' poison, at least of a designation referring to definite conditions of soil, moisture, and water-supply." Dr. Vandyke Carter concludes by a reference to Professor Maclean's concluding remark on the essential nature of malaria in Quain's *Dictionary of Medicine*, p. 914, with reference to Laveran's and Richard's researches on the spherical organisms developed in connection with the red corpuscles, to the effect that "should future investigations by independent observers in other malarious regions confirm these conclusions, it would be difficult to overrate their importance." On this remark Dr. Vandyke Carter adds, "and now it may be seen how far, as regards India, such confirmation has been realised." It should be added that the author quoted by Dr. Vandyke Carter in discussing the question of the bacillus malarie in his published lectures, does not dispute the existence of such a fungus, or that its discoverers found it in the organs of men who have died of malarial fevers, but he points out "that these fevers prevail in regions widely different from that of the Agro Romano, in arid sandy districts where it is difficult to believe that such a bacillus could find the conditions needful for its existence." Whether this observation will apply with equal force to the blood-organisms described by Laveran, Richard, and Carter, experience must decide. Meanwhile this gentleman's researches are as welcome as they are interesting.

We must postpone notice of the author's other papers to a future opportunity.

A COURSE OF QUANTITATIVE ANALYSIS FOR STUDENTS. By W. N. HARTLEY, F.R.S. 8vo. London: Macmillan and Co.

THIS is a carefully-executed little book, which will form in many respects a valuable laboratory outline to students engaged in quantitative chemical analysis. It is not, nor does it profess to be, a complete work on the subject, and requires abundant amplification on the part of the student, by reference to larger and more exhaustive treatises. The examples are well selected, but the scope of the work might with advantage have been considerably widened. Thus, we cannot consider that a student has passed through a satisfactory course of even elementary quantitative analysis without having made himself acquainted with the methods of determining the ultimate constituents of organic compounds, yet of this important branch of analytical chemistry there is no mention.

For the same reason we are somewhat surprised to see a method of coal analysis described without any reference to the mode of determining the elementary ingredients—carbon, hydrogen, nitrogen, and oxygen. Again, the analysis of urine given is so incomplete as to be practically valueless. We cannot help thinking, therefore, that it would be desirable to indicate in the title that the "course of quantitative analysis" described is of a purely mineral character.

We are perfectly aware that a student has rarely sufficient time to pass through a longer course of quantitative analysis than that given in this volume; but it is extremely important that his work should be of as varied a character as possible. Indeed, we should like to see the tasks allotted to the several students working side by side in a laboratory more differentiated than is

usually the case at present, so that each student might be profiting from his neighbour's operations as well as from his own personal experiences. We take it that Professor HARTLEY'S work is hardly calculated to encourage this mode of laboratory teaching, but rather to foster excessive uniformity.

A TEXTBOOK OF BIOLOGY: comprising Vegetable and Animal Morphology and Physiology. Designed more especially to meet the Requirements of the Intermediate Science and Preliminary Scientific Examinations of the London University. By J. R. AINSWORTH DAVIS, B.A., etc., Lecturer on Biology in the University College of Wales, Aberystwith. With numerous Illustrations, Glossary, and Examination Questions. London: Charles Griffin and Company.

THE useful fashion of preparing a monograph on the anatomy and physiology of some animal or plant easily procurable in this country is still in vogue amongst the best scientific writers. Perhaps a strictly practical and analytical work of that kind is particularly suited for the student, as it represents the most thoroughly scientific manner of studying Nature. It teaches the student to begin with observation, and to dissect, rather than to learn a number of hard words in a particular order, for that is what is meant by getting up classification before opening the book of Nature. Nevertheless, systematic and synthetical biology must be learnt, and that work on the subject is the best which is the most comprehensive. The student who has studied a few good monographs on typical plants and animals will be well prepared for Mr. DAVIS'S work, which maintains, as far as can possibly be managed, the analytical description of each type.

No doubt, to include the whole range of the vegetable and animal kingdom in a textbook of no very rudimentary character was a bold deed. Mr. Davis has not failed in his attempt, though perhaps his manual is rather too deep to be read through for examination purposes. The study of certain departments marked off by examining boards for some particular examination will prove profitable to the candidate; for, as we have already noted, each organic form is treated in an analytical fashion. At the same time, the candidate will be able to trace the relations of the form allotted to him for study, by perusal of neighbouring departments of the *Textbook*. As a general work of reference, Mr. Davis's manual will be highly serviceable both to medical men and to amateur or professional scientists.

Mr. Davis has not been sparing in his selection of types from the lower forms of vegetable and animal life. Thus from "fungi" he selects saccharomyces, bacteria, mucor, and penicillium. From the vertebrata he has chosen the frog, alone, as representing the ichthyopsida, the pigeon to exemplify the sauropsida, and the rabbit to demonstrate the anatomy and physiology of the mammalia. This arrangement was partly rendered necessary on account of the greater variation in essential organs amongst the lower types.

THE PRINCIPLES OF CANCER AND TUMOUR FORMATION. By W. ROGER WILLIAMS, F.R.C.S., Surgical Registrar to the Middlesex Hospital, Surgeon to the Western General Dispensary. London: John Bale and Sons.

MR. ROGER WILLIAMS, undoubtedly a good philosophical pathologist, has conceived the bold scheme of writing a treatise on the pathology and treatment of cancer and tumour formation in six parts. This work forms the first part of the contemplated treatise. His ideas recall the principles of Darwin's great theory, and much stress is laid on elementary pathology, on which Sir James Paget has often dwelt. The author reviews cell-multiplication and the phenomena of more complicated types of reproduction, and then turns to the evolution of vegetable neoplasms, to which subject he devotes a highly instructive chapter. Animal neoplasms are next described and discussed. The author lays stress on the great influence of evolution, the ancestry of a cell determining its growth often uncontrolled by different surrounding circumstances. Thus the normal ovum of any species of plant develops that species alone; and changes in surrounding conditions may check the growth of the ovum, or kill it, but cannot make it develop another species of plant. In a similar manner, a cell when morbidly grafted on a structure more or less distant from the tissue whence it originated can only develop similar tissue. Cells engaged in the evolution of highly organised structures suffer im-

pairment of their reproductive power, owing to their protoplasm being chiefly converted into special tissue. They are little, if at all "emancipated," as Mr. Roger Williams loves to express the fact, from their parental structure; hence when they form a tumour it is a comparatively inert mass, living, it is true, and histologically identical with the parental structure, but devoid of infective or malignant qualities. But lowly organised cells are more thoroughly "emancipated" from their source in lowly organised tissues; they exert a powerful autonomy seen in malignant tumours and in the metastatic deposits to which those growths give rise.

No doubt the author works on sound principles; his method is scientific and, if his inferences be not infallible, he has arranged his facts well, so as to be of service to others. Medical teachers are more enlightened than they were twenty or thirty years ago. In those days students were sometimes, though not always, taught microscopic pathology, and though an old-fashioned hospital surgeon is said to have discouraged an enthusiast by saying "Bother your sarcomas, stick to something practical," most students were shown sections of carcinoma, enchondroma, and other tumours. Yet normal human histology was much neglected. The faithful study of that subject in British medical schools during the past ten years has done much to promote good pathological work in this country. Mr. Roger Williams represents a yet newer type of pathologist, who studies cells in the lower animals and in plants, in order to compare them with the cells which form tumours in man, an improvement on the unscientific system of teaching the histology of the human viscera from sections of guinea-pigs' and cats' livers, kidneys, etc. The disadvantage of that practice is obvious when it is borne in mind that the student may thereby be led into error when examining sections of human kidneys supposed to be diseased. Being ignorant of the histology of the human kidney in health, he cannot judge soundly of its morbid appearances. Mr. Roger Williams's plan may profitably be extended from the study of cells to the study of tissues. A thorough investigation of the histology of the succulent, lowly-organised tissues abundant in some of the lower animals might throw yet more light on neoplasms; but the work must be done by pathologists and biologists simultaneously.

ORTHOPÄDISCHE CHIRURGIE. DR. AUGUST SCHREIBER. Leipzig and Wien: Franz Deuticke. 1888.

THIS is the most recent German publication upon this important branch of surgery, and contains a large amount of useful information clearly put. The work is one of 340 pages, but contains no fewer than 388 figures, and though these are not all of the usual excellence of German illustrations, they add very materially to the usefulness of the book. Both the deformities to be treated and the means of treating them are thus readily grasped, and many of the figures will be found of service by English readers. Moreover, there is a very full list of the literature—English, German, French, and Italian—given at the head of each subject treated, and this is not only full, but remarkably well posted up to very recent date. We notice, for instance, that references are given to papers in the *JOURNAL* of 1887, and previous years upon that curious congenital affection of dislocation at the hip-joint, and its treatment by Barwell, Black, and W. Adams. Other subjects are equally well given.

A short notice of hammer-toe is not so satisfactory, and does not throw much light on its cause or best treatment as we are now inclined to regard them. There are special chapters on rickets, torticollis, deformities of spine and thorax, contractions, ankyloses, knocked knees, deformity of the foot, paralytic deformities, and congenital dislocation. Delore's method of forcible straightening of bent bones, lately advocated by Mr. Edmund Owen, is mentioned here, but these and many similar violent proceedings seem to us to require special skill and experience, and are likely to do more harm than good in inexperienced hands.

The work has much to recommend it to German readers, and will prove of great use, especially for the illustrations and references. It is unfortunate that the binding of so many of these foreign books is so unsatisfactory that they fall to pieces before they have been looked through, but they contain an amount of material in them that puts our English works very often to shame.

DR. MAXWELL T. MASTERS, F.R.S., Vice-President of the Linnæan Society, has been elected a *Correspondent Étranger* of the Académie des Sciences of Paris.

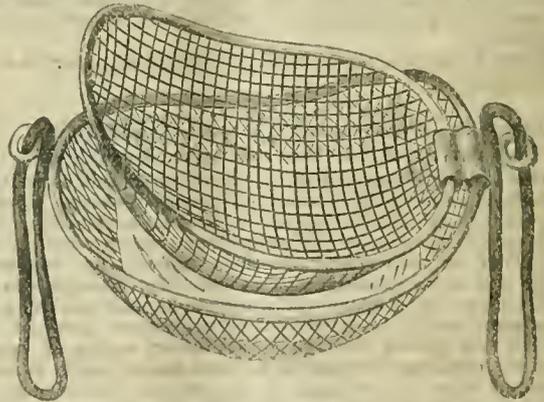

NOTES ON BOOKS.

Nature's Hygiene. By C. T. KINGZETT, F.I.C., F.C.S. Third Edition. (Baillièrè, Tindall, and Cox).—The increased knowledge of sanitary matters and the ever-deepening consciousness of the importance of everything which bears upon the maintenance of health, which has characterised English literature during the last few years, may account sufficiently to some minds for the appearance of a third edition of this work. May it not be also conversely true that the publication of such works as this does very much to increase that widespread sanitary knowledge which is a "consummation most devoutly to be wished" amongst our community? The author offers his information to all, for whilst scientific experts find a record of the most recent researches, the uninitiated are provided in the first two or three chapters with an introduction to such elementary chemical facts as are indispensable to a proper understanding of what is to follow. The chapters on the origin and prevention of infectious and contagious diseases, on antiseptics, on the treatment of the sick and on the relations of micro-organisms to disease, are of special interest to medical men. In Part II will be found a most interesting account of the eucalyptus and of pine and camphor forests, together with the details of the author's researches on the action of essential oils and terpenes as antiseptics and disinfectants. The type of this book is remarkably clear and pleasant to the eye, and there is a good table of contents and an efficient index.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS, IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

AN INHALATION RESPIRATOR.

A SIMPLE and effective inhalation respirator, very similar to Mr. James's "pneumatikon," described in the *JOURNAL* of May 26th, has been made for me for some months past. It consists of two layers of light wire-meshed gauze hinged together, between which the layer of lint is placed (see block). There are several inhalation

respirators in use on the same principle, but they are cumbersome and unsightly for indoor and outdoor use. The good effects of inhalation of various drugs, particularly pure terebene, in chronic coughs, loss of voice, and catarrhal affections of the respiratory passages is undoubted, while the simplicity and trifling cost of the respirator made for me places these advantages within the reach of the poorest patient. JOHN A. SHAW-MACKENZIE.

14, Old Burlington Street, W.

COMBINED NASAL AND ORAL RESPIRATOR.

THE fact that we do not breathe through the mouth but through the nostrils should be sufficient indication that the respirator now generally used by those suffering from pulmonary affections is conceived upon entirely erroneous views. I have, therefore, been induced to bring before the profession a combined nasal and oral

respirator, which has been carefully and efficiently made by Messrs. Arnold and Sons, of West Smithfield.

There may be at first a natural aversion to wearing a nasal respirator, but, as the feeling of novelty wears off, this will probably disappear, and the comfort experienced by the wearer will more than compensate for the appearance. The nasal respirator should be alone sufficient, and will probably prevent many a coryza to which persons are so liable in this changeable climate; but for those who still adhere to the old-fashioned respirator, there is an oral part attached which can be worn separately or with the nasal part, to which it is secured by a movable silver pin.

Briefly the respirator may be thus described. The nasal portion consists of celluloid fitting close to the nose, and having at the bottom an air chamber, with silver wire at the top and bottom of the chamber. The bottom part of silver wire is movable, so that it may be taken out and a piece of gauze fixed in, so as to regulate the amount and degree of air to be inhaled. The oral portion, also of celluloid, is devoid of metal, and consists of two parts, which can be taken apart at will. When in contact, they form a chamber in which gauze once, twice, three times or

more in thickness can be placed according to the exigencies of the case. It can be taken to pieces, cleaned, and fresh gauze put in as required. It presents in celluloid a much better appearance than the black respirator now worn.

E. WATSON PAUL, M.K.Q.C.P.Irel. and L.M.Dub., M.R.C.S.Eng. Bristol.

BISHOP'S GRANULAR EFFERVESCENT ANTIPYRIN.

Messrs. Alfred Bishop and Sons, of Speck's Fields, E., have added another to their already numerous effervescent preparations of important drugs. The "granular effervescent antipyrin" manufactured by them contains 5 grains of antipyrin in each drachm. The preparation is well granulated, it effervesces freely when added to water, the solution has a pleasant taste, and physiological effects are produced by it as well as by the simple chemical.

A NEW SYRINGE FOR RECTAL INJECTION OF GLYCERINE.
 FINDING great difficulty in obtaining a syringe suitable for injecting glycerine into the rectum as a useful adjunct in the treatment of chronic constipation, Dr. W. Barrett Roué, Physician to the Bristol Hospital for Children and Women, has suggested an invention for meeting the difficulty, of which we append an illustration. It consists of a simple glass graduated cylinder capable

of holding three drachms: the piston and mounts are of vulcanite, and the nozzle (a very important part of the instrument) is two inches long, of sufficiently large bore to provide for the entrance and exit of the glycerine, and which, being first oiled and then warmed, may be bent to almost any curve. The instrument has, under Dr. Roué's direction, been made by Messrs. Ferriss and Co., surgical instrument makers, Bristol, of whom it may be obtained.

SELF-DIGESTING WHOLE MEAL FOOD.

CORRECTION.—The title which was affixed to the note on Messrs. Savory and Moore's whole meal food in the JOURNAL of June 2nd, p. 1171, was incorrect, the word "bread" having been accidentally substituted for "food."

The Committee of the Birmingham Hospital Saturday Fund are enabled to divide a sum of £7,600 among the medical charities of the town this year.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1888.

SUBSCRIPTIONS to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the West Central District Office, High Holborn.

The British Medical Journal.

SATURDAY, JUNE 16TH, 1888.

SELF-HELP FOR HOSPITALS.

THE great political problem, how to deal with the poor, which we are perpetually trying to solve, but which appears as far off as ever from practical adjustment, has received a fresh impulse from the important testimony of some of the professional witnesses examined by the House of Lords Committee, now considering the question of poor-law relief. Much of the evidence will be found to have a remarkable and direct bearing on medical relief, whether of an eleemosynary or of a strictly poor-law character, nor are there wanting healthy indications that the entire subject is becoming better understood. It is impossible for those who have daily dealings with the poor not to be strongly impressed with the fact that, while distress abounds in our midst, the agencies at work to mitigate it have no greater obstacles to contend with than the utter absence of self-help on the part of a large proportion of the population most clamorous for charity. The justly repressive character of our poor-law system of relief may possibly deter thousands from seeking State aid, who, on the other hand, have no hesitation in availing themselves of privileges they can grasp from purely charitable and voluntary sources, nor is it at all surprising that the desire should keep pace with the indulgence, or be aggravated thereby.

Indiscriminate medical charity may possibly occupy higher ground in public estimation than indiscriminate almsgiving, but there can be no doubt of its influence being equally pernicious, and there is a growing desire on the part of a large body of the medical profession, as well as of the discriminating supporters of hospitals and curative institutions generally, that the demoralising tendency should be restrained by the adoption of repressive expedients to check its growth. It is of primary importance, also, that while such measures may be made profitably helpful to the hospital or dispensary and morally beneficial to the patients, they must not be permitted to slacken the interest in public charity but rather tend to encourage its increase where it is known to be judiciously administered. Our main difficulty lies in the enforcement of schemes likely to meet with general acceptance. We are naturally opposed to reversing the charitable instincts of our predecessors in matters of medical relief. The principles on which our hospitals and free dispensaries were first founded have been mellowed by time. We have become the inheritors of their free traditions, and, notwithstanding the changes which under the name of reform have taken place in most of our public institutions,

we are unwilling to interfere with the economic arrangements of establishments which have served us so well in the past.

It is true, nevertheless, that at the time when the great bulk of our voluntary hospitals were established, the poor-law medical service was in a miserable condition; it could scarcely be said to have had any existence at all, and the indigent sick were not long in discovering the advantages of the new asylums over the infirm wards of the workhouses. The latter have survived till our own day, but it is to the credit of the present generation that they have been for the most part supplanted in London and all large towns by a series of imposing edifices which, as regards sanitary construction and details bearing on internal economy, leave little to be desired. Erected entirely by State agency these hospitals, except in the matter of surgical casualties, appear to meet all the wants of the destitute sick, and it is not surprising, having regard to freedom of access, especially to such as have been instituted for the treatment of infectious disease, that the deterrent effect of our poor-law medical service is losing ground, while the constitutional abhorrence of the workhouse test retains its full force. Whether this disarming of prejudice will in the end extend to a higher grade of people in the social scale than it does at present must, in great measure, depend on the facilities for treatment afforded by the voluntary hospitals and the accommodation at their disposal, for it is hard to believe that the inherent and healthy dislike of pauper relief will be overcome so long as opportunities are offered for avoiding it.

It is significant, however, of the progress of events that while the sick asylums, backed by the public purse, show a disposition to increase out of all proportion to the normal condition of pauperism in the country, the hospitals and other medical charities are barely kept alive by bequests and constant appeals to the benevolent, their subscription lists, which formerly were their mainstay, yielding, according to Lord Randolph Churchill, only 16 per cent. of their expenditure. From their exclusive constitution and the indisposition of the local authorities the hope that the rate-supported hospitals will ever become schools of medical instruction, as in other countries, is far from realisation, and there is all the more need of extending the work of those voluntary institutions which contribute so much to the public advantage.

Prior to, and afterwards in a measure parallel with, the improvements which have taken place in poor-law medical relief, the voluntary hospitals have also undergone a process of evolution of a not less satisfactory character, which has made their value doubly appreciated, less, perhaps, by the sick poor than by the classes above them. It is a matter of common observation that few persons belonging to the middle class enjoy in their private homes the same medical skill and careful nursing when overtaken by disease or accident as patients possess in well regulated hospitals. The admission of such is governed less by their poverty than by urgency of symptoms and clinical importance, and it naturally follows that a fair proportion are able of themselves, or through their friends or employers, to make some restitution for benefits received.

The pay system, as it is sometimes called, although recognised as an important factor in the receipts of foreign hos-

pitals, has been slow of introduction into those at home, but it has had a beginning, and for the past twenty years has formed the main support of the cottage hospitals and convalescent homes which have sprung up in such numbers in so many parts of the country. The experiment has also been attempted, and with satisfactory results, in at least two of the old hospitals, and in a large number of special hospitals; and there is every reason to hope that it will be looked upon as a necessary part of the constitution of every hospital of the future. It is clear, however, that unless the scheme provides for a scale of charges, ranging in proportion with the means of patients, and precautions are taken to prevent its abuse, the pecuniary results will be disappointing.

In the out-patient departments of hospitals the primary difficulties are more capable of solution. Here, it has been the cry for years that consultative advice and physic have been unsparingly and indiscriminately administered to all comers, provided they are content to sit placidly for hours in a crowded room among a motley group of people bent on the same errand. Many remedies have been suggested, and some attempted, to check the generally acknowledged abuses of the department, but none have been found so effective as the imposition of a small money payment, not sufficient to enable the system to cope with that of the outside practitioner or even to cover the cost of the drugs supplied, but enough to make the recipient feel that he is receiving something which possesses a money value. It must be admitted, nevertheless, that the axiom of there being no rule without exceptions applies with special force in dealing with medical charity, and it will always be found imperatively necessary to guard against the possibility of the deserving sick suffering and being sent empty away on account of their poverty. However stringent our rules, regard must be had to the necessities of individual cases by supplying them in the first instance with the gratuitous assistance required, which should be given with the proviso that on the occasion of their next visit they should come furnished with a voucher from a minister of religion, respectable householder, or contributor to the hospital or dispensary, confirming their inability to pay.

Nothing in the past has tended more to lower the value of the practitioner's art in the great centres of population than the freedom with which medical relief has been administered, nor is it at all difficult to see how this tendency could be restrained and an inestimable boon conferred on the charities, provided the principle of self-help was judiciously introduced. It is the business of the managers of these establishments, who as a rule are keenly alive to their financial difficulties, to promote measures helping to increase their resources, and which, after all that may be said to the contrary, must confer moral advantages on the population.

Much has been done in various parts of the country, and especially in the manufacturing towns, to infuse a helpful spirit into the workpeople in aid of their local charities, but in London, on account probably of the shifting and miscellaneous character of the operatives, comparatively little has been effected, and that little in a vicarious way by street-collections instead of by a systematic organisation to bring the appeal home to every warehouse and workshop. It can hardly be disputed that there is here a vast field waiting for the husband-

man, which hospital managers seem loth to cultivate, but which ere long, when wiser counsels have prevailed over their timidity, will afford them an abundant harvest.

We are proud of our hospitals and medical charities on account of their national characteristic in being entirely free from State control; but if their prestige is to be maintained and their utility still further developed, substantial assistance must be accorded them by those who participate most in their privileges, and who are, or ought to be, most concerned in their maintenance. Experience has shown that such aid may be forthcoming without pressing too harshly on the resources of the industrious, and while cordially sympathising with the objects of the charitably disposed, it is a duty we owe alike to them and to their suppliants to inculcate in health those moral lessons of self-help and independence which may be relied on as best fitted to grapple with disease.

SUMMER IN THE MOUNTAINS.

WE had last week the satisfaction of announcing that the suicidal policy of seeking to exclude English medical practitioners from Swiss health resorts except under conditions too onerous to be generally fulfilled had been abandoned in the canton of the Grisons, where the agitation was first commenced. Attention was first called to the ill-considered action of the Swiss Government in these columns, and our Swiss correspondent has kept the English public informed of the progress of events. The arguments advanced in editorial articles in this JOURNAL have, as was stated in the letter from a London physician who has had special opportunities for knowing all the circumstances, had due effect with the interests most immediately concerned, and it is much to be hoped in the interests of all parties that the last may now be heard of this proposal, and that nothing of the same nature may occur to disturb the pleasant relations which have so long existed between the two nations. The summer season is just about to begin, and though in this respect less important than the winter season, it is satisfactory that the difficulty is in a fair way to adjustment before its commencement.

It is indeed rather remarkable that while so much has been said in recent years on the beneficial effects in certain classes of cases of prolonged residence at high altitudes during winter, but little has been written on the therapeutic qualities of mountain air in summer. Perhaps the reason is that the public has found out for itself without medical guidance that there is no tonic for the tired brain and relaxed body which can surpass, if indeed even the sea can equal, the pure bracing atmosphere of the "playground of Europe." Oertel and his followers have indeed written a good deal about mountain resorts in summer, but it has been chiefly if not entirely in connection with the so-called "gymnastic" treatment of cardiac disease, and has had special reference rather to the facilities afforded at the various resorts for this mode of treatment than to their altitude.

The health resorts of Switzerland may be roughly divided into three classes: the mountain stations, with an elevation at or above 4,000 feet; the hill stations, with an elevation ranging from 2,000 to 3,000 feet; and the lacustrine and valley resorts. The latter belong to an altogether different

category, and it is with the first-named—the mountain resorts proper—that we need alone concern ourselves here.

The climate of these elevated valleys varies considerably in certain respects, especially with regard to the period of greatest rainfall and the degree of moisture, but they all have certain qualities in common. In all the diminished barometric pressure causes the atmosphere to be more rarified, and this has at first the effect of causing the respirations to be more numerous and the pulse faster; but after a short period of acclimatisation both return to the normal—if, indeed, they do not in time sink below it; the inspirations, however, become deeper, and the aëration of the blood in the pulmonary vesicles is effected with greater ease and rapidity. The air at these altitudes, even in summer, is drier than at lower levels, consequently evaporation is more rapid, and the combined effect of these two peculiarities of mountain air is to produce a decided diminution in the weight of the body owing to increased loss of water and of carbonic acid.

There are only two other qualities which need now detain us; these are the increased diathermancy of the air and its purity. As to the latter, it would be rash to say more than that the beautiful observations of Mentschnikoff have suggested that the possession of this negative virtue may very materially diminish the calls made upon the cellular activity of the tissues, and especially of the blood. As to the former, its effect upon the human organism is clearly seen in the rapid tanning of the exposed skin, and there are good grounds for believing that direct sunlight has an important and beneficial chemical action on the metabolic processes.

It is especially in certain of the diseased conditions—or perhaps, it should be said, tendencies towards disease—promoted by modern urban civilisation, that a summer holiday in a mountain resort is so beneficial; but the cases are not to be entirely confined to these. Dr. Veraguth,¹ of St. Moritz, has recently published some interesting observations on the influence of high altitudes, made in the Upper Engadine. He states that in a healthy person the pulse and respirations are at first quickened, but that after a short time both return to the normal; the amount of carbonic acid and water in the expired air is increased, but the quantities of urea and uric acid are unaltered; he has also noticed a general entaneous hyperæmia, and a slight diminution in the body-weight. His observations thus confirm and slightly extend those previously reported by others.

It is known that high altitudes have a beneficial effect in chronic malaria, but it is doubtful whether it is correct to speak of a specific action. Dr. Veraguth, however, makes use of this much abused term with reference to cases in which there is enlarged spleen, anæmia, occasional pyrexia, and intermittent neuralgias. In anæmia from other causes high altitudes in summer are also, as a rule, beneficial, but Bright's disease, old age, and leucocythæmia afford exceptions; atonic dyspepsia and neurasthenia are also benefited, but in grave structural disease of the nervous centres, in ataxy, and paralysis due to apoplexy or softening, a residence at high altitudes is not to be recommended, neither does Dr. Veraguth approve of the advice often given to phthisical patients to spend the summer at high altitudes, considering that the

¹ *Thèse de Paris*, 1887, and *Lyon Medical*, lviii, 20.

sudden changes of temperature, the frequent winds, and, it may be added, the hay harvest and the not infrequent rains, are likely to have a prejudicial effect unless the pulmonary lesions are absolutely quiescent.

As to heart disease, apart from the question whether regulated exercise is or is not of advantage in certain cases, it would seem that when compensation has been long established, a tendency to failure may be checked by the special conditions of the atmosphere at high altitudes; the greater ease with which respiration is performed, and the somewhat larger call upon the left ventricle, while the vigour of metabolism is at the same time increased, favour the healthy nutrition of the heart muscle.

THE PRIVY COUNCIL AND THE ROYAL COLLEGE OF SURGEONS.

THE further instalment of official correspondence which we publish at page 1290, will not tend to diminish the astonishment of the Members of the College and the profession generally at the singular proceedings of the Privy Council on this very grave and far-reaching question. It is now clear that there has been a settled intention to drop the petition of the Members into the waste-paper basket, and say as little as possible about it. But a plea for constitutional rights within their own College, put forward by an enormous proportion of the Members, at a time when the authorities themselves had challenged an expression of opinion on the subject, is not a thing which the advisers of Her Majesty are entitled to pass by in silence. The Clerk of the Council informs us that the petition of the 4,665 members of the College "was referred, with all other petitions on the subject, to the Committee of the Lords of the Council." Until now the Members and signatories have had no notice of these proceedings. What they desired, and still desire, is to be heard before such a Committee in some such way as may satisfy the profession and the public that their claims have received a fair hearing. It appears to be the present theory of the Privy Council that the claims of the Members to some share in the management of their own business and in the control of their own property may be shunted by modifying in one or two unimportant details the draft of the Charter submitted by the present executive of the College.

The Members will have to take vigorous measures to bring home to the Lords of the Council the fact that this is equivalent to a refusal without a hearing, and that, even at the eleventh hour, the Members expect to be heard. The occasion of an application for a new charter—rendered necessary as it was by the growth of the College property—is evidently the proper and legal occasion for the reconsideration of the present executive arrangements, which were introduced by gradual innovations in times very different from our own, and which are eminently unsuited to the present conditions of medical life in this country, and eminently unsatisfactory to the great bulk of those who compose the College itself. The contention of the Members in their petitions, and on the one occasion when a deputation from them was admitted, was that the College, by its nature and history, and by every consideration of public policy, is and ought to be a "fraternity;" that, as to the property and buildings and policy of the College, the Mem-

bers have a right to be heard; and that the arrangements by which a small executive can claim to override the general sense of the College is an anomaly, an anachronism, and an abuse.

If the Privy Council consider that "no legal question is involved," they strangely misconceive the Members' position. It is perfectly true that the broadest and clearest basis for the prayer of the petition is that of public policy; but the statements submitted to the Privy Council embodied also a legal and historical claim of great strength. If these contentions, either in law or policy, or both, can be answered, the profession is entitled to know what the answer is. If they cannot be answered, Her Majesty's advisers are surely bound by every principle of the constitution to refrain from using one of the few remaining forms of the absolute prerogative of the Crown so as to stifle the present demand for the redress of a great grievance, and remit the Members to an indefinite prospect either of litigation or of parliamentary agitation.

LEGALISED ADULTERATION OF WINE.

WE do not pretend to an acquaintance with the procedure of Her Majesty's Customs, but would like to have an official and explicit assurance that certain practices alleged to be, or to have been, carried on in the docks under the eyes, and, so long as the legal duty was paid, with the approval or connivance, of the excise officers, have been since discontinued, or, rather, prohibited. Reading over the evidence of various experts on the adulteration of wines prior to and after importation into this country, as given before Royal Commissions, in reports on Exhibitions, and in other publications, we came across some astounding revelations. Mr. Walter Burton, an ex-Customs House officer, stated, not many years ago, that "a wine jobber having 1,000 gallons of wine (already adulterated and fortified) can add thereto 100 gallons of spirit, thereby converting so much crude potato spirit, diluted with London water, and costing about a shilling a gallon, into, it may be, a 'special sherry' or 'vintage port.'" There is, he believed, no record kept of the quantity of spirit so turned into wine, "but seeing that a large staff of officers are continuously employed in superintending such operations, the increase to our stock of wines from this source must be considerable." Well may he add that "it is most objectionable to pay public officers to legalise the manufacture of such compounds in our docks and warehouses."

Whether it be possible to devise means whereby some limitation could be put to the adulteration and manufacture of "wines" so-called in Spain, Portugal, and elsewhere, and the passing at the Customs House, on the sole condition of paying duty, of liquids whose composition alone proves them to be frauds, we will not pretend to say. We do, however, think that on hygienic, moral, and commercial grounds, it is not justifiable to pass into the market mixtures which it is self-evident cannot be drunk until they have undergone further dilution, doctoring, and other adulteration, such, for example, as "sherries" in which the bitartrate of potash—the "wine stone," as the Germans call it—has been replaced by the sulphate, and to which a further dose of raw sulphuric acid, a pound to each butt, has been added, while the percentage of alcohol, which in a natural

wine cannot exceed 14, has been raised by the addition of potato spirit to 35, or even 59, per cent. of proof spirit—in fact, to the strength of ordinary brandy, and others in which the colour is given by fuchsine with its attendant arsenic; and, so far as we are aware, the clearing of cloudy wines by sugar of lead has not been the subject of proceedings under the Sale of Foods and Drugs Act.

But we would ask whether it is consistent with the Act that Government officials should superintend the process of “mixing, colouring, etc.,” wines with substances injurious or otherwise, so as “to fraudulently increase the bulk, weight, or measure” of the same, “or to conceal the inferior quality thereof;” that a publican should be fined for adding pure water to his spirits, while the excise officers connive with impunity at the addition of water, raw spirits, etc., to wines in the docks.

If the ultimato decision must rest on the question of £ s. d. rather than on the public health, the pure wine-growers of Australia and other countries might well remonstrate against the legalising of “operations” by which the production of Spanish and Portuguese wines is fraudulently doubled or trebled to their manifest injury, as those of France have against “salicylage” as a means of preserving fictitious clarets from changes tending to render them undrinkable.

WE regret to announce the death of Dr. T. Harrington Tuke, which occurred on June 9th, after a long illness.

MR. T. PRIDGIN TEALE, M.B., F.R.C.S., of Leeds, and Dr. Henry Trimen, Director of the Royal Botanic Gardens, Ceylon, are the only members of the medical profession who have been elected Fellows of the Royal Society this year.

THE second congress of the German Gynæcological Society, which has been held in Halle, has resolved, in consideration of the International Medical Congress to be held in Berlin in 1890, to hold its next congress next year. Freiburg is chosen as the place of meeting.

THE preparations for the medical and scientific exhibition, which is to take place in Cologne, next September, in connection with the sixty-first meeting of the German Medical and Scientific Association, are making rapid progress. Already 100 firms, including several important Austrian and English houses, have announced their intention to exhibit.

THE annual meeting and dinner of the Cambridge Medical Graduates Club will be held at the Hotel Victoria, Northumberland Avenue, on Wednesday, June 20th. The guests will be Sir Andrew Clark, Bart., and Sir James Paget, Bart. Members of the club who intend to be present are requested to communicate with either of the Honorary Secretaries on or before June 18th.

PARTHENICIN.

AN alkaloid, to which the name “parthenicin” has been given, has been isolated by Dr. Ulrici, of Cuba, from the leaves and flowers of *Parthenium hysterophorus*, commonly called *Artemisilla* or *Escoba amarga*. It is a crystalline substance, with an intensely bitter taste. It poisons animals, the temperature being previously greatly reduced, and it appears to have antipyretic, anti-intermittent, and analgesic effects on the human subject. It has been given in doses of fifteen grains once a day.

CORROSIVE SUBLIMATE INJECTIONS IN LUPUS.

THE *Gazzetta degli Ospitali* describes a case of lupus hypertrophicus of the nose where Dr. Tassinari, after finding that many other local and constitutional remedies were useless, injected solutions of corrosive sublimate, in strength from $\frac{1}{2}$ to 1 per cent. There appears to have been no local or constitutional irritation, and the disease disappeared after twelve injections.

OCTO-CENTENARY OF THE UNIVERSITY OF BOLOGNA.

THE celebration of the eighth centenary of the University of Bologna commenced on June 12th; it was attended by the King and Queen of Italy, and by representatives of nearly every existing university of the world; the students of many universities also sent delegates, who met with a warm welcome from the Bolognese students. The universities of the United Kingdom which were represented were Oxford, Cambridge, London, Victoria, Durham, Edinburgh, Glasgow, Aberdeen, St. Andrews, and Dublin. Among the recipients of honorary degrees were Sir Spencer Wells and Dr. Weir Mitchell in medicine, and Professors Huxley, Cayley, Adams, Sir William Thomson, and Agassiz in science.

THE CONTROL OF LOCAL AUTHORITIES.

AT the last meeting of the Committee of the Hull Sanitary Association a report of a sub-committee on the effect of the Local Government Bill in existing sanitary legislation was considered, and a resolution was passed expressing the opinion that the effect of the Bill would be to leave the powers of control over negligent local authorities in a very unsatisfactory state, and to perpetuate the present unsatisfactory condition of the sanitary oversight of rural districts. The Committee consider that the Bill ought to be so amended that the control of the Local Government Board over defaulting local authorities may be preserved. The view generally held by those acquainted with the working of sanitary law that the medical officers ought to be appointed by and responsible to the County Councils and not to the District Councils, was also endorsed by the Hull Committee.

YOUNG MOTHERS.

A CASE of very early child-bearing has occurred at Ilkeston, the mother being only 12 years old; and a paragraph is going the rounds of the press stating that this is an unprecedented fact. Though very remarkable, especially in a temperate climate, the case is not unprecedented. Reference was made in this JOURNAL eighteen months ago to a case in which the mother was only 11½ years old; and in Barnes's *Obstetric Medicine and Surgery* several authentic cases of precocious maternity are cited, notably one by Mr. Dodd, of Billington, who himself attended the labour of a woman on August 8th, 1871, when a girl was born. This girl Mr. Dodd delivered of a healthy child, weighing seven pounds, on March 17th, 1881, just 147 days before she had reached the age of 10 years. Mr. Dodd supplied Dr. Barnes with authentic proofs of the facts of this case.

CHRONIC GLANDERS IN MAN.

A RUSSIAN medical paper, the *Medizinskoye Obosrenie*, states that a young soldier, who had been a waggoner before his admission into the army, was received into the military hospital suffering from two foul ulcers on the hard palate, which had perforated the nasal fossæ and destroyed the inferior turbinated bones. Three weeks later a swelling appeared over the left eyebrow, a fortnight afterwards he complained of pain on the inner side of the left knee around the internal tuberosity of the tibia. Then purulent discharge occurred in the left ear, and an abscess on the back of the right hand, which appeared as a deep purple tubercle, with a hard circumference and sunken towards the centre; purulent discharge oozed from its surface. At first, for a short time after

admission, the temperature varied, rising of an evening to 103° or 104°; later on it fell to normal. The disease was mistaken for syphilis, and iodide of potassium was given without the least benefit. About ten weeks after admission he was in better health and left hospital, receiving his discharge from the army. Within a few weeks he returned with extension of the ulceration of the hard palate; the uvula was destroyed. The characteristic tubercles, the "farcy buds," appeared in the face, the metastatic abscess on the back of the hand remained. The patient ultimately died of exhaustion. Before death some of the tubercles were extirpated; they were found to contain micro-organisms resembling the glanders bacillus of Löffler and Schütz.

INTERCOLONIAL MEDICAL CONGRESS OF AUSTRALASIA.

THE second session of the International Medical Congress of Australasia will assemble at Melbourne, Victoria, on January 7th, 1889, and the sittings will continue on the five following days. The official memorandum, dated April 5th, states that next year has been chosen in order that the session of the Congress may coincide with the Centennial Exhibition in Melbourne. The Secretaries have addressed to us a letter, in which they state that the Congress will be thoroughly representative of the profession in Australasia, and add the expression of a hope that visitors from Europe and America may be able to attend. The means of communication, they say, between Europe and the Colonies are now so rapid and easy that, with an absence of four months from Europe, a visitor would be able to spend six weeks in the Australian colonies. The Centennial Exhibition will be a remarkable display, and during the time it is opened other technical congresses will be held, and social entertainments, in which the Government of Victoria has promised to lend material assistance, will be provided on a generous scale. Members of the Congress will be able to travel at greatly reduced rates, and any member of the profession intending to be present is promised a most cordial and hospitable reception. The President is Mr. T. N. Fitzgerald, F.R.C.S.I.; the Treasurer, Dr. George Graham; the Honorary Secretary, Professor H. B. Allen; and the Associate Secretaries, Drs. J. W. Barrett and G. A. Syme. A strong and representative provisional committee has already been formed. All communications should be addressed to Professor Allen, M.D., at the University, Melbourne, Victoria.

THE PHYSIQUE AND DIET OF THE SOLDIER.

In a lecture at the Royal United Service Institution, Colonel G. M. Onslow expressed his views on "The Physique of the Soldier and his Physical Training," and gave his experience as Inspector of Gymnasia. A man must eat to live, and a young man needs both plenty of food and exercise to aid his growth and development. The average age of a soldier is now 25 years, the minimum standard in height is 5 feet 4 inches, with a chest limit of 33 inches, while 769 men per 1,000 are 35 inches in chest measurement. Our age limit is lower than that of foreign armies, but our minimum standard is higher. Colonel Onslow says the British soldier has not enough to eat, and that if we cannot give him more food, we should give him his last meal later than his tea at 4.30, as at present. Military drill is not physical training, and it is said that, *per se*, the drill does little to render the men stronger and more supple; it is of no use to drill a man until he is made strong, active, and self-reliant by gymnastic training. Lord Wolseley agreed with the remarks of the lecturer, and referring to the prospects of army recruiting, expressed his fears that difficulties might occur in the future, from the decline of the physical condition of our young men in towns, and the decrease of the agricultural population. He then proceeded to advocate the provision of gymnasia in all Board schools, under the supervision of

good drill instructors. In considering the physique of the young men of London, we are glad to see that a new gymnasium has been opened in the old Queen's Theatre, Long Acre; the hall is spacious, lofty, well lighted and ventilated, and provided with every appliance and means of physical exercise, so that we may hope that something is being done to keep up the physique of our young men in London.

SUTURE OF WOUNDED LIVER.

THE *Riforma Medica* of June 9th contains a full account of Professor Postempski's operation for wounded liver, of which mention was made in the *JOURNAL* of May 5th (p. 992). Antonio A., aged 28, was stabbed under the arch of the ribs, on the right side, on April 18th. The cutaneous wound, which was parallel to the costal margins, was five centimètres in length, whilst that of the liver (left lobe) was seven centimètres long, and three in depth at the deepest part. The patient, when seen, was in a state of profound collapse from loss of blood. There was no difficulty about the diagnosis, as exploration with the finger served to disclose the nature of the case. Professor Postempski, who had satisfied himself so far back as 1885, by experiments on dogs, that the liver-substance could be stitched without giving way, determined to try that mode of treatment. He accordingly enlarged the wound in the skin by five centimètres, and made a second vertical incision in the middle line across the first. The wounded lobe was pushed forward as far as possible, and, while the pieces of sublimated gauze, with which the wound had in the first instance been plugged, were being withdrawn, six points of chromicised catgut suture were passed through the whole depth of the wound with extremely fine curved needles. The sutures were very carefully tightened as they were introduced, the edges of the wound being at the same time gently pressed together, so that the loop of catgut did not draw them into contact, but merely kept them in apposition. The sutures were tied in a simple knot, and there was not the slightest laceration of the liver-substance through which they were passed. Hæmorrhage ceased at once, but the critical condition of the patient made it impossible to wash out the peritoneal cavity at all thoroughly, and Dr. Postempski believes that the greater part of the extravasated blood remained in the abdomen. There was no rise of temperature, however; but, on the second day after the operation, there was very abundant albuminuria, which lasted for twenty-four hours, when it completely ceased. The patient got up on the eighteenth day, and he is now perfectly well, without any local pain, or any appreciable enlargement of the liver.

CANCER OF THE LARYNX: THE RESULTS OF TREATMENT.

ALL the published reports of cases of laryngeal cancer which have been observed in various countries since 1880 have been carefully examined and tabulated by Dr. Max Scheier, of Berlin. His analysis is to be found in the current number of the *Deutsche Med. Wochenschr.* (June 7th), and elaborate tables of the cases, 125 in number, are supplied in an appendix to that issue. In these tables the source of information about each case is stated, together with the age and sex of the patient, the actual condition before treatment—the laryngoscopic appearance being detailed in most cases—and the treatment, with its results. Moreover, the tables state whether a microscopic examination was made or not in each case, so far as known. The author of this paper acknowledges his indebtedness chiefly to the *Internat. Centralb. für Laryngologie und Rhinologie*, edited by Dr. Felix Semon; the *Centralblatt für Chirurgie*; and the *Jahresbericht* of Virchow and Hirsch. The cases are arranged in six tables. The first table comprises cases in which no operation was done—four cases, all fatal; the second, cases in which tracheotomy alone was done—seventeen, all fatal

but three; the third table gives the cases in which laryngotomy with extirpation of the tumour was performed, nine in number—in three death ensued within fourteen days, in three there was relapse, two had shown no relapse within the first few weeks, and one remained well nearly three years afterwards; the fourth table gives the partial extirpations of the larynx, twenty-three in number—two died soon after operation, three about a month afterwards, five survived operation but relapsed later on, eight are reported as cured but not observed long enough as to relapse, and five remained well sixteen months and more after operation. One of the latter cases showed no relapse two years after operation, another three years, and another seven years. This last, one of E. Hahn's cases, mentioned in all statistics of the subject, is a case of only partial resection of the larynx. The patient has been recently examined, and the right vocal cord with the right arytenoid can be seen to move during respiration. The other cases were treated by Semon, Schede, Störk, and Fränkel respectively. The fifth table gives the cases of total extirpation of the larynx, sixty-eight in number. Of these, eighteen died within a fortnight, and five more soon afterwards; seventeen survived the operation, but relapsed within a year (one excepted, but fatal in the second year); six died of intercurrent diseases; thirteen are reported cured, but not observed a sufficiently long time to determine as to relapse, and nine remained free from relapse sixteen months and longer. Lastly, the sixth table gives the cases in which an endo-laryngeal operation was performed, four in number. In one swallowing was painless eight days afterwards, the second died in an epileptic fit five months afterwards, the third case affords no data as to the operation, the fourth (B. Fränkel's case) underwent several operations, and remained quite well four years after the last, with a good voice. Dr. Scheier requests the various operators to favour him with the further results in the several cases mentioned in the tables so far as known up to the present.

LIABILITY FOR DEFECTIVE DRAINS.

THE verdict in the case of Butler v. Goundry, which was tried last week before Mr. Justice Mathew and a common jury, seems to have been misunderstood. The action was to recover damages, which the plaintiff alleged he had suffered owing to the reckless misrepresentation (in other words fraud) of the defendant, in stating that the drains of a house, No. 148, Brompton Road, were in perfect order. The plaintiff had taken the house in question on lease from the defendant, and his case was that during the negotiations he inquired particularly about the drains, and was assured that they were all right, and had only recently been put in perfect repair. Soon after he took the house he and his family became ill. The drains were then examined, and found to be most defective. They had never been connected with the sewer, and the soil under the house was saturated with sewage. The defendant did not dispute that the drains were in fact defective, but denied that he knew them to be so, or that he had made the representations on which the plaintiff relied. He swore that all that he had stated was that "for old-fashioned brick drains they were as good as could be expected." He had had them examined by a builder, who told him he had done what was necessary, and believed them to be in fair and good order. The builder who had examined the drains had to admit himself to be without any proper knowledge of his business, and his examination of the drains must have been conducted most perfunctorily; but there was nothing to show that the defendant knew him to be incompetent, or had any reason to distrust his assurance that the drains were all right. The jury found their verdict—and they certainly had evidence to justify the finding—that the defendant had no knowledge of the defective state of the drains, and himself believed them to be in a fair condition, and that his statements to the

plaintiff amounted to no more than this. On that state of facts he was entitled to a verdict in his favour. In an action of deceit or fraud judgment must go to the defendant, unless it is shown that, with the intention of their being acted on, he made statements which he knew to be untrue, or which, at any rate, he did not believe to be true. Mr. Goundry was found to have seriously believed that the drains were in fair order, and consequently not to have made a wilful or reckless misrepresentation to his incoming tenant. All the evidence given to prove the defective condition of the drains was therefore immaterial, because the plaintiff failed to prove the fact on which his whole action depended. If it could have been alleged that the defendant had warranted the drains to be in proper order, or that their being in such order was one of the conditions of the tenancy, proof of their being defective would have been most important, and the evidence given on this head would probably have been conclusive in the plaintiff's favour. The action was not brought on the contract at all, no doubt because the plaintiff's legal advisers knew that it would be impossible to prove any contract as to the condition of the drains. The plaintiff's case as to fraud was answered, and he is left without remedy for having suffered in health and been put to considerable expense in rectifying the pestilential condition of his house. The moral of the case is, that intending purchasers or tenants of houses should not rest satisfied with any verbal assurances as to the sanitary condition of the premises they propose to take. They should either themselves have the place examined by some person in whom they have confidence, or, better still, have a clear undertaking in writing, as part of their contract, that the drains are not defective. If the vendor or lessor, being a respectable man, will give such an undertaking, he is pretty sure to have satisfied himself that he may safely do so.

VENTILATION OF BOARD SCHOOLS.

LIGHT and air are essential conditions to growth and good brain-work, especially for school-children. If we wish to make children like and respect our schools, we must make them more attractive than the dull and too often squalid homes from which they come to their daily lessons. Good ventilation is always possible; for besides the ordinary means of natural ventilation, there is always the possibility of mechanical ventilation. The baneful effects of foul air are very obvious in some schools, where we have seen groups of children presenting the signs of exhaustion from this cause—the pale faces, dull eyes, and restless movements indicating only too plainly the distress caused by want of free supply of oxygen, and accounting for the inattention complained of by the teachers. This cause of exhaustion is easily removable by proper ventilation, and by preventing overcrowding; this is a state of things that must not be confounded with over-pressure from lessons; no child can work well unless there be elbow-room, and plenty of light and air around. It is very desirable to train children in our primary schools to value cleanliness, but this valuable lesson will not be efficiently instilled into the young mind without the supplies of fresh air and light which are needful to invigorate their nerve-system. The mental and bodily exhaustion which arises in a school from want of sufficient ventilation is too often visible, not only in the children, but also in the teachers; those of us who have worked many hours in ill-ventilated outpatient rooms know how hard it is to maintain complete intellectual activity and amiability to all around in crowded rooms that are wanting in fresh air. Cases of anæmia among female teachers and in the pupils may often be attributed to want of sufficient light and air in school-rooms, rather than to too many hours of work. Education ought to teach practically the laws of health, and should be undertaken under healthful conditions, for the final educational aim should be *mens sana in corpore sano*.

THE COUNCIL OF THE COLLEGE OF SURGEONS.

WE announced, last week, that Sir Joseph Lister had decided not to offer himself again for re-election. There is a widespread feeling of regret amongst the Fellows that he has come to this decision, for a surgeon of such world-wide reputation would have proved an ornament to the chair, and Sir Joseph Lister, honoured alike by his followers, and by those who, on scientific grounds, oppose his well-known system, is known to be far more in sympathy with reform than are many others who, like himself, stand very high in the ranks of the profession. On the other hand, the Fellows and Members appear, as far as we can glean, to admire him as setting a good example in making way for others, and so doing his best to counteract any impression that there are some who seek the questionable privilege of what is practically permanent membership of Council. The necessity of a reform in the manner of electing the President is becoming more and more evident. There are five candidates for the three vacancies to be contested on July 5th, including Mr. Bryant and Mr. Cadge, who seek re-election. The five, arranged in order of seniority of Fellowship are: Mr. W. Cadge, of Norwich (F. 1848, M. 1845); Mr. T. Bryant, Gny's Hospital (F. 1853, M. 1849); Mr. J. Couper, London (F. 1861, M. 1859); Mr. T. Pickering Pick, St. George's (F. 1866, M. 1862); and Mr. A. Trehern Norton, St. Mary's (F. 1867, M. 1862). The merits of the candidates must be generally known, and the representation of different medical schools in London may safely be left to those most nearly concerned in the matter, by sentiment or by interest, two inevitable factors in any election. Of the new candidates, Mr. Couper and Mr. Pick are teachers of recognised ability, and the same may be said of Mr. Norton, an earnest advocate of reform.

TUMOUR OF THE SPINAL CORD; REMOVAL; RECOVERY.

IF it be the pleasure and privilege of knowledge and skill to put health in the place of disease, and comfort in the place of agony, it will be plain to anyone who cares to read that Dr. Gowers and Mr. Victor Horsley have enjoyed high privilege and reaped full pleasure. If it be a peculiar enjoyment to open a new way for others to like pleasures and privileges, they will have that special character to their enjoyment. It has been very generally known for some time that by an accuracy of knowledge that is only possible to a few, and a surgical talent that can embody prudence without losing inventiveness, a perfectly new surgical success has been won in England, of which we are a little timid as yet in measuring the effects. We are slow in getting used to the idea that under proper conditions of precaution many tumours of the brain may be removed *en masse* with the gain of life, and not the losing of it; and now, further, we must grant that the spinal cord, that most inaccessible and inviolable of organs, may be laid bare of part of its bony covering—man may become for the time and in part an invertebrate—in order that it may be set right, not by the gentlest of manipulations, but by the surgeon's knife. At the concluding meeting of the Royal Medical and Chirurgical Society, which was held on Tuesday, June 12th, the most important paper of this session, from Dr. Gowers and Mr. Victor Horsley, was presented, relating in such detail as the novelty and complexity of the facts demanded a unique case of the successful removal of a tumour of the spinal dura mater from within the bony canal, and the complete recovery of the patient. At a previous meeting of the Society the patient, a private gentleman, an officer in the Merchant Service, had most willingly attended to show to all who cared to see them the proofs of what had been done to him, and to express his deep gratitude for the change it had made in his life. Since 1884 he had had a nearly constant pain under his shoulder-blade, with long fits of agony that maddened him, as

some of his friends said in all seriousness, and with no hyperbole or metaphor. He might well have been glad of some last straw to break his back, and bring him to an end; but science could break his back to more profit. After due consideration and explanation, Mr. Victor Horsley laid bare the spinal column from the third to the seventh dorsal vertebra, and cut off the fourth, fifth, and sixth spinal processes with strong bone-forceps. He made his way through the laminae on both sides, and the still more obstinate ligamenta subflava, slit the dura mater up the middle line, and laid bare the spinal cord. When the opening was first made the injury had been suspected, but the tissues were healthy. That the attempt should be abandoned was counselled from some quarters, but Mr. Horsley preferred to complete his task, removed the posterior part of another superior vertebra, and there found this tumour of the dura mater compressing the cord. It could easily be shelled out of its deep bed, the wound was carefully closed and drained, and healed by first intention. Slowly the great power of nervous recovery showed itself, and the pain and paralysis disappeared. This is not easy surgery; and the many details, hints, and conclusions that find a place in Mr. Horsley's paper will need careful consideration when we receive it at length in print. It was more than a summer gathering of the Royal Medical and Chirurgical Society could do to discuss it; it must be left to take its permanent place among the forward steps of the progress of the healing art.

THE HIGH DEATH-RATE OF MANCHESTER.

IT is to be hoped that the conference which was held in Manchester on June 6th, under the auspices of the Manchester and Salford Sanitary Association, will stimulate the local public health authorities to increased efforts to reduce the high death-rate of the city. At present, as the returns of the Registrar-General show, Manchester stands in this matter at the bottom of the list of the twenty-eight large towns of England, and has a rate of mortality more than 50 per cent. in excess of that of the whole country. If the whole of England be represented by 1,000, Manchester has to be represented by 1,578. The local authorities during the last twenty years have done much to reduce the death-rate, but more has been effected in other towns. In fact, as one speaker at the conference remarked, Manchester has been left behind in the race for health. Not so very long ago the death-rate of Liverpool was 39, while that of Manchester was 26 per 1,000. Now the Liverpool death-rate is 26, and that of Manchester is 31.6 per 1,000. There are undoubtedly many circumstances existing in Manchester, many evils incidental to life in a large manufacturing town, which it is difficult to deal with, except by education and improvements in the modes of living; but there are at the same time many directions in which the sanitary authorities can work with immense advantage. The rivers in the district—the Irwell, the Irle, and the Medlock—are little better than open sewers. There is much overcrowding, not only of persons in dwellings, but of dwellings on area. The existing fever dens should be abolished, and more breathing spaces should be provided. More inspectors are wanted to detect unwholesome conditions and secure their abatement, the present number of fourteen being quite inadequate for a town of 385,000 inhabitants. And last but not least, the terrible smoke nuisance in Manchester should be earnestly attacked. The Manchester and Salford Sanitary Association have done much to secure reforms in these and other directions in the past, and have earned more than local respect. We hope that their renewed efforts will result in further benefit to the public health of the locality.

DR. METHNER, of Breslau, who held the rank of Privy Councillor, has just died at the age of 72, leaving directions in his will that his remains should be conveyed to Gotha, and there disposed of by cremation.

SCOTLAND.

THE list of names of the newly-elected Fellows of the Royal Society includes that of Mr. J. T. Bottomley, M.A., Lecturer on Natural Philosophy in the University of Glasgow. Mr. Bottomley is the author of many investigations in physical science, of which the best known are his research on the conductivity of heat by liquids, and an elaborate research on thermal radiation, published last year in the Royal Society's *Transactions*.

GLASGOW SOCIETY FOR THE PREVENTION OF CRUELTY TO CHILDREN.

THIS society is carrying on its operations with marked energy. During May 96 cases, involving the welfare of 127 children, were dealt with. Thirty children had been sent to industrial schools, training ships, and training homes, 28 had been placed in day schools, and 29 under the supervision of the School Board. During the month 92 children had received temporary shelter, 698 meals were given, and 31 children had been clothed.

FINAL M.B. EXAMINATIONS, GLASGOW.

THE final examinations for degrees in Medicine and Surgery at the University of Glasgow began on June 11th with the Clinical examinations at the Western Infirmary. The examinations in Operative Surgery begins on July 6th; the written examination on July 9th, and the oral on July 12th. There are in all 134 candidates.

GLASGOW HOSPITAL FOR SICK CHILDREN.

THE following appointments have been made to the new dispensary department of this institution:—*Extra Honorary Surgeons*: A. Ernest Maylard, M.B.; T. Kennedy Dalziel, M.B.; Quentin McLennan, M.B. *Extra Honorary Physicians*: Robert S. Thomson, M.B., B.Sc.; J. Lindsay Steven, M.D.; Charles Workman, M.D.

EDINBURGH UNIVERSITY: NEW ACADEMIC HALL.

THE final step towards the completion of Edinburgh University is about to be taken in the building of the new Academic Hall. As will be remembered, the hall is the gift of Mr. Wm. McEwan M.P. Dr. Rowand Anderson, architect, has now so far elaborated the plans that the building operations will shortly commence. The hall will occupy a site in close contiguity to the new medical buildings of the University, and, when completed, will probably stand unequalled among similar halls throughout the kingdom. It is to be named the McEwan Hall, after the generous donor.

THE UNIVERSITIES (SCOTLAND) BILL.—THE COMMISSION.

THE constitution of the proposed Scottish University Commission has produced much adverse criticism in Edinburgh. More especially it is felt that the Commission will be weak in representation of the medical faculty. Considering the important part which the medical faculty plays in the University policy, in three at least of the four universities, it has appeared surprising that the number of proposed experts for this department should have at first been limited to one, Sir J. Crichton Browne. The announcement of Mr. Erichsen's inclusion in the amended list has, therefore, been hailed with much satisfaction. Still it is felt that, in order to ensure justice in the consideration of the weighty issues which the rapid advance and development of medical teaching necessarily raise, the list of medical authorities ought to be extended. The nomination of the Government has been further assailed by the camp of advanced University reformers. It is fully hinted that an excellent Bill has been spoiled through the weakness of the proposed executive.

ENDOWMENT OF RESEARCH AT EDINBURGH UNIVERSITY.

A STRENUOUS effort is being made by the Committee of the Association for the Better Endowment of Edinburgh University in the direction of obtaining more funds for the encouragement of original research in the various scientific laboratories. This year the Senatus has been able to make special grants to students who have graduated with distinction, with a view to their prosecuting special studies in foreign universities. The terms of the particular endowments necessitated their allocation for travelling purposes; but it is to be hoped that money will be forthcoming which may have the effect of keeping graduates round their *alma mater*, where tradition and opportunity ought both to combine in affording stimulus towards the higher work.

IRELAND.

It is announced that Dr. Thompson, of Omagh, who was recently appointed an inspector under the Local Government Board, has resigned.

PETITION OF RIGHT.

A CURIOUS case came before Chief Baron Palles on Friday, June 8th, when Professor Pye, of Queen's College, Galway, personally appeared to claim compensation from the Crown for loss of fees consequent on the abolition of the Queen's University and the foundation of the Royal University in its place. The petitioner is Professor of Anatomy in the Queen's College, and in the course of his argument he said that by Clause 14 of the Royal University Act provision was made for compensation for the loss of any "office of profit," any "salary," etc. It seemed to him that it would be a cramped construction to say that the word "salary" did not include fees. The Lord Chief Baron reserved judgment, which he said he would give only on the facts, leaving the questions of law to be decided when the case came before the full Court.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

DR. ROBERT McDONNELL's term of office as President of this body will expire in October next, and Dr. G. H. Kidd and Dr. S. Gordon are candidates for the position. Some hot feeling has already been produced. The physicians claim that it was originally understood that the President should be alternately selected from their ranks and the ranks of the surgeons, and that Dr. Kidd, being an obstetric surgeon, seeks to succeed a surgeon. It is a pity that any misunderstanding should occur, and we hope a satisfactory arrangement will be arrived at. The Academy is considered to have been such a brilliant success that all would regret to see it in any way marred.

THE CASE OF DR. MAGNER.

THE following communication has been forwarded to the Clonakilty Guardians by the Local Government Board:—"Adverting to the resolution contained in the minutes of proceedings of the Board of Guardians of the Clonakilty Union at their meeting on the 25th ult., respecting the appointment of Dr. Magner as medical officer of the Timoleague Dispensary district, the Local Government Board desire to acquaint the Guardians that they have received the minutes of proceedings of the Timoleague Dispensary at their meeting on May 21st, and also Dr. Magner's letter on the subject, and the Board have informed the committee that as Dr. Magner declines to give an undertaking not to join in any illegal combination or conspiracy such as that for which he was convicted they therefore refuse to sanction his appointment."

SCOTCH UNIVERSITY AND COLLEGIATE BILLS.

Universities (Scotland) Bill.—The House of Lords went into Committee on this Bill on June 7th. Lord Rosebery proposed a definition of affiliation, as "such a connection between an existing University and College as shall be entered into by their mutual consent, under conditions approved by the Commissioners, or after the determination of their powers by the Scottish Universities Committee of the Privy Council." This proposal met with general approval, and was inserted. Lord Watson then inserted a definition of "College" as "an institution established on a permanent footing, for the purpose of teaching the higher branches of education, and which shall be sufficiently endowed, in the opinion of the Commissioners, and after the expiry of their powers, of the University Committee." Considerable objection was taken by Lords Camperdown, Watson, and Rosebery, to the number of the representatives of affiliated colleges on the University Court. It was thought that the representatives of the University might be swamped, and Lord Rosebery moved an amendment to leave the representation of the Colleges to the Commissioners. This, however, was lost on a division. Various other amendments were moved to increase the powers of the Court over property; to enable the Court to appoint certain committees, and to appoint certain representatives to the governing bodies of affiliated colleges, and on other small matters of detail, but most of them were postponed to the report stage. The Government amendments on the original Bill seem to have so cleared up doubtful points that but little of importance was left for discussion, and no attack was made on the general principles of the measure. After the Commissioners' names were inserted, the Bill passed through Committee, and was ordered to be reported. The Commission is to consist of Lord Kinneir (Chairman); the Dean of Faculty; the Earl of Crawford; Lord Watson; the Marquis of Bute; Dr. A. B. McGrigor; Sir Charles Dalrymple, M.P.; Mr. Craig-Sellar, M.P.; Mr. Donald Crawford, M.P.; Mr. J. A. Campbell, M.P.; Mr. Vary Campbell; and Sir James Crichton Browne.

St. Mungo's College Bill.—The Glasgow magistrates submitted to the Town Council at its last meeting a minute of date May 28th, stating that, having carefully considered this Bill and the representations made thereon by the directors of the Royal Infirmary and the Senate of the University, and having also had before them the fact that the Government have introduced a Universities Bill, applicable to all the universities of Scotland, under which provision is to be made for affiliating, incorporating with, or uniting colleges to, any of the universities, and for admitting the teaching of such colleges as qualifying for graduation in such universities, they resolved to recommend the Town Council not to take any action with reference to the St. Mungo's College Bill. The Lord Provost said this recommendation was made because it was thought the object sought might be better secured under the Universities (Scotland) Bill. It was pointed out that the St. Mungo's College was not "incorporated," and could not take advantage of the affiliating clauses of the Universities Bill, and after some discussion the council adopted the following general deliverance: "That this council is of opinion that in any measure for the better administration of the universities of Scotland provision should be made for the incorporation of institutions as colleges, with a view to being affiliated to one of the universities." The Town Clerk was instructed to forward a copy of this deliverance to the Secretary for Scotland.

THE ASSOCIATION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

The following letter has been addressed to the Honorary Secretaries of the Association of Members of the Royal College of Surgeons by the Clerk to the Privy Council.

"Privy Council Office, Whitehall, June 7th, 1888.

"SIR,—I am instructed by the Lord President of the Council to acknowledge the receipt of your letter of May 31st, transmitting a petition addressed to Her Majesty in Council, praying that the petition of 4,665 Members of the Royal College of Surgeons, in relation to a proposed supplemental charter to that College and other papers in connection therewith, may be referred for the consideration of the Privy Council, or some members thereof, sitting in judicial capacity.

"In reply, I am instructed to inform you that the petition in

question, together with all other petitions on the subject, was referred by Her Majesty to a Committee of the Lords of the Council, and that, as no legal question was involved, their lordships did not think it necessary to hear counsel on the subject.—I am, Sir, your obedient servant,
C. L. PERL.

"W. Ashton Ellis, Esq."

The Council have transmitted the following reply:—

"To the Right Honourable the Lord President of the Privy Council.

"14, Grosvenor Road, Westminster, S.W., June 12th.

"SIR,—I am instructed by the Committee of the Association of Members of the Royal College of Surgeons of England to acknowledge the receipt of your communication of June 7th.

"I am also instructed by the said Committee to state that they desire respectfully to point out that no reply has as yet been vouchsafed to the prayer of the petition, signed by 4,665 Members of the College, and lodged at the Privy Council Office on May 3rd, 1887, praying for participation by the Members of the Royal College of Surgeons of England in the management of their College and other matters, on all of which the said Committee and the general body of Members of the said College most anxiously await your lordship's answer.—I am, Sir, your lordship's most obedient servant,
WM. ASHTON ELLIS,

"Honorary Secretary to the Association of Members of the Royal College of Surgeons of England."

ASSOCIATION INTELLIGENCE.

COUNCIL.

NOTICE OF MEETING.

A MEETING of the Council will be held at the Offices of the Association, No. 429, Strand (corner of Agar Street), London, on Wednesday, the 18th day of July next, at 2 o'clock in the afternoon.

FRANCIS FOWKE, *General Secretary.*

June 14th, 1888.

NOTICE OF QUARTERLY MEETINGS FOR 1888.

ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Meetings of the Council will be held on July 18th, and October 17th, 1888. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before each meeting, namely, June 27th, September 26th, and December 28th, 1888.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No member can be elected by a Branch Council unless his name has been inserted in the circular summoning the meeting at which he seeks election.

FRANCIS FOWKE, *General Secretary.*

GRANTS FOR SCIENTIFIC RESEARCH.

THE Scientific Grants Committee of the British Medical Association desire to remind members of the profession engaged in researches for the advancement of medicine and the allied sciences, that they are empowered to receive applications for grants in aid of such research. Applications for sums to be granted at the next annual meeting should be made without delay to the General Secretary, at the office of the Association, 429, Strand, W.C. Applications must include details of the precise character and objects of the research which is proposed.

Reports of work done by the assistance of Association grants belong to the Association.

Instruments purchased by means of grants must be returned to the General Secretary on the conclusion of the research in furtherance of which the grant was made.

COLLECTIVE INVESTIGATION OF DISEASE.

THE Report upon the CONNECTION OF DISEASE WITH HABITS OF INTEMPERANCE, which was presented to the Section of Medicine in the Annual Meeting of 1887, will shortly be published in the JOURNAL.

Reports upon the two remaining inquiries, namely, that into DIPHTHERIA, and that into the GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES, are in preparation, and will be published as soon as ready.

The following inquiry only of the first series remains open, namely, that on the ETIOLOGY OF PHTHISIS.

A fresh inquiry into the ORIGIN AND MODE OF PROPAGATION OF EPIDEMICS OF DIPHTHERIA has been issued.

Memoranda upon these subjects, and forms for recording observations, may be had on application to the Secretary of the Collective Investigation Committee, 429, Strand, W.C.

BRANCH MEETINGS TO BE HELD.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.—The next meeting of this Branch will be held at the Braes of Gight on Wednesday, June 20th, at 1.45 P.M., the President, Dr. Smith, of Kinnairdy, in the chair. Business: 1. Minutes, nomination of new members. 2. Ballot for the admission of Dr. Jenkyns, Belize, British Honduras; Dr. W. L. Mackenzie, Royal Infirmary; Dr. W. R. C. Midleton, Royal Infirmary; Dr. Rannie, Peterculter; Dr. J. Scott Riddell, 7, Ferryhill Place; Dr. A. M. Will, Royal Infirmary. 3. Notes on Gight and its Castle, by Dr. Alexander Cruikshank, Aberdeen. An omnibus excursion to the Braes of Gight, through the grounds of Haddon House, has been arranged for those who can meet at Old Meldrum at 11.30 A.M. A train leaves Aberdeen at 10.20 A.M. and arrives at Old Meldrum at 11.30 A.M., where carriages will be in waiting. Dinner (inclusive of attendance but exclusive of wine) in a marquee at the Braes of Gight at 5s. per head. Arrangements have been made for members from Buchan to drive from Mand Junction (11.15 A.M.), and for those from Banff from Fyvie (1.15 P.M.) to the Braes of Gight, in time for the meeting and dinner, and returning to catch later down trains. Members from the north will meet the party at Inverurie at 10.50, those from the south and Deeside at Aberdeen at 10.20. A train leaves Old Meldrum at 5.25 P.M., arriving in Aberdeen at 6.40 P.M. Members are invited to bring medical friends.—**ROBERT JOHN GARDEN** and **J. MACKENZIE BOOTH**, Honorary Secretaries.

BORDER COUNTIES BRANCH.—The twenty-first annual meeting of this Branch will be held at Penrith on Friday, July 13th. The chair will be taken by Dr. MacLeod at 1.30 P.M. The usual election of office bearers for the year will be held. Dr. Robertson, Penrith, will deliver his presidential address. Intimations of papers for reading or communications of any kind should be sent to the Secretary as soon as possible.—**H. A. LEDIARD**, 41, Lowther Street, Carlisle, Honorary Secretary.

CAMBRIDGESHIRE AND HUNTINGDONSHIRE BRANCH.—The annual meeting of this Branch is appointed to be held at Ely on Friday, July 6th. Members wishing to make communications, to exhibit specimens, or to propose new members are requested to signify their intention to Dr. Anningson, Cambridge, for insertion in the order of proceedings.—**BUSHELL ANNINGSON**, Honorary Secretary.

GLOUCESTERSHIRE, WORCESTERSHIRE, AND HEREFORDSHIRE BRANCHES.—The conjoint meeting of these Branches will be held, under the presidency of Dr. Currie, at the Bell Hotel, Gloucester, on Tuesday, June 13th, when Dr. J. Hughlings Jackson will deliver an address on "The Diagnosis of Brain Disease." The meetings will be at 4, and dinner at 6 P.M.—**G. ARTHUR CARDEW**, G. W. CROWE, Honorary Secretaries, Cheltenham.

METROPOLITAN COUNTIES BRANCH.—The thirty-sixth annual meeting of this Branch will be held at the Holborn Restaurant on Wednesday, June 27th, 1888, at 5.30 P.M. President, Arthur E. Durham, Esq., F.R.C.S.; President-elect, C. Brodie Sewell, M.D. An address will be given by the new President. At 7 P.M. precisely the members will dine together; C. Brodie Sewell, Esq., M.D., President, in the chair; tickets, 7s. 6d. each, exclusive of wine.—**GEORGE EASTES**, M.B., 69, Connaught Street, W.; **E. NOBLE SMITH**, F.R.C.S., 24, Queen Anne Street, W., Honorary Secretaries.

NORTH OF IRELAND BRANCH.—The annual meeting of this Branch will be held in the Belfast Royal Hospital, on Wednesday, July 11th, at 4 P.M. Gentlemen who desire to read papers or to bring any other business before the meeting will kindly communicate as early as possible with the Secretary, **JOHN W. BYERS**, M.D., Lower Crescent, Belfast.

READING AND UPPER THAMES BRANCH.—The annual meeting of this Branch will be held in the Library of the Royal Berkshire Hospital, Reading, on Wednesday, July 11th, at 4.15 P.M. The chair will be taken by the President (Dr. C. H. Tench), who will introduce the President for the coming year (W. B. Holderness, Esq., of Windsor), who will then take the chair. Members willing to read short papers or bring forward cases of clinical interest are requested to communicate with the Honorary Secretary without delay. The annual dinner will take place on the same evening at 6.15 P.M., at the Queen's Hotel, Reading. Dinner tickets (5s. without wine, or 10s. including wine) should be obtained from the Honorary Secretary on or before Saturday, July 7th.—**H. HEXGATE PHILLIPS**, 43A, London Road, Reading, Honorary Secretary.

SOUTH-WESTERN BRANCH.—The annual meeting of this Branch will be held at the Devon and Exeter Hospital, Exeter, on Tuesday, June 26th, under the presidency of Dr. John Woodman, F.R.C.S. Notices of motion or communications to be intimated to the Honorary Secretary without delay, and it will facilitate arrangements if members will inform the Honorary Secretary as soon as possible if they hope to be present at the meeting. The following motion was passed at the Council Meeting on May 2nd:—"That inasmuch as the annual meeting assumes more or less the character of a day of recreation, and with a view of encouraging the district meetings, the business of

the annual meeting shall be confined to the President's address, the business of the Branch, the exhibition of cases or of specimens with notes, and the annual dinner."—**P. MAURY DEAR**, Wouford House, Exeter, Honorary Secretary.

SOUTH WALES AND MONMOUTH BRANCH.—The eighteenth annual meeting of this Branch will be held at the Infirmary, Cardiff, on Wednesday, June 27th. Further particulars in circulars. Members wishing to read papers, etc., are requested to send titles to Dr. Sheen.—**A. SHEEN**, M.D., Cardiff, **D. ARTHUR DAVIES**, M.B., Swansea, Honorary Secretaries.

WEST SOMERSET BRANCH.—The annual meeting of this Branch will be held at the Squirrel Hotel, Wellington, on Thursday, June 28th, at 4 o'clock. **Abraham Colles**, Esq., M.D., President-elect, will take the chair on ita being vacated by **Edward Stephens**, Esq. The dinner will be at 6 o'clock. Members desirous of reading a paper or making a communication to the meeting are requested to give early notice to the Honorary Secretary; they are also requested to give early notice of their intention of attending the annual dinner.—**W. M. KELLY**, M.D., Honorary Secretary.

YORKSHIRE BRANCH.—The annual meeting of the Yorkshire Branch will be held in the Museum of the Yorkshire Philosophical Society at York on Wednesday, June 27th, when the representatives of the Branch on the General Council and the officers for the ensuing year will be elected. Members intending to read papers and show specimens, are requested to communicate at once with **ARTHUR JACKSON**, Secretary, Sheffield.

EAST YORK AND NORTH LINCOLN BRANCH.

The thirty-second annual meeting was held on May 30th. There were thirty-eight gentlemen present.

Report of Council.—The retiring President, **Mr. THOMPSON**, having resigned the chair to his successor, **Dr. FRANK NICHOLSON**, and the minutes having been read, the SECRETARY read a brief report of the Council, and **Mr. DIX**, the representative of the Branch, made a statement.

Election of Council, 1888-89.—President: **J. N. Nicholson**, M.D. President-Elect: **J. Merson**, M.D. Ex-President: **H. Thompson**. Vice-Presidents: **E. O. Daly**, M.D.; **E. H. Howlett**. Secretary and Treasurer: **E. P. Hardey**. Representative of the Branch: **J. DIX**. Representative on the Parliamentary Bills Committee: **R. H. B. Nicholson**. Council: **W. C. Appleton**; **T. M. Evans**; **G. F. Elliott**, M.D.; **M. D. Macleod**, M.B.; **D. Lawson**, M.D.; **H. W. Pigeon**, M.B.; **J. A. Locking**; **C. H. Milburn**, M.D.

Appointment of Medical Officers of Health.—**Mr. ROBERT H. BOURCHIER NICHOLSON** proposed the following resolution: "That the interests of the public would be best served by the appointment of medical officers being entirely vested in the County Councils, instead of the District Councils, as arranged in the Local Government Bill." This was supported by **Dr. MACLEOD**, and opposed by **Mr. APPLETON**, **Mr. KEETLEY**, and **Mr. DIX**. On a vote being taken, **Mr. Nicholson's** resolution was carried.

New Members.—**Dr. Morley**, of Barton, and **Mr. Williams**, of Hull, were elected.

Grants of Money.—Grants of £2 2s. were voted to the Medical Benevolent Fund and to the Royal Medical Benevolent College.

Papers and Cases.—A child with a large mixed nœvus on the shoulder was exhibited by **Mr. EVANS**.—**Dr. PIGEON** gave a demonstration of the method of applying flannel and plaster-of-Paris splints, and spoke of their advantages.—**Mr. EVANS** read the notes of two cases of tumour of the bladder. In the first, a papillomatous growth was removed by suprapubic operation; the patient was shown. In the second, external urethrotomy was performed to explore the bladder, when a broad-based malignant growth was discovered; rigors and high temperature followed, and the patient died on the fourteenth day. One kidney was disorganised and the bladder ulcerated.—**Mr. R. H. BOURCHIER NICHOLSON** read the notes of a case of removal of the whole of the interior of the os calcis. **Mr. Nicholson** also read notes of two cases of removal of calculi from the kidney, and showed the calculi removed. He also exhibited calculi removed *post mortem* from two other cases.—**Dr. EDWARD DALY** read a paper on the hypodermic injection of morphine.

Head Injury.—**Mr. TOMALIN** exhibited a patient who had been run over by a furniture van. His frontal bone was dislocated at the suture, and was lying on the right cheek, the orbital plate being jammed into the brain. The orbital plate was removed, and a free drain was established from the frontal sinus down the nose, and the parts replaced. He had opium every four hours, and recovered without a bad symptom.

Surgical Instruments.—Surgical instruments were exhibited by **Messrs. Wood**, of York, and **Messrs. Lynch**, of London.

Dinner.—In the evening the members dined at the Victoria Hotel. The President was cordially congratulated on his recovery from his recent severe illness.

SCOTCH UNIVERSITY AND COLLEGIATE BILLS.

Universities (Scotland) Bill.—The House of Lords went into Committee on this Bill on June 7th. Lord Rosebery proposed a definition of affiliation, as "such a connection between an existing University and College as shall be entered into by their mutual consent, under conditions approved by the Commissioners, or after the determination of their powers by the Scottish Universities Committee of the Privy Council." This proposal met with general approval, and was inserted. Lord Watson then inserted a definition of "College" as "an institution established on a permanent footing, for the purpose of teaching the higher branches of education, and which shall be sufficiently endowed, in the opinion of the Commissioners, and after the expiry of their powers, of the University Committee." Considerable objection was taken by Lords Camperdown, Watson, and Rosebery, to the number of the representatives of affiliated colleges on the University Court. It was thought that the representatives of the University might be swamped, and Lord Rosebery moved an amendment to leave the representation of the Colleges to the Commissioners. This, however, was lost on a division. Various other amendments were moved to increase the powers of the Court over property; to enable the Court to appoint certain committees, and to appoint certain representatives to the governing bodies of affiliated colleges, and on other small matters of detail, but most of them were postponed to the report stage. The Government amendments on the original Bill seem to have so cleared up doubtful points that but little of importance was left for discussion, and no attack was made on the general principles of the measure. After the Commissioners' names were inserted, the Bill passed through Committee, and was ordered to be reported. The Commission is to consist of Lord Kinnear (Chairman); the Dean of Faculty; the Earl of Crawford; Lord Watson; the Marquis of Bute; Dr. A. B. McGrigor; Sir Charles Dalrymple, M.P.; Mr. Craig-Sellar, M.P.; Mr. Donald Crawford, M.P.; Mr. J. A. Campbell, M.P.; Mr. Vary Campbell; and Sir James Crichton Browne.

St. Mungo's College Bill.—The Glasgow magistrates submitted to the Town Council at its last meeting a minute of date May 28th, stating that, having carefully considered this Bill and the representations made thereon by the directors of the Royal Infirmary and the Senate of the University, and having also had before them the fact that the Government have introduced a Universities Bill, applicable to all the universities of Scotland, under which provision is to be made for affiliating, incorporating with, or uniting colleges to, any of the universities, and for admitting the teaching of such colleges as qualifying for graduation in such universities, they resolved to recommend the Town Council not to take any action with reference to the St. Mungo's College Bill. The Lord Provost said this recommendation was made because it was thought the object sought might be better secured under the Universities (Scotland) Bill. It was pointed out that the St. Mungo's College was not "incorporated," and could not take advantage of the affiliating clauses of the Universities Bill, and after some discussion the council adopted the following general deliverance: "That this council is of opinion that in any measure for the better administration of the universities of Scotland provision should be made for the incorporation of institutions as colleges, with a view to being affiliated to one of the universities." The Town Clerk was instructed to forward a copy of this deliverance to the Secretary for Scotland.

THE ASSOCIATION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

The following letter has been addressed to the Honorary Secretaries of the Association of Members of the Royal College of Surgeons by the Clerk to the Privy Council.

"Privy Council Office, Whitehall, June 7th, 1888.

"SIR,—I am instructed by the Lord President of the Council to acknowledge the receipt of your letter of May 31st, transmitting a petition addressed to Her Majesty in Council, praying that the petition of 4,665 Members of the Royal College of Surgeons, in relation to a proposed supplemental charter to that College and other papers in connection therewith, may be referred for the consideration of the Privy Council, or some members thereof, sitting in judicial capacity.

"In reply, I am instructed to inform you that the petition in

question, together with all other petitions on the subject, was referred by Her Majesty to a Committee of the Lords of the Council, and that, as no legal question was involved, their lordships did not think it necessary to hear counsel on the subject.—
I am, Sir, your obedient servant,
C. L. PERL.

"W. Ashton Ellis, Esq."

The Council have transmitted the following reply:—

"To the Right Honourable the Lord President of the Privy Council.

"14, Grosvenor Road, Westminster, S.W., June 12th.

"SIR,—I am instructed by the Committee of the Association of Members of the Royal College of Surgeons of England to acknowledge the receipt of your communication of June 7th.

"I am also instructed by the said Committee to state that they desire respectfully to point out that no reply has as yet been vouchsafed to the prayer of the petition, signed by 4,665 Members of the College, and lodged at the Privy Council Office on May 3rd, 1887, praying for participation by the Members of the Royal College of Surgeons of England in the management of their College and other matters, on all of which the said Committee and the general body of Members of the said College most anxiously await your lordship's answer.—I am, Sir, your lordship's most obedient servant,
WM. ASHTON ELLIS,

"Honorary Secretary to the Association of Members of the Royal College of Surgeons of England."

ASSOCIATION INTELLIGENCE.

COUNCIL.

NOTICE OF MEETING.

A MEETING of the Council will be held at the Offices of the Association, No. 429, Strand (corner of Agar Street), London, on Wednesday, the 18th day of July next, at 2 o'clock in the afternoon.

FRANCIS FOWKE, *General Secretary.*

June 14th, 1888.

NOTICE OF QUARTERLY MEETINGS FOR 1888. ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Meetings of the Council will be held on July 18th, and October 17th, 1888. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before each meeting, namely, June 27th, September 26th, and December 28th, 1888.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No member can be elected by a Branch Council unless his name has been inserted in the circular summoning the meeting at which he seeks election.

FRANCIS FOWKE, *General Secretary.*

GRANTS FOR SCIENTIFIC RESEARCH.

THE Scientific Grants Committee of the British Medical Association desire to remind members of the profession engaged in researches for the advancement of medicine and the allied sciences, that they are empowered to receive applications for grants in aid of such research. Applications for sums to be granted at the next annual meeting should be made without delay to the General Secretary, at the office of the Association, 429, Strand, W.C. Applications must include details of the precise character and objects of the research which is proposed.

Reports of work done by the assistance of Association grants belong to the Association.

Instruments purchased by means of grants must be returned to the General Secretary on the conclusion of the research in furtherance of which the grant was made.

COLLECTIVE INVESTIGATION OF DISEASE.

THE Report upon the CONNECTION OF DISEASE WITH HABITS OF INTEMPERANCE, which was presented to the Section of Medicine in the Annual Meeting of 1887, will shortly be published in the JOURNAL.

June 16, 1888.]

Reports upon the two remaining inquiries, namely, that into DIPHTHERIA, and that into the GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES, are in preparation, and will be published as soon as ready.

The following inquiry only of the first series remains open, namely, that on the ETIOLOGY OF PHTHISIS.

A fresh inquiry into the ORIGIN AND MODE OF PROPAGATION OF EPIDEMICS OF DIPHTHERIA has been issued.

Memoranda upon these subjects, and forms for recording observations, may be had on application to the Secretary of the Collective Investigation Committee, 429, Strand, W.C.

BRANCH MEETINGS TO BE HELD.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.—The next meeting of this Branch will be held at the Braes of Gight on Wednesday, June 20th, at 1.45 P.M. The President, Dr. Smith, of Kinnairdy, in the chair. Business: 1. Minutes, nomination of new members. 2. Ballot for the admission of Dr. Jenkyns, Belize, British Honduras; Dr. W. L. Mackenzie, Royal Infirmary; Dr. W. R. C. Middleton, Royal Infirmary; Dr. Hannie, Peterculter; Dr. J. Scott Riddell, 7, Ferryhill Place; Dr. A. M. Will, Royal Infirmary. 3. Notes on Gight and its Castle, by Dr. Alexander Cruikshank, Aberdeen. An omnibus excursion to the Braes of Gight, through the grounds of Haddon House, has been arranged for those who can meet at Old Meldrum at 11.30 A.M., where carriages will be in 10.20 A.M. and arrives at Old Meldrum at 11.30 A.M., where carriages will be waiting. Dinner (inclusive of attendance but exclusive of wine) in a marquee at the Braes of Gight at 5s. per head. Arrangements have been made for members from Buehan to drive from Maud Junction (11.15 A.M.), and for those from Banff from Fyvie (1.15 P.M.) to the Braes of Gight, in time for the meeting and dinner, and returning to catch later down trains. Members from the north will meet the party at Inverurie at 10.50, those from the south and Deeside at Aberdeen at 10.20. A train leaves Old Meldrum at 5.25 P.M., arriving in Aberdeen at 6.40 P.M. Members are invited to bring medical friends.—ROBERT JOHN GARDEN and J. MACKENZIE BOOTH, Honorary Secretaries.

BORDER COUNTIES BRANCH.—The twenty-first annual meeting of this Branch will be held at Penrith on Friday, July 13th. The chair will be taken by Dr. McLeod at 1.30 P.M. The usual election of office bearers for the year will be held. Dr. Robertson, Penrith, will deliver his presidential address. Intimations of papers for reading or communications of any kind should be sent to the Secretary as soon as possible.—H. A. LEDIARD, 41, Lowther Street, Carlisle, Honorary Secretary.

CAMBRIDGESHIRE AND HUNTINGDONSHIRE BRANCH.—The annual meeting of this Branch is appointed to be held at Ely on Friday, July 6th. Members wishing to make communications, to exhibit specimens, or to propose new members are requested to signify their intention to Dr. Annington, Cambridge, for insertion in the order of proceedings.—BUSHELL ANNINGSOX, Honorary Secretary.

GLOUCESTERSHIRE, WORCESTERSHIRE, AND HEREFORDSHIRE BRANCHES.—The conjoint meeting of these Branches will be held, under the presidency of Dr. Currie, at the Bell Hotel, Gloucester, on Tuesday, June 19th, when Dr. J. Hinglins Jackson will deliver an address on "The Diagnosis of Brain Disease." The meeting will be at 4, and dinner at 6 P.M.—G. ARTHUR CARDEW, G. W. CROWE, Honorary Secretaries, Cheltenham.

METROPOLITAN COUNTIES BRANCH.—The thirty-sixth annual meeting of this Branch will be held at the Holborn Restaurant on Wednesday, June 27th, 1888, at 5.30 P.M. President, Arthur E. Durham, Esq., F.R.C.S.; President-elect, C. Brodie Sewell, M.D. An address will be given by the new President. At 7 P.M. precisely the members will dine together; C. Brodie Sewell, Esq., M.D., President, in the chair; tickets, 7s. 6d. each, exclusive of wine.—GEORGE EASTES, M.B., 68, Connaught Street, W.; E. NOBLE SMITH, F.R.C.S., 24, Queen Anne Street, W., Honorary Secretaries.

NORTH OF IRELAND BRANCH.—The annual meeting of this Branch will be held in the Belfast Royal Hospital, on Wednesday, July 11th, at 4 P.M. Gentlemen who desire to read papers or to bring any other business before the meeting will kindly communicate as early as possible with the Secretary, JOHN W. BYERS, M.D., Lower Crescent, Belfast.

READING AND UPPER THAMES BRANCH.—The annual meeting of this Branch will be held in the Library of the Royal Berkshire Hospital, Reading, on Wednesday, July 11th, at 4.15 P.M. The chair will be taken by the President (Dr. C. H. Tench), who will introduce the President for the coming year (W. B. Holderness, Esq., of Windsor), who will then take the chair. Members willing to read short papers or bring forward cases of clinical interest are requested to communicate with the Honorary Secretary without delay. The annual dinner will take place on the same evening at 6.15 P.M., at the Queen's Hotel, Reading. Dinner tickets (5s. without wine, or 10s. including wine) should be obtained from the Honorary Secretary on or before Saturday, July 7th.—H. HEXGATE PHILLIPS, 43A, London Road, Reading, Honorary Secretary.

SOUTH-WESTERN BRANCH.—The annual meeting of this Branch will be held at the Devon and Exeter Hospital, Exeter, on Tuesday, June 26th, under the presidency of Dr. John Woodman, F.R.C.S. Notices of motion or communications to be intimated to the Honorary Secretary without delay, and it will facilitate arrangements if members will inform the Honorary Secretary as soon as possible if they hope to be present at the meeting. The following motion was passed at the Council Meeting on May 2nd:—"That inasmuch as the annual meeting assumes more or less the character of a day of recreation, and with a view of encouraging the district meetings, the business of

the annual meeting shall be confined to the President's address, the business of the Branch, the exhibition of cases or of specimens with notes, and the annual dinner."—P. MAUBY DEAS, Wouford House, Exeter, Honorary Secretary.

SOUTH WALES AND MONMOUTH BRANCH.—The eighteenth annual meeting of this Branch will be held at the Infirmary, Cardiff, on Wednesday, June 27th. Further particulars in circulars. Members wishing to read papers, etc., are requested to send titles to Dr. Sheen.—A. SHEEN, M.D., Cardiff, D. ARTHUR DAVIES, M.B., Swansea, Honorary Secretaries.

WEST SOMERSET BRANCH.—The annual meeting of this Branch will be held at the Squirrel Hotel, Wellington, on Thursday, June 28th, at 4 o'clock. Abraham Colles, Esq., M.D., President-elect, will take the chair on its being vacated by Edward Stephens, Esq. The dinner will be at 6 o'clock. Members desirous of reading a paper or making a communication to the meeting are requested to give early notice to the Honorary Secretary; they are also requested to give early notice of their intention of attending the annual dinner.—W. M. KELLY, M.D., Honorary Secretary.

YORKSHIRE BRANCH.—The annual meeting of the Yorkshire Branch will be held in the Museum of the Yorkshire Philosophical Society at York on Wednesday, June 27th, when the representatives of the Branch on the General Council and the officers for the ensuing year will be elected. Members intending to read papers and show specimens, are requested to communicate at once with ARTHUR JACKSON, Secretary, Sheffield.

EAST YORK AND NORTH LINCOLN BRANCH.

The thirty-second annual meeting was held on May 30th. There were thirty-eight gentlemen present.

Report of Council.—The retiring President, Mr. THOMPSON, having resigned the chair to his successor, Dr. FRANK NICHOLSON, and the minutes having been read, the SECRETARY read a brief report of the Council, and Mr. DIX, the representative of the Branch, made a statement.

Election of Council, 1888-89.—President: J. N. Nicholson, M.D. President-Elect: J. Merson, M.D. Ex-President: H. Thompson. Vice-Presidents: E. O. Daly, M.D.; E. H. Howlett. Secretary and Treasurer: E. P. Hardey. Representative of the Branch: J. H. B. Representative on the Parliamentary Bills Committee: R. H. B. Nicholson. Council: W. C. Appleton; T. M. Evans; G. F. Elliott, M.D.; M. D. Macleod, M.B.; D. Lawson, M.D.; H. W. Pigeon, M.B.; J. A. Locking; C. H. Milburn, M.D.

Appointment of Medical Officers of Health.—Mr. ROBERT H. BOURCHIER NICHOLSON proposed the following resolution: "That the interests of the public would be best served by the appointment of medical officers being entirely vested in the County Councils, instead of the District Councils, as arranged in the Local Government Bill." This was supported by Dr. MACLEOD, and opposed by Mr. APPLETON, Mr. KEETLEY, and Mr. DIX. On a vote being taken, Mr. Nicholson's resolution was carried.

New Members.—Dr. Morley, of Barton, and Mr. Williams, of Hull, were elected.

Grants of Money.—Grants of £2 2s. were voted to the Medical Benevolent Fund and to the Royal Medical Benevolent College.

Papers and Cases.—A child with a large mixed nevus on the shoulder was exhibited by Mr. EVANS.—Dr. PIGEON gave a demonstration of the method of applying flannel and plaster-of-Paris splints, and spoke of their advantages.—Mr. EVANS read the notes of two cases of tumour of the bladder. In the first, a papillomatous growth was removed by suprapubic operation; the patient to explore the bladder, when a broad-based malignant growth was discovered; rigors and high temperature followed, and the patient died on the fourteenth day. One kidney was disorganised and the bladder ulcerated.—Mr. R. H. BOURCHIER NICHOLSON read the notes of a case of removal of the whole of the interior of the os calcis. Mr. Nicholson also read notes of two cases of removal of calculi from the kidney, and showed the calculi removed. He also exhibited calculi removed *post mortem* from two other cases.—Dr. EDWARD DALY read a paper on the hypodermic injection of morphine.

Head Injury.—Mr. TOMALIN exhibited a patient who had been run over by a furniture van. His frontal bone was dislocated at the suture, and was lying on the right cheek, the orbital plate being jammed into the brain. The orbital plate was removed, and a free drain was established from the frontal sinus down the nose, and the parts replaced. He had opium every four hours, and recovered without a bad symptom.

Surgical Instruments.—Surgical instruments were exhibited by Messrs. Wood, of York, and Messrs. Lynch, of London.

Dinner.—In the evening the members dined at the Victoria Hotel. The President was cordially congratulated on his recovery from his recent severe illness.

METROPOLITAN COUNTIES BRANCH; WESTERN DISTRICT.

THE last meeting of the District for the present season was held at the St. Marylebone Infirmary, Notting Hill, on Tuesday, June 5th. In the absence of the Vice-President, Dr. SINCLAIR THOMSON was voted to the chair. Nineteen members and visitors were present.

The minutes of the preceding meeting were read and confirmed.

Treatment of Eye Affections.—Mr. HENRY POWER read a paper on some points in the treatment of injuries and diseases of the eye, in the course of which he drew attention to the value of eserine and atropine respectively in cases of cuts of the cornea near the centre and near the periphery, prior to any attempt being made to reduce prolapsed iris. He also dwelt upon the great importance, in many cases of wounds of the eye, of applying a pad and bandage to both eyes instead of to one. Various cases were adduced in which, by the adoption of the principle of complete rest to both eyes, dangerous wounds of the ciliary region had completely recovered. Some remarks were also made on the treatment of cuts of the lids and of burns with lime.—A discussion took place, in which Dr. SINCLAIR THOMSON, Mr. LAMB, and Mr. LUNN took part, and Mr. POWER replied.

Cases.—Mr. LUNN then exhibited an interesting group of male and female patients, to the number of twenty-three, including five cases of locomotor ataxy, two cases of glaucoma, as well as various examples of iritis and cataract. Three most interesting cases of myxœdema, a case of osteitis deformans, a case of ichthyosis of the tongue, one of popliteal aneurysm (cured), as well as examples of lateral and disseminated sclerosis, were among the diseases brought before the meeting.

Re-election of Officers.—The present officers of the District were then unanimously re-elected, and the proceedings closed by a hearty vote of thanks to Mr. Power, Mr. Lunn, and the Chairman.

BATH AND BRISTOL BRANCH.

THE sixth ordinary meeting of the session was held at the Museum and Library, Bristol, on Wednesday, May 30th, G. F. BURDER, M.D., President, in the chair. There were also present forty-six members and two visitors.

New Members.—The following gentlemen were elected: J. L. Livingston, M.A., M.D., M.Ch. R.U.I., Bristol; W. N. Nevill, M.B., B.Ch.T.C.D., Bristol; F. Woods, M.R.C.S., L.R.C.P., Bath; C. E. F. M. Biggs, M.R.C.S., Malmesbury; F. E. Pearce, M.D., Frome.

Joint Meeting.—An invitation from the Gloucestershire Branch to a joint meeting at Gloucester with the Worcestershire and Herefordshire Branches was cordially accepted.

Lunacy Acts Amendment Bill.—After a prolonged discussion this subject was referred to a subcommittee consisting of Drs. Harrison, Bonville Fox, Marshall, Shaw, and Mr. Scott, with power to take such steps as they might think fit.

Cases.—Dr. F. ST. JOHN KEMM exhibited a case of Graves's Disease successfully treated with strophanthus.—Dr. J. MICHELL CLARKE exhibited two cases of Pseudo-hypertrophic Paralysis, upon which Drs. WIGAN and MARKHAM SKERRITT made some observations.—Mr. W. J. PENNY exhibited four cases of "Bone-setting," which Mr. Cross commented upon.

Papers.—Mr. C. F. PICKERING read a paper on the Treatment of Discharge from the Ear, which was discussed by Mr. HARSANT, Dr. SWAYNE, and Mr. EWENS.—Dr. J. G. SWAYNE read a paper on The Hour of Delivery. Drs. BEDDOE, AUST LAWRENCE, WAUGH, HINTON, DUNCAN, and the PRESIDENT joined in the discussion which followed.—Dr. H. WALDO read a paper on Embolic Hemiplegia.

BRITISH MEDICAL ASSOCIATION.

FIFTY-SIXTH ANNUAL MEETING.

THE fifty-sixth Annual Meeting of the British Medical Association will be held at Glasgow, on Tuesday, Wednesday, Thursday, and Friday, August 7th, 8th, 9th, and 10th, 1888.

President: John T. Banks, M.D., D.Sc.(Hon.), F.K.Q.C.P.I., Regius Professor of Physic in the University of Dublin.

President-Elect: Professor W. T. Gairdner, M.D., LL.D., Professor of Medicine in the University of Glasgow.

President of the Council: Thomas Bridgwater, M.B., J.P., Harrow-on-the-Hill.

Treasurer: Constantine Holman, M.D., J.P., Reigate.

An Address in Medicine will be delivered by Thomas Clifford

Allbutt, M.D., F.R.S., Consulting Physician, Leeds General Infirmary. An Address in Surgery will be delivered by Sir George H. B. Macleod, M.D., Surgeon in Ordinary to Her Majesty in Scotland.

An Address on his "Recent Investigations in Surgery" will be given by William Macewen, M.D., Lecturer on Clinical Surgery, Glasgow Royal Infirmary.

An Address in Physiology will be delivered by John Gray McKendrick, M.D., LL.D., F.R.S., Professor of Institutes of Medicine, University of Glasgow.

All the rooms required for the purposes of the meeting will, by the kindness of the authorities, be provided in the University of Glasgow.

PROGRAMME OF PROCEEDINGS.

TUESDAY, AUGUST 7TH, 1888.

9.30 A.M.—Meeting of 1887-1888 Council. Randolph Hall.

11.30 A.M.—First General Meeting, Report of Council. Reports of Committees. Bute Hall.

4 P.M.—Service in the Cathedral. Sermon by the Very Rev. John Caird, D.D., LL.D., Principal and Vice-Chancellor of the University of Glasgow.

8.30 P.M.—Adjourned General Meeting from 11.30 A.M. President's Address. Bute Hall.

WEDNESDAY, AUGUST 8TH, 1888.

9.30 A.M.—Meeting of 1888-89 Council. Randolph Hall.

10.30 A.M. to 2 P.M.—Sectional Meetings.

3 P.M.—Second General Meeting. Address in Medicine by Thomas Chifford Allbutt, M.D., F.R.S. Bute Hall.

9 P.M.—*Conversazione* given by the Professors of the University.

THURSDAY, AUGUST 9TH, 1888.

9.30 A.M.—Address on his Recent Surgical Investigations by William Macewen, M.D. Bute Hall.

11 A.M.—Meeting of Council. Randolph Hall.

10.30 A.M. to 2 P.M.—Sectional Meetings.

3 P.M.—Third General Meeting. Address in Surgery by Sir George H. B. Macleod, M.D. Bute Hall.

7 P.M.—Public Dinner. St. Andrew's Hall.

FRIDAY, AUGUST 10TH, 1888.

10.30 A.M. to 1.30 P.M.—Sectional Meetings.

3 P.M.—Concluding General Meeting. Address in Physiology by John G. McKendrick, M.D., F.R.S. Philosophy Class-room.

9 P.M.—*Conversazione* given by the Corporation of Glasgow at St. Andrew's Hall.

Garden Party given by the Faculty of Physicians and Surgeons at the Botanic Gardens.

SATURDAY, AUGUST 11TH, 1888.

Excursions.

The following discussions and papers are promised up to the present time.

SECTION A.—MEDICINE.

Humanity Class Room.

A. MEDICINE.—*President,* Professor T. McCall Anderson, M.D. *Vice-Presidents,* R. L. Bowles, M.D.; George F. Duffey, M.D. *Honorary Secretaries,* J. McGregor Robertson, M.A., M.B., 400, Great Western Road, Glasgow; Robert M. Simon, M.D., 27, Newhall Street, Birmingham.

The President will open the proceedings by introducing a discussion on the Diagnosis and Treatment of Syphilitic Disease of the Nervous System. Dr. Thomas Buzzard, Dr. T. S. Clouston, Dr. William Moore, Dr. Ross, Professor Grainger Stewart, Professor Julius Dreschfeld, Dr. J. G. Sinclair Coghill, Dr. Francis Warner, Dr. Frederick Bateman, and Dr. C. W. Suckling will take part in the discussion.

On the third day of the sectional proceedings, the Value of Inhalations in the Treatment of Lung Disease is set down for discussion, to be opened by Dr. C. Theodore Williams. The following gentlemen have already indicated their intention to engage in this discussion: Dr. Burney Yeo, Dr. W. W. Ireland, Dr. C. F. Knight, Dr. J. A. Lindsay, Dr. J. G. Sinclair Coghill, and Dr. E. Markham Skerritt.

Drs. Byrom Bramwell and Milne Murray will give a demonstration of their Method of Graphically Recording the Exact Time Relations of Cardiac Sounds and Murmurs.

The following papers have been promised.

COGHILL, J. G. S., M.D., Ventnor. The Treatment of Phtisical Pyrexia.

FINLAY, David W., B.A., M.D. Bronchiectasis treated by Incision and Drainage.

FREW, W., M.D., Kilmarnock. Prevalence of Cerebro-spinal Fever in Scotland.

GREENE, G. E. F., L.K.Q.C.P. A Note on a Recent Epidemic of Erysipelas.

MYRTLE, A. S., M.D., Harrogate. Nourasthenia, True and False: Diagnosis and Management.

STRAHAN, John, M.D. (*Title not received.*)

SUCKLING, C. W., M.D. (*Title not received.*)

TOMORY, J. K., M.B. East African Fever, with special reference to Climatic Conditions.

WARNER, Francis, M.D. 1. Methods of Studying and Examining the Nerve System. 2. Imbecility in Children from Chronic Meningitis.

Sir W. Roberts, Dr. Lauder Brunton, Dr. Russell Reynolds, Dr.

F. W. Pavy have also intimated their intention to take part in the proceedings of the Section.

SECTION B.—SURGERY.
Chemistry Class Room.

B. SURGERY.—*President*, George Buchanan, M.D. *Vice-Presidents*, James Dunlop, M.D.; Charles Robert Bell Kettle, F.R.C.S. *Honorary Secretaries*, David Neilson Knox, M.B., 8, India Street, Glasgow; Walter Pyc, F.R.C.S., 4, Sackville Street, Piccadilly, London, W.

As already announced, in this Section discussions have been arranged for on the following subjects:

1. The Surgical Treatment of Abscess of the Lung and of Empyema. To be introduced and supported by Mr. T. Pridgin Teale (Leeds), Sir Spencer Wells (London), Mr. A. Pearce Gould (London), Mr. R. J. Godlee (London), and Mr. W. Thomas (Birmingham).

2. The Operative Treatment of Club-Foot. To be introduced and supported by Sir William Stokes (Dublin), Mr. E. Lund (Manchester), Dr. Alexander Ogston (Aberdeen), Mr. R. W. Parker (London), Mr. E. M. Little (London), Mr. John Chiene (Edinburgh), Mr. W. J. Walsham (London), and others.

Noble Smith, Esq., will give a demonstration of the Reduction of Fractured Vertebrae.

The following papers have also been promised.

BENTON, Samuel, Esq., London. On the Treatment of Stricture of the Rectum by Electrolysis.

CLARK, Sir Andrew, London. The History of a Case of Catheter Fever.

CLARKE, W. Bruce, Esq., London. (*Title not received.*)

FRYCK, E. Hurry, Esq., London. Notes from the Experience of 450 Cases of Organic Stricture of the Urethra.

FLEMING, W. J., M.D., Glasgow. 1. On Continuous Extension in Spinal Curvature. 2. On the Treatment of Perineal Fistula.

HARRISON, Reginald, Esq., Liverpool. On an Improvement in the Construction of Ships' Berths, relative to the Treatment of some Surgical Injuries and Diseases at Sea (with models).

KETLEY, C. B., Esq., London. Plastic Amputations of the Foot.

MCINTYRE, John, Esq., Glasgow. The Electric Illumination of the Cavities of the Body.

OWEN, Edmund, Esq., London. A Case of Intra-cranial (Subdural) Hemorrhage; Localisation; Trephining; Recovery.

RAKE, Beaven, M.D., Trinidad. The Value of Nerve Stretching in Leprosy, based on One Hundred Cases.

ROTH, Bernard, Esq., London. On Scoliosis, or an Accurate Method of Recording Cases of Lateral Curvature of the Spine.

SILCOCK, A. Quarry, Esq., London. On Excision of Enlarged Bursa in the Popliteal Space.

STOKES, Sir William, Dublin. Modification of Grigg's Amputation; and will show Casts of Stumps.

SECTION C.—OBSTETRIC MEDICINE.
Medical Jurisprudence Class Room.

C. OBSTETRIC MEDICINE.—*President*, Thomas More Madden, M.D. *Vice-Presidents*, William Leishman, M.D.; J. Halliday Croom, M.D. *Honorary Secretaries*, William Walter, M.D., 20, St. John Street, Manchester; W. L. Reid, M.D., 7, Royal Crescent, Glasgow.

The following two special discussions will take place:—

1. On Intra-uterine Death; its Pathology and Preventive Treatment. To be opened by Professor Simpson. The following gentlemen will take part in the discussion:—Drs. R. Barnes, Graily Hewitt, More Madden, W. D. Priestley.

2. On Obstructive Dysmenorrhoea and Sterility. To be opened by Dr. Halliday Croom. The following gentlemen will take part in the discussion:—Drs. Aveling, Bantock, F. Barnes, R. Barnes, Cranny, Duke, Edis, Graily Hewitt, Macan, More Madden, Professor Stephenson, J. W. Taylor, W. Walter.

Dr. Samuel Sloan (Glasgow) will show his Antero-posterior Compression Forceps, and will explain their use in Flat Pelvis.

Wm. Walter, M.D., Manchester, will exhibit his instruments for Securing the Broad Ligaments during Extirpation of the Uterus per Vaginam.

The following papers are promised.

CAMERON, Murdoch, M.D., Glasgow. 1. On Caesarean Section, with Notes of a Successful Case. 2. On the Thermostatic Nurse, with Cases.

DUKE, A., M.D., Dublin. On the Rapid Expansion of the Cervical Canal by a New Method.

HART, D. Berry, M.D., Edinburgh. Successful Case [of Caesarean Section (Porro's modification)].

IMLACH, Francis, M.D., Liverpool. The Function of Anemia in Gynaecology.

MADDEN, More, M.D., Dublin. On the Causes and Treatment of Dyspareunia.

STEPHENSON, William, M.D., Aberdeen. On the Influence of Permanganate of Potass on Menstruation.

TAIT, Lawson, Esq., Birmingham. The Treatment of Uterine Myoma.

SECTION D.—PUBLIC MEDICINE.
Greek Class Room.

D. PUBLIC MEDICINE.—*President*, Henry Duncan Littlejohn,

M.D. *Vice-Presidents*, James Christie, M.D.; D. Page, M.D. *Honorary Secretaries*, Ebenezer Duncan, M.D., 4, Royal Crescent, Crosshill, Glasgow; John C. McVail, M.D., Holmhead, Kilmarnock.

1. Sanitary Legislation. This discussion will be introduced by the Opening Address of the President of the Section.

2. The Communicable Diseases Common to Man and Animals, and their Relationships. Discussion to be opened on the second day of the sectional meetings by George Fleming, LL.D., F.R.C.V.S., Chief of the Veterinary Department of the Army.

3. The Disposal of Sewage (a) in Large Towns; (b) in Small Towns and Country Districts. Discussion will be opened on the third day by Dr. James B. Russell, Medical Officer of Health, Glasgow.

The following papers are promised.

DRYSDALE, Charles R., M.D. 1. On Indigence as a Main Cause of High Death-rates. 2. The Berlin and Parisian Sewage Farms.

HIME, T. W., M.B. Milk Scarlet Fever.

KERR, Norman, M.D. Some Risks of Sanitation.

NASMYTH, T. G., F.R.S. A Report on the Chemical and Biological Conditions of the Air of Coal Mines, together with Mortality Statistics of a Mining District, being a report to the Scientific Grants Committee of the British Medical Association.

SIMPSON, —, M.D., Medical Officer of Health, Calcutta. On Cholera and its Fostering Conditions in the Endemic Area.

SUTHERLAND, J. Francis, M.D. National Sanatoria.

SECTION E.—PSYCHOLOGY.
Hebrew Class Room.

E. PSYCHOLOGY.—*President*, James C. Howden, M.D. *Vice-Presidents*, James Rutherford, M.D.; Julius Mickle, M.D. *Honorary Secretaries*, A. R. Urquhart, M.D., Murray House, Perth; Alex. Newington, M.D., Ticehurst, Sussex.

Dr. J. C. Howden, the President of the Section, will deliver an Address.

Dr. C. M. Campbell will introduce a discussion on the Uniform Recording of *Post-Mortem* Examinations in Asylum Reports.

Drs. A. Yellowlees and A. Campbell Clark will introduce the following subject: The Sexual and Reproductive Functions—Normal and Perverted—in Relation to Insanity. 1. Menstruation: its Commencement, Irregularities, and Cessation; 2. The Sexual Instinct and its Abuse; 3. Pregnancy, Parturition, the Puerperal Period, and Lactation.

Dr. Clouston will initiate a discussion on the Principle of Construction and Arrangement of an Asylum for Private Patients of the Richer Classes.

The following have promised papers: Drs. Savage, Hack Tuke, Fletcher Beach, Charles Mercier, W. J. Mickle, and Turnbull.

SECTION F.—ANATOMY AND PHYSIOLOGY.
Anatomy Class Room.

F. ANATOMY AND PHYSIOLOGY.—*President*, John Cleland, M.D., LL.D., F.R.S. *Vice-Presidents*, R. J. Anderson, M.D.; Henry Edward Clark, F.F.P.S.G. *Honorary Secretaries*, John Barlow, M.D., 27, Elmbank Crescent, Glasgow; Charles Barrett Lockwood, F.R.C.S., 19, Upper Berkeley Street, Portman Square, W.

C. B. Lockwood, F.R.C.S., will introduce a discussion on the Teaching of Anatomy; and will show sections illustrating the Development of the Organs of Circulation and Respiration.

The following papers are promised.

BROOKS, Henry St. John, M.D. On the Morphology of the Epitrochleo-anconus or Anconus Sextus (Gruber).

BROWN, J. Macdonald, M.B., F.R.C.S. The Construction of the Cardiac Ventricles in the Mammalia.

CLELAND, Professor, M.D., F.R.S. On the Nature of Certain Forms of Double Monstrosity.

COLLIER, Mark P. Mayo, M.B., F.R.C.S. On the Mechanism of the Heart and Pulse.

LANE, W. Arthurot, M.B., F.R.O.S. The Influence Produced by Excessive Strain upon Muscles and Ligaments (to be illustrated by specimens).

PATERSON, A. M., M.D. On the Position of the Vertebrate Limb, considered in the Light of its Innervation and Development.

SECTION G.—PATHOLOGY.
Law Class Room.

G. PATHOLOGY.—*President*, Sir William Aitken, M.D., LL.D., F.R.S. *Vice-Presidents*, Alexander Davidson, M.D.; Joseph Coats, M.D.; Charles Roy, M.D., F.R.S. *Honorary Secretaries*, G. Sims Woodhead, M.D., 6, Marehall Crescent, Edinburgh; J. Lindsay Steven, M.D., 34, Berkeley Terrace, Glasgow.

Arrangements are being made to hold a discussion on Cancer originating apart from Epithelial Structures, in which Mr. Lawson Tait (Birmingham), Dr. Joseph Coats, Dr. John Carlyle (Greenock), and others are expected to take part.

The following papers have been promised.

BRUCE, Alex., M.B., F.R.C.P. Edin. On Disseminated Sclerosis.

COATS, Joseph, M.D. On a Case of Lipæmia in Diabetes, with Suggestions as to the Source of the Fat.

KENNEDY, —. On Case of Cystic Kidneys and Liver.

MAPOTHER, E. D., M.D., Dublin. An Anomalous Form of Eczema.

MAYLARD, A. E., M.B., B.S. Lond. The Results of some Bacteriological Cultivation Experiments with Iodoform.

RAKE, Bevan, M.D. Lond. Medical Superintendent of the Trinidad Leper Asylum. The Percentage of Fibrin in the Blood of Lepers.

RUSSELL, William, M.D. The Pathology of Pernicious Anæmia.

The following gentlemen have also intimated their intention of contributing to the business of the Section by reading papers or otherwise: Professor Greenfield, Professor Roy, Professor D. J. Hamilton, Dr. William Hunter, Dr. Barrett (Edinburgh), Dr. McFadyean (Edinburgh), Alex. Edington, M.B. (Edinburgh), etc.

Demonstrations.—Dr. Alexander Bruce (Edinburgh) will give a Magic Lantern Demonstration on Diseases of the Spinal Cord; and Alexander Edington, M.B. (Edinburgh), a Bacteriological Demonstration. Arrangements are also being made for a series of Microscopical Demonstrations illustrative of Tumours, Tuberculosis, etc.

Pathological Section of the Annual Museum.—Intimation has been received of the following exhibits for this Section of the Annual Museum: 1. Calculi removed by Lithotomy, by Professor George Buchanan. 2. Calculi removed by Lithotripsy or by Scoop, by Professor George Buchanan. 3. Miscellaneous Objects removed from the Body, by Professor George Buchanan, namely: Bullets, Needles, Cases of Teeth, Impacted Pessaries, etc., also Isolated Bones of the Tarsus Excised. 4. Rhinoplasty; Wax Cast, by Professor George Buchanan. 5. Bladder and Urethra showing False Passages. 6. Selected Specimens from the Private Collection of Professor W. T. Gairdner. 7. A Series of Specimens of Tumours of the Brain, by Dr. Joseph Coats. 8. A Series of Specimens illustrative of Diseases of the Kidneys, by Dr. David Newman. 9. A Series of Specimens illustrative of Leprosy, by Dr. Beaven Rake (Trinidad). 10. A Series of Large Sections illustrating Malignant Tumours of the Lung; and a Series of Specimens illustrating Deformities of the Liver, by Drs. Woodhead and Bruce. 11. Drawings and Sections to illustrate Diseases of Bone and Joints, by Mr. F. M. Caird (Edinburgh). 12. A Series of Specimens illustrative of Diseases of the Heart, by Dr. John Lindsay Steven.

As space for the Museum is somewhat limited, gentlemen intending to send specimens should intimate their intention without delay to John Lindsay Steven, M.D., 34, Berkeley Terrace, Glasgow, Honorary Secretary of the Section of Pathology of the Annual Museum.

SECTION II.—OPHTHALMOLOGY.

Midwifery Class Room.

H. OPTHALMOLOGY.—*President*, Thomas Reid, M.D. *Vice-Presidents*, J. R. Wolfe, M.D.; C. E. Glascott, M.D. *Honorary Secretaries*, Henry Bendelack Hewetson, M.R.C.S., 11, Hanover Square, Leeds; A. Freeland Fergus, M.B., 41, Elmbank Street, Glasgow.

Mr. Brudenell Carter will open a discussion on the Treatment of Senile Cataract. Drs. Prichard, Meighan, Mason, Teale, and others have promised to take part in the discussion.

The President of the Section intends to give a Demonstration of several Instruments of Use in Ophthalmic Diagnosis.

The following papers are promised.

BICKERTON, T. H., M.D., Liverpool. Sailors and their Eyesight.
MACKAY, George, M.D., Edinburgh. A Contribution to the Study of Hemianopsia of Central Origin, with special reference to Acquired Colour Blindness.
MURPHY, T. S., M.D., Glasgow. On the Treatment of Symbblepharon by Transplantation of Mucous Membrane from the Lip.
REXTON, J. C., M.D., Glasgow. The Value of the Caustery in the Treatment of Ulceration of the Cornea

SECTION I.—OTOLOGY.

Biblical Criticism Class Room.

I. OTOLOGY.—*President*, Thomas Barr, M.D. *Vice-Presidents*, John Astley Bloxam, F.R.C.S.; J. J. K. Duncanson, M.D. *Honorary Secretaries*, Johnstone Macfie, M.D., 23, Ashton Terrace, Glasgow; James Black, F.R.C.S., 16, Wimpole Street, London.

The following special subjects have been proposed for formal discussion:

1. The Conditions calling for Perforation of the Mastoid Portion of the Temporal Bone, and the Best Methods of Operating. Mr. Peter McBride has promised a paper on this subject.

2. The True Value of those Aids to Hearing usually termed "Artificial Tympanic Membranes." Dr. W. L. Purves has promised a paper on this subject.

3. Adenoid Growths in the Naso-Pharynx; their Influence on the Middle Ear, and their Treatment.

The following have promised papers.

BROWNE, Lennox, Esq. (*Title not received.*)
TORRANCE, R., Esq. On Syphilitic Cochlelitis.
WARDEN, Charles, M.D. (*Title not received.*)

SECTION J.—DISEASES OF CHILDREN.

English Literature Class Room.

J. DISEASES OF CHILDREN.—*President*, Walter Butler Cheadle, M.D. *Vice-Presidents*, James Finlayson, M.D.; Henry Ashby, M.D. *Honorary Secretaries*, George S. Middleton, M.D., 23, Sandyford Place, Glasgow; W. Arbuthnot Lane, M.S., F.R.C.S., 14, St. Thomas's Street, S.E.

The following two discussions will take place:

1. Diphtheria: (a) Etiology. (b) Relationship to other Infectious Diseases, and to other Forms of Sore Throat; Occurrence on Open Wounds and on Mucous Membranes other than those of the Throat. (c) Diagnosis. What are the Distinctive Features, especially those Distinguishing the Lesion in the Throat from other Forms of Sore Throat? Does Membranous Croup occur apart from Diphtheria? (d) Pathology and Sequelæ. (e) Medical Treatment. (f) Surgical Treatment; Tracheotomy; Tubage. This will be opened by Dr. A. Jacobi (New York). Messrs. R. W. Parker, E. Owen, H. R. Hutton, and Drs. W. T. Gairdner, James Finlayson, D. Newman, John Macintyre and J. S. Cameron will take part in the discussion.

2. Rickets: (a) Etiology and Prevention. (b) Its Connection with Syphilis and Scurvy. Is Enlargement of the Liver and the Spleen always present, more or less, in Rickets; or only in Cases of Syphilitic Origin? (c) Medical Treatment. (d) Surgical Treatment; at what Stage, and in what Way? Drs. Macewen, Ogston, and Marshall, and Messrs. R. W. Parker, H. R. Hutton, R. Hagyard, L. W. Marshall, E. L. Freer, John Gordon, and W. A. Lane will take part in the discussion.

Drs. Jacobi (New York), Keating (Philadelphia), Ranke (Munich), and Sanné (Paris), and other members of the profession on the Continent have been invited.

SECTION K.—PHARMACOLOGY AND THERAPEUTICS.

Conveyancing Class Room.

K. PHARMACOLOGY AND THERAPEUTICS.—*President*, James Morton, M.D. *Vice-Presidents*, John Dougall, M.D.; Theodore Cash, M.D., F.R.S. *Honorary Secretaries*, Alexander Napier, M.D., 3, Royal Terrace, Crosshill, Glasgow; Sidney Harris Cox Martin, M.D., 60, Gower Street, London, W.C.

A special discussion will be opened by Professor Theodore Cash, M.D., F.R.S., on Carbolic Acid, Antipyrin, Antifebrin, and their Allies, especially as regards their Antipyretic, Analgesic, and Antiseptic Actions. Drs. Walter G. Smith (Dublin), A. D. Macdonald, and Prosser James will take part in the discussion.

Dr. W. Allan Jamieson (Edinburgh) will show two cases of Xeroderma Pigmentosum.

The following have promised papers.

DAVISON, James, M.D. The Pine Treatment.
DOUGALL, J., M.D., Glasgow. (*Title not received.*)
DRYSDALE, C. R., M.D. 1. On the Therapeutic Value of Alcohol. 2. The so-called Abortive Treatment of Syphilis.
PEARSE, T. F., M.D. The Treatment of Eczema.

SECTION L.—LARYNGOLOGY AND RHINOLOGY.

Divinity Class Room.

L. LARYNGOLOGY AND RHINOLOGY.—*President*, Felix Semon, M.D. *Vice-Presidents*, George Hunter Mackenzie, M.D.; Peter McBride, M.D. *Honorary Secretaries*, D. Newman, M.D., 18, Woodside Place, Glasgow; A. E. Garrod, M.D., 9, Chandos Street, Cavendish Square.

The following subjects are proposed for special discussion:

1. The Use and Abuse of Local Treatment in Diseases of the Upper Air Passages. To be opened by Dr. de Havilland Hall (London) and Mr. Stoker (London).

2. The Causes, Effects, and Treatment of Nasal Stenosis. To be opened by Dr. Macintyre (Glasgow) and Mr. Creswell Baber (Brighton).

3. Hæmorrhages from the Pharynx and Larynx, and other Hæmorrhages which simulate these. To be opened by Dr. Percy Kidd (London) and Dr. Hodgkinson (Manchester) (probably).

The following gentlemen hope to take part in the discussions: Dr. Prosser James (London), Dr. McBride (Edinburgh), Dr. Charles Warden (Birmingham), Dr. Cartaz (Paris), and Mr. Richard Ellis (Newcastle-on-Tyne).

The following papers have been promised.

JOHNSTONE, R. Mackenzie, M.D. Account of a Case of Tumour of the Naso-Pharynx.
MCBRIDE, P., M.D., Edinburgh. On Hay-Fever and Allied Conditions.
MACINTYRE, J., M.D. Anatomical Demonstration of the Larynx.

June 16, 1888.]

NEWMAN, D., M.D. Two Cases of Complete Laryngeal Stenosis produced by Wounds of the Larynx in Attempted Suicides.
 WARREN, C., M.D. (Title of paper not yet received.)

ANNUAL MUSEUM.

THE Annual Museum will be held on August 7th, 8th, 9th, and 10th, in the Examination Hall of the University of Glasgow, and will be arranged in the following six Sections:

SECTION A.—Food and Drugs, including Antiseptic Dressings, and other Chemical and Pharmaceutical Preparations. (Honorary Secretary, R. S. Thomson, B.Sc., M.B., C.M., 3, Melrose Street.)

SECTION B.—Pathology, comprising Casts, Models, Diagrams, Microscopical Preparations, and Micro-organisms. (Honorary Secretary, J. Lindsay Steven, M.D., 34, Berkeley Terrace.)

SECTION C.—Anatomy, comprising Special Dissections, Methods of Mounting, Abnormalities, Drawings, Medals, etc. (Honorary Secretary, J. Yule Mackay, M.D., 34, Elmbank Crescent.)

SECTION D.—Physiology, consisting of Apparatus, Microscopes, Microtomes, and Microscopical Preparations of Normal Histology. (Honorary Secretary, J. McGregor Robertson, M.A., M.B., C.M., 400, Great Western Road.)

SECTION E.—Instruments and Books, including Appliances—Medical, Surgical, and Electrical. (Honorary Secretary, J. Macintyre, M.B., C.M., 173, Bath Street.)

SECTION F.—Sanitation (1) Domestic Sanitary Appliances, embracing all Improvements applicable to the Treatment of the Sick in Private Dwellings. (2) Personal Hygiene, including Dress and Gymnastic Appliances. (3) Ambulances, Carriages, and all other Appliances used for the Conveyance and Treatment of the Sick and Wounded, either in Civil, Naval, or Military Practice. (4) Drawings, Models, and Apparatus illustrative of the Ventilation, Lighting, and Draining of Hospitals. (5) Hospital Furniture. (6) Sanitary Appliances in connection with Educational Institutions and Public Buildings. (Honorary Secretary, 1, 2, 3, Robert Pollok, M.B., C.M., Pollokahelds; Honorary Secretary, 4, 5, and 6, A. W. Russell, M.A., M.B., C.M., Western Infirmary.)

Intending exhibitors should communicate as early as possible with the Secretary of the Section in which they propose to exhibit, as the Museum Catalogue must be complete one month before the date of meeting. Inquiries as to advertisements in the Catalogue should be sent without delay to Dr. Thomson, 3, Melrose Street, Glasgow.

Honorary General Secretaries of Museum Committee, A. Ernest Maynard, B.S., M.B., 4, Berkeley Terrace; R. S. Thomson, B.Sc., M.B., C.M., 3, Melrose Terrace.

Honorary Local Treasurers, Joseph Coats, M.D.; Jas. B. Russell, M.D.

Honorary Local Secretaries, John G. McKendrick, M.D., F.R.S., 45, Westbourne Gardens, Glasgow; James Christie, M.D., Hillhead, Glasgow; John Glaister, M.D., 4, Grafton Place, Glasgow.

EXCURSIONS.

THE following eight excursions will take place on Saturday, August 11th.

1. *Lanark and Falls of Clyde.*—The party, limited to 100, will leave the Central Station by special train about 10 A.M., for Tullieculdlem, where, by the kind permission of the Earl of Home, an opportunity will be given to visit the ruins of Craignethan Castle, the scene of Sir Walter Scott's *Old Mortality*; proceeding on foot through the picturesque ravine of the River Nethan for about a mile; the party will then be conveyed by coach through some of the most charming Clydesdale scenery to the Falls, visiting Stonebyres, and then, by the kindness of the proprietor, will enter the Corehouse estate, to see Cora and Bonnington Linns. Returning by coach to Lanark, dinner will be served about 2.30 P.M., in the Clydesdale Hotel. After dinner the party will be shown the library of Dr. William Smellie, the famous obstetrician, which was bequeathed by him to the Grammar School of that town. It is a very interesting collection of books, containing two or three black letter volumes. It is also expected that the Lee talisman, or "Lee Penny," will be shown to the visitors. This charm was taken from the Saracens by Sir Simon Lockhart, of Lee, after a battle, as part ransom of a captive. It was deemed a charm of great medicinal virtue in the end of the last century. It gives the title to *The Talisman*, another of the novels of Sir Walter Scott. Afterwards short excursions may be made on foot to Cartland Craggs, Roman Bridge, Old Abbey, and Smellie's grave. The party will return from Lanark by special train to Glasgow, arriving not later than 8 P.M.

2. *Ayr and the Land of Burns.*—The party, fixed at 100, will leave Glasgow about 9.30 A.M., by special train to Ayr. Thence by conveyance it will proceed, *via* Maybole, to Crossraguel Abbey (one of the finest Gothic remains in Great Britain), thence to Culzean Castle, where it is expected the party will be received by the most Honourable the Marquis of Ailsa, and returning to Ayr by the sea-shore to Burns's Monument, Alloway Kirk, Burns's Cottage, and "Twa Brigs." Dinner will be served at the Station Hotel, after which, by special train, the party will return to town.

3. *The Perthshire Highlands, Lochearnhead and Crieff.*—The party, numbering 100, will leave Buchanan Street Station about 9.15 A.M., in special saloon carriages, for Lochearnhead, and during the journey will see some of the finest Highland scenery; thence by coaches *via* Loch Earn, to St Fillans, where a halt will be made for refreshments, at the Drummend Arms Hotel; then to the Devil's Comrie, where a second halt will take place to visit the Devil's Cauldron, and thence to Crieff, where the party will be entertained to dinner by Dr. Meikle, at his Hydropathic Establishment. After dinner, short walks to places of interest in the neighbourhood may be made, and the party will leave Crieff in the same saloon carriages for Glasgow, where it will arrive about 8 P.M.

4. *Callander and the Trossachs (Loch Katrine).*—The party, 100 in number, will leave the same station as last at the same hour, in special saloon carriages, for Callander, where coaches will be in readiness to convey them to Loch Katrine. Dinner will be served about 2 P.M., in the Trossachs Hotel, after which visitors may enjoy a sail on the loch to the Silver Strand, mentioned by Sir Walter Scott in the *Lady of the Lake*. The party will return by the same route to Glasgow, where it will arrive about the same time as the former excursion.

5. *Arran.*—The party, numbering 100, will leave Bridge Street Station in saloon carriages about 9 A.M., for Wemyss Bay, where, it will join the famous Clyde steamer *Ivanhoe*, which *en route* to Arran calls at Rothesay, and passes through the Kyles of Bute. Dinner will be served on board during the passage. On landing on the island the party will be enabled to visit Brodick Castle, by the kind permission of his Grace the Duke of Hamilton. The party will return to Glasgow by the same route, arriving there about 7.30 P.M.

6. *Stirling, Bridge of Allan, and Dunblane Cathedral.*—The party, limited to 100, will leave Buchanan Street Station about 9.15 A.M. by special train for Stirling. On arrival, visits will be paid to the Castle of historic renown, the Royal Infirmary, High Church, etc., under the conduct of Provost Yellowlees of that town, and Dr. Haldane, of Bridge of Allan, returning to the Smith Institute, where cake and wine will be served. Thence the party will proceed by conveyances to the Wallace Monument, *via* the King's Park, where an unrivalled view is to be obtained, then through the demesne of Airthrey, the seat of the Right Honourable Lord Abercromby, to Bridge of Allan, where dinner will be served in the new Museum Halls. After dinner seats in the conveyances will again be taken, and the party will then drive through the grounds of Keir, the seat of the late Sir W. Stirling-Maxwell of bibliophilic fame, and Kippencross, to Dunblane, where the Cathedral and Library of Archbishop Leighton will be visited. The party will then return by the famous Wharry Glen to the Spa at Bridge of Allan, where tea will be provided for the visitors at the Hydropathic Establishment. The party will leave Bridge of Allan for town, arriving there about 8 P.M.

7. *Rothesay and the Kyles of Bute.*—The party, fixed at 250, will leave Central Station about 9 A.M., by special train for Greenock, where it will join the new steamer *Victoria*, specially chartered for the trip. The steamer will then sail down the Firth of Clyde to Rothesay, and thence will proceed through the Kyles of Bute, up Loch Ridden, and then round the Island of Bute to Kilchattan Bay pier, where those of the party who choose may land to walk to Mount Stuart, the seat of his Grace the Marquis of Bute, visiting on the way the beaver colony, now an almost unique sight. The remainder of the party will return to Rothesay by the steamer, where conveyances will be in readiness to convey them to Mount Stuart; on returning, the party will alight at the Glenburn Hydropathic Establishment, where, by the kindness of Dr. Philp, the proprietor, tea will be served to the party at 5 P.M. Dinner will be served on board the *Victoria en route*. After tea a visit may be paid to Rothesay Castle. The return journey to Glasgow will be made by the same steamer, either to Greenock or

Wemyss Bay (not yet decided), and thence by special train, arriving in town about 8 P.M.

S. Loch Lomond.—The party, numbering 150, will leave the North British Railway Station, Dundas Street, at 10 A.M., by special train for Balloch Pier, where it will be waited for by a special steamer; during its passage to the head of the loch all the places of historic interest will be pointed out. Facilities will be given, by arrangement made before or in the early part of the meeting, for an ascent of Ben Lomond by a small party. On arriving at the head of the loch fifty of the party (to be fixed by ballot or choice) will land, the remainder returning by the same steamer to Tarbet, where dinner will be served about 2.30 P.M. in the hotel. From here parties may visit Loch Long by a very picturesque road. For the party of fifty left at the head of the loch a special dinner will be provided on board the steamer, arriving there about 2 P.M. The return journey will be made by steamer to Balloch, and by special train to town, arriving about 8 P.M. As this is the busiest time of the tourist season, intending visitors to this place should apply early, in order that completely comfortable arrangements may be made.

Short descriptive sketches of the different excursions will be given in the JOURNAL from week to week, in order to enable visitors to determine their choice, and also that early applications may be made during the meeting for tickets.

FRANCIS FOWKE, *General Secretary.*

SPECIAL CORRESPONDENCE.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

Respiratory Hysteria.—Disadvantages of Saccharin.—Dynamic Arseniate of Gold.—Papain in Dyspepsia.—Chemical Vaccine.

THE *Journal de Médecine* of May 6th publishes a paper by M. Henri Huchard on hysteria of the respiratory organs. The author has already remarked how frequently simple laryngitis, angina pectoris, or bronchitis are transformed into aphonia, spasmodic contraction of the cesophagus, or hoarse, sonorous cough; symptoms which antiplogistic treatment entirely fails to combat, but which disappear spontaneously. M. Léon Petit describes a case of pulmonary hysteria which M. Huchard regards as one of hæmoptysis of hysterical origin. The spasms may be localised in the nose, the larynx, the diaphragm, bronchial tubes, etc. M. Huchard quoted cases of spasms of hysterical origin in the respiratory organs, when tracheotomy was resorted to, but without modifying the symptoms. He points out the difficulty and, at the same time, the importance of determining the exact relations between hysteria and the affections of the respiratory organs, without confusion. In the second stage of consumption a sonorous incessant cough will appear quite suddenly, followed by aphonia, hæmoptysis, which usually recurs at the menstrual period, complete and persistent anorexia, and in some cases irrepressible vomiting, which may last for months or even years; the pulmonary lesions, however, are not aggravated; all the pathological activity is monopolised by the hysteria. In other cases tuberculosis predominates, and hysteria plays merely a subordinate part. Brachat affirmed that hysteria favoured the evolution of tuberculosis; other authors have stated that tuberculosis determines the appearance of hysteria. Both these conclusions are erroneous. Without entirely admitting the truth of Leudet's theory that phthisis and hysteria are mutually antagonistic, M. Huchard affirms that in many cases he has observed that the combination of the two affections in the same patient changes the habitual aspect of each of the affections. In tuberculous hysterical patients there is a complete disparity between the relatively mild local condition and the serious character of the functional disturbance. The consequence is that errors in diagnosis may often arise. It is most important to distinguish the effects of hysteria and tuberculosis respectively in the same patient, and to determine exactly which symptoms are due to each affection.

M. Worms read a paper at the Académie de Médecine, in which he stated that he administered saccharin, in varied forms, to four persons suffering from diabetes. One, after a course of two months, still suffered no inconvenience therefrom; but the other three, at the end of a fortnight, complained of loss of appetite, indigestion, and weight in the stomach, which symptoms continued for eight

days after leaving off the saccharin. The doses were resumed in the case of one of the patients, and a return of the symptoms complained of took place at the end of ten days. This proved that it was dangerous to put saccharin into the food of anyone suffering from diabetes; and, moreover, that as it was an indigestible substance, the general employment of it might result in serious consequences to the public health. This fact is at present worth knowing, as it is proposed to substitute saccharin for cane sugar in many ways, such as in sweetening acid wines, and in the manufacture of syrups; its price being half, and its power of sweetening so much greater than, that of sugar.

Dr. Addison has successfully combined gold and arsenic under the name of dynamic arseniate of gold. This preparation possesses the valuable therapeutical properties of both substances. Gold, it is well known, is used in different preparations (gold iodide, auric acid, etc.), with excellent results, in the treatment of diseases of the skin, syphilis, amenorrhœa, etc. Arsenic is successfully employed in hysteria, scrofula, rheumatism, irritable forms of tuberculosis, and in other affections. Its action is strengthening and antiplogistic. It moderates fever, and acts as a sedative. Dr. Addison's dynamic arseniate of gold, which is destined to render great services in the treatment of cutaneous affections, secondary and tertiary syphilis, different forms of cachexia, nervous diseases, etc., is employed in progressive doses, from one to thirty milligrammes. It is highly digestible.

Dr. Pol Vernon highly recommends the use of papain in the treatment of dyspepsia. Papain is nothing but a vegetable pepsine, and, as the late M. Wurtz said, "acts with extraordinary energy and promptitude, and, as a vegetable ferment, dissolves at least one thousand times its weight of humid fibrin, which is at once disintegrated into a semi-liquid pulp, chemically similar to peptone." The action of papain extends, of course, to egg albumen, to gluten, and to all proteid substances, both animal and vegetable. By its influence the food is immediately transformed into a completely elaborated nutritious fluid. It is, therefore, indispensable in cases where over-nutrition is required—diabetes, tuberculosis, consumption, etc. It can be used in very small doses, whereas pepsine must be administered in large quantities. The action of papain extends to all forms of gastro-enteric dyspepsia, which are, according to G. Séé, only defective chemical operations. The illustrious Vauquelin compared it to "blood deprived of its coloured pigment," and called it "vegetable lymph." This substance can be administered as syrup, as an elixir, in wine, and in the form of bonbons.

The *Gazette des Hôpitaux* of May 12th publishes a communication made by M. Peyraud (of Libourne) to the Académie de Médecine, on May 8th, on chemical vaccine or "hydrophobie." M. Peyraud referred to his former researches on tannic acid, its relation to genuine rabies, the preventive measures for both these affections by means of chloral, and inoculation with tannic acid, preceded and followed by antirabic vaccination. The discovery of chemical vaccine has been attested by MM. Charrin, Roux and Chamberland, Widal and Chantemesse, and the chemical vaccine of several virulent affections has been discovered, independently of microbial inoculation, in the isolated poison of those nerve-centres presenting morbid fermentation. M. Peyraud made the following experiment in order to obtain the isomeric of tannic acid, the rabid virus of rabies. The brains of twenty-two mad rabbits were reduced to a pulp, and macerated in alcohol at 90°. After the substance was filtered and exposed to the atmosphere at a temperature not exceeding 50°, M. Peyraud obtained a fluid which had the taste and odour of tannic acid, and which, injected subcutaneously into four small rabbits, immediately determined the biological phenomena characteristic of paralytic rabies. M. Peyraud also made control experiments with the same number of brains of healthy rabbits. None of the above results were obtained.

VIENNA.

[FROM OUR OWN CORRESPONDENT.]

Subcutaneous Injection of "Grey Oil" in Syphilis.—Hemianopsia Superior.

At a recent meeting of the Imperial Royal Society of Physicians of Vienna, Professor Edward Lang read a paper on the subcutaneous injection of mercury in syphilis. He had long endeavoured to discover some form of preparation in which mercury could be used for subcutaneous injections, and had arrived at the following formula: hydrargyri, lanolini, aa three parts; olive oil, four parts.

Such a preparation contained 30 per cent. of mercury. As to the quantity of the oil to be injected, he tried to determine this point by experiments, the result of which showed that even small quantities of mercury had a powerful influence on the disease. In ordinary cases of syphilis the injection of three decigrammes of the oil for one week was sufficient to cause most of the symptoms to disappear, or at least to diminish their severity for a period of from two to three weeks. Professor Lang therefore injected a quantity of from 1 decigramme to 15 centigrammes of the "grey oil" in two places on the back or the buttocks during from five to eight days. These injections were continued from two to three weeks, when a pause of from seventeen to twenty days was made; the injections of similar or smaller quantities of the "grey oil" were then resumed, and so on, until a quantity amounting altogether to from $1\frac{1}{2}$ to 2 grammes was injected. This was the general plan of the treatment in such a case, which had, of course, to be modified according to the particular features of each case. The effect of these injections was easily understood when we estimated the quantity of the mercury injected by comparing it with sublimate. According to the calculations of Professor Ludwig, 39 per cent. of metallic mercury was contained in 1 cubic centimetre of the "grey oil," this being a quantity of mercury which corresponded to 0.52 cubic centimetre of sublimate. As usually one Pravaz-syringeful (equal to 1 cubic centimetre) of the 1 per cent. solution of sublimate was injected, it was evident that 52 syringefuls would have to be injected in order to introduce into the organism as much mercury as was contained in 1 syringeful of the "grey oil." When "grey oil" was properly prepared, and the injection was properly performed with antiseptic precautions, good results would invariably be obtained. Professor Lang prefers frequent injection of small quantities of mercury to large doses at long intervals, as absorption is better insured by such a procedure. When due attention was paid to the treatment, stomatitis and other symptoms of mercurialism were but very seldom observed after injections of the "grey oil." Moreover, the preparation was very well borne by patients. He had in only five cases been obliged to discontinue the treatment with the "grey oil," on account of a special idiosyncrasy with regard to mercury. The advantages of this plan may be summed up as follows: 1. The "grey oil" is a very efficient mercurial preparation, the effect of which is gradual; moreover, it permits of exact dosage, which is not the case with inunction. 2. The method is convenient for the physician and the patient. 3. The injections, when carried out with due care, cause but slight reaction. Neither Professor Lang nor his assistants have noticed any suppuration at the site of injection, though several thousands of injections have been made. 4. The "grey oil" is a mercurial preparation analogous to the mercurial ointment in which metallic mercury is contained in the most efficient form. The "grey oil" should be used in all those cases of syphilis in which general mercurial treatment is required. The best opportunity of testing the effect of an anti-syphilitic remedy is offered by syphilitic affections of the nerve-centres; and in cases of syphilis of the brain and spinal cord, subcutaneous injections of "grey oil" were attended with very satisfactory results. The "grey oil," moreover, had an advantage from another point of view, namely, that, locally applied, it facilitated the absorption of syphilitic products situated near the point of injection, in a similar way to the "grey plaster." Gummatous infiltrations on the forehead, the nose, etc., rapidly disappeared when from 0.01 to 0.05 cubic centimetre of the "grey oil" was injected. The "grey oil" can also be used in cases in which the "grey plaster" and the "grey ointment" cannot be applied. Professor Lang had, on one occasion, to deal with a gummatous cavity of the tibia which was accessible only through a very small orifice. He injected "grey oil" into it by means of a specially constructed instrument, and healing speedily took place. The mercurial oil can also be used for injections into the external auditory meatus, the membrana tympani, and the tympanic cavity through the Eustachian tube. Syphilitic affections of the larynx and the nasal cavities are better treated by a simultaneous intralaryngeal and intra-nasal application of the "grey oil." The same also applies to affections of the eyes.

Professor Nothnagel brought before the same Society a case of hemianopsia superior, which was of great physiological interest—owing to the localisation of the cause of the disease. The patient, a tailor, aged 46, became suddenly blind. His intellectual faculties were impaired. Except a fracture of the left leg, he said he had always been in good health. His sudden blindness had super-

vened two months before he came under notice, and when seen he complained of transient headache on the left side. The eyeballs were normal in appearance, and ophthalmoscopic examination of the fundus oculi revealed no abnormality. The pupils varied in size and reacted, but not energetically. The mobility of the eye was unimpaired. At first sight the patient gave one the impression of a perfectly blind man. He had no perception of light in the upper part of the field of vision, but this was present in the lower one. As the patient was not wholly blind, Professor Nothnagel called the affection superior hemianopsia. The patient could not distinguish colours, nor had he an exact idea of the size of objects shown to him. Professor Nothnagel had found only three cases of superior hemianopsia in literature, one having been reported by Mauthner, and two by Schweigger. No necropsy was performed in any of these cases. As to Mauthner's case, he had admitted the presence of a tumour which compressed the chiasma nerve. Professor Nothnagel, however, believed that in his case there was an affection of the centre of vision in the cerebral cortex—hence in the occipital lobe. He could not imagine that the disease should be localised at the base of the brain, and that the compression of the chiasma should not be attended with any other cerebral symptoms besides those present in the case under consideration. Haemorrhage at the base of the brain had also to be excluded, owing to the absence of coma. The cause of the disease must be localised in the cerebrum itself—a conclusion which was supported by the sudden occurrence of the blindness and the fact that the patient was not in the possession of his normal intellectual faculties. The fact that the disease had come on simultaneously in both hemispheres of the cerebrum could not be looked upon as disproving this hypothesis. Professor Nothnagel remembered a case under his care in which the patient, who was suffering from pulmonary disease, suddenly became blind during the night. The *post-mortem* examination revealed the presence of bilateral softening of the occipital cerebral cortex. Only the superficial parts of the cortex were affected, and the patient had nevertheless suddenly become blind. The simultaneous bilateral softening was due to bilateral thrombosis of the cerebral blood-vessels. There was no sure evidence of the presence of a thrombosis in the case under consideration; but, as the patient was forty-six years of age, it was possible that his arteries had already become atheromatous. The fact that the pupillary reflex was intact could be looked upon as a proof that the lesion was situated in the cortex of the occipital lobe; the thalamus opticus and the corpus quadrigeminum must be considered free from disease. Should the *post-mortem* examination verify the diagnosis, this case might be regarded as an illustration of the experiments of Munk, according to which the retina was quasi-projected on the surface of the occipital lobe.

SWITZERLAND.

[FROM OUR OWN CORRESPONDENT.]

Professor Kocher's Case of Pancreatic Cyst cured by Abdominal Section.

DR. LARDY describes (*Correspondenzblatt für Schweizer Aerzte*, May 1st, 1888, p. 279) a rare case of pancreatic cyst, in which the disease was correctly diagnosed and afterwards treated surgically with the best results by Professor Kocher. A well-built and previously healthy man, aged 37, was suddenly seized with violent abdominal pain (on December 20th, 1886): this ceased spontaneously the next morning, but only to recur on January 17th, 1887. For three hours the pain was as severe as on the first occasion, and then somewhat decreased. About eight or ten days later the man noticed that the upper part of his abdomen was growing larger from day to day, and in a fortnight it had attained the size which it presented before the operation. The abdominal pain increased on walking, and then was accompanied by a sensation of great tension. The stools became somewhat discoloured and flattened, but were otherwise normal. In June a severe attack of vomiting came on; this afterwards recurred with gradually increasing frequency, until latterly it happened almost daily. In October agonising pain in the left hypogastric region supervened, while the patient steadily lost flesh and strength, and he was at last compelled to seek admission to Professor Lichtheim's clinic. An exploratory puncture into the epigastric tumour gave issue to a dark-red, blood-like fluid, which under the microscope proved to contain numerous intact red-blood corpuscles, fairly

numerous large spheres with fatty granules and occasional hæmoglobin scales and cholesterol crystals. The puncture was followed by marked peritonitic symptoms, which lasted eight days. The patient was transferred to Professor Kocher's wards (on December 6th), when an enormous and fairly uniform distension of the abdomen was found; this was due to the presence of a very large, smooth, non-adherent, fluctuating, globular tumour occupying the epigastrium and reaching downwards as far as midway between the umbilicus and the pubes. In front of the mass a curved transverse band was felt, which, on inflating the intestine with air through the rectum, proved to be the transverse colon. Inflation of the stomach (through a stomach tube) showed that that organ was also situated in front of the tumour in the left hypochondrium. Taking all these facts into consideration, Professor Kocher diagnosed a cyst of the pancreas; and on December 30th, 1887, proceeded to make a median incision, 12 centimetres long, midway between the xyphoid cartilage and the umbilicus. The gastro-colic omentum, which was very thick and vascular, having been incised, a smooth, whitish-blue cyst presented itself; it was fixed with sutures to the upper and lower angles of the abdominal wound and emptied with a large Spencer Wells's trocar. The opening was subsequently enlarged and its edges stitched to those of the abdominal wound. About ten litres of dark-red viscid fluid were removed. The inner surface of the sac was fairly smooth, of a whitish-yellowish colour. There was no tendency to bleeding, and the cyst immediately contracted pretty firmly. Its cavity was plugged with iodoform gauze, and a sublimate corrosive dressing was applied. A rapid, uninterrupted recovery took place, the wound healing by second intention without any fever. On examining the patient about two months later, he was found to be stouter; a fairly thick cord could still be felt at the site of the shrunken cyst. According to Dr. Lardy's statement, based on the work of Dr. C. Hagensbach, of Basle, this is the seventeenth case in which a pancreatic cyst has been operated upon. It is, however, only the third in which the disease was correctly diagnosed before operation.

EGYPT.

[FROM OUR OWN CORRESPONDENT.]

Three Cases of Local Massage.—Surgery at Kafr Zayat Dispensary.—Theatricals at Tantah Hospital.—Annual Report by Sanitary Administration.

CASE I.—Female child, aged 7. Admitted six months ago with a burn of third degree, extending round left lower extremity from ankle to knee, with the exception of a strip of skin, one inch broad by four inches long, on the calf. After three months' treatment, the greater part had skinned over, leaving a patch, three inches by two, over fibula and extensor muscles. Transplantation of skin; pressure by strapping; stimulants, irritants, and vesicants, incision of edges, and galvanisation were all used patiently during two months without effect. Daily massage of the whole limb, and especially of the cicatrix and deep tissues, produced complete healing within three weeks. **CASE II.**—Boy, aged 11. Fibrous ankylosis of knee, after six months' treatment by splint for abscess of thigh. The adhesions were broken down under chloroform, and complete mobility restored; but imperfect power of movement remained, owing to atrophy of extensor muscles, and gradual contraction of the flexors from want of opposition. Galvanisation of the extensors for one month was followed by very slight improvement; massage of the whole limb was then added, and at the end of another month the patient had almost entirely regained power over the limb. The treatment is still being continued. **CASE III.**—Girl, aged 5. Turkish origin. Extensive scrofulous ulceration of arms and legs. During two months she was treated by anti-scrofulous drugs and applications with very little benefit; massage was then added, and within three weeks nearly the whole of the lesions had healed up.

The newly instituted dispensaries are beginning to bear fruit. At Kafr Zayat—an important town in Lower Egypt—the medical officer, who is an excellent surgeon, reports a rather remarkable case. It seems that a Greek, while using a sharp knife, completely detached a joint and a half of the index finger of his left hand. The severed portion fell to the ground, but he immediately picked it up and applied it as well as he could to the stump, and, holding it in this position, proceeded to the dispensary, which was distant a two hours' journey. As soon as he arrived, the medical man at once washed the parts with carbolic acid lotion and liquor

Van Swieten; sewed the several portions on accurately; and applied an iodoform dressing. In ten days the wound was healed, but the joint has so far remained ankylosed. The patient was 25 years old, and in perfect health at the time.

At Tantah, which is the third town in Egypt and has a Government hospital of 70 beds, there has lately been quite a new departure. In order to acquire funds for the benefit of the sick, the medical staff organised a theatrical representation, which resulted in a clear benefit of no less than £80. The greatest credit is due to Dr. Selim Fahung, who managed the whole affair; and it would be well if his example were followed by other hospitals in Egypt, for there are many little luxuries, inestimable to the sick, which cannot well be provided by the administration.

The Sanitary Department is about to produce an annual report—the first of its kind on record. This report will necessarily be crude and imperfect; but it is, nevertheless, a beginning, and therefore worthy of commendation. It is to be hoped that the defects therein portrayed may not react injuriously on the compiler.

MANCHESTER.

[FROM OUR OWN CORRESPONDENT.]

Conference on Mortality in Manchester.—Small-pox in Preston.—Conversation in Owens College.—Candidates for Vacant Chair of Surgery.

A CONFERENCE, called together by the Manchester and Salford Sanitary Association, was held on June 8th to consider the excessive mortality in Manchester. The Chairman, Dr. Ransome, stated that the death-rate was 50 per cent. greater than that of the kingdom at large. In the last two years it had reached 60 and 70 per cent. respectively. A series of resolutions were passed, including recommendations to avoid the pollution of the air and water-courses, avoidance of intra-mural interments, that the number of nuisance inspectors be increased, there being at present only fourteen for a population of 385,000. Much has been done by the corporation within the last few years to improve the material surroundings of the poor in this city, but it is obvious that much remains to be done, and we trust that the efforts of the Sanitary Association will suffice to press home the unpleasant facts to the corporation and ratepayers, and that preventive measures to reduce the mortality will soon be vigorously carried out.

Within the last few days there has been an extraordinary outbreak of small-pox in Preston. The number of patients up to June 4th was about 200, and new cases are reported every morning. On June 8th, a young man, suffering from the disease, was found in a delirious state in the streets. The epidemic has spread to an out-district, and a case is reported from Warrington. Several deaths are reported.

On June 8th a *conversazione* was given in Owens College, on the occasion of the opening of the new Museum buildings. There were present between three and four thousand persons; in spite of the number, the rooms were so spacious and the arrangements so complete, that there was no crowding. There were numerous exhibits of scientific and popular interest in the various laboratories.

Saturday, June 9th, was the last day for receiving the applications for the vacant Professorship of Surgery. The local candidates are Mr. Southam, Assistant Lecturer on Surgery in Owens College; Mr. Thomas Jones, Lecturer on Practical Surgery in Owens College; Mr. Wright and Mr. Hardie. All four surgeons are on the staff of the Royal Infirmary. The only other candidate is Mr. Arthur W. Hare, who is Assistant to the Professor of Surgery (Mr. Chiene) and Senior Demonstrator of Surgery in Edinburgh University. It is too soon to forecast the probable chances of the several candidates.

INCREASE OF LUNACY.—At a recent meeting of the Committee of the Woodilee Asylum some startling statements were made as to the rapid increase in the number of lunatics in the asylum. The asylum was opened in 1875, with a licence to accommodate 400 patients, and there were at that time only 248 patients chargeable to the parish. There were at the present moment 551 patients in the asylum, and 92 boarded out, or a total of 643. It was remitted to the acting inspector and medical superintendent to inquire into the apparent cause of the increase, and to report to the Committee, together with any recommendation for their guidance.

CORRESPONDENCE.

THE TREATMENT OF AURAL EXOSTOSES.

SIR,—Sir William Dalby misses my point—when and where did he first operate with the drill? He observes, in the JOURNAL for June 9th, that in his paper at the Royal Medical and Chirurgical Society “references were made to the account published in 1876 of my operation in 1874, also to his (Mr. Field’s) first operation in 1877.” But Sir W. Dalby’s operation mentioned in 1876 as performed in 1874 was by means of the continuous current of electricity passed for two minutes by two needles inserted at the base of the exostosis.¹ It is quite true that in 1876 Sir William Dalby suggested in a vague manner² (but with what success we are not informed) that since 1874 he had employed the dental engine for aural exostosis; but, as I have before now pointed out, he had not then favoured the medical world with details of a single instance of the operation as performed by him. As in our correspondence in June, 1885, he failed to prove a similar assertion, it is somewhat surprising to find that he now reiterates it.

I am willing to furnish my authorities for the following facts to your columns if Sir William Dalby so desires:

1. In April, 1881, Sir William Dalby came, at his own request, to one of my operations for exostosis, and, being asked by a colleague of mine whether he had performed an operation in the same way, replied “Never.”

2. A gentleman, upon whom I operated this year, told me recently in the presence of his medical attendant, that Sir W. Dalby, when consulted by him about six years ago, observed, as regards the drilling of aural exostoses, “I have only done one of these operations.”

I might say more under this head, but will merely add that Sir William Dalby would do well, if unable to call to mind precise particulars of such cases as he claims to have treated since 1874, to refresh his memory by reference to any gentlemen who were present at his operations. Some account of the first of these would not be devoid of historic interest; but until he gives some data in support of his asserted priority in the use of drilling for aural exostoses, he can scarcely blame me or others for deeming that he has made “a sinner of his memory.”

Doubtless, the idea of drilling for exostoses occurred previous to 1874 to many; I have always myself given the credit of its initiation to Dr. Mathewson, of Boston, who, unlike Sir William Dalby, has given us the benefit of his experience in an actual case of operation. It was not until I had detailed my third series of cases, so late as 1885, that Sir William Dalby assumed the rôle of a pioneer.—I am, etc.,

GEORGE P. FIELD.

P.S.—I forward a letter from Dr. Mackesy:—

“June 2nd, 47, Lady Lane, Waterford.

“Dear Field,—In the BRITISH MEDICAL JOURNAL of May 26th, I see that Sir W. Dalby claims to have introduced the American dental drill for removal of aural exostosis so far back as 1874. Now, in justice to yourself, I think it right to say that I have always been, and still am of opinion, that I was myself the first case in which the American dental drill was used in Great Britain for removal of double aural exostosis. You may remember you operated upon me in the autumn of 1877, and I am thankful to

¹ “The removal of exostoses in the external auditory canal is beset with difficulties. The very position of the growth makes it necessary that all work must be done under light reflected from a mirror worn on the forehead of the operator. Again, the size of the canal not only limits the movements of instruments, but also their use to but few, and any bleeding checks all proceedings until such bleeding can be stopped. Moreover, the intense hardness of the exostosis does not facilitate matters. There are two modes of operating which are deserving of especial mention. The first was originally suggested and successfully practised by Dr. Thos. E. Clarke, of Bristol, in 1873, in a case of a large exostosis which almost filled the meatus. Three needles were introduced into the growth, two at the base, and one at the anterior edge. Through these needles a continuous current of electricity from six pairs of plates of a Stöhrer’s battery was passed for three minutes. Fourteen days afterwards this was repeated, and three weeks later the growth was so loose as to be easily extracted, and the patient made a very good recovery. Since Dr. Clarke’s case was published, in adopting similar measures owing to the extreme hardness of the bone, I have found it convenient to drill holes into the base of the tumour to permit of the introduction of the needles; and I can testify to the success which attends this plan of removing bony growths.”—*Lancet*, January 22nd, 1876.

² “The removal of exostoses in the external auditory canal is not sufficiently common to supply a very large experience, but I must confess to have kept on the safe side since this case” (the case in November, 1874, just alluded to in the earlier part of the article from which this is taken), “and to have employed another method, which is entirely free from the slightest risk of any like catastrophe. It consists in grinding the bone away, and the most satisfactory appliance for this purpose I find to be the drill which is in common use among dentists.”—*Lancet*, January 22nd, 1876.

say with most satisfactory result, as I was very deaf, but my hearing is now excellent. Except Sir W. Dalby can show some very conclusive proof to the contrary, I refuse to be convinced, and shall continue to claim for myself the notoriety of being the first case so operated upon in Great Britain by dental drill. I have no recollection of having seen any case published prior to that date. You may publish this if you think well of doing so. I am glad to be able to add that Mr. Goff, and also my brother, upon whom you also operated for double exostosis, continue quite well.

“GEO. I. MACKESY.

—Faithfully yours,
“P.S.—You may recollect that Sir W. B. Dalby kindly saw me in consultation with yourself, and, to the best of my belief, he did not at that time make any mention of having treated any case of aural exostosis by the drill.”

ECTOPIC GESTATION.

SIR,—To substantiate the remark that Dr. Aveling proposed electricity “for the arrest of hæmorrhage in cases of ruptured tubal pregnancy” would require me to reproduce a long discussion which took place recently at the Gynecological Society, and a still longer paper of Dr. Aveling’s interpolated in that discussion. The debate took place on a paper of my own on a series of cases of “Ruptured Tubal Pregnancy,” in which the whole and sole issue was the necessity of acting on the surgical rule of “tying the bleeding point.” Dr. Aveling interposed with a long argument that electricity should be used, and he again brought back his solitary chicken from the Brighton meeting. But that reiterated case has nothing to do with the issue, for it was clearly a broad ligament pregnancy, and ought to have been allowed to go to term and been delivered alive, as these broad ligament cases easily can be.

That only accomplished electricians should meddle with this most dangerous business was well illustrated in my presence not long ago, when two practitioners warmly disputed whether a galvanometric reading was genuine or approximate, but the difference was nearly 300 milliampères. So much for accuracy of dosages. Finally, we want no more whimsical theories; we want the authentic facts.

I have just read the interesting account of Dr. Herman’s case, and have to say that it possesses in my mind a much larger interest concerning a point where it is only the second case of the kind I have known, than in all the points which seem to have attracted Dr. Herman’s attention.

I have published in your columns, and in the *Transactions of the Gynecological Society*, thirty-five cases of the kind, but I could not occupy space in giving all the details of every one of those cases, and I contented myself with recording such matters only as seemed to me of the most pressing interest. I did not think it in the least degree necessary to say how many days or hours elapsed between the period of first rupture and the operation, but in very many of them only a short time elapsed. I think it very likely that some of them had a period as short as in Dr. Herman’s case.

The great interest of Dr. Herman’s case seems to me that the operation was performed for the secondary, and not for the primary, rupture—that is to say, that the real rupture of the tube took place about December 20th, and that that rupture was into the cavity of the broad ligament, and that it was a secondary rupture of the broad ligament cyst into the peritoneal cavity for which Dr. Herman performed his operation on February 10th. The history of the case makes this sufficiently clear, and the fact that the pregnancy seems to have gone on to the fourth month makes it almost certain, for in all the cases which I have examined in the shape of museum specimens and *post-mortem* examinations where death took place from the rupture, and where, therefore, it was made perfectly certain that the rupture was a primary one and not secondary, the rupture had taken place not later than thirteen weeks. To this there is no exception whatever. If Dr. Herman will turn to Nonat’s case in Bernutz and Goupil’s book (p. 239, vol. i), to which full reference is given in my Ingleby lecture of 1886 on this subject, he will see clearly enough what I mean. The point is one of intense interest, for the full account of which I could not ask space in your columns; but it will be, I think, made abundantly clear in a work on the subject which is now going through the press.

I agree also with Dr. Herman that it is almost certain that his patient in 1885 was the subject of a tubal rupture; and it is quite clear from the story he gives that the rupture also took place into the cavity of the broad ligament, making an extra-peritoneal

hamatocele, that in the act of rupture the ovum was destroyed, this being a not uncommon termination of such cases. When the ovum is not destroyed the pregnancy may go on to full time, and may be (as I think, most improperly) killed by an electric shock, as in the case cited by Dr. Aveing; but such cases belong to an altogether different category from those in which intra-peritoneal hamatoceles are formed either by primary or secondary rupture.—I am, etc.,

LAWSON TAIT.

Birmingham, June 2nd.

THE ELECTRICAL TREATMENT OF FIBROIDS.

SIR.—Much has been written and said about the electrical treatment of fibroids. Surely this new treatment should be given a fair chance, and those who do not believe in it might wait a little while before condemning it in its infancy. Would it not be better for those unbelievers to follow exactly the rules laid down by Dr. Apostoli, instead of fighting over theories and new methods? Everyone seems to be trying to improve on Apostoli's treatment, instead of following his directions. To my mind, this is the chief cause of failure. I would even go further, and divide those who condemn this treatment into three classes—namely: 1, those who have had no experience whatever; 2, those who have failed from want of patience; 3, those who have neglected Apostoli's rules.

When I hear of failure of Apostoli's treatment, I am inclined to think that it has been imperfectly carried out; certainly this was the fact in some of my own early cases, and, after months of disappointment in my results, I found out that if I wished to succeed, something more than a knowledge of gynaecology was necessary. I mention this to show that I for one do not consider this electrical treatment so simple as some of your correspondents would have us believe.

Before this treatment can be given the position claimed for it by Dr. Apostoli and others, corroborative clinical experience, extending over several years, is absolutely necessary; and until we have this clinical experience, the profession ought, at least, to suspend judgment.—I am, etc.,

35, Brook Street, W.

A. C. BUTLER-SMYTHE.

ON HYDROPHOBIA AND ITS TREATMENT.

SIR.—In an article under the above heading in the last issue of the JOURNAL (June 9th), Mr. Victor Horsley says: "For there is no single case of reputed cure of developed hydrophobia by drugs or other means that will bear close investigation." Is this correct?

If this statement is meant to apply only to cases treated by narcotic or supposed specific drugs or by the hot-air bath, I dare say it is perfectly true; but if it is meant to include those which have been treated by a different method (though there is no reference to it in the article above referred to), far more potent as a sedative, and far more likely to avail, I doubt whether it is so.

I refer to the employment of copious blood-letting, relying chiefly on the authority of Benjamin Rush and Clutterbuck: the former especially being an opinion of great weight, as a bold and judicious physician of wide experience, probably second only to Sydenham among modern physicians. Each of these, in writing upon the subject, mentions several cases (about a dozen altogether) successfully treated after this fashion, not however within their own observation, but quoted from reports published in well-known medical or scientific periodicals in the latter part of the last or beginning of the present centuries. If these reported cases were genuine instances of hydrophobia—and it seems scarcely possible that the diagnosis should have been erroneous in every one—then it has been proved incontestably that bleeding to a large amount has actually saved some patients suffering from the disease. I have not been able as yet to get access to the original reports of these cases to verify the quotations and read the histories in full, except an abstract of one (that of Hartley in the *Philosophical Transactions*, which seems to have been genuine, though the symptoms were comparatively mild, perhaps cut short), and I should be glad to know whether or not there is any fallacy in the accounts; for if, as it appears, even these few cases have been saved in this way, it will be only right and proper to resort to it again whenever the occasion presents, until a surer and milder remedy is devised.

The procedure seems severe—it is necessary generally to withdraw about 120 ounces of blood before the disease is overcome, and of course in a short period of time—but desperate diseases

justify heroic remedies, and this loss is not very serious when inevitable death is the alternative.

Rush also states that two rabid dogs have been cured by free bleeding, by cutting off parts of the tail or ears. In the *Philosophical Transactions* also there is an account of an outbreak of rabies in a pack of hounds, where several dogs that were attacked were cured by mercurial salivation.

In the human subject, certain auxiliary measures were usually employed in addition to the repeated bleedings, principally cold bathing and mercury. Opium was sometimes found to do harm. Hydrophobia presents some resemblance to puerperal convulsions, and who that has tried venesection will dispute the sure and immediate efficacy of the remedy in this complaint, far better than any mortal drug? I believe that most cases of puerperal convulsions yield to comparatively moderate bleedings, say 20 to 30 ounces at the outside; but if not, it is perfectly legitimate to follow the excellent guidance of Gooch, who urges the repetition of bleeding up to a total of 70 or 80 ounces if necessary; and it is not such a very long step up to the 100, 120 ounces or more that will probably be needed in hydrophobia.

At any rate, if this method offers a fair chance of success, I think it preferable to depend on it rather than undergo M. Pasteur's system and run the risk of being inoculated fatally with the disease by the antidote.

Before putting the method of copious venesection into practice, it would be as well (as it is almost a lost art now) to read Rush's arguments on the subject (*Inquiries*, vol. ii) and to bear in mind his recommendations and cautions, for unless the plan be thoroughly and efficiently carried out, it may fail—really from misapplication. Unfortunately Rush's works are scarce, and not in easy reach of everyone. It is a pity that the New Sydenham Society does not republish an edition of a classic of such value.—I am, etc.,

F. LUCAS BENHAM, M.D.

Elizabeth Street, S.W.

ALBUMINOUS FOOD IN OBESITY.

SIR.—A high authority in the medical profession has recently raised an objection against the use of Professor Oertel's method of treating obesity, on the ground that an excessive consumption of albuminous food is apt to give rise to a uræmic condition. This implies that an excessive use of albumen is recommended by Oertel, which is not the case. It is not easy to see how this error can have arisen, for Oertel's quantities are repeatedly set forth with elaborate distinctness in his work (*Therapeutics of Circulatory Derangements*). We there find, in the "Special Diet in Obesity and Circulatory Derangements," that 156.7 and 170 grammes are allowed as the minimum and maximum quantities respectively of albumen from all sources. These amounts are 5.5 and 6 ounces av. respectively. According to Moleschott, the average amount of dry nitrogenous food per diem, suitable for a male European doing moderate work, is 4.5 ounces; and Letheby's estimate is the same. Oertel expressly states that the larger amount (6 ounces) "can only be given when, owing to strenuous muscular activity, as in mountaining-climbing, there is increased destruction of non-nitrogenous material within the body, and increased need for food." In the above calculations, the total amount of albumen is considered. If we regard the flesh meat alone, we find that Oertel recommends only 350 grammes (12.3 ounces) daily. Three-quarters of a pound of lean flesh meat can scarcely be called an excessive amount likely to set up a uræmic condition in a man who is made to work. In a few of Oertel's cases rather more than the above-stated amount was prescribed, but this never exceeded 450 grammes (nearly 1 lb.). It is a pity that a system of treating obesity which has received such recognition of various authorities on the Continent should in this country be dismissed to oblivion by a few vague words about the dangers of an excessive supply of albuminous food, when Oertel himself has indicated the suitable quantities in the most precise manner; and these quantities, as we have seen, are by no means excessive.—I am, etc.,

Acacia Road, N.W.

EDWARD J. EDWARDES, M.D.

THE CONTAGIOUS DISEASES ACTS IN INDIA.

SIR.—All honour to Sir W. Foster for his clear definition of the true position which these Contagious Diseases Acts now hold in the opinion of the medical profession, and it is well for the British Medical Association that one holding with such merit such a high and important position in what is probably the largest Medical Association in the world speaks with no uncertain sound on one of the burning questions of the day.

Military officers holding the highest positions in the army in India have had their fair fame temporarily stained and their high character for morality spoken lightly of by their being, unknown to themselves, the official channels for the immoral sewage of the Sanitary Department in India. I have known that Department for twenty years, and withdrew from it and resigned the service as I felt I could not serve in it as an honest man; and if the language of some medical officers is to be taken as a sample of its requirements under the Contagious Diseases Acts, and the duties of medical officers, as lately hinted at if not laid down by the Sanitary Commissioner of the North West Provinces and Oudh, as what may be expected of the medical officers under its orders, it seems now to be one unfit for a modest, as it was for an honest, man.

The whole case of these Contagious Diseases Acts it is clear rests now with the medical profession; and if Reuter's telegram from Simla of June 7th, published in the papers of June 8th, is to be accepted, then "the members of the Indian medical profession" (which I presume means Service) "have resolved to memorialise Parliament against the repeal of the Acts." Judged by the verdict given by Parliament on June 5th, I think they will find, if possible, a stronger opposition when the true source of that circular is known, and a sturdy opponent in Sir W. Foster. For myself, as one who in 1864 was in the Sanitary Department before the passing of these Acts, I will undertake on any professional platform to support the entire repeal of the Acts on purely medical grounds, as I utterly fail to see how an instance of such transparent Jesuitism can be supported on moral grounds, when good, either physical or moral, is expected to result, not only from doing, but actually encouraging, what, under the circumstances, is physically injurious and under every condition morally wrong.

The British Medical Association is peculiarly fitted to take the matter up, and I am ready to prepare, read, and defend a paper at the meeting in Glasgow in August on the subject of the total repeal of the Contagious Diseases Acts in India on physical grounds and for medical reasons.—I am, etc.,

ROBERT PRINGLE, M.D., Surgeon-Major,
late Sanitary Department, Her Majesty's Bengal Army.
Blackheath, S.E., June 8th.

METHYLENE AS AN ANÆSTHETIC.

SIR.—Believing as I do that methylene is the nicest anæsthetic we possess, I am very glad to see the remarks of Sir Spencer Wells in the JOURNAL of June 9th. Whatever chemists may tell us of the results of their analysis of its composition, I am perfectly sure that, in giving it, we are not giving chloroform. Its effect upon the patient is quite different. The rapidity with which consciousness returns contrasts strongly with the prolonged stupor produced by chloroform, and is a great element of safety.

My experience of Junker's apparatus is limited. Having to give methylene here for Sir Spencer Wells, some years ago, to a lady on whom he performed ovariectomy, I used the Junker apparatus, which he brought down with him, and found it answer admirably. On trying the same form of apparatus shortly after, however, on a strong man, I found it so difficult to get him under the influence of the anæsthetic that I had to resort to the common perforated ether inhaler, which I usually use, and which, if properly managed, is, I think, all that can be desired. The great thing is, after inducing thorough anæsthesia for the first and most painful part of the operation, to give repeated doses of quite a small quantity, say ten or fifteen drops, and thus to just keep the patient insensible to pain and nothing more. In this way, anæsthesia may be kept up during the longest operation by an agent which is safer than chloroform and pleasanter than ether.—I am, etc.,
E. FIELD, M.D.
Bath, June 9th.

INCAUTIOUS PUBLICATION OF A CASE.—The proprietor of a private asylum for lunatics at Besançon was recently condemned on appeal to 500 francs fine and 2,000 francs damages for having published the clinical history of a patient who had been placed in his charge, he having described the patient under the initial letters of her name and in such a way that the identity of the subject of the report was easy to ascertain. The judges ruled that a medical man has no right to divulge matter confided to him in the exercise of his professional duties in such a manner as to permit the public to ascertain the identity of the individual whose case is described.

NAVAL AND MILITARY MEDICAL SERVICES.

CHANGES OF STATION.

The following changes of station among the officers of the Medical Staff of the Army have been officially notified as having taken place during the past month:—

	From	To
Surgeon-General W. S. Murray, M.B. ...	Egypt ...	Portsmouth.
Dep.-Surg.-Gen. J. A. Marston, C.B., M.D. ...	Headquarters ...	Woolwich.
Brigade-Surgeon H. F. Paterson, M.D. ...	Dublin ...	Colchester.
" A. B. R. Myers ...	Scots Guards ...	Brig. Foot Gds.
Surgeon-Major C. F. Churchill, M.B. ...	Colchester ...	Bengal.
" M. D. O'Connell, M.D. ...	Bengal ...	Dublin.
" J. Latham, M.B. ...	Aldershot ...	Nova Scotia.
" C. B. Dwyer ...	Athlone ...	Hong Kong.
" J. C. Dorman, M.B. ...	Bengal ...	Dublin.
" A. H. Stokes, M.B. ...	Ceylon ...	Devonport.
" E. H. Fenn ...	Grenadier Guards... ..	Coldstream Gds.

" J. Girvin ...	Colchester ...	Home District.

ARMY MEDICAL DEFENCE FUND.

SIR.—In the JOURNAL of June 9th "Medical Staff" has written to you regarding the grievances of the Army Medical Department, and thus concludes his letter: "It only remains for Surgeon-General Irving to lay the details of his scheme before the medical officers of the army through the columns of the JOURNAL, calling for the names of those willing to subscribe, and the necessary financial support will be at once secured him." To this I reply that in my letter to you published in the JOURNAL of May 5th, all that I intended was to make a suggestion as to the means of redressing grievances in the Army Medical Department which had had a good effect when carried out in reference to the Indian Service. From the letter of "Medical Staff," and from others which I have received, however, it seems to be taken for granted that I am anxious to enter into the controversy. But this is not the case, as I should be quite out of place if I did. The cause of the officers of the Army Medical Department must be taken up by retired officers of their own service, of whom no doubt there are many in London able and willing to fight for their brethren whose mouths are closed. If anything is to come of it, men in the service must at once get retired officers to form a Committee, and this Committee should engage a paid secretary and hire a room for an office in town. An appeal should then be made to members on the active list for a small subscription towards the carrying out the objects of the Committee. All this was done in the case of the Indian Medical Department, and should be as easy of accomplishment in the case of the Army Medical Department if the members of the latter service really wish it. But writing is of little use until some action is taken so as to secure the names of men to serve on the Committee. The secretary need not necessarily be a medical man. What is wanted is a good man of business who will receive his instructions from the Committee, and carry them out.

No doubt it is true, as "Medical Staff" says, that officers on the active list cannot appear as initiators of the movement, but they can induce those on the retired list to take up the matter, and through the latter bring forward all that it is desired to have redressed. Except this be done it is hardly likely that retired officers will take the initiative or act unless they perceive that those

defect was one of the objects of the Bill. Complaints had been made of the lax enforcement of the law by the Pharmaceutical Society, which had not money to carry on prosecutions. It had been suggested that some of those who had taken advantage of the lax state of things should be allowed to continue their trade if they passed a modified examination, and should have their names inscribed on the register. A similar provision was made for the protection of assistants. There were also provisions for removing uncertainty as to the proprietorship of establishments where the sale of poisons was carried on, and requiring that they should in all cases be under the personal management of qualified persons.—Earl CADOGAN said that the subject of the Bill was not only one of great importance, but also one of great complexity. It was extremely difficult to unravel the various differences which had arisen between the several bodies who produced poisons in Ireland. The Government of Ireland were anxious that the Bill should not pass without further examination, but they had no prejudice against it. They were determined to ask the House to read the Bill a second time on the understanding that it should be referred to a Select Committee. To that course his noble friend had assented, and he now begged to recommend their lordships to adopt it. The Bill was read a second time, and was then referred to a Select Committee.

HOUSE OF COMMONS.—Tuesday, June 5th.

English Doctors in Switzerland.—Dr. FARQUHARSON asked the Under Secretary of State for Foreign Affairs whether he was aware that certain legally qualified English medical practitioners had lately been fined and threatened with imprisonment by some of the authorities for practising among invalids visiting Swiss health resorts; and whether, in the interests of such invalids and of members of the English medical profession, he would make representations to the Swiss Government on the subject.—Sir J. FRIGGUSON replied that the statement in the first paragraph was true. The laws of Switzerland did not permit foreign doctors to practise there without the Federal authorisation. Her Majesty's Government had for some time been endeavouring to arrange with the Swiss Government reciprocal privileges for the medical profession in either country, but as yet without success.

Monday, June 11th.

The Royal College of Surgeons.—Sir G. HUNTER asked the Vice-President of the Committee of Council on Education when a reply to the deputation of the Association of Members of the Royal College of Surgeons, received by the Lord President of the Council on November 11th, 1887, might be looked for.—Sir W. HART DYKE said, since the Lord President received the deputation of November 11th, he had fully considered the statement submitted by them. All petitions and statements on the subject were referred to a Committee of the Privy Council; and, as no legal questions were involved, it did not appear necessary to hear counsel. In consequence of the circumstances brought forward, the supplemental charter, as submitted by the College, had been considerably modified.

PUBLIC HEALTH

AND

POOR-LAW MEDICAL SERVICES.

DISEASES OF THE RESPIRATORY ORGANS AT MIDDLESBROUGH.

THE number of deaths from pneumonia in Middlesbrough continues to be very large. In the first eleven days of this month thirty-two deaths are stated to have been registered as due to pneumonia; of these twenty occurred in the week ending June 9th. The Local Government Board has directed an inquiry to be made which will be conducted by Dr. Ballard, one of the Medical Inspectors of the Board, who has already caused inquiry forms to be issued by the Local Sanitary Authority to medical practitioners in the town asking for information with regard to all cases of pneumonia which have occurred since November.

DIPHThERIA ON SHOOTER'S HILL.

FROM some correspondence which is taking place in the *Kentish Independent* we regret to learn that there is at present, and by no means for the first time, an epidemic of diphtheria on Shooter's

Hill. Indeed, Captain Vivian, the author of a sensible letter on the subject, speaks of an "annual epidemic," and states that he has refused to pay any local rates "until an efficient inquiry is instituted into the general question of the drainage of this district."

HEALTH OF ENGLISH TOWNS.—During the week ending Saturday, June 9th, 5,506 births and 2,915 deaths were registered in the twenty-eight large English towns, including London, which have an estimated population of 9,398,273 persons. The annual rate of mortality per 1,000 persons living in these towns, which had declined from 18.9 to 17.6 in the three preceding weeks, further fell to 16.2 during the week under notice, a lower rate than in any week since September last. The rates in the several towns ranged from 12.5 in Birkenhead, 12.8 in Newcastle-upon-Tyne, 12.9 in Nottingham, and 13.6 in Derby to 22.3 in Huddersfield and in Norwich, 22.4 in Blackburn and 25.0 in Manchester. The mean death-rate in the twenty-seven provincial towns was 17.3 per 1,000, and exceeded by 2.4 the rate recorded in London, which was only 14.9 per 1,000. The 2,915 deaths registered during the week under notice in the twenty-eight towns included 265 which were referred to the principal zymotic diseases, against 330, 285, and 282 in the three preceding weeks; of these, 81 resulted from whooping-cough, 42 from diarrhoea, 40 from measles, 36 from scarlet fever, 31 from diphtheria, 24 from "fever" (principally enteric), and 11 from small-pox. These 265 deaths were equal to an annual rate of 1.5 per 1,000; in London the zymotic death-rate was 1.6, while it averaged 1.4 per 1,000 in the twenty-seven provincial towns, and ranged from 0.0 in Portsmouth, Norwich, Birkenhead, Halifax, and Sunderland to 2.9 in Huddersfield and in Cardiff, and 3.0 in Preston. Whooping-cough caused the highest proportional fatality in Wolverhampton, Bolton, Manchester, and Huddersfield; and scarlet fever in Cardiff. The 31 deaths from diphtheria in the twenty-eight towns included 22 in London, 2 in Liverpool, and 2 in Birmingham. Of the 11 fatal cases of small-pox recorded during the week under notice, 6 occurred in Sheffield, 4 in Preston, and 1 in Bristol. No small-pox patients were under treatment in the Metropolitan Asylums Hospitals on Saturday, June 9th. These hospitals contained 853 scarlet fever patients on the same date, showing a slight further decline from recent weekly numbers; there were, however, 89 admissions during the week, against 66 and 78 in the two preceding weeks. The death-rate from diseases of the respiratory organs in London was equal to 2.3 per 1,000, and was considerably below the average.

HEALTH OF SCOTCH TOWNS.—In the eight principal Scotch towns 849 births and 468 deaths were registered during the week ending Saturday, June 9th. The annual rate of mortality, which had been 20.9 and 19.3 per 1,000 in the two preceding weeks, further declined to 18.5 during the week under notice, but exceeded by 2.3 per 1,000 the mean rate during the same period in the twenty-eight large English towns. Among these Scotch towns the lowest rates were recorded in Leith and Dundee, and the highest in Aberdeen and Perth. The 468 deaths in these towns during the week under notice included 44 which were referred to the principal zymotic diseases, equal to an annual rate of 1.7 per 1,000, which exceeded by 0.2 the mean zymotic death-rate during the same period in the large English towns. The highest zymotic death-rates were recorded in Aberdeen and Glasgow. The 211 deaths registered in Glasgow included 14 from whooping-cough, 5 from measles, 3 from scarlet fever, and 2 from diphtheria. The death-rate from diseases of the respiratory organs in these Scotch towns during the week under notice was equal to 4.1 per 1,000, against 2.3 in London.

HEALTH OF IRISH TOWNS.—During the week ending Saturday, June 9th, the deaths registered in the sixteen principal town-districts of Ireland were equal to an annual rate of 24.3 per 1,000. The lowest rates were recorded in Kilkenny and Wexford, and the highest in Galway and Lisburn. The death-rate from the principal zymotic diseases in these towns averaged 2.8 per 1,000, against 1.5 in the twenty-eight large English towns. The 147 deaths registered in Dublin during the week under notice were equal to an annual rate of 21.7 per 1,000, which showed a further decline from the rates recorded in the two preceding weeks. The 147 deaths included 19 which resulted from the principal zymotic diseases (equal to an annual rate of 2.8 per 1,000), of which 11 were referred to whooping-cough, 3 to scarlet

fever, 3 to "fever," 1 to measles, 1 to diarrhoea, but not one either to small-pox or diphtheria.

QUALIFICATION AND DIPLOMAS IN STATE MEDICINE.

C. F. REDD.—We would refer our correspondent, who asks for information respecting the qualification, etc. given by Cambridge University for medical officers of health, to the Students' Number of the JOURNAL for September 10th, 1887, where he will find full details given (page 593).

UNIVERSITY INTELLIGENCE.

CAMBRIDGE.

LECTURESHIP IN GEOGRAPHY.—The Committee of Election (representing the council of the Senate and the Royal Geographical Society) have selected, as the first holder of the new Lectureship in Geography, Francis, Henry Hill Guillemard, M.A., M.D., of Gonville and Caius College, and formerly of St. Bartholomew's. Dr. Guillemard is a Fellow of the Geographical, Linnean, and Zoological Societies, and is well known as the author of the *Voyage of the "Marchesa" to Kamschatka and New Guinea*. He is at present in Cyprus, aiding in the archaeological explorations undertaken there by the universities, but is expected to return and enter on his duties in the Michaelmas term. Dr. Guillemard has published a pamphlet *On the Endemic Hamaturia of Hot Climates*, and is credited with other professional papers in the medical and scientific journals.

MEDICAL NEWS.

MEDICAL VACANCIES.

The following Vacancies are announced:

- ANDERSON'S COLLEGE DISPENSARY, Glasgow.**—Physician. Applications to David Wilson, Esq., Honorary Secretary, 42, Bath Street, Glasgow.
- ANDERSON'S COLLEGE DISPENSARY, Glasgow.**—Surgeon. Applications to David Wilson, Esq., Honorary Secretary, 42, Bath Street, Glasgow.
- DUFFUS PAROCHIAL BOARD.**—Medical Officer. Salary, £35. Applications by June 23rd to John Nicoll, Esq., Inspector of Poor, Hopeman, N.B.
- EAST LONDON HOSPITAL FOR CHILDREN, Shadwell, E.**—Resident Clinical Assistant. Board and lodging. Applications by June 25th to the Secretary.
- EDINBURGH CITY POOR HOUSE, Craiglockhart.**—Resident Medical Officer. Salary, £75 per annum, with board. Applications by June 25th to Mr. G. Greig, Inspector, City Parish Chambers, 2, Forrest Road, Edinburgh.
- EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge Road.**—Surgeon to Out-patients. Applications by June 25th to the Committee of Management.
- GLASGOW HOSPITAL FOR SICK CHILDREN.**—Assistant House-Surgeon. Applications to M. P. Fraser, Esq., 91, West Regent Street, Glasgow.
- GUEST HOSPITAL, Dudley.**—Resident Medical Officer. Salary, £110 per annum, with board and residence, etc. Applications by June 21st to the Secretary.
- LONDON TEMPERANCE HOSPITAL, Hampstead Road.**—Surgeon. Applications by June 16th to the Secretary.
- LONDON THROAT HOSPITAL, 204, Great Portland Street, W.**—House-Surgeon. Applications by June 27th to the Secretary of the Medical Committee.

- BERRY, James, M.B., B.S., Lond., F.R.C.S.**, appointed Assistant-Surgeon to the Royal Free Hospital, Gray's Inn Road.
- CAGNEY, James, M.D.**, appointed Assistant Physician and Registrar to the Hospital for Epilepsy and Paralysis, *vice* H. W. Syers, M.D., resigned.
- CARR, J. W., M.D., B.S., F.R.C.S.**, appointed House-Physician to the Victoria Hospital for Children, S.W., *vice* H. Cholmeley, M.B., resigned.
- CHAMBERS, James, M.D.**, appointed Assistant Medical Superintendent to the Counties Asylum, Carlisle, *vice* S. R. Macphail, M.D., resigned.
- CLARK, F. W., L.R.C.P., M.R.C.S.**, appointed Assistant Medical Officer to the Darent School for Imbecile Children, *vice* W. T. Maddison, M.B., resigned.
- CUMMING, Robert, M.B., C.M., Aberd.**, appointed Assistant Medical Officer to the Perth District Asylum, Murthly.
- HACON, Walter E., L.R.C.P., Lond., M.R.C.S. Eng., L.S.A., Lond.**, appointed Honorary Physician to the Christchurch Hospital, New Zealand.
- HALL, A. R., M.D., Brux., L.R.C.P., M.R.C.S.**, appointed Surgeon to the Hampstead Provident Dispensary.
- HARVEY, F. G., M.R.C.S., L.R.C.P.**, appointed Resident Medical Officer to the Hospital for Diseases of the Throat, Golden Square, *vice* P. S. Hutchinson, M.R.C.S., L.S.A., resigned.
- HERNIMAN, T. M.B., C.M.**, appointed Assistant Resident Medical Officer to the Children's Hospital, Birmingham, *vice* E. T. Roberts, M.B., resigned.
- HOLT, A. K., M.R.C.S. Eng., L.R.C.P., Lond.**, appointed House-Physician to the North Staffordshire Infirmary, *vice* S. K. Alcock, M.R.C.S., resigned.
- INGLE, A. C., M.B., M.R.C.S.**, appointed Surgeon to the Lowestoft Friendly Societies Medical Institution, *vice* D. C. Smith, M.D., resigned.
- MACKENZIE, W. J., M.B., C.M., Glas.**, appointed Medical Officer to the Parish of St. Mary, Islington, *vice* J. R. Donald, F.R.C.S., resigned.
- MACPHAIL, S. R., M.D., Edin.**, appointed Medical Officer to the Derby Borough Asylum.
- MORISON, F. W., M.R.C.S., L.R.C.P., Lond.**, appointed Surgeon to the Chelsea, Brompton, and Belgrave Dispensary, *vice* Leonard Mark, M.R.C.S., L.R.C.P., resigned.
- PROWSE, J. S., M.B., B.S., Camb.**, appointed Junior House-Surgeon to the Western General Dispensary.
- ROBERTS, E. T., M.B., C.M.**, appointed Resident Medical Officer to the Children's Hospital, Birmingham, *vice* G. W. Powell, M.B., resigned.
- ROBSON, E. S., M.R.C.S.**, appointed Honorary Surgeon to the Durham County Hospital, *vice* F. W. Barron, M.B., M.R.C.S., resigned.
- STALNTHORPE, T. M.D., F.R.C.S.**, late President of the North of England Branch of the British Medical Association, appointed Consulting Physician to the Tynedale Hydropathic Mansion, Hexham.
- STAVELY, W. H. C., L.R.C.P., M.R.C.S.**, appointed House-Surgeon to the Victoria Hospital for Children, S.W., *vice* H. C. Kidd, F.R.C.S., resigned.

THOMPSON, A., L.D.S.R.C.S., appointed Honorary Surgeon-Dentist to the Durham County Hospital.
 THOMPSON, E. E., L.R.C.P., L.S.A., appointed Medical Officer to the Munslow District of the Ludlow Union, *vice* A. C. Malley, M.B., B.S.Dub., resigned.
 WHITTAKER, George O., L.D.S.Eng., appointed Honorary Dental Surgeon to the Manchester Hospital for Consumption and Diseases of the Throat.
 VINRACE, F., M.D.Lond., F.R.C.S., appointed Acting Surgeon to the Birmingham and Midland Skin and Lock Hospital, *vice* H. T. Bassett, M.B., resigned.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having passed the necessary examinations on May 23rd, 24th, 25th, 26th, 28th, and 29th, 1888, for the diploma of Fellow, were, at a meeting of the Council on June 14th, admitted Fellows of the College.

J. Adams, M.D.Aberd., Ashburton, Devon; A. S. Morton, M.B., C.M.Edin., 26, Weymouth Street, W.; J. A. Kempe, L.R.C.P.Lond., Royal Alexandra Hospital, Brighton; J. Mackern, M.D.Cantab., 30, Cambridge Street, Hyde Park, W.; T. F. Pearce, L.R.C.P.Lond., 10, Montague Street, Russell Square, W.C.; H. W. Dodd, L.R.C.P.Lond., 47, Kensington Park Gardens, W.; C. A. Morris, M.B.Cantab., 33, Myddelton Square, E.C.; W. Hind, M.D.Lond., 8, Woodhouse Terrace, Stoke-on-Trent; E. W. Willett, M.B.Oxon., 60, Welbeck Street, Cavendish Square, W.; E. C. Arnold, L.R.C.P.Lond., Hurst, Fairfield Road, Croydon; G. L. Wells, M.B. and B.S.Lond., 16, Heathcote Street, W.C.; J. H. E. Brock, M.B.Lond., 115, Adelaide Road, South Hampstead; A. J. Drew, L.R.C.P.Lond., 62, St. John Street, Oxford; T. P. Beddoes, L.S.A., 89, Lambeth Palace Road; F. C. Hart-Smith, M.B.Lond., St. Peter's Rectory, Bedford; H. Armstrong, L.R.C.P.Lond., Aylestone Hill, Hereford; R. R. Whishaw, L.R.C.P.Lond., 17, Mount Road, New Brighton, Cheshire; H. S. Walker, L.R.C.P.Lond., The Blms, Wakefield; R. F. Jowers, L.R.C.P.Lond., 27, Old Steyne, Brighton; H. Tonks, L.R.C.P.Lond., Parkwood Grange, Knowle, Warwickshire; K. Totsuka, L.R.C.P.Lond., 65, Lambeth Palace Road; E. Solly, M.B.Lond., Congleton, Cheshire; C. J. Shields, M.B.Melb., 389, City Road, E.C.; A. S. Taylor, M.B.Cantab., Richmond House, Blot Park, Blackheath, S.E.; F. H. Taylor, M.B.Lond., 8, Pyrland Road, N.; A. A. Kanthack, L.R.C.P.Lond., 1, Betley Villa, Church Grove, Hampton Wick, Middlesex; P. W. Rattray, M.B., C.M.Aberd., 7, Approach Road, E.; D. R. McKinnon, M.B., C.M.Aberd., Bethnal House, Cambridge Road, E.

Fifty-six candidates presented themselves for examination, 31 of whom passed (including 3 candidates who have not yet attained the legal age) and 25 failed.

The following gentlemen having passed the necessary examination at previous meetings of the court, and having since attained the legal age (25 years), were also admitted Fellows.

W. Fox, L.R.C.P.Lond., 3, Brambletyre Park Hill, Croydon; J. W. Washbourn, The Friars, Gloucester; P. A. Lloyd, L.R.C.P.Lond., 101, St. Mark's Road, North Kensington.

The following gentlemen having passed the necessary examinations, and having obtained medical qualifications, were admitted Members of the College.

V. Allen, L.R.C.P.Lond., 99, Belgrave Road, S.W.; U. Banerji, L.R.C.P.Lond., Rairfur, Bombay; G. A. H. Barton, L.S.A., St. Mary's Hospital; R. J. Braye, L.R.C.P.Lond., 13, Lincoln Street, Leicester; M. P. Cooke, L.S.A., Fern House, Landkey, Barnstaple; W. L. Mathias, L.R.C.P.Lond., 49, Montpelier Road, Brighton; A. A. Parry, M.B.Melb., 9, Euston Square, N.W.; E. V. Phillips, L.R.C.P.Lond., Kibworth, Beauchamp, Leicester; E. T. M. Tunncliffe, L.S.A., Whetstone, N.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—At a special examination for the Licence to practise Midwifery of the College, held on Friday, May 18th, 1888, the following candidate was successful.

H. A. Logan, M.D., R.U.I., Belfast.

At the ordinary monthly examinations for the Licences to practise Medicine and Midwifery of the College, held on Monday, June 4th, 1888, and three following days, the undermentioned candidates were successful.

For the Licences to Practise Medicine and Midwifery.—W. A. Murray, L.R.C.S.I., Dublin; T. H. Straugman, L.R.C.S.I., Waterford.

For the Licence to Practise Medicine only.—J. A. O'Finigan, L.R.C.S.I., Dublin.

For the Licence to Practise Midwifery only.—W. D. Moore, M.D., Q.U.I., Belfast.

ROYAL COLLEGE OF SURGEONS, IRELAND.—Mr. J. Bellew Kelly was erroneously stated in our last number to have been returned as a member of Council. Dr. H. G. Croly has declared himself a candidate for vice-presidency in 1889. It is stated that another candidate will also be in the field.

At a meeting of the Council of the Pharmaceutical Society of Great Britain on June 6th, Mr. Michael Carteighe, F.I.C., F.C.S., was elected President of the Society for the seventh year in succession.

PRESENTATION.—Upon June 12th Dr. W. E. Dawson, medical officer, was presented by the members of Court Wenlock, A.O.F., with a silver casket, richly gilt and engraved.

DR. MAZZARINI, late Assistant Surgeon in Professor Loreta's wards, in Bologna, has succumbed to splenic fever.

A COURSE of clinical lectures and demonstrations is to be given during June at the Hospital for Sick Children, Great Ormond Street. The medical course will be delivered by Dr. Sturges on Fridays, at 3.30; the surgical course by Mr. Edmund Owen, on Saturdays, at 9.30 A.M. During the remainder of the summer season, Dr. Barlow will give weekly demonstrations of cases in the wards at 10.15 A.M. on Tuesdays, commencing June 26th. Mr. John Morgan will lecture on Saturdays at 10.30, on congenital deformities, commencing June 30th.

GEH. RATH. PROFESSOR DR. V. BERGMANN has been elected an honorary member of the St. Petersburg Surgical Society.

DIARY FOR NEXT WEEK.

MONDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 5 P.M.—Mr. R. Marcus Gunn (Arris and Gale Lecturer): On Light-percipient Organs.

TUESDAY.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, 5 P.M.—Dr. Donald MacAlister The Croonian Lectures on Antipyretics.

WEDNESDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 5 P.M.—Mr. R. Marcus Gunn (Arris and Gale Lecturer): On Light-percipient Organs.

HOSPITALS ASSOCIATION, 8 P.M.—Governors' Hall of St. Thomas's Hospital. Adjourned discussion of a paper by W. Burdett-Coutts, Esq., M.P., on Contributions by Patients in Relation to the Financial Condition of London Hospitals.

ROYAL METEOROLOGICAL SOCIETY, 7 P.M.—The Hon. Ralph Abercromby: First Report of the Thunderstorm Committee. On the Photographs of Lightning Flashes. Mr. Charles Harding: The Cold Period from September 1887 to May 1888. The Hon. Ralph Abercromby: Observations on Cloud Movements near the Equator, and on the general Character of the Weather in the Doldrums.

THURSDAY.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, 5 P.M.—Dr. Donald MacAlister: The Croonian Lectures on Antipyretics.

OBSTETRICAL SOCIETY OF LONDON, 8 P.M.—Adjourned debate on papers by Dr. Steavenson, Dr. Lovell Drage, Dr. Gibbons, and Dr. Shaw on Electrolysis in the Treatment of Diseases of Women.

FRIDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 5 P.M.—Mr. R. Marcus Gunn (Arris and Gale Lecturer): On Light-percipient Organs.

SATURDAY.

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND, Anatomical Museum of the University of Cambridge, 4.30 P.M.—Alex. Macalister, F.R.S.: Dissecting-room Notes and Specimens. John Curnow: Specimen of Abnormal Development of the Skull. Johnson Symington: (1) Two Adult Temporal Bones, with non-union of the Periosteal and Squamous Portions. (2) A Section of the Head to show the Air-passages connected with the Ear. (3) Sections of a Female Pelvis. W. H. Gaskell, F.R.S.: Preparations illustrating the Structure of the Cranial Nerves. A. M. Paterson: Microscopic Specimens illustrating the Development of the Spinal Nervous System. W. H. Caldwell: A new Microtome. Frederick Treves: Hernia into the Foramen of Winslow. Johnson Symington: On the Rectum and Anus. Alexander Hill: (1) Subcallosal Convolution. (2) A new Staining Method for Nerve-cells.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 5s. 6d., which should be forwarded in stamps with the announcement.

BIRTHS.

HERBERT.—On June 7th, at 7, Abbey Terrace, West Cliff, Whitby, the wife of Johnson Herbert, L.R.C.P., etc., medical officer of health, of a daughter.

HOLTS.—On May 3rd, at Yass, New South Wales, the wife of Alton Kingsley Holts, M.R.C.S.Eng., of a daughter.

NELIGAN.—On May 8th, at Penmorfa, Friends' Road, Croydon, the wife of J. W. Neligan, M.D., of a son.

MARRIAGES.

BRETT—TELFORD.—On June 5th, at Brighton, near Melbourne, Victoria, John Talbot Brett, M.R.C.S.Eng., L.R.C.P.Lond., eldest son of the late Deputy Surgeon-General Her Majesty's Indian Army, to Margaret Stirling, third daughter of the late James Campbell Telford, M.D., of Cobran, New South Wales. (Per Renter's cable.)

STAINTHORPE—PEAT.—On June 5th, at the West Free Church, Broughty Ferry, by the Rev. G. E. Troup, M.A., William Waters Stainthorpe, M.D., of Kirkleatham, Redcar, to Clementina Janet Peat.

DEATHS.

EWAN.—At Parkeston, Harwich, on Saturday, June 9th, John Frazer Ewan, M.D., B.Sc., Edinburgh, of Sydney, New South Wales, aged 33 years.

TIJKE.—On June 9th, at Chiswick, Thomas Harrington Tjke, M.D., F.R.C.P., etc., of the Manor House, Chiswick, and 37, Albemarle Street, aged 62.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY.....10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's (Ophthalmic Department); and Royal Westminster Ophthalmic.—2 P.M.: Metropolitan Free; St. Mark's; Central London Ophthalmic; Royal Orthopaedic; and Hospital for Women.—2.30 P.M.: Chelsea Hospital for Women.

TUESDAY.....9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's; St. Bartholomew's (Ophthalmic Department); St. Mary's; Royal Westminster Ophthalmic.—2 P.M.: Westminster; St. Mark's; Central London Ophthalmic.—2.30 P.M.; West London; Cancer Hospital, Brompton.—4 P.M.: St. Thomas's (Ophthalmic Department);

WEDNESDAY.....10 A.M.: National Orthopaedic.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: Middlesex.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: London; University College; Westminster; Great Northern Central; Central London Ophthalmic. 2.30 P.M.: Samaritan Free Hospital for Women and Children; St. Peter's.—3 to 4 P.M.: King's College.

THURSDAY.....10.30 A.M.: Royal London Ophthalmic.—1 P.M.: St. George's.—1.30 P.M.: St. Bartholomew's (Ophthalmic Department); Guy's (Ophthalmic Department); Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; St. Thomas's (Obstetric Department); Central London Ophthalmic; Hospital for Diseases of the Throat; Hospital for Women.—2.30 P.M.: North-West London; Chelsea Hospital for Women.

FRIDAY.....9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.15 P.M.: St. George's (Ophthalmic Department).—1.30 P.M.: Guy's; Royal Westminster Ophthalmic.—2 P.M.: King's College; St. Thomas's (Ophthalmic Department); Central London Ophthalmic; Royal South London Ophthalmic; East London Hospital for Children.—2.30 P.M.: West London.

SATURDAY.....9 A.M.: Royal Free.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: King's College.—1.30 P.M.: St. Bartholomew's; St. Thomas's Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Middlesex; Royal Free; Central London Ophthalmic.—2.30 P.M.: Cancer Hospital, Brompton.

HOURS OF ATTENDANCE AT THE LONDON HOSPITALS.

CHARING CROSS.—Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; Skin, M. Th., 1.30; Dental, M. W. F., 9.

GUY'S.—Medical and Surgical, daily, 1.50; Obstetric, M. Tu. F., 1.30; Eye, M. Tu. Th. F., 1.30; Ear, Tu. F., 12.30; Skin, Tu., 12.30; Dental, Tu. Th. F., 12.

KING'S COLLEGE.—Medical, daily, 2; Surgical, daily, 1.30; Obstetric, Tu. Th. S., 2; o.p., M. W. F., 12.30; Eye, M. Th. 1; Ophthalmic Department, W., 1; Ear, Th., 2; Skin, Th.; Throat, Th., 3; Dental, Tu. F., 10.

LONDON.—Medical, daily, exc. S., 2; Surgical, daily, 1.50 and 2; Obstetric, M. Th., 1.30; o.p. W. S., 1.30; Eye, W. S., 9; Ear, S., 9.30; Skin, Th., 9; Dental, Tu. F., 1.30; o.p. W. S., 1.30; Eye, W. S., 8.30; Ear and Throat, Tu., 9; Skin, Tu., 4; Dental, daily, 9.

ST. BARTHOLOMEW'S.—Medical and Surgical daily, 1.30; Obstetric, Tu. Th. S., 2; o.p., W. S., 9; Eye, Tu. Th. S., 2.30; Ear, Tu. F., 2; Skin, F., 1.30; Larynx, F., 2.30; Orthopaedic, M., 2.30; Dental, Tu. F., 9.

ST. GEORGE'S.—Medical and Surgical, M. T. F. S., 1; Obstetric, Tu. S., 1; o.p., Tu., 2; Eye, W. S., 2; Ear, Tu., 2; Skin, W., 2; Throat, Th., 2; Orthopaedic, W., 2; Dental, Tu. S., 9, Th., 1.

ST. MARY'S.—Medical and Surgical, daily, 1.45; Obstetric, Tu. F., 1.45; o.p., M. Th., 1.30; Eye, Tu. F. S., 9; Ear, M. Th., 3; Throat, Tu. F., 1.30; Skin, M. Th., 9.30; Electrician, Tu. F., 2; Dental, W. S., 9.30; Consultations, M., 2.30; Operations, Tu., 1.30; Ophthalmic Operations, F., 9.

ST. THOMAS'S.—Medical and Surgical, daily, except Sat., 2; Obstetric, Tu. F., 2; o.p., W., 1.30; Eye, M. Th., 2; o.p., daily, except Sat., 1.30; Ear, M., 12.30; Skin, W., 12.30; Throat, Tu. F., 1.30; Children, S., 12.30; Dental, Tu. F., 10.

UNIVERSITY COLLEGE.—Medical and Surgical, daily, 1 to 2; Obstetrics, M. Tu. Th. F., 1.30; Eye, M. Tu. Th. F., 2; Ear, S., 1.30; Skin, W., 1.45, S., 9.15; Throat, Th., 2.30; Dental, W., 10.30.

WESTMINSTER.—Medical and Surgical, daily, 1.30; Obstetric, Tu. F., 3; Eye, M. Th., 2.30; Ear, M., 9; Skin, Th., 1; Dental, W. S., 9.15.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS FOR THE CURRENT WEEK'S JOURNAL SHOULD REACH THE OFFICE NOT LATER THAN THE FIRST POST ON WEDNESDAY.

COMMUNICATIONS respecting editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

IN order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the office of the JOURNAL, and not to his private house.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate beforehand with the Manager, 429, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication. CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

QUERIES.

AN OLD SUBSCRIBER asks where wicker coffins can be obtained.

TREATMENT OF DIABETES BY OXYGENATED WATER.
DR. C. GUNN (125, Stephens Green West, Dublin) asks whether a patient who has suffered from glycosuria for many years, but by taking care gets fair health, would be likely to be benefited by using oxygenated water.

TREATMENT OF WEBBED FINGERS.
A MEMBER asks which of the many methods employed in the treatment of webbed fingers is to be recommended.

TREATMENT OF WOUND OF LEG.
S. H. J. asks: What is the best dressing for a clean wound over the shin bone caused by the blow of a cricket ball?
My patient is a healthy, muscular man, with perhaps a little gouty tendency, but although I have tried all the usual remedies the wound (a fortnight old) shows little tendency either to heal or granulate. The limb is having perfect rest.

TREATMENT OF DYSIDROSIS.
T. E. L. L. would be very much obliged for any information any reader of the JOURNAL can give him on the treatment of dysidrosis attacking the outer and inner sides of the hands at the junction of the dorsal and palmar surfaces. It appears every year about April and lasts during the hot weather; there is little or no itching, but the scales drying at one place, while fresh "sago grains" are appearing in another, are very unsightly. He has tried internally arsenic and general tonics, and locally, glycerine, boro-glyceride, carbolic soap, ung. zinci, etc. His general health is and always has been perfect.

ANSWERS.

ADMIRALTY EXAMINATION.
SURGEON R. N. writes: In reply to the request of "W. E. M." in the JOURNAL of June 9th, I would quote for his information and guidance, in giving an opinion in the case he refers to, the following from the Queen's Regulations and Admiralty Instructions, paragraph 1,075, clause No. 1, which applies to all persons, of whatever class or age, entering Her Majesty's navy: "Seven teeth deficient or defective (unless special authority is obtained from the Admiralty), or if the biting or grinding capacity be seriously impaired owing to a smaller number of absent or unsound teeth, for example, three or four incisors or four molars in the same jaw. Beyond the above no exact rule with respect to defective teeth can be laid down, but the examining medical officer should take into account the condition of the teeth generally, and the probability of their lasting."

METHYLENE.

IGNORANTIA sends the following string of questions with regard to methylene: 1. How is it used? 2. What is the usual quantity required to produce anaesthesia? 3. How much is required to keep the anaesthesia profound? 4. What are the indications of danger? 5. How are they best combated? 6. What firm is the best for a supply of pure methylene?
. We have referred the questions to Sir Spencer Wells, who has been good enough to send the following replies: 1. By Junker's inhaler. 2. Two or three drachms. 3. About one drachm for each ten minutes. 4 and 5. Same as chloroform. 6. Krolne and Sesemann, Duke Street, Manchester Square.

A SOURCE OF INFECTION.

DR. ARCHIBALD D. MACDONALD, (Liverpool) writes: Assuming that the case of "so-called puerperal fever" were really a case of puerperal septicemia, let me tell your correspondent, and during labour the washing of his hands in iodised water (about one drachm of liquor iodi to a pint and a half) he did not use "the strictest antiseptic treatment that here iodine is the question. There is substantial reason for believing that here iodine is the antiseptic. Had your correspondent employed it, he might not have had occasion to refer to the so-called puerperal fever at all; the borrowed Higginson would not have become the unconscious instrument of conveyance of possible septicæmia in spite of the antiseptic employed for the irrigations; thirty-two lines of the JOURNAL would in all probability not have been occupied in reiterating the warning, "Beware of the germs which lurk in the nooks of used instruments," and this letter would not have been written. The syringe, I hold, should have been purified by iodine and not recommended to be corrosive sublimate before return to the chemist, and not recommended to be destroyed. A working man cannot afford to throw away or burn a ninth or tenth part of a week's income, and antiseptics are either effective or they are shams. Most of us believe them to be effective; let us then practically show our faith in them.

PRACTICE IN AUSTRALIA.

SEVERAL correspondents have recently made inquiries with regard to the prospects before a medical practitioner emigrating to Australia as compared with those which he has in the United Kingdom. No general answer to such a question can be given, as much depends upon personal and physical qualifications and upon the colony chosen; but it must be remembered that there is as yet no legal restriction upon the practice of unqualified persons, and

that consequently quackery is rampant. Further, the number of qualified practitioners in proportion to the population is already large. In his annual address to the Sydney and New South Wales Branch of the British Medical Association, the Hon. Dr. J. M. Creed, the retiring President, referred to this subject; the number of medical practitioners who were arriving in Australia from all parts of the world for the purpose of settling in practice was, he said, disproportionate; "the hopes of many of these gentlemen," he said, "are fated to disappointment, for the number of medical men in proportion to the population is rapidly becoming so large that remunerative practice can be but the reward of very few of them." He added that whereas there was one medical practitioner to every 1,562 inhabitants in England, in New South Wales there was more than one to every 1,250, if the men practising without qualifications were included in the calculation.

THUNDERSTORMS AND LIGHTNING ACCIDENTS.

MR. H. NEWMAN LAWRENCE, Electrician to the Institute of Medical Electricity (24, Regent Street), writes that the Institute is very desirous to obtain authentic information concerning lightning accidents, whether fatal or otherwise. Electrical and physiological details are most required, but reliable general information is stated to be often very valuable, and will be gratefully received.

THE TREATMENT OF ECZEMA.

DR. C. R. ILLINGWORTH (Accrington) writes: The prescription given by Dr. Hawkins is lacking in one essential; it contains no antiseptic. For several years I had very good results with a mixture of equal parts of zinc ointment and glycerine, but since I made the preparation antiseptic with glycerine of borax I have effected much more rapid cures. The same ointment also gives great relief in pruritus ani, itself an eczematous or quasi-eczematous affection; whilst for acne rosacea and other allied affections of the skin it is (if there be any justification in the use of the term) an absolute "specific."

ON THE USE OF CODEINE TO RELIEVE PAIN IN ABDOMINAL DISEASE.

MR. J. MATTHEWS (Liverpool) writes: I read with much pleasure the paper on Codeine by Dr. Lauder Brunton in the JOURNAL of June 9th. I have now under treatment a lady who has recently ceased menstruating and who has suffered for nearly a year from vomiting attended occasionally by hæmorrhage—hysterical vomiting and vicarious hæmorrhage. She complained much of pain in various parts, specially under the lower edge of the ribs and over the ovaries. I had tried everything I thought likely to relieve her with little or no effect, when Dr. William Carter suggested codeine. We gave it in half-grain doses three times a day with very decided benefit. Contrary to the opinion expressed in the paper referred to, my impression is that it tends to constipate, and I add one grain of compound rhubarb pill to each dose.

A PIN PASSED PER ANUM IN FORTY HOURS.

DR. J. McANDREW, M.B. Ed. (Huddersfield) writes: A child aged 2 years was brought to me on June 4th by its father, who averred that it had swallowed a small pin about an hour previously. I carefully examined the mouth and fauces, but could discover no pin there. As the child seemed to be suffering no discomfort, I concluded that perhaps, unknown to the mother, it had dropped the pin from its mouth—in fact, that it had not swallowed the pin after all. However, I told the father to give the child plenty of solid food, very little liquid, and on no account to give a purgative. I also told him to have every stool examined carefully; this was done, and the result was that they found the pin embedded in a mass of fæces passed on Wednesday morning, June 6th.

I merely note this case because, in the first place, it is not very common to find a sharp and somewhat lengthy body like a pin pass through the intestinal tract without producing any untoward symptoms; and in the second place because of the short time—about forty hours—that elapsed between its entrance and exit from the alimentary canal.

EUGENIA JAMBOLANA.

DR. GEO. SUTTIE (Detroit, Michigan, U.S.A.) writes: There appeared in the JOURNAL of May 5th a small paragraph headed "Jambul from the Dutch Indies," in which the botanical name was given as *syzygium jambolana*. Beneficial results were also recorded from the use of this drug in a case of diabetes mellitus, and the paragraph concluded by saying that "it is not clear whether this is the same plant as *eugenia jambolana*."

Since the members of the profession on both sides of the Atlantic are somewhat interested in this drug as a promising remedy in diabetes, it would be conducive to their intelligent understanding of the therapeutics of jambul to know that reports of its effects as given under the name of *syzygium jambolana* and that of *eugenia jambolana* relate to the same remedy, and can be incorporated in collective investigation.

The urgent necessity which exists for more stringent rules of botanical classification in order to get the infinity of names within bounds called for the fusion of the genus *syzygium* into *eugenia* by Bentham and Hooker when writing their *Genera Plantarum* (vol. i, part ii, page 119), and as this work is recognised as authoritative on taxonomy, jambul should now be known as *E. jambolana*, Lam.

Your readers may have access to either or all of the works mentioned below, and which can be consulted for a record of synonymy: De Candolle's *Prodrromus*, vol. iii, p. 259; Drury's *Useful Plants of India*, p. 421; Rosenthal's *Heil-Nutz- und Giftpflanzen aller Länder*, p. 930; Baker's *Flora of Mauritius and the Seychelles*, p. 116; Hooker's *Flora of British India*, vol. ii, p. 499, etc.

COMMUNICATIONS, LETTERS, etc., have been received from:

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE "BRITISH MEDICAL JOURNAL."

Seven lines and under	£0	3	6
Each additional line	0	0	4
A whole column	1	15	0
A page	5	0	0

An average line contains seven words.

When a series of insertions of the same advertisement is ordered, a discount is made on the above scale in the following proportions, beyond which no reduction can be allowed.

For 6 insertions, a deduction of	10 per cent.
" 12 or 13 "	20 "
" 26 "	25 "
" 52 "	30 "

Special terms for occasional change of copy during series:

20 per cent. if not less than 26 pages be taken	or their equivalent
25 "	in half or
30 "	quarter pages.

For these terms the series must, in each case, be completed within twelve months from the date of first insertion.

Advertisements should be delivered, addressed to the Manager at the Office, not later than noon on the Wednesday preceding publication; and, if not paid for at the time, should be accompanied by a reference.

Post-Office Orders should be made payable to the British Medical Association, at the West Central Post-Office, High Holborn. Small amounts may be paid in postage-stamps.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-Offices letters addressed to initials only.

REPORTS OF THE COLLECTIVE INVESTIGATION COMMITTEE OF THE BRITISH MEDICAL ASSOCIATION.

REPORT ON THE INQUIRY INTO THE CONNECTION OF DISEASE WITH HABITS OF INTEMPERANCE.¹

PREPARED BY ISAMBARD OWEN, M.D., M.A., F.R.C.P.,
Secretary to the Committee.

The inquiry of the Collective Investigation Committee into the above subject was carried on from May 9th, 1885, to December 11th, 1886.

The form of inquiry-paper used was suggested by Dr. Edward Casey, of Windsor, who has taken a part in preparing the Report. It consisted essentially of a table containing seven columns. The table was divided horizontally into twenty-five spaces, and each space was distinguished by a numeral placed in the first column. The second, third, and fourth columns were headed, "Occupation or Social Position," "Age at Death," and "Cause of Death."

The contributor to the inquiry was requested to take his death certificate book for the past three years, and to fill in columns 2, 3, and 4 from the counterfoils of his certificates of males over 25 years of age, in order as they came.

In column 5 he was requested to append a mark signifying whether the deceased had ever suffered from gout or not, wherever such information was available.

In the 6th column he was requested to indicate the alcoholic habit of the deceased by an index-letter, A, B, C, D, or E, corresponding with the following scale of alcoholic classes:—

"Class A.—Total Abstainers.

"Class B.—The Habitually Temperate.—That is, men who drink small amounts, and only with meals, and rarely take spirits, except for medicinal purposes (the latter part of the definition not to apply to whisky drinking countries.)

"Class C.—The Careless Drinkers.—Men who, without being 'intemperate' or 'free drinkers,' yet do not confine themselves within a rigid rule; who do not demur to drinking spirits occasionally as a beverage; who may at times drink between meals, or even to the extent of intoxication occasionally, but who do not make these practices a habit; and, on the average, do not materially exceed what has been termed the 'physiological amount' of 1½ ounce of pure alcohol daily.

"Class D.—The Free Drinkers.—Men who 'drink a fair amount,' or 'take their wine freely,' habitually exceeding the physiological amount to a material extent; but yet who cannot be called 'drunkards,' or considered to have forfeited a character for sobriety.

"Class E.—The Decidedly Intemperate.—'Drinking men,' 'hard drinkers,' and 'drunkards.'

"If a doubt exist to which of two classes a patient should be considered as belonging, he may be placed between the two by joining the letters, as AB or CD.

"If required, the duration of the patient's latest habits may be indicated; for example, as follows.

"A 3 yrs. } meaning a total abstainer the last three years of life;
"E prev. } decidedly intemperate previously."

The 7th column was devoted to further remarks on the cases. In such an inquiry there are certain obvious possibilities of error.

1. There is the possibility of the cause of death being incorrectly stated, owing to difficulty of diagnosis; but the statement of the cause of death in this inquiry is drawn from the selfsame source which is relied on in the Registrar-General's returns, and the suspicion of error which attaches to this inquiry is no greater than that which may be held to vitiate the Registrar-General's statistics.

2. The individual's alcoholic habits may be incorrectly stated, either from want of accurate knowledge on the part of the con-

¹ Read in the Section of Medicine of the Annual Meeting of the British Medical Association held at Dublin in August, 1887.

tributor, or from his statement being biased by his views upon temperance questions. By this is meant that one man may entertain a more rigid standard of temperance than another, and place an individual in Class C, whom his fellow would include in Class B.

These errors were, however, foreseen, and provided against as far as was possible.

1. Each contributor was requested to leave a blank in the column if he were unable to index the individual with confidence; and, as a matter of fact, a large number of such blanks were left.

2. The meaning of the different classes was defined with as much accuracy as such a definition admitted of.

3. The contributors were allowed, when in doubt about the alcoholic class, to place the patient in an intermediate position between two classes. Thus, in addition to the five classes, four sub-classes were introduced, making altogether nine degrees upon the alcoholic scale. It might, the Committee thought, be fairly assumed that with so many divisions on the scale the place accorded to any individual would seldom be far removed from the right one, and that on the whole slight errors in one direction might be taken to counterbalance similar errors in another direction.

The inquiry was placed in the hands of all members of the Association, and 178, whose names are printed in an appendix (A), responded to it, forwarding 250 schedules of returns, including altogether 4,234 cases in which the alcoholic class was named, without counting those in which a blank was left.

The returns as received were copied out on fresh sheets, each case being placed under the heading of its respective alcoholic class. In making this classification, regard had to be paid to those cases in which the individual was stated to have altered his habits in the course of his life (see the form of inquiry paper above). Of such there were 118. Twelve of them are placed in a separate category as unclassified cases.

The claim of the remaining 106 to belong to particular classes was held on careful consideration not to be modified by the alteration in habits stated to have occurred. For instance, a man dying of chronic renal disease at the age of 75 is included in Class E, although stated to have drunk hard for eleven months before his death; and, on the other hand, a man who died of phthisis at the age of 27 is retained in Class E, though stated to have been a total abstainer for the last twelve months of life.

Of these 106 cases 3 are included in Class A, 5 in B, 1 in BC, 23 in C, 2 in CD, 25 in D, 4 in DE, and 43 in E. Details of them are given in an appendix (B).

THE ALCOHOLIC HABITS OF THE GENERAL AGGREGATE.

The aggregate of cases, being distributed into the respective classes, gives the following figures:—Class A, 122; AB, 54; B, 1,529; BC, 178; C, 977; CD, 112; D, 547; DE, 100; E, 603; unclassified, 12.

Translating these figures into percentage² parts of the aggregate, we get in Class A, 2.8; in AB, 1.2; in B, 36.1; in BC, 4.2; in C, 23.0; in CD, 2.6; in D, 12.9; in DE, 2.3; in E, 14.2; and in the unclassified, 0.2 per cent.

TABLE I.—Table showing the Number of Cases falling in each Class, and the Percentage* of each Class on the Aggregate of Cases.

Class.	No. of Cases.	Percentage.
A	122	2.8 p.c.
AB	54	1.2 p.c.
B	1,529	36.1 p.c.
BC	178	4.2 p.c.
C	977	23.0 p.c.
CD	112	2.6 p.c.
D	547	12.9 p.c.
DE	100	2.3 p.c.
E	603	14.2 p.c.
Unclassified	12	0.2 p.c.
Total	4,234	

* Carried to one place only of decimals.

These figures may be somewhat differently arranged, as in Tables II, III, IV.

In Table II each sub-class is added into the class immediately succeeding; in Table III it is added into the class immediately preceding; and in Table IV it is divided between the preceding and the succeeding class.

TABLE II.—(Table I otherwise stated).

Class.	No. of Cases.	Percentage.
A ...	122	or 2.8 p.c. of 4,234
B and AB ...	1,583	or 37.3 p.c. "
C and BC ...	1,155	or 27.2 p.c. "
D and CD ...	659	or 15.5 p.c. "
E and DE ...	703	or 16.6 p.c. "
Unclassified ...	12	or 0.2 p.c. "
Total ...	4,234	

TABLE III.—(Table I otherwise stated.)

Class.	No. of Cases.	Percentage.
A and AD ...	176	or 4.1 p.c. of 4,234
B and BC ...	1,707	or 40.3 p.c. "
C and CD ...	1,089	or 25.7 p.c. "
D and DE ...	647	or 15.2 p.c. "
E ...	603	or 14.2 p.c. "
Unclassified ...	12	or 0.2 p.c. "
Total ...	4,234	

TABLE IV.—(Table I otherwise stated.)

Class.	No. of Cases.	Percentage.
A and half AB ...	149	or 3.4 p.c. of 4,234
B and half AB, BC ...	1,645	or 38.8 p.c. "
C and half BC, CD ...	1,122	or 26.4 p.c. "
D and half CD, DE ...	653	or 15.4 p.c. "
E and half DE ...	653	or 15.4 p.c. "
Unclassified ...	12	or 0.2 p.c. "

Roughly stated, it may be said that of the four thousand two hundred and odd individuals reported on—all, be it remembered, males over the age of 25—about 45 per cent. were habitually moderate in their alcoholic habits, 25 per cent. were careless, and 30 per cent. more or less distinctly intemperate (15 per cent. decidedly so).

OCCUPATIONS.

We have further classified the individuals in each class according to their respective occupations. As the numbers in most of the individual occupations are small, we have grouped them under the fourteen following heads: "Independent Property," "Professional Occupations," "Clerical Occupations" (the clerks, not the clergy, are here meant), "Mercantile Occupations," "Tradesmen," "Licensed Victuallers," "Artisans," "Labourers," "Driving Occupations," "Farming Occupations," "Soldiers," "Sailors," "Domestic Servants," "Miscellaneous Occupations," and "Blanks."

Table V shows the aggregate number of cases in each of these fourteen groups, and the percentage incidence of each group in the different alcoholic classes. At the head of the Table is placed the percentage incidence of the whole 4,222 classified cases, the twelve unclassified being neglected throughout.

TABLE V.—Table showing the Aggregate Number of Cases in each of the Fourteen Occupation-groups, and the Percentage of each such Group in the several Alcoholic Classes A to E; with the Normal (or Total) Percentage Incidence prefixed for purposes of comparison.*

	Aggregate Number.	Percentage Falling in Class—									
		A.	AB.	B.	BC.	C.	CD.	D.	DE.	E.	
Total ...	4,222*	2.8	1.2	36.2	4.2	33.1	2.6	12.9	2.3	14.2

Miscellaneous and blank ...	265	36.0	22.6	16.3	20.8

* The unclassified are here neglected.

We have further constructed a table—Table VII—showing the relative alcoholic habits of the fourteen occupation-groups in a simpler but rougher manner. In this table the number of cases falling in the lower half of the alcoholic scale for each group is compared with that falling in the upper half of the scale. By the lower half of the scale is meant A+AB+B+BC+ $\frac{1}{2}$ C; by the higher half E+DE+D+CD+ $\frac{1}{2}$ C. The comparison is expressed in the form of a ratio, the lower half of the scale being taken as unity.

For the sake of convenience this ratio will be termed "the Ratio of Minor Drinking Habits," and the reverse ratio will be called "the Ratio of Major Drinking Habits," or more briefly, "the Ratio of Minor Habits" and "the Ratio of Major Habits."

In Table VII the occupation-groups are placed in the descending series of their ratios of minor habits; and the ratio for the whole 4,222 cases is placed at the head for comparison.

The table is divided by two gaps. First we have six groups in which the ratio of minor habits is higher than the normal; next, four in which it is lower than the normal, but still not less than unity; and finally, four groups in which the less temperate end of the scale exceeds the more temperate.

TABLE VII.—Table showing the Ratio between the Cases falling in the Lower and those in the Higher Half of the Alcoholic Scale ("Ratio of Minor Habits") for each of the Fourteen Occupation-groups.

(The lower half includes A, AB, B, BC, and half of C. The higher half includes E, DE, D, CD, and half of C.)
Ratio for all occupations ... as 1 to 0.73

1. Professional occupations ... " 1 " 0.51
2. Clerical occupations ... " 1 " 0.57
3. Farming occupations ... " 1 " 0.65
4. Artisans ... " 1 " 0.66
5. Labourers ... " 1 " 0.71
6. Sailors ... " 1 " 0.76

7. Independent ... " 1 " 0.83
8. Mercantile occupations ... " 1 " 0.84
9. Tradesmen ... " 1 " 0.87
10. Miscellaneous occupations ... " 1 " 0.91

11. Domestic servants ... " 1 " 1.25
12. Soldiers ... " 1 " 1.60
13. Driving occupations ... " 1 " 1.80
14. Licensed victuallers ... " 1 " 3.81

Let us now inspect Tables VI and VII. It will be seen that the ratio of minor habits is highest in the "professional" group, being, in fact, nearly 2 to 1. On turning to Table VI we observe that this group scores highest of all in classes A and B, and lowest of all in classes D and E taken together.

Clerks, farmers, artisans, labourers, and sailors follow in order. It will be noted in Table VII that the clerks show the lowest

percentage of drunkards, but that the percentage of "free" and "careless" drinkers is higher than in the case of the professional men, this being at the expense of A and B.

The farmers show a low percentage of total abstainers, few drunkards, the average number of free drinkers, a larger than average percentage of temperate, but at the same time a larger than average percentage of "careless" drinkers.

Among the artisans a large proportion of teetotallers appears, but the ratio is made somewhat lower by the increasing percentage of drunkards.

Among labourers the tendency is to accumulation in the "careless" class, the proportion of free drinkers and drunkards being below the average.

Among sailors there is a fairly high percentage of teetotallers, but the "moderate" class is less well represented. This, however, appears to be in some measure due to the large proportion of dubious cases entered in BC (Table V). The drunkards are comparatively few (sailors get few opportunities of continued intemperance), but the "free" drinkers are in excess, and there is a considerable accumulation in the "careless" class.

Proceeding in the order of Table VII, men of independent property show a tendency to extremes, the drunkards and the moderate drinkers being the only classes which rise above the average.

The tendency among mercantile men is also rather to extremes, but less to drunkenness than to "free" drinking. The "careless" class is here the lowest of all.

Among tradesmen, also, the extreme classes are raised at the expense of the "careless," but the rise is rather more in the higher half of the scale than in the lower.

Among domestic servants the tendency is strongly upwards; the percentage of total abstainers is smallest of all, and that of moderate drinkers nearly the smallest, while C, D, and E are considerably swollen. Careless drinking is here most in vogue.

Among soldiers it is the "decidedly intemperate" who raise the ratio of major habits. Among the simply "free" drinkers they show the smallest percentage of all the groups; but the intermediate group of the "careless" amounts to 36 per cent., the highest of all; while the temperate have sunk to not quite 16 per cent., nearly the lowest of all. It is noticeable, however, that the percentage of abstainers is comparatively high. The group, it must be noticed, is a very small one, and is largely made up of pensioners and "retired" men.

Men engaged in driving occupations show a distinct tendency to the higher half of the scale, the decidedly intemperate being numerous, and the free drinkers much above the average.

Finally, the licensed victuallers and their assistants exhibit the most marked tendency towards the top of the scale, teetotallers being entirely absent, the percentage of moderate drinkers the lowest of all, those of free drinkers and drunkards a long way the highest of all, and the ratio of major habits nearly 4 to 1.

We have, further, taken all the individual occupations of which not less than twenty examples are reported, and have drawn out a table for them (Table VIII) on a similar plan to that of Table VII. As the aggregates were so low, we have not thought it worth while to construct a percentage table after the plan of Table V.

TABLE VIII.—Table showing similar Ratios for certain special Occupations.

PROFESSIONAL—			
Ministers of religion (47)	as 1 to 0.09
Scholastic occupations (29)	" 1 ,, 0.38
Officers in the army and navy (28)	" 1 ,, 0.47
Medical men (41)	" 1 ,, 0.57
Lawyers (31)	" 1 ,, 0.93
ARTISANS—			
Weavers (58)	" 1 ,, 0.43
Boot and shoe makers (61)	" 1 ,, 0.45
Tailors (69)	" 1 ,, 0.50
Carpenters and joiners (76)	" 1 ,, 0.76
Blacksmiths (39)	" 1 ,, 0.85
Painters (38)	" 1 ,, 0.90
Masons (58)	" 1 ,, 1.07
LABOURERS—			
Agricultural and farm labourers (155)	" 1 ,, 0.45
Gardeners (67)	" 1 ,, 0.45
Miners (141)	" 1 ,, 1.23
TRADESMEN—			
Butchers (59)	" 1 ,, 2.60

MISCELLANEOUS—

Railway men (30)	as 1 to 0.42
Paupers (25)	" 1 ,, 1.76
Travellers (20)	" 1 ,, 1.85

We notice in this table that the ministers of religion honourably head the whole list, not only of professional men, but of all occupations, showing a ratio of minor habits higher than 10 to 1.

Among professional men, schoolmasters follow; then officers in the army and navy; next medical men, whose ratio of minor habits is slightly below that of professional men generally, but considerably above that of the whole series; and, finally, lawyers, whose ratio of minor drinkers is very near unity, not much more than half of the general ratio of professional men, and considerably below that of the whole series.

Among artisans, we find weavers, boot and shoe makers, and tailors to be the most temperate. Carpenters and joiners almost touch the general ratio of the whole series. The blacksmiths and painters give a somewhat low ratio of minor habits, and in masons the higher half of the scale exceeds the lower.

Agricultural and farm labourers and gardeners appear as very temperate bodies of men, but miners show a ratio of major habits greater than unity.

Among tradesmen the occupation that stands out most prominently is that of the butcher, with a ratio of major habits as high as 2.6 to 1.

Railway men appear as a tolerably temperate body. The few paupers on the list have a high ratio of major habits, and one still higher is shown by commercial travellers.

It must be noted that in some cases the classification of special occupations was a little dubious. For instance, in the case of a "tailor," a "baker," or a "saddler" it was not clear whether the tradesman or the journeyman of that name was intended. In such cases the classification was decided by the probabilities of the case. The following is the list of the dubious cases, and the mode in which they have been settled: "No occupation" (27 cases) was entered under "independent property," "engineer" (11) as "professional" (16), "business man" (1), "maltster" (3), "manager" (9), "organ builder" (1), "saltmaker" (1) as "mercantile"; "baker" (23), "coach" and "carriage builder" and "maker" (8), "decorator" (3), "gunmaker" (1), "harnessmaker" (4), "saddler" (7) as tradesmen; "basketmaker" (1), "bellhanger" (1), "boilermaker" (1), "blindmaker" (1), "blockmaker" (1), "boatbuilder" (1), "book-binder" (1), "boot" and "shoemaker" and "cordwainer" (61), "brickmaker" (6), "capmaker" (2), "cabinetmaker" (13), "calico printer" (2), "chairmaker" (2), "clogger" (1), "cloth dresser and worker" (11), "cooper" (7), "currier" and "leather dresser" (3), "cutler" (3), "dyer" (5), "gasfitter" (1), "hatter" (2), "hurdlemaker" (1), "inkmaker" (1), "iron founder" (2), "locksmith" (12), "paperhanger" (4), pipemaker (2), "printer" (13), "tailor" (69), "tinman" (3), "watchmaker" (8) as artisans; "warehousemen" (16) as labourers; "pensioners," without further qualification (20), as soldiers.

AGES AT DEATH.

We now proceed to ascertain the average age at death for the individuals in each class. This is given in the following table. The table has been constructed simply by adding up in each class the ages given in the returns, which, it will be remembered, are the ages at death, and striking an average. The average age at death of the whole number is given at the foot of the table for purpose of comparison.

TABLE IX.—Average Age at Death for each Class.²

Class	Years.		or	Years. Days.	
	Years.	Days.		Years.	Days.
Class A	51.22			51	80
" AB	56.72			56	215
" B	62.13			62	50
" BC	62.42			62	155
" C	59.67			59	246
" CD	60.35			60	130
" D	57.59			57	216
" DE	53.64			53	233
" E	52.03			52	14
Unclassified	60.91			60	334
Total	58.92 ³			58	336

² It must be remembered that in the returns the years of life only are given, and not the odd days. To interpret Table IX correctly, therefore, we must say, not that the average age in Class A, for instance, is 51 years 80 days, but that it is somewhere between 51 years 80 days and 52 years 80 days.

³ Farr's English Life Table, No. 3, deduced from the population as shown by the censuses of 1841 and 1851, and the deaths registered during the years

It will be seen in this table that of the main classes the average age in B is the highest of all, and that a gradual diminution, amounting in all to rather more than ten years, takes place as we pass from B to E.

The smaller sub-classes, CD and DE, follow pretty fairly the descending series, the average of BC alone being a trifle above that of the class preceding it. Thus we may see as far as these cases go, that as the alcoholic habit increases the average duration of life diminishes. The difference in duration between the habitually temperate and the decidedly intemperate (both classes, be it remembered, having already passed the age of 25 years, and all who died below that age being excluded) amounts to a period of some ten years.

But the average age furnished by the total abstainers is somewhat startling, for we find that it is not only far below the average age attained by the moderate drinkers, but it is even a year below that reached by the decidedly intemperate. It must, however, be remembered in interpreting this figure correctly that the class of total abstainers is somewhat differently constituted from any of the other classes.

It will not, I think, be disputed that the total abstinence movements which have played so prominent a part in this country of late years have made many more converts among the young than among the middle-aged or elderly. If this is admitted, it will necessarily follow that the average age of total abstainers—I mean of living total abstainers—at any time during the three years covered by this inquiry, was considerably less than the average age of the rest of the community; so that the class of abstainers has contained a proportion much greater than the average of individuals susceptible to early death, or, to put it in another way, has had a greater average liability to early death, apart from any question of alcohol, than any of the other classes.⁴

These considerations are borne out to some extent by the tables immediately following. Table XII, for example, the construction of which will be presently described, shows that the stress of mortality among abstainers comes quite in the early years, especially before the age of 30 is reached. We have, therefore, constructed two fresh tables (Tables X and XI) on the model of Table IX. These two tables, to put it briefly, are repetitions of Table IX, but in the one all cases of death under 30 are omitted, and in the other all cases of death under 40.

TABLE X.—Average Age at Death for each Class, Omitting all Cases of Death under 30.

Class	Cases.	Years.	Years.	Days.
Class A	98, average	57.31	or 57	115
" AB	47, "	61.19	" 61	69
" B	1,433, "	64.48	" 64	177
" BC	173, "	63.43	" 63	156
" C	925, "	61.52	" 61	189
" CD	110, "	61.009	" 61	3
" D	525, "	58.87	" 58	317
" DE	96, "	54.73	" 54	266
" E	571, "	53.42	" 53	155
Total	3,978, "	60.87 ⁵	" 60	319

TABLE XI.—Average Age at Death for each Class, Omitting all Cases of Death under 40.

Class	Cases.	Years.	Years.	Days.
Class A	79, average	62.74	or 62	270
" AB	39, "	66.84	" 66	306
" B	1,294, "	67.71	" 67	270
" BC	154, "	67.006	" 67	2
" C	829, "	64.65	" 64	237
" CD	99, "	64.12	" 64	43
" D	464, "	61.98	" 61	357
" DE	78, "	59.42	" 59	153
" E	468, "	57.47	" 57	259
Total	3,504, "	64.41 ⁶	" 64	152

1835-54, gives the average age at death for males who have attained the age of 25 (England and Wales) as 61.12. The Supplement to the Forty-fifth Annual Report of the Registrar-General, 1885, calculating from the population as shown by the census of 1871 and the deaths registered in the years 1871-80, gives it (p. vii) as 60.65. The cases on which our report is based are chiefly furnished by England and Wales.

⁴ It is probable that the average age at death shown by the other classes is affected to some degree by similar circumstances. If the alcoholic habit tends to increase, as generally supposed, from youth up to about 45 or 50 years of age (cf. Neison, *Journ. Statist. Soc.*, xiv, p. 216), the average age of the class of the population corresponding to our class B will be somewhat lower than that of the classes corresponding to C, D, and E. Our inquiry has taken no account of the age at which intemperate habits began in each case. This information we feared we should fail to obtain.

⁵ Farr (*loc. cit.*): 62.76. Registrar-General (*loc. cit.*): 62.10.

⁶ Farr (*loc. cit.*): 66.06. Registrar-General (*loc. cit.*): 65.30.

It will be seen that in Table X, though there is as much as 11 years difference between the average age of Class B and that of Class E, the difference between the average age of B and that of A is reduced to 7 years. In Table XI, while the averages for B and for E are 10 years apart, those of B and A are separated by little more than 5 years.

Decades.—We have further distributed the cases occurring in each class into their respective decades, that is to say, we have classified them according as the deaths occurred in the twenties, the thirties, the forties, and so on. Tables XII and XIII show this classification; but instead of giving the aggregate numbers we have reduced them, for convenience of comparison, to percentages. In Table XII is shown the percentage of each class falling in the several decades. In Table XIII, on the other hand, is shown the percentage of each decade falling in the several classes. One centenarian occurs in Class B. This case has been included in the nineties, so as not to complicate the table.

TABLE XII.—Table of Decades, showing the Percentage of each Class falling in the several Decades.

	Twenties	Thirties	Forties	Fifties	Sixties	Seventies	Eighties	Nineties
A	19.6	15.5	15.5	17.1	9.0	13.9	7.3	1.6

Table XIV is a modification of Table XIII, with the subclasses divided and added into the adjacent classes, in the same manner as has been done in Tables IV and VI.

TABLE XIV.—The same as Table XIII, with the Subclasses Merged in their adjacent Classes.

	A.	B.	C.	D.	E.	Unclassified.
Twenties
Thirties
Forties
Fifties
Sixties
Seventies
Eighties
Nineties
Total

On inspecting Table XII we observe that in Class B the stress of deaths falls in the sixties and seventies, especially in the latter, while nearly 16 per cent. are found in the eighties.

In Class C the stress is still in the sixties and seventies; but the preponderance of the seventies is less, and the eighties are reduced to about half the percentage seen in B. The forties and fifties here begin to mount.

In Class D the stress is in the fifties and sixties, especially

the sixties; the seventies and the decades above them have been markedly reduced, and the thirties as well as the forties begin to mount.

In Class E the eighties and nineties are in very slender proportion, the seventies have again fallen considerably, and the stress now lies in the forties, fifties, and sixties, but with a strong tendency towards the forties. The thirties have again mounted.

Taking the main classes alone, we see that in the thirties, forties, and fifties, the percentage of deaths steadily mounts from B to E; in the seventies, eighties, and nineties it as steadily falls, while in the sixties it remains nearly at a level, mounting slowly from B to D, and then falling to its original amount.

In the twenties the percentages are very small in all these four classes; in C and E the percentage is equal, in D it is slightly lower, and in B a little higher.

But when we look at Class A we see (as was stated above) that the stress of deaths lies between the twenties and the fifties, and that the percentage is highest of all—in fact, all but 20 per cent.—in the twenties. The sixties and seventies together show a lower percentage here than in any other class. The eighties, however, are above those of D and E, and nearly equal to those of C, and the nineties are equal to any but those in AB.

THE INCIDENCE OF PARTICULAR FORMS OF DISEASE IN THE SEVERAL CLASSES.

We next proceed to investigate the connection of particular forms of disease with the different varieties of the alcoholic habit. This investigation must necessarily be divided into at least three parts; the deaths in youth must be considered separately from the deaths in middle life, and those again from the deaths in advanced age.

Two reasons require this division. In the first place, the same form of disease may differ altogether in its etiology according to the time of life at which it appears. A granular kidney, for example, occurring in a man of 30 will, in the majority of cases, possess an entirely different etiology to a similar lesion occurring at the age of 50.

In the second place, there are diseases which are especially prevalent in youth, diseases especially prevalent in middle life, and diseases especially prevalent in old age; but the average alcoholic habits of youth, of mid life, and of old age are very different, as will be seen at a glance by examining the headings of Tables XV, XVI, and XVII. It would, therefore, convey a totally wrong impression if the alcoholic habits of persons dying, for instance, from a disease of old age were to be compared with the average alcoholic habits of all ages together, and not with the alcoholic habits of elderly people alone.

And even further subdivision of this investigation than into three might have been advisable had the number of cases been sufficient. With those at our disposal the triple division was all that could be carried out.

We have, therefore, divided the 4,234 cases into the three following groups, each distinguished by a Greek letter: α , deaths in the young, or those aged from 25 to 40; β , deaths in the middle-aged, or those from 40 to 65; γ , deaths in the elderly, or those from 65 upwards. Group α contains 719 cases; Group β , 1,705 cases; Group γ , 1,810.

We next proceeded to construct a table for each group, classifying the cases of death from each form of disease under their respective alcoholic classes, just as has been done in Tables V and XIII.

Two difficulties had to be dealt with in this classification. The first was due to the different nomenclature employed by different contributors, on which point we shall speak further when we come to Table XV.

The second difficulty was owing to the entry, in many instances, of two or more pathological conditions against a single case. This second difficulty was treated by the observance of the following rules:—

1. If the several pathological conditions entered represented distinct and independent diseases, the case was entered under both heads. This, however, occurred in but very few instances.
2. If the second pathological condition mentioned was merely a symptom, result, or customary complication of the main one, as frequently occurred—such, for instance, as “hemiplegia” added to “apoplexy,” “dropsy” given with “heart disease,” or “gangrene” with “diabetes”—it was omitted altogether.
3. If pathological conditions were given, which, though inde-

pendent, could presumably have had no material influence in producing death—such, for instance, as “rheumatism” with “cancer”—they were omitted altogether.

In a large number of cases the diagnosis given was of a vague character, such as “abdominal tumour,” “paralysis.” These cases were classified as cases of insufficient diagnosis.

Neglecting in each group those diseases of which less than twenty instances occurred, we proceeded to construct Table XV. This table shows for each disease quoted the total number of cases in the group, and the incidence of the disease in the different alcoholic classes. The incidence is given, to facilitate comparison, in percentages instead of in the actual numbers. At the head of each group is given the percentage incidence of the whole group in the different alcoholic classes.

TABLE XV.—Table showing the Percentage Incidence of Deaths from Particular Forms of Disease in the different Alcoholic Classes for each Group— α , β , and γ .

<i>a. Deaths between 25 and 40 years of age.</i>

* Those only are given of which at least 20 examples are found in one group, α , β , or γ .

† It will, of course, be understood that “young,” “middle-aged,” and “elderly” are here used in an arbitrary sense for the purpose of convenience.

Before proceeding further we must state the meaning conveyed by the nomenclature in the first column. We take the names in alphabetical order.

Apoplexy includes all cases entered as "apoplexy," "hemiplegia," "cerebral hæmorrhage," "sanguineous apoplexy;" also, in β , 2 "paralysis and coma;" and in γ , 2 "paralytic seizure," 1 "aphasic paralysis;" 2 "congestive apoplexy;" 1 "cerebral effusion."

Arterial degeneration (in γ only) includes "calcareous degeneration of arteries," "senile gangrene," "gangrene of foot," "gangrene of leg," and 1 case termed "gangrene" only. In these cases of "gangrene" there is no wound or injury assigned as the cause. They have therefore been taken to be also senile gangrene.

Bronchitis includes "bronchitis," "acute bronchitis;" "chronic bronchitis," "capillary bronchitis," and "broncho-pneumonia;" also, in α , 1 case of "plastic bronchitis;" in β , 1 case of "catarrhal pneumonia."

Cirrhosis (in β only) includes "cirrhosis," "hypertrophic cirrhosis," "fibroid liver," "fibroid degeneration of liver;" also 2 "hepatic dropsy;" 1 "liver disease and ascites;" 1 "liver disease and dropsy;" 1 "disease of stomach and liver; anasarca."

Cystitis (in γ only) includes "cystitis," "acute" and "chronic" ditto, and "catarrh of the bladder;" also 2 cases of "bladder disease," and 1 of "paralysis of the bladder."

Diabetes (in β only) includes "diabetes" and "diabetic coma."

Diarrhœa (in γ only) includes "diarrhœa," "intestinal catarrh," "enteritis," "gastro-enteritis," and 1 case of "British cholera."

Heart disease (valve).—This is a somewhat uncertain heading. In it have been included all the cases recorded as dying of "morbus cordis," or of "heart disease," or "cardiac disease," without further qualification, as well as disease "of the valves" and its different varieties when definitely stated. In α and β "cardiac dropsy" has also been entered under this heading, though in γ we have placed it under the next; it also includes, in α , 1 "cerebral embolism;" 1 "hemiplegia from valve disease;" in β , 1 "atheroma and thickened valves;" 1 "pulmonary embolism;" in γ , 1 "cardiac apoplexy;" 2 "cerebral embolism;" 1 "cardiac embolism;" 1 "paralysis from embolism."

Heart disease (wall) includes "fatty heart," "heart degeneration," "cardiac degeneration," "cardiac failure," "heart failure," "weak heart," "senile heart and dropsy," "hypertrophy of heart," "dilated heart," "hypertrophy and dilatation," "aneurysm of heart," "rupture from dilatation;" also, in α , "cardiac bronchitis," "cardiac asthma," and "cardiac dropsy;" in β , 8 "angina pectoris;" in γ , 2 "syncope."

Intestinal obstruction (in γ only) includes "intestinal obstruction," "obstruction of bowel," "ileus," "intussusception," "stricture of ileum."

Malignant disease includes "cancer," "carcinoma," "scirrhus," "encephaloid," "epithelioma," "melanosis," "sarcoma," "malignant disease," "malignant tumour;" also, in β , 1 "lymphoma," 1 "lymphadenoma," 1 "general glandular enlargement;" in γ , 1 "lymphadenoma," 2 "rodent ulcer," 1 "stricture of œsophagus," 1 "stricture of pylorus," 1 "stricture of rectum."

Nerve decay (in β) includes "brain softening," "white brain softening," "atrophy of brain," "spinal atrophy," "nerve decay," "debility," "atrophy," "atheroma and paralysis," "brain disease and degeneration of arteries;" (in γ) includes "cerebral atrophy," "cerebral degeneration," "cerebral softening," "white" ditto, "chronic" ditto, "cerebro-spinal degeneration," "spinal atrophy," "cirrhosis of spinal cord," "atheroma of cerebral arteries," "degeneration of cerebral vessels," "general paralysis;" also 2 "old age and paralysis;" 1 "senile dementia," 1 "chronic cerebral disease."

Old age (in γ only) includes "old age," "senility," "senile debility," "senile degeneration," "senile atrophy," "senile decay," "general decay," "gradual decay," "natural decay," "decay of nature," "general decline," "general decline of bodily powers," "general debility," "debility," "exhaustion," "asthenia," "atrophy."

Pleurisy (in β only) includes "pleurisy," "pleuritis," "empyema," "pyo-pneumo-thorax" (1 case).

Pneumonia includes "pneumonia," "acute pneumonia," "pleuro-pneumonia."

Renal disease (chronic) includes "chronic renal disease," "Bright's disease," "chronic nephritis," "granular kidney," "chronic granular kidney," "gouty kidney," "renal degeneration," "cirrhosis of kidney," "fibroid degeneration of kidney," "degene-

ration of kidney;" "interstitial nephritis," "chronic desquamative nephritis," "chronic albuminuria;" also, in β , 1 "albuminuria and gout;" in γ , 1 "gout and dropsy;" 2 "albuminuria and uræmia."

Prostatic disease (in γ only) includes "prostatic disease," "prostatic troubles," "enlarged prostate," "disease of prostate," "prostatitis."

Tubercle includes "phthisis," "acute phthisis," "chronic phthisis," "laryngeal phthisis," "tracheal phthisis," "abdominal phthisis," "tuberculosis," "tubercle" of lungs, peritoneum, intestines, mesentery, and brain; also, in β , 1 "stonemasons' phthisis;" in γ , 1 "miners' phthisis."

Typhoid fever includes "typhoid fever," "enteric fever."

We have also constructed Table XVI, a modification of Table XV, made in the same manner as Table VI from Table V and Table XIV from Table XIII, by halving the subclasses between the adjacent classes.

We have also constructed Table XVII, showing the ratio of minor to major habits for each of the diseases quoted.

TABLE XVI.—The same as Table XV, with the Subclasses merged in the Adjacent Classes.

a. Deaths between 25 and 40.

TABLE XVII.—Table showing the Ratio between the Cases falling in the Lower and those in the Higher Half of the Alcoholic Scale, for the same Forms of Disease.

a. In the Young, Aged from 25 to 40.

RATIO FOR THE WHOLE GROUP α , (390 to 327,* OR) 1 TO 0.8.
 For tubercle (334 cases) 1 to 0.7
 „ typhoid fever (33 cases) 1 „ 0.7

* Where such alternative terms as "cerebral softening," "brain softening," and "softening of the brain" occur together, they are considered as identical, and one only is quoted here.

For heart-valve disease (39 cases) ...	1 to 0.8
" pneumonia (59 cases) ...	1 " 0.9
" bronchitis (20 cases) ...	1 " 1.8

β. In the Middle-aged, from 40 to 65.

RATIO FOR THE WHOLE GROUP β, (811 to 888,* or) 1 TO 1.09.

For malignant disease (116 cases) ...	1 to 0.6
" tubercle (275 cases) ...	1 " 1.0
" heart-valve disease (182 cases) ...	1 " 1.04
" pleurisy (23 cases) ...	1 " 1.09
" pneumonia (159 cases) ...	1 " 1.1
" bronchitis (144 cases) ...	1 " 1.1
" typhoid fever (21 cases) ...	1 " 1.1
" disease of heart-wall (35 cases) ...	1 " 1.1
" nerve decay (40 cases) ...	1 " 1.1
" apoplexy (111 cases) ...	1 " 1.2
" diabetes (28 cases) ...	1 " 1.3
" chronic renal disease (89 cases) ...	1 " 1.8
" cirrhosis (67 cases) ...	1 " 15.7

γ. In the Elderly, from 65 upwards.

RATIO FOR THE WHOLE GROUP γ, (1,171 to 635*, or) 1 TO 0.54

For old age and natural decay (287 cases) ...	1 to 0.36
" cystitis (32 cases) ...	1 " 0.39
" diarrhoea (32 cases) ...	1 " 0.4
" prostatic disease (34 cases) ...	1 " 0.4
" bronchitis (321 cases) ...	1 " 0.4
" apoplexy (198 cases) ...	1 " 0.5
" malignant disease (100 cases) ...	1 " 0.5
" pneumonia (82 cases) ...	1 " 0.5
" intestinal obstruction (21 cases) ...	1 " 0.5
" diseases of the heart-wall (61 cases) ...	1 " 0.6
" diseases of the heart-valves (160 cases) ...	1 " 0.7
" chronic renal disease (48 cases) ...	1 " 0.7
" nerve decay (67 cases) ...	1 " 0.7
" tubercle (35 cases) ...	1 " 0.8
" arterial degeneration (24 cases) ...	1 " 1.1

* The twelve unclassified cases are omitted from these totals.

On looking through these tables we notice the following:

Cirrhosis, in group β, shows an overwhelming preponderance of major habits, their ratio to minor habits being nearly 16 to 1. In Table XV it will be seen that no case of cirrhosis occurs lower in the scale than BC, and very few below D, and more than 65 per cent. in E and D.

The few cases that occur in α and γ tell the same tale.

There is no other disease which shows anything like such a marked preponderance of intemperate habits as cirrhosis.

Next in order, but at a long distance behind, comes chronic renal disease, which in β gives a ratio of major habits of 1.8 to 1, nearly 2 to 1, or not far from double the normal ratio of the group. In γ the ratio of major habits is also large, though less strikingly so than in β.

In Table XV it will be seen that no case in β, and few in γ, occurs below B. Even the B's are few in both β and γ.

Cases of arterial degeneration, in which term senile gangrene is included, give in γ a major habit ratio of 1.1 to 1, as against about half that ratio for the whole group. The cases however are very few.

Apoplexy, on the other hand, gives a nearly normal ratio, both in β and γ. The percentages in Table XV will be seen also to correspond pretty closely with the normals. The numbers here are large.

Tubercle gives a ratio of major habits higher than the normal in γ, but not so high in α and β. This accords with the opinion generally held that senile phthisis is induced by alcoholic excess, but that at other times of life it has a retarding influence, if any, upon the production of tubercle. We must add, however, that the aggregate of phthisis in γ is not more than 35.

Disease of the heart valves, which in advanced life is to a large extent atheromatous, shows in γ a slight preponderance of major habits as compared with the normal ratio. In α and β the ratio is practically normal.

The same applies to diseases of the heart-wall.

Mr. Butlin's conclusions as to the absence of connection between alcoholic habits and the production of malignant disease are fully borne out here, and some countenance given to the belief that the use of alcohol hinders its formation for a time. In one hundred cases of malignant disease, in Group γ, the ratio is normal, though Table XV shows that there is a slight tendency

towards careless drinking, C and BC being filled at the expense of A and B. In 116 cases in β the minor habits markedly preponderate, the ratio being nearly double the normal, and A and B in Table XV being filled at the expense of D and E.

The mortality from pneumonia is not shown by these Tables to be markedly influenced by alcohol. In α (59 cases) the ratio of minor habits is barely below the normal. In β and γ (159 and 82 cases) it is about equivalent to the normal, though in Table XV a certain tendency towards the upper columns of the scale may be detected, E being in excess in both cases, and B in β. In γ, indeed, the percentage of the decidedly intemperate is almost double that of the normal.

In typhoid fever the proportion of minor habits is above the normal in α, and equal to the normal in β. The numbers however are few.

The elderly bronchitic patients show a slightly lower ratio of major habits than the normal. The middle-aged, in Table XV, exhibit a tendency towards careless drinking. In the young the minor habits are to the major as 1 to 1.8, and the proportion of drunkards is very high. There are, however, but a bare score of cases to draw from.

Prostatic disease and cystitis, of which, however, the cases are few, show a higher ratio of minor habits than the normal in group γ, the only one in which they appear.

In the few cases of diabetes that appear, the proportion of major habits is rather higher than the normal:

As one would have surmised, the highest ratio of minor to major habits in Group γ occurs in those said to have died simply of old age or natural decay.

GOUT.

The incidence of gout in the different classes is not shown in the above tables, which include only mortal diseases. A special column, it will be remembered, was devoted to gout in the inquiry paper, the question being put in reference to each case whether the person had ever suffered from gout or not.

In 1,268 of the 4,234 cases a blank was left, the reporter not possessing the desired information.

In the remaining 2,966 the fact was stated, as requested in the inquiry paper, by an affirmative or a negative mark. These 2,966 cases, being distributed into their respective classes and sub-classes, give us the following results. The triple division into young, middle-aged, and elderly is again made in this table, the three groups being distinguished as before by the letters α, β, γ.

TABLE XVIII.—Showing the Incidence of Gout in the Different Alcoholic Classes.

Class.	α			β			γ		
	Total Cases.	Gout.	No Gout.	Total Cases.	Gout.	No Gout.	Total Cases.	Gout.	No Gout.
A ...	37	—	37	30	1	29	23	1	22
AB ...	7	—	7	9	1	8	12	1	11
B ...	180	2	178	308	21	287	603	75	528
BC ...	17	1	16	49	8	41	75	18	57
C ...	100	1	99	273	41	232	341	87	254
CD ...	8	—	8	37	7	30	33	13	20
D ...	46	4	42	181	83	118	154	75	79
DE ...	16	—	16	29	13	16	17	11	6
E ...	85	11	74	213	71	142	83	41	42

For the purpose of showing the incidence of gout in a more convenient form we have constructed Table XIX, showing in each group, α, β, and γ, the percentage of gouty cases upon the whole number reported upon in each class.

TABLE XIX.—Showing in each Group, α, β, and γ, the Percentage of Gouty Cases upon the whole number reported upon in each Alcoholic Class.

Class.	α	β	γ
A	0.0	3.3	4.3
AB	0.0	11.1	8.3
B	1.1	6.8	12.4
BC	5.8	16.3	24.0
C	1.0	15.0	25.5
CD	0.0	18.8	39.3
D	8.6	34.8	48.7
DE	0.0	44.8	64.7
E	12.9	33.3	49.3

The significance of these figures is such as hardly to require comment. We see, speaking generally, in each group the percentage steadily rising from A to E, the percentages being, as might be expected, higher in β than in α , and in γ than in β . It will be noted, however, that there is only a very slight rise from D to E, there being, indeed, a slight fall in the case of β , so that it would appear that prolonged "free" indulgence in alcoholic liquors carries the gouty tendency nearly to its height, there being no additional rise when the stage of habitual drunkenness is reached.

It must be remembered that the effects of indulgence in alcoholic liquors is here shown, not the effects of indulgence in pure alcohol. We have no information in most cases as to the kind of liquor consumed; but if the reader refers to Appendix A, he will see that the majority of the cases are reported from England and Wales, so that on the whole it is the effect of the kind of liquor consumed in England and Wales that is here shown. The same, of course, applies to Tables XV—XVII.

TUBERCLE.

A special interest attaches to the subject of tubercle, on account of the widely conflicting views held as to the action of alcohol upon the production and the progress of the disease. While some believe that alcohol takes a large share in the production of the disease, it has been taught by other authorities that exactly the reverse obtains: that drunkards and free drinkers are less liable to tubercular disease than the temperate, and that the administration of material amounts of alcohol is necessary, or at least desirable, in the treatment of the affection.

We have already seen from Table XVII that among those dying under 40 from tubercular disease the ratio of major habits is rather less than the normal of the group, that the same obtains in the middle-aged, but that among the elderly the ratio of major habits is considerably more than the normal of the group; and in Table XV we have seen that in Group α there is a slight excess of tubercle over the normal in Classes A and B, Classes D and E being deficient; while in Group β , though Class A is not in excess, Class B is markedly so, and both D and E slightly deficient.

Again, in the same Table, under the heading γ , we have seen that Class E is greatly in excess, and Classes A and B very deficient; so that it would seem, as we have above stated, that alcoholic habits were not inducive of tubercle in the young, but rather the reverse, while in the old they predisposed to the disease.

To place this most important subject in a clearer light we have taken both the total number of cases and the total number of cases of phthisis in each class for each group, and have constructed Table XXI, which shows for each group, and for each class, the percentage of individuals who have died from or with phthisis.

TABLE XX.—Showing the Distribution of the Cases of Phthisis in the Different Classes for each Group, α , β , and γ , with the Aggregate Numbers of each such Class.

Clas.	α		β		γ	
	Phthisical Cases.	All Cases.	Phthisical Cases.	All Cases.	Phthisical Cases.	All Cases.
A	22	42	7	46	0	34
AB	8	15	1	15	0	24
B	121	235	96	490	13	804
BC	7	24	5	63	0	91
C	78	148	58	393	12	436
CD	6	13	11	50	0	49
D	34	83	40	263	4	201
DE	10	22	6	50	0	28
E	48	135	50	329	6	139
Unclassified	0	2	1	6	0	4

TABLE XXI.—Showing for α , β , and γ respectively the Percentage of Individuals in each Class who Died of, or with, Tubercular Disease.

In Class	In α	In β	In γ
A	52.3 per cent.	15.2 per cent.	—
AB	53.3	6.6	—
B	51.4	19.5	1.6 per cent.
BC	29.1	7.9	—
C	52.7	14.7	2.7
CD	46.1	22.0	—
D	40.9	15.2	1.9
DE	45.4	12.0	—
E	35.5	15.1	4.3
Total	46.5	16.1	1.9

Here we see that among the young the percentage remains practically the same until Class C is reached, that it then falls somewhat rapidly, the percentage in E being but two-thirds of that in A.

In β the percentages are irregular, but on the whole they are nearly the same for the five main classes, B being somewhat in excess.

In γ we have no cases in A or AB, and the percentage is three times as great in E as it is in B. The numbers here, however, are very small.

On the whole, the results we have obtained certainly give some countenance to the belief that as regards the young alcoholic drinks act as a preventive of tubercle; but as regards the old they appear to favour the contrary opinion. In the middle-aged the two principles of action appear to neutralise each other.

CHRONIC RENAL DISEASE.

It has been suggested that the influence of alcoholic beverages in the production of renal disease, which we believe ourselves to have ascertained, is of a secondary character, the kidney lesion being due to gout, which, as we have seen, is strongly induced by alcoholic liquors. In order to bring this as far as possible to the test, we have taken from the list of cases of chronic renal disease those in which the existence or non-existence of gout is stated. We have distributed these into a table (Table XXII) constructed on the exact plan of Table XVIII. This table shows the incidence of gout for the different alcoholic classes in cases dying of or with chronic renal disease alone. The numbers are very few, but, nevertheless, we have translated them into percentages (Table XXIII) for the sake of comparison with Table XIX.

TABLE XXII.—Showing the Incidence of Gout for the different Alcoholic Classes in cases of Chronic Renal Disease.

	α			β			γ		
	Total.	Gout.	No Gout.	Total.	Gout.	No Gout.	Total.	Gout.	No Gout.
A
AB
B	2	...	2	11	3	8	11	4	7
BC	3	...	3	3	1	2
C	2	...	2	9	3	6	6	5	1
CD	1	...	1
D	11	7	4	4	3	1
DE	3	1	2
E	1	...	1	10	3	7	2	2	...

TABLE XXIII.—Showing in each Group α , β , and γ , the percentage of Gout Cases upon the whole number reported on in each Alcoholic Class of cases of Chronic Renal Disease.

	α	β	γ
A
AB
B	0.0	27.2	36.3
BC	...	0.0	33.3
C	0.0	33.3	83.3
CD	...	0.0	...
D	...	63.6	75.0
DE	...	33.3	...
E	0.0	30.0	100.0

Allowing for the very possible fallacy involved in the smallness of the numbers treated, Table XXIII certainly seems to bear out the supposition above alluded to, for the percentages of the main groups almost throughout are very considerably higher than those in Table XIX.

SUMMARY.

On the whole, then, in addition to the information that we obtain from these returns as to the alcoholic habits of the inhabitants of this country, and as to the relative alcoholic habits of different occupations and classes, we may not unfairly claim to have placed upon a basis of fact the following conclusions:

1. That habitual indulgence in alcoholic liquors beyond the most moderate amounts has a distinct tendency to shorten life, the average shortening being roughly proportional to the degree of indulgence.
2. That of men who have passed the age of 25, the strictly temperate, on the average, live at least ten years longer than those who become decidedly intemperate. (We have not in these returns the means of coming to any conclusion as to the relative duration of life of total abstainers and habitually temperate drinkers of alcoholic liquors.)
3. That in the production of cirrhosis and gout alcoholic excess plays the very marked part which it has long been recognised as

doing; and that there is no other disease anything like so distinctly traceable to the effects of alcoholic liquors.

4. That, cirrhosis and gout apart, the effect of alcoholic liquors is rather to predispose the body towards the attacks of disease generally than to induce any special pathological lesion.

5. That in the etiology of chronic renal disease, alcoholic excess, or the gout which it induces, probably plays a special part.

6. That there is no ground for the belief that alcoholic excess leads in any special manner to the development of malignant disease, and some reason to think that it may delay its production.

7. That in the young alcoholic liquors seem rather to check than to induce the formation of tubercle; while in the old there is some reason to believe that the effects are reversed.

8. That the tendency to apoplexy is not in any special manner induced by alcohol.

9. That the tendency to bronchitis, unless, perhaps, in the young, is not affected in any special manner by alcoholic excess.

10. That the mortality from pneumonia, and probably that from typhoid fever also, is not especially affected by alcoholic habits.

11. That prostatic enlargement and the tendency to cystitis are not especially induced by alcoholic excess.

12. That total abstinence and habitual temperance augment considerably the chance of a death from old age or natural decay, without special pathological lesion.

It is very greatly to be regretted that the returns to this inquiry were not very numerous than they actually were. The conclusions drawn from the inquiry would have had much more weight had we been able to base them upon an aggregate of ten or twenty thousand cases, instead of four thousand and odd only.

Should the publication of this report arouse sufficient fresh interest in the subject it would be possible to reissue the inquiry; but the Collective Investigation Committee would not feel justified in doing so without some decided expression of opinion by the members of the Association that the reissue should be made.

I have much pleasure in thanking Mr. Frederick Hendriks, F.S.S., Actuary of the Universal Life Assurance Society, and Mr. Frank B. Wyatt, Actuary of the Clergy Mutual Society, for information and references which they have afforded me, and in acknowledging the valuable aid rendered me throughout by my assistant, Mr. Joseph Perrott.

APPENDIX B.—DISTRIBUTION OF THE 118 CASES IN WHICH THE ALCOHOLIC HABITS WERE STATED TO HAVE BEEN CHANGED DURING LIFE.

The *Italic Titles* indicate the healings under which the cases come in Tables XI, XVI, and XVII. Cases not included in these Tables have no italic title given. A capital G. signifies that the Patient was reported to have suffered from Gout, the figure 0 that he was stated not to have so suffered.

GROUP A.	
In Class B (235 cases) are included two:—	
Age 31, Pneumonia (<i>Pneumonia</i>), 0	C the last 6 months
36, Phthisis (<i>Tubercle</i>), 0	A the last 3 years
In Class C (148 cases) are included three:—	
Age 29, Phthisis (<i>Tubercle</i>), 0	F previously
39, Urinary Fistula and Phthisis (<i>Tubercle</i>), 0	B the last 6 years
38, Cardiac Asthma and Bronchitis (<i>Disease of Heart</i> Wall), 0	D previously
In Class D (83 cases) are included five:	
Age 32, Enteric Fever (<i>Typhoid Fever</i>), 0	F lately
35, Locomotor Ataxy, 0	E at times
28, Phthisis (<i>Tubercle</i>), 0	B lately
29, Emphysema (<i>Pleurisy</i>), 0	B the last 4 years

Age 34, Phthisis (<i>Tubercle</i>), 0	B the last 3 years
In Sub-class DE (22 cases) one is included:				
Age 35, Meningitis from Injury, 0	E previously
In Class B (135 cases) are included three:—				
Age 27, Pneumonia and Delirium Tremens (<i>Pneumonia</i>), 0	D till last 3 years
.. 27, Phthisis (<i>Tubercle</i>), 0	A the last year
.. 35, Hepatic Disease, 0...	A the last year
GROUP B.				
In Class A (46 cases) one is included:—				
Age 44, Phthisis (<i>Tubercle</i>), 0	B till last 7 years
In Class C (393 cases) are included twelve:				
Age 61, Cardiac Degeneration (<i>Disease of the Heart Wall</i>), 0	B the last 5 years
.. 60, Albuminuria, 0	B lately
.. 59, Hematemesis, Liver Disease, G.	D previously
.. 49, Bronchitis, Renal Dropsy, G.	D at times
.. 57, Bronchitis, Asthma, Pleuro-pneumonia (<i>Bronchitis</i>), G.	D previously
.. 49, Phthisis, Pleuro-pneumonia (<i>Tubercle</i>), G.	D previously
.. 62, Diabetes, Bright's Disease, Carbuncle (<i>Diabetes</i>), 0	B the last 6 years
.. 49, Epilepsy, Apoplexy (<i>Apoplexy</i>)	B lately
.. 49, Chronic Desquamative Nephritis, Uremia (<i>Chronic Renal Disease</i>)	B lately
.. 58, Renal Cancer (<i>Malignant Disease</i>), 0	A the last 2 years
.. 50, Chronic Bright's Disease and Dilatation of Heart (<i>Chronic Renal Disease</i>), G.	A the last 4 years
.. 59, Heart Disease (<i>Disease of Heart Valves</i>), G.	B the last 3 years
In Class D (263 cases) are included twelve:—				
Age 45, Epilepsy, G.	E at times
.. 54, Cancer of Stomach, Extreme Atrophy (<i>Malignant Disease</i>), G.	E at times
.. 61, Bright's Disease (<i>Chronic Renal Disease</i>), G.	E the last 4 years
.. 59, Fatty Heart, Congestion of Lungs, Dropsy (<i>Disease of Heart Wall</i>), 0	B the last 9 years
.. 55, Pyæmia, 0	A the last 2 years
.. 63, Mitral Disease, Anasarca (<i>Disease of Heart Valves</i>), 0	B lately
.. 81, 0	E till last 20 years
.. 58, Chronic Granular Kidney, Uremia (<i>Chronic Renal Disease</i>), G.	bc lately
.. 47, Paralysis from Injury, Cystitis, 0	B the last 3 years
.. 94, Miners' Lung and Dropsy, 0	B the last 4 years
.. 51, Phthisis (<i>Tubercle</i>), 0	A lately
.. 45, Erysipelas, Pyæmia, 0	B the last 3 years
In Sub-class DE (50 cases) are included two:—				
Age 63, Chronic Bronchitis (<i>Bronchitis</i>)	bc lately
.. 63, Chronic Liver Disease, Strangulated Hernia (operation), Diarrhoea, Exhaustion	B lately
In Class E (329 cases) are included fourteen:—				
Age 56, Cancer of Liver (<i>Malignant Disease</i>), 0	D till last 2 years
.. 62, Heart Disease (<i>Disease of Heart Valves</i>), G.	D till last 10 years
.. 51, Bronchitis (<i>Disease of Heart Valves</i>), G.	A the last 6 months
.. 52, Pyæmia, G.	B the last 2½ years
.. 41, Pneumonia (<i>Pneumonia</i>)	A lately
.. 53, Chronic Disease of Stomach and Liver (?) Cirrhosis, G.	B the last 6 years
.. 62, Sanguineous Apoplexy, Syphilis (<i>Apoplexy</i>)	A the last 12 years
.. 58, Bronchitis (<i>Bronchitis</i>), 0	B the last 2 years
.. 43, Epilepsy	D previously
.. 57, Cancer of Stomach, Perforation (<i>Malignant Disease</i>), 0	A the last 5 years
.. 41, Chronic Phthisis (<i>Tubercle</i>), 0	B the last 2 years
.. 62, Phthisis (<i>Tubercle</i>), 0	B the last 4 years
.. 54, Pneumonia (<i>Pneumonia</i>), 0	D lately
.. 60, Congestion of Liver, Asthma, Bronchitis, 0	A the last 10 years
GROUP Y.				
In Class A (34 cases) are included two:—				
Age 80, Old Age, Paralysis, 0	E lately.
.. 71, Bright's Disease (<i>Chronic Renal Disease</i>)	B lately
In Class B (804 cases) are included three:—				
Age 75, Chronic Bright's Disease (<i>Chronic Renal Disease</i>)	E the last 11 months
.. 73, Enlarged Prostate, Acute Cystitis (<i>Prostatic Disease</i>), 0	A till last 10 years
.. 86, Old Age (<i>Old Age</i>), 0	C previously.
In Sub-class bc (91 cases) one is included:—				
Age 78, Apoplexy (<i>Apoplexy</i>), 0	B the last 3 years.
In Class C (436 cases) are included eight:—				
Age 79, Senile Decay, Partial Hemiplegia (<i>Apoplexy</i>)	E lately
.. 73, Heart Disease, Bronchitis (<i>Disease of Heart Valves</i>)	B the last 4 years
.. 78, Gradual Decay, Bronchitis (<i>Bronchitis</i>), G.	B lately
.. 77, Dyspepsia, General Decline (<i>Old Age</i>)	D lately
.. 80, Deranged Liver, Weak Heart, G.	B lately
.. 65, Bronchitis (<i>Bronchitis</i>), 0	B lately
.. 74, Brain Softening (<i>Nerve Decay</i>), G.	B the last 10 years
.. 77, Senectus (<i>Old Age</i>), 0	A lately.
In Sub-class cd (49 cases) are included two:—				
Age 69, Mania (Inherited), 0	bc previously
.. 67, Fatty Heart, Hemiplegia, 0	B the last 10 years.
In Class D (201 cases) are included eight:—				
Age 69, Paralysis, G.	A the last 3 years
.. 70, Anthrax, Diarrhoea	E lately
.. 60, Cirrhosis of Liver, G.	R previously
.. 71, Cardiac Disease (<i>Disease of Heart Valves</i>), G	B lately
.. 63, Fatty Degeneration, Mitral Disease of Heart (<i>Disease of Heart Valves</i>), 0	C the last 3 years
.. 66, Phthisis (<i>Tubercle</i>)	B lately
.. 74, Chronic Bronchitis, Heart Disease, Kidney Disease (Bright's), Dropsy (<i>Chronic Renal Disease</i>), G.	B lately
.. 75, Bronchitis (<i>Bronchitis</i>), G.	B the last 5 years.

In Sub-class DE (28 cases) one is included:—				
Age, 71, Chronic Bright's Disease, Heart Disease (<i>Chronic Renal Disease</i>)	B lately
In Class E (139 cases) are included twenty-six:—				
Age, 68, Pneumonia (<i>Pneumonia</i>), 0	D previously
.. 77, Cystitis (<i>Cystitis</i>), G.	D previously
.. 67, Leucocythæmia, Dyspnoea, 0	B the last 4 years
.. 70, Bronchitis (<i>Bronchitis</i>), 0	B the last 3 years
.. 70, Heart Disease, Hypertrophy of Left Ventricle (<i>Disease of Heart Valves</i>), 0	B the last 3 years
.. 65, General Paralysis (<i>Nerve Decay</i>), 0	B the last 5 years
.. 79, Rheumatic Arthritis	B lately
.. 70, Chronic Disease of Stomach and Bowel, G.	D lately
.. 91, Senile Decay (<i>Old Age</i>)	C lately
.. 73,	B lately
.. 76, Congestion of Lungs, Heart Disease (<i>Disease of Heart Valves</i>)	B lately
.. 71, Hepatitis, Pneumonia, G.	D lately
.. 72, Albuminuria, 0	B lately
.. 67, Apoplexy (<i>Apoplexy</i>), 0	D the last 5 years
.. 72, Bronchitis (<i>Bronchitis</i>)	B the last 10 years
.. 80, Chronic Bronchitis (<i>Bronchitis</i>), 0	A the last 3 years

APPENDIX C.—PREVIOUS WORK IN THE SAME DIRECTION.

Two inquiries had previously been conducted upon somewhat similar lines; one by Mr. Neison, about forty years ago, and one by the Harveian Society of London in 1879 and 1880.

Mr. Neison's paper On the Rate of Mortality among Persons of Intemperate Habits was read before the Statistical Society on June 16th, 1851, and published in Volume xiv of its journal, pages 200 et seq.

Mr. Neison's inquiry concerned only persons of decidedly intemperate habits, corresponding as far as possible to our Class E., the rate of mortality of whom he compared with the general rate for England and Wales. He did not take account, as our inquiry has done, of the minor degrees of the alcoholic habit. He included women as well as men. His inquiry paper particularly asked for a statement as to the duration of intemperance in each individual, an essential point for the purpose he had in view. He also inquired, and apparently obtained information, as to the kind of liquor taken.

Mr. Neison obtained and classified 357 complete cases, comprising 6,111.5 years of life during which intemperance was practised. In the result he showed that the rate of mortality among the intemperate was more than five times that of the general community between the ages of 21 and 30; more than four times as great from 31 to 50; nearly three times as great from 51 to 60; about twice as great from 61 to 80; and equivalent to it from 81 to 90.

Proceeding further, he showed that the equal chances of life of temperate and intemperate persons might be compared at different ages as in the following table.

At Age	An Intemperate Person has an equal chance of living to	A Temperate Person has an equal chance of living to
20	35.6 years	64.2 years
30	43.8 "	66.5 "
40	51.6 "	71.3 "
50	60.8 "	74.3 "
60	68.9 "	

We have no direct means of comparing these results with our own, as the exact duration of the intemperate habit in each case was not asked for in our inquiry, which was not primarily designed with a view to vital statistics. We have been able only to reckon the average age at death of all individuals entered in

each alcoholic class. We have, however, extracted from Mr. Neison's Table I the aggregate age of the 347 individuals in his schedule who died over the age of 25, and have struck an average, which comes to 47.54 years, that is to say five years less than the average furnished by our Class E. The comparison, however, is not even yet a fair one, as Mr. Neison's schedule contains an unnamed proportion of women, who, on his showing, suffer more severely under the abuse of alcohol than men. It is doubtful, however, if the elimination of the female element would add more than two years at the outside to the average age at death of Mr. Neison's cases, and this would leave it still three years less than the average of our Class E. It is more than possible that in the earlier half of this century intemperance implied a much greater consumption of alcoholic liquor than it does in its ninth decade.⁹

Mr. Neison also found that the intemperate use of spirits was more hurtful than the like use of beer, but that immoderate indulgence in both was more injurious than the exclusive use of either. "Mechanics, working and labouring men," according to his figures, withstood the effects of intemperance better than "traders, dealers, and merchants," the latter better than "professional men and gentlemen," and all better than women.

As regards diseases, he found that "head diseases" (diseases of the nervous system) among the intemperate were greatly in excess of the general average. It must be noted, however, that more than half of this category is made up by delirium tremens. In our returns delirium tremens played a very much smaller part, so small, indeed, that it did not obtain admission as a distinct category into Table XV. This perhaps may be also a result of the diminished use of alcohol even among the intemperate since the year 1851. "Diseases of the Digestive Organs," a category which is somewhat largely made up of "liver disease and dropsy," "ascites," and "atrophy" of the liver, also showed a great excess. "Diseases of the respiratory organs" were relatively deficient; "phthisis" and "decline" do not appear to be in excess.

The Harveian Society appointed a committee in the early part of 1879 to investigate the extent of the mortality referable to alcohol, and its proportion to the mortality from all causes; the proportion in which it is distributed between the two sexes; the ages at which, and the occupations in which, it chiefly occurs; and the modes of death (*Report*, par. 2).

The plan of the inquiry paper, which the Committee sent to all general practitioners in London, was closely similar to that which our Committee adopted, but women were included as well as men.

The reporters were, as in our inquiry, requested to fill up the preliminary columns from the counterfoils of their death-certificate books. They were then requested to refer each case, if possible, to one of three categories: (A) Deaths in no wise due to alcohol, (B) deaths accelerated or partly caused by its abuse, and (C) deaths wholly due to it (*JOURNAL*, 1880, i, p. 177. *Report*, par. 12).

There is a somewhat odd confusion between facts and theories in the definition of these categories, but there is no doubt that a great deal of valuable information was obtained by means of the inquiry. Reports of 7,505 cases were obtained from private practice, which, with the addition of 1,172 infirmary and asylum cases, 646 hospital, and 677 inquest cases (about the normal proportion for London) brought the total of deaths up to 10,000 (*Report*, par. 10).

The Report of the Committee was published in the *JOURNAL* of January 20th, 1883, pp. 97 *et seq.* According to this report alcohol was stated to play some part in the causation of about 13 per cent. of all adult deaths, from 1½ to 4 per cent. appearing to be directly due to its action (pars. 15, 20). Females and males were nearly in normal proportion in the whole number of cases; but in Class B the males were nearly twice as numerous as the females; in Class C only about as 5 to 3. The Committee concluded that severer forms of intemperance were relatively more prevalent among women than the minor forms (par. 21).

The deaths in B were found to have taken place at an earlier

age, and those in C at a much earlier age than in A. Three-fourths of Class C and two-thirds of Class B had died between the ages of 50 and 60, the normal proportion for the adult population being somewhat about one-half (par. 22).

The information obtained as to occupations only sufficed to show the preponderance of publicans in B and C (par. 24).

As regards the modes of death, the Committee reported: "We find, therefore, upon the whole, reason to think that, in the metropolis, the mortality among any considerable group of intemperate persons will differ from that generally prevailing among adults in the following important particulars—namely, a fourfold increase in the deaths from disease of the liver and chylipoietic viscera; a twofold increase in the deaths from disease of the kidney, a decrease of half as much again in those from heart disease, a marked increase in those from pneumonia and pleurisy, a considerable increase and an earlier occurrence of those from disease of the central nervous system; a marked decrease in those from bronchitis, asthma, emphysema, and congestion of lungs; a decrease nearly as great in those from phthisis, and a later occurrence, or at least termination, of the disease; a very large decrease in those from old age, with an increase in those referred to atrophy, debility, etc.; and the addition of a considerable group referred in general terms to alcoholism or chronic alcoholism, or resulting from accidents" (par. 45).

The Committee's conclusions under this head roughly correspond with our results as regards diseases of the liver, kidney, and nervous system, and also as regards old age and phthisis, but not as regards diseases of the heart, pneumonia, bronchitis, etc., "atrophy" and debility.

I have found no statistics supplying the deficiency of our results as regards a comparison between the longevity of total abstainers and moderate drinkers respectively. I am informed that the experience of the United Kingdom Temperance and General Provident Institution is undoubtedly favourable to the abstainers as compared with the rest of the community, but no detailed report has, I believe, been published.

I extract the following from *The Insurance and Finance Leader* of May, 1888.

"In his speech at the recent annual meeting of the Whittington. Mr. Bowser made some interesting remarks regarding the question of Temperance sections in Insurance Companies that are worth quoting. The experience of the Company since the last valuation and bonus in 1884 was that the rate of mortality in the ordinary section was 16.35 per 1,000 per year, while the rate in the Temperance section was 8.74 per 1,000 per year.

"But," he said, "as the lives assured in the Temperance section are somewhat younger than in the other, because they commence the provident habit of paying for life assurance at an earlier age than others, I have separated those above thirty years and under fifty, and I find the difference not so much in favour of the Temperance section, but still considerable. I find the rate in the ordinary section is 10.05 per 1,000; in the Temperance section, 6.72 per 1,000."

"Then, going deeper into the subject as to the causes of death, Mr. Bowser found that:

"More than one-fourth of the whole number of deaths amongst the assured arises from various affections of the lungs and respiratory organs. The proportion in the Temperance section is slightly in excess of the ordinary section. About one-eighth of the deaths arise from various affections of the brain. Here, again, the mortality in the Temperance section is slightly in excess of the other. These two causes of death seem to show that the practice of teetotalers has but little influence on the rate of mortality from these causes. But when we come to the affection of the heart, of the stomach, of the liver, and of the kidneys, then the difference is most serious indeed. In the ordinary section the number who die of heart affections is nearly three times as many as those in the Temperance section, but of those who die of diseases of the stomach, of the kidneys, and kindred diseases, etc., the proportion is four times as many as those who die from the same causes in the Temperance section; still more, against the proportion of 32 per 1,000 persons in the ordinary section who have died directly of liver diseases, not one has died of such affections in the Temperance section. Again, the deaths by accidents of various kinds (including suicide) are in the proportion of one in the Temperance section, against thirteen in the ordinary section. These statistics are gathered from a number of assured lives; persons known to be intemperate are absolutely excluded when proposed for life assurance."

⁹ "During the last quarter of a century, the drinking practices of society have much altered, and what is now commonly regarded as free living, would have some years since been looked upon as only moderation; so, in like manner may it be hoped that the usages of society will continue to improve, and, at no distant date, the habits now considered not to exceed the bounds of moderation be altogether unknown in polite and refined society. It is, therefore, possible that what has hitherto been regarded as intemperate habits, may differ very widely from that which may be looked upon as intemperate some years hence." Neison. *Loc. supra cit.*, page 201.

Dr. Casey has sent me the following table, exhibiting in parallel columns the comparative drinking habits of certain occupations as shown by our Report and the comparative mortality of males in the same occupations at the ages 25 to 65, as given by Dr. William Ogle in the *Supplement to the Forty-Fifth Report of the Registrar-General*, p. xxv. The figures in the first column are the percentages of the less temperate in each occupation, drawn from our Tables VI and VII and compared with the general percentage taken as 100. Those in the second column are from Dr. Ogle's table, the general mortality being reckoned as 100 instead of 1,000.

The figures in the second column for weavers, miners, and "driving occupations" are rough estimates only, as these categories are divided by Dr. Ogle into groups, of which the relative proportions are not ascertainable.

Dr. Ogle's figures are drawn from the returns for 1880-2.

	Ratio of the less Temperate. 100 = average.	Comptve. Mortality at ages 25-65 (Ogle). 100 = General Mort. of Males at same ages.
Clergymen, etc. ...	19	55.6
Schoolmasters ...	63	71.9
Weavers ...	69	94.2 (?)
Gardeners ...	71	59.9
Agricultural labourers ...	71	70.1
Shoemakers ...	71	92.1
Tailors ...	76	105.1
Medical men ...	82	112.2
Carpenters ...	88	82.0
Blacksmiths ...	104	97.3
Lawyers ...	110	84.2
Painters ¹ ...	111	120.2
Masons and Bricklayers ² ...	118	96.9
Miners ...	126	110.0 (?)
Commercial travellers ³ ...	148	94.8
Driving trades ⁴ ...	146	118.4 (?)
Butchers ...	165	117.0
Publicans ⁵ ...	181	152.1

¹ Plumbers and glaziers are included by Dr. Ogle, not by the Collective Investigation Committee.

² Builders are included by Dr. Ogle, not by the Collective Investigation Committee.

³ Probably many travellers retire before advanced age.

⁴ Grooms are included by Dr. Ogle, not by the Collective Investigation Committee.

⁵ Potmen, barmen, etc., are included by the Collective Investigation Committee in its "Licensed Victualling" group. Dr. Ogle makes a separate category of "Inn and Hotel Servants," with a comparative mortality of 220.5.

THE RELATION OF ALCOHOLISM TO INEBRIETY.

BY NORMAN KERR, M.D., F.L.S.

ALCOHOLISM is a term which has been somewhat loosely employed. It has been applied by some almost at random to designate all drinking (moderate or immoderate), or any kind of intoxication. By others its scope has been restricted to the mental and moral perversion (apart from the physical degradation) consequent on excessive drinking. Confusion has arisen probably from ignorance. Only within recent years has there been clearly revealed the existence of the disease of inebriety, a disease often associated, but sometimes altogether unconnected, with alcohol. It may, therefore, be useful to direct attention to the distinction between alcoholism and inebriety.

Alcohol is an irritant narcotic poison, and the term alcoholism should be applied only to the toxic phenomena directly or indirectly arising from the action of that poison on body and brain. This would include acute alcohol poisoning (fatal or non-fatal) and chronic alcohol poisoning. Under this designation would be comprised all the functional disturbances and tissue degenerations produced by alcoholic inebriating drinks in various doses, the vitiation of the blood, the circulatory tumult, the nervous perturbation, the vasomotor paralysis, the cerebral automatism, with the incomplete paralysis (with or without unconsciousness) of transient alcoholic excitement; as well as the tremors of delirium tremens, the madness of *mania a potu*, the depraved digestion, the cerebro-spinal paralysis, the delusions, and the insanity of more permanent and graver alcoholic lesions. Under the term alcoholism would also be ranged the mental and moral depravities induced by the toxicating agency of alcoholic inebriants, the selfishness, untruthfulness, cunning, and deceit of the alcohol inebriate, as well as the transmitted proclivities to excess, instability of brain, and feeble will-power begotten of the alco-

holic inheritance. In most cases of alcoholism of long standing there are fatty or other degenerations of the liver, kidneys, heart, brain, and other organs.

Inebriety, on the other hand, is a disease of the higher nerve centres, allied to insanity, which may or may not be of alcoholic origin. It consists of an intense morbid impulse to, or crave for, not intoxicants, but intoxication. The intoxicant consumed may be any narcotic which has an anæsthetic effect. It is this benumbing, this prompt, even if evanescent, satisfaction of an abnormal or unhealthful impulse or crave for relief which is sought after. The intoxicant is the agent by which this fleeting relief is obtained, the particular drug resorted to being determined by the idiosyncrasy of the patient, the narcotic to which he has had access, or which is in common use where he lives, or other conditions. Inebriety is, therefore, a true intoxication mania, or, as I propose to call it, narcomania, that is, a mania for narcotism.

Inebriety or narcomania assumes varied forms. As regards the inebriant, it may be alcohol, opium, morphine, chloral, chloroform, ether, chlorodyne, or cocaine inebriety, the second, third, fourth, and fifth forms being considerably on the increase amongst us. Cocaine inebriety I have seen only a few cases of. Inebriety the disease may be constant or periodic, social or solitary. There are periodicities of function, of nerve energy, of time, of occupation, of climate, of season, and of occasion. Under a third classification of complicatory disorders we have the inebrieties of insanity, of syphilis and other diseases, of convalescence from fevers, of heat apoplexy, of operations, of head or other injuries (traumatic inebriety), and of nerve shock generally. The most striking differences are between alcoholomania and opiomania or morphinomania. Alcoholic inebriety is both organic and functional. The opiate form is a disease of function, no such unmistakable organic lesions having been observed as with alcohol. Again, alcohol maddens, while opium as a rule soothes. The lower animals are easily affected by alcohol, while many of them can live and thrive on opium. Alcoholists, too, are more untruthful. There is a wide difference also in the therapeutic treatment of these two forms of the disease. With alcohol, the sudden withdrawal of the toxic agent is safe, with opium usually unsafe.

The etiology and pathology of inebriety of all types is a profound and intricate study. Some progress has been made, but much is yet unknown. The state of alcoholic trance, for example, is one of grave import, and has as yet met with scanty recognition. This obscure and extraordinary phenomenon of inebriety has been known to include voyages and travels of weeks' duration, the subject of this diseased condition sometimes fully awaking to consciousness only to find himself in a foreign country, though he had been able to speak and act automatically to all appearance like other people around him. A knowledge of the various causes exciting and predisposing to inebriety is essential to enable a successful method of cure to be devised, this disease being as curable as most other diseases. The alcoholic is, therefore, but one of many forms of inebriety, which latter is a constitutional disease of the nerve centres which may be altogether non-alcoholic in its inception.

The disease of inebriety may be either inherited or acquired. In the former case, the transmitted disease may be latent, not a single inebriate outbreak occurring in a lifetime.

All drunkards are not subjects of the inebriate diathesis. There are those who drink from sheer "cussedness." They drink, as they bet, simply in pursuit of pleasure, their pleasure consisting in aiming at every questionable indulgence. Such cannot be deemed diseased persons, at least at the outset of their alcoholic career, but even in their case a chain of abnormal symptoms of pathological degradations may ultimately establish a state of true disease.

There may be alcoholic inebriety without what may be called the coarser manifestations of alcoholism. In some cases of intractable alcoholic inebriety, no organic lesions of any consequence have been visible after death, and no symptoms of disordered digestion, visceral derangement, or other organic function have been observed during life. The nervous affection has apparently been the only departure from health. There may thus be alcoholic drunkenness with no true inebriety, and inebriety or narcomania with no actual intoxication by alcohol.

DR. CUMMING said it was impossible to enter into the consideration of the enormous amount of facts just laid before them by Dr. Owen. He was, however, not quite sure that Dr. Owen was justi-

fied in dealing as he had done with the comparative tables of longevity in the total abstinence class. It did not convey to his mind anything that really threw doubt on the fact as stated. He was not in favour of alcohol, and, even if he were, he would hesitate to express such an opinion in the presence of Dr. Norman Kerr. He suggested that children who took alcohol were probably not the stronger and more robust, as surmised by Dr. Owen, but rather the weaker among them. The second point was in reference to the etiology of gout as a consequence of intemperance. He was inclined to think that Dr. Owen's statistics must have been drawn largely from England. Irish experience was that gout was not frequently the result of alcoholic indulgence. It was probably rather a consequence of drinking certain beverages of alcohol, and not of alcohol itself.—Dr. MARTIN (of Portlaw) said, as regards the etiology of gout, he could name family after family in which the members were perfectly temperate, but whose ancestors were notorious for their drinking habits, yet their descendants were gouty. In those days the principal drink was French wine. In the lower classes gout was a disease rarely met with.—Dr. NORMAN KERR expressed his regret that Mr. Owen's paper had been read immediately after his—their aim being essentially different. He pointed out that the whole number of cases observed did not exceed 4,234, a much smaller number than many on which others had declined to draw dogmatic conclusions in times gone past. The total death-rate for this country was upwards of 7,000, and to come to any conclusion whatever with regard to the mortality of alcoholism in so small a number would be contrary to scientific accuracy. They could only be tentative, and some of them would have to be revised. He had carried out several inquiries on this subject, and he had never come to any other conclusion than that there were at least 40,000 deaths due directly to alcoholic intemperance, and at least double that number due to it indirectly. This had been borne out by the researches of the Harveian Society, which dealt with 10,000 observations, more than double the number of to-day. Whatever the value of these conjectures might be, there were those independent series of investigation by the Harveian Society, by Dr. Owen and by himself, which all seemed to point to about the same number of deaths due to alcohol. With regard to the statistics now before them, he would make one or two observations. With respect to soldiers, he was happy to say that a large proportion of them were abstainers; some 12,000 in the Indian army, and probably not less than one in seven at home. The probable mortality was shown by the life-tables of the insurance companies. These companies had to do with hard facts, and they showed a difference in favour of abstainers to the extent of 25 per cent. He took exception to the assertion that alcoholic excess did not produce pathological conditions. [Dr. Owen explained that his conclusion was that alcohol did not kill so much by producing one or two pathological conditions, but by rendering the body liable to pathological conditions all round.] He (Dr. Kerr) still objected even to that assertion, because a great many of these cases of death were produced by alcoholic excess, although not so stated in the certificate—bronchitis, pneumonia, apoplexy, etc., for instance. With a large experience of work in London, he was certain that alcoholic excess did produce death directly. There were a certain few—phthisis, for example—which were caused by alcohol. At the same time, alcoholic indulgence undoubtedly predisposed to disease. With regard to gout, he would say that he had only been able to find one case of gout in a life teetotaler.—Dr. DRUMMOND asked what form of phthisis Dr. Kerr considered was due to the use of alcohol.—Dr. KERR, in reply, referred Dr. Drummond to a monograph on the subject by Dr. Richardson.—Dr. DRUMMOND said he thought some answer to this question should be given, for he did not think it ought to go forth that they admitted that there was a special form of phthisis due to alcoholic indulgence.—Professor GAIRDNER said that Dr. Owen's manipulation of his facts was beyond all praise. He would, however, like to allude to a fact that had not been mentioned by Dr. Owen, and he hoped it might be introduced in the form of a footnote or otherwise. Dr. Norman Kerr had said that there was a form of alcoholic phthisis, but that he was disposed to deny. He did not deny that alcohol might have a good deal to do with phthisis, but he was not prepared, from anything he had seen himself, to say that there was any particular form of tubercular disease attributable to alcohol. He did not think one could, by examining a man, either alive or dead, find anything in his lungs to denote that he had been a drunkard. On the other hand, quite an opposite opinion prevailed, and, having to teach this subject to

students, he was obliged to be very careful to allude to only what he knew himself on the subject, and that was remarkably little. He had, however, put before them statements which had been confidently put forward that phthisis was positively restrained by the use of alcohol, not only in moderation but in excess. He had avoided touching on this, in the absence of absolute proof, and he should be glad of some information bearing on this subject. It professed to be based on a large number of observations. At all events, it was connected with the examination of a large number of persons who had died of drink diseases, and in whom they very rarely found tuberculous disease. He said that was a very curious fact if it were true, and he had little doubt that it was so. Persons who died of "gin-drinker's liver," or other well-defined disease of alcoholic origin, were very rarely tubercular. From this it had been inferred that alcohol was a preventive of tuberculosis; but he thought this subject ought to be studied with this opinion full in view. He thought it, however, quite possible that tuberculous persons were less disposed to alcoholic indulgence than others. He alluded to the story told of an old relation of Lord Eldon, who was a gentleman of the olden times, and a firm believer in the virtues of toddy, alluding to a rising young man, he was wont to observe: "He's a guid young fellow; but he's nae right. He canna tackle his drink." That led him to suppose that youths who could not "tackle their drink" were probably wanting in physique.—Surgeon-Major GUNN had no hesitation in saying that many soldiers fell victims to a form of phthisis directly due to the use of alcohol.—Dr. GILBERT SMITH said he had been working for fifteen years in the out-patient department of the Hospital for Consumption, and nearly as long in the out-patient room of the London Hospital. As a teetotaler of ten years' standing, he had taken very great interest in looking out for cases of phthisis in connection with alcoholic tendencies, and he had been greatly astonished with the very few cases of phthisis which came before him in men who were habitual drunkards, and he was also astonished to see how long these cases dragged on. He began the inquiry in the belief that alcohol would hasten their doom, but his experience pointed the other way. Working among the non-alcoholic, he found that phthisis could not be treated except with proper doses of alcohol. In private practice he never thought of treating a case of phthisis without alcohol. In every case where he had tried to do without it he had failed. Now they had to take facts as they found them, and not try to make them fit with preconceived ideas. With regard to gout, he might say that before he was a teetotaler he never had either rheumatism or gout, but he had had both ever since.—A MEMBER said he thought a great deal of weight was due to the observation of Dr. Owen on the longevity of total abstainers. They must remember that the total abstinence movement was only fifty years old, and that only during the last fifteen or twenty years had it really commenced to make great progress. Consequently the members of the Band of Hope of that time could not yet have attained the age to influence statistics. By-and-bye they would become old people, and so increase the average age. As regarded the treatment of phthisis, he had personally treated many cases at the Temperance Hospital, many of whom had gone out greatly benefited without any alcohol at all; therefore it could not be said that it was impossible to treat phthisis without it.—Surgeon-Major GUNN asked whether Professor GAIRDNER meant that people who suffered from phthisis ought to take alcohol in excess.—Professor GAIRDNER said he merely wished to ask the opinion of the Section on the subject, but Dr. Gilbert Smith's remarks certainly seemed to point in that direction.—Dr. GILBERT SMITH said that, whatever he thought, he should not be prepared to advise evil that good might come.—Dr. ISAMBARD OWEN said that his remarks as to the longevity of abstainers were put forward as a suggestion, but not as an explanation. He thought it was extremely doubtful whether the stronger or weaker members of the community took more kindly to total abstinence. With regard to gout, his observations had been drawn from England, and must be taken to affect only the particular kind of beverage indulged in. He hoped to preface his report with a geographical tabulation of the drink distribution. Dr. Norman Kerr spoke of the number of his observations being so small; of course he would like to have dealt with a larger number, but as a matter of fact they had been disappointed; they had hoped to get at least 40,000, and he hoped that the interest which the publication of this report would excite might lead to further additions to this number. As to the inquiry instituted by the Harveian Society, it had been conducted on somewhat dif-

ferent lines. Their cases were required to be divided into certain classes; those due directly to alcohol, and those supposed to have been hastened by alcohol, etc. In fact, it was rather an opinion upon the results of alcohol that was settled rather than a statement of facts. It was a much simpler inquiry than theirs, and had been very successful. Their own inquiry had been for facts respecting certain definite diseases, which had for an object rather to make out the connection of the alcoholic habit with certain definite lesions than to ascertain the relative mortality. Statistics of insurance societies only concerned insurable lives, whereas their inquiry took in any kind of life, good or bad. He should be glad to get any further information out of these returns with regard to the very important point raised by Professor Gairdner as touching alcohol in checking phthisis. Something of the kind could already be got out of Table VII.

THREE LECTURES ON TUBERCULAR JOINT-DISEASE AND ITS TREATMENT BY OPERATION.

Delivered at the Royal College of Surgeons of England, June, 1888,

BY ARTHUR E. J. BARKER, F.R.C.S.

Hunterian Professor of Surgery and Pathology at the Royal College of Surgeons; Surgeon to University College Hospital; and Teacher of Practical Surgery at University College.

LECTURE III.

I SHALL to-day ask your attention to the application of those principles of treatment which I have endeavoured to sketch in our first two lectures to the actual removal of tubercular disease as found in some of the principal joints of the extremities.

Taking the knee first as a simple articulation, and one which claims attention more frequently, perhaps, than any other, I would venture to insist that hitherto we have been too much in the habit of regarding the prospect of a movable joint after operations for the removal of tubercular disease as altogether remote. In considering conservative interference with this disease here, it has until recently nearly always been a question either of complete excision of the whole joint or of trusting to simple drainage without removal of tissue; and yet, if the matter is carefully examined, there are many cases in which such disease has existed for a long time—now in the synovial membrane, now in the bones—and yet, *without operation*, repair has taken place with little or no impairment of the movements of the part, and surely we may imitate such results by early operation.

It will be said that in such cases the primary focus had not extended actually to the surfaces of the articulation, and had been arrested early. But in the majority of cases—at all events in children—tubercular disease probably starts as a focus not actually in contact with the surfaces of the joint, and remains for a time quite outside the latter. For instance, it often begins at the growing epiphysary lines of the bones, as in the specimens from which I have drawn Figs. III and IV (hip), and V, VI, and VII (knee), and only gradually works its way either through the cartilaginous covering or out to the lateral aspect of the femur or tibia. Again, it may commence in the subendothelial tissue of the synovial membrane, and develop into a considerable caseating focus before it makes a breach of surface and attacks the parts which actually move one upon the other. We know, of course, that if such cases are left alone, this is not the rule, unfortunately; and that a large number of them will run on to destruction of the proper surfaces of the joint, and then all hopes of preserving its movements become very remote indeed.

Ought we not, then, to look out for cases in which we may by limited operation anticipate this extension of the process to the surfaces, or, at all events, arrest its destructive action on the latter? Undoubtedly; and, if we work more in this direction, the reward will be not only the frequent arrest of *general tubercular* disease, but also the preservation of the movements of many a knee in which otherwise a more complete excision of one kind or another would have to be performed later on.

A good method of exploring the knee-joint in which such disease is suspected to be on the increase, but where there is a hope

of preserving the movements of the part, becomes, then, an important desideratum. Out of the large number of operations proposed and practised since the days of Filkin and Park, the most experienced surgeons to-day appear almost universally to adopt the well-known "horse-shoe" or "U-shaped" incision of Moreau, modified more or less. When exploration alone is the first object, half this incision may be made on one side, reaching from above the joint to the border of the patellar ligament, as in Fig. VIII. Or, again, the two halves of the curves may be made down to each side of the latter, but without dividing it. Adopting one or other of these methods of exposing the surfaces of the articulation, its general condition may be fairly estimated in most cases, and indications for further action be discovered. In the first place, while making such an incision, especially in a case of early disease, it may be found that the knife passes through the tubercularised area before it actually opens the joint. A large quantity of granulation tissue, with or without caseous foci, may be met with, and quite possibly in such a position that it can be freely removed without interfering with the essential structures of the joint. Or, again, the appearance of the lateral aspect of the femur or tibia may indicate the presence of centres of tubercular osteomyelitis about their growing epiphysary lines, as in Figs. V, VI, and VII. In such a case it may be quite feasible to remove all the infected medulla either by gouge or sharp spoon without the least damage to the gliding surfaces of the bones; and, even if the cartilaginous covering be encroached upon to some small extent either from within the bone or from without, it is quite possible to sacrifice a certain amount of it without injury to the prospect of a movable joint. Some cases in which this has been done have been put on record lately by Sendler, with the result of almost perfect preservation of the functions of the part. And, after all, this result will depend almost entirely on the stage at which operation is performed, now that antiseptics has eliminated the risks of setting up true suppuration in the joint by our operation. For of course the mere rupture of a caseous focus into a joint does not mean the general suppuration of the latter, unless the focus itself also communicate by a sinus with the external one.

Now the moment such tubercular tissue is found the risks of re-inoculation from it during its extirpation must be kept in view, especially if it have reached the stage of caseation. If it be possible, by turning back the skin and muscles on either side, to expose the whole diseased focus from our limited incision, it should be isolated by as careful a dissection as if it were a malignant growth, and the knife should at every stroke be carried through sound tissue around. At the same time the escape of caseous matter into the fresh wound, or into the cavity of the articulation, should be prevented by every means in our power. If, unfortunately, it should be impossible to prevent such contamination of the cut surfaces altogether, they should be as rapidly and as thoroughly cleansed as possible by irrigation with one or other of the powerful germicides at our command. The choice here appears to lie either between carbolic solution or bichloride of mercury.

Large areas of diseased synovial tissue may in this way be extirpated from the knee, as low as the ligamentum patellæ and as high as top of the subcrural bursa, without any interference with the continuity of the lateral, crucial, or patellar ligaments. Cases are now accumulating in which this has been done, and all the movements of the joint have remained perfect. Koenig's and, more recently, Sendler's cases are perhaps the most encouraging, especially as in some of the latter portions of bone had been also removed.

The actual opening up of the joint in such a case should be postponed until the diseased area in the synovial tissues has been isolated as far as possible. Finally, after flushing the parts divided with our germicide solution, the separation of the infected tissue is completed, and it is lifted out *en masse*. The condition of the ends of the bones can now be examined, and, if the patient is an adult, it is quite possible that the cartilaginous surfaces may be almost or quite intact, unless the disease has been allowed to run on too long. In such a case, after careful irrigation of all the pockets of the articulation, and subsequent drying out with sponges, all the exposed surfaces should be dusted with finely crystalline iodoform.

Deep stitches, including the muscular expansion and skin, should then be inserted, about half an inch apart, throughout the whole length of the wound. These silk threads are not tied until all are in place, and until the final toilet of the wound has been completed. A drain-tube is not always indispensable, but may

with advantage be left in one of the angles of the wound, for the first twelve hours or so, in most cases.

But, supposing that the free single or double lateral incision reveal the fact that the cartilage-covered ends of the bones are seriously affected, either primarily or secondarily, the joint must be more freely exposed. This is best done by completing the formation of the U-shaped flap (Fig. VIII), in order to turn it up from the lower and anterior surface of the femur. In doing this, of course the simplest plan is to sever the ligamentum patellæ, trusting afterwards to careful suturing to restore its continuity. But, if there is any prospect of preserving the movements of the articulation, this structure should be kept intact, if possible, for obvious reasons. This can only be done by removing the tuberosity of the tibia, and leaving it attached to the ligament of the patella. There is no difficulty in this, if a good chisel is used, and is driven obliquely upwards and backwards, under the tuberosity, into the joint. The scale of bone thus removed can subsequently be wired down in its old bed, and one of the chief supports of the joint will be thus preserved intact. When the long U-shaped flap has been formed, as just described, and has been turned well up, there is no part of the joint which cannot be thoroughly examined during complete flexion.

Another method of exposing the interior of the knee-joint, while preserving the extensor mechanism intact, has been often practised within the last few years, and deserves some notice. This is the transverse incision across the middle of the patella, the latter being sawn completely through. Now there is no doubt that, with the safeguards of asepsis, this method is as justifiable as any other for opening the knee-joint, and that, when subsequently wired, the patella becomes as sound as ever, and the action of the extensors is preserved. But it is agreed by those who have had most experience of it that the transverse incision alone does not give as free access to the various parts of the joint as is required; and even Volekmann, with whom the plan I believe originated, was obliged to supplement it by vertical lateral incisions, which enabled him to turn the soft parts upwards and downwards with more freedom. Neither this method, nor that of Verneuil (lately revived), in which an H-shaped cut is made with the transverse stroke *above* the patella, appear likely to hold their own against the old U-shaped incision, which possesses many of the advantages of the other methods without their drawbacks.

If, in performing the operation by this U-shaped flap, the tuberosity of the tibia be lifted up with the latter, and then subsequently wired down *in situ*, all the advantages of the method of dividing the patella are secured, and there can be no question of the freer access to the joint. But, whatever else is done, it should never for a moment be forgotten that our first object is to rid the patient of a distinctly dangerous new growth, and that all questions as to the functions of the joint must take a second place.

The points to be specially examined in these cases will be, first, the several synovial pockets, and then the epiphysary lines of the femur and tibia, especially at their lateral aspects. Here it will be frequently found in early cases that a focus of tubercular osteomyelitis extends more or less deeply into or across the bone, sometimes without transgressing the cartilage (Figs. V and VI). In such a case, let me repeat, it may be quite feasible to remove all the diseased tissue by careful gouging from the side without damaging the joint-surfaces at all. But, be this as it may, it must be remembered that, if be possible to cut around the focus in healthy tissue, and to lift the diseased mass bodily out without crushing it, and with a layer of sound material around it, the chance of re-inoculation of the medulla remaining is much diminished. Even from the joint-surface it is quite possible to do this without serious interference with the shape of the articular facets in many cases. A few months ago I was able thus to remove one of those conical foci of carious bone the shape of which, as Koenig points out, suggests their formation by the blocking of a nutrient artery by tubercular disease. It lay in the external condyle of the femur, with its base at the articular surface; and, though the gouge was carried well outside of it in healthy tissue, and a portion of the inner aspect of the external condyle as large as half a walnut was removed, the shape of the joint has not been damaged; and I have lately seen the patient walking about comfortably, although in this case with a stiff joint, but not in the least a shortened limb.

In passing I may remark that such cases as the one just referred to offer an excellent illustration of the advantages of the

most recent methods of dealing with tubercular joint-disease. Here was a girl of eighteen who had been under my care for the same affection for eight years, during the last three of which she walked about on a Thomas's splint and never put the foot to the ground. All this time she was carefully treated both at home and in hospital, but the knee remained swollen, tender, and was now quite stiff, and walking was impossible. Last Christmas she and her mother begged that she should be operated on. I therefore laid open the joint by the U-shaped incision, removed all the infected synovial tissue, and a large focus of tubercular osteomyelitis from the femur as described. The wound healed by first intention under the second dressing, which was replaced by dry wool and a plaster-of-Paris case on the tenth day. A day or two later the patient was out of bed; within a month from operation she was at the seaside, and within six weeks was able to walk about on the limb, which had not been used for years. She wore the same plaster case for about another month, and on her return to London I removed it, and found the state of the joint all that could be desired. She could walk well without the splint, but was given a lighter support instead. I believe that for the last couple of months she has been *at work* again; and I saw her yesterday, perfectly well.

In this case, an operation, which did not interfere with the length of the limb or its growth, which did not confine the patient to her bed for a fortnight, or to the house for a month, gave her back the use of her leg within eight weeks—a result which eight years of careful treatment by other means had failed to produce. From what was found at the operation on this joint, it is probable that further delay would have resulted in extension of the disease, which would then have required for its removal the sacrifice of some of the length of the bones, to say nothing of the other risks to which the patient would have been subjected.

It is perhaps a little too soon in this case to pronounce that re-inoculation of the system from the wounded surfaces cannot have taken place during the operation. But we know enough to say that this is unlikely. From all the cases where such an occurrence has taken place that I have been able to study, it seems probable that, unless there is evidence that the disease has taken a fresh start locally or in internal organs within a couple of months or so, it is not likely to reappear at all from this cause, provided the patient's surroundings are healthy.

There can be no question, as already stated, that such reinoculation of the soft parts and of the fresh cut bone does often take place in excisions of tubercular joints. Cases have been recorded specially to elucidate this point, and leave no doubt, to my mind, upon it. It is probably a frequent cause of that secondary development of foci of disease, long after operation, which is well known to us all. Hitherto it has been the custom to attribute this reappearance of the disease to its spread from portions of the original foci not thoroughly removed by the operation. But although this explanation will meet some cases, it will not account for all. The evidence is strong that a healthy cut surface of bone may be inoculated from the caseous *débris* in process of removal from another part of the joint, and may develop fresh foci of tubercular osteomyelitis as a consequence in due course. Much may be done, of course, in the way of washing away tubercular *débris*, accidentally distributed over the fresh cut surfaces in the course of an operation, and germicides may be brought to bear upon them before the wound is closed. But as the latter must be used sparingly in view of their toxic effects on the system, it should be our aim to prevent, by every means in our power, the scattering broadcast over the wounded surfaces of the part those seeds of further disease which we know from experiment are so ready to strike root even in uninjured tissues, and the evil effect of which we have heretofore been only too familiar with when, after an excision has been soundly healed for some time, caseous abscesses have formed, and have slowly worked their way to the surface.

Not infrequently, in examining a tubercular focus in the cancellous tissue of the end of a bone, we will observe that its spread has been prevented, as it were, by a process of sclerosis in the tissue around—a process quite analogous to the formation of the limiting area of exudation tissue, demonstrated by experiment, around points inoculated with tubercle in the eye and elsewhere. (Fig. 1.) If such a sclerosis exist in any given case, we should be careful, in gouging out the diseased matter, not to go beyond this barrier, erected by the natural processes against the spread of the disease.

I shall now ask to be allowed to describe in detail the method I

should employ to get rid of the infected tissues from a knee which has been discovered by exploration to possess a *widely* diseased synovial membrane, the bones being little or not at all affected. If I venture to describe this as the plan I have adopted myself, it is with no wish to dogmatise. No one is entitled to do this in the case of a subject so comparatively new to us all, and where all our individual experiences must still be relatively scanty. My wish is simply to express, in a definite form, the conclusions which have gradually worked themselves out during many years in which I have been a close observer of the methods of others in this field of surgery, as well as an anxious student of my own clinical and pathological material. We have all, Sir, no doubt been obliged to revise our procedures over and over again, in view of the advances in the theories of wound-treatment, and of the pathology of tuberculosis; and all of us must be conscious that we are still but feeling our way. Those who have given the most attention to the subject will be the readiest to admit that it is still fraught with difficulty. Of my own experience of the methods about to be described, I will only say that, as far as it goes, it is most encouraging, contrasted with older procedures; and that the results have been far beyond what I should have believed within the range of possibility a few years ago. And I know, further, that this has been the experience of many others whose line of action has been practically the same.

The limb having been kept in the vertical position for five minutes, so as to reduce the blood-stream to the utmost, a broad band of india-rubber is placed tightly around it, as near to the groin as possible. It is well not to use the Esmarch's bandage in the ordinary way for several reasons. In the first place, its pressure may break up some of the caseating foci, and disperse their contents either into the tissues around, producing local infection, or into the lymphatics or veins, and so lead to general infection of the system. In the second place, it is an advantage to leave a small amount of blood in the vessels of the part, so that these may be recognised when cut, and tied before the elastic tourniquet is removed. Finally, the loss of tone in the walls of the vessels, produced by the prolonged pressure of the elastic band, is usually followed by such copious oozing as to necessitate an early change of the first dressings. Such a disturbance of the wounded surfaces is most undesirable, if it can be avoided. Quite apart from the increased risks of septic inoculation from every exposure of the wound, disturbance of the part is likely to produce increased vascular excitement, and this again favours the development of tubercular infection, both local and general, as we have seen. Again, if extravasated blood find its way into the tissues around the field of operation, such blood offers one of the best cultivating media for the bacillus tuberculosis that could be provided, and is very likely to be inoculated during operation. The compression of the joint, then, by means of the elastic band is better dispensed with.

After every precaution as to asepsis, the knee is now laid open by the U-shaped incision, and the resulting flap, including all the structures down to the bone, is turned up. Then, commencing at the tip of the flap, the thickened synovial tissues are dissected cleanly off from the under surface of the quadriceps in one continuous strip, until the upper reflection of the subcutaneous pocket is reached. The dissection is then carried down over the front of the femur, leaving the latter quite clean. The joint is next well bent, and all diseased tissue is carefully cleared away from the inter-condyloid notch and ligamentum posticum, and, finally, from the lateral aspects of the joint, and from the upper surface of the tibia. In short, the whole synovial membrane is peeled systematically from the surfaces of the cavity, as nearly as may be, in one continuous tract. If the crucial and lateral ligaments are sound, they should be spared, and the same may be said of the semi-lunar cartilages. The surfaces of the bones and their epiphysary lines of growth must now be very carefully examined, and all tubercular foci be removed with a sharp spoon or gouge. Gentle pressure on the soft parts will now make evident any small vessels by forcing out their contents. These can be treated either by twisting or ligature, but, as a rule, there are very few bleeding points to be seen, and these can be quite adequately dealt with by a few minutes' forcipressure while the other steps of the operation are being completed.

The whole area of operation is next flushed with our germicide solution in such a way as to remove all traces of *débris* and blood clot, and carefully dried with perfectly clean sponges. It is then lightly dusted with finely crystalline iodoform, in such a way that every portion of the cut surfaces is reached by it, *but in small*

quantity. After this, the flap is laid down, and the sutures of carbolised silk are placed *in situ*, but not yet tied, the whole cavity under the flap being in the meanwhile filled with sponges, with which pressure is kept up upon every part of the wound. When all the sutures are in position, the sponges are removed, together with the last traces of moisture, and the bones are finally adjusted in a straight line with one another. Then the stitches are tied evenly, closing the wound everywhere except at either angle, where a small drain-tube is placed.

The dressing which I have myself used in cases of this kind is ordinary salicylic wool, but I have no doubt that there are other aseptic materials equally good. But much depends upon the way in which the first dressing is adjusted—more, I believe, than upon the aseptic material employed. Our aim is to apply even pressure in such a way as to check, as far as possible, all oozing into the extensive wound underneath, and at the same time to allow of the escape of any blood or serum which may be exuded in spite of the pressure within the first forty-eight hours. Perhaps the best way of attaining these objects is to cut a flat pad of salicylic wool, one inch thick, exactly the size and shape of the flap, and lay it upon the latter; then to carry a strip of the same wool, about three inches broad in the line of the wound, but about half an inch from it. The incisions and drain openings are now seen between the edges of the two pieces of wool, which do not touch or press exactly upon them. Then long strips of wool are carried round the joint, including the two pieces first applied, until it is covered deeply from well above to well below the knee. This thick layer of dressing, if evenly adjusted, may be firmly bandaged, and thus all the deeper parts of the wound are brought into contact, except at the drain openings.

Nothing now remains but to remove the elastic tourniquet, and secure the limb in an apparatus. In these cases, probably, no appliance is superior to a piece of Gooche's scored splint, carried from the fold of the nates to the tendo Achillis, and well and evenly lined with wool. When firmly bandaged over the latter, it gives all the support that is required to the joint.

As soon as the patient is in bed, the limb should be placed in the *vertical* position, and be secured thus; this is a most important part of the after-treatment, lessening as it does the tendency to oozing of blood into the wound, with all its attendant inconveniences and risks.

After this, the less we interfere with the wound the better. If the pressure on the wool have been properly graduated, the whole wound will in most cases heal by first intention under the dressing which was applied on the operating table. Those who proceed as above have many such cases to point to. But, if there be any soaking of serum through the dressing, and it appear under the gluteal fold, the limb, at the end of twenty-four or forty-eight hours, should be placed in the horizontal position, the Gooche's splint be unfolded, and the moistened dressings be replaced by dry antiseptic wool, applied as before, the incision and its neighbourhood being dusted with iodoform. At the same time, the drains may be removed. Personally, I prefer at this dressing to put the limb up once for all in plaster-of-Paris from foot to groin, and leave it untouched for two or three weeks. The plaster case can then be slit up, and the stitches be removed, without any lifting of the limb out of its bed; and, when a little fresh wool has been laid over the incision, a few turns of a bandage will make all as secure as before, and such a splint will last until the patient is able to walk about.

But perhaps it might be better to advocate, as a routine treatment, the use of the Gooche's splint for the first ten days, then the removal of drains and sutures at the same time, and the application of the plaster splint once for all.

It will be observed that no mention is made of provision for purulent discharge. The reason is that pus is not seen in cases thus operated on except as a very rare exception. We expect these cases to heal by first intention, and they do so. I am speaking now of cases in which no sinuses existed at the time of operation. And, even in a case with a few sinuses, union without suppuration may sometimes be achieved if the dissection of the diseased tissues has been very complete, and if the borders of the openings have been thoroughly cut away at the operation. But it is to be devoutly hoped that in the future all cases of this disease will be treated by operation before sinuses have formed. Scraping out of the latter, it should be noted, is not sufficient as a rule; they must be cleanly dissected out, so that union by first intention may take place along their track.

Treatment such as the above combines nearly all the require-

ments which, as I have already shown, are demanded in an operation for tubercular disease of the joint, whether we aim at the preservation of movement or at ankylosis. If the first, the absolute rest will favour repair without exudation, and if the latter, consolidation will be promoted in the best way. I cannot think that any pegging or wiring of the bones is necessary except in rare cases. If the patient is young the ends of the bones are mostly cartilaginous, and no amount of wiring will cause them to unite by osseous tissue; and if they are adults, and the encrusting cartilage has been damaged, firm union is to be expected if the parts be simply kept in close apposition and immovable. In any case, no displacement can or will take place if the joint is firmly splinted from the first in the fully extended position, and as long as it is thus supported, especially with plaster-of-Paris, there need be no fear on this score. Young patients will always require such a support for months after operations in which the ligaments of the joint have been destroyed, for there is a great tendency to flexion and displacement if the limb be left to itself; but this tendency can be counteracted by splints until it ceases.

Now as to the question of formal classic excisions, with sawing off of the entire ends of bones. I venture to foretell that after the next few years when the principles underlying the treatment of tubercular disease are better understood and the necessity of early operation is recognised, such operations will be some of the rarest in surgery. They will be replaced entirely, I believe, by the extirpation of localised foci in the bones without any sacrifice of their length and growing power. What a gain this alone is likely to be, need not be further dwelt upon. And that it will affect the subsequent course of the whole tubercular process in the system I firmly believe time will show, when we have accumulated enough cases operated on by the newer methods for reliable statistics.

OPERATIONS ON THE HIP-JOINT.

In operations for the removal of tubercular disease of the hip-joint, bone will almost always have to be sacrificed for several reasons. In the first place the disease starts more frequently in the head of the femur than elsewhere as far as can be ascertained at present, and I have sketched in Figs. III. and IV. the usual position of its initial lesion. Secondly, the anatomical arrangement of the synovial membrane is such that it can hardly be infected to any marked degree without participation of either the head of the thigh-bone, the acetabulum, or both together. And although attempts have been made to extirpate the diseased synovial membrane without excision of the bones, I believe such attempts have so far proved abortive. But although all this may be admitted, it is equally clear from our present knowledge of the pathology of the affection and our experience in its treatment that we ought nowadays to be able to effect the objects we have in view by a far more limited removal of bone than was formerly considered necessary in most cases. Remembering that primary osseous disease of this joint is always limited at first to the head or its epiphysary growing line (Figs III. and IV.), or to the epiphysary lines of the acetabulum, and, that having once started in either of these situations it cannot spread far without involving the whole joint in a very serious way, it ought to be our object to interfere at a very early stage. If this is done, it will never be necessary to undertake those ghastly operations in which in former days the whole acetabulum, with large portions of the ilium, ischium, and pubes, together with the whole head, neck, and trochanteric portions of the femur were removed at one or more sittings. In the future if we watch the early development of hip-disease closely, we ought never to find it necessary to remove more than the head and part of the neck of the femur, and in some cases, the central portion of the acetabulum. Hence the wide-reaching incisions of former days are no longer necessary as regards the soft parts, and the forcible dislocation of large portions of the femur out of the wound are quite unneeded for. In every case now considered suitable for excision, the head of the bone can be sawn off *in situ*, and the acetabulum be dealt with through very limited incisions in the soft parts. Allow me to remind you again that I am referring now to cases in which no sinuses are present or have only very recently formed. Where many sinuses exist and true suppuration has been present for some time I believe that a case has been made out fully against any formal excision and that such cases as a general rule stand a far better chance when treated simply by rest and the laying open and washing out of abscesses with free drainage.

For excision of the hip then as we hope to see it practised from

henceforth, very limited incisions are demanded, and there are now two such which appear to compete closely for the general favor, namely, that on the outside of the joint (Fig. IX.) and that on its anterior aspect (Fig. VIII.). The first of these, known throughout Germany as Langenbeck's operation, is notwithstanding acknowledged there to be merely a revival of the original procedure proposed by C. White, of Manchester, for the removal of the hip-joint, in the year 1769. The second, or anterior incision, was first adopted in Germany by C. Hueter in 1878, but independently, I believe, a little later by Mr. R. W. Parker in this country, by whose name it is perhaps best known here.

Fig. VIII.—Excision of the Hip-Joint by External Incision. The incision runs in a line from the posterior superior iliac spine over the middle of the trochanter, the limb being semiflexed and adducted.

In White's operation, the limb being semiflexed and adducted, a straight incision is made over the head and neck of the bone in the direction of a line running from the posterior superior iliac spine to the middle of the trochanter (Fig. IX.). This incision should commence fully two inches above the tip of the trochanter and be continued down on the outer aspect of the latter for an inch and a half. It should lay open the capsule of the joint with one stroke, after which there is but little difficulty in dividing the neck of the femur with a narrow saw outside the focus of disease and removing the proximal portion of the head and acetabulum while the edges of the wound are held aside. Occasionally, however, there may be some difficulty in reaching all parts of the affected cavity through this single incision, in which case those operators who employ this method habitually are accustomed to split the trochanter vertically for about an inch with a chisel, and then separate the two halves without disturbing the tendons inserted into them. This method undoubtedly gives much freer access to the neck of the bone, and indeed to all parts of the joint, and adds but little to the severity of the operation. Subsequently the two halves of the trochanter fall together and adjust themselves in their old position until they are united.

But though this operation has found favour with many experienced surgeons, and has largely supplanted that by posterior curved incision, it in its turn is likely to be abandoned in favour of the method by anterior incision. Having myself employed the latter almost exclusively for the last five or six years I am more and more inclined to prefer it to all other modes of excision, and shall now describe it in detail in the hope of inducing others to test its advantages.

The patient lies on his back with the limb as much extended as possible. A single straight incision is made from a point imme-

diately below the anterior superior spinous process of the ilium, downwards and slightly inwards for three or four inches. (Fig. VIII.) As the knife sinks into the limb it passes between the tensor vaginae femoris and glutei muscles on the outside and the sartorius and rectus on the inside.

The lower inch or so of this cut should only divide the skin; the upper two-thirds should reach the neck of the femur at once. In this way the capsule is laid open vertically, and this opening can be enlarged by a little further dissection with the knife, care being taken, however, that the Y ligament is left as far as possible intact. The state of the joint having been now ascertained with the point of the index-finger a narrow-bladed saw is introduced along the latter and the neck of the femur is divided from above downwards. Then the head is extracted with a sequestrum forceps, and the acetabulum, if diseased, is carefully gouged out clean or scraped thoroughly with sharp spoons. Every trace of diseased synovial tissue discoverable is now removed with scissors,

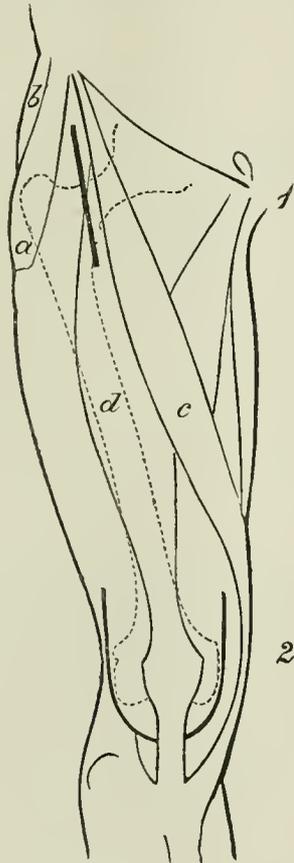

Fig. IX.—Excision of Hip and Knee. 1. Anterior incision for removing the hip-joint (Hueter's and Parker's method). The incision runs downwards and a little inwards between the tensor vag. fem. (a) and glutei (b) externally and the sartorius (c), and rectus (d) internally. 2. Moreau's U-shaped incision for removing disease of the knee.

knife, and sharp spoon, special care being also taken to clear out any caseating abscesses communicating with the joint. All this should be done with as little violence to the tissues around as possible, so that none of the tubercular debris shall be forced into the fresh cut surfaces. When every portion of diseased tissue has been thoroughly removed, the cavity is freely flushed with our germicide solution until all loose particles have been washed away. It is then sponged dry from the bottom and is immediately dusted with iodoform, which may be carried further into the ramifications of the cavity on the end of the finger. It is well, I think, after this again to introduce a small sponge for the purpose not only of finally drying the part but also of wiping away any excess of iodoform which may be about. This sponge should be left in until the sutures which close the wound are in position and are ready to be tied. It is then removed and the

threads are knotted, a medium-sized drain-tube being carried down as far as the acetabulum. A thick dressing of salicylic wool, arranged in strips, so that interstices are left into which serum can escape, completes the operation.

At first, I think the patient is much better without a splint of any kind. He simply lies on his back in bed with the limb fully extended by pulley and weight; indeed, the latter may often be dispensed with altogether. The first dressing may usually remain undisturbed for some days, after which it is well to replace the serum-soaked wool by a fresh dressing of the same kind.

Except for the drain opening such wounds heal, in my experience, as a rule by first intention. The fluid, moreover, after the first day or so, which comes from the drain-tube, is little more than thick odourless serum. It exudes in very small quantity and ought never to become truly purulent. This is the reason why the opening, although anterior, is perfectly adequate for the drainage of the cavity left by the operation. I have often been asked, "Do you find this anterior incision gives sufficient drainage for the discharges?" My answer always is, "Certainly, for there are no discharges worth mentioning after the first oozing of blood and serum immediately following operation." Those who ask this question have doubtless in their eye the older experiences of excision of the hip, when the operation was usually undertaken in an advanced stage of the disease, when suppuration had already set in freely with ramifying sinuses. I am not alluding to such cases, believing as I do that experience shows, and especially Mr. Marsh's figures alluded to already, that, beyond aseptic drainage, they are best left to Nature and are unsuitable for excision. But in relatively early cases treated carefully as just described we have usually, and ought always to have healing without suppuration at all properly so called. I could produce a series of cases illustrating this fact from my own practice and from that of my colleague Mr. Bilton Pollard, who operates on exactly the same lines at the Children's Hospital, and I believe other surgeons have found the same thing. It must not be forgotten that when an excision is performed early and all tuberculised tissue is removed, a clean-walled cavity is left, most of which is quite capable of healing by first intention, when its different surfaces are brought into contact by firm pressure. And in these cases, the head of the bone being removed and the acetabulum quite clean, the cut surface of the neck of the femur can be brought close up to the latter, so that although there is potentially a large space in the field of operation, there ought to be actually little or no cavity left if pressure have been properly applied from the first. There is no need then in such cases after the first day or so for extensive drainage, if the wound be kept aseptic. If it is not so, of course the case is totally different, and drainage is absolutely necessary. For my own part I intend to try whether some of these early excisions cannot be left to heal absolutely by first intention without any drainage at all, just as in many cases tubes can be dispensed with altogether in analogous cases of operation on the knee.

All that has just been said about the details of operation applies with equal force to that by external incision. But the anterior method has several advantages that cannot be claimed for the latter. In the first place not a single muscle fibre need be divided in the anterior operation and consequently none of the support of the muscles is lost to the joint. Nor are any vessels of importance divided if the deeper part of the incision be not carried too low in the thigh, and the same may be said of the nerves. Finally, the very fact of the wound into the joint being an anterior one enables us to place the patient on a double Thomas's splint a week or so after operation, and to keep him on this without any need to move the limb for as long a time as is desired. He can also now be placed for part of the day either on his face or his side for change, and this is usually very much appreciated. When supported with such a splint a patient can also be taken out of bed within ten days of the operation and can have all the benefits of the open air and change almost from the first. We are thus enabled to send our hospital patients home or to the country long before the wound is healed, and without risk, if ordinary care as to antiseptic dressing be observed. In this part of the treatment the iodoform emulsion will be found very valuable. A little of this fluid injected daily into the drain-tube will sink into all the deeper parts of the wound, whether it is filled with blood or serum, or even pus, by virtue of its high specific gravity, and will not only prevent or check the growth of pyogenic micrococci, but also arrest the development of any bacilli tuberculosis accidentally scattered through the wound by the

operation. If in the intervals between these injections the hip be kept well enveloped in salicylic wool there will be but little risk of septic infection. When a Thomas's splint is employed after excision of the hip it is well to have its rods made to diverge widely so that the affected limb shall be strongly abducted during convalescence. When the joint becomes firm in this position the effect is of course to cause tilting downwards of the pelvis on the affected side when the patient begins to walk. The result is that the limb is restored almost or completely to the same level as its fellow, and the actual shortening is compensated for.

The absolute rest secured to the hip-joint from the first by the treatment just described does for it what the plaster-of-Paris does for the knee. Not only does it save the patient from suffering, but it diminishes the hyperæmia about the joint, and thus in all probability reduces the risk of a local or general spread of the disease after operation. At the same time the patient can cease to be confined to bed the moment it is applied.

I had hoped, Sir, to be able to consider the application of the principles of treatment we have been discussing to the removal of tubercular disease from the elbow and shoulder joints; time fails me, however. But I trust that in what I have said, however imperfectly, I have justified the remark made in the first of these lectures—namely, that the excision of scrofulous or tubercular disease from a joint is no longer a mere mechanical problem; that it is no longer a mere question of removing a certain amount of dead or inflamed bone in the readiest manner, and drainage of the resulting wound until it heals. I hope that I have made good the claim of the operator in this field of surgery to be considered, not a mere skilful artificer, but a scientific worker, who brings a knowledge of anatomy, physiology, biology, and chemistry to a glorious task.

I trust, also, that what I have said may appear to others to justify that *hopefulness* as regards our future success in the struggle against tubercular disease which I feel myself. If the affection is parasitic, as no doubt it is, we may expect to check its spread in the future in ways never yet attempted, or, indeed, thought of. If the belief is warranted that tuberculosis is not inherited in the vast majority of cases, but acquired, how much more promising the outlook! If the disease be inoculable on any surface of the body, and if it is capable of being reinoculated from one part of an operation wound to another, we may hope to prevent its inroads by very simple precautions never taken before; and, when it has gained access to the body, and is making local ravages, our hopes of arresting them by operation are far greater now than heretofore. For now, relieved of the nightmare of the septic wound diseases, we can undertake operations at an early stage of the affection without fear, and remove all the local mischief without those wide-reaching resections of bone which brought shock and other attendant risks in their train; and we can do so with better prospects as regards the functions of the joint than formerly. The pain of the after-treatment has also been immensely reduced by the possibility with aseptic wounds of permanent dressings, and the patient may consequently be invited to face such an operation with far less fear than of old.

In conclusion, I should like to say that I have purposely abstained from troubling my audience by quoting either my own experiences or observations or the authorities in detail for all the observations alluded to in the course of these lectures. The subject is so large, and its literature so very extensive, that this would have been intolerably wearisome to you. I shall, however, append a list containing some of those sources of information which have appeared to me most reliable, on careful study, and to which reference can be made by those who desire to pursue the subject further.

I hope also before long to be able to collect a sufficiency of reliable statistics of recent experiences in this field of surgery to emphasise more fully those conclusions I have ventured to put forward, to which you have listened with so much forbearance.

Note.—A typographical error was overlooked in Lecture II, page 1263, by which 195 stands for 95 in Willemer's statistics (three lines from bottom of second column). These figures thus corrected show Willemer's statistics in the least favourable light. But if all cases treated by incision and drainage be included the total number rises to 123, making the mortality only 10 per cent., and if the cases treated by primary amputation be excluded the percentage of deaths further falls to 9.0.

REMARKS ON PAROXYSMAL SNEEZING.

BY SYDNEY RINGER, M.D., F.R.S.,
Holme Professor of Clinical Medicine, University College, London.

AND
WILLIAM MURRELL, M.D., F.R.C.P.,
Lecturer on Materia Medica and Therapeutics, Westminster Hospital, London.

PART II.

THE intimate relation existing between intermittent sneezing and asthma has already been referred to, and we might narrate many cases in which the symptoms of both have been observed in the same person; but the following brief outline will serve equally well to illustrate the point. A patient for some years suffered from severe intermittent sneezing, which then became complicated with asthma, the asthma steadily increasing in severity, whilst the sneezing grew less and less, till at last it almost ceased. The asthma was of the peptic variety, and unassociated with bronchitis. Bed-dust always induced severe attacks, first of sneezing then of asthma. As bed-dust is insoluble, the part affected must have been either the mucous membrane or the terminations of the nerves, first of the mucous membrane of the nose, next of the lungs, whilst the change in the type of the disease from intermittent sneezing to well-marked peptic asthma favours the theory that the seat of the affection was in the nervous centres.

Our cases show that paroxysmal sneezing is related on one hand to bronchitic and peptic asthma, and on the other to hay fever. They are allied to the bronchitic form of asthma in being excited by dust, cold, and direct irritants, and to bronchitic asthma through those cases which commence with paroxysmal sneezing, and are subsequently complicated with bronchial asthma. To the peptic forms of asthma this paroxysmal sneezing is related through those cases in which the attack is excited by food.

In nearly all these cases, judging from the extent of the itching, a part or even the whole of the nasal passages is affected, and often the eyes, soft palate, and throat are also involved. In some instances, however, we have found that the nervous structures implicated are much more limited; indeed, the nose may altogether escape. In one very curious case the itching was entirely confined to the inner canthus of the eye, whilst in another it involved the whole of an eyeball.

The following series of cases occurring in the course of three generations of the same family serves to demonstrate the hereditary connection existing between intermittent sneezing and asthma.

The first member of the family, whom we will call the grandfather, was troubled with asthma for years, in fact, up to the time

of his death, which occurred at the age of 80. His son, whom we will call the father, and who was under our care, suffered from hay-asthma from childhood, his attacks lasting for only about six weeks in the hay season. On going into a hayfield, or, indeed, near one, he is seized immediately with intense itching of the whole of the inside of the nose, and of the entire conjunctiva of both eyes and of the throat, accompanied by violent sneezing and profuse discharge from the eyes and nose. His eyes become blood-shot and the lids swell, often to such an extent that he can scarcely see. His breathing is very difficult, but there is no expectoration. So intensely susceptible is he that a field a mile off will affect him, and if his children play in the field and then come indoors, he has an attack. All flowers will at this particular time bring on an attack, but they do not do so at any other season. Strong sunlight will excite an attack, and he usually takes the precaution of wearing big blue spectacles when outdoors. His sister, who is now 24 years of age, has had hay-asthma for about four years. His son, who represents the third generation, is aged 10, and has suffered severely from asthma since a sharp attack of bronchitis which he had when 3 years old. He suffers all the year round almost continuously from severe itching inside the nose, in the eyes, throat, and under the chin. When these symptoms are aggravated he has severe sneezing, with free discharge of a clear fluid from the nose. Any kind of dust aggravates the symptoms, pollen especially. He suffers also from wheezing, and, when the itching and sneezing are aggravated, from violent cough and difficulty of breathing. All these symptoms are influenced by food; thus, the itching and the dyspnoea are always made worse by pastry, sweets, and especially by a heavy meal taken in the evening or late at night. He has been much worse since an attack of measles three months ago, and now almost any food, even bread and butter, increases both the itching and difficulty of breathing.

In another case, a lady who suffered from bronchial asthma subsequently replaced by hay-fever, had two children, one of whom, the elder, has been subject to asthma and bronchitis since the age of 5, whilst the younger is a paroxysmal sneezer. We have other cases which illustrate the intimate relation which exists between bronchitic asthma, peptic asthma, paroxysmal sneezing, and hay-fever, these varieties of the same complaint occurring in different members of the same family, either concurrently or in successive generations. In one case a lady who was an asthmatic for many years, had twelve children, all of whom, without exception, suffered from one or other form of this complaint.

The change in the type of a disease in its transmission from parent to child is frequently met with in asthmatics. For example, an asthmatic parent who suffers from peptic or bronchitic asthma may have children, one of whom has hay-fever, another intermittent sneezing, apparently independent of pollen, and a third who is the subject of simple peptic asthma. The influence of hereditary transmission is well illustrated by the following case.

A lady, aged about 60, suffers from sneezing, but only in the morning before breakfast. She is unable to assign any exciting cause for the attacks. Food, stimulants, dust, flowers, hay and smoke do not affect her. Damp places and damp weather favour the occurrence of the attacks, but will not excite them. Change of air gives relief for about a fortnight, but then loses its effect. Any change is temporarily beneficial, and it makes no difference where she goes. In former years she was always worse just before and during a period. She has intense itching in the right nostril under the bridge of the nose, and where the nasal bones join the cartilages. The itching extends to the right eye and the lower lid. During the attack the sneezing is very violent, so that it exhausts her and strains her muscles. There is a profuse watery discharge from both eyes and from the nose during the attacks. When she catches a real cold, it runs its usual course, and the other symptoms cease. She has one son, who is a violent paroxysmal sneezer, another who is a hay-asthmatic, and a third who is a morning sneezer. This case also illustrates the influence of unilateral stimulation in inducing bilateral secretion.

A certain vague hereditary relationship can sometimes be traced between paroxysmal sneezing, asthma, migraine, and some forms of hysteria. For example, we had under treatment a young lady, aged 20, who for many months persistently refused food, taking nourishment in the smallest possible quantity compatible with the maintenance of life. She lived in the country, and until she was nearly 19, was a hearty, well nourished woman, re-

nowned over the whole country side for her beauty and buoyancy of spirits. She was fond of riding, walking, tennis, and all outdoor sports, and was always the life of the party. Suddenly and without any assignable reason, and without the existence of organic disease as far as could be ascertained, she changed her habits, and spent the whole day moping about the house, taking no interest in anything. Her tastes were peculiar. She disliked peas and strawberries, ices, and many other articles of diet usually affected by ladies, and preferred castor oil to champagne. Her favourite dishes were slate-pencil, cinders, and sealing-wax. She rapidly lost weight, and when she came under our care turned the scale at very little over six stone. She speedily improved under massage, but it was no easy matter to get her to take a good meal. Her family history was peculiar. Her father suffered severely from neuralgia, and his mother was for years afflicted with migraine. The father's brother was a paroxysmal sneezer, whilst one of his daughters, until she married, had a great dislike for food of all kinds, and lived chiefly on sweets. Her brother, a young fellow of 30, rarely or never eats meat. The patient's only sister is fastidious in her dietary, and suffers severely from asthma, but whether peptic or bronchitic we were unable to learn.

Sometimes both in asthma and bronchitis we meet with cases where irritation of some distant spot far removed from the chest or seat of pain will induce an attack. In a case recorded by Anstie it is stated that irritation of a small spot at the back of the head, over the occipital nerve, would immediately induce an attack of supraorbital neuralgia, whilst in another instance the application of cold to one instep invariably induced a paroxysm of dyspnoea. A clergyman assured us that he could at any time induce an attack of paroxysmal sneezing, lasting ten minutes, and accompanied by profuse running from the nose, by rubbing his tongue against the roof of the mouth, close to the teeth. He cannot discover that anything else brings on an attack, and he is quite unaffected by pollen or dust of any kind.

It is generally recognised that when attacks of sneezing and asthma both affect a patient, they do not, as a rule, occur at the same time; one form replacing the other; in fact, local applications which arrest the sneezing sometimes induce an attack of dyspnoea. It often happens that as the asthmatic paroxysms become more frequent and more prolonged, the attacks of sneezing temporarily cease.

In children sneezing is easily provoked, and their occurring frequently without assignable cause is not infrequently the first indication of an asthmatic tendency—a fact not generally recognised. Sometimes, however, both in children and adults asthma precedes the attacks of paroxysmal sneezing. The influence of locality in exciting or warding off attacks of asthma is well known, and this applies equally to cases of sneezing. A patient who was under our care for hay-asthma was severely affected in his native county Sussex, but was quite free from his complaint, even when the grass was in full bloom, in Devonshire, at Windermere, and in Scotland. Another patient, a lady who, when at Hampstead, suffers from fits of sneezing alternating with attacks of asthma, is perfectly free from both at Brighton, Eastbourne, Hastings, Bournemouth, and other seaside resorts. This immunity is not due to the direction of the wind, for she is quite unaffected whether there be a sea-breeze or a land-breeze. To use her own expression, the place which suits one of her complaints suits both.

Not uncommonly as the patient grows older, or as the bronchial attacks decrease in frequency and severity, they are replaced by sneezing or peptic asthma. Sometimes, too, as the attack of bronchitis or bronchial asthma subsides, it is followed by an attack of paroxysmal sneezing lasting for some days, with but slight intermission. This was observed in the case of a lady who uniformly had three or four bad attacks of bronchitis every year, each being followed by a week's sneezing.

We know that asthma, like many other neuroses, is greatly influenced through the emotional centres, that a sudden fright will sometimes at once cut short an attack of asthma, or may, on the other hand, induce a paroxysm. Salter relates the case of an asthmatic who was at once relieved of a severe attack by the occurrence of a fire in the opposite house. At the time the alarm was given he was in bed, breathing with the greatest difficulty, and unable to move. When the excitement was at its height he was seen, to the astonishment of his friends, standing at the open window in his night-shirt, cheering the efforts of the firemen. This is equally true of paroxysmal sneezing, and it is a common

practice in some parts of the country to arrest an attack by suddenly slapping the patient on the back, or startling him in some similar manner. Sometimes an attack of paroxysmal sneezing is uniformly excited, not so much by emotional causes as by ideation, or the association of ideas. A young lady, a native of Queensland, who for many years suffered from hay-asthma and paroxysmal sneezing, was convinced that the seat of her malady was in the left arm, and she assured us that any movement of that member, however slight, would invariably induce an attack. So convinced was she of this that she used only the right arm and hand, keeping the left supported by her dress or in a sling. If inadvertently she used the left hand, even for the simplest purpose, a paroxysm was excited. She was most explicit on this point, and, as far as we were enabled to test the matter for ourselves, her statement appeared to be correct. Carrying a fan or her umbrella in the left hand would act as the exciting cause, but, curiously enough, not until her attention was called to the fact. Here the impression must have been purely emotional or ideal, for it is inconceivable that the movement of any particular joint or the contraction of any special group of muscles could act in any other way in inducing a paroxysmal condition, which often failed to expend its force for many hours. In the same category of ideal, or perhaps we should say nondescript, cases, may be included the well known instance of the lady who had an attack of rose-fever from smelling an artificial rose. She was probably of the same temperament as the patient who was attacked with coryza from standing for a few minutes in front of a picture of a hay-field at the Academy.

The remedies employed in the treatment of paroxysmal sneezing may be divided into two categories: first, those which break up the paroxysm; and, secondly, those which by a gradual action so modify the pathological condition of the mucous membrane that the predisposition to their return is removed. In the former class first and foremost comes cocaine. Some three or four years ago we had under our care a student of the Westminster Hospital, Mr. John Watson, who gave a most interesting account of his observations on the topical application of cocaine tablets. The attacks in his case usually commenced about the last week in May, and continued without intermission until the end of July, the discomfort and inconvenience experienced being so great that during the summer months he was practically incapacitated for work. Over and over again has he left our lecture on *materia medica*, his handkerchief to his nose and his eyes suffused with tears. His most prominent symptom was sneezing, which came on in paroxysms often in the most interesting part of an exposition of the physiological action of some new and valuable drug. The attacks, he assured us, were quite uncontrollable, and he often had to resort to violent muscular exercise, such as a game of billiards, to subdue them. He was fond of theatrical entertainments, and found peculiar relief in the atmosphere of the playhouse. Other symptoms were itching and irritation of the nose, with smarting and tickling of the mucous membrane of the nares and septum. There was an irresistible desire to violently rub the offending member with a coarse pocket handkerchief, although painful experience had taught him that it ultimately intensified the trouble and irritation, which returned with redoubled vigour immediately after the application. At the same time there was a copious secretion of acrid mucus, which seemed to act as an irritant and inflame the surface with which it came in contact. There was tickling and itching of the margin of the lids, which were pressed together in the vain hope of obtaining relief. The hard palate burnt and itched so intensely that the tongue had to be forced backwards against it in order to relieve it. The pollen of hay, either growing or stacked, was found to be the most potent cause, but minute particles of any kind floating in the air would act in a like manner. The susceptibility was so great that no remedy which had been tried, and they were many, had afforded the slightest relief. At last, at our suggestion, he obtained some tablets of cocaine, which he introduced into each nostril, pushing them well up with the tip of the little finger. It was found that they would adhere to the mucous membrane without difficulty, and that they caused no pain or irritation, but afforded prompt and instant relief, not only to the coryza, but to the accompanying symptoms. The tablets first employed contained a sixth of a grain, but subsequently the half-grain tablets were substituted with advantage. As a rule, a single application checks the paroxysm, but some patients find it necessary to repeat the application several times a day. We learn from a communication recently received from Mr. Watson that he has adopted this

mode of treatment in a large number of cases, and with uniform success.

As an example of the rapidity with which cocaine acts in cutting short hay-fever and paroxysmal sneezing, we may mention that at a public dinner last summer we sat next to an American gentleman, well known on both sides of the Atlantic, whose misfortune it was to have to deliver the speech of the evening. The table was covered with flowers, and our friend, who was a hay-asthmatic, soon commenced sneezing, and rapidly exhausted the resources not only of his pocket-handkerchief, but of the spare table napkins. He could hardly breathe, and certainly for the moment he was no orator. It suddenly dawned on us that we had a tube of cocaine tablets in our waistcoat pocket. We offered them to him, and, instantly recognising their use, he plunged them up his nostrils. Almost immediately relief was obtained, and a few minutes later he was on his legs, speaking with that fluent ease and distinctness for which he is justly renowned.

We have prescribed these cocaine tablets for many actors and reciters who have been subject to sneezing, and they have rarely failed to effect the desired object. We prefer them to bougies and other gelatine preparations of cocaine. In one case the cocaine, topically applied, arrested the sneezing and irritability of the nose, but induced an attack of asthma.

Pungent inhalations of all kinds are useful in cutting short the attacks of sneezing, and apparently they act by substituting for the pathological irritation another and an artificial form which is powerless to excite the paroxysm. Strong ammonia, carbolic acid, camphor, and iodine may all be employed for the purpose. The pungent smelling salts sold in the shops often answer admirably, but the palm, we think, must be given to iodine. We usually order it in the form of the liniment, instructing the patient to carry a small bottle in his pocket, taking care, of course, that it does not escape, and to take a sniff or two on the onset of the symptoms. We have notes of many cases in which this simple method of treatment has proved wonderfully efficacious. Pure terebene, pinol, and eucalyptine are useful to inhale, and are preferred by some patients. A few drops of chloroform placed in the palm of the hand and inhaled during the attack will sometimes cut it short. In some cases of hay-fever we have found inhalations of creosote useful. The best strength is ten drops in a pint of hot water, the steam being inhaled for a few minutes. A popular remedy is essence of camphor, a saturated solution in alcohol, two or three drops being taken on sugar every ten minutes. Inhalations of camphor are also useful.

Tobacco smoking will often answer admirably, though in some cases we have known it fail. During the hay-asthma season, from about the middle of May to the end of July, the sufferer should regularly smoke a good cigar as a preventive the last thing on going to bed, or, better still, when he is in bed. The sedative influence of the cigar will often ensure a good night's rest, but the powerful depressing action of strong tobacco may be necessary to cut short the paroxysm when once established. Some patients prefer the Indian tobacco, *lobelia inflata*, to the ordinary cigar or pipe. Nitre papers burnt in the bedroom may prove useful, but those commonly prepared are too weak to do much good. We employ a nitre paper consisting of six thicknesses of blotting paper steeped in a saturated solution of nitrate of potassium and chlorate of potassium. When dry it should be sprinkled with essence of camphor, compound tincture of benzoin, tincture of essence of camphor, compound tincture of benzoin, and burnt on a tin sumpul, or some preparation of stramonium, and burnt on a tin plate at the bedside. The efficacy of Himrod's powder is so generally recognised as to call for no comment. It, like its congeners, the Green mountain cure, Bliss's cure, and their numerous imitations, probably contains nitre, lobelia, and stramonium. Coffee is not uncommonly employed to cut short attacks of hay-fever, but to be of use it must be black and strong, and should be taken quite at the onset of the paroxysm. It is so valuable a remedy that the hay-asthmatic should never drink it as a beverage, but should reserve it strictly as a medicine. We often prescribe the effervescent citrate of caffeine with advantage.

A nasal douche or spray of sulphate of quinine is said to be useful in hay-fever, but in our hands it has not yielded good results in the treatment of paroxysmal sneezing. Hazeline, an aqueous distillate prepared from the fresh bark of *hamamelis virginica* is a capital remedy both for hay-fever due to pollen and simple sneezing. When snuffed up the nostrils it aborts the attacks, and when taken internally in twenty-minim doses three times a day, it lessens the hyperexcitability of the mucous membranes of the nose and respiratory tracts.

Foremost in our second category of remedies, that is to say, those which modify the condition of the mucous membranes, and prevent the occurrence of the attacks, we place the iodides. It matters little, we think, whether the potassium, sodium, or ammonium salt be given. We prescribe it either alone in water or in a mixture flavoured with syrup of Virginian prune. The inhalation of iodine is indicated when there is itching of the nose or of the inner canthus of one or both eyes, sneezing, running at the nose of a clear watery fluid, weeping of the eyes, and severe frontal headache. Our plan is to warm a jug holding about a quart by rinsing it out with boiling water, then partly to fill with hot water, and add from twenty to thirty drops of tincture of iodine. The patient is directed to put his mouth over the jug and inhale the iodised steam, his head and the jug being covered with a large towel. This method will be found in many cases to be very successful.

One of our patients, in whom iodide of potassium and the other iodides produced a very disagreeable prickly sensation in the throat, experienced the same phenomenon after a trial of a preparation called "spirone," and he was convinced that it contained iodine in some form. Mr. Martindale was good enough to analyse it for us in his laboratory, and found that it consisted essentially of a mixture of iodide of potassium and acetone. It was then submitted to Dr. Paul of the Pharmaceutical Society, who reports as follows:

"It has a specific gravity of 1.029. Nearly half its volume consists of acetone with a little water. It yields, on evaporation, about 24 per cent. of glycerine, and about 2 per cent. of saline residue, which, when incinerated, is found to consist of 1.7 per cent. of iodide of potassium."

It is a somewhat curious coincidence that for some years we have employed with advantage a 2 per cent. aqueous solution of iodide of potassium in the treatment not only of sneezing but of chronic bronchitis and asthma. Our attention was directed to this remedy when making a series of experiments on the value of the ipecacuanha-wine spray in winter cough. We know that iodide of ethyl is useful in asthma, and it is probable that its beneficial effects are due to the iodine which it contains.

Arsenic is useful in many forms of paroxysmal sneezing, but we have found it of little or no value in true hay-fever, where the attacks are excited by pollen. It is indicated when the patient is seized several times a day, usually in the morning soon after rising, with profuse running from the eyes and nose, accompanied by frontal headache. The attacks are excited by exposure to cold, by dust, and other causes, and are usually accompanied, or perhaps preceded, by itching at a small spot situated inside one or both nostrils, not far from the orifice. This complaint, unless actively treated, often persists for years. Arsenic is also useful when the attack is excited by food, and lasts for half an hour or so after the chief meal of the day. In children who after a severe attack of bronchitis catch cold on the slightest provocation, the same method of treatment may be employed, especially when there is much wheezing and embarrassment of breathing. Coryza sometimes precedes the dyspnoea for three or four days, the whole attack lasting a week or more. Sometimes we meet with cases where the patient suffers from asthma for several years, and is then seized with severe attacks of sneezing.

In many cases of sneezing the excitable or susceptible condition of the mucous membrane of the nose is due to the presence of a polypus, or some other similar morbid condition, and then operative procedures afford the best chance of relief. When there is much hypertrophied tissue the electrical cautery, after the application of a strong solution of cocaine or antipyrin as a local anæsthetic, is recommended.

When the attacks are attended with itching or irritation of some particular spot or region, the local application of aconite liniment or aconitia ointment may at once give relief. A lady, aged 22, who was under our care, suffered persistently for some years from sneezing. The fits occurred in the morning, lasted several hours, and were accompanied by considerable pain over the forehead. The sneezing was often so violent as to exhaust her for the greater part of the day. She complained of intense itching, both of the inside and outside of the nose, and also of part of the face, the itching lasting during the whole of the paroxysm of sneezing. Her health had given way, and she was pale and thin. The free application of aconite liniment to the outside of the nose and part of the face, which was the seat of the itching, immediately gave relief, curing both the itching and the sneezing. The attacks of sneezing returned once or twice in a mitigated form,

but a fortnight's persistence in the treatment effected a complete cure.

ABSTRACT OF THE CROONIAN LECTURES ON ANTIPIRETICS.

Delivered before the Royal College of Physicians, June, 1888.

By DONALD MAC ALISTER, M.A., M.D., F.R.C.P.,
Fellow and Lecturer of St. John's College, Cambridge.

LECTURE I.

THE lecturer began by explaining that the lectures he proposed to deliver were complementary to the Goulstonian Lectures of last year. In these the treatment of fever had been intentionally passed over. But treatment could not long be absent from the thoughts of a physician, however theoretical the bent of his mind; and when very unexpectedly he was offered another opportunity of addressing the College as Croonian Lecturer, he had proposed, and the President and Censors had approved the choice, to deal with the practical bearing of the theory of fever. The regulations under the new scheme prescribed "lectures on one or more subjects in anatomy, physiology, and pathology, with a view to the prevention, control, and cure of diseases." Though the subject of the lectures was for brevity given as "Antipyretics," he did not propose to limit himself to the drugs so called or their pharmacology. He would discuss rather (1) the light thrown on the nature of fever by the means employed successfully for its treatment, and (2) the lessons in the treatment of fever which flow from a right understanding of its nature.

The outlines of the theory presented last year were recalled. The nervous mechanisms of heat-loss or thermolysis, of heat-production or thermogenesis, of heat-balance or thermotaxis, constituted the thermal nervous system, and these mechanisms were in ascending order of complexity and of evolution. Fever was a dissolution beginning with thermotaxis and extending to the inhibitory mechanism of thermogenesis. Hyperpyrexia was a still deeper dissolution, and extended to thermolysis. Much still remained to render complete our knowledge of the anatomy and physiology of these several mechanisms, but contributions were constantly being made and obscurities cleared away. As he was anxious to strengthen in their minds the conviction of the objective reality of the thermal system, he would first call attention to certain recently-acquired anatomical and physiological facts which had not yet received sufficient notice.

First, as to the physiology of thermolysis.

The Harveian Orator, Dr. Stone, had pressed on the College the importance of physical investigations in medicine, and regretted that they were at present less regarded than researches in histology or bacteriology. A series of valuable experiments, involving high skill in physics and in mathematics, and therefore perhaps overlooked, had been made on the radiating power of the skin, by Dr. Masje, under Professor Eichhorst, of Zürich. Probably, sixty per cent. of the heat leaving the body did so by radiation. But the laws of this loss had not been inquired into, or had been assumed to be governed by physical analogies. At the Zürich Hospital, by the aid of an instrument of great delicacy and precision, on the principle of Langley's holometer, the true laws of skin-radiation had been worked out, and had proved to be strikingly suggestive.

A hot body radiates less as its temperature falls. This was the physical law, but not the physiological. A part of the skin suddenly uncovered naturally became cooler, but its radiation increased steadily as the temperature fell, until a certain limit was reached. Radiation was more intense in men than in women, in boys than in girls, in young persons than in old, in the vigorously healthy than in the feeble or convalescent. In other words, radiation was more active as the processes of nutrition and metabolism were more active.

Reasons were given for believing that the radiating power of the skin, which would be shown to depend on its physical and chemical constitution, was subject to nervous control; and thus, what was apparently the most purely physical of all the thermolytic processes was not outside the domain of the thermal nervous system. In discussing the value of an antipyretic method, in ex-

plaining its mode of action, we could not in future ignore the questions: What changes does it call forth in the texture of the skin? How does it modify the great thermolytic function of radiation?

Another subject connected with thermolysis deserved some mention, namely the connection of peripheral temperatures with central. The lecturer, in common with many others, had been perplexed and baffled by the apparent lawlessness of surface temperatures as taken by any of the ordinary methods. So doubtful were any results based on them that experts regarded with suspicion all observations but their own. Recent inquiries, also carried out at Zürich under Professor Eichherst, showed that the difficulty lay chiefly in an erroneous method of procedure. When peripheral temperatures are taken continuously for some hours (eight or ten) instead of some minutes, it appears that in health as well as in disease the curves obtained consist of two distinct portions. The first corresponds to a stage of an hour or so, in which the temperature is highly irregular and different from the central temperature. This is the *ambiguous* stage. The second is marked by much greater uniformity and by nearness to the central temperature. Like the latter it tends to be constant and stable. This is the *continuous* stage, and it is so regular, so normal, that we are safe in drawing conclusions from its changes. Observers hitherto had seldom got beyond the ambiguous stage, and hence the irregularity and confusion already alluded to. The effects of antipyretic methods on the continuous stage of the peripheral temperature would form an interesting and trustworthy study later on.

Next, the anatomy and physiology of the thermogenic system had received valuable contributions. New points in the thermogenic tract had been made out (he would not call them *centres*) by Ott and others in America, using the methods and working under the inspiration of Professor Wood. In the rabbit four points in the cerebral axis were known, the stimulation of which gave rise to increased heat-production, not simply rise of temperature. Two were at the anterior and median borders of the corpus striatum, one between that body and the thalamus, and a fourth at the anterior end of the thalamus. Dr. Hale White had in part verified the localisation as regards the anterior striate centre and had made out that unilateral irritation gave rise to bilateral pyrexia. It thus appeared that in the rabbit the lateral differentiation of the thermal tracts, like that of the motor, was still incomplete.

The question of whether these points were on excitator or inhibitory tracts was next discussed, and the experiments of Girard in Geneva, and Baginsky and Lehmann in Berlin, were adduced as apparently bearing on the question in opposite senses. It was shown how they might be reconciled. Reasons were given for thinking that the so-called "striate heat-centre" might be a passing-place if not a meeting-place for both anabolic and catabolic fibres. Ott, the other day, had announced certain new discoveries which pointed to cortical areas being concerned in heat regulation. An area at the upper end of the Sylvian fissure appeared to control the striate region. Thus, when thermogenesis was induced by puncture of the striate "centre," and an abiding pyrexia resulted, stimulation of the cortical area lowered the temperature and diminished the thermogenesis. The bearing of such observations on the localisations and nature of the thermotaxic mechanism was alluded to, and the probability of further advance estimated. In Dr. Gaskell's pregnant hint, namely, that his explanation of inhibition as anabolism is applicable to nerve-centres as well as to peripheral organs, the lecturer saw the promise of much new light on the mechanism of thermotaxis.

ON THE MANAGEMENT OF FIBROMYOMATA COMPLICATING PREGNANCY AND LABOUR.

By JOHN PHILLIPS, B.A., M.B.Cantab., M.R.C.P.,
Physician to the British Lying-in Hospital.

THE subject under consideration is of such vital importance to the obstetrician that there is ample reason for an inquiry into the present means at our disposal to cope with what is too often a formidable complication of childbirth. I have as far as possible examined all pamphlets and papers written on it during the past ten years, and have endeavoured to compare the treatment suggested or adopted, and the results obtained, with those of past years.

Now, in what ways may a fibroid or fibroids modify the course of pregnancy, labour, and the puerperium?

1. During pregnancy their presence may induce a premature termination, for a tumour in the uterine wall materially interferes with the regular development of that organ.

2. They may set up localised peritonitis, which will produce adhesions with various organs—that is, intestines, liver, and rectum. In addition, they are the cause of such intense pain and distension as to necessitate operative interference during an early period of the pregnancy.

3. A tumour may mechanically obstruct the passage of the fœtus through the pelvic canal, and may thus even occasion resort to Cesarean section or the Porro-Cesarean operation.

4. Frequency of fœtal malposition is very common, and is a noteworthy fact as leading to increased infant mortality.

5. After birth of the child the placenta may be found adherent to the tumour, rendering manual delivery necessary, and consequent bruising of its substance. Placenta prævia is certainly more frequently found as a concomitant of fibroids.

6. Uterine contraction after expulsion of the placenta may be more or less inefficient, owing to the presence of the tumour, and hæmorrhage may result. Involution is also much delayed.

7. Morbid softening and disintegration may take place either before or after labour, leading to peritonitis and its concomitant evils. Torsion of the pedicle and subsequent gangrene of the tumour have been noted.

It will be found convenient, for the purposes of description, to divide the uterus into three divisions:

1. The superior or upper segment.
2. The inferior segment.
3. The cervix.

As a rule, fibroids of large size, or multiple in character, arising in the superior segment give trouble during pregnancy, while their presence in the two latter situations usually only becomes noticed from the pressure symptoms they may produce, or at labour, when they form a more or less serious obstacle to delivery. Although we can with some propriety call these latter "dangerous zones," the upper is very little less so during pregnancy, both to maternal and fœtal life.

The line of demarcation between the upper and lower segments is impossible to define clearly, for it must be remembered that a fibroid, which during the earlier months is high up, may descend as pregnancy advances, and not seldom it is found that true interstitial fibroids split the uterine tissue in their descent, and penetrate into the thickness of the anterior or posterior lip of the cervix. Moreover, pedunculated subserous fibroids, by lengthening or stretching of their pedicles, may descend into the true pelvis, form adhesions with adjacent organs, and practically act as if arising from the inferior segment or the cervix.

On the other hand, there is undoubted evidence to show that a fibroid in the inferior segment (provided it has not any cervical connections) may gradually ascend during pregnancy, probably from the contraction of the longitudinal uterine muscular fibres, while the phenomenon becomes most marked (in some fortunate cases) during labour, where, as the os uteri dilates, so the apparently irresistible obstacle gradually ascends, and the fœtal presentation takes its place. Fibromyomata arising in the anterior or posterior cervical lip are, if they attain any size, most serious impediments to delivery. The difficulty is, however, to make an absolutely certain diagnosis that they are not pedunculated subserous fibroids which have descended. The surrounding parts are much distended and displaced, thus rendering a most important and vital point in the question of treatment in the highest degree uncertain. Unlike pelvic bony narrowing, it is difficult to fix with any precision the size of a fibrous body which can be called an obstruction to labour; in fact, it is entirely arbitrary. Fibroids in the posterior wall are much more likely to lead to obstruction than those in the anterior, owing to the powerful retraction which takes place in this latter situation.

Although fibroids undergo a peculiar softening, so that during labour they can be flattened out somewhat, still it is far from a condition that can be depended upon as likely to occur, and should it do so, the effects of the bruising may be disastrous in the extreme. As a consequence, no definite rules can be laid down, and each case must be, to a great extent, treated on its own merits.

The thesis by Lefour¹ supplies 307 cases as occurring up to 1879-80, but 7 of these I found had to be put aside from insufficient details, thus leaving 300. These include those mentioned

TABLE I.—*Porro-Cesarean Operations.*

No.	Author and Reference.	Age.	Parity.	Tumour.	Period of Pregnancy.	Previous Obstetrical Interference, Treatment of Stump, etc.	Result.		Condition of Patient at Time of Operation.	Remarks.
							M.	Ch.		
1	Storer; Journal of Gynecological Society Boston, 1869, i, p. 223	37	I-p.	Fibrocystic of anterior wall with intimate adhesions to pelvis	T	Cesarean section intended only at first; after cut into tumour, hæmorrhage so great that Porro-Cesarean necessary. Double metallic ligature with clamp shield. Stump canterised and fixed in lower angle of wound	D 68 hrs.	D*	Very unfavourable	Pelvic portion of tumour was left below the ligature; death from septicæmia. Available pelvic space $1\frac{1}{2}$ inch.
2	Tarnier; Annales de Gynecolog., 1879, xii, p. 81	33	"	Tumour posteriorly at cervico-corporal junction and adherent in pelvis; softened centres full of putrid material <i>post mortem</i>	T	Müller-Rein modification; extra-peritoneal treatment of stump; Cintrat's serre-neud and long pin	D 3rd day	D*	"	In labour 7 days; death from septicæmia.
3	Zweifel; Archiv. f. Gynäk., 1881, Bd. xvii, p. 371	37	"	Size of a cocoa-nut in cervix filling whole pelvis. Uterus consisting of tuberculous tumours as hard as cartilage.	T	Müller-Rein modification and elastic ligature; after removal of Koberle's serre-neud, found impossible to treat extra-peritoneally; pedicle broad 15×11 cm.; a cone-shaped piece excised; pedicle ligatured with silk and catgut, and dropped into cavity	D 6th day	A	"	Several hours in labour; death from septicæmia; available pelvic space $1\frac{1}{2}$ inch.
4	Cataliotti; Annali di Ostet. Ginecol. e Ped., 1882, p. 455	41	"	Interstitial in posterior uterine wall extending into vagina; upper portion strongly adherent to liver	7 mths.	Uterus opened <i>in situ</i> ; serre-neud and catgut ligature in lower angle of wound. Transfixion by pin	R	A	Unfavourable	In labour a few hours; abundant ascitic fluid escaped during operation. Induction of labour impossible from blocking up of vagina. Tumour weighed 5 kilogrammes (about $11\frac{1}{2}$ lbs.)
5	Prochownik; Deutsche Med. Wochen., 1882, No. 40	40	"	Uterine myoma impacted in pelvis	"	Müller-Rein modification; Pean's constrictor with 2 long pins in stump; stitched into lower angle of wound	D 60 hrs.	A	"	Discharge of liquor amnii 24 hours; death from septicæmia; child lived a few minutes.
6	Denaré; Lyon Médicale, 1883, vol. xliii-xliv, No. 20, p. 69	42	XIV-p.	Tumour in left iliac region filling up almost entire pelvis and dipping into posterior cervical lip; interstitial	T	Twins diagnosed. Reposition failed. Six hours' railway journey. Cintrat's serre-neud and metallic thread; 2 needles through stump and pedicle in lower angle of wound; tumour below ligature	R	D*	"	Placenta on posterior wall; bronchial catarrh and prolonged suppuration followed. Tympanitic distention of transverse colon necessitated puncture. 3 days in labour. Available pelvic space four-fifths of an inch.
7	Simpson; Edin. Med. Journ., 1884, xxx, p. 9	27	II-p.	Tumour extending from lower uterine segment and between layers of broad ligament to the left of pelvis	T	Müller-Rein modification; ligature above tumour; serre-neud; stump in lower angle of wound	D 7th day	D*	Very unfavourable	Was 15 hours in labour. Discharge fetid. First child stillborn after 3 days' labour. Urine highly albuminous.
8	Handfield-Jones; Obstetrical Trans., 1885, xxvii, p. 4 (Assisted at operation)	38	I-p.	Tumour size of fetal head with broad pedicle from lower segment of posterior wall; peritonitic adhesions	T	Reposition attempted under ether, forceps and craniotomy. Uterine flaps clamped by hammer-head forceps to arrest hæmorrhage. Stump in lower angle of wound	D 3rd day	D*	Most unfavourable	First seen at fifth month of pregnancy. Tumour then impacted. Attack of peritonitis.
9	Filipi; Annali di Ostet. Gyn. e Ped. 1885, p. 450	32	"	Subserous multiple fibromata, one large one projecting into pelvis, left side and behind	T	Elastic ligature. One silk thread ligatured right broad ligament and 2 through left. Stump extra-peritoneally treated in lower angle of wound	D 24 hrs.	D*	Unfavourable	In labour 4 days; death from collapse. Blood found in peritoneal cavity; a ligature on left side had given way in consequence of movements of patient. Tumour weighed $3\frac{1}{2}$ lbs.
10	Sänger; Centralblatt für Gynäk., 1885, Bd. ix, p. 348	41	"	5 myomata, 2 very large, and in a state of degeneration	T	Müller-Rein modification; serre-neud and stump in lower angle of wound	D 2½ days	D*	"	Sterile many years; death from septicæmia. One fibroid cleft by uterine incision.
11	Klotz; Centralblatt f. Gynäk., 1887, Bd. xi, p. 345	31	"	Pelvis filled by tumour, apparently in right broad ligament, impacted	T	Elastic ligature; stump with peritoneal flaps sewn over it, dropped into abdominal cavity; placenta at uterine incision	D	A	Favourable	Liquor amnii not escaped; sterile 15 years. Faecal vomiting after operation, secondary abdominal section, duodenum and intestine adherent to stump. Immediate relief to vomiting. Suicide. Available pelvic space $\frac{3}{4}$ inch.
12	Sir Spencer Wells; BRIT. MED. JOURNAL, 1887, vol. i, p. 1267	37	"	Tumour filling up entire pelvis, with several sub-peritoneal growths	T (-)	Uterus punctured and then torn. Steel wire constrictor, no elastic ligature, stump in lower angle of wound, and saturated with perchloride of iron. No drain-tube	R	A	"	A tumour found free in abdominal cavity, closely adherent to cocum and omentum. Head appeared at incision; fibroids known to exist before pregnancy. Weight of uterus and tumour 9 lbs.
13	Schröder, in Hofmeier; Zeitschrift für Geburt. u. Gynäk., 1887, Bd. xiv, p. 99	45	II-p. 1 abort.	Uterus permeated by several tumours, one size of fist in right cervical wall	T	Elastic ligature, incision into uterus and cord tightened; appendages ligatured. Amputation at level of internal os uteri. Funnel-shaped excision cervical canal, peritoneum sutured over it; deep silk ligatures; intra-peritoneal	R	A	"	Artificial abortion attempted third month. Liquor amnii escaped 2 hours before operation. Fibroids known to exist before pregnancy. Child asphyxiated, but recovered with Schultz's treatment.

* Fœtus dead, or dead and putrid before operation.

by Puchelt, Süsserott, Nauss, Dubar, and Chahbazian, and may be considered as a fairly comprehensive review of the subject up to the time stated. Since then I have collected 59 cases where some difficulty occurred during various periods of pregnancy and labour, but where the treatment by abdominal section was not required, and 47 cases in which one or other of the varieties of abdominal section was performed. These I have tabulated under separate heads.

(a) *Treatment During the Early Months of Pregnancy, that is, before the Fœtus is Viable.*—Under this heading are included assumption of genu-pectoral position, enucleation *per vaginam*, induction of artificial abortion, and reposition of the tumour under an anæsthetic. These methods are well known, but I cannot pass them by without giving a word of warning before they are resorted to.

Artificial abortion was produced purposely 3 times, and once

TABLE II.—Cases of Müller's Ablation,
(i.e., Abdominal Section with removal of Tumour and Uterus containing Non-viable Fetus.)

No.	Author and Reference.	Age.	Parity.	Tumour.	Period of Pregnancy.	Operation and Treatment of Pedicle.	Result.	Reason for Interference.	Remarks, Condition at Time of Operation, &c.
1	Robert Barnes; St. George's Hospital Reports, 1874-6, vol. viii, p. 90, case xxii		I-p.	Uterine strangulation by 2 fibrous tumours; the anterior and smaller reaching 2 in. above umbilicus. The pelvic cavity almost obliterated by posterior and larger one	2 mths.	Attempts at reposition under ether failed; aspiration of pelvic tumour <i>per vaginam</i> . During operation great difficulty in dislodging pelvic tumour. Broad ligaments tied, severed by the cautery, whipcord ligature to stump and dropped into cavity	D 30 hrs.	Rapid increase during gravidity, enormous distension of abdomen, with vesical and rectal troubles	Peritonitis before operation, vomiting excessive. Condition most unfavourable.
2	Wasseige; Bulletin de l'Acad. Roy. de Méd. de Belgique, xiv, ser. 3, No. 4	35	1 abort.	Left antero-lateral cysto-fibroma of uterus filling pelvis, tumour reaching 3 inches above umbilicus	18 wks.	Ecraseur provisionally; stump ligatured, peritoneum sutured over it and dropped into cavity. No drain-tube	D 5th day	Violent abdominal pain. None but dorsal decubitus possible; dysuria, dyschezia. Excessive distension	Cause of death indefinite. no peritonitis, suppuration or hemorrhage. stump quite healthy. Condition unfavourable.
3	Kaltenbach; Centralbl. für Gynäk., 1880, Bd. iv, p. 345	32	I-p.	Multiple subserous fibroids. Large interstitial reaching to fundus uteri, with many softening centres	22 wks.	Mass everted; temporary elastic ligature. Stump ligatured and kept in abdominal wound by 2 long pins	R	Considerable antepartum hemorrhage, with dyspnoea, vomiting, oedema of legs and vulva	Placenta over site of tumour which weighed 6½ lbs. Condition most unfavourable from hemorrhage.
4	Knowsley Thornton (private communication)	38	1 abort.	Aggregation of fibroids at fundus filling false pelvis, weighing after excision 16 lbs.	4½ mths.	Koerberle's serre-neud and stump kept out of cavity by 2 long pins	"	Rapid growth of tumour, emaciation and anaemia	Some of tumours very soft and fluctuant. Condition unfavourable.
5	T. Savage; BRITISH MEDICAL JOURNAL, 1882, vol. ii, p. 423	25	I-p.	Tumour occupying right side of uterus, and reaching up to umbilicus	16 wks.	Pedicle ligatured, clamped and stitched to lower angle of wound. Glass drain-tube above stump	"	Excessive pain and emaciation with very rapid increase in size	Tumour, uterus, and contents weighed 9 lbs. Right Fallopian tube and ovary in front of tumour and almost black from compression. Condition fairly good.
6	Walter; BRITISH MEDICAL JOURNAL, 1883, vol. ii, p. 718	29	"	Right side of inferior uterine segment; another on posterior aspect low down, the two weighing 10 lbs. and 1½ lbs. respectively	4 mths.	Ablation after attempted enucleation and opening of uterine cavity. Pedicle clamped and 2 needles passed, then ligatured to lower angle of wound	D 9th day	Bedridden 12 weeks, suffering intensely from constant pain and pressure symptoms; repeated attacks of peritonitis	Peritonitis cause of death. The funis escaped through uterine aperture; several ounces of fetid fluid in pelvis, <i>post mortem</i> . Condition fairly favourable.
7	Hayes Agnew; BRITISH MEDICAL JOURNAL, 1884, vol. i, p. 158 (Godson's list)	44	"	Tumour filling entire pelvis	6 mths.	Stump ligatured and secured with large clamp	D 64 hrs.	In labour five days—fœtus putrid	Death from vomiting and exhaustion. Condition very unfavourable.
8	Hofmeier; "Die Myomotomie," 1884, Stuttgart, p. 77, and Fig. 27	41	"	Multiple sub-peritoneal with fundal tumour, size of adult head	3 mths.	Amputation at level of internal os uteri. Stump sutured and dropped into cavity	R	Very rapid growth of tumour after gravidity	Sterile three years, tumour slowly growing. Condition good.
9	Hofmeier; "Die Myomotomie," 1884, Stuttgart, p. 78 and Fig. 28	40	"	Sub-peritoneal and interstitial chiefly at fundus of enormous size	2½ mths.	Amputation at level of internal os uteri. Stump sewn with catgut and silk. Intra-peritoneal	"	Rapid growth of tumour after gravidity	Bronchitis retarded convalescence. Copious hemorrhage during operation. Condition good.
10	Etheridge; Jnl. Amer. Med. Assoc., 1886, vol. ii, p. 466	34	"	Multilocular fibroma, occupying whole anterior wall. Cervical canal 5½ inches long	3 mths.	Capsule of tumour buttoned and tumour partially enucleated to allow formation of pedicle. Serre-neud at first and vessel tied. Cone-shaped piece excised, stitches inserted, peritoneum drawn over it. Stump dropped into cavity	D 11 days.	Great pain and emaciation	Abortion had been attempted before operation, tumour had caused retroflexion before gravidity. <i>Post mortem</i> examination showed pelvis filled with pus and blood. Condition unfavourable.
11	Kaltenbach; Vogel's Diss. Giessen, 1886, and Centralbl. f. Gynäk., 1887, Bd. xi, p. 435	23	II-p.	Interstitial myoma in anterior wall, size of fetal head; softening centre	3 mths.	Amputation at level of internal os uteri. Stump in lower angle of wound	R	Enormous increase in size	At operation uterus of size of eight months gravidity. Condition favourable.
12	Granville Bantock; British Gyn. Trans., 1886-7, vol. ii, p. 65, (and private communication)	34	I-p.	Two pedunculated tumours, one 11 lbs., the other 1½ lb. The former with firm and extensive omental adhesions	3½ mths.	Pedicle fixed in angle of wound. Serre-neud and 2 pins	"	Enormous distension and rapid increase in size	Pregnancy unsuspected; she could not have gone to term owing to distension; tumours would not have interfered with labour. Condition good.
13	Granville Bantock; Amer. Gyn. Trans., 1887, vol. xii, p. 211, (and private communication)	40	VI-p.	General fibroid enlargement with hydraemias. Twins	4 mths.	Serre-neud with one pin. Pedicle in lower angle of wound	"	Dyspnoea from rapid increase in bulk, oedema of vulva and extremities	Between 12 and 13 pints of fluid in amniotic sacs. Ovarian tumour with thin walls diagnosed with pregnancy. Condition unfavourable.
14	Granville Bantock; (private communication)	31	II-p.	Multiple fibroids with dead retained fetus	—	Serre-neud with two pins. Extra-peritoneal treatment of stump	"	Operation deemed safer than attempt to remove dead fetus, and to render repetition impossible	—
15	Dirner; Centralbl. für Gynäk., 1887, Bd. xi, p. 119	40	I-p.	Interstitial and subserous tumours generally distributed. Pelvis blocked; tumour reaching above umbilicus	2 mths.	Ablation. Enucleation of cervical tumour. Intra-peritoneal treatment of stump	"	Enormous increase in size during gravidity; incarceration symptoms well marked	Convalescence delayed by cystitis from catheterism and stitch abscess. Condition favourable.

TABLE 11.—(Continued.)

No.	Author and Reference.	Age.	Parity.	Tumour.	Period of Pregnancy.	Operation and Treatment of Pedicle.	Result.	Reason for Interference.	Remarks, Condition at Time of Operation, &c.
16	Karström; Hygiea, 1887. Bd. xlix, pp. 215-34	36	II-p.	Sessile tumour, intra-ligamentous on left side. Weight 40 lbs	4½ mths.	Abdominal section. Attempted enucleation, severe hæmorrhage. Iliac ligature, Müller's ablation; peritoneum sewn over stump and dropped into cavity. Two drain tubes	R	Pressure symptoms. Ascites, which was tapped; wound continued discharging	At first pregnancy tumour necessitated podalic version. Phlegmasia dolens in left leg slightly 30th day. Condition favourable.
17	Meridith; (private communication)	38	I-p.	Tumour size of adult head, with thin pedicle attached to right uterine cornu	2 mths.	Tumour ligatured and removed. Then Müller's ablation. Stump in lower angle of wound with serre-nœud. Iodine to surface	D 6th day	Increasing pain and rapid emaciation cause of abdominal section	Ablation for fear ligature should give way, if miscarriage occurred. Surface treated with Zn Cl ₂	R	Pressure symptoms urgent	Placenta inserted upon site of tumour. Abscess in abdominal wall delayed recovery. Condition favourable.

only by mistake in the 59 cases I have detailed, and all 4 recovered; but on referring to Table 11, Case 10 (Etheridge), it will be seen that an unusual complication occurred which is worthy of note, namely, elongation of the cervical canal to five inches and a half; this was produced by the fibroid in the anterior wall. Abortion was attempted and was thought to have succeeded, but the subsequent operation showed that the three months' ovum was quite intact. The dangers of the other operations I shall allude to later.

Two other methods I must enter into in detail, as they are comparatively recent improvements in these cases; I allude to "myotomy" and "Müller's ablation" (Table 11).

By "myotomy," is meant abdominal section and removal of one or more fibroids by ligature and closure of the incision, in the hope that pregnancy may go on to term. It is manifestly only permissible:—1. When the fibroid is attached in an accessible situation. 2. When its presence is causing either intolerable pain or discomfort from distension.

Mr. Knowsley Thornton first performed it in 1879³, but labour supervened, constant sickness and death followed, from intestinal obstruction; this also occurred in a case of Porro-Cæsarean operation by Klotz (Table 1, No. 11), which he removed by secondary abdominal section. Landau⁴ and Schröder⁵ have published details of successful cases, labour occurring at term, while Martin's⁶ and Krukenberg's⁷ both terminated fatally, in consequence of the occurrence of abortion. So that we have as a result five cases with a favourable result in two, and a mortality of 60 per cent., almost 10 per cent. less than the statistics of Cæsarean and Porro-Cæsarean operations show.

I must now call your attention to Table 11. Müller's ablation must not be confused with the Porro-Cæsarean operation, as is almost always the case. The latter is utero-ovarian amputation, as complete of the Cæsarean section, while the former may be defined as "abdominal section with removal of the tumour and the uterus containing the non-viable fœtus." There is no question here of the life of the child, the maternal conditions being so grave as to preclude the pregnancy going to term.

The total number of cases on record is 19, with 7 deaths, or a mortality of 36.8 per cent. The reasons for the performance of such an operation are naturally of the greatest importance; fortunately I have been enabled to obtain them in every instance, and they are given in the last column but one in Table 11. It

will be seen that the operation was performed for removal of a dead fœtus twice, in one after a labour of five days (vii, xiv). Violent pain is mentioned as occurring in 6 cases, rapid increase in the size of the tumour in 10 was noticed, emaciation in 4, while pressure symptoms demanded interference in 5 cases. In Case iii severe *ante partum* hæmorrhage was the preponderating cause. Besides the above, in 4 cases other conditions were found during the operation, which not only showed its justifiability, but its absolute necessity for the saving of the mother's life. There was uterine strangulation with recent peritonitis in Case i; softening centres were found in the fibroids in Cases iii and xi, while in Case v, the right Fallopian tube and ovary were almost black from compression.

Of the 19 cases, 13 were treated by the extraperitoneal method, with 9 recoveries, and 6 by the intraperitoneal method with 3 recoveries. Into the relative value of the two proceedings I do not here desire to enter.

It will be seen that in all the cases given, the likelihood of the patient going to term was untenable, and the question arose, what was the best mode of treatment to be adopted. All those already given would have been useless or indeed impossible, excepting provocation of abortion, and the course to be adopted would therefore have been this with its accompanying dangers and chance of repetition, or the unsexing of the patient, removal of a useless and dangerous complication and leaving no chance (in the event of recovery taking place) of further impregnation. No one who looks at the two figures in Hofmeier's work (*Myomotomie*) will doubt for an instant the wisdom of the step he took, and he is to be congratulated on the brilliant results he obtained. The mortality is nearly half that obtained in the Porro-Cæsarean and improved Cæsarean operations during the past nine years; but, on the other hand, there is the counter-balance of saving of foetal life which must not be neglected. With the scanty records we have, I think it would be most unwise to lay down any rules concerning this operation; every case must be judged by itself, and it seems to be one which should not be undertaken without consultation.

(8) *Treatment of Fibromyomata during Fœtal Viability, including Labour.*—The question of the saving of the child's life will naturally somewhat modify the line of treatment. Labour was induced 6 times in Lefour's 300 cases, with the result of 1 maternal death and in the birth of 1 living child. Among the 59 collected cases this operation has been performed 3 times, with the discouraging result of 2 maternal deaths, and the survival of 1 child only. Two of them occurred in my own practice, both, unfortunately, ending fatally. The first is already described and figured in the *Obstetrical Transactions* for 1886, vol. xxviii, p. 138

I saw her in consultation with her medical attendant in consequence of acute pain, rapid pulse, with a temperature of 101.4 F., with a dry brown tongue, and a purplish discoloration of the abdomen. The multiple fibroids were complicated by twins. This condition appears to add additional gravity to the case, for out of 7 cases I have met with no less than 5 were fatal. The second was unfortunately also fatal. I was asked to see her with regard to the question of interference at the seventh month, or the possibility of abdominal section at term. The obstacle to delivery was a kidney-shaped tumour at the junction of the cervix and lower uterine segment, and occupying nearly two-thirds of the pelvic inlet. There were, in addition, two large fundal abdominal tumours, which would have been serious complications in the Cæsarean section. Knowing the importance of handling tumours of this kind as little as possible, I attempted induction by the subcutaneous injection of pilocarpine four times, which, although productive of full constitutional effect, nevertheless failed to produce any labour pains. A bougie was passed, labour followed, and was very lingering in character. Death occurred on the eighth day from peritonitis, commencing over the larger abdominal tumour. My own experience, then, decidedly opposes this method, even when the alternative be the dreaded Cæsarean or Porro-Cæsarean section. By forcible reposition is meant the pushing up of the tumour during labour, and thus permitting the presenting part to occupy the inlet of the pelvis and delivery effected.

Dr. Playfair has strongly advocated this plan of treatment in two papers read before the Obstetrical Society.⁵ In three cases related by him the fibroid tumours occupied such a position in the pelvis, that had it not been possible to get them out of the way, the Cæsarean section would have been inevitable. In all three upward pressure succeeded in dislodging them, so that delivery was effected *per vias naturales*, twice by turning and once by the forceps. He concludes with these words: "These cases teach us the hopefulness of such a procedure, and the advisability of making a strong and persistent effort at reposition, in which an amount of force may be necessary which would be quite unjustifiable were there any less terrible alternative to be selected than the Cæsarean section." In opposition to these conclusions I have but few remarks to make.

Take for instance the case related by Knowsley Thornton already alluded to. After abdominal incision the tumour was forced up from the pelvis, and such furious bleeding occurred that for a moment the safety of the iliac vessels was feared. What a calamity would have been produced if this line of treatment had been adopted; uncontrollable hæmorrhage would have taken place within the abdomen, and the patient have died probably in a few minutes.

Again, take the case which I had the opportunity of seeing with Dr. M. Handfield-Jones (Table I, No. 8); there it was attempted with the greatest persistence but without success, and the *post-mortem* examination showed the tumour to be much bruised, and perhaps partly the cause of death. I think that with two cases like the above, forcible reposition should not be undertaken without considerable forethought, and should certainly not be too long continued.

In the *Transactions of the American Gynecological Society* for 1884, Dr. Mundé relates a very brilliant result from removal of an enormous cervical fibroid *per vaginam* during labour. Braxton Hicks⁸ and Lomer¹⁰ also have performed this operation successfully. It is, however, only possible when the tumour is connected with some portion of the cervix, and there is considerable difficulty in being absolutely certain that this is the case, as the parts are always distorted and much swollen. Doubtless in suitable cases it is infinitely safer and preferable to the dreaded alternative Cæsarean section; while, on the other hand, the great liability to septic infection and the likelihood of the attempt failing must be borne in mind.

A case requiring the Cæsarean section recently came under my notice, and details are fully given elsewhere (*Lancet*, 1888, vol. i, p. 919). The fibroid was firmly impacted in the pelvis, and the uterine body infiltrated with several smaller ones. Interference was necessary from serious pressure symptoms. The Porro-Cæsarean operation was impossible, and it appears to have been a case with which the resources we have at our disposal at present are unable to cope.

I have been able to collect twelve other cases as having occurred during the past eight years, and I have tabulated the results below. They have been selected from the papers by Baker,¹¹ Slavianski,¹² Sanger,¹³ and Parish.¹⁴

Up to the end of June, 1876, when Späth operated, every Cæsarean case for a hundred years had proved fatal in the Viennese Lying-in Hospital, and from 1787 to 1879 a similar result occurred in the Paris Maternité; nor were the results in England much better, as shown in Radford's¹⁵ laborious and accurate tables on the subject.

In Table I are collected all the cases of Porro-Cæsarean operation for this complication which have occurred since the introduction of the operation. They are, curiously enough, identical in number with those of Cæsarean section for the past eight years, and, what is more remarkable still, the maternal mortality is the same.

If we compare the dangers of the Porro-Cæsarean operation and Cæsarean section, we find six chief ones noticeable as the cause of death in the latter: (1) peritonitis, (2) metritis, (3) hæmorrhage, (4) septicæmia, (5) shock, and (6) intestinal obstruction occasionally; while in the former we have only peritonitis, septicæmia, shock, and intestinal obstruction. In addition to the elimination of metritis and hæmorrhage as dangers in the Porro-Cæsarean operation, the risk of septicæmia is much less. Moreover, the danger of peritonitis is much reduced also; for, depending as it does in a great measure on the presence of irritating fluid in the peritoneal cavity, it is less likely to result where the uterus is removed than where, with often a gaping wound, it is left behind. These facts point to the necessity where possible of performing the Porro-Cæsarean section for preference; but sometimes, as in the case already alluded to, the formation of a pedicle may be a matter of impossibility.

Statistics of Cæsarean Section.		Porro-Cæsarean.	Müller's Ablation.
Up to 1880.	From 1880-1888.	Total Number on Record.	Total Number on Record.
Total number = 33	13	13	19
Maternal deaths = 28 or 84.8 per cent.	9 or 69.22 per cent.	9 or 69.22 per cent.	7 or 36.8 per cent.
Children alive ... 13	8	6	—
Dead before operation ... 11	4	7	—
Doubtful ... 9	1	0	—

On referring to Table I it will be seen that in 10 cases the extraperitoneal method of treatment of the stump was adopted, with 3 recoveries; while in 3 the intraperitoneal was used, once from necessity (Case iii), and twice from choice, with one recovery only (xiii). In all the cases I have as far as possible taken note of the condition of the patient at the time of operation, and more especially as to whether there had been previous obstetrical interference or not; in other words, whether the operation was selective or complete. In only 3 cases (Spencer Wells, Klotz, and Schröder) was the condition of the woman favourable; 2 of these recovered, and the third committed suicide while doing well after secondary laparotomy for intestinal obstruction. By Müller-Rein modification is meant the evisceration of the whole mass before incision into the uterus. As far as my tables show, no increase of fetal mortality was the result of the procedure. In the remaining 10 cases the woman's condition was more or less unfavourable, the patient being much exhausted by prolonged labour or repeated but futile attempts at delivery by vagina. I think nothing shows more decidedly the value of this operation being performed as a selective one. From the tables given it will be seen how extremely high the mortality is in these cases, but it is characteristic of fibromyomata to resent any interference.

¹⁵ *Observations on the Cæsarean Section, Craniotomy, etc.* 1880.

⁸ *Obstetrical Transactions*, vol. xix, 1877, p. 111; and vol. xxiii, 1881, p. 27.

⁹ *Obstet. Trans.*, 1871, vol. xii, p. 273.

¹⁰ *Zeitschrift für Geburt. und Gynäk.*, 1883, Bd. ix, p. 302.

On reviewing Lefour's cases we find that, of 66 which terminated unassisted, 32 ended fatally, or a mortality of 48.4 per cent. Of 35 cases of version, 21 died, or 60 per cent.; while the percentage mortality attached to forceps and embryotomy is 25.9 and 55.5 respectively. Fœtal mortality is also particularly high, being 77.7 per cent. in version. These figures amply prove the fact that fibromyomata are a most dangerous complication of pregnancy and labour, whether operative treatment be adopted or not.

I have dwelt somewhat at length upon myotomy, Cæsarean section, the Porro-Cæsarean operation, and Müller's ablation, because they are, comparatively speaking, modera improvements, and it is in the perfection of them, I think, that our great prospect lies of reducing the hideous mortality which I have shown exists in cases where they are rendered necessary.

ERRATUM.—In Mr. Hurry Fenwick's paper on "The Value of Inspecting the Orifices of the Ureters by Electric Light, etc.," in the second sentence of the first paragraph (line 5), for "it" read "method."

TOXICOLOGICAL MEMORANDA.

ATTEMPTED SUICIDE BY SWALLOWING CARBOLIC ACID: RECOVERY.

E. W., female, aged 20, on the morning of May 12th, 1888, purchased a ten-ounce bottle of carbolic acid from a neighbouring chemist, and drank three ounces of it. Three-quarters of an hour after she had taken it I found her lying on the floor in great agony. Not having my stomach-pump with me, I gave her a hypodermic injection of one-tenth of a grain of apomorphine, and administered olive oil and lime water freely. This was followed almost immediately by copious vomiting. At the expiration of half an hour I gave another injection of one-twentieth of a grain of apomorphine, and continued to give small quantities of lime water. Shortly after she became insensible, and remained in a comatose state for eight hours. When consciousness returned I had her removed to hospital, from which she was discharged on May 19th.

Clifton House, Battersea Park, S.W.

CLINICAL MEMORANDA.

A CASE OF PERNICIOUS ANEMIA TREATED BY REPEATED TRANSFUSION.

G. P., aged 58, came under care on July 23rd, suffering from intense anæmia; he was very thin, with an anxious careworn expression. The skin was uniformly of a tawny colour, without any intensification in any locality, the mucous membranes were free from pigmentation, the sclera was pearly white, the ears thin, pointed, white, almost transparent. There was no splenic, hepatic, or glandular enlargement; no pulmonary disease. A hæmic murmur was marked over the aortic and pulmonary orifices; the cardiac impulse was very feeble; there was no anasarca or chubbing of fingers or toes. Urine, specific gravity, 1010; no albumen. Microscopical examination of blood showed twenty or thirty white corpuscles in one-fifth field; one or two nucleated red ones. Retina almost white; here and there some yellowish spots; on right one or two linear extravasations of a recent date in the vicinity of the macula (the sight of this eye had been impaired for some time); over both retinae there were some small extravasations in various stages of absorption. History: A butcher—an enormous worker—reducing sleep to meet his business requirements, eating largely, and abusing the use of stimulants; had never lived in a malarious district, and had not suffered from syphilis.

REMARKS.—This was considered to be a case of pernicious anæmia or Addison's disease. He was treated by a continual recumbent position because of his dyspnoea. Iron and arsenic in effervescent form were given for some months. Peptonised fluid aliment and brandy were given with strict regularity. At one time more than four quarts of peptonised milk were consumed in twenty-four hours. After a few months it was apparent that the treatment was of no avail, so I resolved to transfuse as often as it might be necessary. Mr. G. S. Watson kindly gave me his assistance, and on December 12th I injected about ten ounces of blood into his left median basilic by Aveling's apparatus, from a healthy strapping lad—his nephew. The immediate effect was brilliant; a slight colour came into his cheeks and ears, and he expressed

himself as "expanded" by the dose. For a few hours he breathed 30 per minute. Temperature rose to 103 about six hours afterwards, but no pulmonary trouble appeared, and the next day he was quite brisk. The improvement gradually waned, and by the 16th the operation was again necessary. The left arm could not again be utilized, because the use he had made of the veins had completely obliterated all the large ones on the surface, so the right median basilic was chosen, and ten ounces injected with the same train of symptoms as before. On the 22nd, the right median cephalic was used, and ten ounces injected. This last injection completely occluded the surface veins of the right arm, so that when on the 30th the transfusion was again necessary, the left external saphena was chosen, and ten ounces used. This was the last that was done, for, on January 11th, the attempt to open the lumen of veins in either leg was impossible from their extreme tenuity.

He lingered a few days and then sank, without any evidence of organic disease save pulmonary hypostasis. His existence simply abandoned him. No *post-mortem* was permitted.

Tunbridge Wells.

CLELAND LAMMIMAN, F.R.C.S.

SURGICAL MEMORANDA.

GUNSHOT WOUND OF THE FACE.

W. L., when leading a horse and cart along the road, heard two shots in quick succession; the second struck him in the face. When he applied, his right cheek and lower lip were swollen. There was a roundish wound, with scooped-out and rather lacerated edges, large enough to admit a finger, to the right of the middle line and just below the lower half of the orbicularis; also a small wound on the cheek, which might have been made by a single pellet of shot. The right canine and central incisor, with their sockets, were gone; the intervening tooth, with its socket, was still held by the periosteum and gums of the inner aspect of the maxilla. The gums on the outer surface were lacerated and separated from the bone, which was roughened and scored, down to its lower border. No shot could be felt—only some bone-grit. The jaw was broken, but the structures on its inner aspect were uninjured. Some days afterwards there was a sinus from the wound on the cheek to that over the chin, and a cavity formed below the chin on the right side. Here the probe detected some hard substance, which, after the sinus had been slit for some part of its length, was grasped by forceps, but crumbled under its grip. Withdrawal of the forceps was accompanied by a shower of shot falling to the floor. The blades held a lump of four pellets firmly stuck together, and much of what was then and subsequently removed consisted of pellets in twos and threes. The amount of shot recovered was one-third of an ounce. Recovery was rapid. The shot was fired from the raised bank of the Trent across a field, the distance to the road being 133 yards. It was fired at and killed a pheasant. The shooter saw the cart, but said it was out of the line of fire. He was not seen by the wounded man till after the accident, but a lad leading another cart behind saw the shot fired.

The points worthy of notice are: 1, the distance—133 yards; 2, the amount of shot recovered—one-third of an ounce; 3, the statement that the man was out of the line of fire. In regard to point 3, I have been told of two other cases of *stray* pellets hitting persons quite out of the line of fire. As to 2, the shot was carried in a lump, and this perhaps explains 1.

M. R. J. BEHRENDT, L.R.C.S. and P.E.D.

Burringham, Doncaster.

CASE OF FRACTURE OF THE BASE OF THE SKULL: PROLONGED INSENSIBILITY.

On December 30th, 1887, I was sent for early in the morning to see a gentleman who was thrown from his horse on the common. On reaching the spot I found Mr. F., aged 48, standing up talking incoherently, and not knowing of his accident; blood was flowing freely from his left ear, but there was no external wound. I got him home, and telegraphed for Mr. Edmund Owen. In the course of half an hour he vomited at least half a pint of blood; he was very excited, and at times violent. Mr. Owen confirmed my opinion that he had fracture of the base of the skull, applied blisters behind the ear, and gave calomel and bromide of potassium. At 8 p.m. he had an epileptic convulsion; evening temperature 101.2°. I passed the catheter, and emptied his bladder. The

left eye was insensible to light, and pupil contracted to pin's point; the left side of face was paralysed.

On January 1st he fell into a quiet, semi-comatose state, taking liquid nourishment freely. Urine and faeces passed in the bed. Temperature 97.6°, pulse 76. He remained in this state till the 12th, when he became violently excited, talking, singing, and whistling; sensation returned to left eye and side of face; pupil of normal size, but not sensible to light. Temperature 97.6°; pulse 84, feeble. I gave beef-tea, and administered brandy and eggs freely. On the 13th Dr. Buzzard saw him with me, and located the fracture as through the petrous portion of the temporal bone, with injury to the portio dura and auditory nerves; and that there had been effusion of blood round the fifth nerve, which was partially absorbed. He gave on the whole a favourable prognosis, and advised a continuance of the same treatment. On the 24th the patient became more restless and troublesome. Temperature varied in three hours from 100° to 101°, and to 99.6°. He was freely purged with calomel. From the 25th to February 3rd he lay in a quiet, unconscious state, occasionally talking nonsense, but he took his nourishment—beef-tea, eggs, and brandy—well. On the 8th I gave him potass. iodi. gr. ij, twice a day. About February 20th he began to be much troubled with sleeplessness. I tried paraldehyde, urethran, and bromide of hyoscyne, instead of the bromide, without much effect. On the 23th he had a free discharge of purulent matter from his left ear. Temperature 101.8°; returned to bromide and opium. On March 10th he was very stupid and heavy, but could not get any real sleep. I tried paraldehyde again, and gave port-wine and syrup of iodide of iron. On the 18th there was decided improvement; he knew me, but was not conscious of where he was. On the 25th he knew his wife and all around him, but was very queer in his ideas. On the 30th he was quite unconscious again. I gave chloral and croton chloral freely till the evening of April 2nd, when he slept soundly, and on the 8th became quite conscious. He got up on the 10th, came downstairs on the 11th, on the 14th went for a drive, and on the 19th went to the sea-side, and, with the exception of a slight epileptiform seizure on the 29th, after a very indigestible meal, has gradually improved ever since. He returned to his business on the 14th, doing a little each day; he has still some paralysis of the left side of the face, especially his eyelids.

Wimbledon. THOMAS EDWARD PARSONS, M.R.C.S. Eng.

REPORTS

OF

HOSPITAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN, IRELAND, AND THE COLONIES.

LIVERPOOL ROYAL INFIRMARY.

A CASE WHERE A DAMSON-STONE WAS LODGED IN THE RIGHT BRONCHUS: TRACHEOTOMY: RECOVERY.

(Under the care of Mr. REGINALD HARRISON.)

JANE S., aged 8, was admitted on April 4th, 1888. Ten days previously, while laughing when eating some damson jam, she thought she had swallowed a stone. This was immediately followed by a violent fit of coughing, for which medical aid was summoned. These paroxysms of coughing were repeated at intervals. On admission there was slight flattening of the right side of the chest posteriorly, with diminished expansion; and a rhonchus was distinctly audible. Breath-sounds feeble towards base, the rhonchus increasing in loudness as the bronchus was approached opposite the fourth dorsal vertebra, where the sound was best heard. The rhonchus was twofold, inspiratory and expiratory; and there was sometimes a sound as if something fell between expiration and inspiration. Breath-sounds on left side normal, but with transmitted rhonchus; respirations 22; pulse 80. Whilst she was under observation in the infirmary she had several attacks of violent paroxysmal cough, when various expedients, including inversion and slapping on the back, were tried, with the view of favouring the expulsion of the damson-stone, which evidently had found a resting-place in the right bronchus. On one occasion she expectorated a little blood, but as a rule she was going about the ward apparently well.

On April 21st she was placed under chloroform, and Mr. Harrison performed tracheotomy. An incision having been made as

low down as possible through the skin, the trachea was quickly bared with a blunt director. A free incision into the trachea was then made, three or four rings being divided. Just as the child was being inverted the stone was shot out into the wound, where it was easily seized with the fingers. A tracheotomy tube was introduced and retained for a few hours, but proved useless. The patient breathed freely through the opening, and expectorated for the first four or five days a considerable amount of pneumonic-looking sputum. Then convalescence rapidly took place, and she left the infirmary fourteen days after the operation quite well, with the wound soundly healed.

Mr. Harrison observed that, from a perusal of Mr. Durham's valuable article (Holmes's *System of Surgery*) on this subject, it appeared that the mortality in cases of this kind where no operation was performed was very considerable. In this instance the patient had most alarming symptoms of suffocation the night before tracheotomy was resorted to, which might have been immediately fatal had not assistance been at hand. The very free incision into the trachea not only favoured the immediate expulsion of the damson-stone without the least trouble, but proved of service as a vent for the free expectoration that followed. The latter was probably due to the inflammatory action which the stone had excited in its neighbourhood.

We are indebted to Mr. J. Teare for the notes of this case.

CIVIL HOSPITAL, CALCUTTA, MADRAS PRESIDENCY.

WOUND OF LEFT WRIST AND RIGHT UPPER ARM: BRACHIAL ANEURYSM, LIGATURE: RECOVERY.

(Under the care of Surgeon-Major H. D. COOK, M.B., Civil Surgeon, Calcutta.)

I., aged 32, was admitted on June 8th, 1886, with a transverse wound over the anterior aspect of the left wrist, dividing the tendons of the flexor carpi radialis and palmaris longus, but without injuring the radial or ulnar arteries. The distal ends of the tendons could be easily seen; not so the proximal ends, which were drawn up by contraction of the muscles. He had also a punctured wound on the inner side of the right arm, middle third, from which venous blood was freely oozing. The bleeding from the wrist was arrested, the edges of the wound brought together by sutures, cold water dressing applied, and the wrist kept in a flexed position. A cold compress was applied to the wound in the arm.

On the third day after admission the wound over the wrist assumed a very unhealthy appearance, with offensive sanious discharge. Subsequently the distal end of the flexor carpi radialis sloughed off and the palm of the hand inflamed, becoming swollen, hot, and very painful, with fingers flexed. The inflammation was accompanied by traumatic fever. The extremity was supported on a splint, and charcoal poultices applied. The wound in the arm rapidly healed. On account of the destruction of tissue at the wrist, the formation (frequent) of palmar abscesses, matting of the tendons, etc., and foreseeing the complete uselessness of the hand, he was advised to submit to amputation of the forearm in its lower third, but this he positively refused to do. The wound of the wrist has since healed up, but the hand is quite useless, and is a burden to the man.

On June 20th the patient drew attention to a pulsating swelling in the right arm. Its position corresponded to the course of the brachial artery and punctured wound already described. The swelling was sacculated with a slight depression to one side, and had all the appearance of an aneurysmal varix. Palpation showed the tumour to be pulsatile with a distinct thrill, and auscultation revealed a loud rasping *bruit*. Pressure over the axillary artery caused the thrill and *bruit* to disappear and the sac to collapse.

On July 25th, with the assistance of Surgeon Routh, M.S., an incision three inches long was made over the axillary artery, as high up as possible in its third portion, and the artery ligatured. The pulsation in the tumour ceased at once. The extremity was wrapped in cotton-wool and flannel, and the patient put to bed.

On August 10th the ligature came away. He was discharged from hospital on the 20th, the tumour being hard and small, and pulsation absent.

¹ Communicated to the South Indian Branch of the British Medical Association.

THE GREAT NORTHERN CENTRAL HOSPITAL.—In consequence of the death of the German Emperor, the Prince and Princess of Wales have postponed the ceremony of opening the Great Northern Central Hospital until the latter part of July.

REPORTS OF SOCIETIES.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

THURSDAY, JUNE 14TH, 1888.

J. W. HULKE, F.R.S., President, in the Chair.

Paralysis of the Fifth Nerve associated with Cataract.—Dr. W. J. COLLINS showed a case of paralysis of all parts supplied by the sensory branches of the right fifth nerve; muscles of mastication unaffected. No history of syphilis and no cerebral symptoms. The patient had suffered from severe pain in the anæsthetic parts for eight months and the sight of the right eye had failed. There had been no herpes and no conjunctival or corneal affection whatever. There was diffuse opacity of the right lens; the left eye and side of face were normal, and vision was good. He considered that the lesion was located somewhere between the root of the nerve in the pons and the subdivision of the Gasserian ganglion. This case conflicted with the views of Snellen and others respecting trophic nerves. Here the lens, non-innervated, and protected from foreign irritants, suffered, while the highly-innervated and anæsthetic cornea retained its pellucidity, notwithstanding eight months' habitual exposure.—Mr. T. BRIDGIN TRALE mentioned a case of cataract, in which puncture of one lens was followed by supuration of the globe. The patient died shortly afterwards with aphasia, due to cerebral hæmorrhage, which was not entirely recent but partly resulted from an accident many months previously. He suggested that the disastrous results to the eye might have been the result of the nervous lesion.—Dr. COLLINS briefly replied.

Exostosis of Frontal Bone and Orbit with an Intracranial Growth.—Dr. EMRYS-JONES mentioned a case, and showed specimens, of a large orbital exostosis associated with a myxomatous tumour in the anterior lobe of the brain. There had been some epileptiform attacks, the existence of which the patient denied on account of his anxiety to have the growth removed. The attempt at removal had to be abandoned and the patient died five days later from septic meningitis.—Mr. JONATHAN HUTCHINSON had seen several cases of exostosis of the frontal bone. In one case of a young man the exostosis grew into the frontal sinus on the left side and was removed by trephining; later on there grew another exostosis from the right side which was early removed, but septic inflammation and death followed. In another case of a young woman the exostosis was very large, and a long time was spent and many saws were used in attempting to remove the growth, but only with partial success, a raw surface with bony base being left; this suppurated and remained open for twelve months, when further surgical interference led to the shelling out of the remainder of the exostosis, a deep cavity was left, at the bottom of which some mucous material was seen, but the dura mater remained sound; the eye had been previously lost; ultimately the case did well and the wound healed.—The PRESIDENT said these cases pointed to the great risk of interfering when the cranial wall was perforated. He referred to two cases where the inner table only was involved, the roof of the orbit being free, in which removal of the exostosis was quite easy.

Optic Atrophy in Three Brothers (Smokers).—Mr. EDGAR BROWNE (Liverpool) read a paper on this subject. In the first patient, aged 40, vision had failed at the age of 27. A diagnosis of tobacco-amblyopia was made. The patient reduced smoking gradually, but continued to chew. Vision had steadily failed to shadows, but the pupils were three millimètres diameter, acted to light, and the patellar reflexes were good. Previously, vision was good; general health always good. Optic discs, typical skim-milk atrophy, with attenuated vessels. He could see a flame or bright reflection from white at periphery of fields. The second patient was aged 33; sight became very bad six months before; he also both smoked and chewed tobacco; he could see a little in twilight. The knee-jerks were good. Pupils, three millimètres diameter, acted to light. The optic discs showed a general appearance of atrophy; vessels pervious, but rather small. He could see white paper test in lower temporal (right) and lower nasal (left) fields, but not at all centrally. In the third patient vision had failed for two years, patient being aged 23; could read J. 16. This patient discontinued smoking when warned. Pupils sluggish, but acted to light. Peripheral fields for white, both eyes normal; central scotoma for white and red in left eye, for red only in right; colour vision with wools good. Optic discs very white and smooth; veins perhaps a

little large. The original assumption that tobacco could cause atrophy had been rather discredited since the significance of axial neuritis had been understood. These cases were closely related to the hereditary optic atrophy of Leber (though occurring rather late), but the term hereditary should not be adopted till our information was much more exact. In all three cases, tobacco was probably the determining cause of the atrophy. In all perception of light was better towards periphery than centre; none had visible neuritis; none had cerebral or spinal symptoms. The father, mother, and two sisters had good sight; a collateral relation had suffered. These cases might be taken as types of one group—namely, those in which an axial neuritis being once established tended to spread to the peripheral fibres, involving both sets in the subsequent atrophy. Exactly the opposite occurred in ordinary neuritis, in which the central fibres (and vision) might escape for a time. The following grouping of cases was suggested: 1. Ordinary tobacco-amblyopia, involving only central fibres; transient, and recovery on removal of the cause. 2. A class beginning with central negative scotomata, which progressed downwards till central defect became positive (or nearly so), and axial atrophy might be assumed, peripheral vision being unaffected. The part played by tobacco in these cases required investigation. 3. Cases like those under consideration, where retro-bulbar neuritis, beginning centrally, spread peripherally, giving rise to more or less pronounced atrophy. Here the personal proclivity was shown in young persons, members of the same family. If similar groups were found among non-smokers, search would not be required to discover the exciting agent. Beyond these were (4) consecutive atrophy, and (5) atrophy accompanying spinal degeneration. At present the two last groups were well understood, but cases illustrating the second and third groups should be collected.—Mr. HUTCHINSON mentioned a group of three, consisting of two young males who smoked and the mother of one of them (and aunt of the other) who did not smoke, all affected with optic nerve atrophy. In the case of the woman the inherited predisposition to nerve lesion must have been very strong. Eventually she became quite blind, but had very good health. Perhaps abuse of tea or coffee might have had a share in bringing about this effect; he was sure that they sometimes caused deafness. He thought the Society might investigate the very rare group of women affected with this form of atrophy who did not smoke at all. Mr. Browne had mentioned that his first patient was a total abstainer, this, in his experience, rather led to the production of the atrophy than the reverse; those who indulged in alcohol as well as tobacco were less liable to tobacco atrophy than were abstainers. These cases occurring in families were much more severe, more liable to end in blindness, and much less easily cured than the other forms.—Dr. EMRYS-JONES mentioned the case of a family of nine children, but only five living, in which two children had atrophy of the optic disc without definite cause, the girl at the age of seventeen and the boy aged nine; total blindness ensued.—Dr. HABERSON referred to his paper read at a former meeting of the Society, dealing with hereditary cases of optic atrophy; in some a sexual cause appeared to operate.—Mr. WALKER thought that great losses of blood and a numerous family in the mother and grandmother might be a cause of optic atrophy in children.—Mr. BROWNE hoped an investigation, as suggested by Mr. Hutchinson, would be undertaken by the Society. Subjects of tobacco amblyopia had often been drinking heavily; if they left off alcohol and tobacco they did well.

Card Specimens and Living Patients.—Mr. SILCOCK, 1, Sarcoma of Frontal Bone; 2, Sarcoma of both Orbits.—Mr. JESSOP, Case of Symmetrical Pigment Ring on Anterior Capsule of Lens.—Mr. J. HUTCHINSON, jun., Two Cases of Cicatrices on Vitreous and Retinas.—Mr. G. E. WALKER, Case of Recovery from Occlusion of Pupil without Iridectomy.—Prof. BERGER, 1, Sarcoma of Cornea; 2, Refraction Ophthalmoscope.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

FRIDAY, JUNE 1ST, 1888.

C. B. BALL, M.D., President, in the Chair.

Peritonitis from Perforation.—Mr. M'ARDLE communicated a case of peritonitis from perforation, and commented upon the cause of death in such cases.—Dr. JAMES LITTLE said that on more than one occasion in cases of the kind he had opened the abdomen during life; and when he afterwards opened the abdomen in the same cases after death, most important appearances,

June 23, 1888.]

which had indicated hyperæmia and inflammation, short of actual effusion of lymph, had disappeared. It was therefore rash to conclude as to what existed in the abdomen during life from what one found there after death.—The PRESIDENT said the paper raised the question as to how far in such cases death was attributable to shock to the nervous system. If that were so to any extent it might preclude surgical interference with so important a cavity as the abdomen, because the immediate effect of it might be to augment the efficacy of one of the causes of death. If, on the other hand, death exclusively resulted from absorption of materials effused from the peritoneal cavity, or from putrefactive gases, which would interfere with the heart's action, the objection to operative interference would not arise.—Mr. M'ARDLE, in reply, said he had not made sufficiently plain the point adverted to by Dr. Little. In the case of stomacic perforation he had to deal with symptoms which tallied exactly with the introduction of sepsin pure and simple into the peritoneal cavity, and also with the symptoms which resulted from septic absorption in any place. In his detail of the case he mentioned that immediately on the perforation of the stomach taking place collapse occurred; but that collapse was afterwards completely recovered from, and the patient became conscious and fairly vigorous. But there afterwards ensued the same symptoms that were obtained by the injection of sepsin. He agreed with Dr. Little that the peritoneum and the contents of the peritoneal cavity changed materially after death. He had opened the abdominal cavity a fair number of times for inflammatory conditions; he never saw anything capable of disappearing that could do any harm. Inflammation of the peritoneum might do very little harm, and, at all events, would not produce death. Hyperæmia alone would not account for death. There was another reason why he hesitated to regard any of those things that were capable of disappearing as likely to cause death. Within the last five or six years it had become the custom, in cases of peritonitis that seemed to be beyond recall, to open the abdominal cavity and wash it out; and if the contents that produced fatal results were got away, the patients recovered in a large majority of the cases. This had been done in a number of cases within the last three years; and in 70 per cent. of cases that if left alone would have ended fatally, there had been recovery after the washing out of the abdomen. In the case of perforation of the stomach which he had brought forward, no fecal gas from the lower bowel got into the peritoneal cavity. The patient no doubt got a shock, and if in such cases a large amount of material were extruded into the peritoneum, inflammation would be set up; but it was the ultimate development of the septic materials that produced the fatal result. But in the case of intestinal perforation—and he had lately had experience of six such cases—the collapse that occurred continued persistently from the beginning to the end of the case; and he attributed it to the effusion from the intestines of gaseous contents—chiefly sulphuretted hydrogen.—Dr. FINNY requested leave to make an observation, notwithstanding that the discussion had closed. He understood Mr. M'ARDLE to say that it had been found during the last five or six years that in 70 per cent. of the cases of acute penetrative peritonitis, in which operative interference had been resorted to, there had been recovery. According to his recollection the facts were quite of an opposite character. In cases of chronic peritonitis, where there was purulent discharge, good results from operative interference might be hoped for; but, according to his recollection, in acute cases attended with perforation of the stomach or intestines, any such proceeding had been followed by death.—Mr. M'ARDLE explained that his statement had reference only to cases of septic peritonitis, which were not perforative.

Pyæmia of Dental Origin.—Dr. A. W. BAKER communicated a case of pyæmia of dental origin.—Dr. LITTLE said he believed physicians and surgeons in ordinary practice were not sufficiently alive to the possibility of various troubles—neuralgic, cerebral, and gastric—resulting from infection coming from the teeth. He had seen three cases of the kind within the last three or four years. One was that of a young man whom he found suffering from acute phthisis, and he only lived a short time. At first his relations had not thought that there was anything seriously wrong with him, because he only had a bad tooth; but inflammation began at the root of the tooth, and as the young man became worse he (Dr. Little) was sent for. He found that he had a large cavity in one lung, and the case ended fatally.—Dr. BAKER, in reply, said he had never seen any case in which phthisis could be traced to alveolar inflammation.

Microscopical Appearances in Locomotor Ataxy.—Dr. FINNY communicated a case of locomotor ataxy. The patient had died in Sir Patrick Dun's Hospital, to which he was admitted as a patient at the age of 38, in December, 1885, of emphysema and cardiac dropsy, with a history of tabes of some ten years' standing. He had been under Dr. Finny's observation three years previously, and had exhibited at that time the following features of the disease, which were still better marked in 1885: Sensory disturbances; diminution of tactile sensibility in the legs and arms, but more particularly in the forearms. He was unable to state where his feet were, when in bed, until he struck the foot-board with them; and on one occasion, while pinning on his left cuff, he passed the pin through the flesh of his wrist and was not aware of it, until finding the cuff was fixed, he tore away the flesh by pulling it down. He had some paræsthesia of the fingers, and described a sensation of great heat in the tips of the right hand, and said that their moisture would at times rise as steam from them. Neuralgic pains were occasionally present in both legs and arms, but was not by any means a prominent symptom. Motional disturbances: Unsteadiness in walking and in turning round; difficulty in maintaining the equilibrium while standing with the eyes closed, or on looking up at a height. There was no ataxic gait, the gait being that more of uncertainty and debility. He had great difficulty in walking in the dusk. He experienced great difficulty in buttoning his clothes, more especially behind him. Reflexes: The patellar reflexes were absent, and the Argyll-Robertson phenomenon was sufficiently marked, though the pupils were not markedly contracted. The sexual reflex: At the time of his last illness the sexual appetite was not inordinate, though early emission followed upon excitement; but for many years preceding it, as early as twelve years of age, the sexual desire was greatly increased, and venery and masturbation were immoderately practised. There was no distinct syphilitic history, though he had venereal disease at the age of 18, and there were no appearances of scars, or of tertiaries. The patient's whole history pointed to a life of sensuality and alcoholism. The notable features in his case were: 1. Early and immoderate sexual appetite. 2. The slight amount of tabetic gait. 3. The greater implication of the cervical region of the cord.—Dr. BEWLEY exhibited microscopical specimens of the cord in the case brought forward by Dr. Finny, and mentioned that the disease affected the upper cervical portions of the cord more than the lumbar portions. There was another peculiarity which he had not seen in any drawings of cords affected by locomotor ataxy—namely, that in the cervical region the posterior third of the internal part of the postero-internal column was sclerosed, the middle portion was not sclerosed, and the anterior portion was again sclerosed. The posterior third derived its ascending fibres from the lumbar region, in which there was some disease, and those fibres were consequently degenerated. The dorsal region was not much diseased. The middle third, containing fibres from that portion of the cord, was fairly healthy. The anterior third, containing ascending fibres from the diseased cervical region, was much sclerosed.

Separation of the Coracoid Epiphysis of the Scapula.—The SECRETARY read a paper by Dr. E. H. BENNETT, who was absent, on a case of separation of the coracoid epiphysis of the scapula.

Cirrhosis of the Liver and Portal Thrombosis.—Dr. BEWLEY submitted a case of cirrhosis of the liver and thrombosis of the portal vein. The specimens were taken from a man, aged 60, who had enjoyed fairly good health, with the exception of occasional attacks of bronchitis, until the 18th or 20th of last March. First piles came on and gave him considerable trouble. Then his feet swelled, and his legs became œdematous. Afterwards his abdomen began to swell. He lost flesh, strength, and appetite, and his abdomen and legs rapidly increased in size. After about two and a half weeks jaundice came on, and on April 7th he was admitted into the Adelaide Hospital, under the care of Dr. Wallace Beatty. He was then extremely weak and emaciated. His abdomen measured forty-four and a half inches round the umbilicus, and contained a great deal of ascitic fluid. On account of the accumulation of fluid it was not possible to make a thorough examination of the viscera; but it was apparent that the upper and lower borders of the liver were normal—at least nothing abnormal could be discovered below the costal arches. The spleen did not appear to be very large. He had slight bronchitic rales and also a mitral systolic murmur, but there was not much engorgement of the veins of the neck. His urine had been very scanty for three weeks before his admission, and at the time he came into

the hospital presented a slight amount of bile pigment. On May 12th he was tapped. Up to that time it was uncertain whether it was cirrhosis or cancer of the liver that he had. When the tapping was performed the fluid that came away was ascitic and largely coloured with blood. A hard nodulated mass was then felt under the right costal arch, extending out to the epigastrium. The diagnosis then arrived at was, that it was malignant disease of the liver. At the tapping, 18½ pints of fluid were withdrawn. His abdomen refilled; he grew weaker and weaker, became unable to take food, and died on May 21st. On *post-mortem* examination, his abdomen was found to be again immensely distended with fluid, the quantity being between two and three gallons. This fluid also was extremely bloody, and from the deeper portions of the peritoneal cavity large soft blood-clots came. The liver, which weighed 4½ lbs., was found to be in a curious condition. The left lobe presented very typically the characters of extreme cirrhosis, being extremely hard, and converted, for the most part, into bands of greyish dense fibrous tissue. The right lobe was largely increased in size from above downwards, and was bright yellow-coloured, the yellow-coloured part being marked off by a distinct line from the grey cirrhosis in the neighbourhood. This yellow part was perfectly soft, while the left lobe was like a mass of leather. About half of the right lobe was in this peculiar soft yellow condition. The trunk of the portal vein was filled for an inch or two with a soft clot; but the walls of the vein were perfectly healthy, and the vein at some distance from the liver was healthy also. The gall-bladder and bile-duct were full of healthy bile, and were not diseased. The other viscera were healthy, except that there was some thickening of the mitral valve, and that the lungs were somewhat emphysematous. The idea they conceived was that there had been thrombosis of the portal vein, and that the blood passing slowly through the vein clotted for some distance back. The branch to the right was more firmly clotted than the branch to the left, and the tissue of the right lobe had become almost necrotic from the interference with the blood supply.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

TUESDAY, APRIL 3RD, 1888.

T. W. HIME, M.B., President, in the Chair.

Some Destructive Diseases of the Eye.—Dr. BELL read a paper on this subject, with special reference to glaucoma. He had in the course of his experience at the Bradford Eye and Ear Hospital seen no disease of the eye the nature of which seemed so easily to escape the notice of medical men until it was too late to repair the damage done, and this was especially the case in the more chronic forms of the affection.—Drs. HIME, MAYOR, and BELL took part in the discussion.

Gonorrhoeal Ophthalmia.—Dr. BURNIE read a note in which he said he wished it to be understood that he looked upon gonorrhoeal ophthalmia and purulent ophthalmia of infants as two distinct affections. The former only occurred in subjects suffering from gonorrhoea. It had never in his experience affected both eyes, but might do so. It was not caused by direct contagion, or it would be much more frequent; but was due to metastasis, similar to gonorrhoeal synovitis. The appearance of the eye was also different from that presented by eyes which had been directly infected by means of towels, etc. The semi-ptosed condition of the eyelid was particularly characteristic. In purulent ophthalmia of infants the disease usually attacked both eyes, and was caused by direct infection.—Drs. BELL, WOODS, HIME, GOYDER, and BRONNER took part in the discussion.

Acute Atrophy of Liver.—Dr. WOODS related two cases of this condition. CASE I.—On January 11th, 1887, a temperate man, aged 25, who had never suffered from syphilis, and who had spent all his life in England, was admitted to hospital apparently suffering from a slight attack of jaundice. The skin was yellow, the urine saffron-coloured, and the patient was constipated. Pulse 80, temperature 99°. No tenderness over the liver, but diminished area of dulness on percussion. The bowels were easily moved by aperient medicine, and no particular symptoms presented themselves till January 25th, when the bowels were relaxed and motions dark coloured. The urine was now of a dark-brown colour; it was tested for blood and bile acids with negative results. Pulse 88, temperature 99.8°. The patient on this date (fourteen days in hospital) began to wander a little, becoming delirious on the 26th, and gradually passing into a state of coma, well marked on the 28th, which lasted till next day, when he died. On *post-mortem*

examination nothing abnormal was found in the head or thorax; the liver was much reduced in size, specially the left lobe, the weight being only twenty-seven ounces. The spleen weighed seven ounces, and was normal in appearance. CASE II.—A man, aged 39, of intemperate habits, who had suffered from syphilis and intermittent fever, and had served fourteen years in India in the army, was admitted February 28th, 1888, suffering from jaundice. The skin was yellow, the urine dark coloured, the bowels obstinately confined; all food was vomited as soon as taken; no tenderness over liver; area of dulness diminished. Pulse 68, temperature normal. Bowels remained confined until March 3rd, when a dark-coloured liquid motion was passed; vomiting was now very distressing, the vomited matter being dark-coloured. The urine was brownish in colour, depositing brown sediment. It was tested for albumen, blood, and bile acids with negative results. Pulse 110, temperature 99.6°. Five days after admission the patient became violently delirious, but lapsed into semi-unconsciousness in the afternoon, becoming comatose next morning, and remained in this condition until he died at noon on the 5th. On *post-mortem* examination, nothing abnormal was found in the head or chest; the spleen weighed seven ounces. The intestines contained bile. The liver was small and shrunken, and weighed twenty-six ounces; it was of a deep yellow colour, passing here and there into dark red patches. Its tissue was very friable. On microscopic examination the liver-cells were entirely destroyed, only a few nuclei being left here and there. The liver was reduced to fibrous tissue radiating from the portal spaces, in which it was most abundant, and near which some agglomerations of nuclei were seen. Fat globules and granular *débris* were present in large amount. Leucin and tyrosin could easily be demonstrated. There were cases of jaundice without obstruction, and the clinical features were not unlike those present in cases of poisoning by alkaloids, curare, muscarin, etc. If the secreting portion of the liver was impaired, as in acute yellow atrophy, whatever bile was secreted was of inferior quality, and peptone, and leucomaines were allowed to enter the circulation. The bile itself was absorbed into the blood, and stained the tissues, never, however, to any great extent. In jaundice with obstruction of the bile-duct, bile did not enter the intestine, and, therefore, did not act there on the peptones and leucomaines, but, being rapidly absorbed into the blood, acted there as an antidote to the leucomaines, preventing them from producing the alarming symptoms observed in cases of jaundice, where no obstruction existed, but where, owing to impaired action of the liver, bile, incapable of exercising its proper functions, was secreted.—Dr. A. BRONNER, in the absence of Mr. J. APPELBYARD, with that gentleman's kind permission, recorded a similar case which he had seen by his courtesy. The patient, a remarkably tall and strong man, about 35 years of age, who had always lived a most temperate life, and had always been perfectly healthy (with the exception of a very slight mitral *bruit*), had been very much depressed some weeks before the first definite symptoms. Having received a chill at a railway station, and the same evening having eaten some sausage, the next morning diarrhoea set in and slight jaundice, the urine also becoming distinctly tinged. This was looked upon as an ordinary case of jaundice consequent upon gastro-duodenal catarrh, and under treatment the bile-pigment disappeared from the urine, and the jaundice almost entirely disappeared. The patient got up, felt much better, and nothing whatever occurred to point to the true nature of the case. On the evening of the eighth day after the appearance of jaundice, the patient went to bed, complaining of very severe headache. In the morning he was in a state of excited delirium, tearing down the bed-curtains, etc., recognising nobody. In the course of the day he became quieter, lying in bed with his hand to his head, as though in great pain. There were no convulsions. The pupils were dilated, and did not react to light. The urine became highly icteric, and there was a dirty-yellow deposit in it, which microscopically consisted of detritus of cells. No albumen. The urine was tested for leucin and tyrosin, but no crystals were found. The spleen was not found enlarged. There was no enlargement or diminution of the area of dulness of liver. No hæmorrhages from stomach or bowels, and no petechiæ. The jaundice increased in the course of the day, and the patient gradually became more comatose, and died at ¼ A.M., thirty hours from the commencement of the headache. Only a partial necropsy was allowed. There were hæmorrhages on the omentum and the bowels, also on the kidneys, where they presented the wedge shape of infarction on section. The liver was a soft, pulpy mass, which could be easily torn with the fingers. Under the microscope

the liver structure was almost obliterated. The field of vision was covered with detritus masses, and with fat-globules. Professor Greenfield, of Edinburgh, who was kind enough to examine some of the liver and kidney, pronounced the case to be one of undoubted acute atrophy of the liver. There had never been any complaint of pain or uneasiness in the region of the liver.—A discussion followed, in which Drs. H. BRONNER, LODGE, jun., and LAMBERT took part, Dr. WOODS replying.

REVIEWS AND NOTICES.

TECHNICAL SCHOOL AND COLLEGE BUILDING. Being a Treatise on the Design and Construction of Applied Science and Art Buildings, and their suitable Fittings and Sanitation, with a Chapter on Technical Education. By EDWARD COOKWORTHY ROBINS, F.S.A. 4to. London: Whittaker and Co.

THERE is probably no more important "question of the day" than that of technical education, and if evidence were needed of the satisfactory progress which we are making towards its practical development, it might surely be found in the appearance of this important volume. At a time when our leading politicians and economists are unanimous in declaring that, if England is to maintain her position in the forefront of the great producing countries of the world it must be by the thorough technical training of the "skilled artisan" section of her industrial population, it cannot but be regarded as a hopeful sign that one of our leading architects should have devoted so much study and attention to the construction and arrangement of the buildings necessary for this class of instruction, as must have been required to produce the work before us.

Mr. ROBINS has produced a thoroughly practical book, which must prove of the greatest value to his professional *confrères*, who may be called upon to design technical science buildings, and which contains much that should be carefully studied by those who may have to take an active part in developing and guiding through its proper channels the undoubted impetus which technical education has lately received.

There is of course some difference of opinion as to what is rightly to be regarded as the scope and object of technical education, and in his opening chapter Mr. Robins discusses this question, and gives the views of various eminent authorities, amongst others those of Professor Ayrton, who says: "By a technical school I understand not one in which the manipulation or routine of a trade is taught, but a school where a lad receives general instruction in the principles of applied science, and special instruction in the application of these principles to the particular trade he is following, or which he is about to follow," an opinion shared by Professor Huxley, and by the late Professor Fleming Jenkin, who characterised as a "mischievous delusion," the idea that the object of technical education is "to teach a man his business." Mr. Robins accompanied Professors Armstrong and Ayrton in a tour of inspection of the polytechnic schools of the German speaking countries, in 1882, and gives an interesting summary of the results. This is followed by an analysis of the second report of the Royal Commissioners on Technical Education which is of considerable value, as it is a brief but clear *exposé* of the subject, and describes the different classes of technical schools existing on the Continent, from the elementary schools to the great universities. In the next chapter Mr. Robins somewhat briefly deals with the principles which should govern the planning of technical schools, pointing out that to be effectively taught, many subjects, such as chemistry and physics, anatomy and physiology, botany, and forestry, etc., require specially designed buildings. In the examples of foreign buildings for technical instruction, which follow, a large proportion are chemical laboratories, and include those of Bonn and Berlin, of the Zurich Polytechnic School, the new University of Strasburg, Munich University, and others; there are also plans of the Academy of Sciences, Munich; the Berlin Physiological Institute, the Physical Institute, Würzburg; the Chemnitz Royal Trade School, the Technical High School at Hanover, the Royal Technical School, Stockholm, etc., accompanied with descriptions which further elucidate the carefully figured plans, and increase their value for study and comparison. As we pointed out above, the majority of the foreign buildings illustrated are chemical laboratories, but as an exception, the Technical High School at Hanover may be noted, this being a remarkably complete scheme,

embracing well nigh all the subjects which can be brought within the range of technical education. We have next plans and descriptions of some of the principal English technical buildings, commencing with Mr. Waterhouse's well considered and magnificent pile, erected for the City and Guilds of London Technical Institute, at South Kensington, which it is to be regretted has not yet, probably owing to its situation, succeeded in attracting students in anything like the same proportion as the Finsbury building for the same institute, which is next illustrated, and the success of which, under Professor Silvanus Thompson, is most gratifying. The other English buildings of which the plans are given, are the Yorkshire College, Leeds; the Merchant Venturers' School, Bristol, a most successfully designed building by Mr. Robins, opened in 1885; the Oldham School of Science and Art; the Mason Science College, Birmingham; St. Thomas's Hospital Medical School; the Oxford Physiological Laboratory; the Cambridge University Laboratory, and some half-a-dozen more, without which Mr. Robins's series of examples would be by no means complete. The following chapter deals with fittings for applied science instruction buildings, and is very fully illustrated by drawings, showing students' working tables, sinks and draught closets, arrangements for carrying off noxious gases from the work table, and various details from some of the buildings already mentioned, and others, including the College of Engineering, at Yeddo, in Japan. This is a very valuable section of the book, and the drawings are most carefully produced to scale. A valuable chapter on heating and ventilation, considered generally, is followed by one dealing with the subject in special reference to applied science instruction buildings, the importance of which cannot be over-estimated, as in addition to ordinary room ventilation, special means for the removal of noxious fumes generated in the laboratories have to be provided. Mr. Robins describes the systems adopted at the Finsbury Technical College, the Central Institution, South Kensington; the Yorkshire College, Leeds; and the Merchant Venturers' School, Bristol. Buildings for Secondary Educational Purposes, is the title of the next chapter, which is illustrated by views and plans of several buildings of this class designed by Mr. Robins, and includes the South Hampstead High School for Girls; Milton Mount College, Gravesend—a school for 150 girls, and some other smaller buildings of this class. A chapter on Sanitary Science in its relation to Civil Architecture, concludes the volume, and the author is so high an authority on this subject, that we commend it to all our readers who are interested in it, as sure to repay careful perusal. We have said enough to indicate the extent of the information which Mr. Robins has collected together, and we think he deserves our thanks for giving this information to the public. His book contains upwards of sixty large plates, photolithographed from drawings, the preparation of which alone must have entailed a considerable amount of labour and expense. It is well printed and bound, and will certainly be of much service in furthering the object its author obviously has at heart by facilitating the design and construction of technical science buildings, perfectly adapted to the purpose they are required to fulfil.

GUIDE TO THE HEALTH RESORTS IN AUSTRALIA, TASMANIA, AND NEW ZEALAND. By LUDWIG BRUCK. 12mo., pp. 183. Sydney, 1888. London: Baillière, Tindall, and Cox.

THIS book marks very strongly the progress of our Australian colonies in European ways. It also forms an excellent and practical supplement to Mr. Bonwick's useful little works on the climate, etc., of the different southern settlements. It is difficult to analyse a work, itself an abstract of what has been done by others, but a few general remarks occur to us. Seaside resorts, winter resorts, high altitude resorts up to 3,500 feet are all to be found in the southern hemisphere, and arrangements for the accommodation of visitors seem to make great progress.

On the whole, while New Zealand abounds in mineral waters, most of them of a high temperature, the Australian continent appears to have singularly few. In Victoria there are pleasant acidulous springs, more or less of the character of Seltzer, with some iron at Ballan and Drysdale, a good chalybeate at Hepburn, and a weak bitter spring at Stratford.

New South Wales seems to have only two—Dubbo and Rockflat, both acidulous.

Queensland only boasts of one spring, Herbertson, not very perfectly known, but undoubtedly hot, which none of the other Australian ones are. Accounts of travellers have made the

wonderful hot springs of New Zealand tolerably familiar to the public, and most of us have read of the baths which the Maoris use, and of those beautiful natural deposits, known as the white and pink terraces, which are reported to have been unfortunately destroyed by the earthquakes of 1886. The chief groups of hot springs appear to be:—

1. Ohinemutu, with Rotorua, has no fewer than 25 hot springs, that have been described as essentially sulphur with chloride of sodium. A powerful smell of sulphur pervades the atmosphere in their neighbourhood. In one bath, Camerons (known as the laughing-gas bath), the use of which is dangerous, the discharge of sulphuretted hydrogen is so strong as, when inhaled, to cause faintness, and great excitement of the vascular and respiratory systems.

2. Taupo, with 23 springs, of high temperature, and low mineralisation. They are admirable specimens of indifferent waters, and available for a great variety of purposes.

3. Te Aroha, a set of thermal alkaline baths, of which 18 have been described; 54.60 and 63 grains per pint of carbonate of soda are present in some of the waters, which are, therefore, more powerful than any of the known similar waters of Europe.

4. Hanmer has hot springs with strong escapes of sulphuretted hydrogen, and possessing similar curative effects to those at Rotorua.

5. Masterton, with five principal springs, strange to say, cold. Most of them are of strong chloride of sodium, and one of the springs contains 2.127 of iodine free and combined, a very high figure indeed.

While New Zealand falls short in acidulous springs, it has abundance of those rich in alumina, in sulphuric, and hydrochloric acids.

It thus appears from this survey that New Zealand abounds in sulphur, alkaline, and indifferent thermal waters which can compare with any of their respective kinds in the world. Establishments have been already organised at most of these baths, and the acidulous waters of New South Wales are charged with carbonic acid, bottled, and exported, as in Europe. For further details, especially on climatic matters, on which we have no space to enter, we would refer to the capital guide-book of Mr. BRUCK.

THE THERMAL SPRINGS OF AIX-LA-CHAPELLE AND BORCETTE.

By Dr. BEISSEL. Svo., pp. 145. Aix la Chapelle: Mayer. 1887.

This appears to be a full and trustworthy guide to the waters of Aix-la-Chapelle and the neighbouring Borcette. Full details are given about the different springs and baths, also about the diseases most commonly treated at Aix-la-Chapelle. There is a chapter on Mercurial Inunction, in which Dr. BEISSEL discusses the theory of its mode of absorption, and how far the heat of the baths volatilises the mercury, which (as one channel) may be absorbed through the lungs.

NOTES ON BOOKS.

The Treatment of Uterine Fibroids by Electrolysis. By W. E. STEAVENSON, M.D. Cantab., M.R.C.P.; in charge of the Electrical Department at St. Bartholomew's Hospital; Physician to the Grosvenor Hospital for Women and Children. (London: J. and A. Churchill.)—The author states that he has been so frequently asked for the details of the operation by electrolysis in the treatment of uterine tumours that he has published in advance this part of a work which is in preparation on "The Use of Electrolysis in Surgery." This first instalment is in the form of a pamphlet. The author gives very clear directions concerning the application of the electrodes. As must now be pretty generally known, Dr. Steavenson has contrived a new form of intra-uterine electrode, more flexible and therefore more introducible than Apostoli's, and far cheaper on account of the smaller amount of platinum which is used in its manufacture. The author fully recognises the objectionable character of the external potter's clay electrode, and hopes for some better form which will diffuse the current equally over a large surface. There can be little doubt that patients object to the clammy poultice of potter's clay more than to any other feature of the new treatment of fibroids. There is little or no controversy in this pamphlet, but operators may

take exception to the manner in which abdominal section is condemned. Treatment by electrolysis "is not difficult," we are told, "to those who understand the medical and surgical uses of electricity. It is not unduly painful. It is, if properly applied, practically free from danger." Dr. Steavenson's qualifications are sufficient to prove that electrolysis can hardly be trusted out of the hands of experts, else it will speedily be discredited. A trivial knowledge of gynaecology, combined with an imperfect acquaintance with electricity, can only cause disaster.

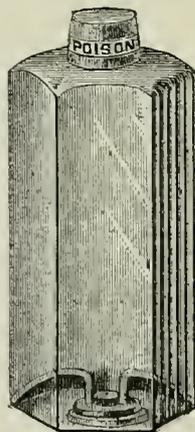

Principles of Forensic Medicine. By the late WILLIAM A. GUY, M.B., F.R.S., and DAVID FERRIER, M.D., F.R.S. Sixth Edition. (London: Henry Renshaw. 1888. Pp. 600. Price, 12s. 6d.)—That this well-known manual continues to hold its own in public estimation is abundantly evidenced by the appearance of a sixth edition. Owing to Dr. Guy's death a year or two back the preparation of this edition has devolved entirely upon Dr. Ferrier, who has made but very slight changes in the text, recent important cases such as the Pimlico chloroform poisoning case or the Lamson trial being briefly alluded to in a foot-note. The size of the page has been somewhat enlarged, thus making the book less bulky and far more handy, and the headings of the different subdivisions of each subject have been brought into prominence by being printed in thick black type, so that they catch the eye on the most cursory glance. This will greatly facilitate the finding of any particular subject, and consequently it will increase the value of the book as a work of reference.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS, IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

MEDICINE AND POISON BOTTLE.

CAREFUL attention should always be paid to any suggestions made to lessen liability to accidental poisoning, and, although we think that precautions of a mechanical nature may be carried to an excess in the dispensing of medicine, so that intelligent watchfulness may relax, it is almost impossible to adopt the many safeguards when poisons are handed over to patients or attendants.

Mr. E. S. Hermes, of 6, Farleigh Road, Stoke Newington, N., has invented a bottle for poisonous liniments and similar preparations, which would seem to preclude the possibility of an error being accidentally made. The bottle is hexagonal, with three sides ribbed, is of blue glass, and has the appearance of an ordinary poison bottle. But it is closed where the mouth of an ordinary bottle exists, and the contents are poured from an orifice placed in a depression at the bottom; hence the bottle must be actually reversed before the contents can be got at.

HARTMAN'S SANITARY WOOD-WOOL BAPKINS.

THE Sanitary Wood-Wool Company, of Hatton Garden, have discovered still another way in which the wood-wool manufactured by them can be usefully employed.

The bapkins made by the Company are intended to supersede the linen napkin ordinarily used for children in arms. They are pads of wood-wool of a convenient size and thickness enclosed in gauze. Being antiseptic and highly absorbent, they present obvious advantages over the ordinary linen napkin. By their use the infant is less exposed to chill, and its skin is much less liable to become irritated, while the comfort of the mother or nurse is greatly increased. The bapkins are to be burnt after use, but, as their price is moderate, their employment only involves small expenditure.

DONATION.—Mr. John Eric Erichsen, F.R.C.S. Eng., F.R.S., has given £200 to the rebuilding fund of University College Hospital.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1888.

SUBSCRIPTIONS to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the West Central District Office, High Holborn.

The British Medical Journal.

SATURDAY, JUNE 23RD, 1888.

THE DEATH OF THE GERMAN EMPEROR.

To medical men the long tragedy on which the curtain fell last week at Potsdam has been one of painful but absorbing interest throughout its progress, and to them, beyond all others, it must have been a relief to know that an end had at length come to the last and most distressing stages of that protracted agony. None can realise as they do how true it is that, in such conditions, death should be welcomed as a deliverer; and precious as was the lesson of uncomplaining submission to the inevitable so grandly taught by the stricken Emperor, no one could have wished his hopeless suffering prolonged. It does not fall within our province to discuss the political consequences that may follow the death of Frederick the Third; but it may not be out of place to refer to some of the medical aspects of the case, which, it is generally allowed, presented many features of exceptional interest clinically as well as pathologically.

There can be no doubt that the diagnosis was for a long time surrounded with unusual difficulty. It is true that the disease was at a very early period judged to be malignant by the German authorities, but we cannot help thinking that this opinion was in part rather a suspicion bred by the over-anxiety naturally engendered by the transcendent importance of the case, than a logical conclusion drawn from the observed facts. It is inevitable that regret should now be felt by many that an operation which offered the only chance of eradicating the disease was not attempted when possibly there was yet time; but, taking all the circumstances into account, it is difficult to see how any other course could properly have been adopted than that which was actually chosen. The diagnosis was at best doubtful, while the immediate risk was certain, and the prospect of permanent cure, if the suspicion as to the nature of the disease proved to be well founded, very slight. Few medical men would, we imagine, care to undergo in their own persons a dangerous and disabling operation, unless there was the clearest evidence of its necessity. In the present case we understand that the illustrious patient had thoroughly made up his mind not to submit to any operation that might shorten his life or destroy his voice. This decision was altogether independent of medical advice, though it was afterwards strengthened, as was natural, by the negative results of Sir Morell Mackenzie's clinical, and Professor Virchow's pathological, examinations.

At a later period, when the worst fears seemed to be con-

firmed, there were still elements of uncertainty in the case which placed it outside common experience. The visible healing of ulcerated surfaces, the widespread inflammation, the exfoliation of cartilage, and the general predominance of necrotic processes over the formation of new growth, combined to make up a clinical picture very unlike ordinary cancer of the larynx. The microscopic evidence was contradictory, or, to speak more accurately, was differently interpreted by equally competent authorities. On the whole the microscope gave little help, and one valuable practical lesson taught by this case is that it is a dangerous mistake to attach much importance to its testimony so long as it is merely negative. Part of the obscurity of the case was no doubt due to the difficulty of making satisfactory laryngoscopic examinations, and part also, as we hinted some time ago, to the unprecedented closeness with which the clinical phenomena were studied. It is tolerably obvious that our present knowledge of laryngeal growths, both benign and malignant, their life-history and mutual relations, is by no means so perfect as could be wished; and it is to be hoped that this historic case, the development of which has been watched with so much anxiousness, and in the sight, as it were, of the whole medical world, may stimulate observation and research on these points.

We have dealt with the case thus far in its purely scientific aspects; but there is, of course, another side to the question. Even in the lowliest hospital patient, the expediency of interference, which may prove more rapidly fatal than the disease, is not to be determined solely from the surgical standpoint. In the case of the late Emperor there were other considerations which he himself looked upon as of far greater importance, and on these rather than on a regard for his own ultimate recovery he, with the full knowledge of what he was doing, elected to take his stand. From this point of view it is sufficient to justify the course adopted if it can be said that it was not positively unsurgical. But it only requires a glance at the ghastly records of such operations on the larynx as were here in question to convince anyone that in the present case it would have been an experiment of the rashest kind to have attempted such a thing. The "expectant" treatment was adopted in accordance with the expressed wish of the patient, which, moreover, coincided with the scientific opinion of his adviser. It is no secret that the result was considered by those most directly interested—including the Emperor himself—fully to justify the course that was pursued.

The severe criticism to which Sir Morell Mackenzie has been subjected in various quarters was no doubt dictated by honest conviction, but it is most unfortunate that a professional difference should have degenerated into a mere personal squabble, and still more deplorable that the quarrel should have been carried on to so large an extent before the public. We do not wish to offer any opinion on the matters in controversy, or to pass judgment on the conduct and motives of the disputants. We have not the least doubt that they all did, or tried to do, what they believed to be best in the interests of the angust sufferer. It was perhaps natural that a certain amount of national feeling should have been aroused in Germany, but it is one of the most legitimate boasts of the healing art that it is of no particular clime or country, and narrow jealousies are altogether unworthy of a profession

which is the most truly cosmopolitan of human institutions. We earnestly hope that the world has heard the last of these unseemly disputes, and that the medical advisers of the late Emperor will agree to bury their differences in the grave of their illustrious patient, who was, above everything, a lover of peace.

NATIONAL PENSION FUND FOR NURSES.

AN esteemed provincial physician writes to point out that it is generally understood that the attacks upon this fund, which have appeared in one or two quarters, are inspired by personal pique. He refers to the article which appeared in the JOURNAL on May 6th last, and asks us to restore confidence by proving that the rates are not excessively high, and to publish the opinion of an independent actuary upon them. We have already done this in the JOURNAL (pp. 811, 815, and 983), where it is pointed out that this fund is managed gratuitously by some of the most able and representative City authorities, including Lord Rothschild, Mr. Henry Hucks (Gibbs (late Governor of the Bank of England), Mr. E. A. Hambro and Mr. Clifford Wigram (directors of the Bank of England), Mr. Walter H. Burns (of Messrs. J. S. Morgan and Co.), Mr. Alfred de Rothschild, and Mr. Edward Rawlings, as well as by eminent medical men and hospital managers, including Sir Edmund Currie, Major Ross, M.P., Dr. Bristowe, F.R.S., Mr. Thomas Bryant, Mr. R. Brudenell Carter, and Dr. Steele, of Guy's Hospital; that the fund commences with a bonus income of about £1,000 per annum; that generous donors have provided the deposit of £20,000; that the fund is a mutual fund, and that, assuming the rates are higher than necessary, which they are not, the full value of each nurse's money entrusted to the managers will be returned to her when her pension falls in, because the pensions stated are the lowest amounts payable irrespective of bonus additions, whilst those quoted by insurance offices are the highest sums which will be paid under any circumstances. Indeed, the rates are from 7 to 10 per cent. lower, as we have already pointed out, than the Post Office rates, which will shortly be raised in consequence of the conversion of Consols from 3 to 2½ per cent.

The unsoundness and absurdity of the comparisons made between the Pension Fund rates and those nominally offered by a first-class office like the Prudential is well proved by Mr. George King, the actuary of the fund, who has ascertained from the actuary of the Prudential that his company has been doing business in immediate annuities at a loss, and that the whole of the annuity tables of that office are about to be revised. The truth is that those who have criticised the rates offered to nurses by the managers of this fund must be either ignorant or ill-disposed. As a matter of fact, no man of business dare advise a nurse to invest her small savings in any office which undertook to do deferred annuity business at lower rates than those offered by the Pension Fund.

The statements which have been published and are being circulated, intimating that the payments required are, from an actuarial point of view, excessive, have also been effectually refuted by Mr. King, and by independent evidence, and the comparisons therein made are based upon palpable error. This is admirably proved in the address of Dr.

Bristowe to the Members of the Hospitals Association, wherein he gives the opinions and verdict of an eminent and independent actuary, to whom he had referred the Pension Fund rates. Copies of Dr. Bristowe's address may be obtained on application to the Secretary of the Fund, 38, Old Jewry, E.C.

It is gratifying to read in the published statement that the success of this fund is now assured; 120 policies have already been accepted, 326 proposals have been received, and 1,600 nurses have applied at the office for forms of proposal to fill up, whilst similar applications are being made in increasing numbers every week. We congratulate the promoters upon this success, knowing as we do that the scheme is absolutely sound, that the *bona fides* of its promoters is unassailable and undoubted, and that the financial strength of the National Pension Fund can be classed with that offered by the British Funds and the Bank of England.

No such opportunity can again be anticipated by women of the nursing profession of providing for themselves by reasonable and moderate payments. The medical profession will, therefore, we are convinced, not fail to impress upon those nurses with whom they come in contact the duty of self-help, and the importance of availing themselves of the thoughtful munificence and well-devised administration which are now provided by this fund on their behalf. The feeling of indignation against the reckless and unthinking opponents of this noble undertaking, to which our correspondent gives expression, is manifesting itself in many places throughout the country; and medical officers—honorary and resident—as well as laymen and officials, are taking opportunities of bringing the matter under the notice of the nursing staff of the institution to which they are attached. Further, the responsible managers of the great London hospitals are arranging a conference to determine how they can best help their nurses to join the fund. They could render no greater service. In some instances inquiry will show that the net emoluments of the nurses do not amount to £15 per annum, as is the case at the London Hospital, the largest in the country, owing to the extra expenses devolving upon the nurses there, each of whom has to provide herself with washing and with other things which it should be the first duty of the managing body to provide free of cost.

We cannot believe that the London Hospital Committee, the Chairman of which is also Chairman of the General Purposes Committee of this fund, will consent to permit the present unsatisfactory and unjust arrangement to continue. We trust that it will promptly consent to pay its nurses at any rate as much as is paid to those who labour in poor-law infirmaries. In any case, it is the duty, as we feel sure it will be the pleasure, of medical men and hospital managers to interest themselves in the Pension Fund, and to use their utmost endeavours to secure that every nurse with whom they come into communication shall at once, or as speedily as possible, avail herself of the great advantages and protection which this fund affords to the whole nursing body.

THE ARMY MEDICAL RESERVE OF OFFICERS.

We publish elsewhere a letter from Dr. Baines—and we do so the more readily because no one can doubt his absolute honesty of intention, while he may also be fairly considered a representative man—first and generally of those

medical volunteers who have seen their way to join this Reserve, and secondly and particularly as being the first strictly metropolitan medical volunteer who, as a reservist, has placed himself unreservedly at the disposal of the War Office. Few medical volunteers in London and other great centres have as yet joined the Reserve; its recruits hitherto have mostly come from outlying parts and the now somewhat ancient Militia Medical Service.

Our sorrow would indeed be deep and heartfelt could we believe with Dr. Baines that our criticisms hitherto on the Reserve were "calculated to spread erroneous ideas;" on the contrary, we imagined and still think we were letting daylight into a scheme which appeared not only singularly crude, but even dark, and possibly in its scope deceptive. We have no cause to regret the note of caution we sounded, and some may probably feel grateful we did so.

According to Dr. Baines, the promulgation of the Reserve Warrant, which had been hatching for some time, was "hastened" by the late rather factitious "cry of retrenchment." Now, what is this but an admission that the scheme, if not a part of, had at least a direct bearing upon and connection with, reckless economies meditated against the regular medical vote? We have always suspected the true inception of the scheme was in finance, not in military efficiency. If the scheme was an honest endeavour to create a *bonâ fide* reserve in support of the Army Medical Department, and not an attempt to cut down and supplant it, then why weave into the Warrant the clauses about "contract rates," and charge of troops at home? Dr. Baines talks—without reference, be it noted, to any particular national emergency—of "freeing" the Medical Staff for "more active service," by employing volunteer reservists at home in their place. This is undoubtedly the main drift of the scheme; volunteers are to be bound beforehand to undertake charge of troops at home at "contract," or, in other words, pauper-like rates, in order that the Medical Staff at home may be reduced to the lowest possible peace limits, whilst its members abroad are saddled with an addition to the already grievous burden of tropical service! We feel assured that the vast majority of our medical volunteers will not lend their aid to so disastrous a policy. We have always insisted that our regular medical service must be kept up at home in sufficient numbers to meet the sudden mobilisation of at least one, if not two, army corps; and when the full pay men are so employed they might be "freed" by calling out the reserve of retired-pay medical officers.

We would remind Dr. Baines that "the reserve of combatant officers" is composed of those who have already served in the regular army—not of *quasi*-civilians: the combatant reserve is entirely similar to the retired-pay medical reserve.

Dr. Baines evidently recognises the validity of our contention that, in the extreme "case of invasion," the proper place for medical volunteers is with volunteer, not regular, troops. True, as he says, a certain number of regimental medical officers might be detached from their corps; but not, we maintain, to join regular troops, but to form field hospitals and bearer companies for the mobilised volunteer army. They would thus, equally with regular troops, demonstrate their "jealous honour" as patriots.

To Dr. Baines the "idea of the reserve is the offspring of

common sense;" if he had said "a reserve," we would readily agree with him; but as he means this particular reserve, we can only say we are not alone in differing from him.

Dr. Baines does not see, or refuses to admit, the extremely anomalous position in which, as we and many others capable of judging consider, the acceptance of the Warrant puts him and his fellow reservists. The argument is this: The auxiliary forces exist and serve under certain Acts of Parliament, supplemented by Orders in Council; what, then, we want to know authoritatively is the exact legal position which the medical reservists occupy under these Acts? Dr. Baines signs himself "Surgeon-Major, Army Medical Reserve of Officers, and 1st Middlesex Engineer Volunteers, R.E." How, we would ask, can he be both? Under what authority can he hold at the same time two active commissions in Her Majesty's forces? Can he fulfil simultaneously the duties pertaining to both? How can he be reckoned an efficient volunteer, earning a capitation grant for his corps, and at the same time hold a commission rendering him liable for military service, not only not connected with his corps, but not even connected with the volunteers? Did he seek or obtain the sanction of his immediate commanding officer in joining the reserve? We will not rashly assume that these questions cannot be answered in his favour, but as ordinary laymen we demand some elucidation.

But, outside the serious, we even see a comical side to the dual existence assumed or claimed by the medical reservists. Suppose the medical reserve from the auxiliary forces suddenly called out and mustered, in what uniform would they appear? Why, in every shape and shade of red, blue, green, and grey—from Surgeon-Major Jones, as a Royal Engineer, to Surgeon-Major Mactavish, in the full war-paint of the "Stuart" Highlanders. Such a piebald gathering would no doubt be highly successful in a burlesque, but we can hardly afford to have a medical reserve laughed at.

Dr. Baines declares he does not want to "flutter under an army rank;" nevertheless, he expresses no little satisfaction in having received "army rank with all its privileges." Would that his brethren of the regular service thought likewise! But they persist in saying that their army rank is only a mockery, a delusion, and a snare. They, of course, have to bear it about with them every day of their lives; Dr. Baines puts it on and off at civilian convenience!

DR. MACDONALD, M.P., has been elected Coroner for the new division of East Middlesex.

THE Mansion House Metropolitan Hospital Sunday Fund amounted on Wednesday last to rather more than £28,000.

IN August, next year, an International Congress for Dermatology and Syphilography will be held in Paris. It will be presided over by M.M. Ricord and Hardy. Communications may be directed to M. Feulard, Hôpital St. Louis, Paris.

SIR ROBERT RAWLINSON, K.C.B., will give a lecture in the Theatre of the Chemical Society, Burlington House, on Wednesday next, at 4 P.M., to the College of State Medicine; the lecture is entitled "The Rise and Progress of Sanitary Engineering within the present Century."

Two of the four foreign members elected into the Royal Society this year are physiologists; Professor Pflüger, of Bonn, and Professor Julius Sachs, of Würzburg; the name of the latter is as well known in vegetable as is that of the former in animal physiology.

THE PREVENTION OF HYDROPHOBIA.

At a meeting of the General Committee of the Society for the Prevention of Hydrophobia and Reform of the Dog Laws, held on June 13th, it was decided, in view of the refusal of the Government to introduce a Bill for the suppression of rabies in dogs, that the Society would at once seek to promote its own Bill, for that object, in the House of Lords. It was further decided to agitate for a repeal of all exemptions from the dog tax.

PRIZE DISTRIBUTIONS.

The medals and prizes to the successful students at Guy's Hospital will be distributed on Wednesday, July 4th, at 4 P.M., by Mr. Cosmo Bonsor, M.P. The Guy's Hospital Biennial Festival will be held on the evening of the same day, at the Holborn Restaurant; and Dr. H. P. Pye-Smith, F.R.S., will be the Chairman. Mr. Davies-Colley is the Honorary Secretary for the Festival. The prizes to the students of the Medical School of St. Thomas's Hospital will be distributed by Professor George Gabriel Stokes, D.C.L., LL.D., M.P., etc., President of the Royal Society, in the Governors' Hall, on Thursday, July 5th. The prizes to the students of Charing Cross Hospital Medical School will be distributed by the Master of Trinity College, Cambridge, on Friday, June 29th, at 3.30.

ASSOCIATION OF FELLOWS OF THE COLLEGE OF SURGEONS.

The members of this Association should bear in mind that, as has already been announced, a General Meeting will be held on Thursday, July 5th, at 2 P.M. in the Arbitration Room at the Inns of Court Hotel, Lincoln's Inn Fields, where questions of importance will be considered. This Association has, it cannot be denied, rendered good service to the cause of College reform. Without combination there can be no progress, and the necessary combination of individual Fellows for united action has been brought about mainly by the agency of the Association of Fellows, which, on the other hand, scrupulously avoids discouraging independent action or dictating to those who hold the diploma of Fellow. The Association has studiously pursued certain aims from the very moment of its foundation; especially has it insisted that the President should be elected by the Fellows, that a true Annual Report be presented to the Fellows and Members at every General Meeting of Fellows and Members, and that no alterations be made in the charter or by-laws without consulting the Fellows and Members. The entrance-fee to the Association is five shillings, the annual subscription half-a-crown. Fellows who desire to join the Association should communicate with the Honorary Secretaries, Mr. Bruce Clarke, 46, Harley Street, or Mr. Herbert Allingham, 25, Grosvenor Street, W.

THE COLLEGE OF SURGEONS.

As might be expected, there is little excitement about the coming election, although the withdrawal of Sir Joseph Lister has created a stir unforeseen a fortnight ago. Still, as the modifications in the charter do not come into force this year, the Fellows and Members do not deem it advisable to offer any opposition to the obstructive policy of the Council. There can be little doubt that proxy-voting will greatly alter the character of the annual contest at the College. At present, the candidates from the larger medical schools in the metropolis have still a great advantage over their rivals from small schools and from the provinces, as each large school includes a number of young men living in London,

within walking distance of the College, who are certain to support their candidate, or, in default of a candidate, they will support one from another large school, as experience has amply proved. With proxy-voting, the elections will certainly bring about the election of a more representative Council. For no Council can be termed representative if it fails to represent what it professes to represent. The Council may professedly represent the pick of Fellows of the College; at present it really represents the large London schools—noble institutions, no doubt, but designed for the care of their patients and the education of their students, and not for rule over qualified surgeons.

BEAUTIFYING AN INSANITARY CITY.

As is proved by the sanitary report for May, Prague still enjoys the unenviable reputation of being one of the most unhealthy cities in the world, the mortality from April 29th to June 2nd being 47.90 per mille. Small-pox and typhus and measles have, a correspondent informs us, been raging for the last five or six months, killing a great number of children among the poor. There have been numerous cases of typhoid, scarlet fever, diphtheria, and croup. A large number of cases of typhus are and have been treated in the General Hospital, and two medical officers, two medical students, and three nurses have already died from it, not less than twenty-three nurses having caught the infection. Privat-Dozent Dr. Haas, Physician to the Spital des Barmherziger Bruder, and one of the most respected medical men of the city, also died lately of typhus, which he had caught at his hospital. The Town Council have done a great deal in the way of beautifying the town, but seems entirely callous to the claims for pure water and a proper drainage. Anything more abominable, says our correspondent, than the stench in the streets and the filthy state of the drinking-water cannot be imagined.

CULTURE, ART, AND SCIENCE, VERSUS DIRT.

The Rev. Prebendary Billing has made some remarks before the Select Committee of the House of Lords, which is now investigating what is known as the "sweating system," as to the hygienic and moral condition of the Jewish poor in East London, and thinks there is much need for strong and continuous effort for their improvement and the care and education of their children. As to the care of the children, it is satisfactory to know that the Jews' Free School provides for more than 5,000 of them within its walls, and thus proves an immense factor in Anglicising the children of those poor people who are mostly fugitives from oppression, and tries to make them respectable members of society. It must be borne in mind that most of the Jews in East London come from countries such as Russia and Poland, where there exist no such sanitary laws as we have in England, and if their habits are not in accord with our ideas of right living, the duty of helping to reform them presses upon us the more strongly. We have been told by many members of the profession practising in East London that most of the cases of diphtheria in children come from among this alien population, a fact which should stimulate efforts for their improved condition as a hygienic precaution. Many efforts are being successfully made to elevate the physical and moral tone of the East-ender. The Rev. S. A. Barnett has long laboured in this direction, and has demonstrated by successful and highly appreciated art exhibitions that Whitechapel people are capable of culture, and of receiving pleasure from good pictures and refined society. In Toynbee Hall 1,000 learners are now assembled every week, and the principles of sanitation and good living, as well as some learning, are thus instilled into some of the mass of the population, helping to take them out of the narrow ruts of a drudgery life. Science in an attractive form is also being brought home to the East-ender in other ways. The East London Natural History and Microscopical Society have inaugurated a

series of "exhibition nights" at the Bow Vestry Hall, which seem to be very popular. It is also satisfactory to hear that the Bethnal Green Board has been stirred up by the action taken by the Home Office. The Commissioners, in their report, insist upon the re-organisation of the sanitary department of the parish, and the establishment of an adequate system of inspection, and the active interference of the Metropolitan Board of Works to compel the authorities to cause the necessary repairs to dilapidated property to be executed. It may thus be hoped that the combined effects of the many efforts now being made to improve the moral and physical condition of East London will lead to improved conditions of living among the population.

CALISTHENIC EXERCISES FOR GIRLS.

MORE general interest ought to be felt in the importance of physical training for girls. It is not enough that their mental powers should be trained, the general laws of hygiene obeyed, and their dress arranged so as not to be harmful. It is also necessary that scientific care should be used in aiding the regular and systematic development of their bodies. Scientific calisthenics should moreover have an aim beyond this, in exercising and training the nerve-centres. The work of the drill-sergeant may suffice for getting up the muscles, but in endeavouring to train the brain by use of calisthenics, it is necessary that the teacher should produce accurate, harmonious, and graceful movements, independent of the amount of muscular exertion. Last week the Princess of Wales took part in the Centenary of the Royal Masonic School for Girls, as celebrated at the Albert Hall, when a striking feature of the ceremony was the performance of some beautiful calisthenic exercises by the girls, with free movements, marching, and drill. Calisthenic exercises, when conducted on scientific principles, are of great value in regulating the nerve-centres; well co-ordinated series of movements imitated from the teacher, or produced to the word of command, tend to produce a well-knit nerve and muscular system responding with ease and gracefulness to impressions received through the eye and the ear. The tendency to asymmetry of postures, and ill-balanced positions of the head and spine, with excess of movement, is often pronounced in growing girls, especially those of hysterical temperament; such conditions may be checked and brought under control through the eye and ear. Quickness of brain action, and of the interaction of the senses and the hands, may be cultivated by exercises with balls. There is another advantage in such exercises, as the ball is thrown or caught by the child the eyes follow the moving object as it recedes or advances towards her, and thus the power of accommodating the vision is brought into play. In young and delicate girls great care is necessary in using such exercises as throw great strain upon special groups of muscles, and in the use of exercises designed to regulate brain action fatigue should be carefully avoided, and throughout the lesson the signs of weakness and exhaustion should be carefully looked for, so that the strain may not be injuriously prolonged. To conduct such exercises and training with success, especially in weakly children, requires special training and skill in the teacher.

INVALID MONARCHS.

THE sad case of the late Emperor Frederick III. is without parallel in modern history. The partial invalidism of several European monarchs has influenced politics in a marked manner. William III. of England suffered from bronchitis and emphysema, and the condition of his health was a factor in the calculations of politicians for years before his death, which, after all, was caused by accident. Louis XIII. was phthisical, and his ill-health to a great extent brought about the absolute rule of Richelieu, but the king, though he succumbed to tubercular ulceration of the large intes-

tine, lived over his forty-second birthday. Putting aside aged popes; sultans, always under tutelage whether healthy or sickly; nominal monarchs like Louis XVII. and Napoleon II., and two Czars said, on not sufficient grounds, to have been insane when murdered, there remains the great historical case of King Charles II. of Spain. He appears to have been of weak intellect and there is some record of congenital malformations, including deficient development of the lower jaw. This natural mental weakness, however, was certainly aggravated by bad education and by the custom of his father's Court, which kept him from the wholesome society of youths of his own age; yet his mental weakness was not so great as to prevent him from feeling much irritation at the conduct of England, France, and Germany towards his country. He succeeded to the throne in 1665 and did not die till 1700; in 1668 when the Treaty of Aix-la-Chapelle was signed, his death was hourly expected, but his sickly existence was protracted for thirty-two years. After his death in 1700 the war of the Spanish Succession soon followed. His case, had it been properly reported, would be of high clinical interest. With the sole exception of the invalidism in both instances, the reigns of Frederick III. of Germany and Charles II. of Spain stood in strong contrast. A medico-historical moral may be drawn therefrom. The short reign of a wise ruler, stricken with a deadly disease, is better than the long reign of a half imbecile monarch afflicted with a chronic disorder.

DR. GEORGE JOHNSON, F.R.S.

A NUMEROUS company of ladies, members of Council, colleagues, past and present students of King's College, assembled recently in the large theatre of that institution, to witness the presentation to Dr. George Johnson, F.R.S., of his portrait, painted by Mr. Frank Holl, R.A., subscribed for by his friends and pupils on his recent retirement from the Professorship of Clinical Medicine, after forty-five years' service at King's College and King's College Hospital. Sir Joseph Lister, F.R.S., in making the presentation on behalf of the subscribers, warmly referred to Dr. Johnson's personal character, the advantages of his teaching to many generations of students, and to the valuable researches by which he had advanced medical science; and, in thanking his friends and pupils for their kind testimonial, Dr. Johnson gave an interesting summary of the circumstances which had determined him to begin the study of medicine, the incidents attending the publication of his views on some disputed points of medical practice, and other features of interest connected with his long period of work at the College and Hospital.

ARSENICAL TISSUES.

MR. F. E. MATTHEWS, of Cooper's Hill, who for some time past has been investigating the subject of arsenic poisoning by means of cretonnes, imitation Indian muslin, etc., gives the following results of his inquiries in the *Daily Telegraph*. Dr. Giffard, the Medical Officer at Cooper's Hill, had brought him some cases in which he thought he detected symptoms of arsenic poisoning; and in every case the source of the poisoning was traced either to a cretonne or to an imitation Indian muslin, used as a decoration by the student. The samples upon which the experiments have been performed were supplied by a local tradesman. The results obtained on analysis were as follows:—Forty-four samples of cretonne have been analysed, and of these none were found absolutely free from arsenic, three contained only the very faintest trace, and twenty-one contained larger traces. The remaining samples all contained arsenic in poisonous quantities. Eleven of them were grouped as "very bad," and the other nine as bad and distinctly dangerous. One of the worst specimens had been examined quantitatively, and yielded an amount of arsenic equivalent to rather more than 19½ grains of white arsenic [As₂O₃]

per square yard. Mr. Matthews adds: "It is quite a common occurrence to have enough of these substances in a room which would contain sufficient arsenic to give 100 people a fatal dose. As far as the analyses have gone at present, they do not show that any one colour is more poisonous than another, as, strange to say, the greens and blues, that would be the first suspected, have until now proved purer than reds, browns, and blacks. In the case of imitation Indian muslins, five samples only have been analysed, but they all contained arsenic in poisonous quantities." The subject is one which has repeatedly been brought to official and public notice. The National Health Society carried out a very full investigation of the matter, and prepared a conclusive report, drafting also a Bill for Parliament, designed to avoid these dangers; but neither legislators nor officials were prepared to assent to such a measure. Perhaps in time and by frequently reading disclosures of the existing perils to health, public opinion may be ripened.

THE MEDICAL SERVICE AND THE INTERESTS OF THE PLANTERS AND COOLIES IN BRITISH GUIANA.

We have received from "The British Guiana Planters Association" a communication enclosing further documents with reference to the recent report of the Medical Inspector. The most important of these is the Report of the Immigration Agent General on the Report of the Medical Inspector. This Report deals at great length and in much detail with the various statements contained in Dr. Williams's Report, and cannot be analysed here within a reasonable space. Its general tenour is fairly indicated by the conclusion, which is, "that the irritation to which his report has given rise is due, not only to its exaggerated and misleading character, but also to the censorious spirit in which it is written and to the absence of any recognition or sign of appreciation of the readiness on the part of proprietors of estates to comply with all reasonable requisitions, and their desire to meet the wishes of the Government, in spite of the well-known difficulties with which they have had to contend during the last few years." As will be seen by the answer given by Baron de Worms to Dr. Farquharson which is published at p. 1363, the Colonial Secretary does not think it desirable to send a Commission of Inquiry, and has determined on removing Dr. Williams from the office of Medical Inspector of Hospitals. It is impossible to look upon this as a satisfactory termination of the difficulty. The intemperate articles which have appeared in the Colonial press appear to show that a certain section of the planters resent all criticism, and are ready rather than tolerate it to attempt to upset the present constitution of the Medical Service of the Colony. This intemperate attitude was also evidenced by a resolution proposed by one of the members of the Combined Court to the effect that the Governor should be requested to remove Dr. Grieve from the office of Surgeon-General to the Colony because he had forwarded his report—a printed public document—to this JOURNAL.

MEDICINE IN CEYLON.

THE inaugural address of the President of the Ceylon Branch of the British Medical Association has been issued as a pamphlet; in it the Hon P. D. Anthonisz, M.D., sketched the progress of medicine and surgery in Ceylon during the last five-and-forty years. He instanced the greater precision in the diagnosis of the fevers prevalent in the island, the recognition of typhoid fever and its more rational treatment, as among the greatest advances of the period. The larger part of the address, however, was occupied with an able summary of the means of preventing the spread of small-pox, cholera, and other epidemic diseases. He strongly advocated the early and complete isolation of cases of cholera, all persons who had come in contact with patients being kept under observation for at least ten days; he laid stress on Dr. Koch's

observation that the comma bacillus grew readily in animal but not in vegetable media, observing that the last epidemic of cholera in Colombo continued so long as the water of wells sunk in the midst of dirty little habitations with cesspits and cattle sheds all around them, and the soil saturated with the excreta of man and beast, was drunk; but when these wells were closed, and water from unaffected localities was supplied, the disease subsided, notwithstanding that the cakes and other farinaceous food which had been cooked in and were exposed to the air of the room where the sick person was, were freely used, thus showing that the bacillus could only be cultivated in animal matter, and that it would not grow on starch or farinaceous food. The flies would otherwise, he thought, have been a source of contagion, as they settled in drains full of the discharges of the patients and the washings from the rooms, and afterwards on the food. He also stated that Dr. Koch's opinion that the only way to destroy the bacillus was drying was confirmed by the observation that cholera never reappeared in huts with mud floors, where the ground was thoroughly baked by lighting fires on it; in former epidemics these huts had constantly afforded instances of recrudescence. The readiness to apply the latest results of scientific research to practice is in itself a striking proof that the medical profession in Ceylon has advanced with the rest of the world; further evidence of this enterprising spirit is afforded by the appearance of the *Ceylon Medical Journal*, published quarterly. The fourth number of this periodical, completing the first volume, was issued in May, and contains many excellent papers on topics of general or special interest. The first paper, by Assistant-Surgeon Gratiaen, on Some Cases of Anchylostomiasis, affords interesting confirmation of Dr. Kynsey's view, that these parasites are a frequent as well as a very effective cause of severe anæmia; in all cases of anæmia in hospital the fæces are examined for the ova, and when these are discovered, a calomel purge (gr. vii in divided doses) is given at night, followed by senna mixture in the morning; then 30 grains of thymol is administered and repeated in two hours. Iron and digitalis or strophanthus are given for a week or ten days, and the fæces again searched; if ova are found the treatment is repeated; recoveries from "an almost hopeless condition" are reported under this line of treatment. The proceedings of the Ceylon Branch of the British Medical Association are reported in the *Ceylon Medical Journal*, and it is satisfactory to learn that the first year of the journal's existence has been successful.

DISPENSING DEATH.

A LAMENTABLE case of gross negligence was disclosed at an inquest held on Wednesday on the body of an unfortunate man named Brewster, the proprietor of a public-house at Lewisham. It seems that a certain Mr. Malcolm Cowan, who said he was a medical student at King's College Hospital, and had been a dispenser for five years, prescribed for this unfortunate man, who "did not feel well and thought his liver was out of order," a seidlitz powder with five drops of liquor strychniæ. Mr. Cowan seems to have gone into a chemist's shop kept by a Mr. Henry in the district, and asked Mr. Eugene Henry, aged 22—who said he had been apprentice to his father for three years and his assistant for three years—to make up a draught containing the alkaline part of a seidlitz powder in a two-ounce phial, and to add five drops of liquor strychniæ. Hereupon Mr. Henry made up a draught containing not five drops of liquor strychniæ but five grains of strychnine in solution. And this probably intensely poisonous solution he labelled "the draught," acting therein upon Mr. Cowan's suggestion; he did not mark it "poisonous," neither did he make any observation to Mr. Cowan, his excuse being that he allowed his judgment to be overweighed by the order of Mr. Cowan, whom he supposed to be a medical man. All parties are alike blameable in this tragedy, Mr. Cowan for under-

June 23, 1888.]

taking to prescribe under the circumstances, and Mr. Eugenio Henry is chiefly and most fearfully to blame in putting up, under whatever misunderstanding, five grains of strychnine into a two-ounce bottle, which he labelled "the draught," without making any observation to Mr. Cowan, and without labelling it "poison." The authorities of the Pharmaceutical Society ought, we think, to take some notice of this matter. We have seldom had to record so full and so fatal a case of neglect in dispensing.

ENGLISH PRACTITIONERS IN SWITZERLAND.

DR. F. R. HOLLAND, writing from St. Moritz and referring to a telegram which we published in our issue of June 9th, to the effect that a law permitting a limited number of English doctors to practise has been carried by an enormous majority, says:—"Having initiated the action both legally and by personal canvass of the Grosse Rath, or Grand Council, which has led to a friendly concession from them, kindly permit me to place before your readers the exact position of affairs, for otherwise an erroneous impression is nearly sure to prevail. 1. The decision of the Grosse Rath is not really a law, it is only an order (*ordnung*) made to suit a special case, and does not apply to medical men generally. 2. The action of the Government of one Canton in a case of this sort in no way holds good of any other part of Switzerland. 3. The law in the Grisons which prevents foreign practitioners from practising unless they hold a Federal diploma is still in force. Now, with regard to this same law which has been the subject of much criticism, I must say something in its favour, although I personally have suffered from its application. Its object is not only to interfere with the existence of quacks, but also to prevent alien doctors from taking the bread out of the mouths of the native medical men. From the Swiss doctors' point of view, their health-resorts afford a happy hunting ground to needy practitioners from southern winter places—men who bring nothing to the country, but take all they can out of it. They do not help to develop a new place, and they often interfere with the prosperity of the established cure places. These are the men that the authorities and the people desire to keep out. On the other hand, the relief just granted to the English doctors in the Engadine for establishing winter stations there is an earnest that, where a medical man can prove that his presence is a real desideratum, special privileges for practising shall be granted to him."

AN EXHIBITION OF GROWING BACTERIA.

THE following description of the collection of bacteria which Professor Soyka, of the Hygienic Institute of Prague, is at present exhibiting at Brussels and Copenhagen, has been sent us by a correspondent at Prague. Each collection contains about 60 pure cultivations, each in 3 to 5 specimens, and consists of 2 groups, namely, in round glass boxes on potatoes or Soyka's milk rice (10 parts of rice flour, 15 of milk, and 5 of beef-tea, fractionally sterilised, forms a beautifully white homogeneous surface), and, secondly, in flat, round flasks in gelatine, agar-agar, and blood serum. The former ones are produced in the following manner: the nutritive materials mentioned are put into cylindrical glass boxes (of the shape of pill-boxes), with exactly fitting lids, sterilised and inoculated. When the desired growth has taken place they are hermetically closed in the following manner: a circular glass plate is heated to about 100° or 120° C., and put on the glass box at the same moment that the lid is removed. The latter is quickly cleaned, heated to 150° to 170°, and placed on the hot plate face downward. As soon as it can be held with the hand for a moment, it is dipped into melted paraffin, and, whilst the plate is removed with the left hand, put on the box with the other hand. The rim is hermetically closed by painting on paraffin. The cultivations remain pure and able to germinate (latent) for an indefinite period, so far observed for two years and

a half. The second group (Soyka's Dauerplatter) is prepared in circular flasks flattened on two sides, with cylindrical necks, filled with gelatine or agar to about two thirds. After liquifying these substances, and whilst they are cooling, six to seven dilutions of the materials to be inoculated are prepared in beef-tea; the first to sixth dilution is inoculated, and after solidification has taken place, whilst the flask is lying on one of its flat sides, the mouth of the neck is dipped into paraffin and hermetically closed. The colonies grow isolated and energetically. The most important point is the finding of the right dilution in order to get only a small number of colonies, which can be examined microscopically. Professor Soyka claims for his method the following advantages: 1. Possession of a museum for demonstrations; 2. existence for a long time of pure, unchangeable material for inoculations; 3. possibility of fixing the duration of the latent life of the organisms; 4. possibility of creating the most intense processes of growing, and of observing the same for an indefinitely long period.

TUBERCULOUS ULCERATION OF THE VULVA,

DR. M. ZWEIFBAUM, of Warshan, records a case of this rare manifestation of tuberculosis in the *Berliner Klin. Wochenschrift*, May 28th, 1888. The patient came under his observation in 1885, but the year before had been treated for fungous ulceration of the vaginal portion of the uterus. Paquelin's cauterisation was used, and the patient was discharged "cured." She was thirty-two years old, and had had five children. On admission under Dr. Zweifbaum's care there was a deep, painful ulcer just within the left posterior vaginal wall, forming a cavity an inch and a half long and an inch deep, together with cauliflower excrescences of the portio vaginalis. The left labium minus was almost destroyed by ulceration, and microscopic examination of a portion revealed abundant tubercle bacilli. The apex of the right lung showed obscure signs of phthisis on auscultation and percussion. The spleen was somewhat enlarged, and the patient was feverish. In five months death ensued from exhaustion, the lungs having shown further alterations. There had been purulent expectoration, and towards the end œdema of the lower limbs. Syphilis was positively excluded in this case, which was examined by several colleagues. Dr. Zweifbaum has carefully examined the literature of the subject, and finds only two cases of tuberculous ulceration of the vulva recorded (Deschamps, Chiari). Taking into account the vagina and cervix uteri, twenty-nine cases of primary disease are recorded by various observers, and a short synopsis of each case is here given. The disease is by no means rare in the course of general tuberculosis, but is rare when primary. Cohnheim gives one case, Fernet four cases, of infection by coitus. Others are ascribed to examinations, syringing by nurses who are tuberculous or much in contact with tuberculous patients. Numerous cases are recorded as having occurred immediately *post partum*. Intercourse with phthisical patients appears also to be more or less dangerous; for example, by the use of the same bedclothes, closets, or baths. Auto-infection may also occur from the sputa or feces, and thus a secondary tuberculosis may be set up. Frerichs disputes the possibility of infection from without, and argues that it takes place by conduction from the Fallopian tubes, more rarely the uterus. The stages successively occupied by infectious material are very difficult to make out, because each organ or part successively traversed may show no trace of the virus afterwards, the nidus being unsuitable. We do not yet know the conditions which favour the establishment of the tuberculous process in a particular part. It is probable that certain pathological processes induce a predisposition for tuberculous, as in the lungs. Thus comments Dr. Zweifbaum on his case, which teaches us above all the value of cleanliness, or rather the great dangers which attend its absence.

SCOTLAND.

SMALL-POX IN KILMARNOCK.

A CASE of small-pox has been discovered in Kilmarnock. It was that of a football player of Preston, who came to Glasgow on Saturday, the 2nd inst., to play in a match, but was prevented by illness, which has since been found to be due to small-pox. He was removed to hospital, and all necessary precautions were taken.

VISIT OF THE QUEEN TO GLASGOW.

THE QUEEN has intimated her intention of visiting Glasgow in order to inspect the International Exhibition, on August 23rd. The arrangements for the visit have not yet been made public, but it is hoped that in addition to inspecting the exhibition, Her Majesty may consent to open the New Municipal Buildings.

VICTORIA INFIRMARY.

AT a meeting of the executive committee of the Victoria Infirmary it was intimated that subscriptions to the building fund now amounted to £25,000. Estimates for the building were considered and accepted, and it was arranged that in view of the expected visit of the Queen to Glasgow an effort should be made to get Her Majesty to lay the foundation-stone.

CHILDREN'S FRESH-AIR FORTNIGHT.

THE committee carrying out this scheme in Glasgow have, since May 15th, sent 776 of the neediest children to the country for a fortnight, and marked success is attending the development of the scheme. The system of boarding out the children with respectable cottagers is succeeding admirably.

THE UNIVERSITY OF BOLOGNA.

THE delegates from Glasgow at the octo-centenary of the University of Bologna were Professors Ramsay, Ferguson, and Jebb, the last-named also representing the University of Cambridge. Professor Jebb, in honour of the event, has composed a very elaborate and beautiful Greek Pindaric ode, in which he eulogises the University of Bologna for the distinguished part it played in the revival of learning, law, and medicine. At the end of the poem he makes graceful allusion to the connection of Glasgow with Bologna—the constitution of the former University being originally drawn by Pope Nicholas V. in 1451 on the model of that of Bologna. This fact is again referred to in a Latin address of congratulation sent by the Senate of the University of Glasgow to the Rector and Senate of the University of Bologna, and which concludes thus:—*"Liceat igitur Universitati nostræ, ut, felicissimum hoc nancta gratulationis offerendæ tempus, simul gaudii quod omnibus commune est, se participem esse declaret, simul proprio quodam sensu arctioris instincta necessitudinis, tanquam matri venerandæ filia caritatem atque amorem testificetur."*

IRELAND.

THE LOCAL GOVERNMENT BOARD INSPECTORSHIP.

DR. ROBERT CLEMENTS, medical officer to No. 1 Dispensary, Belfast, has been appointed an inspector under the Local Government Board, in room of Dr. E. Thompson, resigned.

BELFAST WATER SUPPLY.

THERE has been a very copious rainfall in the neighbourhood of Belfast during the past two or three weeks, and some dissatisfaction has been expressed at a meeting of the Water Board that measures have not been taken to store supplies in the new reservoirs at Stoneyford. Some difficulty regarding the report of the

Local Government arbitrator is the alleged cause of this apparent neglect.

IRISH BRANCH OF THE BRITISH MEDICAL TEMPERANCE ASSOCIATION.

THE annual meeting of the Irish Branch of the British Medical Temperance Association was held at the Royal College of Surgeons of Ireland on June 8th. The report read by Dr. MacDowell Cosgrave, Honorary Secretary, stated that the number of members and associates had increased during the year. The President (Deputy Surgeon-General Gunn) expressed a wish that more students would join as associates. The object of the Association is to promote investigation of the alcohol question, which was of great importance in its relation to the health of the nation, and of especial interest to members of the medical profession and students of medicine.

DR. MAGNER.

THE Local Government Board having declined to sanction the appointment of Dr. Magner to the Timoleague Dispensary, the County and City of Cork Medical Protective Association have passed the following resolution: "That we regard any attempt by a public board to exact any pledges, political or otherwise, from a registered medical practitioner who is a candidate for a medical appointment as an undue interference with professional rights; that we believe the requirements of a pledge unconnected with the discharge of his professional duties not to be in the interests of the sick poor, and we feel confident no honourable member of our body would enter into an engagement that would subject him to civil disabilities; and we are further of opinion that the acceptance of office under such conditions would be derogatory to the profession."

KIDDERMINSTER AMBULANCE CLASSES.—Dr. J. Lionel Stretton has recently conducted ambulance classes for men and women in Kidderminster with great success. The male class, numbering 72, of whom 69 went up for examination and 67 passed, expressed their gratitude by presenting Dr. Stretton with a pair of bronze trays. The female class, numbering 40, presented 15 candidates for examination, of whom all passed.

LARGE VESICAL CALCULUS.—At a recent meeting of the St. Petersburg Medical Society, Dr. H. J. Turner showed (*Vratch*, No. 15, 1888, p. 298) an enormous ellipsoid stone weighing ten ounces, and consisting of urates and oxalates. It was removed from the bladder of a man, aged 32, by suprapubic operation. The patient survived twenty-six days. At the *post-mortem* examination both kidneys were found full of pus, and disorganised by extensive cystic degeneration.

SANITARY SURVEYORS AND INSPECTORS.—At the examinations held by the Sanitary Institute this month 10 candidates presented themselves for certificates of competence as local surveyors, of whom only 2 were successful; 65 candidates presented themselves for certificates of competence as inspectors of nuisances, of whom 46 were successful.

DEATH FROM CHLOROFORM.—The death of a woman aged 35, when under the influence of chloroform, occurred last week at St. Bartholomew's Hospital. The deceased, the wife of a bricklayer, was suffering from an abscess in the neck. Chloroform was administered with every precaution, but the woman almost immediately died.

ON the occasion of the presentation of medallions and certificates to the successful pupils of the St. John Ambulance Association class at Newark Dr. F. H. Appleby was presented with a silver tea-kettle and salver, as a token of appreciation of the services rendered by him in connection with ambulance work in Newark.

WE understand that Mr. Henry A. Allbutt, of Leeds, has initiated legal proceedings with the view of compelling the General Medical Council to restore his name to the *Medical Register*.

THE LATE GERMAN EMPEROR.

CLINICAL HISTORY OF THE CASE.

THE first definite symptoms of the illness which, on June 15th, deprived Germany of a truly enlightened ruler and the world of a most noble-hearted man appear to have shown themselves in January, 1887. There is said to be a somewhat remote history of cancer in the family, and for many years the late Emperor suffered from a certain delicacy of the throat. In 1886 he had an attack of measles, from which he recovered without any bad after-effects, but it was noticed that he never quite regained the high spirits for which he had before been remarkable. In the latter part of the same year he suffered from a succession of obstinate "colds," which finally culminated in such extreme and persistent hoarseness that his physician in ordinary, Dr. von Wegner, called in Dr. Carl Gerhardt, Professor of Medicine in the University of Berlin and a recognised authority on diseases of the throat. On laryngoscopic examination a small growth was seen springing from the left vocal cord and interfering with its action. This was in great part destroyed by electric cautery, and in the spring the illustrious patient was sent to Ems, where it was hoped that the waters would complete the cure. The symptoms, however, returned with greater severity, and the growth increased in size so rapidly that suspicion of its being malignant was excited. Professor Ernst von Bergmann, the leading surgeon in Berlin, and soon afterwards Professor Tobold, one of the pioneers of laryngology, were consulted, and it was agreed that an operation was desirable in order to determine the nature of the disease, and, if possible, extirpate it. With this view it was proposed to perform thyrotomy in the first place, and, if necessary, to follow this up by such further surgical measures as the circumstances of the case might seem to call for. Before carrying this plan into execution, however, the medical attendants being fully alive to the vast responsibility of their position, were anxious to have the advice of some laryngoscopic authority whose opinion would command general respect. It was unanimously decided to call in Sir (then Dr.) Morell Mackenzie, who accordingly proceeded to Berlin on May 20th. He found a sessile growth about the size of a split pea, but oval in shape, situated on the posterior extremity and inner surface of the left vocal cord, the mobility of which was distinctly impaired. There was general congestion of the mucous membrane of the larynx. Dr. Mackenzie did not consider the clinical evidence decisive one way or other as to the character of the affection, and suggested that before any further steps were taken a portion of the growth should be removed through the mouth and examined microscopically. He succeeded in thus extracting two or three fragments, which were at once submitted to Professor Rudolf Virchow. That eminent pathologist having failed to find any trace of malignant structure in them, it was unanimously agreed that Dr. Mackenzie should take the case into his own hands for a time, and should attempt to eradicate the disease without external operation. In June the Emperor (then Crown Prince) came to England, and Dr. Mackenzie removed the remaining portion of the growth. After examination, this was, on July 1st, pronounced by Professor Virchow to be a "hard compressed warty growth that has started from a moderately irritated and thickened surface, and the examination of its base has not afforded the least support for the idea of a new formation penetrating inwards." The voice was at this time so much improved that, on July 14th, the Prince, in visiting the Throat Hospital, made a little speech to the patients in which he expressed a hope that they might be cured as quickly as he had been. The larynx, however, remained somewhat irritable, and the whole throat showed a tendency to become congested on very slight provocation.

At the beginning of August there were signs of recurrence of the growth, and Dr. Mackenzie applied the electric cautery on two occasions with the result of destroying it entirely. The Prince then went to the Isle of Wight, the climate of which, however, proved too relaxing, and his throat gave him a good deal of trouble. Dr. Norris Wolfenden, who attended him while there, observed a slight thickening of the mucous membrane at the back of the larynx in the form of a ridge extending horizontally from the base of one arytenoid cartilage to the other. The action of the vocal cord was still somewhat defective, as it had been in Berlin. The bracing air of Braemar was next tried, and considerable improvement took place in the local condition; the thickening just mentioned was absorbed, the congestion of the larynx disappeared, and the affected cord moved more freely. Early in

September, however, there was a relapse, and on the 18th of that month, while the Prince was at Toblach in the Tyrol, Mr. Mark Hovell, who had succeeded Dr. Wolfenden, noticed a swelling half-an-inch below the left cord and parallel with its free border. This increased in size; o-dema of the left aryteno-epiglottic fold supervened, and there was some constitutional disturbance. The acute symptoms passed off in a few days, and the Prince proceeded to Italy. Towards the end of October, active hyperæmia of the whole interior of the larynx came on somewhat suddenly; the swelling under the left cord increased in size and began to ulcerate, and a reddish projection was noticed below the right cord. Early in November the appearances were so ominous that it was thought expedient to have further advice, and Professor Leopold von Schrötter of Vienna, Dr. Moritz Schmidt of Frankfurt, and Dr. (now Professor) Hermann Krause were summoned to San Remo. After consultation the diagnosis of cancer of the larynx was arrived at, and the propriety of a radical operation was discussed. The illustrious patient having fully considered the question, decided not to submit himself to any procedure involving immediate risk to life, but to take his chance with treatment of a purely palliative kind. From this point onwards the disease made steady progress, with occasional exacerbations of the symptoms owing to the intercurrent development of inflammatory processes in various parts of the larynx. These, in the early part of this year, became so pronounced as almost entirely to mask the essential disease, and hopes were entertained by some of the physicians that the affection might after all prove to be one of perichondritis depending on chronic laryngitis of exceptional severity.

About the end of January the glottis began to be encroached on to a serious extent, and on February 9th, tracheotomy became necessary. Professor von Bergmann was telegraphed for, but before he could reach San Remo the dyspnoea became so urgent that the operation was performed by Dr. Bramann in the presence of Sir Morell Mackenzie, Dr. Krause, Dr. Schrader, and Mr. Hovell. The Prince did not rally from the effects of the operation for some time, and it became clear that the general health was beginning to give way. It was feared that secondary formations had developed in the lungs; but Professor Kussmaul, who was summoned, could find no evidence of such a complication. Soon afterwards, however, Professor Waldeyer, to whom in the absence of Professor Virchow, the microscopic examination of the expectorated matters had been entrusted, pronounced the laryngeal affection to be cancerous. The tracheotomy wound was for a few days in a very unhealthy state, and there was a good deal of suppuration. Great difficulty was experienced in finding a tube to fit comfortably in the wound, and finally Sir Morell Mackenzie was obliged to fashion one with his own hands. The illustrious patient thereupon recovered his appetite, and was able to sleep; and he regained his strength to such a degree that when his father, the Emperor William, died on March 9th he insisted on returning at once to Germany, although the weather was most inclement. At Charlottenburg the new Emperor was able for a time to discharge many of the duties of his exalted position, and he threw himself into the conduct of State affairs with such energy that his physicians were anxious to get him away from the neighbourhood of Berlin. On April 13th the tracheotomy tube became partially blocked by a mass projecting into its lower end, and some difficulty occurred in replacing it by a longer one. There was a good deal of hæmorrhage, the blood finding its way into the lungs and setting up bronchitis. Diffuse suppurative inflammation of the loose tissue surrounding the trachea ensued, and for some days there was considerable pyrexia with occasional rigors. Apprehensions were felt that pyæmia was setting in, but the general condition improved on the establishment of a profuse purulent discharge which continued more or less till the end. In May the inflammatory element in the case underwent a notable abatement, and there was a pause in the progress of the disease for two or three weeks. At this time Professor Virchow again examined some of the discharge, without finding in it anything that to his mind was a proof of cancer. On June 8th it was obvious that a fresh complication had occurred; difficulty of swallowing came on, and it was thought that perforation into the œsophagus had taken place. On June 9th Trendelenburg's tampon cannula was substituted for the ordinary tracheotomy tube with the view of preventing the food from escaping into the air-passages. The Emperor meanwhile was losing ground very fast, and on the 13th Sir Morell Mackenzie had to feed him with the

oesophageal tube. On the evening of the 14th pneumonia rapidly supervened and death took place on the forenoon of the 15th.

The medical men in attendance on His Imperial Majesty at the time of his death were Sir Morell Mackenzie, who had been constantly with him since the beginning of February, and who has throughout had the responsible management of the case with the exception of the period immediately following the operation of tracheotomy; Professors von Bardeleben, Senator, Leyden, and Krause; Drs. von Wegner and Schrader, and Mr. Mark Hovell. During the last few months Sir Morell Mackenzie has been on duty during the day, while Mr. Hovell has watched at night. In addition to the above-mentioned gentlemen, the following members of the profession have at one time or another been connected with the case: Professors Gerhardt, von Bergmann, von Schrötter, Kussmaul, Virchow, Waldeyer, Drs. von Lauer, Tobold, Bramann, Moritz Schmidt, Landgraf, and Norris Wolfenden. Dr. Robert C. Myles, an American physician, also examined the late Emperor's throat on one occasion when he was in England.

The *post-mortem* examination, which was made on June 16th by Professor Virchow and Dr. Langerhaus, in the presence of Sir M. Mackenzie, Drs. von Wegner, von Bardeleben, von Bergmann, Waldeyer, and Bramann, and Mr. Hovell, proved that the disease was cancer complicated by suppurative inflammation of such intensity that the whole structure of the larynx was destroyed, its place being taken by a large abscess-cavity. Although a summary of the results of the *post-mortem* examination has already appeared in the daily newspapers, we regret that we are unable to give the full report, as orders were issued at the last moment that it should not be published.

Before the necropsy was made Sir Morell Mackenzie, at the request of Prince Bismarck, drew up the following report on the case, which he presented to the new Emperor, and which was deposited among the State archives:

"In my opinion the disease from which the Emperor died was cancer. The morbid process probably commenced in the deepest tissues of the cartilaginous structures of the larynx, and they became affected at a very early date. A small growth, which was present when I first examined the late Emperor, was removed by me by several operations, and all the portions taken away were submitted to Professor Virchow. He was unable to detect in them any evidence of the existence of cancer. Examinations made at the beginning of March by Professor Waldeyer, however, led to the belief that cancer was then present. Whether the disease was originally cancerous or assumed a malignant character some months after its first appearance it is impossible to state. The fact that perichondritis and caries of the cartilages played an active and important part in the development of the disease no doubt largely contributed to make it impossible to form a decided opinion as to its nature till quite a recent date.

"MORELL MACKENZIE."

To this report was appended the following statement from Mr. Hovell:—

"In so far as my observations since last August permit me to form an opinion, I concur entirely with Sir Morell Mackenzie's view."
"T. MARK HOVELL."

The subjoined account, which we have received from Sir MORELL MACKENZIE, of the closing events of the late Emperor's illness will be read with particular interest:—

"A few days before the Emperor left Charlottenburg, he began to lose ground, a tendency which continued to show itself after His Majesty arrived at Potsdam. There was, however, nothing alarming in the symptoms until the early morning of June 8th, when Professor Krause (who in the absence of Mr. Hovell was sitting up with the Emperor) observed that, in drinking milk, some of it passed down the trachea into the lungs, producing violent coughing, whilst some came out directly through the tracheal wound. During the day His Majesty was able to swallow solids moderately well, but in taking liquids, the greater part was lost in the way already described. It was generally agreed that a fistula had developed, but Sir Morell Mackenzie suggested the possibility that the liquid might pass directly into the larynx through the epiglottis not acting properly.¹ He, however, agreed with his colleagues that in all probability ulceration had taken place through the posterior surface of the larynx into the oesophagus. On the evening of the 9th, in the presence of Professors Bardeleben, Leyden, and Krause, and Generalarzt von Wegner, Sir Morell Mackenzie inserted a tampon cannula, which was immedi-

¹ This suggestion eventually proved to be correct.

ately inflated. After this no fluid passed down the trachea, but in drinking, nearly all the liquid taken still passed into the larynx and escaped by the side of the cannula. On the 10th the condition remained unchanged, and on the following morning it was unanimously agreed that Sir Morell Mackenzie should attempt to feed the Emperor with an oesophageal tube. A tendency of the posterior wall of the trachea to bulge forwards and thus obstruct the lower orifice of the cannula having been lately noticed it was believed that this structure was very soft, and it was thought that a false passage might easily be made. Hence it was considered that the passing of an oesophageal tube would not be unattended with danger.² Nevertheless, the operation was carried out with perfect success, and from Monday, June 11th, till Friday, June 15th, at 6.30 A.M., His Majesty was regularly fed with condensed milk, cream, beef-tea, eggs, and whisky.

On Tuesday, in the middle of the day, it was noticed that the Emperor's breathing became obstructed, and this difficulty gradually increased, till at 7 P.M. it became serious. It had been arranged in the morning that in the evening a longer tube, which had been prepared a day or two previously, should be inserted; and Sir Morell Mackenzie intended waiting till 10 P.M. in order that he might introduce it in the presence of Professor Bardeleben, who was expected at that hour. At 9 P.M., however, the breathing became so bad that Sir Morell Mackenzie found it necessary to take immediate steps, without waiting for the Professor. Before changing the tube, Sir Morell Mackenzie determined to try if he could alter the position of the cannula after inserting a pilot through the tube. The attempt was perfectly successful. On inserting the pilot it was discovered that the posterior wall of the trachea projected against the lower end of the cannula and partially covered its orifice. By tilting the cannula forwards Sir Morell Mackenzie succeeded in releasing the lower end of the tube from the projecting surface of the trachea, and the breathing at once became perfectly easy.

The pulse became very quick and the breathing rapid, and on the night of Wednesday, June 13th, it was evident that pneumonia had set in. The temperature on that evening was 103°, whilst on the two or three previous nights it had varied between 101° and 102°. From this date it was only a question of struggling on for a day or two, and at a quarter past eleven on Friday morning the illustrious patient passed away.

During his long and tedious illness, in which the prospect of recovery was repeatedly darkened by sudden relapses, no word of complaint ever passed his lips, no sign of impatience was ever seen. His medical attendants and faithful servants will always cherish the recollection of his grateful acknowledgment of services which ordinary patients exact as a right."

A CENSUS OF REGISTERED MEDICAL PRACTITIONERS IN ENGLAND AND WALES.

A REPORT has recently been issued by the Statistical Committee of the General Medical Council which contains a great deal of curious information about the distribution of medical practitioners in England. A comparison has been made between the census of the profession in 1881 and in 1886, and the present report contains the results for England and Wales; subsequent reports will deal with Scotland and Ireland.

Number of Practitioners and Proportion to Area and Population.—The number of registered practitioners increased from 15,022 in 1881 to 16,930 in 1886, an increase of 21.7 per cent., or 2.42 per cent. per annum; the population only increased at the rate of 1.40 per cent. per annum, so that whereas the average number of persons to each practitioner in 1881 was 1,747, in 1886 it had sunk to 1,662, and consequently each practitioner had on the average 85 potential patients less than in 1881. The same fact is expressed in another way by the statement that the net increase of the profession during the quinquennium was 826 beyond what was requisite to keep pace with the population; this is equal to an annual excess of 165 a year.

Distribution in Districts.—The first point to be settled is whether this increase is general or has been confined to certain districts. For this purpose the whole country has been divided into eleven districts: (1) LONDON; (2) SOUTH-EASTERN DISTRICT

² This supposed soft condition of the walls was not found after death, and it is probable that the bulging of the posterior wall was due to the destruction of the cricoid cartilage and the upper rings of the trachea, in consequence of which the posterior wall of the windpipe was no longer properly supported.

June 23, 1888.]

(Sussex, Hampshire, Berkshire, and the extra-metropolitan districts of Kent and Surrey); (3) SOUTH MIDLAND (Herts, Bucks, Oxfordshire, Northamptonshire, Huntingdonshire, Bedfordshire, Cambridgeshire, and the extra-metropolitan portion of Middlesex); (4) EASTERN (Essex, Suffolk, and Norfolk); (5) SOUTH-WESTERN (Wilts, Dorset, Devon, Cornwall, and Somerset); (6) WEST MIDLAND (Gloucestershire, Herefordshire, Shropshire, Staffordshire, Worcestershire, and Warwickshire); (7) NORTH MIDLAND (Leicestershire, Rutlandshire, Lincolnshire, Nottinghamshire, and Derbyshire); (8) NORTH-WESTERN (Cheshire and Lancashire); (9) YORKSHIRE; (10) NORTHERN (Durham, Northumberland, Cumberland, and Westmoreland); (11) WALES. In only two of these districts did the proportion of registered practitioners to the population decrease; these were the North Midland and the Northern; in two, the South Midland and the Eastern, the proportion was practically unaltered, though showing a slight decrease in both; in the remaining nine districts there was an increase varying from $9\frac{1}{2}$ to $3\frac{1}{2}$ per cent.; the increase was most considerable in Yorkshire, and least, curiously enough, in the neighbouring counties of Lancashire and Cheshire.

Relative proportion of Urban and Rural Practitioners.—In 1881 there were 6,179 registered practitioners in the twenty-eight large towns, and 8,843 in the rural districts; in 1886 there were in the towns, 7,120; and in the rural districts, 9,810. The proportion of the profession in the towns had thus slightly increased (41.14 per cent. in 1881, and 42.06 per cent. in 1886); during the quinquennium, however, the population had been gravitating towards the towns, but not quite so fast as the medical practitioners, the average number of persons in the towns to each practitioner having been 1,360 in 1881, and 1,284 in 1886. The country practitioners had also increased in relation to the population, from 1 to 2,017 in 1881, to 1 to 1,936 in 1886.

Urban Practitioners.—Brighton enjoys the doubtful honour of possessing more medical practitioners, in proportion to its population, than any other town in England or Wales; out of every 727 living souls in that salubrious town, one is a duly qualified and registered practitioner of medicine. It is probably to its very reputation for salubrity that Brighton owes this extraordinarily dense population of "doctors," for it ought to be stated that it is the only health-resort which appears on the list of large towns. London stands next to Brighton, with 1 registered practitioner to every 939 people; this is partly owing, no doubt, to the large floating population of newly qualified men still engaged in study. The only towns in which the proportion of practitioners to the population has notably decreased are Manchester, Bradford, Preston, and Leicester. In Liverpool, Hull, Blackburn, and Sheffield, there has been a slight decrease; in all the other towns an increase. In connection with the decrease in Manchester, it ought to be noted that there has been an enormous increase, more than one-third, of practitioners in Salford, which however still has fewer than any other large town (1 to 3,908 people).

Rural Practitioners.—As has been said above, the increase in practitioners in rural districts has been, relatively to the population, slower than in the large towns; but an examination of the table in which the figures are set out for each county show many strange and apparently capricious variations. Thus there has been a notable decrease in such apparently dissimilar counties as Middlesex and Surrey on the one hand, and Derby and Northumberland on the other. Somerset, Devon, Hants, and Westmoreland, are the counties most copiously supplied; Durham, Derby, Flint, and Stafford, the least. During the five years, practitioners seemed to have flocked into Westmoreland, Cardiganshire, the East Riding, and Berks; while Derbyshire, Northamptonshire, Durham, Nottinghamshire, and Worcestershire, were apparently out of favour.

Number and Source of the Qualifications held.—This section of the report is of little or no value, owing chiefly to the deliberate choice of the Council, which, though charged with the duty of keeping its Register correct and exacting an enormous fee for the insertion of a name for the first time in the Register, yet refuses to make the necessary additions to the Register unless an additional fee is paid. This unjust and impolitic exaction is resented, and consequently the *Medical Register* remains utterly valueless as a gauge of the advance of the profession in this matter of qualifications and degrees. The mean and pettifogging spirit which dictated this paltry policy would be ridiculous if it had not a more serious aspect; the money now spent in providing free lunches for the members of the Council (as though the councillors were vestrymen!) would more than recoup any loss which might

be incurred if the Council thus fulfilled the spirit as well as the letter of its statutory obligations. So far as the statistics on this head can be trusted to prove anything, they tend to show that double qualifications and treble qualifications had grown more common. There also appears an increased tendency to obtain qualifications north of the Tweed.

Death-Rate and Fluctuation in the Number of Practitioners.—No direct relation could be traced between the death-rate of a district and the number of practitioners in it; the death-rate did not always decline as the number of practitioners increased or *vice versa*, and the report contains an expression of the opinion that there is "a limit to the requisite number of practitioners to produce the most beneficial results."

Miscellaneous Sections.—The report also contains sections on practitioners holding foreign qualifications; on practitioners in practice before 1815 (only seven altogether, of whom three had no qualification); and on the circumstances in which the profession is placed as regards the financial condition of the several divisions, so far as this is indicated by the rateable value per head of the population. This last section is unfortunately very inconclusive; the valuation for poor-rate is given for each division, and an elaborate equation is framed, but as three out of the six factors are unknown, and apparently undiscoverable, the equation is of no more practical value than a chess-problem. Each division of the subject is fully illustrated in carefully prepared tables, and there are three coloured plates showing in a striking manner some of the facts above embodied in figures.

The report, reflects the greatest credit on the ability and industry of the Registrar, Mr. W. J. C. Millar, and his assistants. It may be obtained, together with Minutes of the Council and its Committees from January 1st, to June 1st, 1888, from Messrs. Spottiswoode & Co., publishers to the Council, or from the office, 299, Oxford Street.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An ordinary meeting of the Council was held at the College on Thursday, June 14th. The minutes of the ordinary council, held on May 10th were read and confirmed.

Reports from the Court of Examiners on those found qualified at the recent examinations for the diplomas of Fellow and Member of the College were read, and it was resolved to issue the diplomas to those gentlemen whose names were contained in the respective reports.

The report of the Museum Committee was received, and it was resolved, as recommended therein, that the Museum Committee be authorised to employ persons specially qualified for the duty to complete the catalogues of the birds, reptiles, amphibia, and fish in the Museum.

A report was read from the Committee on the Extension of the College Premises, which was approved and adopted by the Council.

The Committee reported that a difficulty having arisen with the occupiers of No. 45 Lincoln's Inn Fields on the question of air and light as affected by the building of the proposed Museum on the site of houses Nos. 8 and 9, Portugal Street, at the rear of houses Nos. 43 and 44, Lincoln's Inn Fields, a proposal sanctioned by the Council at a cost of £10,000 on February, 1887, it became necessary to consider an alternative scheme for the erection of New Museums on the site occupied by No. 8, Portugal Street and No. 43, Lincoln's Inn Fields; and the Committee, having examined those plans, recommended that two Museums should be erected on the last-named site at an approximate cost of £7,500 for the smaller museum at the back of the premises and of £11,000 for the larger museum, with its frontage in Lincoln's Inn Fields. The Committee further reported that, as it would probably not be possible to obtain possession of the front house, No. 43, Lincoln's Inn Fields until Michaelmas Day, 1889, the construction of the smaller museum ought first to be undertaken, whereby the cost of the whole undertaking would be spread over a longer period. The Committee further recommended the Council to authorise an expenditure for installation of electric light in the ground and first floors of the main building and basement of new library, painting and decorating old libraries, and alteration of railing to library gallery, amounting altogether to £839 14s. 7d.

The following gentlemen were nominated for election in July as professors and lecturers during the forthcoming year:—Present holders of the officers, Professors Bryant, Barker, Stewart, Lockwood, Jessop, Sutton, Cheyne, Mr. Ballance (Erasmus Wilson Lecturer), Mr. Gunn (Arris and Gale Lecturer), of whom Professors

Bryant, Jessop, and Cheyne, and Mr. Gunn are not candidates for re-election. Mr. E. Hurry Fenwick and Mr. Priestley Smith were also nominated. It was referred to a committee, consisting of Messrs. Hutchinson and Hill, together with the President and Vice-Presidents, to consider the appointment of professors and lecturers, and to report to the Council on the nominations.

A letter was read from Mr. Marshall, President of the General Medical Council, reporting, as the representative of the College, the proceedings of that Council at its late session. The letter was received and ordered to be entered on the minutes, and the best thanks of the Council were given to Mr. Marshall for his services as the representative of the College in the General Medical Council.

A letter was read from Mr. Marshall, President of the General Medical Council, forwarding a memorandum prepared by him on the disciplinary or penal powers of the Qualifying Medical Authorities, and it was resolved to refer the memorandum to a committee, consisting of Messrs. Marshall, Hulke, and Heath, with the President and Vice-Presidents, to report thereon to the Council.

A letter was read from Mr. C. L. Peel, forwarding a copy of a Draft Supplemental College Charter, as revised by the law officers of the Privy Council, and requesting to be favoured with any observations which the Council of the College may have to offer thereon before it is submitted to the Lords of the Council. The Council approved of the Draft Supplemental Charter as revised by the legal advisers of the Privy Council.

A letter was read from Surgeon-General Wm. Robert Cornish, F.R.C.S., Hon. Secretary and Treasurer of the College of State Medicine, requesting, by direction of the Council of that College, that the Council of this College will assist in procuring the insertion into the Local Government Bill of a clause requiring that all medical officers of health appointed after a certain time should be required to possess a diploma in public health.

THE PAY SYSTEM IN HOSPITALS.

A DISCUSSION on a paper recently read by Mr. Burdett-Coutts, M.P., on the advisability of introducing a system of small payments by patients in our great hospitals, in view of the present serious financial difficulties of these institutions, took place on Wednesday last at St. Thomas's Hospital.—Dr. STEELE, medical superintendent of Guy's Hospital, said this self-help system had worked most successfully at Guy's, and he could scarcely exaggerate the importance of the moral argument in favour of it. Indiscriminate medical relief had the same evil effect on a people as indiscriminate almsgiving.—Mr. J. NIXON, Secretary of the London Hospital, said that his hospital had recently adopted a system of inspection of and inquiry into the means of patients attending the out-patients' department, in order to prevent abuse of the charity. From this department they kept out all who could afford to pay, but it was impossible to clear the inwards of persons who were relatively well-to-do.—Prebendary BARNES thought that a Commission should be appointed to decide what steps should be taken. He believed that some degree of payment, as advocated by Mr. Burdett-Coutts, would then be recognised as a necessity.—Dr. GEORGE STOKER recommended that patients should be charged a sum proportioned to their means; this cast the onus of proving inability to pay on the patient himself, and not on the hospital.—Sir S. WATERLOW said all agreed that none should receive charitable medical relief who could afford to pay for it, but he thought there should be separate institutions, one for the reception of paying patients and another for free cases.—Dr. JAMISON referred to the Cottage Hospital at St. Helen's, Lancashire. Of an income of £1,206, working men combined to contribute £800 by weekly payments, and he held it was equally possible for men to combine in London for the same purpose.—Mr. H. C. BURDETT said the London hospitals now derived £44,000 a year from patients' payments; but there were still between three and four thousand beds which were perforce unoccupied in London. He strongly urged the systematic collection of weekly subscriptions from workmen.—Dr. WALSH opposed the system as a general practitioner.—Dr. BRISTOWE coincided in the view of Sir S. Waterlow.—Mr. BURDETT-COUTTS, M.P., said the system prevailed everywhere throughout the civilised world except in England, and he denied that the pay system would injure the general practitioner. Any general hospital which confined itself to the poor patient, excluding others, was adopting a form of the pay system; but one person in four in London received hospital treatment, and could it be maintained they were

all really destitute, and, as such, proper objects of charity? He asked whether hospitals were to remain pauperising institutions, dependent on the adventitious aid of charity.

ASSOCIATION INTELLIGENCE.

COUNCIL.

NOTICE OF MEETING.

A MEETING of the Council will be held at the Offices of the Association, No. 429, Strand (corner of Agar Street), London, on Wednesday, the 18th day of July next, at 2 o'clock in the afternoon.

FRANCIS FOWKE, *General Secretary.*

June 14th, 1888.

NOTICE OF QUARTERLY MEETINGS FOR 1888. ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member *by the Council* or by any recognised *Branch Council*.

Meetings of the Council will be held on July 18th, and October 17th, 1888. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before each meeting, namely, June 27th, September 26th, and December 28th, 1888.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No member can be elected by a Branch Council unless his name has been inserted in the circular summoning the meeting at which he seeks election.

FRANCIS FOWKE, *General Secretary.*

GRANTS FOR SCIENTIFIC RESEARCH.

THE Scientific Grants Committee of the British Medical Association desire to remind members of the profession engaged in researches for the advancement of medicine and the allied sciences, that they are empowered to receive applications for grants in aid of such research. Applications for sums to be granted at the next annual meeting should be made without delay to the General Secretary, at the office of the Association, 429, Strand, W.C. Applications must include details of the precise character and objects of the research which is proposed.

Reports of work done by the assistance of Association grants belong to the Association.

Instruments purchased by means of grants must be returned to the General Secretary on the conclusion of the research in furtherance of which the grant was made.

COLLECTIVE INVESTIGATION OF DISEASE.

REPORTS upon the two remaining inquiries, namely, that into DIPHTHERIA, and that into the GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES, are in preparation, and will be published as soon as ready.

The following inquiry only of the first series remains open, namely, that on the ETIOLOGY OF PHTHISIS.

A fresh inquiry into the ORIGIN AND MODE OF PROPAGATION OF EPIDEMICS OF DIPHTHERIA has been issued.

Memoranda upon these subjects, and forms for recording observations, may be had on application to the Secretary of the Collective Investigation Committee, 429, Strand, W.C.

BRANCH MEETINGS TO BE HELD.

BORDER COUNTIES BRANCH.—The twenty-first annual meeting of this Branch will be held at Penrith on Friday, July 13th. The chair will be taken by Dr. McLeod at 1.30 P.M. The usual election of office bearers for the year will be held. Dr. Robertson, Penrith, will deliver his presidential address. Intimations of papers for reading or communications of any kind should be sent to the Secretary as soon as possible.—H. A. LEDIARD, 41, Lowther Street, Carlisle, Honorary Secretary.

BATH AND BRISTOL BRANCH.—The annual meeting of the Branch will be held on Thursday, June 28th, at the Royal Mineral Water Hospital, Bath, at 4.30 P.M., when G. F. Barber, M.D., will resign the chair to Jos. Hinton, Esq., President-elect. The business of the meeting will be to receive the report of the Council; to elect the Officers of the Branch; to transact the necessary business; and to discuss such subjects connected with the interest of the Branch and of the profession as may be brought before it. The Honorary

Secretaries will feel much obliged if members will kindly send them notice of any alterations in their diplomas or addresses. N.B.—Members who have not paid their subscriptions are requested to do so immediately to the Local Secretaries, in order that the accounts may be made up before the anniversary meeting of the Association. The dinner will be held at the Grand Pump Room Hotel, Bath, at 6.30 P.M.—R. J. H. SCOTT, Honorary Secretary for the Bath District, 13, Bladud Buildings, Bath; E. MARKHAM SKERRITT, Honorary Secretary for Bristol District, Thornton House, Richmond Hill, Clifton.

CAMBRIDGESHIRE AND HUNTINGDONSHIRE BRANCH.—The annual meeting of this Branch is appointed to be held at Ely on Friday, July 6th. Members wishing to make communications, to exhibit specimens, or to propose new members are requested to signify their intention to Dr. Anningson, Cambridge, for insertion in the order of proceedings.—BUSHELL ANNINGSON, Honorary Secretary.

EAST ANGLIAN BRANCH.—The annual meeting will be held in the Town Hall, Eye, on Friday, June 29th. Edgar George Barnes, M.D., Lond., President-elect, 12.30 P.M.; Meeting of Council in Council Chamber of Town Hall, 1 P.M.; Luncheon in Town Hall, by invitation of Town Hall. Agenda: 1. Address by General Meeting in Council Chamber of Town Hall. 2. Business. 3. President's Address. On the Etiology of Diphtheria. 4. Rev. Donald Campbell, M.A., Vicar of Eye, on the Etiology of Diphtheria. 5. Rev. Donald Campbell, M.A., Vicar of Eye, on the History of Eye. 6. F. Bateman, M.D. (Norwich); Obscure Case will take part in the discussion. 7. H. Dickman, M.B., C.M. (Eye), of (Edematous Laryngitis); Tracheotomy. 8. T. H. Morse, F.R.C.S. (Norwich), will read Notes on a Case of Ovariectomy. 9. The President will show a Case illustrating the Spontaneous Cure of an Extensive Nevus. 10. Mr. G. B. Mead (Newmarket); Facts relating to the Present Position of the Profession in Relation to Bone-setting. 11. H. Dickman, M.B., C.M. (Eye), will read a Case of Phthisis complicated with a Fistulous Communication between Liver and Lung. 5.30 P.M., Visit to Eye Church and inspection of members in the Church. 6 P.M., Tea Vestry. The Vicar of Eye will meet the members in the Church. Tickets, 5s. each.—W. A. ELLISTON, M.D., Ipswich; M. BEYERLE, M.D., Norwich; C. E. ABDOTT, Braintree, Honorary Secretaries.

METROPOLITAN COUNTIES BRANCH.—The thirty-sixth annual meeting of this Branch will be held at the Holborn Restaurant on Wednesday, June 27th, 1888, at 5.30 P.M. President, Arthur E. Durham, Esq., F.R.C.S.; President-elect, C. Brodie Sewell, M.D. An address will be given by the new President. At 7 P.M. precisely the members will dine together: C. Brodie Sewell, Esq., M.D., President, in the chair; tickets, 7s. 6d. each, exclusive of wine.—GEORGE EASTES, M.B., 69, Connaught Street, W.; E. NOBLE SMITH, F.R.C.S. Ed., 24, Queen Anne Street, W., Honorary Secretaries.

NORTH OF IRELAND BRANCH.—The annual meeting of this Branch will be held in the Belfast Royal Hospital, on Wednesday, July 11th, at 4 P.M. Business: 1. To receive the Secretary's report and the Treasurer's statement for the past year. 2. To elect office-bearers for the ensuing year. 3. To elect two members as representatives of the Branch on the Council of the Association, and also the representatives on the Parliamentary Bills Committee. 4. The President (Dr. J. M. Palmer) will deliver an Address. 5. Dr. O'Neill will show a Patient operated on for Extensive Disease of Foot, and also a Patient operated on for Cleft Palate, and will read notes of each case. 6. Dr. W. A. McKeown will show a New Apparatus for Intra-ocular Irrigation in the Extraction of Cataract. He will also show some cases in which Senile Cataract has been extracted without Iridectomy. 7. Mr. Fagan will show a Patient on whom he recently performed Resection of the Wrist-Joint. He will also show a Portion of Bowel, the Seat of Cancerous Stricture removed for Intestinal Obstruction, and give notes of the case; and a Portion of the Saphena Vein removed, and presenting some features of pathological interest. Dr. Byers will show the Instruments employed for the Electrical Treatment of Fibroid Tumours of the Uterus after the Method of Apostoli. The annual dinner will be held on the same evening at 7.30 P.M. in the Royal Avenue Hotel; tickets, ss. 6d. (exclusive of wine).—JOHN W. BYERS, M.D., Lower Crescent, Belfast, Honorary Secretary.

NORTH WALES BRANCH.—The annual meeting will be held at Dolgelly on or about July 10th. Members having any communications to bring before the meeting are requested to intimate the same before June 30th to W. JONES-MORRIS, Honorary Secretary, Portmadoc.

NORTHERN COUNTIES OF SCOTLAND BRANCH.—The annual meeting of this Branch will be held at the Spa Hotel, Strathpeffer, on Thursday, July 5th, at 1.50 P.M. Papers will be read by Dr. Porteus Fox, Strathpeffer, Cases of Venesection, and Dr. Leslie H. Milne, Forre, Notes on the Weir-Mitchell Treatment. A visit will also be paid to the Spa.—J. W. NORRIS MACKAY, M.D., Honorary Secretary, Elgin.

READING AND UPPER THAMES BRANCH.—The annual meeting of this Branch will be held in the Library of the Royal Berkshire Hospital, Reading, on Wednesday, July 11th, at 4.15 P.M. The chair will be taken by the President (Dr. C. H. Tench), who will introduce the President for the coming year (W. B. Holderness, Esq., of Windsor), who will then take the chair. Members willing to read short papers or bring forward cases of clinical interest are requested to communicate with the Honorary Secretary without delay. The annual dinner will take place on the same evening at 6.15 P.M., at the Queen's Hotel, Reading. Dinner tickets (5s. without wine, or 10s. including wine) should be obtained from the Honorary Secretary on or before Saturday, July 7th.—H. HEYGATE PHILLIPS, 43A, London Road, Reading, Honorary Secretary.

SOUTH-WESTERN BRANCH.—The annual meeting of this Branch will be held at the Devon and Exeter Hospital, Exeter, on Tuesday, June 26th, under the presidency of Dr. John Woodman, F.R.C.S. Notices of motion or communications to be intimated to the Honorary Secretary without delay, and it will facilitate arrangements if members will inform the Honorary Secretary as soon as possible if they hope to be present at the meeting. The

following motion was passed at the Council Meeting on May 2nd:—"That inasmuch as the annual meeting assumes more or less the character of a day of recreation, and with a view of encouraging the district meetings, the business of the annual meeting shall be confined to the President's address, the business of the Branch, the exhibition of cases or of specimens with notes, and the annual dinner."—P. MAURY DEAS, Wouford House, Exeter, Honorary Secretary.

SOUTH WALES AND MONMOUTH BRANCH.—The eighteenth annual meeting of this Branch will be held at the Infirmary, Cardiff, on Wednesday, June 27th. Further particulars in circulars. Members wishing to read papers, etc., are requested to send titles to Dr. SIEGHEN.—A. SIEGHEN, M.D., Cardiff, D. ARTHUR DAVIES, M.B., Swansea, Honorary Secretaries.

SHROPSHIRE AND MID-WALES BRANCH.—The annual general meeting of this Branch will be held at the Salop Infirmary, Shrewsbury, on Tuesday, July 3rd, at 2 P.M. The annual dinner will take place at the Raven Hotel after the meeting. Members desirous of contributing papers, notes of cases, etc., are requested to communicate with the undersigned.—EDWARD CURETON, Honorary Secretary, Shrewsbury.

WEST SOMERSET BRANCH.—The annual meeting of this Branch will be held at the Squier Hotel, Wellington, on Thursday, June 28th, at 4 o'clock. Abraham Colles, Esq., M.D., President-elect, will take the chair on his being vacated by Edward Stephens, Esq. The dinner will be at 6 o'clock. Members desirous of reading a paper or making a communication to the meeting are requested to give early notice to the Honorary Secretary; they are also requested to give early notice of their intention of attending the annual dinner.—W. M. KELLY, M.D., Honorary Secretary.

YORKSHIRE BRANCH.—The annual meeting of the Yorkshire Branch will be held in the Museum of the Yorkshire Philosophical Society at York on Wednesday, June 27th, at 3 P.M., when the following business will be transacted: 1. An address by the President-elect. 2. Election of officers. 3. Addition to rules. And the following papers read:—Dr. Churton: A Case of Scirrhus of Pylorus with Excessive Vomiting; repeated Saline Transfusions. Mr. H. Benedick Hewetson: Recent Precautions in Cataract Operations. Dr. James Braithwaite: The Treatment of Exceptional Cases of Retroflexion of the Uterus. Mr. A. W. Mayo Robson: Electrolysis in the Treatment of Uterine Disease. Mr. Atkinson: Ichthyosis Hystrix of the Tongue. Mr. Draper: Suppurating Dermoid Cyst of the Ovary; Ovariectomy; Recovery. Dr. E. H. Jacob: Laryngeal Neuroses.—ARTHUR JACKSON, Secretary, Sheffield.

MIDLAND BRANCH.

The annual meeting was held at the Masonic Hall, Nottingham, on Thursday, June 14th, under the presidency of Mr. HATHERLY. About fifty members were present.

Officers and Council.—Mr. Sympton and Dr. Webb were elected as the Branch representatives on the General Council. In the Branch Council Dr. Pratt and Mr. Franklin replaced Mr. Willan and Dr. Pope for Leicestershire, and Mr. Shipman and Dr. Fawcett replaced Dr. Harrison and Mr. Pilden for Lincolnshire. Mr. Willan (Melton Mowbray) was chosen as President-elect. The Honorary Secretaries and Treasurers were re-elected, with the exception of Mr. Hodges, who retires, and is replaced by Dr. Pope (Leicester).

New Members.—Mr. W. H. B. Brook, Mr. H. Child, Mr. G. N. Robins, Mr. C. Bernard Dalton, Dr. Lamb, Dr. Pegler, Mr. J. F. Knight, and Dr. Rothera were elected members of the Branch.

Alteration of Rule.—On the proposition of Mr. HATHERLY, seconded by Dr. HANDFORD, Rule 6 was amended as follows, namely, "The Vice-Presidents shall be elected annually for each county not already represented by the President or the President elect, and they shall not be eligible for re-election."

President's Address.—Mr. HATHERLY gave an address on Abdominal Surgery.

Papers.—The following were brought before the meeting:—Professor EDGAR M. CROOKSHANK, "On the Alleged Origin of Certain Diseases from the Lower Animals." Dr. FRANK POPE, "A Case of Diabetes, probably of Traumatic Origin." Mr. R. C. CHICKEN, "New Form of Bone Forceps for Sequestromy." Dr. GEORGE ELDER, "Remarks on Cases of Peritonitis Treated by Abdominal Section." Dr. H. HANDFORD, "The Influence of Position on Cardiac Murmurs, and on the Treatment of Heart Disease."

Luncheon and Dinner.—The President entertained the members at luncheon, and after the meeting about twenty-two dined at the Masonic Hall.

SOUTH MIDLAND BRANCH.

The annual meeting was held at Bletchley on June 14th under the presidency of Mr. H. VEASEY, thirty-two members and visitors being present, who were entertained at luncheon by the President before the meeting.

New Members.—Eight gentlemen were proposed and elected members of the Association and Branch, namely, Arthur Lucas, Woburn; T. G. Parrott, Aylesbury (Branch only); J. H. Lloyde, Bedford; H. R. Jacobs, Culworth; H. Gibbons, Desborough; J. A.

Whitfield, Northampton; A. E. Godfrey and A. J. Weatherley, The Infirmary, Northampton.

Election of Officers.—Mr. Crew, Higham Ferrers, was appointed President for 1889-90; Dr. Bryan was placed on the Committee of Management in the room of Mr. Crew, all the other members of the Committee, as well as the Hon. Treasurer and Hon. Secretary, being re-elected; Mr. J. Hughes Hemming, Kimbolton, was appointed representative of the Branch on the General Council and on the Parliamentary Bills Committee.

Combined Meeting.—The Cambs and Hunts Branch proposed a combined meeting this year, but declined to meet at Bletchley as being an inconvenient place, suggesting at the same time that a united gathering of the two Branches be held in the near future either at Bedford or Peterborough. The matter was referred to the Committee of Management.

Donations to British Medical Benevolent Fund and Royal Medical Benevolent College.—The sum of £5 from the Branch funds was voted, to be equally divided between these two institutions.

Luency Acts Amendment Bill.—After some discussion the following resolution was carried, on the motion of the Branch representative, and the Secretary was directed to convey the sense of the meeting to the Chairman of the Parliamentary Bills Committee:—(1) "That the South Midland Branch in annual meeting assembled, having full confidence in the members of the Parliamentary Bills Committee, and believing that their efforts are directed to the benefit of the medical profession in general, and that of the British Medical Association in particular, endorses their action in the matter of the Luency Acts Amendment Bill, 1888, and hereby pledges itself to try and secure the support of the local members to the same in its passage through Parliament."

Autumnal and Annual Meetings.—It was resolved that the autumnal meeting be held at Oundle on October 4th; and that the next annual meeting take place at Northampton.

President's Address.—The PRESIDENT delivered a short extempore address, alluding in the course of it to his having previously occupied the presidential chair.

Papers and Cases.—Mr. MILLIGAN read a case of Strangulated Umbilical Hernia, with recovery after operation for radical cure, and exhibited a large mass of omentum he had removed from the sac.—Dr. GOLDSMITH read a short paper on a Question as to the Etiology of some Nervous Diseases of Children, suggesting the idea of instability of the nervous system in such cases, arising from great inequality in the ages of the parents.—Many members joined in the discussion, pointing out the possibility of a hysterical element, of mimicry, and of the influence produced by syphilitic taint and alcoholism.—Dr. GOLDSMITH, in his reply, stated that in none of his cases was there a trace of syphilis or alcoholism.—Dr. JONES read a paper on Physical Indications in Heart Affections, dwelling particularly on diagnosis and treatment. Under the latter head, he said that the value of rest was not to be over-rated, and recommended in certain cases the hypodermic injection of liquor strychnia, in two-minim doses.—Mr. BULL read an interesting case of Obscure Abdominal Tumour: Abdominal Section: Recovery. He mentioned the great difficulty of diagnosis in the case. In this and Mr. Milligan's case, the members discussed the question of the danger or otherwise of opening the abdomen; also the use of antiseptics in such operations.—Mr. PERCIVAL related two cases of Removal of Tumour; one of Sarcoma in the parotid region, on which three successive operations had been performed; the other a case of Fibro-Sarcoma in the popliteal space. In the latter case, the connections of the diseased mass with the blood-vessels and nerves running through it were of the most intimate character.

Votes of Thanks.—Cordial votes of thanks were passed to the retiring President for his services during the past year; to the President for his address and his conduct in the chair, and also for his hospitality; and to the readers of papers.

Surgical Instruments.—A large selection of surgical instruments was displayed by Messrs. Lynch and Co., of London; a case of Hypodermic Syringe and Solutions, by Messrs. Green and Co.; Eclectic Medicines, by Messrs. Hockin, Wilson, and Co.; and various Essences, by the "Viking" Food Company.

Tea and coffee were served, and a successful meeting brought to a close.

The death is announced, at the early age of 37, of Dr. Ross, for eleven years the highly respected Medical Officer for Blackpool.

SOUTHERN BRANCH.

THE fifteenth annual meeting of this Branch took place at the Grosvenor Hotel, Southsea, on Thursday, June 15th, when there was a large attendance of members. Before the commencement of the business, the President-Elect, Mr. H. Burford Norman, entertained those present at luncheon. At the general meeting which followed the chair was taken by Surgeon-General Sir THOMAS LONGMORE, C.B., F.R.C.S., of Netley.

Election of Officers.—Dr. J. WARD COUSINS (Hon. Secretary) having read the minutes of the last meeting, Dr. J. WATSON, of Southsea, moved that the following gentlemen, nominated by the respective districts, should be elected as officers of the Branch for the ensuing year, namely:—*Vice-Presidents*: Brigade-Surgeon C. H. Godwin, Netley; and Dr. H. P. Blackmore, Salisbury. *Members of Council*: Dr. W. H. Axford, Southsea; Dr. C. G. Beaumont, Shirley; Mr. F. R. P. Darke, Salisbury; Dr. J. Neal, Sandown; Mr. G. H. Snowden, Mr. H. Hemsted. Dr. Ward Cousins was unanimously re-elected Honorary Secretary and Treasurer. The motion was seconded and carried.

Representative on General Council, etc.—Dr. Nicholson, of Broadmoor, was re-elected representative of the Branch on the Parliamentary Bills Committee, and Drs. Trend, of Southampton, and J. Ward Cousins were again chosen representatives on the Council of the Association.

The Late Professor de Chaumont.—Dr. TREND moved a resolution deeply deploring the death of their much beloved member and vice-president, the late Professor de Chaumont, whose singularly high intellectual powers, versatility of genius, and practical skill were blended with a keen sense of humour, which made him in any society a host in himself, and recording deep sympathy with Mrs. de Chaumont in her bereavement.—Dr. AXFORD seconded the motion.

Cases, etc.—Brigade-Surgeon HARMAN, of Winchester, gave particulars of the rapid healing of a gunshot wound. A small revolver accidentally went off, and the left hand was pierced by the bullet.—Dr. WARD COUSINS also mentioned a new apparatus of his invention for dealing with of the lower jaw.

The New President.—The PRESIDENT then left the chair, and introduced his successor, Mr. Burford Norman.

Next Meeting.—It was resolved on the motion of Brigade-Surgeon GODWIN, seconded by Dr. KEALY, that the meeting of 1889 should take place at Salisbury.

The President's Address.—The PRESIDENT then delivered an address on the progress of the medical profession during his own time, and from his own standpoint of observation. The British, originally the Provincial, Medical Association was founded in 1832 in the city of Worcester, and he recollected something about it as early as 1836, when a Branch was formed in the district of West Somerset, where his lot then lay. The Association then published an annual volume of transactions, but had no journal. From being provincial the Association became British, and its progress had been very marked. In welding into one fellowship the members of their profession scattered throughout the whole British Empire and its dependencies, it had added immensely to the influence of the profession both socially and politically, while doing much to promote science and practical medicine. His own connection with the profession dated from Michaelmas, 1835. When he began his apprenticeship the stethoscope was but little used except by hospital physicians and newly educated men just fresh from the schools. About that time, when Dr. Hope was making his elaborate studies in heart disease, aided by its use, the editor of a then influential medical review nicknamed it the "conjuring stick." Anaesthetics were not known, and sanitary science almost unthought of. He did not think there was much cause to complain of the moral tone of the profession or the lack of kindly feeling and mutual respect of its members. In that large town he believed there were scarcely any two men who were not on friendly terms with each other, and ready to render mutual assistance. The local hospital had recently undergone great and important alterations well calculated to promote its efficiency, both in the treatment of diseases and as an educational institution.

Vote of Thanks to President.—Sir THOMAS LONGMORE, in moving a vote of thanks to the President for his address, said he recollected a physician of one of the large London hospitals carrying a stethoscope round the wards as a bouquet-holder for the purpose of depreciating and ridiculing the instrument.—Dr. KEALY seconded the resolution, which was carried, and the PRESIDENT, in reply, said that it was a great satisfaction to

him that he had been thirty-one years in Portsmouth, and he was able to say there was none in the profession whom he could not call his friend.

Sight-seeing and Refreshment.—The members were then driven to the new Jubilee wards of the hospital, and afterwards proceeded to Portsmouth Dockyard, where Fleet-Surgeon Sedgwick entertained them at tea. After visiting the *Victory*, the *Vernon*, and other objects of interest, the party returned to the Grosvenor Hotel for dinner.

BRITISH MEDICAL ASSOCIATION.

FIFTY-SIXTH ANNUAL MEETING.

THE fifty-sixth Annual Meeting of the British Medical Association will be held at Glasgow, on Tuesday, Wednesday, Thursday, and Friday, August 7th, 8th, 9th, and 10th, 1888.

President: John T. Banks, M.D., D.Sc.(Hon.), F.K.Q.C.P.I., Regius Professor of Physic in the University of Dublin.

President-Elect: Professor W. T. Gairdner, M.D., LL.D., Professor of Medicine in the University of Glasgow.

President of the Council: Thomas Bridgwater, M.B., J.P., Harrow-on-the-Hill.

Treasurer: Constantine Holman, M.D., J.P., Reigate.

An Address in Medicine will be delivered by Thomas Clifford Allbutt, M.D., F.R.S., Consulting Physician, Leeds General Infirmary.

An Address in Surgery will be delivered by Sir George H. B. Macleod, M.D., Surgeon in Ordinary to Her Majesty in Scotland.

An Address on his "Recent Investigations in Surgery" will be given by William Macewen, M.D., Lecturer on Clinical Surgery, Glasgow Royal Infirmary.

An Address in Physiology will be delivered by John Gray McKendrick, M.D., LL.D., F.R.S., Professor of Institutes of Medicine, University of Glasgow.

All the rooms required for the purposes of the meeting will, by the kindness of the authorities, be provided in the University of Glasgow.

PROGRAMME OF PROCEEDINGS.

TUESDAY, AUGUST 7TH, 1888.

- 9.30 A.M.—Meeting of 1887-1888 Council. Randolph Hall.
- 11.30 A.M.—First General Meeting. Report of Council. Reports of Committees. Bute Hall.
- 4 P.M.—Service in the Cathedral. Sermon by the Very Rev. John Caird, D.D., LL.D., Principal and Vice-Chancellor of the University of Glasgow.
- 8.30 P.M.—Adjourned General Meeting from 11.30 A.M. President's Address. Bute Hall.

WEDNESDAY, AUGUST 8TH, 1888.

- 9.30 A.M.—Meeting of 1888-89 Council. Randolph Hall.
- 10.30 A.M. to 2 P.M.—Sectional Meetings.
- 3 P.M.—Second General Meeting. Address in Medicine by Thomas Clifford Allbutt, M.D., F.R.S. Bute Hall.
- 9 P.M.—*Conversazione* given by the Professors of the University.

THURSDAY, AUGUST 9TH, 1888.

- 9.30 A.M.—Address on his Recent Surgical Investigations by William Macewen, M.D. Bute Hall.
- 11 A.M.—Meeting of Council. Randolph Hall.
- 10.30 A.M. to 2 P.M.—Sectional Meetings.
- 3 P.M.—Third General Meeting. Address in Surgery by Sir George H. B. Macleod, M.D. Bute Hall.
- 7 P.M.—Public Dinner. St. Andrew's Hall.

FRIDAY, AUGUST 10TH, 1888.

- 10.30 A.M. to 1.30 P.M.—Sectional Meetings.
- 3 P.M.—Concluding General Meeting. Address in Physiology by John G. McKendrick, M.D., F.R.S. Natural Philosophy Class-room.
- 9 P.M.—*Conversazione* given by the Corporation of Glasgow at St. Andrew's Hall.
- Garden Party given by the Faculty of Physicians and Surgeons at the Botanic Gardens.
- SATURDAY, AUGUST 11TH, 1888.
- Excursions.

The following discussions and papers are promised up to the present time.

SECTION A.—MEDICINE.

Humanity Class Room.

A. MEDICINE.—*President*, Professor T. McCall Anderson, M.D. *Vice-Presidents*, R. L. Bowles, M.D.; George F. Duffey, M.D. *Honorary Secretaries*, J. McGregor Robertson, M.A., M.B., 400, Great Western Road, Glasgow; Robert M. Simon, M.D., 27, Newhall Street, Birmingham.

The President will open the proceedings by introducing a discussion on the Diagnosis and Treatment of Syphilitic Disease of the Nervous System. Dr. Thomas Buzzard, Dr. T. S. Clouston, Dr. William Moore, Dr. Ross, Professor Grainger Stewart, Professor Julius Dreschfeld, Dr. J. G. Sinclair Coghill, Dr. Francis Warner,

Dr. Frederick Bateman, Dr. C. R. Drysdale, and Dr. C. W. Suckling will take part in the discussion.

On the third day of the sectional proceedings, the Value of Inhalations in the Treatment of Lung Disease is set down for discussion, to be opened by Dr. C. Theodore Williams. The following gentlemen have already indicated their intention to engage in this discussion: Dr. Burney Yeo, Dr. W. W. Ireland, Dr. C. F. Knight, Dr. J. A. Lindsay, Dr. J. G. Sinclair Coghill, and Dr. E. Markham Skerritt.

Drs. Byrom Bramwell and Milne Murray will give a demonstration of their Method of Graphically Recording the Exact Time Relations of Cardiac Sounds and Murmurs.

The following papers have been promised.

- COGHILL, J. G. S., M.D., Ventnor. The Treatment of Phthisical Pyrexia.
 - COUPLAND, Sidney, M.D. A Case of Subphrenic Abscess.
 - FISLAY, David W., B.A., M.D. Bronchiectasis treated by Incision and Drainage.
 - FREW, W., M.D., Kilmarnock. Prevalence of Cerebro-spinal Fever in Scotland.
 - GREENE, G. E. F., L.K.Q.C.P. A Note on a Recent Epileptic of Erysipelas.
 - HANDFORD, H., M.D. The Influence and Position on Cardiac Murmurs and the Condition of the Heart in Anaemia (Chlorosis).
 - HARRISON, A. J., M.B. Further Researches on the Treatment of Tinea Testicularum. Illustrated with photographs.
 - JONES, A. Orlando, M.D. A New Remedy for Heart Disease.
 - MYRTLE, A. S., M.D., Harrogate. Neurasthenia, True and False: Diagnosis and Management.
 - STRAHAN, John, M.D. (*Title not received.*)
 - SECKLING, C. W., M.D. Notes on Peripheral Neuritis and on its occurrence in Brassworkers.
 - TOMORY, J. K., M.B. East African Fever, with special reference to Climatic Conditions.
 - WARNER, Francis, M.D. 1. Methods of Studying and Examining the Nerve System. 2. Imbecility in Children from Chronic Meningitis.
- Sir W. Roberts, Dr. Lauder Brunton, Dr. Russell Reynolds, and Dr. F. W. Pavy have also intimated their intention to take part in the proceedings of the Section.

SECTION B.—SURGERY.

Chemistry Class Room.

B. SURGERY.—*President*, George Buchanan, M.D. *Vice-Presidents*, James Dunlop, M.D.; Charles Robert Bell Keetley, F.R.C.S. *Honorary Secretaries*, David Neilson Knox, M.B., 8, India Street, Glasgow; Walter Pye, F.R.C.S., 4, Sackville Street, Piccadilly, London, W.

As already announced, in this Section discussions have been arranged for on the following subjects:

1. The Surgical Treatment of Abscess of the Lung and of Empyema. To be introduced and supported by Mr. T. Pridgin Teale (Leeds), Sir Spencer Wells (London), Mr. A. Pearce Gould (London), Mr. R. J. Godlee (London), Dr. J. Ward Cousins, Portsmouth, and Mr. W. Thomas (Birmingham).
2. The Operative Treatment of Club-Foot. To be introduced and supported by Sir William Stokes (Dublin), Mr. E. Lund (Manchester), Dr. Alexander Ogston (Aberdeen), Mr. R. W. Parker (London), Mr. E. M. Little (London), Mr. John Chiene (Edinburgh), Mr. W. J. Walsbam (London), and others.

The following papers have also been promised.

- BEXTON, Samuel, Esq., London. On the Treatment of Stricture of the Rectum by Electrolysis.
- BISHOP, E. Stanmore, Esq., Manchester. Some Cases of Osteotomy, with an Apparatus for fixing the Lower Limbs after Division of the Bones.
- BROWNE, G. Buckston, Esq., London. An Explanation of the way in which Calculi in the Male Urinary Bladder sometimes escapes Detection by the Sound, with a description of a New Form of that Instrument.
- BROWNE, Lennox, Esq., London. Tintage of the Larynx.
- CLARKE, Sir Andrew, London. The History of a Case of Catheter Fever.
- CLARKE, W. Bruce, Esq., London. Prostatic Abscess and its Consequences.
- COUSINS, J. Ward, M.D., Portsmouth. (1) New Apparatus for Treatment of Fractures of Lower Jaw; (2) New Evacuator for Litholapaxy and other Bladder Operations.
- FENWICK, E. Henry, Esq., London. Notes from the Experience of 450 Cases of Organic Stricture of the Urethra.
- FLEMING, W. J., M.D., Glasgow. 1. On Continuous Extension in Spinal Curvature. 2. On the Treatment of Perineal Fistula.
- HARRISON, Reginald, Esq., Liverpool. On an Improvement in the Construction of Ships' Berths, relative to the Treatment of some Surgical Injuries and Diseases at Sea (with models).
- KEETLEY, C. B., Esq., London. Plastic Amputations of the Foot.
- LLOYD, Jordan, Esq., Birmingham. Inflammatory Disease of the Seminal Vesicles.
- MCINTYRE, John, Esq., Glasgow. The Electric Illumination of the Cavities of the Body.
- OWEN, Edmund, Esq., London. A Case of Intra-cranial (Subdural) Haemorrhage; Localisation; Trephining; Recovery.
- PEARSE, T. Frederick, Esq., M.D., London. (1) On Puncture of the Bladder; (2) On Gonorrhoea in Women.
- RAKE, Beaven, M.D., Trinidad. The Value of Nerve Stretching in Leprosy, based on One Hundred Cases.
- RENTON, J. Crawford, Esq., M.D., Glasgow. A Case of Severe Deformity of Lower Lip restored by Mr. Teale's operation six years ago.
- ROTH, Bernard, Esq., London. On Scolio-ometry, or an Accurate and Practical Method of Recording Cases of Lateral Curvature of the Spine.

SMITH, Noble, Esq. Demonstration of the Reduction of Fractured Vertebrae, and the application of Apparatus to Control the Spine.
 STOKES, Sir William, Dublin. Modification of Griffith's Amputation; and will show Casts of Stumps.
 TAIT, Lawson, Esq., Birmingham. A Second Series of One Thousand Consecutive Abdominal Sections.
 THOMSON, Wm., Esq., M.D., Dublin. On Excision of the Knee-joint.
 THORNBURN, Wm., Esq., Manchester. The Distribution of Paralysis and Anæsthesia in Injuries of the Cervical Region of the Spinal Cord.
 VALCOURT, Th. de, Esq., M.D., Cannes. Winter Sea-baths at Cannes in cases of Scrofulous Disease.

SECTION C.—OBSTETRIC MEDICINE.
Medical Jurisprudence Class Room.

C. OBSTETRIC MEDICINE.—*President*, Thomas More Madden, M.D. *Vice-Presidents*, William Leishman, M.D.; J. Halliday Croom, M.D. *Honorary Secretaries*, William Walter, M.D., 20, St. John Street, Manchester; W. L. Reid, M.D., 7, Royal Crescent, Glasgow.

The following two special discussions will take place:—

1. On Intra-uterine Death; its Pathology and Preventive Treatment. To be opened by Professor Simpson. The following gentlemen will take part in the discussion:—Drs. R. Barnes, Graily Hewitt, More Madden, W. O. Priestley.

2. On Obstructive Dysmenorrhœa and Sterility. To be opened by Dr. Halliday Croom. The following gentlemen will take part in the discussion:—Drs. Aveling, Bantock, F. Barnes, R. Barnes, Cranny, Duke, Edis, Graily Hewitt, Macan, More Madden, Professor Stephenson, J. W. Taylor, W. Walter.

Dr. Samuel Sloan (Glasgow) will show his Antero-posterior Compression Forceps, and will explain their use in Flat Pelves.

Wm. Walter, M.D., Manchester, will exhibit his instruments for Securing the Broad Ligaments during Extirpation of the Uterus per Vaginam.

The following papers are promised.

AVELING, J., M.D. The Treatment of Uterine Tumours by Electricity.
 BARNES, R., M.D. Analogies between Menstruation and Gestation and Puerperia in their Physiological and Pathological Relations.
 CAMERON, Murdoch, M.D., Glasgow. 1. On Cesarean Section, with Notes of a Successful Case. 2. On the Thermostatic Nurse, with Cases.
 DUKE, A., F.R.C.S., Dublin. On the Rapid Expansion of the Cervical Canal by a New Method.
 HART, D. Berry, M.D., Edinburgh. Successful Case of Cesarean Section (Porro's modification).
 IMLACH, Francis, M.D., Liverpool. The Function of Anæmia in Gynæcology.
 KENNEDY, Hugh, M.D., Dublin. Notes on the Treatment of Lacerations of the Cervix Uteri.
 MADDEN, More, M.D., Dublin. On the Causes and Treatment of Pseudocystitis.
 ROUTH, A., M.D. Headaches of Pelvic Origin.
 STEPHENSON, William, M.D., Aberdeen. On the Influence of Permanganate of Potass on Menstruation.
 TAIT, Lawson, Esq., Birmingham. The Treatment of Uterine Myoma.

SECTION D.—PUBLIC MEDICINE.
Greek Class Room.

D. PUBLIC MEDICINE.—*President*, Henry Duncan Littlejohn, M.D. *Vice-Presidents*, James Christie, M.D.; D. Page, M.D. *Honorary Secretaries*, Ebenezer Duncan, M.D., 4, Royal Crescent, Crosshill, Glasgow; John C. McVail, M.D., Holmhead, Kilmarnock.

1. Sanitary Legislation. This discussion will be introduced by the Opening Address of the President of the Section.

2. The Communicable Diseases Common to Man and Animals, and their Relationships. Discussion to be opened on the second day of the sectional meetings by George Fleming, LL.D., F.R.C.V.S., Chief of the Veterinary Department of the Army. Professor Edgar Crookshank, King's College, will take part in the discussion.

3. The Disposal of Sewage (a) in Large Towns; (b) in Small Towns and Country Districts. Discussion will be opened on the third day by Dr. James B. Russell, Medical Officer of Health, Glasgow.

The following papers are promised.

DRYSDALE, Charles R., M.D. 1. On Indigence as a Main Cause of High Death-rates. 2. The Berlin and Parisian Sewage Farms.
 HIME, T. W., M.B. Milk Scarlet Fever.
 KERR, Norman, M.D. Some Risks of Sanitation.
 NASMYTH, T. G., F.R.S. A Report on the Chemical and Biological Conditions of the Air of Coal Mines, together with Mortality Statistics of a Mining District, being a report to the Scientific Grants Committee of the British Medical Association.
 SIMPSON, —, M.D., Medical Officer of Health, Calcutta. On Cholera and its Fœtering Conditions in the Endemic Area.
 SUTHERLAND, J. Francis, M.D. National Sanatoria.

SECTION E.—PSYCHOLOGY.
Natural History Class Room.

E. PSYCHOLOGY.—*President*, James C. Howden, M.D. *Vice-Presidents*, James Rutherford, M.D.; Julius Mickle, M.D. *Honorary Secretaries*, A. R. Urquhart, M.D., Murray House, Perth; Alex. Newington, M.D., Ticehurst, Sussex.

Dr. J. C. Howden, the President of the Section, will deliver an Address.

Dr. C. M. Campbell will introduce a discussion on the Uniform Recording of *Post-Mortem* Examinations in Asylum Reports.

Drs. A. Yellowlees and A. Campbell Clark will introduce the following subject: The Sexual and Reproductive Functions—Normal and Perverted—in Relation to Insanity. 1. Menstruation: its Commencement, Irregularities, and Cessation; 2. The Sexual Instinct and its Abuse; 3. Pregnancy, Parturition, the Puerperal Period, and Lactation.

Dr. Clouston will initiate a discussion on the Principle of Construction and Arrangement of an Asylum for Private Patients of the Richer Classes.

The following have promised papers: Drs. Savage, Hack Tuke, Fletcher Beach, Charles Mercier, W. J. Mickle, and Turnbull.

SECTION F.—ANATOMY AND PHYSIOLOGY.
Anatomy Class Room.

F. ANATOMY AND PHYSIOLOGY.—*President*, John Cleland, M.D., LL.D., F.R.S. *Vice-Presidents*, R. J. Anderson, M.D.; Henry Edward Clark, F.F.P.S.G. *Honorary Secretaries*, John Barlow, M.D., 27, Elmbank Crescent, Glasgow; Charles Barrett Lockwood, F.R.C.S., 19, Upper Berkeley Street, Portman Square, W.

C. B. Lockwood, F.R.C.S., will introduce a discussion on the Teaching of Anatomy; and will show sections illustrating the Development of the Organs of Circulation and Respiration.

The following papers are promised.

BROOKES, Henry St. John, M.D. On the Morphology of the Epitrochleo-anconeus or Anconeus Sextus (Gruber).
 BROWN, J. Macdonald, M.B., F.R.C.S. The Construction of the Cardiac Ventricles in the Mammalia.
 CLELAND, Professor, M.D., F.R.S. On the Nature of Certain Forms of Double Monstrosity.
 COLLIER, Mark P. Mayo, M.B., F.R.C.S. On the Mechanism of the Heart and Pulse.
 LANE, W. Arbuthnot, M.B., F.R.C.S. The Influence Produced by Excessive Strain upon Muscles and Ligaments (to be illustrated by specimens).
 PATERSOX, A. M., M.D. On the Position of the Vertebrate Limb, considered in the Light of its Innervation and Development.

SECTION G.—PATHOLOGY.
Law Class Room.

G. PATHOLOGY.—*President*, Sir William Aitken, M.D., LL.D., F.R.S. *Vice-Presidents*, Alexander Davidson, M.D.; Joseph Coats, M.D.; Charles Roy, M.D., F.R.S. *Honorary Secretaries*, G. Sims Woodhead, M.D., 6, Marchhall Crescent, Edinburgh; J. Lindsay Steven, M.D., 34, Berkeley Terrace, Glasgow.

Arrangements are being made to hold a discussion on Cancer originating apart from Epithelial Structures, in which Mr. Lawson Tait (Birmingham), Dr. Joseph Coats, Dr. John Carlyle (Greenock), and others are expected to take part.

The following papers have been promised.

BRUCE, Alex., M.B., F.R.C.P. Edin. On Disseminated Sclerosis.
 COATS, Joseph, M.D. On a Case of Liphæmia in Diabetes, with Suggestions as to the Source of the Fat.
 CROOKE, G. F., M.D., Birmingham. (Title not received.)
 GREVES, E. Hyla, M.D., Bonnamouth. Notes on the Pathology of a case of Pseudo-hypertrophic Paralysis.
 DELÉPINE, Sheridan, Esq. A Few Uncommon Forms of Sarcoma. (Specimens to be shown.)
 HUNTER, W., M.D. On the Pathology of Pernicious Anæmia.
 KENNEDY, —. On Case of Cystic Kidneys and Liver.
 MAPOTHER, E. D., M.D., Dublin. An Anomalous Form of Eczema.
 MAYLARD, A. E., M.B., B.S. Lond. The Results of some Bacteriological Cultivation Experiments with Iodoform.
 O'CONNOR, Bernard, M.D., M.R.C.P. Hydatids of the Spine, Liver, and Brain.
 BAKE, Beaven, M.D. Lond., Medical Superintendent of the Trinidad Leper Asylum. The Percentage of Fibrin in the Blood of Lepers.
 RUSSELL, William, M.D. The Pathology of Pernicious Anæmia.

The following gentlemen have also intimated their intention of contributing to the business of the Section by reading papers or otherwise: Professor Greenfield, Professor Roy, Professor D. J. Hamilton, Dr. William Hunter, Dr. Barrett (Edinburgh), Dr. McFadyean (Edinburgh), Alex. Edington, M.B. (Edinburgh), etc.

Demonstrations.—Dr. Alexander Bruce (Edinburgh) will give a Magic Lantern Demonstration on Diseases of the Spinal Cord; and Alexander Edington, M.B. (Edinburgh), a Bacteriological Demonstration. Arrangements are also being made for a series of Microscopical Demonstrations illustrative of Tumours, Tuberculosis etc.

Pathological Section of the Annual Museum.—Intimation has been received of the following exhibits for this Section of the Annual Museum: 1. Calculi removed by Lithotomy, by Professor George Buchanan. 2. Calculi removed by Lithotomy or by Scoop, by Professor George Buchanan. 3. Miscellaneous Objects removed from the Body, by Professor George Buchanan, namely: Bullets,

Needles, Cases of Teeth, Impacted Pessaries, etc., also Isolated Bones of the Tarsus Excised. 4. Rhinoplasty; Wax Cast, by Professor George Buchanan. 5. Bladder and Urethra showing False Passages. 6. Selected Specimens from the Private Collection of Professor W. T. Gairdner. 7. A Series of Specimens of Tumours of the Brain, by Dr. Joseph Coats. 8. A Series of Specimens illustrative of Diseases of the Kidneys, by Dr. David Newman. 9. A Series of Specimens illustrative of Leprosy, by Dr. Beaven Rake (Trinidad). 10. A Series of Large Sections illustrating Malignant Tumours of the Lung; and a Series of Specimens illustrating Deformities of the Liver, by Drs. Woodhead and Bruce. 11. Drawings and Sections to illustrate Diseases of Bone and Joints, by Mr. F. M. Caird (Edinburgh). 12. A Series of Specimens illustrative of Diseases of the Heart, by Dr. John Lindsay Steven.

As space for the Museum is somewhat limited, gentlemen intending to send specimens should intimate their intention without delay to John Lindsay Steven, M.D., 34, Berkeley Terrace, Glasgow, Honorary Secretary of the Section of Pathology of the Annual Museum.

SECTION II.—OPHTHALMOLOGY.

Midwifery Class Room.

II. OPHTHALMOLOGY.—*President*, Thomas Reid, M.D. *Vice-Presidents*, J. R. Wolfe, M.D.; C. E. Glascock, M.D. *Honorary Secretaries*, Henry Bendelack Hewetson, M.R.C.S., 11, Hanover Square, Leeds; A. Freeland Fergus, M.B., 41, Elmbank Street, Glasgow.

Mr. Brudenell Carter will open a discussion on the Treatment of Senile Cataract. Drs. Prichard, Meighan, Mason, Teale, G. Anderson Critchett, Dr. C. Lloyd Owen, Charles G. Lee, and others have promised to take part in the discussion.

The President of the Section intends to give a Demonstration of several Instruments of Use in Ophthalmic Diagnosis.

The following papers are promised.

- BICKERTON, T. H., M.D., Liverpool. Sailors and their Eyesight.
CRITCHETT, G. Anderson, Esq. Iridectomy and Sclerotomy in Chronic Glaucoma.
GROSSMANN, K. A., M.D. Colour-blindness, with a Demonstration of New Tests.
HEWETSON, B., Esq. General Neuroses of Ophthalmic Origin.
JESSOP, W. H., M.D. Ocular Headaches.
LEE, C. G., Esq. Two Cases of Foreign Bodies.
MACKAY, George, M.D., Edinburgh. A Contribution to the Study of Hemianopsia of Central Origin, with special reference to Acquired Colour Blindness.
MEIGHAN, T. S., M.D., Glasgow. On the Treatment of Symblypharon by Transplantation of Mucous Membrane from the Lip.
REXTON, J. C., M.D., Glasgow. The Value of the Cautey in the Treatment of Ulceration of the Cornea.

SECTION I.—OTOLOGY.

Biblical Criticism Class Room.

I. OTOLOGY.—*President*, Thomas Barr, M.D. *Vice-Presidents*, John Astley Bloxam, F.R.C.S.; J. J. K. Duncanson, M.D. *Honorary Secretaries*, Johnstone Macfie, M.D., 23, Ashton Terrace, Glasgow; James Black, F.R.C.S., 16, Wimpole Street, London.

The following special subjects have been proposed for formal discussion:

1. The Conditions calling for Perforation of the Mastoid Portion of the Temporal Bone, and the Best Methods of Operating; to be opened by Dr. F. M. Pierce, of Manchester. Mr. Peter McBride has promised a paper on this subject. Dr. D. Stewart, of Nottingham, hopes to take part in the discussion.

2. The True Value of those Aids to Hearing usually termed "Artificial Tympanic Membranes." Dr. W. L. Purves has promised a paper on this subject.

3. Adenoid Growths in the Naso-Pharynx; their Influence on the Middle Ear, and their Treatment. To be opened by Mr. Lennox Browne, F.R.C.S.Ed.

The following have promised papers.

- BROWNE, LENNOX, Esq. (*Title not received.*)
TORRANCE, R., Esq. On Syphilitic Cochleitis.
WARREN, Charles, M.D. (*Title not received.*)
Dr. Samuel Sexton, of New York, hopes to be present, and will give a communication on Excision of the Drumhead and Ossicles.

SECTION J.—DISEASES OF CHILDREN.

English Literature Class Room.

J. DISEASES OF CHILDREN.—*President*, Walter Butler Cheadle, M.D. *Vice-Presidents*, James Finlayson, M.D.; Henry Ashby, M.D. *Honorary Secretaries*, George S. Middleton, M.D., 23, Sandyford Place, Glasgow; W. Arbuthnot Lane, M.S., F.R.C.S., 14, St. Thomas's Street, S.E.

The following two discussions will take place:

1. Diphtheria: (a) Etiology. (b) Relationship to other Infectious

Diseases, and to other Forms of Sore Throat; Occurrence on Open Wounds and on Mucous Membranes other than those of the Throat. (c) Diagnosis. What are the Distinctive Features, especially those Distinguishing the Lesion in the Throat from other Forms of Sore Throat? Does Membranous Croup occur apart from Diphtheria? (d) Pathology and Sequelae. (e) Medical Treatment. (f) Surgical Treatment; Tracheotomy; Tubage. The medical and general aspects of the subject will be introduced by Dr. A. Jacobi (New York), and the surgical aspect by Mr. R. W. Parker (London). Messrs. E. Owen, H. R. Hutton, Lennox Browne, R. N. Pugh, and Drs. W. T. Gairdner, George Buchanan, James Finlayson, Henry Ashby, H. C. Cameron, D. Newman, Thos. Buzzard, John Macintyre, and J. S. Cameron will take part in the discussion.

2. Rickets: (a) Etiology and Prevention. (b) Its Connection with Syphilis and Scurvy. Is Enlargement of the Liver and the Spleen always present, more or less, in Rickets; or only in Cases of Syphilitic Origin? (c) Medical Treatment. (d) Surgical Treatment; at what Stage, and in what Way? Drs. Macewen, A. Ogston, L. W. Marshall, H. Ranke (Munich), Thos. Buzzard, Henry Ashby, and Messrs. R. W. Parker, H. R. Hutton, R. Haggard, E. L. Freer, John Gordon, R. N. Pugh, and W. A. Lane will take part in the discussion.

Drs. Jacobi (New York), Keating (Philadelphia), and Ranke (Munich), and Sanné (Paris), and other members of the profession on the Continent have been invited.

The following have promised papers.

- BROWNE, LENNOX, F.R.C.S. Anatomical Facts in support of Intubation in Diphtheria.
CAMERON, J. S., M.D. Etiology of Diphtheria. (1) Predisposition from Recent or Existing Disease, especially Scarlet Fever; (2) Influence of Insanitary Surroundings, especially Rise and Fall of Subsoil Water.
HAGYARD, Robert, M.R.C.S. The Effects of Sunlight on Rickets in Children and in the Lower Animals.
LANE, W. A., F.R.C.S. The Deformity of Rickets.

SECTION K.—PHARMACOLOGY AND THERAPEUTICS.

Conveyancing Class Room.

K. PHARMACOLOGY AND THERAPEUTICS.—*President*, James Morton, M.D. *Vice-Presidents*, John Dougall, M.D.; Theodore Cash, M.D., F.R.S. *Honorary Secretaries*, Alexander Napier, M.D., 3, Royal Terrace, Crosshill, Glasgow; Sidney Harris Cox Martin, M.D., 60, Gower Street, London, W.C.

A special discussion will be opened by Professor Theodore Cash, M.D., F.R.S., on Carbolic Acid, Antipyrin, Antifebrin, and their Allies, especially as regards their Antipyretic, Analgesic, and Antiseptic Actions. Drs. Walter G. Smith (Dublin), A. D. Macdonald, and Prosser James will take part in the discussion.

Dr. W. Allan Jamieson (Edinburgh) will show two cases of Xeroderma Pigmentosum.

It is expected that Professors Liebreich and Dujardin-Beaumetz will be present at the meeting. Dr. Dujardin-Beaumetz will contribute a paper on Phenacetin.

The following have promised papers.

- DAVISON, James, M.D. The Pine Treatment.
DOUGALL, J., M.D., Glasgow. (*Title not received.*)
DRYSDALE, C. R., M.D. 1. On the Therapeutic Value of Alcohol. 2. The so-called Abortive Treatment of Syphilis.
JAMES, J. Brindley, Esq. Scavies and its Treatment.
KERR, J. G. Douglas, M.B. Bath, a Thermal Spa.
MACDONALD, A. D., M.D. Three Cases of Poisoning.
PEARSE, T. F., M.D. The Treatment of Eczema.

SECTION L.—LARYNGOLOGY AND RHINOLOGY.

Divinity Class Room.

L. LARYNGOLOGY AND RHINOLOGY.—*President*, Felix Semon, M.D. *Vice-Presidents*, George Hunter Mackenzie, M.D.; Peter McBride, M.D. *Honorary Secretaries*, D. Newman, M.D., 18, Woodside Place, Glasgow; A. E. Garrod, M.D., 9, Chandos Street, Cavendish Square.

The following subjects are proposed for special discussion:

1. The Use and Abuse of Local Treatment in Diseases of the Upper Air Passages. To be opened by Dr. de Havilland Hall (London) and Mr. Stoker (London).

2. The Causes, Effects, and Treatment of Nasal Stenosis. To be opened by Dr. Macintyre (Glasgow) and Mr. Creswell Baber (Brighton).

3. Hemorrhages from the Pharynx and Larynx, and other Hemorrhages which simulate these. To be opened by Dr. Percy Kidd (London) and Dr. Hodgkinson (Manchester) (probably).

The following gentlemen hope to take part in the discussions: Dr. Prosser James (London), Dr. McBride (Edinburgh), Dr. Charles Warden (Birmingham), Dr. Cartaz (Paris), and Mr. Richard Ellis (Newcastle-on-Tyne).

The following papers have been promised.

JOHNSTONE, R. Mackenzie, M.D. Account of a Case of Tumour of the Naso-Pharynx.
 McBRIDE, P., M.D., Edinburgh. On Hay-Fever and Allied Conditions.
 MACINTYRE, J., M.D. Anatomical Demonstration of the Larynx.
 NEWMAN, D., M.D. Two Cases of Complete Laryngeal Stenosis produced by Wounds of the Larynx in Attempted Suicides.
 WARDEN, C., M.D. (Title of paper not yet received.)

Members desirous of reading papers, or joining in the discussions, are earnestly requested to communicate without delay with the Secretaries of the respective Sections.

FRANCIS FOWKE, *General Secretary.*

SPECIAL CORRESPONDENCE.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

Antipyrin in Eye Surgery.—Balsam of Tolu as an Adjuvant to Creasote.—Carelessness in Prescribing.—Epidemic of Pelada.

At the meeting of the Académie de Médecine on May 8th, M. Grand Clément (of Lyons) communicated the results of his experiments with injections of antipyrin in the temporal region in affections of the eye. He found that this acted rapidly and certainly in relieving ocular pain, especially peri-orbital pain, and to a less extent in ocular spasm. Speedy relief was also given in many cases of keratitis, iritis, and glaucomatous irido-choroiditis; the injections were also useful in a case of old-standing hemimerania; of monocular hemeralopia, and in several cases of ties in the orbicularis palpebrarum, of anterior scleritis and sclero-choroiditis, and of floating bodies in the vitreous humour. M. Clément has made over 300 injections in the temporal region of twenty-five centigrammes of antipyrin, and half a centigramme of cocaine, mixed with ten drops of distilled water. These injections were never followed by abscess, but they always caused slight swelling at the seat of injection, which remained tender for eight or ten days. Occasionally slight œdema of the eyelids was observed. M. Clément attributes the successful results of the injections in part to this subcutaneous derivation.

In the *Union Médicale* of April 22nd, Dr. Lasniée pointed out the advantage of combining beech creasote with tolu balsam and Norway pitch. Creasote, which is so useful in pulmonary and laryngeal affections, is not always easily tolerated, sometimes causing nausea and vomiting. It was therefore necessary to find some means of neutralising these inconveniences. This has been found in tolu balsam, the antispasmodic and anticatarrhal properties of which are well known, and which, together with Norway pitch, forms an excellent and reliable remedy. After numerous experiments the following formula has been adopted by MM. Trouette and Peret, pharmaceutical chemists, in their capsules, called by them "gouttes livoniennes." R 5 centigrammes of pure beech creasote, 7½ centigrammes of purified Norway pitch, 7½ centigrammes of tolu balsam, to make one capsule. In cases of little gravity, and when used as a prophylactic, two capsules morning and evening are sufficient. In more serious cases, one should begin with four capsules morning and evening, increasing the dose if necessary up to twelve capsules a day. After taking the capsules a little water or other liquid should be swallowed, and it is advisable to take them at meal times. When the disorder is relieved, the use of the capsules should not be suddenly abandoned, and it is also good to take some at the commencement of winter, and at any change of season accompanied by damp weather.

Dr. Flocken, of Strasbourg, has lately been sentenced to nine months imprisonment, Greiner, a chemist, to two weeks, and his assistant to two months. The latter was convicted of manslaughter through imprudence. He had made up a prescription of Dr. Flocken's for two patients, but owing to the doses not having been clearly indicated, death from poisoning occurred in both cases. The twofold accident coming to the knowledge of the authorities of the town, the matter was thoroughly investigated and the bodies exhumed. A *post-mortem* examination showed that death had occurred through poisoning caused by overdoses of the medicine prescribed.

An epidemic of pelada has recently broken out among the men of the different fire-brigades in Paris. As many as 130 firemen

are at the present time attacked by the disease, but energetic measures are being taken to quell it. All the bedding is to be renewed in the various firemen's barracks.

VIENNA.

[FROM OUR OWN CORRESPONDENT.]

Professor von Schrötter's Opinion on the Case of the Late Emperor.—Letter from Professor Billroth on Sir Morell Mackenzie.

The *Neue Freie Presse*, of the 15th current, publishes at full length the opinion which Professor von Schrötter gave as to the case when he saw the illustrious patient at San Remo on November 9th. The following is a translation of the text:—"Professor von Schrötter declares that, in his opinion, the new vegetation (Spriessung) is cancer, and that there is no doubt about it; he, therefore, recommends complete removal of the whole of the larynx. He, moreover, holds that an immediate operation would be the most useful. He would, however, also consent to the operation being postponed, as the life of the Crown Prince could perhaps be prolonged for some time by the application of other remedies, and especially by tracheotomy. By complete removal of the larynx the life of the Crown Prince may perhaps be saved, but the operation is most dangerous. By means of other methods, particularly tracheotomy, life could only be prolonged."

The *Neue Freie Presse* of the same date also publishes the following letter, addressed to it, by special request, by Professor Billroth:—

"Vienna, March 27th, 1888.

"With reference to your request for my opinion on Mackenzie, I can only reply that I have always warned people against passing a judgment on a man who, as a physician, occupies so difficult a position. I have never doubted the correctness of the diagnosis of my Berlin colleagues, but I have also never been able to understand what political reasons had made it necessary to communicate this diagnosis to the whole world. It cannot be admitted that Mackenzie with his vast experience has ever doubted the correctness of this diagnosis. If he behaved in such a way as to imply that he had some doubt about the correctness of this diagnosis, this could only be owing to pressure from above or from motives of humanity. I know such situations from my own experience. One is not inclined to disapprove the statements of one's *confrères*, but at the same time one is not inclined to tell the patient that his malady is incurable, for the known want of infallibility in medical diagnosis is almost the sole ray of hope to the unfortunate incurables. Falseness in such cases becomes a moral act. The entire behaviour of Mackenzie must, no doubt, be judged from this point of view. He did as a man and a physician what was still possible to be done when the unfortunate word 'cancer' had already been pronounced.

"In such the same terms as these I have on different occasions expressed myself as to Mackenzie's conduct. I ask you to consider this as a private communication, at least until the sad catastrophe has occurred in Berlin.—Yours most respectfully,

"Dr. TH. BILLROTH."

CORRESPONDENCE.

ARMY MEDICAL RESERVE OF OFFICERS.

SIR,—I think that your remarks in respect to the Army Medical Reserve of Officers are calculated to spread erroneous ideas as to the causes of the formation of this particular class of officers. It may be true that the necessity of this class has been hastened by the late cry of retrenchment, and by the opportunity of using volunteer medical officers for home service if necessary, and so freeing the Medical Staff of the army for more active service. In doing so the authorities have obviated the necessity of establishing a large medical department, which would be uselessly large, expensive, and over-numbered in time of peace. All they do is to be prepared for times of emergency, and to have the Medical Department ready in its effectiveness for any necessities which may arise. Surely it is not unfair to ask the volunteer surgeons to help their Government, should national emergencies arise, especially as the Royal Warrant tends to blend together the medical officers of the army with those in the new reserve, in the same way as the reserve of combatant officers are associated with the regular officers of the army. Volunteer medical officers have undoubtedly gained by the step accorded to them,

and in no way do the officers of the Medical Staff lose any privileges by those granted to us.

As you observe, in case of invasion, the regimental medical officers would be required to attend their regiments in the field; but this applies only to a very limited extent, since all volunteer regiments have several medical officers, and most two at the least; consequently, in case of need, there would be sufficient officers ready to do regimental field work, and a surplus number who would fairly be employed at the departmental centres where most work and attention is required. Without some such supplemental work as is proposed, the bulk of the medical service would be from necessity ineffective from paucity of the number of those officers who could be spared from the army staff, and it behoves us all, as a profession, to be jealous of our honour, and to show to the public at least that the part of the army which affects our interests is ready and prepared in its details should any grave emergency arise.

To my mind, the idea of the reserve is the offspring of common sense, and is conceived in the true desire to render the defences of the country efficient in their medical arrangements, and it would be well if the country could be as well assured of the efficiency of the commissariat and transport departments as it may hope to expect from its Medical Reserve of officers. Such a reserve of officers was shadowed out by myself three or four years ago, and was favourably received by the press and commended by the *Volunteer Review*; but it fell through until its promulgation last month under the Royal Warrant.

We volunteer medical officers do not want to flutter under an army rank; but we have asked for our position to be recognised, and this the authorities have graciously accorded, though in a different way to that which the Volunteer Medical Association asked. We have, however, received army rank with all its privileges, but we have saddled ourselves with certain duties which doubtless would be so arranged, should the time of such a necessity for service ever arise, to meet each medical officer's convenience, as far as would be consistent with the exigency of the need, as would also be the distribution of the volunteers generally throughout the country.

If wanted, let us medical officers of the volunteer force do the work which may be required of us rather than introduce into the medical service of the country so large an influx of civilian element as occurred during the last Crimean war; and it would be as well if the present volunteer medical officers entered into the present reserve with the same patriotic spirit as that which attracted us when, during the scare of a possible war with Russia during Lord Beaconsfield's ministry, most of us volunteered to supplement the Medical Staff, should Government require our services during its continuance.—I am, etc., M. BAINES, M.D. Lond., Surgeon-Major Army Medical Reserve of Officers, and 1st Middlesex and Engineer Volunteers, R.E.

Junior Athenæum Club.

SIR,—When the Royal Warrant was first issued, I was much disposed to join the new reserve; but a little consideration, and consultation with several officers of large experience in my district, caused me to pause and to ask some questions before taking so important and, I may now add, so serious a step. Now, nearly two months ago I applied to the officer commanding my regiment for a definition of the term, "great national emergency," referred to in paragraph 4 of the Secretary of State's instructions on the Warrant. The question in due course gravitated to the Horse Guards, to the Director-General of the Army Medical Department, and finally to His Royal Highness the Commander-in-Chief.

After much delay and more than one reminder, I have, by request of H.R.H. the Commander-in-Chief, been honoured with the following reply from the Director-General:

"It has been decided that, if the National Defence Bill (read a first time in the House of Commons) becomes law, the criterion of a 'great national emergency' will be the embodiment of the militia."

This information may, I think, be of no small importance and interest to brother medical officers who have joined or who contemplate joining the new Army Medical Reserve of officers. To my mind the definition is a most dangerous and serious one for civil practitioners having large professional and domestic responsibilities. Army Medical Reserve service might possibly suit a few junior practitioners who have but little to risk, either professionally or domestically, and who long for military fame at any

price; but even they, I think, would do better to join the regular medical staff out and out than to place themselves in a position so uncertain and so insecure. It is, however, I take it, the services of experienced medical officers of auxiliary forces that the Government wish to secure (as evidenced by the proficiency examination certificate being a necessary qualification), and it is to such men, I repeat, that the terms of the Royal Warrant, as at present defined, might prove not only most disastrous, but even ruinous.

For example, if some colonial war, or even the scare of a Continental war, were to occur, and a few battalions of militia were embodied, no other legal authority would be required to enable the Government to at once call out officers of the Army Medical Reserve, and to send them to any duty, or to any place they might deem fit, utterly regardless, of course, of all private or professional inconvenience or sacrifice to them.

The fact is, Government are endeavouring to provide for a possible great emergency without any cost to themselves. They seek to reduce the medical *personnel* of the army below an efficient standard, regardless of the hardships of entailing an extra amount of foreign duty on those who are now serving in the regular forces. But, lest their device should be too transparent, Government cover their claims on the Medical Reserve by the ambiguous and comprehensive expression, "great national emergency," perfectly well aware that, should pressure arise, those who had unwarily enrolled themselves must obey orders, at whatever cost to themselves. It will be difficult to understand how, after their declaration as to the nature of a great national emergency has been made, men can, with their eyes wide open, rush headlong into such needless and heedless obligations.

Nor ought we, I hold, as a medical body, either on professional or military grounds, by joining the Army Medical Reserve of officers, to help Government in opposing the reasonable claims of the regular Army Medical Staff to have their rank and status definitely established and recognised in Her Majesty's Army, in which they should always consider it an honour and a privilege to serve.

I will only add that this letter is not written without much consideration and careful investigation, and that in enunciating my views I have had accorded to me the advantage of large and eminent military experience.—I am, etc.,

June 5th.

SURGEON AUXILIARY FORCE.

ASSOCIATION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

SIR,—We enclose herewith the reply received by us to the letter addressed by our Committee to the Lord President of the Council.

We may add that Lord Randolph Churchill has consented to receive on Thursday morning, June 21st, a small deputation of our Committee, in order to hear their views as to the position of the Members of the Royal College of Surgeons.—We are, etc.,

WARWICK C. STEELE,
WM. ASHTON ELLIS,

June 20th.

Honorary Secretaries, Association of M.R.C.S.

[60,981.]

"Council Office, Whitehall.

"16th June, 1888.

"SIR,—In reply to your letter of the 12th instant, on the subject of the petition of certain Members of the Royal College of Surgeons, with reference to the constitution of that College (lodged at this office on the 3rd May, 1887). I am directed by the Lord-President of the Council to inform you that it is not usual to send a written reply to petitions on the subject of a question which is before the Privy Council. The petitions or statements in such cases are fully considered before any decision is arrived at, and the result is that Her Majesty is advised either to grant, to refuse, or to modify the proposed charter.—I am, Sir, your obedient servant.
"C. L. PEEL."

SELF-HELP FOR HOSPITALS

SIR,—I would ask space for a few words with reference to your article of June 16th, on this subject.

It is not altogether against the abuse of charity that I am writing, but chiefly on account of the comparative costliness in many instances which attendance in out-patient wards involves, as well as the risk to health and even to life.

Regarding the expense, poor persons often pay, especially in

country districts, much more for travelling backwards and forwards to a hospital than efficient attendance at their own homes would cost. As for the risks, I need only instance a case where a child with chest affection travelled seven miles to a hospital in an open conveyance during inclement weather, and died in consequence of the exposure; all this distance was traversed for the sake of a few grains of a hypophosphite in powder. Under such circumstances as these I consider it nothing less than homicidal to encourage attendance, and the medical officers would best show their humanity by directing such poor persons to any efficient self-supporting dispensary in their own neighbourhood; it would be better, by the bye, if the amount of the subscriptions to these institutions were increased, and if no unqualified person were allowed to be in any way connected with them, unless it were such medical students as had progressed well with their studies and examinations.

Then the scale of payment to poor-law medical officers is very inadequate; this is surely a fitting subject for some of the labour representatives in the Commons to take up. The annual drink bill is still far too large, and I think a small portion of the amount might be worthily diverted for the purpose of medical relief.—I am, etc.,

W. L.

THE TREATMENT OF AURAL EXOSTOSES.

SIR.—In justice to Sir William Dalby, I feel it my duty to state that on January 9th, 1875, I was present with him at an operation for the removal of an exostosis from the ear.

The instrument he used was my dental engine, and I furnished him with the drills employed on that occasion.

I have since assisted him in a similar manner on several occasions.—I am, etc.,

THOMAS EDGELOW, M.R.C.S.,

Late Dental Surgeon, St. George's Hospital.

Savile Row, June 16th.

SETTING-UP DRILL AND HEART DISEASE.

SIR.—It is with much satisfaction I see that a more rational system of "setting up" young recruits is about to be introduced into the army. Colonel Onslow, who has worked hard in this direction, is entitled to much credit for his zeal; but I hope the labours of Surgeon-Major F. Arthur Davy will not be overlooked. Some years ago this officer wrote a pamphlet on the prevalence of heart disease in the army, to which his attention had been called at Netley. Dr. Davy made the system of "setting-up drill" the subject of careful study, and in the *brochure* above referred to demonstrated, on physiological data, the fact that this most mischievous system was one of the chief factors in bringing about first functional and then organic disease of the heart. As I have elsewhere shown, Dr. Davy's observations failed to impress the authorities with their importance. The late Dr. Fagge was one of the first men of eminence in the profession who appreciated their value. The military authorities are now, it would appear, awake on the subject, but there is reason to fear that in this, as in so many other examples, the seed sown by one man is likely to be reaped by another. To prevent this injustice, if this be possible, is the object of this letter.—I am, etc.,

W. CAMPBELL MACLEAN, M.D., Surgeon-General.

Woolston.

ENGLISH MEDICAL PRACTITIONERS IN THE GRISONS.

SIR.—I wrote last month to the proprietors of a large hotel at Davos-Platz (to which I had been in the habit of recommending patients), protesting against the prohibition of English practitioners in the Swiss Cantons. Since you have taken up the subject, I thought the enclosed reply might interest you.—I am, etc.,

HARRISON CRIPPS.

Stratford Place, W.

Grand Hôtel Belvédère, Davos-Platz,
Canton des Grisons, Suisse,

June 13th, 1888.

Sir,—We beg to apologise for the delay in answering your favour of the 21st ultimo; a short absence from home having been the cause of it.

We deeply regret the action taken against your English colleagues in this country, and assure you the great majority of the Swiss people disapprove of this shortsighted persecution, which is caused entirely by the opposition the practice of English medical men meets with on the part of some of the Swiss doctors. It

seems, however, that you are not quite correctly informed with regard to this place (Davos-Platz), and we therefore take the liberty of submitting to you the real state of matters, hoping that we may succeed to make you change your views to some extent.

There are three English doctors practising in this Canton—the Canton des Grisons—namely, Dr. Huggard, in Davos-Platz; Dr. Holland, in St. Moritz; and Dr. Wise, in Maloja. Dr. Huggard (see *Medical Directory*, London), now in practice here for the last two years, has passed the Swiss medical examination at Geneva in 1885, and possesses the Swiss diploma, and, consequently, the recent action taken by the Swiss authorities does not concern him. But we are sorry to say, though he has fulfilled all that they required of him for free practice in Switzerland, he was looked at as an intruder, and was slandered in the most shameful manner, with a view and intention to prevent his getting on in the place. However, his English colleagues sent their patients to him with letters addressed to him, and so Dr. Huggard got on very well in Davos-Platz, in spite of the shameful persecution. You will see clearly that, should you and all other English medical men send no longer any English patients to Davos, Dr. Huggard would be forced to give up his practice there, on account of his colleagues in England, who would have just reached the contrary result of what they wished.

Dr. Holland and Dr. Wise both did not pass the Swiss medical examination, and, consequently, do not possess a Swiss diploma for practice; the persecution of them was therefore directed in another line; they were denounced by Swiss doctors for illegal practice, with a view of getting altogether rid of their competition. But you will be interested to hear that the highest authorities of the Canton des Grisons, that is, the "Cantonal Grosse Rath" (to whom, quite recently, when they were assembled in Chur, Dr. Holland and Dr. Wise submitted their cases), did not adopt the view of the Swiss medical profession, but granted the right to practise to both the above-named doctors, without demanding of them to pass the Swiss examination.

Hoping you will pardon this long intrusion on your valuable time, we have the honour to remain, Sir, yours very obediently,

CHESTER BROTHERS.

** The matter is, as this letter states, now happily settled for the moment in this locality by the judicious action of the Grosse Rath, and we trust it will not arise again. There is at present no established reciprocity between the English and Swiss registration of duly qualified practitioners, but the legal machinery exists under the Medical Amendment Act, 1886, and as a preliminary to further action it might be well to put it in motion.

DR. APOSTOLI'S TREATMENT OF UTERINE FIBROIDS.

SIR.—There is such an amount of evidence in favour of Dr. Apostoli's method of treating uterine fibroids that, after hearing that gentleman at Dublin last summer, and reading an account of his process by Dr. Keith, of Edinburgh, I sent the latter gentleman a lady whose case I had laid before Sir Spencer Wells, and before Dr. Apostoli himself before he went to America. The case was a well-marked one of interstitial fibroid, the uterus being much enlarged, or about the size of a small cocoa-nut or large orange. The patient was under treatment in Edinburgh for about six months, and puncture was made use of frequently. The result has been some slight change for the better in the symptoms, but I cannot say that the size of the tumour has been lessened.

Of course, this is only one case, and I merely give it because experience is what is wanted, and I know the result in this case.—I am, etc.,

C. R. DRYSDALE, M.D.,

June 14th.

Senior Physician Metropolitan Hospital.

NAVAL AND MILITARY MEDICAL SERVICES.

COMMITTEE ON ARMY ESTIMATES.

THE third report of the Select Committee on Army Estimates issued this week as a Parliamentary paper, deals entirely with Vote 4, which provides for the medical establishment, pay, etc., of the Army. The charge for non-effective services paid out of Imperial funds reaches £182,574. The Committee point out that there has been an enormous increase of charge for the medical service of the Army since the year 1872. This increase is mainly accounted for by improved rates of pay and by a large addition to the numbers of the Medical Staff Corps. In conclusion the report says:—"It would appear from the evidence given to your committee by Sir Thomas Crawford that the civil and military authorities at the War Office recognise how very heavily this enormous

June 23, 1888.]

charge for medical establishments in the Army (very nearly £700,000 a year) bears upon Army funds, and are making efforts to reduce both the effective and non-effective charges by the re-employment of retired officers, and by extension of the term of foreign service by one year. Sir Thomas Crawford and Mr. Knox stated to your committee that the medical officers of the Guards, sixteen in number, have up to now retained exemption from foreign service, except with their regiments, and are strongly of opinion that, in the interests of the public service, that exemption should be no longer allowed. Your committee concur in this opinion. . . . Your committee are of opinion that the whole question of the pay of the medical service in all its ranks, the number of medical officers employed, and the periods of retirement require the immediate consideration of the Secretary of State.

CHAIR OF HYGIENE AT NETLEY.

ARMY MEDICAL DEPARTMENT writes: Your correspondent in the JOURNAL of May 26th has accurately described the feeling of the service in regard to the proposed appointment of Deputy Surgeon-General Marston to the Chair of Hygiene at Netley, and his being "seconded" for that purpose. In the first place such an appointment, if made by Sir Thomas Crawford, would be a slight upon the many hundreds of former pupils of the school who have passed through the practical course, and some of whom hold university honours in chemistry, and, unlike Dr. Marston, have studied practical military hygiene with soldiers for years in all climates, and not in the headquarters offices of the department in which Dr. Marston has spent at least twenty years. Dr. Marston, on the suppression of his appointment in London, was ordered on foreign service. If he is now "seconded" he will have another spell of home service out of his turn while running up the list for promotion, and take up the latter when it suits him. The future of the Army Medical School is now trembling in the balance. It costs nearly £7,000 a year. In the interest of the department and economy this appointment should be conferred on some officer of the executive grade, of active habits, with a practical knowledge of soldiering, a good chemist, and who would not require an assistant. Hygiene is taught in every university in the present day. Several officers hold the diploma of sanitary science, which Deputy Surgeon-General Marston does not, and are more capable of giving a short practical course of lectures and demonstrations than the gentleman referred to, however excellent he may be in other respects.

EXAMINATIONS OF SURGEONS FOR PROMOTION TO SURGEON-MAJOR.

A CORRESPONDENT asks: How do the authorities intend to dispose of surgeons who fail in passing the examination for promotion to surgeon-major? At the last examination four surgeons failed to satisfy the examiners, and I have heard are to be allowed one more chance; but if they again fail steps are to be taken to remove them from the service. If this is true, it seems extremely hard. Do they intend to turn a man adrift after spending the best eight or ten years of his life in the service without any compensation?

. We cannot say, we know of no regulation which meets the point. There ought to be very few unable to pass a legitimately conducted examination for promotion; but failure to pass, if unfairly used, might be made a most immoral weapon against individuals. We cannot contemplate such a shameful method of weeding the list. The whole system of these examinations needs to be revised, or they may become a serious injury instead of an advantage to the public service.

MEDICO-LEGAL AND MEDICO-ETHICAL.

SAME NAME.

A CORRESPONDENT writes: James "Blank," M.D.Lond., has been in practice in a moderate-sized town for twelve years under the designation of Dr. "Blank." John "Blank" (same name) M.R.C.S.Eng. and L.S.A.Lond. has been practising in the same town for about six years as Mr. "Blank," surgeon. A few weeks ago Mr. "Blank" removed from a side street to one of the main thoroughfares of the town, and put up the name of Dr. "Blank." Of course a considerable number of people imagine him to be the one who has always been recognised as Dr. "Blank," and a great amount of annoyance and inconvenience is caused. James "Blank," M.D., wishes to know can he prevent John "Blank," M.R.C.S. and L.S.A., from assuming the title of "Dr.," and how he is to proceed if he can? If he cannot do that, what other course ought he to adopt, if any, or is he obliged to sit down without any attempt to vindicate his position?

. It is possible that a conviction would be obtainable under the 40th Section of the Medical Act, 1858, in spite of the pseudo M.D. being registered both as a surgeon and apothecary. Upon this question our correspondent should refer to the judgments delivered in the case of *Ellis v. Kelly*, 3 L. T. (N. S.), p. 330. In that case the defendant was registered, as in the present case, both as an L.S.A. and M.R.C.S., but he also had a diploma of a Bavarian University, and it was, it would appear, owing to the letter circumstance that it was held that the defendant could not be convicted under the Medical Act for adopting the title of "Dr." Failing, or in addition to the remedy under the Medical Act, an injunction could, in our opinion, be obtained on its being shown that rights of property (goodwill, etc.) are being injuriously affected (see *Springhead Spinning Company v. Riley*, 6 L. R. Eq., p. 551).

EASTWOOD v. DALE AND CO.

THE action brought by Dr. Eastwood, the proprietor of Dinsdale Park, Darlington, a licensed house for the insane, against *Rare-Bits* for libel was disposed of by agreement, after judgment and a special jury to assess damages, Dr. Eastwood having accepted £250, costs, and an apology.

DR. DAVIDSON has resigned the Professorship of Pathology in University College, Liverpool, which he has held for several years with energy and distinction.

MEDICO-PARLIAMENTARY.

HOUSE OF LORDS.—Tuesday, June 19th.

Universities (Scotland) Bill.—The report of amendments was received. Several further amendments, proposed by the Marquis of LOTHIAN, were agreed to.—Lord WATSON moved that the number of the representatives of affiliated colleges nominated to serve upon a University Court should not exceed four. The amendment was agreed to.—The Earl of ROSEBURY, on Clause 15, moved to insert a new subsection giving power to the Commissioners to make arrangements where it shall seem requisite for the due representation of the University Court in the governing body of affiliated colleges and of the governing body of affiliated colleges in the University Court, having regard to the circumstances of each particular case, to the relative numbers in the University and the college of the teaching staff and of students proceeding to graduation, to the nature of the connection proposed to be established, and to the purposes for which such representation is desirable.—The amendment was agreed to.—The Marquis of LOTHIAN moved the insertion in Clause 16, page 13, after line 24, of the following new subsection: "(3) In the event of the said University college being affiliated to the said University, to regulate the time, place, and manner of the first election of the assessors to be elected for the University Court by the General Council and by the Senatus Academicus of the said University after such affiliation, which election the Commissioners shall appoint to take place as soon as conveniently may be after such affiliation, and the assessors then in office shall deem office on the date of such election." The amendment was agreed to.—After some further verbal amendments had been inserted in the Bill, the report was agreed to.

HOUSE OF COMMONS.—Monday, June 18th.

Magisterial Visitations of Lunatic Asylums.—On Clause 6 of the Local Government Bill (Powers of Quarter Sessions as to Visiting Lunatic Asylums) Mr. LEIGHTON moved an amendment retaining to single magistrates the powers they now possessed in respect to visiting lunatic asylums.—Mr. RITCHIE thought it would be extremely likely to lead to friction if every magistrate of a county had a right to visit the lunatic asylums. They thought it advisable that a judicial body like quarter sessions should have the power of visiting the asylums and reporting whether any abuses existed; but it would be inadvisable to allow a magistrate as an individual, and not as a member of the committee, to visit the asylums. Guardians had a *locus standi* for visiting paupers from their own unions which magistrates did not possess. The matter was further discussed with the result that the amendment was withdrawn and the clause negatived without discussion.

The Medical Service of British Guiana.—Dr. FARQUHARSON asked the Under-Secretary of State for the Colonies whether it was the case that the Court of Policy of the Colony of British Guiana had passed a resolution requesting the Secretary of State for the Colonies to remove the Medical Inspector of Estates Hospitals from his office; whether this action of the Court of Policy was traceable to a report made by that officer in the course of his duties which was considered to have "injuriously reflected on the planters;" and whether it was the intention of the Colonial Secretary to comply with this demand at present without investigating the correctness or otherwise of the allegations contained in the report.—Baron H. DE WORMS said that the combined Court had passed a resolution of the nature indicated. The action of the Court was understood to be the result of dissatisfaction on the part of the members with the manner in which the officer had discharged the duties of his office, and particularly with certain statements in an official report made by him which they considered to have reflected unjustly on the employers of immigrant labour. The Secretary of State had received such conflicting statements supporting and contradicting the allegations in the report that he would be unable to arrive at a conclusion as to their correctness without a commission of inquiry, and he had not considered the question to be of sufficient importance to justify the expense of such a commission. He had already decided, before receiving this resolution of the Court, to transfer the officer in question to another appointment in the Colonial service.

Tuesday, June 19th.

Folkestone Jubilee Hospital.—Sir H. MAXWELL, in reply to Sir E. WATKIN as to whether the Government would at once decide

whether it would sell the site of the disused battery on the Bayle at Folkestone for the jubilee hospital, said the matter was not yet decided; if sold it would be sold by auction.

British Medical Practitioners in Switzerland.—In the unavoidable absence of Dr. FARQUHARSON, Mr. CAUSTON asked the Under-Secretary of State for Foreign Affairs whether he had any further information to give the House as to the result of the negotiations he had been carrying on with the Swiss Government regarding the rights of English doctors to practise in that country.—Sir J. FERGUSON said he was glad to say that matters had assumed a more hopeful appearance. There was reason to expect that temporary measures would be adopted by certain cantonal authorities by which British physicians would be enabled to practise, and he hoped that a permanent and reciprocal arrangement might be arrived at.—Mr. CAUSTON asked whether it was probable that the more favourable arrangements would apply to the whole of Switzerland.—Sir J. FERGUSON said there were considerable difficulties in the way, but no possible effort would be spared to procure such a satisfactory arrangement.

OBITUARY.

THOMAS HARRINGTON TUKE, M.D., F.R.C.P., Etc.

THOMAS HARRINGTON TUKE, whose death we announced last week, was the son of Edward Francis Tuke, M.D., of Bristol, whose professional life was devoted to the treatment of lunacy. He was born on June 13th, 1826. He studied medicine at St. George's Hospital and at Edinburgh, and also visited Paris, becoming Member of the Royal College of Surgeons in 1847, M.D. of St. Andrews in 1849, and Fellow of the Royal College of Physicians of Edinburgh in 1858. He was elected Fellow of the Royal College of Physicians, London, in 1878.

Dr. Tuke has throughout his career been identified with the treatment of insanity. In 1846 he took charge of the Manor House, Chiswick, founded by his father, and by successive enlargements and alterations much improved it, adding nearly eighteen acres to the original grounds.

In January, 1852, he married Sophia Jane, second daughter of Dr. John Conolly, of The Lawn, Hanwell, his distinguished teacher and kind friend. His professional career was in every way a highly successful one, his practice being large both as a consulting physician and at Manor House, which became well known as one of the leading private asylums in this country, and always maintained a very high reputation. Active, public-spirited, and full of interest in professional and public questions, Dr. Tuke took a leading part in the organisation and scientific progress of his department of medicine. He was a member of many foreign societies, and was for several years secretary of the Medico-Psychological Society. He was a prominent witness before the Select Committees of the House of Commons on amendment of the Lunacy Law. He was the author of several papers on general paralysis and on criminal responsibility, and otherwise a frequent contributor to the *Journal of Mental Science*, as well as to the *BRITISH MEDICAL JOURNAL*, in which his last contribution was published, being a very interesting paper on the trial of the Rev. Gilbert Cooper, and the question of criminal responsibility involved therein (*JOURNAL*, November 26th, 1887; January 14th, 1888).

He took a prominent part in most of the *causes célèbres* in lunacy which have been tried during the last thirty years, especially in the Windham case, the case of Lady Mordaunt, the Bravo, the Townley, and the O'Connor cases. In the last case, it will be especially remembered that his foresight and prudent warnings after the release of this boy from prison put the authorities on their guard against a probable renewal of his insane wanderings to Buckingham Palace, and brought to Dr. Tuke the honour of a letter of thanks from the Home Secretary for the public service which he had rendered. Dr. Tuke was the first to introduce nasal feeding of the insane. His contributions to the literature of psychology and his general attitude in courts of law and in communications with leading officials before the committees of the House of Commons were always of a kind honourable to himself and his profession, humane in the protection which they suggested to the insane, and calculated to bring the law into better accord with the advancing knowledge of psychological physicians.

In private life his marked amiability of character, gentleness,

and generosity secured for him the affection of a wide circle of friends. In the board-room of St. George's and at the hospital he was always a welcome figure. His annual reunions of the old students and staff of the hospital on the eve of the opening of each successive session had become a sort of social institution, and afforded an annual meeting-ground for old friends and early associates, of which a large number of old St. George's men did not fail annually to avail themselves. His death leaves a void which will not easily be filled, and he will long be mourned by a large circle of professional friends, to whom throughout life he had greatly endeared himself. Few men have made so many friends in the course of a long professional life, and it may be said of him that, having made many friends, he never lost them.

He was buried at Chiswick on June 13th. His health had been failing for some weeks before his death, which was due to pulmonary disease. His end was quiet and peaceful. He leaves seven sons—two of whom follow in the same department in the medical profession—and a daughter.

MISS ALICE FISHER.

MANY members of the profession will have heard with deep regret of the death of Miss Alice Fisher, which occurred on June 3rd, at the Philadelphia Hospital, U.S.A., of which institution she had been for nearly four years Lady Superintendent of Nurses.

Miss Fisher entered the Nightingale Home, St. Thomas's Hospital, as a probationer, in January, 1875, and after a year's training was sent as home sister to take temporary charge of the nurses at the Royal Infirmary, Edinburgh.

In the following year Miss Fisher was appointed matron of the Fever Hospital, Newcastle-on-Tyne, and held that post until her election in 1878 as matron of Addenbrooke's Hospital, Cambridge. There she remained four years, during which time the nursing of the hospital was completely remodelled, a training school established, and nurses supplied to the members of the University and residents in the town. The advantages, alike to the hospital, the nurses, and the public which followed the adoption of the latter plan, were so great that it has been indirectly the cause of the foundation of institutes for the supply of nurses to the public in connection with many of the metropolitan hospitals.

Feeling that her special work at Addenbrooke's was done, and that the system which she had introduced could well be carried on by others, Miss Fisher accepted an invitation from the governors of the Radcliffe Infirmary, at Oxford, and subsequently another from the committee of the Birmingham General Hospital, to take charge of the nursing departments there.

At both places the same untiring energy, which was one of her chief characteristics, led to important improvements being effected in the system of nursing.

In October, 1884, Miss Fisher left England to undertake the duties of superintendent of nurses at the Philadelphia Hospital. In America, owing to the greater publicity of official life in any sphere, Miss Fisher's work soon attracted general attention. This was at first due to her calmness and heroism in saving the lives of many of the inmates of the lunatic wing of the hospital during a fire which occurred shortly after her arrival there.

Subsequently she succeeded, as she had previously done at Cambridge, in interesting all classes in the work of the hospital, which became almost a popular resort with the ladies of Philadelphia, who attended her lectures on nursing in large numbers. In the few years she was there a large training-school for nurses sprang up, and an impetus was given to the improvement of nursing which has been felt almost throughout the United States. The American papers were enthusiastic in her praise, and she received applications from all parts for admission to the nursing home.

In the midst of her work she has been cut off by death, due to an affection of the heart which had troubled her for some time, and for which, as one of her physicians said, "she had worn out all power of compensation by overwork." Her interest in the hospital was maintained to the last, and when too ill to walk, she was wheeled through the wards in a Bath chair.

Miss Fisher was in many respects a remarkable woman; of commanding presence, sympathetic in manner, widely read, especially in the best English literature, and herself the author of several works of fiction showing much insight into human motives. She exercised a great influence for good over all with whom she was brought into contact. As a hospital administrator she had few equals, and every institution with which she was connected still

impairment of health, misfortunes that might be averted by early removal to healthy surroundings.

MEDICAL NEWS.

MEDICAL VACANCIES.

The following Vacancies are announced:

- BOROUGH OF BRADFORD.**—Medical Officer of Health. Salary, £500 per annum. Applications by June 30th to the Chairman of the Sanitary Committee.
- CHELSEA HOSPITAL FOR WOMEN,** Fulham Road, S.W.—Resident Medical Officer. Salary, £80 per annum, with board and residence. Applications by July 4th to the Secretary.
- CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST,** Victoria Park, E.—Assistant-Physician. Applications by July 12th to the Secretary.
- CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST,** Victoria Park, E.—Pathologist. Salary, 100 guineas per annum. Applications by July 12th to the Secretary.
- CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST,** Victoria Park, E.—Resident Clinical Assistant. Applications by July 12th to the Secretary.
- DONCASTER GENERAL INFIRMARY AND DISPENSARY.**—House-Surgeon. Salary, £100 per annum, with board and residence. Applications by July 5th to the Honorary Secretary.
- DUFFUS PAROCHIAL BOARD.**—Medical Officer. Salary, £35. Applications by June 23rd to John Nicoll, Esq., Inspector of Poor, Hopeman, N.B.
- DUNDEE ROYAL INFIRMARY.**—Resident Assistant House-Surgeon. Salary, £80 per annum. Applications by June 27th to D. Gordon Stewart, Esq., Solicitor, Dundee.
- EAST LONDON HOSPITAL FOR CHILDREN,** Shadwell, E.—Resident Clinical Assistant. Board and lodging. Applications by June 28th to the Secretary.
- EAST SUFFOLK AND IPSWICH HOSPITAL.**—House-Surgeon. Salary, £50 per annum, with board, lodging, etc. Applications by July 16th to the Secretary.
- EDINBURGH CITY POOR HOUSE,** Craiglockhart.—Resident Medical Officer. Salary, £80 per annum, with board. Applications by June 25th to Mr. G. Greig, Inspector, City Parish Chambers, 2, Forrest Road, Edinburgh.
- EVELINA HOSPITAL FOR SICK CHILDREN,** Southwark Bridge Road.—Surgeon to Out-patients. Applications by June 25th to the Committee of Management.
- GLASGOW HOSPITAL FOR SICK CHILDREN.**—Assistant House-Surgeon. Applications to M. P. Fraser, Esq., 91, West Regent Street, Glasgow.
- KENT COUNTY ASYLUM,** Barming Heath, Maidstone.—Third Assistant Medical Officer. Salary, £120 per annum, with apartments, etc. Applications by June 30th to the Superintendent.
- LONDON THROAT HOSPITAL,** 204, Great Portland Street, W.—House-Surgeon. Applications by June 27th to the Secretary of the Medical Committee.
- PARISH OF EDRACHILLIS,** Sutherland.—Salary, £150 per annum, with free house. Applications by July 15th to Mr. A. R. Cowie, Inspector, Scourie by Larg, N.B.
- PARISH OF KIRKMABRECK,** Kirkcudbrightshire.—Medical Officer for the Poor. Salary, £35 per annum. Applications by July 14th to Mr. J. Carson, Inspector of Poor, Creetown, N.B.
- PARISH OF LOCHS,** Stornoway.—Medical Officer. Salary, £140, house and rates free. Applications by June 23rd to H. McL. Ross, Inspector of the Poor, Lochs, Stornoway.
- PARISHES OF PENNYGOWN AND TOROSAY.**—Medical Officer. Salary, £100 per annum. Applications by July 3rd to Mr. A. McDougall, Inspector of Poor, Auchnacraig, Oban, N.B.
- PRISON COMMISSIONERS, SCOTLAND.**—Resident Surgeon for one of Her Majesty's prisons in Scotland. Salary, £200 per annum, with residence or allowance. Applications by June 25th to the Secretary, Prison Commission for Scotland, 130, George Street, Edinburgh.
- RAMSGATE AND ST. LAWRENCE ROYAL DISPENSARY AND SEAMEN'S INFIRMARY.**—Resident Medical Officer. Salary, £120 per annum, with furnished apartments, etc. Applications by June 23rd to the Secretary.
- SURREY DISPENSARY,** Great Dover Street, Southwark.—House-Surgeon. Salary, £120, and furnished apartments. Election on June 26th.
- WESTPORT UNION.**—Medical Officer, Westport No. 2 and Louisburgh No. 2 Districts. Salary, £39 per annum, and fees. Election on June 24th.
- WEST SUSSEX, EAST HANTS, AND CHICHESTER INFIRMARY.**—House-Surgeon. Salary, £100, with board and lodging. Applications by June 30th to the Honorary Secretary, E. Arnold, Esq., White Hall, Chichester.
- WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.**—Resident Assistant. Board and lodging, etc. Applications by June 25th to the Chairman of the Medical Committee.
- WORCESTER GENERAL INFIRMARY.**—House-Surgeon. Salary, £100 per annum, board and residence. Applications by July 9th to the Secretary, Worcester Chamber, Pierpoint Street, Worcester.

MEDICAL APPOINTMENTS.

- ANDERSON, W. A., M.B., C.M. Edin.,** appointed Assistant Medical Officer to the Bucks County Lunatic Asylum, *vice* H. L. Grant, M.B., C.M. Edin., resigned.
- BROWN, John, M.D. (Glasgow),** appointed Physician to the Anderson's College Dispensary, Glasgow.

- CAMPBELL, S. G., M.D. Edin., M.R.C.S. Eng.,** appointed Surgeon to the Anderson's College Dispensary, Glasgow.
- JONES, Hugh R., M.A., M.B., B.C. (Cantab.), B.Sc. (Lond.),** appointed Surgeon to the Liverpool Corporation Waterworks, Llanwddyn.
- KENNEDY, John, L.R.C.P., L.R.C.S. Ed.,** appointed Physician to the Anderson's College Dispensary, Glasgow.
- MACNAB, Allan J., M.R.C.S., L.R.C.P.,** appointed Ophthalmic Clinical Assistant to King's College Hospital.
- MANBY, E. P., M.B., M.R.C.S.,** appointed Resident Medical Officer to the Chelsea Hospital for Women, *vice* E. G. Peck, M.R.C.S., resigned.
- MARTIN, Sidney, M.D. Lond., M.R.C.P.,** Pathologist to the City of London Hospital for Diseases of the Chest, Victoria Park, appointed Assistant-Physician to the Hospital.
- PENNY, W. J., F.R.C.S. Eng., L.R.C.P. Lond.,** appointed Assistant-Surgeon to King's College Hospital, *vice* W. Rose, M.B., F.R.C.S., resigned.
- RITCHIE, John, M.B., C.M. (Glasgow),** appointed Consulting Surgeon to the West of Scotland Convalescent Sea-side Home, Dunoon, N.B., *vice* James Denniston, M.D., resigned.
- ROSE, W., M.B. Lond., F.R.C.S.,** appointed Surgeon to King's College Hospital.
- SEAL, C. E., M.R.C.S., L.R.C.P.,** appointed Clinical Assistant to the Western Fever Hospital, Fulham.
- SHAW, P. F., L.R.C.P. Ed., L.F.P.S., L.M.,** appointed Surgeon to the Anderson's College Dispensary, Glasgow.
- STARK, J. Nigel, M.B., C.M. Edin.,** appointed Surgeon to the Anderson's College Dispensary, Glasgow.
- SYDENHAM, G. F., M.R.C.S., L.S.A.,** appointed Medical Officer to the Dulverton Union (No. 1 District) and Workhouse, Somerset.

DEATH OF MISS CLUGSTON.—Miss Beatrice Clugston, so well known in Glasgow and the West of Scotland for her philanthropic efforts on behalf of the sick poor, died at Ardrossan on June 4th, at the age of 61. From early womanhood her life was wholly spent in devising means to relieve and comfort the suffering, and her name will always be identified with the institutions she founded and the successful bazaars she promoted to provide funds for their maintenance. Miss Clugston was the originator of the Dorcas Society in connection with the Royal Infirmary. She founded the Convalescent Home at Lenzie, and by a bazaar raised £6,750 for its maintenance. By a second bazaar she raised £5,000, of which £3,000 were given to the Sick Children's Hospital, and the balance is now held by the Glasgow magistrates and council in trust for the Dorcas Societies in connection with the Belvidere, Knightswood, and Govan Fever Hospitals. Miss Clugston's third great bazaar realised £8,500 to establish a convalescent home at Dunoon. Her fourth bazaar was for the Broomhill Home for Incurables, and realised £14,000; while by her latest effort she raised over £16,000 for the benefit of these two homes. In November, 1876, Miss Clugston was presented with £3,000 as a mark of the esteem and honour in which she was held by the community, and recently some of her friends purchased an annuity for her by which, her private means being exhausted, she was enabled to live in comparative comfort. Although she had been for some time in failing health she continued to take a keen interest in the welfare of the various institutions organised under her superintendence.

PRESENTATION TO DR. TALFOURD JONES.—After being connected with the Breconshire Infirmary for twenty-two years, first as House-Surgeon for six years, and then as Physician for sixteen years, Dr. Talfourd Jones recently resigned his appointment there, and removed to Eastbourne for the benefit of his health. The committee of the infirmary appointed Dr. Talfourd Jones consulting physician, and passed a resolution of thanks in recognition of his "very valuable and efficient professional services" rendered to the hospital and the public. The governors and subscribers to the Breconshire Infirmary, and other friends, subsequently raised a testimonial, which was presented to Dr. Talfourd Jones early this month. We may add the expression of our hope that in the more genial climate of the South Coast, Dr. Jones, who is a past-president of the South Wales and Monmouthshire Branch, may shortly be completely restored to health.

THREATENED WATER FAMINE AT LIVERPOOL.—In consequence of the scanty rainfall during the last twelve months, the water in store in the Liverpool reservoir at Rivington Pike is less than half the usual amount, and the supply to the city is turned off for eighteen hours out of the twenty-four. The usual quantity of water is, however, expended for flushing the sewers and other sanitary purposes, water from the Mersey being employed to some extent. To this must be attributed the fact that the death of water seems to have no ill effect on the public health. The death-rate for the week ending June 9th was 14.7 per 1,000, being 1.9 below the rate recorded a fortnight before, and which was stated to be the lowest on record.

UNIVERSITY COLLEGE HOSPITAL.—A public dinner in aid of the funds of this charity was held on Tuesday last at the Hôtel Métropole, Lord Herschell presiding. Lord Herschell, in speaking of the claims of this hospital, said that a scheme was on foot for rebuilding the hospital, and he trusted that when this was done, which must be before long, they would, with the aid of the public, have a building which would befit the great work which the institution was doing for the people of London. The total amount of donations in connection with the festival was announced to be upwards of £1,900.

A CENTENARIAN.—The death of a veteran Polish officer named Kurkovski is reported from Makoff. It is said that it can be clearly proved that he was born in 1772, and fought under Kosciuszko.

IN consequence of the death of the German Emperor, the laying of the foundation stone of the new hospital, to be built in West Ham, by the Duke of Cambridge, arranged for June 23rd, has been postponed.

THE Sheffield guardians have unanimously voted £25 to Dr. G. P. Godfrey, medical officer to the workhouse, for extra services during the epidemic of small-pox.

DIARY FOR NEXT WEEK.

TUESDAY.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, 5 P.M.—Dr. Donald MacAlister: The Croonian Lectures on Antipyretics.

WEDNESDAY.

COLLEGE OF STATE MEDICINE, Burlington House, 4 P.M.—Sir Robert Rawlinson, K.C.B.: The Rise and Progress of Sanitary Engineering within the Present Century.

BRITISH GYNECOLOGICAL SOCIETY, 8.30 P.M.—Specimens will be exhibited by Dr. Fancourt Barnes, Dr. Granville Bantock, Mr. Lawson Tait, Dr. Richard Smith, Dr. Mansell-Moullin, and others. Dr. Henry T. Rutherford: Case of Uterine Fibroid successfully treated by Electricity. Dr. C. D. Sherrard: Retroversion of the Gravid Uterus at the Fourth Month. Council, 8 P.M.

THURSDAY.

PUBLIC HEALTH MEDICAL SOCIETY, 6.45 P.M.—Council's Report and Balance Sheet. Election of Officers. Election of Council. Dinner.

NEUROLOGICAL SOCIETY OF LONDON, National Hospital for the Paralysed and Epileptic, Queen Square, Bloomsbury, 8.30 P.M.—W. H. Gaskell, M.D., F.R.S.: On the plan of formation of the Spinal and Cranial Nerves, together with suggestions on the origin of the Central Nervous System. Professor Schäfer, F.R.S., will exhibit photographs of certain monkeys' brains recently shown to the Society.

FRIDAY.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, 5 P.M.—Dr. Donald MacAlister: The Croonian Lectures on Antipyretics.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the announcement.

BIRTHS.

HOETS.—On May 3rd, at Yass, New South Wales, the wife of Alton Kingsley Hoets, M.R.C.S. Eng., of a daughter.

PARKHILL.—On June 13th, at Church Gresley, Burton-on-Trent, the wife of Saml. J. Parkhill, M.D., of a daughter (premature and stillborn).

DEATH.

BRICKWELL.—At Sawbridgeworth, where he commenced practice in 1829, John Brickwell, M.R.C.S.E., aged 80. Friends please accept this intimation.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS respecting editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

IN order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the office of the JOURNAL, and not to his private house.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL, are requested to communicate beforehand with the Manager, 429, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication. CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with *Depliate Copies*.

QUERIES.

ANTISEPTIC FOR MIDWIVES.

DISPENSARY SURGEON asks: Would any of your readers tell me what is the best antiseptic to recommend for the use of midwives to a dispensary? Besides being efficient it should be safe and not unpleasant for common use, and inexpensive. Creoline has been suggested.

MEDICAL PRACTICE IN ITALY.

F.R.M.S. writes: I recently saw a letter in the JOURNAL stating that medical men with British qualifications are permitted to attend professionally their countrymen residing in Italy without holding any Italian qualification. Is any permission from the Italian Government required, and, if so, how is it obtained? Could a medical man with somewhat delicate chest, who can bear moderate heat or cold when not accompanied by damp, and who has a private income of £350 to £400 a year, add a few hundreds a year to his income by practising in Florence, or Milan, or some other suitable town where English sojourn? Which would be the best place? Coast towns do not suit him owing to the damp. Are there any works on the climatology of the European countries (or any of them) bordering on the Mediterranean, giving minute particulars as to the maximum and minimum temperatures, relative humidity, etc.? The advantage of reciprocal privileges of practising in Continental towns is an additional argument in favour of State examinations which would be mutually recognised by the States as conferring these privileges.

ANSWERS.

TREATMENT OF WOUND OF LEG.

MR. AUGUSTUS CLAY (Senior Casualty Surgeon, Queen's Hospital, and Assistant Surgeon, Orthopaedic and Spinal Hospital, Birmingham) writes: In answer to the query put by "S. H. J." as to the treatment of a wound of the shin, may I confidently recommend strapping as ordinarily applied to ulcers of the leg. The strapping should extend at least three inches above and below the wound, and the leg should then be bandaged over the strapping as high up as the knee. If this does not have the desired effect quickly, the wound should be dusted with powdered boracic acid, and the strapping applied as above.

TREATMENT OF WEBBED FINGERS.

MR. AUGUSTUS CLAY also writes:—In answer to the question as to the best operation for webbed fingers, may I say that where the webbed condition is not due to any osseous or deeper tissue coalescence but merely a prolongation of the skin, I believe Didot's operation is undoubtedly the best, judging by its ultimate results. This, as your correspondent may know, is effected by making two flaps, one from half the dorsal surface of one finger, and by the second from half the palmar surface of the other. These flaps are then turned so that the dorsal flap raised from one finger fits on to the palmar surface of its neighbour and *vice versa*.

LECTURES.

IN answer to several correspondents, we may state that Sir James Paget's address to the students of the London Society for the Extension of University Teaching has been published by the Society, and may be obtained from the office in the Charterhouse, E.C., price 6d. Mr. Murray's lecture on the Physical Training of the Greeks and Romans, given at the Parkes Museum of Hygiene, has not, so far as we are aware, been published in full.

WICKER COFFINS.

MR. WILLIAM KIRBY, basket maker, 40, St. Peter's Street, Derby, writes to say that he is the inventor of wicker coffins, which are, he considers, better named grave baskets, such as were shown at Stafford House some years since. The London Necropolis Company, Lancaster Place, Strand, have given up the use of wicker coffins, which they consider unsuitable, and now employ special "earth-to-earth" coffins, for which they claim the same advantages.

TREATMENT OF ABOBTION.

SURGEON writes: I was asked to attend a Mrs. —, who was threatened with an miscarriage. She was between three and four months pregnant. I did all I could to prevent this occurring, but the event came off, and I delivered her of a fetus about the age above stated, after a great deal of difficulty. I then tried to remove the after-birth, but, in consequence of great adhesions, I could only remove a small quantity. Acting upon the instructions given in Churchill's *Midwifery*, I decided it was better to try the result of ergot, and wait for events; this I did, and, upon the afternoon of the same day, a large clot and another portion of placenta came away, and the hemorrhage decidedly abated. I continued in attendance upon her daily for nearly ten days, when to all appearance she seemed to be nearly well. I cautioned her to keep very quiet until her next monthly period, and to do very little work or walking. She took no notice of my request, and flooding again commenced in three weeks, which again yielded to rest and treatment; and, when nearly well, she intimated a wish to go with some friends to spend the day a distance off. I very reluctantly consented, and then only upon the understanding that she went and returned by tram, instead of which she drove over rough roads, and in a very shaky vehicle. Flooding returned the same night more violently than ever, and, upon examining her, I found the os dilated to the size of one shilling, and, passing my fingers through, I detached a piece of placenta firmly attached to the middle part of the uterus, and extending beyond the reach of my finger; and as I could not get more than one finger into the uterus, I plugged, and waited for three hours, and gave ergot, the flooding still continuing in spite of the plugging. I removed the portion of placenta left. It took me quite half an hour to carefully detach this, in consequence of the undilatable condition of the os uteri.

Now, sir, the points in question are: Did I do right in following out Churchill's instructions, and leaving the portion of placenta; or would it have been better to forcibly dilate the os, and remove it, running the risk of phlebitis and puerperal septicæmia? I am very anxious to have a reply on this point, as I have been greatly blamed by the friends for not doing so at the time, and threatened with all sorts of calamities in consequence. I may say that three medical men of note and standing in the neighbourhood say I did quite the correct thing. One will not give an opinion, and one or two

others are trying to make capital out of it. I shall feel obliged if you will give me your opinion, as all books I have referred to say the course I took was the correct one.

* * In certain conditions, such as the case related presents, it is not wise to persevere too forcibly to detach the whole placenta at once. The very circumstances that lead to the abortion are likely to be attended by undue adhesion. Wait and watch should be the rule. If hemorrhage recur, ergot may be tried according to routine rule; if not stopping, injections of hot water and dilatation to facilitate detachment of placenta come into use. But so long as any placenta remains, rest should be observed. This the patient neglected.

(NOTES, LETTERS, ETC.)

INCOME TAX.

THE INCOME TAX REPAYMENT AGENCY (25, Colville Terrace, W.) write: In consequence of the numerous questions which have been asked us, directly or indirectly, after each letter of ours that you have published, Mr. Chapman has, in his new edition of *Income Tax, and How to get it Refunded*, added (page 29) a special section for doctors, telling them what deductions they are allowed to make from their gross income. It is a most important addition, for our experience has shown us that there is scarcely a medical man who is not greatly overtaxed and does not pay considerably more than he would do if he went the right way to make out his returns. We can boast that scarcely one of our clients in the profession has not either obtained a refund or got a reduction in assessment; often they get both. We know as a fact that, in the month of May alone, the Inland Revenue issued upwards of 20,000 post office orders for refunds, and we take credit to ourselves for a goodly number of these, either directly or indirectly. Another little book we strongly recommend is Lawrie's *How to Appeal against your Rates*. Armed with these two books no person should be over-taxed or over-rated. Mr. Chapman has also published another useful handbook, *Inhabited House Duty*.

AN APPEAL.

WE desire again to call attention to the appeal printed on April 14th (p. 817) to enable a medical man of good position, who has been reduced to destitution through no fault of his own, to buy a small practice and make a living for himself and wife. Contributions may be sent to Dr. Farquharson, M.P., Migvie Lodge, Porchester Gardens, W., or to Mr. Marmaduke Shield, F.R.C.S., 39, Stratford Place. Subscriptions have been received from Sir William Jenner, Sir James Paget, Sir Joseph Lister, Sir Andrew Clark, Sir Prescott Hewitt, Sir Spencer Wells, and others. Since the last insertion of this appeal, the following subscriptions have been received: Dr. Francis Waring (Brighton), £1 1s.; Mr. Bernard Roth, £1 1s. Further subscriptions are still needed.

A SOURCE OF INFECTION.

M.D. writes: Although my notes upon "A Source of Infection" were not intended to initiate a discussion upon antiseptics in midwifery, but to point to a possible hidden source of infection, I see, from the JOURNAL of June 16th, Dr. A. D. Macdonald has adversely criticised my remarks. My answers to his strictures are: first, when I say I used the "strictest antiseptic treatment," I mean it. Although I do not happen to prefer your correspondent's favourite drug (iodine), and although my conception of antiseptic midwifery is not embodied even in the free use of any single antiseptic, yet I flatter myself I carry out in every labour case the strictest antiseptic treatment. I do not feel myself called upon to state *seriatim* what these are, but I may mention the methods I adopt are partly those I carried out when resident accoucheur in a large maternity hospital, and partly those gained by experience and a careful study, not only of new drugs, but new methods. Secondly, your correspondent attempts almost to point the finger of scorn when he insists that, had the syringe been disinfected, there would have been no case of puerperal septicæmia, that the space of the JOURNAL would not have been uselessly occupied, and that he would have had to write pointing out my waywardness. To this I reply that the syringe was disinfected thoroughly before using it. Moreover, I did not begin intra-uterine irrigations until the disease had commenced. Thirdly, Dr. Macdonald advocates the return of the syringe to the chemist, to be given out on loan to other women in childbed, and says: "The syringe, I hold, should have been purified by iodine and perhaps also by corrosive sublimate." Why also by corrosive sublimate if iodine is the antiseptic? If Dr. Macdonald has not faith in iodine alone, why does he advise me to trust it? An antiseptic is either effective or it is a sham. Fourthly, I frankly admit I would rather expose myself to the charge of insisting upon even a working man spending 1s. 6d. or 2s. in purchasing a syringe for no other purpose than destroying it, than burden my conscience with the doubtful economy of sending out on loan any instrument which has been used in a case of puerperal septicæmia washed with two separate antiseptics, evidently suggesting my faith in neither.

COMMUNICATIONS, LETTERS, etc., have been received from:

Mr. H. A. Latimer, Swansea; Mr. E. White Wallis, London; Mr. W. A. S. Roys, Reading; The Publishers of the *Provincial Medical Journal*, Leicester; Mr. F. W. Collinson, Preston; Mr. A. P. Luff, London; Dr. W. A. Carlisle, Lincoln; Mr. A. Crosbie Dixey, Torquay; Dr. H. K. Hitchcock, Bournemouth; Messrs. R. W. SCALE OF CHARGES FOR ADVERTISEMENTS IN THE "BRITISH MEDICAL JOURNAL."

Seven lines and under	£0 3 6
Each additional line	0 0 4
A whole column	1 15 0
A page	5 0 0

An average line contains seven words.

When a series of insertions of the same advertisement is ordered, a discount is made on the above scale in the following proportions, beyond which no reduction can be allowed.

For 6 insertions, a deduction of	10 per cent.
" 12 or 13 "	20 "
" 26 "	25 "
" 52 "	30 "

Special terms for occasional change of copy during series: 20 per cent. if not less than 26 pages be taken } or their equivalent
25 " " 52 " " } in half or
30 " " 104 " " } quarter pages.

For these terms the series must, in each case, be completed within twelve months from the date of first insertion.

Advertisements should be delivered, addressed to the Manager a the Office, not later than noon on the Wednesday preceding publication; and, if not paid for at the time, should be accompanied by a reference.

Post-Office Orders should be made payable to the British Medical Association, at the West Central Post-Office, High Holborn. Small amounts may be paid in postage-stamps.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-Offices letters addressed to initials only.

REMARKS ON MYELITIS.

Read before the North London District of the Metropolitan Counties Branch of the British Medical Association.

By J. S. BRISTOWE, M.D., LL.D., F.R.S.,
Senior Physician to St. Thomas's Hospital.

ACUTE inflammation of the spinal cord is always a serious disease, generally attended with grave danger, and in a large proportion of cases fatal. But it varies so much in its symptoms, in dependence partly on the seat and extent of inflammation, partly on its intensity, that its diagnosis is often very obscure, and it is consequently liable to be confounded with other affections of the cord, or with diseases of the peripheral nervous system.

As a contribution to an exceedingly interesting subject I propose to narrate, and comment briefly on, several cases of what were, or on good grounds were believed to be, cases of acute myelitis, but which yet differed so much from one another in their severity, in their symptoms, and in their event, that they might well seem to have little or no pathological connection with one another.

The first case I shall quote is a typical example of severe myelitis ending in incomplete recovery.

CASE I.—The patient was a rural postman, 19 years of age, who was sent to me on May 17th, 1886, by Mr. Alfred Wright of Romford. On May 9th, while going his usual rounds he felt hot, for the day was sultry, and to cool himself walked into a brook with his boots on, and then lay on the grass and fell asleep. After he had thus rested for a time he walked home, feeling perfectly well, and he remained well during the rest of the day. Shortly after going to bed, however, he experienced some numbness and tingling in his arms and legs, and observed that he had a little difficulty in moving them. These symptoms had become much aggravated by the next morning; when he was found to be suffering from incomplete but well-marked paralysis of the arms and legs, with numbness of the lower extremities. The paraplegic symptoms increased upon him during the ensuing week, at the end of which time he was admitted into St. Thomas's. He had, up to the onset of his illness, always enjoyed excellent health, and had never had syphilis or rheumatism. He was a spare, healthy-looking youth, suffering from paralysis of his limbs and trunk, difficulty of breathing, and want of control over the rectum and bladder. He had absolute motor paralysis of the lower extremities, of the intercostal muscles, and of the other muscles of the walls of the trunk; so that he was quite unable to move any part of the legs, or to shift the position of his body as he lay in bed. The upper extremities were partially paralysed. He could not move his fingers or thumbs in the least degree; he could flex and extend the hands on the forearms slightly, and could also pronate and supinate the forearms. The triceps muscles were almost absolutely powerless; but the flexors of the forearms on the upper arms retained some power, and the arms consequently tended to become flexed at the elbows. He could use the muscles about the shoulder-joints fairly well. His breathing was entirely diaphragmatic; and, though he seemed to breathe without particular difficulty while making no effort, he soon became breathless when speaking or coughing. There was no paralysis of the muscles of the head and neck or face. The paralysed muscles were flabby but not tender. Sensation was impaired, but nowhere absolutely lost, throughout the lower extremities, and the lower part of the trunk to the level of the fifth dorsal vertebra behind and the ensiform cartilage in front. The anæsthesia extended a little higher on the right than on the left side. The tendon reflexes at the knees and ankles were wholly absent. The plantar reflexes were brisk on the left side, feeble on the right. The cremasteric and abdominal reflexes were absent; the scapular well-marked. The scratch of a pin on any part of the body was followed in a few seconds by factitious urticaria. The bladder was distended, the urine dribbling away. This fluid was slightly ammoniacal and cloudy with mucus. Bowels confined; but the feces had escaped unconsciously. The skin over the sacrum was reddened, but as yet free from bed-sore. There was no affection of the organs of sense, and the pupils and optic discs were normal. Temperature, 99.8; pulse, 72; respiration 16.

For some two or three weeks after admission the patient re-

mained very ill, suffering much from inflammation of the bladder, occasional dyspnoea connected with the paralysis of his intercostals, and loss of appetite, and sickness. Moreover the anæsthesia became more pronounced and extended a little further upwards; and the paralysis of the arms, and more especially of the left arm, increased; the arms, too, became rigidly flexed at the elbows, owing apparently to the combination of absolute paralysis of the triceps muscles, with the retention of comparatively considerable power in the flexors; and bed-sores formed. Even during this period, however, there was some return of power to the left lower extremity.

After this there ensued a period of two or three months, in the course of which there was, on the whole, considerable improvement; but during which certain phenomena remained with little change or even underwent aggravation. The anæsthesia gradually disappeared. Its upper limit descended slowly; and recovery advanced more rapidly in the legs and feet than in the thighs and lower part of the abdomen. By the end of August sensation was completely restored. The arms never lost feeling.

The improvement in the voluntary power over the lower extremities was uniform though slow. The left recovered the more rapidly; but slight return of movement was noted in the right as early as June 10th. A week later feeble knee-jerks were for the first time obtained. They were well-marked a few days later, and soon became unduly brisk; and early in July ankle-clonus was elicited on both sides. At this time he was able to move his legs, ankles, and toes freely as he lay in bed, the movements on the right side being feeble, those on the left of considerable power, the muscles of his trunk had all become stronger, and he was consequently able to move himself freely in bed. By the middle of August he could stand with assistance, and early in September he could walk across the ward by himself. At this time the lower limbs were small, having emaciated in some degree during his illness, but there had been no disproportionate wasting of muscles, and the knee-jerks continued excessive and ankle-cloni well-marked.

The recovery of the intercostal muscles was extremely slow; nor was it easy to say when improvement began in them. Early in September, however, it was noted that the lower intercostal muscles acted fairly, although the upper ones seemed still powerless. Not long afterwards the chest moved freely.

As before remarked, the upper extremities, and more especially the left, continued to fail after the patient's admission, so that at the end of a few weeks he had no power whatever in the forearms or hands or in the triceps muscles, though the flexors of the forearms on the upper arms still retained some power, and the muscles about the shoulders, though extremely weak, remained relatively strong. These muscles, moreover, wasted very rapidly. The deltoids became small and the muscles of the upper arms shrank almost to nothing. But the most remarkable attenuation was shown in the forearms and hands. The former became little more than skin and bone, and presented concave depressions before and behind, between radius and ulna in their whole length, the thenar and hypothenar eminences wholly disappeared, and the spaces between the metacarpal bones were deeply depressed. But long before the emaciation of the forearms and hands had attained its extreme point, the muscles about the shoulders and those of the upper arms had begun to improve; so that about the middle of July he could raise his upper arms freely and could extend the forearms. This improvement continued up to the time of his leaving the hospital. But little or no change took place in the condition of the forearms and hands; and the muscles of these parts, for the most part, refused to respond to galvanism. On the right side, however (which had always been somewhat less affected than the left), the patient could adduct the thumb slightly; and the extensors of the wrist and of the fingers showed a trace of galvanic irritability.

The bed-sores, which were in process of formation at the time of admission, were slow in healing. They finally got well during the month of September. It was long also before he obtained complete power over the bladder; the urine up to a late period running away from him involuntarily as he lay in bed. It was long also before the inflammation of the bladder, which presented occasional relapses, wholly subsided, and the urine became absolutely healthy.

He was discharged from the hospital on the 1st January, 1887, being at that time in excellent bodily health. He was very thin; his legs were small, and there was exaggeration of tendon reflexes with ankle-clonus, but he could walk well; his trunk muscles

had recovered perfectly; he had the use of the muscles of the shoulders and upper arm, which, however, were small and weak; but there was scarcely any amendment in the forearms and hands, which still presented no visible trace of muscle, and the latter of which were without power of voluntary motion, and bent into the form of claws.

The treatment consisted mainly in rest, in sedulous attention to the condition of the skin and bladder, in the endeavour to improve the general health with tonics, etc., and for some months in the daily use of the constant current.

There can be no doubt that the case just narrated was a typical case of myelitis, brought on by exposure to cold and wet, affecting mainly the cervical and upper dorsal portions of the cord, and resulting (as so often happens in cases in which the inflammation is extensive and severe) in permanent disorganisation of certain tracts of the cord, and permanent paralysis with nutritive lesions in the peripheral organs innervated from these disorganised tracts. I may add that I have seen the patient at intervals since he left the hospital, and that the condition of his upper extremities remains unchanged, while in all other respects his health has improved.

It is interesting to compare with this case another which has recently been under my care, in which the affection was extremely slight (so slight indeed that possibly some may be inclined to dispute the accuracy of my diagnosis), and from which recovery was comparatively rapid and complete.

CASE II.—A healthy young man of nineteen, a clerk on the Stock Exchange, went on Sunday, December 19th, 1886, for a walk from the West End of London to Hampstead Heath. The day was extremely cold, and he sat and sauntered about on the heath for some time. He walked home, and on his way complained that his legs were cold, and that he could not make them warm. The next day he went to the city as usual, and continued to go backwards and forwards until Christmas Day. During this period the sense of coldness in his legs continued; and occasionally he complained of numbness in them; and of pins and needles, especially when they were touched. On one occasion he went to the closet, and got up after a time, thinking he had gone ineffectually, but found to his surprise that he had passed a large stool. This was the only occasion on which anything definitely amiss was noticed in regard to his emunctories. His brother, who was a medical student, found out also during this week that there was impairment, but not actual loss of feeling, in the feet, ankles, and along the front of the legs, and that his tendon and superficial reflexes were normal. I did not see him professionally until the 25th, when there was already some improvement. At that time he still complained of coldness, with pins and needles, in the legs; and there was marked impairment of sensibility in the regions before named. But his reflexes were normal, and he was healthy in all other respects. In the course of the next ten days the condition of his right leg became normal; but the left leg from the knee downwards still felt slightly numb; and tactile sensibility was obviously impaired in the feet and ankles. At the end of a fortnight from that time he was perfectly well. On subsequently making minute inquiries I learnt, in addition to what is stated above, that while at his worst the passage of his motions was scarcely perceived by him, and that on several occasions he dropped a slipper and walked about without knowing it. His general health throughout was perfectly good; his tendon reflexes remained unaltered, and the muscular strength appeared to be unimpaired. He never had tenderness or pain in the muscles or nerves. He has continued well ever since.

There is no reason to doubt, I think, that this was a slight case of myelitis. The apparent cause, the symptoms, and the result, are all compatible with this view. The only reasonable alternative suggestion is, that it may have been a case of multiple neuritis. Whichever hypothesis, however, be accepted, it is obvious that the sensory region was alone or mainly involved.

In contrast with the last, the next case presented impairment of the motor functions only.

CASE III.—The patient was a married woman, aged 49, who had enjoyed excellent health. She had been nursing her mother, night after night, for some time; going to the house (which was about a mile from her own) every evening. On the evening of January 9th, 1887, which was exceeding cold, she was kept standing outside her mother's house for a considerable time, and she recollects that while waiting she had slight aching throughout the left leg. She sat up as usual, the room being very cold, and her legs feeling very cold. About 3 A.M. she tried to rise from

her chair, and found to her surprise she had lost all power in her legs. She had to be taken home in a cab, and remained paralysed, and with little or no control over her evacuations, until her admission on January 20th. She said that her legs had felt numb for a day or two at the beginning, but that this condition had disappeared.

On admission she had a few small bed-sores; she was unable to stand, but could move her legs feebly in bed; there was no pain or loss of sensation; the knee-jerks and plantar reflexes were present; she could not sit up without assistance; the urine dribbled away and the motions escaped without control; she presented some tenderness along the dorsal spine, and the left lower extremity was somewhat oedematous. It may be added that she had had oedema of the left leg off and on during the last two or three years. With the exception that her bed-sores troubled her for some time, and that for some time her urine was ammoniacal and offensive, she improved rapidly during the early part of her stay in the hospital. The right leg had recovered completely by the end of three or four weeks, and the left leg had improved so much, that with assistance she could walk a little; also she re-acquired control over the rectum and bladder. Then the oedema in the left leg increased, and this limb consequently became weak, and she continued with little change for two or three months. Subsequently the oedema diminished, and the left leg improved again; but when she left the hospital, nearly five months after admission, the left leg was still somewhat oedematous, and was still so weak that (though she could move it freely) she was unable to stand upon it. It was supposed that the oedema was connected with some old plugging of the veins. At any rate, no disease within the abdomen that might account for it could be discovered. I may here mention that the tendon reflexes became unduly brisk.

In this case, as in the last, there is room for difference of opinion with regard to the nature of the disease. It is obvious, however, that the lesion occupied the motor region of the cord, and only a limited extent of it in the dorsal region. There was certainly no evidence of vertebral disease; there was no history of syphilis, nor was she treated for syphilis; there could not have been a tumour. Indeed, the only alternative suggestion is that there may have been sudden hæmorrhage into the substance of the cord. This explanation, however, is for many reasons unlikely.

I pass from these to the consideration of two other cases in which fatal myelitis was associated with similar affection of limited regions of the nervous organs within the skull; cases which seem to show that, just as the more chronic inflammatory condition, commonly called sclerosis, has a tendency to attack at the same time, or in sequence, different parts of the nervous centres, so the more acute form of inflammation may occasionally become disseminated. At any rate they show that inflammatory softening at first limited to the brain or cord is apt to become complicated by inflammatory softening of other parts of those organs which have no direct or apparent connection with the regions affected in the first instance.

CASE IV.—The first of these cases was published in detail in the fourth volume of the *Ophthalmological Society's Transactions* by my colleagues Dr. Sharkey and Mr. Lawford. It was that of a girl, aged 17, who was admitted into the Royal London Ophthalmic Hospital on November 22nd, 1883. She had had fairly good health up to November 9th. On that day her eyesight began to fail, and by the 13th she was quite blind. She had had neither headache, sickness, paralysis, nor fits. On admission she was well nourished but somewhat anæmic. She had slight enlargement of the thyroid body, which had existed as long as she could recollect, but her only complaint was of blindness. The pupils were dilated and inactive to light, but there was no ocular paralysis. Well marked optic neuritis was discovered in both eyes. In every other respect she seemed healthy.

She continued in the same state until December 8th, when she observed a little weakness in the left leg; this rapidly increased, so that on the 12th, when she first complained of it, she could not walk; the leg was powerless and slightly rigid; sensation was impaired in it, and the knee-jerk was excessive. On the 13th the paralysis of the left leg had advanced, and there was also slight loss of power in the right. On the 14th there was absolute loss of power in the left lower extremity, and anæsthesia extended on the same side as high as the nipple; the right leg was partially paralysed and anæsthetic, and she passed urine into the bed for the first time. In the course of the morning she had a fit lasting for about ten minutes, and unattended with unconsciousness, in which the right arm and leg were convulsed. Her tem-

perature, taken in the day, was 100.2° F., and her pulse 96. On the 15th she was emotional and excited at times, and passed her evacuations unconsciously. On this day she was removed to St. Thomas's, and placed under my care. She continued in much the same state. On the 19th, 76 ounces of urine, which were clear and acid, but offensive and containing a trace of albumen, were drawn off. On the 22nd it was noted that there was complete paralysis of both legs, loss of control over the emunctories, evident weakness of the left hand, loss of sensation, not only in the legs and over the greater part of the trunk, but likewise in the left forearm and hand on the ulnar side. The knee-jerk was excessive on the left side, normal on the right; no ankle clonus; no tendon reflexes could be obtained in the arms. On the 23rd sensation was impaired in the right forearm and hand, and she complained of pain across the lower part of the abdomen. On January 4th it was noted that the condition of the legs remained the same, that sensation was deficient in both forearms, and that the urine was offensive and contained pus. The muscles and nerves of the affected limbs were reported by Dr. Kilner to present the reactions of degeneration. The temperature, which had only been moderately raised up to December 29th, had since that date varied between 101° and 105°. There was also much epigastric pain. Little alteration occurred during the next few days, excepting that the presence of peritonitis became evident, and a slight double external squint was noticed. She died on January 10th, sixty-two days from the time when her vision first failed, and twenty-nine after the first appearance of symptoms of paralysis.

Necropsy.—There was acute peritonitis, due to extension of inflammation from the bladder, the mucous membrane of which was intensely inflamed. The inflammation had extended all along the ureters to the pelvis and substance of the kidneys. The thyroid gland was considerably enlarged. The brain and contents of the skull generally to the naked eye appeared to be absolutely healthy; but microscopic examination showed that there was intense inflammation of the optic discs, nerves, commissure, and in a less degree of the optic tracts; and that slight evidences of inflammation were present in the meninges about the chiasma and on the adjacent surface of the frontal lobes. The spinal cord presented no abnormal appearances, except over a space two or three inches in length in the lower cervical and upper dorsal regions; there it was intensely congested and much softened. The microscopic appearances of the affected region confirmed the opinion that the changes were due to inflammation. In the cervical cord above the seat of obvious disease, inflammatory changes were observed extending along the columns of Goll; and, again, in the lumbar enlargement the columns of Goll were alone affected, the nerve-fibres having undergone complete granular degeneration, and some of the vessels being crowded with leucocytes. The other parts of the cord appeared to be healthy.

CASE V.—The next case was sent into the hospital on December 28th, 1886, by Dr. Bower, of Peckham Rye, and placed under my care. The patient was a labour master at the Camberwell Workhouse, aged 24. In 1883 he had had syphilis, followed by slight secondaries, but in other respects seems to have been healthy until last September, when he began to complain of occasional lumbar pain, aggravated by exercise. This, which did not prevent him from working, continued without much change up to eight weeks ago, when it became more severe, extended up the back as high as the shoulders, and outwards into the hips. He was now compelled to take to his bed, and from about this time he gradually lost power over his lower extremities and control over his rectum and bladder.

He was a well-built but pale and spare man, with an anxious expression of face, and complaining of pain at the back and front of the head, of pain in the loins extending at times to the hips, of absolute loss of motor power in the lower extremities, and of incontinence of urine. He had no voluntary power whatever over the legs, but sensation in them was perfect. The knee-jerk was absent on the right side, and feeble on the left; but the plantar reflexes were brisk, as also were the cremasteric and abdominal. No other nervous affection was present, and the pupils acted to light and accommodation. He had no tenderness or curvature in the spine, and there was no evidence of tumour anywhere. The urine was alkaline and ammoniacal, and there was a small bed-sore. His thoracic and abdominal organs appeared to be healthy.

No improvement whatever took place after admission. On the contrary, the symptoms underwent gradual aggravation; the paralytic affection of his lower extremities increased; the bed-

sores extended in area and depth; the bladder (varying a little from time to time) continued inflamed; he lost flesh and strength; and he suffered so much and so constantly from pain in the loins, hips, and back of the thighs, that (although no tumour could be felt) it led me to suspect that he was suffering from malignant disease about the lumbar vertebræ—a suspicion which I entertained to the last.

On January 6th it was noted that sensation had become impaired in the left lower extremity, as high as the knee in front and the buttock behind, that both knee-jerks were now absent, as also the cremasteric and lower abdominal reflexes. Early in February it was observed that his legs were apt to become stiff and drawn up involuntarily; but, excepting that he was weaker and more emaciated, no change of importance had taken place. The plantar reflexes were present, but feeble.

During the afternoon of February 4th it was found that the patient had almost suddenly lost the use of his left arm; he could not lift it from the bed. He had no power of flexion at the elbow, and very little power of flexion or extension at the wrist or finger-joints. The hand felt numb, but there was no discernible anaesthesia. The elbow-jerk was diminished on this side. No pain, giddiness, or fit of any kind attended or had preceded this paralytic attack. On the 6th the loss of power in the arm (which was kept rigidly extended) was absolute, but there was still no anaesthesia in it; also the tongue was protruded to the left, and there was some weakness of the lower part of the left side of the face. These facts were important, for they showed that the paralysis of the arm was not spinal, as had been at first suspected, but cerebral. About this time it was noted that painful impressions made on the left leg were referred by the patient to the right leg; but he was apathetic, and always disinclined to concentrate attention or to answer.

Very little further change occurred. A day or two after the last observation was made the paralysis seemed to have disappeared from the face and tongue, and the patient was able to move his thumb and fingers slightly; but shortly afterwards the weakness of the lower part of the face and tongue had returned. His bed-sore, which had improved, began to extend; his urine was ammoniacal, loaded withropy mucus, and highly offensive; he grew more and more apathetic and drowsy, though still wearing the aspect of much suffering; his pulse became rapid, he perspired profusely, and evidently the end was fast approaching. He died at noon on February 18th, his death being preceded by drowsiness, profuse sweating, great rapidity of pulse, and rising temperature. This had varied for the most part since admission between 97° and 101°, but on the evening of the 15th it rose to 102°; during the 16th and 18th it varied between 98° and 100.4°; at 6 A.M. on the 18th had risen to 105.6°, at 10.30 to 107.6°, and immediately after death was found to be 109.4°.

It need only be stated, as respects treatment, that having regard to his syphilitic history he was put on a course of iodide of potassium and mercury, that morphine was employed to relieve his distress, and that his bladder was systematically emptied and washed out with antiseptic solutions.

Necropsy.—The body was much emaciated, and there was a long and deep bed-sore over the sacrum. There were no syphilitic lesions anywhere, and, with the exceptions to which special attention will be drawn, the viscera were healthy. Membranes of brain healthy. A few patches of thickening were observed in the arteries at the base of the brain, but the vessels were all pervious. In the centre of the right centrum ovale minus was a patch of yellow softening, in which were a few small haemorrhages. It was oval, about three-quarters of an inch in its long diameter, and only a few lines thick. Another patch of softening, about the same size as the last, and also on the right side, involved the posterior third of the lenticulo-striate portion of the internal capsule, and the contiguous parts of the caudate and lenticular nuclei. The two patches were quite independent of one another. In all other respects the brain was healthy.

Membranes of cord healthy. From the tenth dorsal vertebra downwards the cord was extremely soft, in fact almost diffident. The grey and white matter could scarcely be distinguished in the lumbar region. To the naked eye all other parts of the cord seemed healthy.

There was no disease of the bones of the skull or spine.

The bladder was inflamed; the ureters and pelvis of the kidneys were dilated and inflamed, and the substance of the kidneys was congested, and presented a few minute abscesses.

The last case I shall quote is one concerning the nature of

which there may reasonably be, as in regard to my third case, some difference of opinion. On the whole I believe the case to have been one of myelitis; and partly for this reason, but more on account of its clinical interest, venture to include it in the present paper.

CASE VI.—W. J., a carpenter, aged 27, was admitted under my care on March 25th, 1886. His health had been excellent, but he said that he had had local venereal sores, though never secondary symptoms. In the previous November, he was struck in the right flank by a lift, which came down suddenly upon him, and squeezed him against a table over which he was leaning. He was laid up for nearly six weeks, not on account of any spinal symptoms, but mainly because of pain and swelling of the right knee. At the end of that time, though still weak, he resumed his work. His present illness dated from early in January, when he began to suffer from pain in the part of the back where he had been struck. This was followed by numbness and weakness in the left foot, which, in the course of a day or two, extended up to the knee. A fortnight later he began to lose feeling in the right leg. The anæsthesia in his right leg and the loss of muscular power in his left had progressively increased, but he had never had incontinence of urine or feces.

State on Admission.—A healthy-looking, well-developed man. He had complete anæsthesia and analgesia of the right lower extremity and right side of the trunk, as high as the sixth rib in front and tenth dorsal vertebra behind. There was also a belt of anæsthesia and analgesia, about four inches wide, encircling the left half of the trunk, the upper level of which corresponded to the upper level of the anæsthesia on the right side. There was no impairment of sensation on the left side, excepting in the belt above described. There was considerable loss of power in the left lower extremity. He could move all parts of it in all directions, but the movements were very feeble, and could be arrested by the finger. The right leg, he said, was as strong as ever it had been, and it appeared to be normally powerful. He could walk when supported on the left side, but he moved his left leg feebly, and, at the same time, its movements were ataxic. The superficial reflexes were much exaggerated on the right side; brisk, but normal, on the left side. On the right side the tendon reflexes were feeble, but on the left they were excessive, and there were both ankle- and knee-clonus. Moreover, the testing for reflexes in the left leg brought on violent tremors in it, lasting for some time. The abdominal reflex was absent on both sides. There was no loss of control over the rectum or bladder, and no bed-sores, and no affection whatever of arms, head or neck, or organs of sense. There was no pain, tenderness, or curvature in the course of the spine.

It is needless to give details as to the progress of this case. It is sufficient to say that the account above given was fully confirmed by repeated observation; that he complained for some time of more or less uneasiness, pain, and sense of constriction about the loins and upper part of the abdomen; that gradually, in the course of months, sensation returned in great measure to the anæsthetic regions, and the left leg regained power; that after a while (although still the tendon reflexes remained more brisk on the one side, and the superficial reflexes more brisk on the other), the superficial reflexes became nearly equal on the two sides, while some excess of knee-jerk and ankle-clonus became developed on the right side; that delayed sensation was observed on the anæsthetic side as sensibility returned; that no evidence of spinal disease, or of tumour, or of extension of nervous lesion ever appeared; that his muscles had not wasted, and his general health remained good; and that, when he left the hospital on August 11th, although much improved, sensation on the right side was not restored absolutely, and his left leg was so weak that he could only walk with the aid of two sticks. But improvement was still in progress.

For a time the patient was treated (in the hope that his disease was syphilitic) with iodide of potassium and mercury; also an issue was made near the spine, in the neighbourhood of the part on which the blow had been inflicted; and, latterly, the constant current was applied systematically.

In introducing this case I said that there was room for difference of opinion in regard to diagnosis. The accident to which he naturally attributed his paralysis occurred eight or nine weeks before the onset of paralytic symptoms, and, although he was laid up after it for six weeks, this was mainly, if not solely, due to the injured knee; moreover, the blow he received from the lift was on the right side just above the crest of the ileum, and did not involve the spine at all. I was disposed to think at one time that

he had vertebral caries; nor can I be sure that this was not the case, for I have not infrequently known paraplegia to be due to vertebral caries, when there has been not only no spinal curvature, but no pain or tenderness whatever. But there was no direct evidence of caries, and the fact that he continued to improve, although allowed to get up, is opposed to this explanation. Whether the disease was syphilitic remains an open question. The patient seems to have had syphilis, but had never presented any signs of secondary or tertiary disease. The belief that the symptoms were due to inflammatory softening of the cord—which, on the whole, is the view of the nature of the case which I am now disposed to adopt—is not, of course, incompatible with the syphilitic origin of the disease. The case is the most striking example I have ever seen of the limitation, in disease of the cord, of anæsthesia to one side of the body and of motor paralysis to the other side. It is clear that the lesion, whatever it was, involved only a short length of the left half of the mid-dorsal region of the cord.

I have little to add by way of comment on the above series of cases. There are a few points, however, which they seem to illustrate, and to which I may direct attention. In the first place, they show how widely cases of myelitis may differ from one another in degree of intensity and prospect of recovery. In the second place, they show that the inflammation may attack any region of the cord and any extent of it; and that the lesion may be multiple, and (as in disseminated sclerosis) affect at the same time or in sequence different parts, not only of the cord, but of the cord and brain. And, in the third place, they seem to show that, while in some cases the affection comes on immediately after its apparent cause, and rapidly attains its full development, in other cases its onset is insidious and its course progressive.

That myelitis is often attributed to exposure to cold or wet, or to both, is undoubted, and some of my cases are typical examples of this fact. It is probably in such cases that the onset is sudden, and the affection of the cord attains its highest point in a short time; but in some cases there is no evidence that temperature or allied conditions have had any causative relation to the attack. In my last three cases no such explanation was suggested. In two of them there was a history of syphilis, but there is no sufficient reason to assume that in either of them syphilis was the cause of the myelitis. In one of these two the patient had received an injury, but so long an interval had elapsed between the accident and the coming on of paraplegia, that it seems scarcely likely that this was the actual cause. In the remaining case, that of the girl of 17, there was no hint of syphilis or injury, and the girl had been a healthy girl up to the very moment at which failing sight gave the first indication of cerebral mischief. In her case, as also in my fifth case, the disease was prolonged and rendered fatal by secondary extension or dissemination of softening; but this extension would seem to imply the persistence and widening operation of the cause on which the primary lesion itself depended, and would suggest, therefore, either the presence of infective organisms or some constitutional defect, such as tendency (from whatever cause) to obstructive disease of small arteries, and consequent nutritive changes in the part to which the obstructed vessels are distributed. I am inclined, arguing from the facts of certain cases of softening of the pons Varolii and other parts of the brain which I have met with, and some of which I have published, to believe that in many cases of softening of the cord the softening is immediately due to obstruction (thrombotic or other) of the smaller arteries. And I may point out that the strict limitation of the lesion to the lateral half of the cord, as occurred in my last case, is best explained by this hypothesis. Such obstructions, as I have already hinted, might of course be syphilitic.

THE CONTAGIOUSNESS OF LEPROSY.—The Rev. Canon Baker, of Cape Town, to whom we are indebted for an interesting pamphlet—*Remarks on the Spread of Leprosy at the Cape of Good Hope*—writes to us, expressing his belief in the contagiousness of leprosy, and mentions a remarkable circumstance as being within his own knowledge, namely, that in a certain house three consecutive cases of this disease occurred in individuals not connected by consanguinity or marriage.

DONATIONS.—Mr. J. C. Burton Borough, of Chetwynd Park, has given £200 to the Salop Infirmary, Shrewsbury, in lieu of an intended legacy.—Lord Robartes has given a hundred guineas, and the Rev. J. Harvey £50, to the North London Hospital for Consumption.

ABSTRACT OF
THE CROONIAN LECTURES
ON
ANTI-PYRETICS.

Delivered before the Royal College of Physicians, June, 1888.

By DONALD MAC ALISTER, M.A., M.D., F.R.C.P.,
Fellow and Lecturer of St. John's College, Cambridge.

LECTURE II.

IN the first lecture the anatomy and physiology of the thermal nervous system was dealt with, in order, among other things, to show that, in the minds of those who are most actively engaged in experimental inquiry, the conviction of its existence is a guiding principle, and no longer a plausible speculation only. Without a sufficient belief in the definite character of the apparatus of thermal nerves and centres, some of what was about to follow would appear more theoretical than it really was.

In the second lecture, partly by way of relief, certain questions would be discussed connected with what might be termed the teleological pathology of pyrexia. It was admitted that fever is a sign of disorder, of disturbance, of a physiological function or functions. But in all ages some had maintained, and the proposition was now being revived, that this disorder is not wholly or not in itself injurious. It was regarded as a wholesome reaction against a *materies morbi*, a manifestation of the *vis medicatrix*. Cohnheim had asked: "What is the deeper meaning, the true significance underlying the febrile process? Does the organism gain any advantage from the rise of temperature which characterises pyrexia?" He had answered that it might plausibly be maintained that in febrile heat we should recognise a sanative power, by which the body consumed and destroyed a virus it could not directly eliminate. From a practical point of view it might be more urgent to appraise the dangers which menace the body in fever, and, before a conclusion was reached, it would be necessary to distinguish with certainty and precision between the parts played by the specific febrile disease and the disorder of the body-heat which accompanied it. "But," added Cohnheim, "when that time comes, I anticipate that physicians will more and more regard fever, not, indeed, as a condition free from danger, but as, on the whole, a wise provision of Nature."

Hilton Fagge was inclined to take a like view, but had given few reasons other than those based on a possible explanation of the phenomena of relapsing fever and ague. It would be well to examine more closely the grounds of this view that fever serves a salutary purpose.

After the long prevalence, especially on the Continent, of the idea that the dangers of fever are primarily due to the high temperature, and that to reduce the latter is the chief end of treatment, the reaction is remarkable. It was due, to some extent, to disappointment with the effects of vigorous antipyretic treatment, external and internal, on the course of the specific fevers. Expectations had been exaggerated because based on a one-sided theory, and they had not been fulfilled.

Another factor in the reaction was the growth of the germ-theory. The thesis of those who extended their bacteriological speculations to fever appeared to be—the specific fevers are due to the intrusion into the body of certain specific living cells or microphytes. These engage in a struggle for subsistence with the tissue-cells of the body. Pyrexia is a reaction brought about, by natural selection, to favour the latter in the struggle, and to hamper or disable the former. The result is, or should be, that the microphytes are overcome, consumed, and thus through fever the body is restored to health.

It was true that some of the best known microphytes were checked in their growth or multiplication by high temperatures. Gaffky showed that typhoid bacilli formed spores with difficulty at 107.5° F.; Koch, that tubercle bacilli ceased to grow after being kept for some weeks at a like temperature. The bacillus anthracis continues to grow, but loses in virulence if kept for some weeks at 108.5° F., or for some days at 109.5° F. Surely it could not be held that such facts were really relevant. A body-temperature of 107° to 109°, kept up for days or weeks, was too

powerful a remedy. The body would be consumed before its parasite.

A less direct explanation was suggested in a recent lecture by Von Ziemssen, namely, that the pyrexia so alters the constitution of the tissues, that the microphytes no longer find in them a suitable soil and so perish. But against this was the fact that the exanthemata tended strongly to run a definite course, whether the fever were high or low. The gravity of the infection stood in no proportion to the less or greater intensity of the pyrexia. Rather was it the case that the highest fevers were the most enduring, the slighter forms the briefest.

The cases cited by Hilton Fagge, by Murri, by Finkler and others, in which the febrile paroxysm seemed to have a destructive effect on the living virus of relapsing and of intermittent fevers were then discussed, and were shown to admit of a simpler explanation, one applicable to all the specific diseases attributed to microparasites. These parasites seem, like other living creatures, to have a definite life-period, in which they grow, multiply, exert their special action, and decay. This period is independent of pyrexia, independent of antipyretic treatment, independent of external conditions. The definite duration of its virulence in typhus, measles, small-pox, etc., the sudden extinction of its vitality at the crisis in croupous pneumonia bespoke a normal biological property in the virus, a law of its life which forbade it to endure longer than a certain time.

It had shrewdly been asked (by Goldscheider): If pyrexial temperatures are not in themselves dangerous, but merely serve to purify the body without injuring it, why are they in ordinary cases confined within such narrow limits? If fever be a process with a purpose, would it not be better to nip the growth of the microphyte in the bud by a prompt and intense rise of temperature at the beginning of the illness?

In concluding this part of the argument, the lecturer asked a question of those who relied on the all-embracing doctrine of evolution, and argued that so universal a symptom as fever following on bacterial invasion could only, in the course of ages, be developed if it conveyed some advantage in the struggle for existence. Were not the bacterial plants also engaged in a like struggle? Had they not, too, in the course of ages, acquired properties which helped them to grow and multiply? Might not the fever they induced be salutary—to the bacteria? He laid no stress on such an argument, but adduced it to show that the reasoning of the germ-theorists on fever was two-edged, and could be turned against themselves.

A general fallacy underlay many speculations of this kind. In speaking of fever generally, of its treatment, of antipyretics and antipyresis, the febrile process had been too much regarded as a single entity. There were many morbid processes having fever as a concomitant; some one or other of these was studied, and the laws arrived at for its causation, pathology, and treatment were too hastily generalised, so as to apply to other and widely different morbid processes. If we were to admit it possible that, in relapsing fever and in ague, the pyrexial attack conveyed some benefit, it would be rash to infer at once that all pyrexia is beneficial, and apply the law to cover acute rheumatism or septicæmia. In fact, fever was at best a symptom, and a symptom whose significance was very different in different cases. Parallel illustrations from the phenomena of cough and of pain were given. The only sound therapeutic method was to study the particular circumstances in which the symptom arose. Yet there were two extreme schools—one insisting that all pyrexia is dangerous, and that high temperature must be lowered at any cost; the other, whose headquarters were at Vienna, maintaining that, as fever is salutary, it should not be meddled with—the school of pure expectancy.

The postulate of the latter had been dealt with; it was worth while to examine the postulate of the former: that high temperature is purely mischievous, and the efficient cause of all the dangers that threaten a fever-patient's life. Dr. Cayley, in a previous course of Croonian Lectures (1880), had dealt with this question in a masterly way, and his conclusions were quoted. He thought it decisively proved that the view in question was only in part correct, and that many of the morbid phenomena accompanying fever occurred independently of it. The lecturer would not go over the same ground, but adduced new considerations, bearing out and strengthening Dr. Cayley's conclusions. In the first place, he referred to his Gulstonian lectures in illustration of the point that "high temperature" was an ambiguous term, and might or might not connote pyrexia. The temperature might be raised in various ways, some of them harmless. In thermal ataxia,

in disordered thermolysis without other change, the temperature might rise and remain high. But there was good ground for the belief that such non-pyrexial elevation of temperature was not in itself dangerous. Take, for example, the cases of aseptic operation, described by Volkmann and other surgeons, in which a temperature of 104° or 105° was accompanied by no loss of appetite, no distress, no symptom such as could be called characteristically febrile.

Many of the current beliefs as to the beneficial effects, functional and textural, of mere high temperature were based on experiments in which animals were forcibly overheated. These experiments were examined critically, and in the light of fresh researches, such as those of Naunyn, and Welch of Baltimore, shown to be capable of other interpretation. With due precautions, such animals could be kept in comfort and without permanent damage for days or weeks, their rectal temperature being, on the average, 106° F. Danger did not arise till a much higher point was reached; and then the evidence proved that the overstrain on the thermal system broke down the regulating mechanism, and complete thermal dissolution or hyperpyrexia set in.

The phenomena of relapsing fever were adduced as bearing in the same direction. In this disease, the subjects of which were often weak and anæmic, temperatures of 107°, enduring for five or six days, were common, and were tolerated well, as was shown by, among other things, the small mortality (4 or 5 per cent.).

The conclusion ultimately reached was: That high temperature in itself was not proven to be salutary, neither was it in itself the efficient cause of all the morbid phenomena commonly described as febrile.

ON RARE DISEASES AND EXCEPTIONAL SYMPTOMS.

By JONATHAN HUTCHINSON, F.R.C.S., F.R.S., LL.D.,
Emeritus Professor of Surgery at the London Hospital.

(Continued from page 1112.)

XXXIII.—ON THE SIMULATION OF OBSTRUCTION OF THE BOWELS BY ATTACKS OF GALL-STONE COLIC.

At the Association Meeting at Brighton, Dr. Ord gave a valuable address on some of the rarer symptoms produced by gall-stones. The diagnosis of hepatic (or cystic) colic is of much interest for surgeons, on account of the frequency with which the passage of a gall-stone simulates abdominal obstruction. I am not thinking of cases of real obstruction by the impaction of a gall-stone in the bowel, but of cases in which constipation and vomiting are due to a stone of small size impacted in the neck of the gall-bladder or its duct. I can fully support Dr. Ord's statement that attacks of gall-stone are often not attended by jaundice. I well remember many years ago meeting two physicians, together with the family surgeon, at the bedside of a gentleman who was supposed to be the subject of acute internal strangulation. There had been much vomiting, and forty-eight hours constipation. The way in which the pain had begun, and the patient's distinct reference of it to the region of the gall-bladder, with other symptoms, made me think that it must be a case of gall-stone. On expressing that opinion I was met by the rejoinder that there was no jaundice. The discussion was vigorous, and the family surgeon, taking the matter up warmly, had the motions carefully strained, with the result that three days afterwards a gall-stone as big as a horse-bean came away. Dr. Ord states that gall-stones are often present, and may even pass into the bowel, without there ever having been present any of the symptoms usually supposed to indicate them. If by this statement is meant only the absence of severe attacks of colic with vomiting and jaundice, then I can quite agree with it. I believe, however, that almost always minor attacks of pain, more or less sudden, such as are often called "spasm of the stomach," have been present. It is difficult to accept the statement that gall-stones may leave their location and escape by the bowel, there having been from first to last no symptoms of their presence. Hepatic colic is a far more common event than it is generally supposed to be, and many cases escape recognition because there is a general belief that jaundice ought to be present.

We are indebted to Dr. Ord for showing that this symptom may be wholly absent, even in severe cases and where the stone is large. With Dr. Ord's second proposition I can also fully agree. It is

that gall-stones, far too big to pass through the common duct, and which can, therefore, only get into the bowel by the formation of an ulcer of communication, do escape by that process without producing any very severe symptoms, either general or local.

I have several times known stones of very large size, big enough to quite plug the bowel for a time, to be got rid of by patients who had never been seriously ill. I do not say that they had never had tenderness over the part, nor that slight paroxysms had been wholly absent, but these had been so unimportant as to attract but little notice. In cases in which in reference to proposed operative measures it is necessary for the surgeon to diagnose as to gall-stones, it is of great importance to take cognisance of these slight attacks of colic. They may have been very transitory, but if they have been present they count for much in helping us to an opinion.

The use of anæsthetics to full insensibility, kept up for a long time, and both preceded and followed by opiates, is, I suppose, the best treatment for all forms of gall-stone colic. It does not matter whether the stone is impacted in the common duct or in the bowel, we can scarcely do better than prevent spasm and favour relaxation of the parts concerned. By these measures I have, in several cases in which I had been called in with a view to operation, succeeded in quite removing symptoms which were very urgent.

It is of interest to know that attacks referred to stomach disorder from indigestible food are often really hepatic colic due to the presence of gall-stones. By the patient I have no doubt that this mistake is constantly made, and the surgeon must be cautious of taking the lead suggested. A gentleman was liable to attacks of pain which he referred exactly to the site of the gall-bladder, but which, he said, were produced by certain articles of food, such as carrots, broad beans, etc. The pain, he said, was often terribly severe, and might last a whole night, and even on one recent occasion for three days. It always left a sense of soreness over the whole region. He had never had jaundice. I told him that, in spite of his impressions as to the influence of food, I had no doubt that his attacks were due to gall-stones. He corroborated my diagnosis by at once telling me that his father and a sister were known to have voided them.

XXXIV.—ON THE ACUTE BRONCHOCELE OF ADOLESCENTS. AN AUNT AND NEPHEW AFFECTED AT CORRESPONDING AGES. COMPLETE RECOVERY OF THE FORMER.

There is a variety of bronchocele which, as far as my experience has gone, is almost peculiar to adolescents, which increases very rapidly, and is sometimes attended by urgent symptoms of tracheal compression. It is worth study as a form of constitutional disease, and the following narrative affords two good examples of it.

M. P., aged 18, was brought to me by Dr. Greenwood, of Dalston, for a very large, soft bronchocele which embraced the whole front of his neck and was already causing some difficulty of breathing. He did not know how long it had existed, but thought that it had been there only a few weeks. He was a tall lad, of rather dark complexion. His pulse was soft, and his hands chilly and rather dusky. He considered himself in good health, and there were no indications of Graves's disease excepting a certain degree of irritability of the heart. I inquired carefully as to family history, and was told, that the disease had never occurred in the family before, and that none of his predecessors had lived in Derbyshire. A month later M. P.'s mother came with him, and I then got a fresh fact as to the family history. She said that her eldest sister had, when about our patient's age, suffered from an exactly similar affection to that which her son now had. This sister was now 60 years of age, very thin, but in tolerably good health. When adolescent she was much out of health, and was for two years under treatment for "Derbyshire neck." The bronchocele at length entirely disappeared, and at the present time her neck is thin rather than otherwise. No other relative was known to have had bronchocele, but my patient's mother, who was a very intelligent woman, said that it was the rule with all her relatives to be delicate from the ages of 16 to 25; several had been seriously ill, and two or three had died (of phthisis?). Those who survived became stronger as years advanced.

XXXV.—OPHTHALMOPLÉGIA EXTERNA WITHOUT ASSIGNABLE CAUSE.

The late Dr. Moxon was kind enough to send to me a very in-

interesting example of ophthalmoplegia externa, for which no cause could be assigned. The patient was a florid, healthy-looking lady, aged 33. Her features, teeth, and complexion were as far as possible removed from those suggestive of inherited syphilis. She was single, and there was not the slightest reason for suspecting that she had ever suffered from the acquired disease. Her father came with her, and in answer to a direct question assured me that he had never had any suspicious disease. He had a large, healthy family.

Miss ———'s symptoms were remarkable for their symmetry and evenness. Both eyelids drooped so as to almost cover the pupils. She could move both eyeballs a very little in all directions and almost equally in all. It was exceedingly little. I could not detect any squint, and she had seldom or never been troubled with diplopia. A very remarkable point was that her pupils acted fairly well, and that she could still use her accommodation. Her pupils were of normal size and equal. As she was myopic there was a fallacy as to the accommodation, but with glasses which enabled her to see well in the distance she could still see to read. I had not time to test this in detail. She was accustomed to read a good deal, and was able to see downwards well in spite of the drooping lids. Two photographs produced showed that the ptosis was commencing three years ago, and that it was quite absent ten years ago. She believed that from girlhood she had been accustomed to turn her head when others would turn their eyes. It had been, she said, a matter of remark by her companions. Her father did not, however, know anything of this.

Miss ——— had no other symptoms of nervous disorder. Dr. Moxon informed me that her knee-jump was good. She had never had any lightning pains. The only ailment which she would confess to was occasional very severe headaches. To these she had been liable from childhood, and was sometimes laid up for a day by them.

I do not think that I have ever seen a syphilitic case of ophthalmoplegia externa in which the symptoms were so regular. Almost always one or more of the ocular muscles escapes paralysis to a large extent.

(I know nothing as to the sequel of this case. I never saw one quite like it, and should be very glad to know the result if any of my readers can give the information.)

XXXVI.—DIPHTHERITIC PARALYSIS OF ACCOMMODATION AFTER A SORE THROAT SO SLIGHT THAT IT HAD BEEN FORGOTTEN.

I believe that it is well known that paralysis of the muscle of accommodation, such as is usually described as "diphtheritic," may occur after very slight forms of sore throat. I have myself seen and recorded several such cases, in which the sore throat had been so slight and transitory that it had been forgotten, and one such is at present under my observation. A healthy-looking girl ten years old was brought to me on account of failure of sight, which I at once found to be paralysis of accommodation. I inquired as to the sore throat, and was told by her mother that the child had not been ill in any way. At the second visit, however, two facts were remembered which had been at first forgotten. One month before coming to me the child had been in company with a little boy who had been suffering from a bad sore throat, and some time ago had had diphtheria. Three weeks prior to this, however, the child herself, while staying at Sandown, had had a three days' sore throat; it had not been bad enough to necessitate medical advice. Such were the very trivial, but I have no doubt really important, facts. The child, under treatment, recovered perfectly in about three weeks, and had no other symptoms of paralysis. I cannot doubt that the failure of sight was of the nature of diphtheritic paralysis. Does the case prove that true diphtheria may occasionally be so slight as to be overlooked, and yet be efficient to the production of paralysis as a sequela? This is my own belief, and it seems to me to establish a very important fact with reference to the natural history of the disease. I believe that it is generally acknowledged that the severity of diphtheritic paralysis is not usually in ratio with the severity of the throat affection. I have never, however, myself seen general paralysis after a slight form of sore throat like that described above; but, on the other hand, I have seen many in which the eye only, or the eye and palate only, have been affected.

NOTES ON THREE YEARS' OVARIOTOMY WORK IN THE SAMARITAN FREE HOSPITAL: EIGHTY-TWO CASES WITHOUT A DEATH.

By GEORGE GRANVILLE BANTOCK, M.D., F.R.C.S.ED.,
Surgeon to the Samaritan Free Hospital.

On March 21st, 1885, a widow, aged 56, the mother of seven children, was admitted under my care into the Samaritan Free Hospital. She was very thin, and had lost flesh rapidly of late. The abdomen was considerably distended; and this distension, added to some chronic bronchitis, caused difficulty of breathing and a troublesome cough. On the evening of admission the temperature was 99.4°, and was probably due to the mechanical irritation of the numerous adhesions which were subsequently found. With the view of relieving the breathing and cough, and of giving the patient some sleep by enabling her to lie down, I removed twelve pints and a half of a dark-coloured fluid by aspiration on the 23rd, and on April 1st I performed double ovariectomy, removing a tumour of the right ovary weighing thirteen pounds, and the left ovary, which was as large as a hen's egg. The pedicle was twisted until its vessels were strangulated, and subsequent or consequent hæmorrhage into the large cyst accounted for the dark colour of its contents. There were very extensive adhesions involving the parietes wherever the tumour came into contact with them, the omentum, uterus, and other pelvic structures, and about two feet of small intestine with its mesentery. About twenty ligatures were applied to bleeding points in omentum, mesentery, intestine, back of uterus, and in the parietes, where the bleeding points were so numerous, and the difficulty of applying ligatures or even pressure forceps so great, that I was induced to try the thermo-cautery of Paquelin, but without success. Finally, I washed out the peritoneal cavity with warm water, inserted a drainage-tube, and closed the wound. After the operation there was an aggravation of the bronchial symptoms and cough, and the patient died on the sixth day. *Post-mortem* examination revealed some peritonitis and extensive pulmonary congestion. I may remark that the operation lasted an hour and a half, and it will be gathered from the foregoing that the case was altogether a desperate one and gave little hope of a successful result.

From the middle of April, 1885, to the corresponding date this year I have performed 82 ovariectomies in the Samaritan Free Hospital, and all the patients have recovered.

On the whole the cases have been of a rather severe character, as the following details will show. Thus, in more than one-half—47—there were adhesions properly so called; in small proportion the adhesions involved the parietes only or omentum only; in large proportion both these structures were involved at the same time; in considerable number the tumour was adherent to the pelvic organs to a varying extent, and in a few instances to the intestines also. In one of parietal adhesions only the patient had just completed seven months of her first pregnancy, in the course of which she had been twice tapped. (This case was published in the JOURNAL, February 11th, 1888, p. 296.)

Excluding all these cases of adhesions proper, there were 6 cases in which there was no pedicle, and the tumour had to be enucleated. In one of these the cyst was in a state of suppuration; in another nine stout ligatures were required to arrest the bleeding from the torn structures left after removal of a tumour involving the left broad ligament and left side of the uterus, and in the last case of this kind operated upon, the last but one of this series, the operation was so severe that when the patient was put into bed, the pulse could scarcely be counted at the wrist. In yet another the tumour apparently involved both ovaries, and when the enucleation was completed the uterus was so bereft of support, in addition to being extensively injured, that I was compelled to remove it also at the level of the internal os in my usual way.

Thus, of the 82 cases there were adhesions or their equivalent in about two-thirds or 54, leaving 28 in which there were no adhesions and there was a pedicle capable of being treated by ligatures. In one of these 28 cases there was a serious complication in the form of a large umbilical hernia, measuring over 4 inches across. After removing an ovarian tumour of ten pounds (right side), I slit open the hernial sac by continuing the abdominal incision, applied several ligatures to, divided the adherent omen-

PRESENTATION.—Dr. Walter Kent has been presented with a valuable medical chest and an illuminated address by his friends and patients, on leaving Biddulph, Staffordshire, for America.

tum, and then dissected off the peritoneum from the various pouches, cutting away the redundant and thinned skin and peritoneum. In closing the wound I first brought the peritoneal edges together in the region of the hernia by closely applied silk-worm gut sutures, of which the ends were cut off short, and then the skin and intervening tissues by deep sutures running along under the raw surface, and not going through the peritoneum. The remainder of the wound, in which the fatty layer measured nearly two inches in depth, midway between the umbilicus and pubes, was closed in the usual way. Convalescence was uninterrupted, and the hernial sac was completely obliterated.

As further evidence of the severity of the cases I may point out that the drainage-tube was used in more than one-half, or 45, and in these, with few exceptions, the peritoneum was washed out with warm water.

In 34 cases the second ovary was more or less diseased, and was accordingly removed. It is sometimes very difficult to decide whether the ovary is sufficiently diseased to justify its removal. In a large majority of the cases there was no difficulty whatever, and a very recent case induces me to believe that I shall find less difficulty in the future by requiring less distinct evidence than hitherto. I removed an ovarian tumour of 9½ lbs. eleven years ago. The other (left) ovary appeared to be quite healthy, and this view may be said to have been confirmed by the fact that within two years the patient gave birth to twins (one of each sex). But there is pretty conclusive evidence that it did not long remain healthy, for there is a history of gradual increase in the size of the abdomen for several years, and I have recently removed this second ovary, forming a tumour of 18 lbs. In this instance I was asked why I had not removed the second ovary at the first operation.

In all there were 9 cases of dermoid tumours, and in one of these both ovaries were diseased, the one containing skin and hair, and the other containing teeth. This is the second instance of double dermoid disease I have seen. The other was a private case. In only 4 of these cases were there adhesions; the remaining 5 were free, though in one the pedicle was twisted. The absence of adhesions in this instance was to be explained by the fact that the circulation through the pedicle had not been sufficiently interfered with to set up degenerative changes in the tumours.

In 8 cases the pedicle was twisted, and 3 of these belonged to the dermoid variety. In all but one there were more or less extensive adhesions, and in these 7 the peritoneum was washed out and drained.

There were 5 cases of ruptured cyst, in all of which the whole peritoneal cavity was thoroughly washed out and a drainage-tube was used.

In 3 cases the disease was malignant, and in 2 of these the malignancy was recognised at the time of the operation. In the first case the patient died in about fourteen months with extensively disseminated cancer. In the second the patient made a rapid and uninterrupted recovery, leaving the hospital on the twentieth day. In a few weeks more a small tumour formed in the region of the pedicle, painful and tender, without any rise of temperature or increase of pulse, and accompanied with rapid emaciation, and she died on July 6th. In the third case there was great œdema of the lower extremities, gastric irritation with frequent vomiting, and considerable distension of the abdomen by free fluid. At the operation twenty-five pints of free fluid were removed together with a sarcoma of the left ovary weighing 6 lbs., and another of the right ovary weighing about ¾ lb., and the pelvic and lumbar glands were already infected. The peritoneum was well washed out and drained, and she recovered without a bad symptom. The disease, however, made rapid progress, though there was no more ascites; the gastric irritation, relieved by the operation, returned in a few weeks along with the œdema of the lower extremities, and she died in seven weeks.

All these 82 operations were done without the use of any so-called antiseptic substance. Warm water—not specially prepared—was freely employed in washing out the peritoneal cavity whenever the contents of the cyst had escaped into it, either by spontaneous rupture before operation, or when, through the breaking down of extensive adhesions, there was any effusion of blood and serum amongst the intestines, rendering the "toilet of the peritoneum" very difficult by any other method. In all these cases the drainage-tube was also employed. In not one single instance was any opium or alcohol administered.

In the year 1882 a comparison was instituted between the results obtained in the Samaritan Free Hospital under the Listerian

and non-Listerian methods, the latter being wholly confined to my practice. That comparison was very much to my disadvantage, and deductions were drawn which even the results of the following year tended to upset, and which those of succeeding years have actually tended to reverse. Again, that comparison was made on the results of only one year. A comparison of results extending over several years will be a more reliable guide, and I now present those for the three years 1885, 1886, and 1887, in the following tables:

Dr. Bantock's Cases.			Listerian Cases (3 Operators).		
Total.	Recovered.	Died.	Total.	Recovered.	Died.
79	78	1	121	110	11

But in September, 1887, Mr. Doran abandoned the Listerian and adopted my method of practice, and if his 3 cases be added in the one table, and subtracted in the other, the following result is obtained:

Dr. Bantock's Cases.			Listerian Cases (3 Operators).		
Total.	Recovered.	Died.	Total.	Recovered.	Died.
82	81	1	118	107	11

If, again, the results for the three years over which the preceding 82 cases extend, namely, from April, 1885, to April, 1888, be taken, the following is the result:

Dr. Bantock's Cases.			Listerian Cases.		
Total.	Recovered.	Died.	Total.	Recovered.	Died.
82	82	0	116	104	12
Plus Mr. Doran's Cases.			Minus Mr. Doran's Cases (3 in 1887 and 1 in 1888).		
Total.	Recovered.	Died.			
4	4	0			

Giving 86 cases without a death, as against 116 cases with 12 deaths, or a mortality of 10.34 per cent.

NOTES ON THREE CASES OF UTERINE FIBROIDS UNDER TREATMENT BY APOSTOLI'S ELECTRICAL METHOD.

By W. J. TIVY, F.R.C.P.E., F.R.C.S.E.,
Clifton.

CASE I.—S. W., unmarried, aged 40, consulted me first in 1884 for an abdominal swelling and metrorrhagia. She was a tall, slight, very anæmic woman; she said her abdomen had been increasing in size for two years; her menses were most profuse, lasting ten or twelve days; she suffered no pain. At this time (1884) I detected three separate, hard, solid tumours; the largest and hardest nearly filled the right side of the abdomen, was freely movable, and extended to the umbilicus; the smallest was in the centre, and on the left side was a third tumour nearly as large as the right one, and also movable. By modified diet, rest, and the use of ergot, the growth of the tumours seemed checked for a time. In 1887, however, in spite of this treatment, I found that the abdomen measured forty inches and a half in circumference, a much larger size than it had been in 1884, and that the tumours were also larger.

In October I commenced Apostoli's treatment, applying the positive pole to the interior of the uterus, which was five inches in depth. By using at first twenty cells of Coxeter's battery I obtained eighty milliamperes; little pain was felt, and the patient was about the next day and after each subsequent electrification. I gradually increased the strength to twenty-five cells, and 140 to 160 milliamperes, and after each application found the abdomen smaller and the tumours reduced. After eleven electrifications the abdomen measures only thirty-four inches in circumference, the tumours are reduced by fully one-half, and the last four menstrual periods have been quite normal.

CASE II.—Mrs. J., aged 53, past menopause two years. She has never been pregnant. She consulted me June, 1887, for a large abdominal tumour nearly filling the whole abdomen; it arose in the right side, was very movable, and extended three inches to the left of the umbilicus; the tumour was solid, round, and very hard. The patient suffered no actual pain, and her menses had always been normal. The tumour was evidently a pedunculated sub-peritoneal fibroid.

On December 1st, 1887, her abdomen measured forty-one inches and a half in circumference. The sound passed five and a half inches in depth. I applied the negative pole internally for ten minutes, and obtained 80 to 90 milliamperes, using twenty cells; this process I repeated every ten or twelve days, gradually increasing the strength to 140 milliamperes. After eight applications the circumference of the abdomen is thirty-five inches; the

tumour is materially reduced, and does not extend two inches to the left of the umbilicus; it is also softer in structure; the patient feels well.

CASE III.—K. F., aged 26, a slight, healthy, unmarried girl, noticed a swelling of her abdomen four years ago, which has steadily increased; she had no profuse menstruation at any time. I saw her first in March, 1887, and she was then seen by two London specialists, who agreed that she had a fast-growing, pedunculated myoma, and proposed hysterectomy.

In November, 1887, when I began Apostoli's treatment for her, the abdomen was thirty-four inches and a half in circumference, and the tumour, a very movable one, filled the right side of the abdomen, and extended two inches and a half to the left of the umbilicus. I applied the negative electrode to the interior of the uterus, which was four inches in depth. I commenced with 20 cells (Coxeter), and obtained 100 milliampères; this strength on subsequent occasions I gradually increased to 25 cells and 145 milliampères; each application lasted ten minutes, and ten or twelve days elapsed between each. There was improvement after each electrification, and now, after eight applications, the abdomen measures thirty-two inches, and the tumour cannot be felt to the left of the umbilicus.

REMARKS.—I applied the electricity to the patients placed in the obstetrical position; and, having passed a Fergusson's speculum, I carefully syringed the vagina with an antiseptic solution before inserting the internal electrode, and again after the operation was completed. The internal electrode was steeped before using in 1 in 20 carbolic lotion. I did no electrification within ten days of the preceding one; antiseptic syringing was done by the patients twice daily in the intervals between each operation. The electricity was never applied for more than ten minutes, and cell after cell was gradually added, up to the strength determined upon, and again slowly diminished in the same way. I use Apostoli's wet clay abdominal electrode, a water rheostat, and a Gaiffe's galvanometer; also flexible platinum electrodes for the uterus, of small calibre, made for me by Coxeter, and insulated up to two inches from the point. Owing to the energetic action of the negative pole, I should not venture to apply more than 150 milliampères of electricity to the uterus.

PREVENTIVE SURGERY, AS ILLUSTRATED IN KNOCK-KNEE AND FLAT-FOOT.¹

By T. S. ELLIS, M.R.C.S.,

Consulting Surgeon (late Surgeon and Ophthalmic Surgeon) to the Infirmary at Gloucester.

PREVENTIVE Surgery, though it sounds unfamiliar, is, I submit, a legitimate expression. As Preventive Medicine sometimes teaches how to cure diseases by presenting, in specially pronounced form, the conditions under which they do not occur, so a study of the means by which deformities are prevented may teach us how to deal with them when actually existing. Let me illustrate this by two kindred deformities having much in common, knock-knee and flat-foot, as acquired independently of paralysis and of bone disease. Both are exaggerations of naturally existing curves. In each the sequence of events is the same—failure of muscular support, yielding of ligaments, altered contour of bone surface. And in each case, also, the leading indication for treatment is the same—to strengthen, by action, the muscles which, in the full exercise of their functions, prevent these deformities.

In the case of knock-knee, the direct influence of muscular action, in cure or prevention, does not seem to be recognised at all by writers. Of the two most recent known to me, Mr. Owen (*Dictionary of Surgery*, Genu Valgum) refers to exercise only to forbid it; and Mr. Arbutnot Lane (*Guy's Hospital Reports*, 1887) advises it only because by this means "the firmness of the joints and ligaments, and the density and resistance of the osseous system, will be improved." That spontaneous recoveries do sometimes occur is well known, and that muscular exercise will completely remove the deformity I have myself seen, although unable until recently to explain how. This I will now endeavour to show. According to the parallelogram of forces, a well known law, if a force acting in the line *a* to *b* (Fig. 1) be opposed by a force acting in the line *a* to *c*, the resultant will be in the diagonal of the completed parallelogram, or towards *d*. But all the muscles attached to the leg bones below and to the pelvis above do act in the line

a to *b*, while the weight of the body acts in the line *a* to *c*. These muscles draw the knee towards a straight line between the foot and the pelvis, when, as in the erect position, the foot is a fixed point. It is important, also, to realise that the peroneus longus, which abducts the foot when free to move, can only abduct the knee when the foot is fixed; so, also, the gluteus medius, which abducts thigh and leg together, can only act on the knee when the foot is fixed. These effects are fully seen in a wooden model (shown), where the part representing the body is kept upright by fixed guides, as it moves up and down, when the effect of the various muscles in correcting knock-knee is demonstrated. This is done by means of strong elastic bands, the parts of the model representing the thigh and leg being united by hinges.

I am fully mindful that in the body, the muscles attached to the leg and to the pelvis are attached also to the thigh, but this does not affect the result described. I recognise, also, that the downward thrust on the knee acts in the line *b* to *a*. This, too, is immaterial, the muscular force being strong enough to overcome it. My contention is that the muscles concerned in raising the body to the full height, and those which draw down the pelvis in opposition to resistance from above, pull the knee towards a straight line between the foot and the pelvis, and that their agency ought to be utilised in correcting knock-knee. In actual practice I have

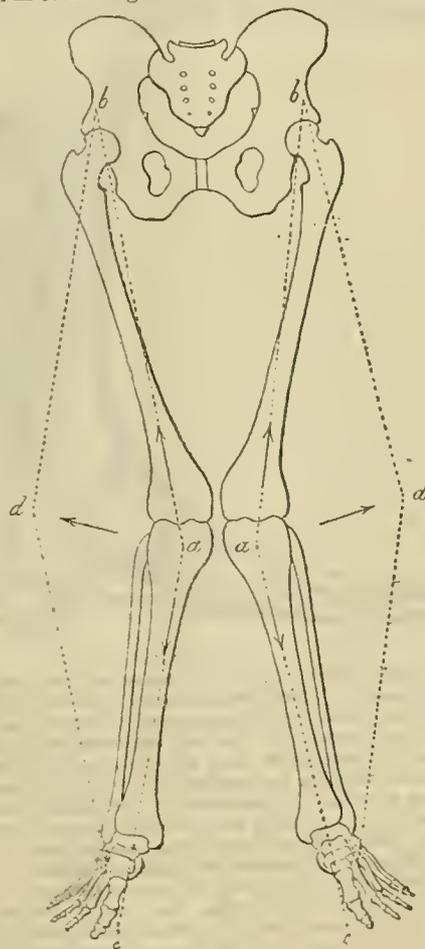

Fig. 1.

found the treatment thus indicated to be highly satisfactory, so much so as to justify a confident opinion that it would be found to be sufficient even for the worst cases. And indeed, as appears to me, if it be admitted that failure of muscular support leads to yielding of ligaments and altered bony surfaces in joints; that vigorous use of muscles makes them strong and taut, even when only in passive contraction; that, in this condition, they not only relax, and thus renew the over-stretched ligaments, but also, by exerting constant pressure on the bony surfaces of the joints, re-

¹ Read before the Gloucestershire Branch.

modify their altered contours—if this be admitted, and if the explanation of knock-knee which I have given be accepted, then I claim that such success accords with reasonable probability.

This view of knock-knee, its prevention and cure—never, so far as I know, given before—I offer now with the more confidence and the more pleasure because it was at a meeting of this Branch, nearly fourteen years ago, that I first pointed out that the arch of the foot is formed, is maintained, and may, when destroyed, be restored, by muscular action. I then narrated how, after an accident which had torn through the calcaneo-scapoid ligament in my own foot, I had myself been the subject of flat-foot in the worst form for more than six years; that, in seeking to discover by what means flat-foot is in Nature prevented, I had, by an observation on a horse, been induced to regard it as a universal law that ligaments liable to great strain are supported by muscles, and from that law had deduced the probability that, if I could only renew the function of the flexor longus pollicis, I might restore my flattened foot. I then described how, after six months' persevering application of the principle involved, a foot which for six years had never risen to tiptoe had become able to bear the strain of hopping over a footstool. To this I may now add that it has never since given me serious trouble, although the original displacements are still evident. I did not, however, at that time convince anyone² that my recovery was wholly due to

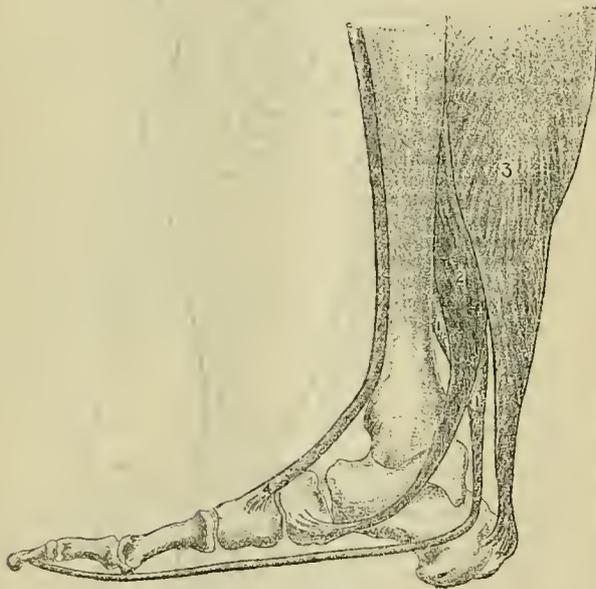

Fig. 2.

exercise, and I had not the boldness to send my paper to a medical journal. Three years later I restated my views in a pamphlet of which Mr. Holmes gave a favourable notice in his *Principles of Surgery* on the first appearance of that book. To those views I have ever since adhered, maintaining, as leading principles in relation to flat-foot: "For prevention promote, for restoration renew, the functions of the flexor longus pollicis." This being done, action of the other important muscles will be attendant. Not so the converse. Distortion of the great toe may suspend the action of its flexor alone. I find it difficult to understand how anyone can consider the position of the tendon (depicted in Fig. 2), having the same relation to the arch as a bowstring to a bow, without recognising that so strong a muscle must exercise a most important influence on the flexible arch, or arc which its tendon subtends. And yet, in all the writings I know where flat-foot and the construction of the plantar arch is discussed—the list is a long one³—there is not one

² Mr. Willet was, I think, the first convert to my views. I learned, years afterwards, that a friendly conversation in the square at St. Bartholomew's had left more impression than I supposed.

³ It includes Professor Humphry, "Flat-foot and Construction of Plantar Arch," *Lancet*, March 20th, 1886; Professor Sayre, *Orthopedic Surgery*; Professor Ogston, *Lancet*, January 26th, 1884; Dr. Little, *System of Surgery*; Mr. Bernard Roth, *BRITISH MEDICAL JOURNAL*, Nov. 18th, 1882, *Dictionary of Surgery*, *New York Medical Record*, March 17th, 1888; Mr. Symington, *Journal of Anatomy and Physiology*, vol. xix; Mr. Golding-Blrd, *Guy's Hospital Reports*, 1883; Mr.

where the writer has regarded this muscle as of sufficient importance even to call for special mention. Perhaps, if the place of the tendon could be occupied by the fleshy mass of the muscle and the tendon inserted in the leg, the effect of action on the arch would be better realised. We call it the flexor of the great toe. The far more important and far more common action is to assist in raising the body, acting from the straight toe as the fixed point. The tendon is, in effect, the most important of those forming the counterpart of the single tendon, which in the horse passes round the hock (the true heel), and is inserted at the toe. Tilt the skeleton (Fig. 2) on one side, imagine an exaggerated toe-nail, a much-enlarged metatarsal bone, and the tibia inclined at a less angle, and we have a horse's leg. Just as the tightening of the tendon of the "flexor perforans" in the rearing position of the horse, the tiptoe of man, relieves the enormous strain on the ligaments binding together the bones between the hock and the hoof, so do the corresponding tendons relieve the ligaments of the human foot as the heel is raised in every step. And, further, insufficient support of these ligaments will lead to "straight joints" in one case, as it does to the counterpart, flat-foot, in the other. I cannot describe how much I owe to this bit of comparative physiology applied to surgery.

I have recorded in the *Lancet* of February 9th, 1884, with my own case, that of a farrier's apprentice, who was under my care in the Gloucester Infirmary some fifteen years ago, with feet so flat and so painful that he could not walk across the ward. He was put in the way of proper exercises, and ultimately became a distinguished dancer in the 2nd Life Guards. I have also there described (September 23th, 1886) the best exercise I know for producing a speedy result in a bad case of flat-foot, and I now say the same in regard to knock-knee. It consists in raising a weight by means of a cord running over pulleys. The object is to bring the foot to extreme tiptoe, the knee and hip to full extension (this with the inspiration, so as to get the benefit of the Silvester method of artificial respiration added to natural breathing); then, after a pause, to suddenly and vigorously draw downwards. Turning a wheel, placed so high that the handle is with difficulty reached when at the highest part of the cycle is a similar movement, available if the patient be strong enough, and having the advantage of being less irksome. Indeed it may be made to combine useful work. So also may pumping, if the handle be placed high enough. Bell-ringing is also an excellent exercise. I cannot imagine it to be possible that persons habitually engaged in such strictly natural occupation as reaching up to and drawing down the boughs of trees would be knock-kneed or flat footed. It is remarkable that no such movement exists in the ordinary occupation of life; it has no place in ordinary gymnastic exercises, and, so far as the book of the Zander Institute shows, is not used even there. On its value in stimulating functional activity this is not the time to insist. Everything, however, which promotes the general health is important; so is everything which promotes nutrition of the muscles, dry friction, massage, and so on. Still, I would insist, on muscular action reliance must after all be mainly placed. In those forms of it described, especially in the first, that great impediment to exercise in these cases, the weight of the body, is partially counter-balanced; but good walking must be the aim, in view of a permanent cure, and should as soon as possible be practised in moderation. Let the toes be pointed downwards and forwards—the position of strength and therefore of activity; not outwards—the position of relaxed ligaments and, therefore, of rest. Let the heel be vigorously raised at every step, the knee being fully straightened. There is nothing strained in this, it is simply good walking. Standing should of course be avoided unless it be with constant springing up on the toes, an excellent exercise. As far as possible, especially in the early stages of treatment, all exercises should be done with bare feet. Remember that the natural plane of movement of the great toe is oblique, downwards and inwards, and take care that neither boots nor socks interfere with it, as will probably have been the case. Of the great importance of this point I have spoken in an article on Deformities of the Great Toe, in the *JOURNAL* of May 20th, 1887. In the treatment of flat-foot I never use supports of any kind. I believe that they do more harm in preventing free action of the short flexor muscles than they do good in propping up the arch. During many years I have seen the worst of cases recover without them. I am equally certain that for knock-knee

Arbuthnot Lane, *Guy's Hospital Reports*, 1887; Hancock, *Anatomy and Surgery of Foot*; Noble Smith, *BRITISH MEDICAL JOURNAL*, June 9th, 1883, "Surgery of Deformities"; and Mr. Mayo Collier, *Lancet*, Sept. 8th, 1886.

they are in principle wrong, and in practice unnecessary. So also of tenotomies in either deformity. Osteotomies and resections I can only regard as unwarrantable mutilations.

TIMES OF SOLDIERS' MEALS.

By J. HICKMAN,
Army Medical Staff.

At present the usual hours for soldiers' meals are: breakfast, 8 A.M.; dinner, 1 P.M.; tea, 4.30 or 5 P.M. The early morning parades are generally about 6 or 6.30, or in summer may be at 5—that is, men coming in late at night are turned out to parade without having had anything to eat. Even considered from the point of view of discipline this practice is to be deprecated; men having partaken of some nourishment, any way a cup of coffee, are in a better humour with themselves and their superiors, and insubordination, absence, and lateness at parades will be found to sensibly diminish. Many go so far as to advocate a regular meal at the time of rising, but it is generally accepted that light refreshment is sufficient to maintain the equilibrium till the breakfast time; hot coffee with plenty of milk may be advised; it is a stimulant to the system, invigorating without depressing. The cooking to provide a full meal could hardly be managed; two good meals are sufficient in the day, and if a hearty breakfast were taken too soon, the interval between it and the other meal would be too great; the work intervening is only an hour's parade, after which breakfast can be taken with leisure and appetite. The morning parade work should not be excessive; no fatiguing duties should be undertaken, as much unaccustomed exercise is likely to be followed by languor through the day. In cold or rainy weather this food before leaving the barrack-room should be specially insisted on. In every campaign, before starting the day's work or march, the rules lay down that soup, erbswurst, or coffee is to be issued. In India early rising is universal, and the habit is generally adopted; on the march the coffee-shop is an institution, and the men avail themselves eagerly of it. It is the universal opinion of medical men abroad that in places where malarious fevers are prevalent the susceptibility to their influence is much increased by starting for the day without food.

In the Aldershot cavalry barracks the men can get a good cup of coffee and a bun for a penny, and a cup of Moore's cocoa and milk, or a tumbler of milk and a biscuit, could be sold for less probably.

This early issue of refreshment should not be dependent on the caprice or wish of the regimental authorities, or on the pocket of the soldier; it should be embodied in the Queen's Regulations that no morning work should be commenced without an attempt to restore the waste of the body during fasting and sleep.

Breakfast only wants a few words; no alteration in the hour can be suggested. According to Dr. Edward Smith the daily distribution of food, supposing a physiological diet of 4,300 grains of carbon with 200 grains of nitrogen be taken, should be:

	C.	N.
For breakfast	1,500	70
For dinner	1,800	90
For supper	1,000	40
	4,300	200

or the total daily food should be distributed amongst them by allotting three parts to the first, four to the second, and two to the third. When dinner is eaten late 4-9ths of the supply may be eaten then and half that quantity at luncheon.

This division would assume that the system requires meat twice a day, to cover the wear and tear and to supply nitrogen, and to produce the highest state of health in the adult. In the recruit whose muscles are developing, and whose actual and reserved energy it is proposed to increase, the bodily waste is far more active, and he requires nitrogenous food twice a day, at breakfast and at midday dinner, and on no account in the after part of the day. In nitrogenous food is comprised fish, bacon, sausage, eggs, etc., with any of which breakfast can be varied.

It need hardly be said that breakfast should be a substantial meal; the digestion early in the day is active, and the work of the day is to follow. Cocoa, milk, hominy, or oatmeal porridge are amongst the best articles; the unsuccessful efforts to introduce into household use "wholemeal" (not simply bran) bread might be renewed and enforced in soldiers' diet.

Now, as to the time for dinner. It is generally assumed that an

ordinary meal is, in a healthy man, completely digested and passed out of the stomach in about four hours. Then, if we add a period of two hours for rest to the stomach, food would appear to be required at intervals of six hours. This is what experience teaches, and what is practically adopted. Sleep means a great diminution of bodily activity, and this greater interval can be accounted for. Breakfast being taken at 8, the midday meal should be ready at about 1, the time chosen by working men and the middle class generally, in schools, prisons, and all institutions. It is laid down that the chief meal of the day, the full meal (by whatever name it is called) should be taken at any hour when active occupation, bodily and mental, can be suspended for from one hour and a half to two hours; in other words, it is not found conducive to health to take a full meal in the midst of the day's work. This does not seem to agree with the popular habit. If soldiers had their dinners late, after they had finished their duties, they would probably remain more in barracks. The question of late dinners for shop-people and clerks has been elaborately argued by Dr. Dobell in a circular addressed to employers of labour, 1852. In the case of the soldier the suggestion may raise a smile, but is worthy of consideration.

Except fatigues, punishment drills, or guard occurring at intervals, the duty of the foot soldier after dinner consists of only an hour's parade, and old soldiers are even exempt from this. In the mounted branches, stables have to be attended, and many other duties may present themselves. If the present agitation for the "square" meal in the afternoon can be justified by the proportion of afternoon work, the mounted corps will surely have a primary claim to this indulgence. The thing to be remembered is to allow time for rest before and after the meal, and the afternoon drill should be delayed to further this object. To recapitulate: to those whose physical powers have been taxed the short perfect rest before is to be recommended; and when the dinner is finished at least an hour should be given to physical tranquillity. After this hour gastric digestion will be established, and the blood and nervous energy employed in the process will no longer be required, and can be devoted to another form of animal force.

In practice, no doubt, work immediately after a meal interferes with digestion, but this only applies to hard work, and most of the working classes can secure a quiet hour for the enjoyment of their dinner. Tea is taken at from 4 to 5 P.M. It really requires little comment. Perhaps the hour is too early, and makes the interval between it and breakfast too long. If delayed later, it would deprive the soldier of his evening walk, and the change would be received with grumbling. It can be urged, while the soldier carries into the army the hours of eating of the working classes in his other meals, in his tea and supper he anticipates his former habits by several hours; it really adds to the necessity of further nourishment before turning in, as going to bed with an empty stomach is to be avoided. Coffee or tea, with bread and butter, lettuce, onions, watercress, or other light things, which are wholesome, and are better and more economical than meat; this is merely added in case the purchase of meat should be made by the soldier. Meat teas are not to be commended; tea is not adapted to accompany meat in the digestion, and is very likely to cause dyspeptic troubles. In many instances the hungry recruit has eaten his portion of bread for his breakfast, and there is absolutely nothing left for his supper. A modification of the rules for issuing bread seems imperatively required. We are led to conclude that the hour of dinner is, like the laws of the Medes and Persians, unalterable, though it might be a little later. As regards supper, in an economic and scientific point of view, it certainly should be postponed for another hour or two. On service, in camps of exercise, or foreign stations generally, where the outside amusements of the soldier are few, the change could be made with advantage.

After 5 o'clock meal the regulations do not provide any more for the soldier, who, as long as he has money in his pocket, generally gets something at the regimental canteen or recreation room bar; this is merely private expenditure, with which no interference can be made. The question naturally arises whether this absolutely necessary amount of nourishment should be dependent on such fleeting and precarious finances.

In the beginning of this paper the dangers of a long fast were insisted on, especially in the case of growing lads. They are too exhausted to sleep comfortably, to rise with vigour, or to enjoy breakfast. The system is weakened and the digestive powers not ready when called upon, or there is a temptation to ravenous haste. The remedy for this is the issue of soup from the cook-house between certain hours in the evening. This basin of soup

and a piece of bread is a sufficient meal in itself, and should be available for nothing to every man who applies for it. The soup can be made from the large bones of the rations; the sale of the refuse will generally be found to cover the cost of the vegetables, split peas, and flour required to complete the soup. This has been adopted in some regiments, and it is found that the applicants for the soup are usually those whose finances are low, and on the days immediately before the pay-day, there is often a difficulty in supplying the numbers. There is naturally a greater demand in the winter. The universal adoption of this plan cannot be too strongly recommended.

A few words as to the times spirit rations should be issued; they are best taken with meals—at dinner time preferably, never before. This is not the place to discuss the merits or the action of alcohol; in small quantities it increases the secretion of the gastric juice and the movements of the stomach, and thus aids digestion. Alcohol should be taken, largely diluted with water, with, or rather at the close of, a meal. In Queen's Regulations, Sect. xv, Para. 103, it is laid down that malt liquor may be taken from the canteen to the barrack rooms for the men's consumption at dinner; this privilege is, however, not acknowledged by all commanding officers and its observance should be universally insisted on.

AFTER-HISTORY OF PNEUMONIA THE GUIDE TO ITS TREATMENT.

By ARTHUR JAMISON, M.D.,
London.

I wish in this paper to give my experience of the imperfect as well as the complete recoveries of my cases of pneumonia during a period of over twenty years. I have never seen its therapeutics discussed from the consideration of the after-history of cases of this disease. I will not, therefore, in this paper discuss the lessons taught me by my fatal cases, but confine my remarks to those that recovered. These observations are founded on 213 cases of all grades of severity of single and double pneumonia, at ages varying from 15 to 73; and by pneumonia I mean croupous pneumonia, characterised by rusty sputa and consolidation afterwards. I was able to trace the after-history of 155 of my cases. Most of them were of the artisan class; some came under my care subsequently for other ailments, some for entrance examination into benefit societies, and I always made it a routine rule to examine the chests of all my cases whenever I could afterwards. Of these 155 cases, I found rather above half—namely, 81—free from any traces of their pneumonia on examination at periods not under two years afterwards. The other 74 had traces left discoverable by finding dulness of the affected region of greater or less extent and degree, indicating impaired lung, and were very frequently ill; 13 of them died of phthisis afterwards.

During my first years of practice my treatment was mainly expectant. I thought and had been taught that pneumonia had a definite course; that drugs could not alter its natural history, and, beyond stimulating the old, rest in bed, a warm poultice, and any sort of a placebo mixture was treatment enough. Symptoms, on an average, subsided on the eleventh day; convalescence seemed established, and expectancy triumphant. Any prolonged debility afterwards was put down to insufficient means, imperfect hygienic surroundings, or to the generally below-par state of health of many operatives living in towns. But I began to wonder if expectancy were the best treatment when I found so many whom I had so treated so frequently ill afterwards. The chief symptoms were slight cough and expectoration, inability to work as well as formerly, a constant sense of slight weariness, and in nearly every case a feeling of flatulent distension and weight after meals, and a varying amount of anorexia. Though the body might be fairly well nourished, yet the face was too thin proportionately to the body, and wore an expression of considerable depression; the bowels usually torpid; the tongue furred, and especially indented with teeth-marks. On closer inquiry I found that for three or four months following the attack of pneumonia these patients got on fairly well, but after then began to droop and never felt up to the mark; and with this chain of symptoms I always found evidences of unresolved pneumonia. I then began to try other measures to prevent these after-consequences if I could. With this view some were treated by quinine in large doses—now we would say in antipyretic doses—by aconite, by ammonia, and by antimony.

Thus, of the 74 cases of unresolved consolidation, 29 were treated by pure expectancy, 20 by ammonia, 10 by quinine in full doses, 7 by aconite, and 8 by antimony in largish doses of its tartrate.

I wish to say a few words on each of these methods of treatment. My experience of aconite in doses to produce any effect is against its use at all in pneumonia, as I feel sure it increases the danger of, and often actually causes, cardiac collapse. The ammonia treatment seemed much the same as the expectant, except that I thought there was more pain in the side during its use. Quinine appeared not so risky as aconite, but just as inefficient to control the disease, even in doses large enough to lower the temperature for a time. My limited experience of it only corroborates the American estimate of its value. On the other side of the Atlantic it has been most extensively used, and last year there was a discussion in the New York Academy of Medicine on the subject. There was a general consensus of opinion upon the inutility of quinine as an antipyretic in the treatment of pneumonia. It was considered useless in small doses, and dangerous in large ones, producing cardiac and nervous depression. My impression very strongly is that any treatment directed to lower the temperature only is bad. But if a remedy is to be had that is able to lower the temperature for a time in a marked degree, surely some will say it must do good. Well, kairin is able to do this; and in the JOURNAL for January 28th there is a record of the antipyretic treatment in *excelsis* so instructive that I wish to quote it before leaving this portion of my subject:

"At first kairin was used in 10-grain doses, and it was always given when the temperature was 104° and over. After each dose the temperature fell rapidly; observations made every quarter of an hour showed that the fall was continuous for about two hours, the total fall being from 3° to 5°. There was a striking constancy in the effects produced by a given dose of kairin, whether the dose was 5, 10, or 15 grains. A dose of 10 grains always gave the best results; 15 grains did no more than 5 grains, and neither did so much good as 10 grains. The stationary period varied, but at most it lasted only a few hours; the longest time recorded was ten hours. The subsequent rise of temperature was as rapid usually as the decline. Each dose of kairin was followed within half an hour by profuse sweating and symptoms of depression, and when two doses were given in close succession (the interval being three hours and a half) marked cyanosis and collapse occurred. Kairin was exhibited twice daily for ten days; on the fourteenth day of the disease the maximum temperature was still 105°."

I wonder how many of us on reading this report of a case of pneumonia rubbed our eyes and thought what blows the pyrexia got even till the patient was black in the face. I wonder also how many were surprised to read further on that the patient died of phthisis ten months afterwards. My opinion is that he treats pneumonia best who, after having the lowest percentage of deaths, has the fewest cases of consolidation afterwards. First, because it diminishes the risk of tuberculosis. Observers like von Brunn, Siegel, and many others make it apparent that the tubercle bacillus finds its best nidus in old inflammatory products. Secondly, the condition of impaired health that too often follows even apparently good recoveries from pneumonia and the dyspepsia which, I believe, is constantly associated with and evidence of incompletely resolved pneumonias, press home this view of the aim of treatment.

My first cases treated with antimony gave better results proportionately than by the other plans of treatment, so that I was led to continue its use further. After a while many reasons led me to prefer small doses frequently repeated to the larger, more knock-down doses recommended by the older writers. These small doses are well borne even by the old. I found $\frac{1}{2}$ grain given every hour for young adults, less frequently for older people, a dose quite large enough. When pain, cough, and chest oppression are relieved, the remedy may be given less often. I continued the use of the drug for several days, often a week, after the temperature had fallen to normal, to ensure removal of the inflammatory products remaining behind. There were no ill effects from the drug used in this dosage, no sickness, no diarrhoea; its action seemed to be simply that of a respiratory sedative. Generally a little tincture of camphor was given with it to ease pain.

Of the 81 cases in which no traces of mischief were to be detected afterwards, no fewer than 65 were treated in this manner. At first I had a dread of cardiac failure, but this, as time went on, grew less and less, as I found these small doses, by easing the strain of respiration, seemed to diminish the danger of sudden heart failure. Moreover, the recoveries seemed, as it were, to be

June 30, 1888.]

so pathologically complete, to coin a phrase, that I have not felt disposed to try any other remedy. What I wish to insist upon is this, that in frequently repeated small doses of antimony we have our best known remedy at present; it not only eases the distress of the acute stage, but one which is superior to any other in inducing the greatest amount of resolution as tested by the condition of the lung afterwards.

The dyspepsia and general want of tone of the system, as well as the subsequent consolidation itself in imperfect recoveries, are best treated by mineral acids in addition to the most careful attention to every hygienic detail. Some I know prefer hydrochloric acid in an aromatic bitter, but nitric acid has appeared to me to be of greater benefit. The acids have always seemed to me to have as great an effect in improving crippled lungs as they have in benefiting atonic dyspepsia. Indeed, I suspect the indigestion they prove most useful in has its origin in some pulmonary cause.

ON THE VARIETIES OF HEPATIC CIRRHOSIS.

By GEORGE MUNRO SMITH, L.R.C.P.Lond., M.R.C.S.,

Lecturer on Physiology, Bristol Medical School; Demonstrator of Morbid Anatomy, Bristol Royal Infirmary.

VARIOUS attempts have been made from time to time to classify the different kinds of general interstitial hepatitis, either in accordance with the microscopic appearances of the organ after death, or according to the supposed causation of the disease. Ziegler doubts the usefulness of such an undertaking, inasmuch as the types pass one into another. He says: "It is enough for the present to distinguish the hypertrophic conditions from the atrophic, and even then it must be borne in mind that these conditions merely represent different degrees or different stages of what is essentially one and the same process." Dr. Sandby, on the other hand, enumerates seven varieties—namely, alcoholic, cardiac or cyanotic, biliary, syphilitic, tubercular, malarial, and scarlatinal. Charcot and Hanot have, moreover, described a "hypertrophic cirrhosis of diabetes," and Cornil and Ranvier a "fatty hypertrophic cirrhosis." My object in this paper is to suggest a grouping of these morbid processes that may, perhaps, serve for a working classification.

After studying the chief literature on the subject, and comparing various sections of diseased liver, it appears to me that confusion has arisen, in the first place, from confounding the cause with the morbid anatomy; secondly, from describing partial cirrhosis as general; and, thirdly, from considering *post-mortem* appearances in early and late epochs of the same disease as two distinct varieties.

For example, Charcot described a condition characterised by considerable enlargement of the liver, jaundice, not usually much ascites, and a rapid course. After death was found a general and uniform increase of connective tissue in the organ, with proliferation of the smallest bile-ducts and capillaries. To this disease he gave the name "biliary cirrhosis," indicating thereby its mode of origin from blocking of the bile-ducts. This term "biliary" has, however, been transferred from its etiological sense, and made to mean increased-formation of the small ducts, a condition not in the least characteristic of this form of cirrhosis, but existing in quite as marked a degree in alcoholic and in cyanotic, as the examination of a few sections will satisfy anyone.

As an example of the second source of error, namely, the confounding together of partial and general fibrosis, two so-called "varieties" may be given, "tubercular" and "hypertrophic diabetic" cirrhosis. Tubercles, of course, frequently form in the liver, generally in or near the capsule; but occasionally there is found an infiltration in the interior of the gland in the interlobular spaces. If the patient lives long enough, this is sure to lead to patches of sclerosed tissue and new formation, probably, of bile-ducts. Yet this certainly should not be looked upon as a variety of cirrhosis; it is a localised inflammation round the irritating masses of tubercle.

As a rule, no lesion of the liver is found in diabetes unless the subject also happens to be an alcoholic; and although Charcot and Hanot have described two cases of enlarged liver with sclerosis in non-alcoholic patients, yet in both these cases distinct

tuberculosis existed in the lungs; hence the appearances found in the liver may, perhaps, have been also due to this cause, and the evidence in favour of a distinct variety is not, I think, clear. "Tubercular cirrhosis" may, I think, be struck off from the list, inasmuch as it is partial and not universal, and, for practical purposes, "hypertrophic cirrhosis of diabetes" may also be omitted.

Again, the period in the course of the disease affecting the liver at which the patient dies must always be taken into consideration. So-called "monolobular cirrhosis" becomes indistinguishable microscopically from "multilobular," and an enlarged liver may shrink until it is exceedingly small. Moreover, morbid anatomy cannot be divorced from clinical history, and a description of tissue change alone is sure to lead to confusion. The classification I suggest is as follows:—(a) *Obstructive cirrhosis* due to either (1) some impediment to the flow of bile, "biliary," or (2) to the flow of blood from the liver (as in pulmonary or heart disease), "cyanotic." (b) *Irritative cirrhosis* caused by the irritation (and chronic interstitial inflammation which follows) of some poison brought to the liver by the portal vein or hepatic artery. Under this heading come (1) "alcoholic," (2) "malarial," and (3) "syphilitic," all undoubtedly well-marked conditions. "Scarlatinal cirrhosis," if such exist, would come in this group, but the evidence of its existence is not very abundant.

The *obstructive* are always "monolobular," that is, the connective tissue grows uniformly, not necessarily round the lobules, but round the hepatic zone as well. In the *irritative* forms the connective tissue grows irregularly; some lobules are divided up by septa, whilst others escape altogether. The "syphilitic" is found only in children; acquired syphilis appears never to produce general cirrhosis. The "malarial" is also chiefly seen in children. In "alcoholic" the disease probably begins (Sabourin) both round the portal and hepatic systems of vessels; it is more distinctly multilobular than any other variety.

In the irritative lesions there is often thickening of the small arteries (peri-arteritis and endo-arteritis). I do not think this is common in the obstructive varieties.

As to the distinction into "hypertrophic" and "atrophic" types, it must be remembered that the liver very readily enlarges; a rich and copious dinner, especially when combined with wine or spirits, may increase its size to one-third greater than the normal. We should, therefore, expect enlargement in the early stages of interstitial hepatitis; but, in the irritative forms, this subsides much more rapidly than in the obstructive, and the latter terminate more swiftly than the former, otherwise the gland would probably dwindle and atrophy. Both forms may be complicated by adenomatous growths, and, when these are multiple, an otherwise atrophied liver appears to be abnormally large.

I offer the above classification in the hope that it may simplify a subject that has, I believe, hitherto been somewhat in confusion.

SURGICAL MEMORANDA.

OSTEOPLASTIC OPERATIONS ON THE FOOT.

It was with the greatest interest that I perused in the JOURNAL of May 5th the report by Sir William MacCormac of an osteoplastic operation on the foot, which generally bears the name of Mikulicz, of Prague, although in the above-mentioned report the credit of first devising and performing the operation is given to Wladimiroff, of Kazan. In Russia it has also been performed by Skleffasowsky, and in this country Sir William MacCormac looks upon himself as the first to do it.

My own interest in it is due partly to the fact that, in 1883, in the presence of Dr. Merson and Mr. Macnab in a case of disease of the tarsus, but unfortunately I found, after removing the posterior half of the tarsus, that the other bones were involved, and I was obliged to amputate in the position of an ordinary Syme, taking a flap from the dorsum of the foot. In addition to this, however, I have for the past few weeks been trying to fix the date of operation in a case of the late Professor Syme's, which, as far as I can see, must have been performed even before Wladimiroff's first case, and which has every appearance of being an identical operation, the foot and leg exactly resembling that figured by Sir William MacCormac in the JOURNAL of May 5th.

The patient, a young woman, frequently appeared in the outpatient room at Huddersfield Infirmary when I was house-surgeon.

4 Cornil and Ranvier, vol. ii, p. 323.

1 A *Text Book of Pathological Anatomy*. By Ernest Ziegler. Translated by D. MacAlister, M.D.

2 BRITISH MEDICAL JOURNAL, June 24th, 1886.

3 The term cirrhosis (*κίρρῶς*, yellow) suggests a condition not always present, but long use has sanctioned it. Sclerosis is, of course, a better word.

geon there, to be treated for a small sore in the foot, due to slight deficiency of skin, and recently Dr. Irvine, of Huddersfield, at my request, searched out her abode again, but she cannot herself remember any particulars. She has, however, communicated with a sister, who, I hope, will be able to help us.

Mr. Macnab, of Hull, tells me he remembers a case of Syme's resembling this in every way, and therefore probably the one to which I refer. It aroused a great amount of interest at the time, and he assigns as the date the years 1865 or 1866. Doubtless some of Syme's old pupils of that date will remember the case, and I hope some of them will be able to give a description of the operation as done by Mr. Syme.

If I am successful in getting the date from the sister, some old case-book may give the required information. In any case, however, if Sir William Mac Cormac is correct in saying that Wladimiroff first performed the operation in 1872, Syme's claim to priority is established, for I think I am correct in placing the date of his death in the summer of 1870. Of course, I am aware it has been the custom to award the honours of priority to the man who publishes first, a method not without its faults, tending to induce premature publication, and perhaps an erroneous estimate of the value of what has been done. Why should the published evidence of a professional journal be preferred to the testimony of living and credible witnesses? I hope to give full particulars soon.

D. LOWSON, M.D.,

Hull. Examiner in Surgery to the Aberdeen University.

A CURIOUS CASE OF FOREIGN BODY IN THE MALE BLADDER.

A GENTLEMAN was sent to me by Dr. Miller on May 19th, 1887, with the following history: The patient assured me that, several years ago, he had been told by a medical man that, if there was ever any difficulty in micturition, a paraffin candle was to be warmed, moulded into the form of a bougie, and passed into the urethra. Six weeks before seeing me, having some slight irritation, these manoeuvres were practised; but, on attempting to remove the paraffin bougie from the body, little more came away than was actually held between the fingers. Since then he had become more and more uncomfortable; the movements of a cab or carriage could not be borne, and he could only walk very slowly. He felt as if "he had a marble in his bladder." The bladder had been sounded and nothing found, and he complained that several surgeons had been incredulous of his story.

He was nervous, and in so much pain, that I declined to do anything until he was in bed. Mr. Charles Moss administered ether, and Mr. H. S. Byam, of Chester Square, kindly assisted me. A wax-like body was at once found in the bladder, and seized by a lithotrite with some hesitation, because there was no means of knowing exactly what had to be dealt with, and I was anxious not to bite into a sticky mass from which the jaws of the instrument might not readily be extricated. However, during its six weeks' sojourn in the bladder, the wax had become incorporated with a good deal of phosphatic matter; it crumbled rather than broke, and very soon nothing of any size remained to be seized by the lithotrite. An ordinary lithotrity evacuating tube was then introduced, but only a small amount of *débris* could be extracted, for it was so light that the bulk of it refused to be drawn into the aspirator. The lithotrite was therefore again introduced into an almost empty bladder; and a good deal of waxy matter, which burnt with a flame when applied to a lighted candle, was withdrawn between the blades of the instrument; the rest was well broken up, and the operation completed. The patient being a comparatively young man, it was thought that almost all might now be left to Nature, and for about two or three weeks not a day passed without some paraffin coming away, either naturally or by the use of a soft catheter and an india-rubber washing bottle. On June 19th, 1887, he passed the last piece, and on the same day was the winner at putting the shot and throwing the hammer at some athletic sports. He has continued perfectly well ever since.

The case is worthy of being put on record, because, as far as I know, it is unique.

G. BUCKSTON BROWNE.

Wimpole Street, W.

BACTERIOLOGICAL courses of study will be held in the Berlin Hygienic Institute during each of the two months, August and November, of this year. Anyone who desires to attend the courses should write early to Dr. C. Fränkel, assistant at the Institute.

THERAPEUTIC MEMORANDA.

ON THE USE OF CODEINE.

I WAS a little surprised in reading Dr. Lauder Brunton's most interesting paper in the *JOURNAL* of June 9th to find him state that codeine is "rarely employed for other purposes than the treatment of diabetes, cough, and irritation of the throat."

For some few years past I have found that in nearly all cases where morphine or opium was indicated for the relief of pain, but contra-indicated from any cause, the desired effect was readily obtained from codeine.

In this way gastralgia in aged patients is easily relieved without risk, and all forms of neuralgic and muscular pain are soon conquered.

I also frequently use codeine for threatened abortion, where opium cannot safely be prescribed, and my friend, Dr. McIntosh, tells me that quite recently he found codeine act splendidly in a case of asthma, where injections of morphine failed.

Though there is much that is instructive in Dr. Brunton's paper, I fancy the use of codeine is more general than he thinks; if not, I hope his paper will induce those who are not familiar with the drug to give it a trial.

PATHOLOGICAL MEMORANDA.

SARCOMA OF SUPRARENAL CAPSULES SIMULATING ADDISON'S DISEASE.

THE following case, which I am enabled to publish through the courtesy of Brigade-Surgeon Warren and Surgeon-Major Steele, is an instance of the truth of the statement made by Dr. MacMunn (*JOURNAL*, February 4th, 1888). "Many believe with Virchow that the train of symptoms, with bronzing of the skin, which are characteristic of Addison's disease, may be brought about by various morbid conditions of the adrenals."

A soldier, aged 23, was admitted into hospital on June 4th, 1887. He had for some months complained of what was called dyspepsia; his skin was muddy, although there was no distinct bronzing; he complained of great pain in the abdomen, which he referred to the region of the gall-bladder and to the pit of the stomach; there was distinct tenderness over the lower dorsal vertebrae; he had constant vomiting, occasional diarrhoea, and profuse perspiration. His temperature was slightly raised for about ten days, when it became normal, and continued so until death. His symptoms increased in severity, and, with the exception of sedatives, no treatment appeared to be of any use. He had attacks of extreme collapse towards the end, during which his pulse was very feeble, and the skin clammy. He died in a delirious condition on July 13th.

At the *post-mortem* examination no diseased condition was discovered, but enlargement of the suprarenal capsules; the right weighed a quarter of an ounce, the left one ounce; the structure was firm; the cut surface presented a number of yellowish nodules, varying in size from a millet-seed to a small nut; those in the left adrenal were largest, and in this there was a star-shaped opening on the anterior surface, about the size of a sixpence, which appeared to be the result of the breaking down of one of these nodules. The contiguous lymphatic glands were not enlarged, nor were there any secondary deposits in lungs, liver, or elsewhere. Microscopic sections made through these nodules showed them to be made up of spindle-celled sarcoma.

Mr. C. Mansell-Moullin very kindly examined the sections, and considered there was no doubt as to their being sarcomatous; saying of the history of the case that the disease "must have proved fatal, not because of the sarcoma, but because of the place in which it occurred before it could effect any general change, which is very unusual."

ALLAN PERRY, Surgeon Medical Staff.

Gibraltar.

MEDICAL EDUCATION IN SPAIN.—On Sunday, May 27th, the first stone of the new buildings of the Faculty of Medicine was laid at Barcelona. In addition to liberal accommodation for teaching and original scientific work, they will include a hospital expressly designed for clinical instruction. The site has been given by the town, and the Spanish Government has made a grant of one million dollars for building purposes.

OF
HOSPITAL AND SURGICAL PRACTICE IN THE
HOSPITALS AND ASYLUMS OF
GREAT BRITAIN, IRELAND, AND THE COLONIES.

NORTHAMPTON GENERAL INFIRMARY.

COMPOUND DISLOCATION OF BOTH ANKLE AND KNEE OF THE
SAME LEG: EXCISION OF ASTRAGALUS: RECOVERY.

(Under the care of Mr. G. H. PERCIVAL.)

[For the report of the case we are indebted to Mr. W. E. AUDLAND,
late House-Surgeon.]

C. B., aged 45, a navy, was admitted into the infirmary at 9 A.M. on May 18th, 1887. The history of the accident was that he was working in a railway cutting, when a fall of earth occurred, and he, while trying to throw himself flat down—seeing that he could not escape—was caught by the falling mass, and his right leg was crushed.

On admission, it was found that he had sustained a compound dislocation of his right knee inwards, his leg being at right-angles to his thigh, and the upper articular surface of the tibia protruding through a lacerated wound on the inner side of the knee. He also had a compound dislocation of the ankle of the same leg outwards, the foot being bent inwards at right-angles to his leg, and the superior articular surface of the astragalus protruding through a large irregular wound on the outer side of the ankle. Both the malleoli were broken off; neither of the tibial arteries was wounded. The patient was in great pain, but not much collapsed. Mr. Percival, having examined the injuries, directed the House-Surgeon (Mr. Audland) to reduce the dislocations as completely as was possible, and to make an attempt to save the limb. Ether, therefore, having been administered, the knee-joint was easily reduced, but he found it impossible to get the foot into good position until the tendo Achillis had been divided, and the whole of the astragalus, with both of the malleoli (which were lying nearly loose in the wound), had been removed. The wounds were then well syringed out with carbolic lotion, the edges brought together with silk sutures, and dressed with iodoform and carbolic gauze. Two drainage-tubes were placed in the wound of the knee, and one into each side of the ankle. Carbolic spray was used. The limb was then put on a back splint with a foot-piece and two side-splints. After the operation, the man soon recovered from collapse, and said he felt much more comfortable and in less pain.

At 6 P.M. the wound was dressed on account of some oozing. At 8 P.M. he was given injection of morphia, one-third of a grain; ordered low diet, beef-tea, and milk.

May 19th. The patient slept well; took food well; complained of some pain in the ankle; ordered pil. morph. $\frac{1}{4}$ gr. h. n.

May 22nd. The wounds were dressed for the first time since the day of the accident. That of the knee looked well; one drainage-tube was left out. Some sloughing of the edges of the ankle wound; not much suppuration.

May 25th. The wounds were dressed and looked well. The patient's general condition was much better; ordered half diet.

May 28th. A large, deeply-seated abscess was discovered and opened, about four inches above the internal malleolus; a drainage-tube was introduced and the cavity washed out with carbolic lotion.

May 29th. Another small abscess nearer the ankle was opened. The wound of the knee had nearly healed; the drainage-tube was left out; no suppuration.

May 31st. Dressed and splint changed.

June 3rd. All the wounds were dressed and going on well; ordered full diet and a pint of porter.

June 23rd. The back splint was changed for a side splint owing to a slight sore of the heel.

July 15th. The patient got up and went out in the grounds in a carriage.

August 3rd. The patient went about on crutches. The wounds of the ankle were nearly healed; that of the knee quite well. He could nearly bear his own weight on the foot. There was considerable movement in the knee-joint.

In October the patient left the infirmary and went to a con-

valescent home for six weeks. He was then again in the infirmary for a few days, as a small piece of necrosed bone was exfoliated from the lower end of the tibia. He finally left the infirmary in December.

The temperature chart of this case was unfortunately lost, but after rising in the evening during the first ten days to 101° or 102° F., it remained normal.

In February, 1888, the patient was seen. Then there was three-quarters of an inch shortening of the right leg; the knee could be bent nearly to a right angle; patella freely movable; there was no roughness or grating. He could bear his whole weight on the leg. The ankle was firmly fixed; free movement in the tarsal joint. There was a small sinus over the inner side of the ankle, which discharged slightly.

I think the interest of this case is in the fact of a man being able to retain such a useful limb after so severe an injury. The good result in the case of the knee-joint is especially noticeable, the movements of that joint being almost entirely regained.

HOSPITAL FOR WOMEN, SOHO SQUARE.

AMENORRHOEA ASSOCIATED WITH ALCOHOLISM.

(Under the care of Dr. C. H. CARTER.)

[Reported by G. H. BURFORD, M.B., House-Physician.]

E. B., aged 26, married three years and having two children, came into hospital with a history of ten months' amenorrhoea, interrupted once only by a three days' metrorrhagia some six months before admission.

Two years ago the patient became profoundly melancholic, ensuing upon the death of a child. Habituation to the free use of alcohol was then begun, and continued up to date, when her daily quantum was about six glasses of neat brandy.

On examination nothing was detected in the condition of the reproductive organs as accounting for the amenorrhoea. "The uterus was high in the pelvis, the cervix small and not lacerated, the os uteri patulous; no pain or tenderness evinced on examination."

General examination showed that the first cardiac sound was feeble, and less marked than the second; the lungs somewhat oedematous; the abdomen tumid, but with no free fluid discoverable. Subretinal effusion was present in both eyes.

The urine was highly albuminous, containing also bile pigment and bile acids; specific gravity, 1025. No incontinence at first, but this symptom developed afterwards.

After a fortnight in hospital, she died with symptoms of cerebral effusion. *Post-mortem* examination by Dr. Dalton showed, in addition to appearances of hepatic and splenic cirrhosis, white patches on the cardiac valves and on the peritoneum. The renal changes were confined to a slight general enlargement of both kidneys, with a cloudy granular appearance of the tubular epithelium. But the ovaries were white and shrivelled, like those of an old woman, and under the microscope fibroid changes were apparent in them. The uterus was apparently normal in character.

REMARKS.—The amenorrhoea in this case seems ascribable in marked degree to the alcoholism, while associated with melancholia and renal lesion also. I can find no recorded instance of melancholia alone causing protracted and continuous amenorrhoea. The renal changes were by no means advanced; whilst the shrivelled ovaries, cirrhotic liver, and fibroid patches on serous membranes are quite in keeping with the clinical history of alcoholism. The uterus, singularly, had undergone no structural lesion. That chronic nephritis will induce secondary amenorrhoea is a well known fact; yet the persistence of the amenorrhoea, with the non-detection of albuminuria until admission into hospital, indicates the commencement of ovarian change prior to any results accruing from the renal lesion. The solitary break in the otherwise continuous amenorrhoea is worthy of note; profuse discharge, not due to miscarriage, seems to have been the final effort of a reproductive system whose functions were being gradually annulled.

MELANA VERA NEONATORUM.—Dr. Otto Tross, of Carlsruhe, has described (*Deutsche Med. Woch.*) a case of the disease, which first showed itself twenty-four hours after birth, by extreme sudden collapse. Camphor-benzole and ergotin were injected, the limbs were bandaged, and an ice-bag was applied to the abdomen. Blood escaped *per anum* for several days, but the child recovered perfectly.

REPORTS OF SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

THURSDAY, JUNE 21st, 1888.

JOHN WILLIAMS, M.D., President, in the Chair.

ELECTROLYSIS IN THE TREATMENT OF DISEASES OF WOMEN.

Adjourned Debate.—The debate on the papers on Electrolysis in the Treatment of Diseases of Women, read at the last ordinary meeting by Drs. Steavenson, Lovell Drage, Gibbons, and Shaw, was resumed.

Dr. PLAYFAIR declared that those who had really mastered the technical details of electrolysis had never found that method useless. It must be justly tried, and then established or condemned, as results might prove. Dr. Playfair, through personal experience, had sufficient evidence to satisfy himself that the agent had great power, but that much was yet to be learnt. Cases should be treated by gynecologists, and not left to professional electricians and to managers of the electrical department of hospitals; as well leave ovariectomy to the cutlers who made the instruments used in that operation. Passing sounds and electrodes required special knowledge of the diseases of women, and the electrician might not necessarily possess that knowledge. Dr. Steavenson did possess it, but he and others similarly circumstanced must treat their cases as gynecologists, not as electricians. Turning to his own clinical experience, Dr. Playfair believed in the hæmodynamic effect of the positive pole in the treatment of fibroids and other forms of uterine hæmorrhage. It sometimes acted most powerfully and, as far as he could ascertain, permanently, in arresting hæmorrhage. In other cases it did good for a time; in only one case had he found it worthless. Dr. Playfair then described some of his own cases. He noted that in none had the patient been laid up, so that the good results could not be attributed to rest. As to the treatment of non-hæmorrhagic fibroids by puncture and the negative current, he had only experience through two cases. He believed this variety of treatment to be the most questionable and dangerous manner of applying electricity; besides, very few such fibroids required any kind of treatment. In both of Dr. Playfair's cases a large mass was impacted in the pelvis, causing severe pressure-symptoms. In the first the tumour had practically disappeared, but there was great constitutional disturbance. In the second, where the pressure had rendered voluntary micturition impossible for a long time, the tumour was much lessened; the patient no longer required the catheter, and felt quite well and comfortable. Dr. Playfair then described some cases which tended to prove that the negative current was of great value in the treatment of severe dysmenorrhœa, membranous dysmenorrhœa, and aggravated uterine catarrh. Time did not allow him to dwell on the use of electricity in promoting the absorption of inflammatory deposit, and on the use of the interrupted current to relieve pain or to cure amenorrhœa. After three uterine faradisations, a patient commenced to menstruate after seven years of amenorrhœa, and had continued regular ever since. In other cases of like nature, electricity had failed to do good. Dr. Playfair, in conclusion, declared that his clinical experience proved that electrolysis was an agent occasionally capable of doing much good. It might do much harm if injudiciously and unskillfully used, but that truth furnished no argument for rejecting electrolysis as a therapeutic agent, but rather demonstrated that the effects of the new method must be carefully studied, its indications noted, and its dangers detected and avoided.

Dr. INGLIS PARSONS said that in the case of uterine fibroids, the results of electrolysis would vary according to the position and structure of the tumour. He had found by experiment that electrolysis occurred only at the poles, and the free acids and alkalis resulting from it also acted locally. When fibrous tissue predominated very little reduction in size was possible, even by puncture, whereas a soft myoma could be disintegrated by puncture. In one case he passed a small platinum needle, insulated to within one quarter of an inch from the end, through the anterior vaginal wall and one inch into the substance of the tumour. The current only came off in the tumour, the vaginal wall remained intact; no sinus was left, as would have been the case had the actual cautery been used, but the puncture closed up at once, whilst at each sitting a large piece of the tumour was destroyed.

By February last the tumour was reduced to one third its original size, and had since remained unaltered. What was left appeared to be fibrous tissue. When the electrode could not be brought into contact with the tumour it might check farther growth, and thus prove of value in the earlier stages of uterine fibroid disease. Family physicians often let the disease advance through dread of advising so serious a step as abdominal section, except as a last resource. Dr. Parsons believed that electrolysis would prove successful in hæmorrhagic cases whenever the electrode could be made to touch the whole of the bleeding surface. He had sent out of hospital a few weeks ago a case where bleeding had been incessant for two years; after twelve applications it stopped, and since then the patient had had two normal periods with only slight show.

Dr. BANTOCK could not express himself in favour of electrolysis. There had been much assertion as to what this treatment was going to do, but little evidence of what it had done. Dr. Playfair's cases failed to convince him of the special advantages of the method. A year ago Dr. Woodham Webb stated that while one of the electrodes was applied over the hypogastrium by means of a filthy mess of potter's clay, the other electrode was always applied within the uterine cavity. This practice was based on an alleged electrolytic action, very beneficial for uterine fibroid disease. Dr. Bantock did not believe there was a tittle of evidence in support of the idea of electrolytic action extending between the poles. Apostoli himself and some of his followers had acknowledged the correctness of this opinion. Through the failure of the supposed electrolytic method they had taken to the totally different practice of thrusting one of the electrodes into the substance of the tumour. This resembled Dr. Greenhalgh's way of treating fibroids by thrusting the actual cautery into their substance—a practice which had fallen into well-merited neglect on account of unfavourable results. Both methods sought to bring about the destruction of the integrity of the tumour, it being supposed that if once the degenerative process were started it continued till the fibroid tumour entirely disappeared, leaving, contrary to Dr. Parsons's evidence, not a trace behind. The caustic action at the poles Dr. Bantock admitted, but he thought that this method offered no advantages over other practices in the treatment of those granulations on which uterine hæmorrhage so often depended. The alleged diminution in the size of the tumour was due rather to a change in the condition of the uterus itself. Seven years ago he removed the appendages of a patient subject to a uterine fibroid; three weeks later the whole mass had diminished by nearly one-half. Within two months, on the return of menstruation, it became as large as before operation, and three years later he had to perform supravaginal hysterectomy. It was the hypertrophied uterine walls which had diminished in size. The statement that although the tumours became smaller after a course of electrolysis, they did not disappear, was astonishing; after the removal of the appendages, if the tumour itself became smaller at all, the process went on to complete disappearance. Dr. Apostoli had insisted that a profound knowledge of gynecology was necessary for the successful application of his method. Dr. Bantock referred to two cases recently published by Dr. Apostoli, where it really appeared that there was a collection of fluid in the pelvis, and the use of a trocar and cannula would have finished the matter in five minutes instead of several days. It was evident that Dr. Apostoli had no idea of the exact nature of the conditions in these two cases. Dr. Bantock did not oppose the method itself, but rather the exaggerated claims which had been set up for it. Nobody could be convinced, either by the cases selected by Dr. Webb from Dr. Apostoli's records of five years' experience, nor by Dr. Playfair's cases. On moral grounds, Dr. Bantock opposed the manner in which this system of treatment by electricity had become a fashion of the day. Dr. Bantock here expressed regret that a Fellow took these remarks to himself. On reading the list of the various and opposite diseases for which the treatment was recommended, we were reminded of the vaunted virtues of patent medicines, such as Holloway's, Beecham's, Cocker's, or Widow Welch's pills. Dr. Bantock concluded by saying that his mind was still open to conviction, and he was content to allow others to pursue the electrical treatment, provided it was done in a truly scientific spirit, free from that empiricism and imposture which at present characterised it.

Dr. ROUTH compared the opposition to the electrical treatment of women's diseases to the similar opposition to the sound and to ovariectomy in past days. Only those who had some experience

of the method could judge of its merits. He believed that it was efficient in many cases. Thus, the negative pole caused dilatation of the contracted passages, as in stenosis of the uterine canal; the extent of its dilating power in this respect had not been sufficiently dwelt upon. In one extreme case he could introduce two or three fingers into the uterine cavity after employing electricity. Hoping to dilate the cavity further, he gave ergot, when, to his surprise, he found that the drug closed the os. Errors of diagnosis had discredited electricity, as in one case of a tumour impacted in the fibroid disease. In its cavity were found a number of small tumours. The case recovered; but had the uterus been first dilated and the tumours removed one by one, the patient would have retained her sexual organs. In 1872 Dr. Routh cured two cases of large fibroid tumour by the electrical cautery, but the wounds made by the electrical agents then in use proved very troublesome to heal. This disadvantage was overcome by Dr. Apostoli's appliances. Dr. Routh stated that clinical experience showed the necessity of antiseptic injections after the application of electricity to fibroids, especially when rise of temperature occurred. The electric wire allowed the operator to limit the application of his remedy, both as to place and time, with great exactness. This was a great advantage, especially in fundal endometritis accompanied with discharge of tenacious mucus or pus. An ordinary caustic could not be applied with the same precision. Lastly, though hysterectomy was often justifiable, we must not forget that it unsexed a woman—a serious effect indeed; so that, if electricity could also cure a fibroid, it would be far preferable to a mutilating operation.

Dr. CHAMPNEYS considered that discussion on the subject, especially as to permanency of success, was premature. Those who disbelieved in the method were not necessarily either ignorant, prejudiced, or even inexperienced; those who did not publish their successes might be perfectly capable of forming a judgment. He had given the method a trial, but did not consider that the time had arrived for the publication of his results. As to the assertion of Dr. Playfair that rest had nothing to do with the cure of his cases of fibroids, his hospital patients being kept out of bed, it must be remembered that, for a poor woman, a residence in hospital was truly rest, even if she did not keep to her bed. Fibroids, again, were liable to extraordinary spontaneous variations in size; this must be remembered in cases where the tumour became markedly smaller after electrolysis; cause and effect might be confounded. In short, Dr. Champneys was not convinced by any of the cases reported in the papers under discussion. In Dr. Shaw's communication decidedly facts scientific were to be found, but the double electro-puncture as carried out in his experiments did not necessarily illustrate what happened in ordinary clinical cases. Finally, Dr. Champneys had heard of widespread suppuration, of septicæmia, and of death after the employment of this method, and regretted that these cases had not been reported.

Dr. GALABIN wished to know if electrolysis and consequent absorption of the cells of the tissues or tumour took place midway between the positive and negative poles, or only at the poles. He criticised the former opinion very strongly on physical grounds, and was inclined to believe that the effects of electric treatment in cases of fibroid were due to caustic action. Dr. Galabin regretted that so little satisfactory evidence on the treatment of fibroids had been brought forward. As a caustic, electricity was valuable when the interior of the uterus required treatment and the cervix was narrow; in other respects it was hardly superior to other caustic agents.

Dr. HEYWOOD SMITH was averse to allowing prejudice and inexperience to shelve the electrical question, but at the same time he thought that the present discussion would be fruitless. The natural fluctuations in the size of fibroids must be more accurately studied. He believed that electrolysis was of value in promoting the absorption of inflammatory deposits in the pelvis after the stage of active inflammation had passed away, as Dr. Parsons had already demonstrated. The methods should be systematically tried in intractable cases of obscure ovarian pain. A good handbook, indicating the right line of investigation as well as the use of instruments, was much needed.

The PRESIDENT did not object to Dr. Playfair's claim that electricity should be placed on its trial. It had been already tried in the treatment of women's diseases for some time. The literature of the subject was not inconsiderable, but it was very disappointing, for it mainly consisted in the description of instruments and

the mode of using them. Dr. Apostoli, in particular, had published little else, except a series of general assertions and sweeping statements. Now, in estimating the value of the published work of an author not personally known to the reader, and whose powers of observation could not be tested personally, the reader should be acquainted with more than one of that author's published writings. He should know the author's record, for one work might throw much light upon the value of another. In 1881 Dr. Apostoli read, before the International Medical Congress, a paper wherein he proposed to treat the uterus during the lying-in period by faradisation, with a view to prevent subinvolution, metritis, and other evils. The Fellows of the Society might form everyone his own estimate of that proposal. In a later work by Dr. Apostoli, on chronic metritis and its treatment by electricity, there was much about instruments, and many sweeping assertions, but not a single case in support of the latter. Dr. Steavenson's paper was not free from similar statements. He said that the contracted cervix could be dilated by electricity, with results more permanent than after dilatation by other means. We had, however, no data which made it possible to form any valid conclusion on the permanency of the effects of tents, bougies, etc. How, again, could Dr. Steavenson justify his assertion that electricity cured the stenosis of the cervical canal caused by amputation of the cervix by the galvano-cautery? The President severely criticised the statements of Dr. Carlet, a pupil of Dr. Apostoli, in a work on the treatment of fibroids by electricity after the method of his master. Dr. Carlet declared that small interstitial fibroid tumours were often regarded as chronic metritis, engorgement of the uterus, ulceration of the neck, antelexion, anteversion, and especially retroflexion and retroversion. Such was the dominant idea in Dr. Carlet's work, as revealed by the ninety-four cases which he described. Fifty-nine were treated by positive galvano-caustic. In four cases only did the canal of the uterus measure over 4 inches, the greatest length being 5½ inches. In twenty-five it measured less than 3 inches! Together with the slight elongation of the canal there was enlargement and induration of the uterus, with hæmorrhage. The President was not ashamed of the ignorance which regarded these cases, with two or three exceptions, as cases, not of fibroid, but of subinvolution or chronic metritis. These cases were treated for hæmorrhage for periods varying from two months to a year; yet in none did the diminution in the length of the canal exceed 1.5 centimètre. They could have been effectually treated in a shorter time by other means. The President then showed that the evidence in respect to twenty-one out of the ninety-four cases treated by negative galvano-caustic was equally unsatisfactory. Five cases were treated by puncture, mostly large fibroids, but in only one could Dr. Apostoli introduce the sound. The canal measured 15 centimètres before and 11½ after treatment. This was a diminution of 3½ centimètres, a little less than 1½ inch—a decrease known to occur as a part of the cyclical changes of fibroids. Inconclusive, in a similar manner, was the record of nine cases treated by positive and negative galvano-caustic. In none out of all these cases did any alteration in size take place which might not be presented by fibroids when not treated at all. The method had thus been put to the test by its founder, and with very unsatisfactory results. There might be a place for the employment of electricity in the treatment of diseases of women, but as yet no case had been made out for it.

Dr. STEAVENSON felt some difficulty in replying to all the questions included in the discussion. He hoped that it would be remembered that he wrote his paper more than a year ago. The method had since undergone modifications. He had not admitted that the electrolytic action of electricity was limited to its cauterising properties, but advocated a more extensive use of electrolysis in those diseases of women where caustics were most usually employed. The apparatus was cumbersome and its management difficult, so that the new method was not likely to supplant others; but to those who could manage the apparatus, electrolysis would prove, as Dr. Horrocks had said elsewhere, a more efficient and elegant way of applying caustic than any other that we possessed. In reply to Dr. Bantock, he maintained that this caustic action was true electrolytic action. Electrolysis certainly took place at the poles, and though this important point was not settled, Dr. Steavenson believed that it also went on in the tissue between the poles, as, for example, in the substance of a tumour. The science of electricity favoured this view, especially when the electric affinities of animal tissues were considered; and Dr. Parsons's scientific experiments were of high value in this respect. Turning to the treatment of erosions and catarrh, he

brought forward evidence to prove that electrolysis, instead of being a longer, was really a shorter, method of cure than any other, for it was a better local remedy than any caustic. Some of his cases certainly required three or four months' treatment by electrolysis; but they had mostly undergone, without benefit, prolonged application of mineral caustics, in some instances for one or two years. Urethral caruncle, was best treated by galvanocautery, with cauterisation of the raw surface left after removal of the growth. Turning to Dr. Playfair's remarks, Dr. Steavenson said that gynecologists should not attempt this treatment without some knowledge of electricity, nor electricians without some knowledge of gynecology. Dr. Playfair had urged that cases suitable for treatment could only be selected by men who had a superior knowledge of diseases of women. Dr. Steavenson had enjoyed that privilege at St. Bartholomew's Hospital. In reply to the President, he thought it premature to say that the enlargement of the cervical canal for dysmenorrhœa produced by electrolysis was more permanent than when it was effected by mechanical dilatation or by incisions; but the President admitted that some contraction occurred at once after the canal had been stretched to a large size by dilatation. Dr. Steavenson declared that the case was different after electrolysis. There was no immediate contraction, and certainly none for a month or six weeks; but for how long the enlargement of the canal was maintained he had not sufficient experience to prove. As to the taunt that if cicatricial tissue out of sight in the pelvic cavity could be made to disappear by electrolysis, cicatricial tissue on the surface of the body might be and ought to be removed by the same method, though the advocates of electrolysis shirked that test, Dr. Steavenson said that, on the contrary, he had tried electrolysis with success on cicatrices at the meatus of the urethra, and on the brawny tissue around old perineal and scrotal fistulæ. The dense tissue had visibly softened down.

Dr. GIBBONS admitted that some of his cases might have been cured by other means, but maintained that the results seemed more satisfactory, and, where he could trace the history, the patients seemed more thoroughly cured by electrolysis than by other methods. The caruncle case, criticised by Dr. Herman, required two applications for a special reason, which he explained. He further admitted that the method was very unsuitable for private and general practice, yet, with all its present disadvantages, it was a means of treatment well worthy of prolonged trial by those who had patience and material at their disposal. He admitted again that, as Dr. Playfair had insisted, clinical facts must be sought and recorded; yet already he had known of great temporary benefit from electrolysis in a case of bleeding fibroid. Dr. Bantock was clearly prejudiced against electrolysis. Dr. Gibbons, while insisting that electrolysis as a means of curing fibroids deserved more trial, and would be better, if successful, than oophorectomy or hysterectomy, wished it to be remembered that the method gave promise in other directions, as his own paper demonstrated. Electrolysis should be carefully applied in obstinate, intractable affections like chronic metritis, and not rejected until wide experience had proved it to be unworthy of support.

Dr. SHAW believed that an increase of arterial tension really took place, and continued after the application of the current, and had no doubt that what was understood by electrolysis really took place, for, at the positive and negative poles, together with acids and alkaline bases respectively, there were acid and alkali albumens. Some of the cases of failure were due to local irritation, the result of a too early or too vigorous use of the hæmostatic action of the positive pole. A preliminary or occasional resort to the derivative action of the negative pole appeared advisable. The negative pole acted, he believed, in a twofold manner on a stricture or a closed cervix. First, it caused the swelling up of capillary granulations; secondly, it exercised a directly solvent action on the fibrous tissue. Dr. Shaw had satisfied himself by a series of experiments, a description of which was appended to his paper, that electrolysis went on between, as well as at, the poles.

BRITISH GYNÆCOLOGICAL SOCIETY.

WEDNESDAY, JUNE 13TH, 1888.

ARTHUR W. EDIS, M.D., F.R.C.P., President, in the Chair.

Supravaginal Hysterectomy.—Dr. G. GRANVILLE BANTOCK exhibited a multiple fibroid tumour of the uterus, weighing 1 lb. 9 ozs., removed from a single woman, aged 27. The sym-

ptoms were severe dysmenorrhœa and menorrhagia, obliging the patient to relinquish her occupation. She was very anæmic from loss of blood. The tumour was removed on May 9th, and the patient was convalescent. A very small portion of the cervix was left, and for some time there was a free communication between the vagina and the stump-hole along what remained of the canal of the cervix. He had observed this in several cases, but in all the fistulous track had closed, and he regarded it as a matter of no importance. In addition to the tumour in the fundus, forming the bulk of the mass, there were numerous small fibroids scattered through the organ, and at least five small fibroids pedunculated in the cavity; also a large single fibroid of the soft œdematous variety, situated in the right wall of the uterus, and weighing $\frac{1}{2}$ lbs., which he had removed from a widow, aged 40. The tumour had grown rapidly. Up to six months previously menstruation had been regular and quite moderate, but since then had become more and more abundant, until in the last two periods the flow was excessive. Supravaginal hysterectomy was performed on May 28th, and the patient was doing well. In both cases he used his new serre-nœud and wire of Delta metal. There was a marked absence of any blackening of the stump, and of that disagreeable odour which was so inseparable from the use of the iron instrument and wire. If properly treated it would stand any strain that was required.—Dr. ROUTH, in reference to the first case, remarked that removal of the tubes, expecting thereby to effect a cure, would have failed. Electricity also would have been, useless. He maintained that if the uterus had been well dilated, it would have been possible to find out the presence and to remove the uterine tumours, and so stop the hæmorrhage.—The PRESIDENT exhibited a large fibroid similar to the one exhibited by Dr. Bantock. It was very large, and occurred in a young widow, aged 23. The prominent appearance of her abdomen seriously interfered with her prospects. Two and a half years before she had given birth to a living child, the confinement being followed by some trouble. Two years later she again became pregnant, but miscarried at an early date. Shortly after this hæmorrhage declared itself, and was so severe she almost sank. She rallied, however, and was enabled to resume her duties. He thought that by removing the ovaries the bulk of the tumour might diminish, but the operation had proved so difficult that he determined to remove the growth in its entirety. This he effected in the usual way, and the patient recovered without a bad symptom. He also exhibited the ovaries, one of which was very much enlarged and the other showed signs of commencing cystic disease, which he had removed from a patient with a fibroid not larger than the double fist. In that case the hæmorrhage was the reason for surgical interference. Hydrastis canadensis had checked it for a time, but the following period was again profuse. The patient had made a good recovery. In reference to exploring the cavity of the uterus beforehand, he observed that the result was very often to set up some cellulitis. In the first case it was the size of the tumour, and not the hæmorrhage, which necessitated the interference, the converse being the case in the latter instance. In neither patient would dilatation of the cervix and exploration of the uterine cavity have been a prudent plan. Nothing could have been gained by it in the first, and distinct risk to the patient would have followed in the latter case.—Mr. LAWSON TAIT said that, if one believed the descriptions published, it was just in such a case as the first exhibited by Dr. Bantock that electricity should prove useful, otherwise it was of no use at all. It was a pity it had not been tried, but of course the actual condition of things was not known. Dilatation in nineteen cases out of twenty did no good, and in such a case its risks would be nearly as great as hysterectomy. They were beginning now to hear the other side of the story of electrolysis, and a death had occurred at Liverpool. He had that day operated upon a lady who had been treated by electricity for months, not only without benefit, but with absolute detriment.—Dr. ROGERS agreed that such a fibroid had far better be removed. He had, however, seen electricity do a great deal in the removal of these fibroids, both small and large. Deaths had occurred in London as well as Liverpool, but the success had been great in other cases.

Ruptured Tubal Pregnancy.—Mr. LAWSON TAIT brought before the Society a case of this nature. The patient was brought two weeks ago with a history of having just recovered from a severe attack of ovaritis. She was 28 years of age, had been married nine years, and had three children, the last ten months ago. She had been ill ten months, losing a good deal of blood, with pain in the

lower part of the abdomen, and was really very ill. A large cystic mass could be felt in the pelvis, rising three inches above the brim. He considered that it was a case of suppuration, and therefore opened the abdomen. It turned out to be nothing of the kind. The broad ligament on the left side was distended with a large quantity of blood-clot, and it was very difficult to ascertain what the condition really was. In the Fallopian tube, which he had laid open, the ovum was found. The patient was not very intelligent, and no history was obtainable. There had been nothing to lead one to suspect pregnancy, but the anatomical relations of the parts made it clear that it was a case of tubal pregnancy which had ruptured into the broad ligament. Had he known he might, of course, have operated from the vagina; but even then he would have done exactly the same thing. There were evidences of great recent bleeding into the cavity, and that might have continued unless the broad ligament had been tied.

Extra-Peritoneal Cysts.—Mr. LAWSON TAIT had had two of these rare cases within a week. The first was in a child of 14, and he had at first taken it for a parovarian cyst. On the operating table an alteration in the zone of resonance and dulness was rather puzzling. On opening the abdomen, he found it was one of those extra-peritoneal cysts, lined with the usual amniotic membrane. Bearing in mind the unsatisfactory results of drainage in these cases, he scraped the wall, washed the cavity well out, and then filled it with water, hermetically closing the wound. The high temperature at once subsided, and there was no appearance of the sac refilling. If it refilled, he meant to tap it and inject iodine. In future he would do this at the time of operation. In the second case, there were very acute symptoms. The patient, a woman, aged 21, looked very ill. He recognised the condition at once, but, in addition, he found the two Fallopian tubes greatly distended, covered with granulations, and full of a cheesy material, being the tubes occurring in the cysts. The first patient recovered, and had since continued quite well; and so far this young woman had done well also. The stuff was undoubtedly tubercular. If the patient continued to go on well, it would go far to render necessary a revision of the views on the pathology of tubercle, which might, after all, prove to be a merely local disease.

The Influence of Removal of the Uterus and its Appendages on the Sexual Appetite.—Mr. LAWSON TAIT read this paper. He said that the popular belief on many points was singularly erroneous. For instance, it is believed that removal of both testicles in a male deprives him not only of the power of impregnating the female, but also of the power of engaging in sexual intercourse. The only ground for this belief, freely asserted in many published authorities, seemed to be a hastily constructed conclusion not substantiated by facts. Granted that the removal of both testicles from any animal before it had reached puberty would have such an effect, it by no means followed that removal of the testicles in an adult would do more than prevent him procreating. He had the evidence of a patient in whom one testicle had been removed at the age of 19 for scrofulous disease, and the other at 39 years of age for some growth which was stated at the time to be cancer. Intercourse had been subsequently as satisfactory as when first married. From extended inquiries in cases where both ovaries had been removed for many and various reasons, and at all ages from 17 to 60, he was satisfied that the ovaries had nothing to do with the sexual appetite. The test cases were not those where the operation had been performed after marriage or other experience of sexual intercourse. Evidence of the retention of the sexual appetite in such cases would mean nothing at all. But the evidence of women who have been operated upon in early youth in conditions of ascertained virginity, who have married afterwards, and yet in whom a sexual appetite had been developed, was absolutely unanswerable. He had had the opportunity of making inquiries in seven such cases, where the ovaries had been removed, and in three cases where the uterus as well as its appendages had been removed for fibro-myoma. The evidence given was always that of the husband, for many reasons a better witness than the patient herself. —Mr. HARVEY agreed as to the general result of the removal of the ovaries, but he had met with one case where the loss of sexual appetite had followed their removal. —Dr. MANSSELL-MOULLIN said that the popular impression was largely shared by the profession: No one would hesitate now to remove the ovaries and appendages where they were obviously diseased, but there was a large class of women whose sufferings were undoubted, but in whom no manifest disease could be detected. The fear of "unsexing" the patient had acted as a restraining influence, and such cases were allowed

to drift on indefinitely. The evidence which Mr. Tait had brought before them would materially strengthen their hands in dealing with such cases.—Dr. GRANVILLE BANTOCK, Dr. HEYWOOD SMITH, Dr. FANCOURT BARNES, Dr. ROUTH, and others took part in the discussion.—Mr. LAWSON TAIT replied.

CEYLON BRANCH.

SATURDAY, MARCH 3RD, 1888.

DR. VAN DORT, Vice-President, in the Chair.

Anchylostomiasis.—Mr. FERNANDO, at the request of the Honorary Secretary, read, on behalf of Mr. GRATIAEN, his paper entitled "Notes on some Cases of Anchylostomiasis."—Dr. ATTYGALLE regretted to find that no facts or reasons were given to show that the disease was directly caused by the presence of the anchylostoma in the duodenum. No doubt it was found in some persons who died of anæmia, but so were the round worms, and if the disease was caused by the former, why not equally by the latter? He had before him the result of seventy-eight *post-mortem* examinations, in which diligent search was made for anchylostoma in the intestines both by himself and by his house-surgeon, Mr. Rosairo, when he was in charge of the Kandy Hospital some time ago. Of these, sixty-eight were well marked cases of anæmia, in all of whom, if the theory put forward by Dr. Lutz and others were correct, he ought to have found the parasite in question in the intestines. But he found it only in thirty-six of the cases, and in thirty-two, or 47.05 per cent., it was absent; but lumbrici were observed in most of the cases, both in those in which the anchylostoma duodenale was present, and in others in which it was absent. The remaining ten patients were all plethoric subjects; of these, nine died of acute diseases, such as pneumonia and continued fever, and one from injury to the spine. In these, the anchylostoma was present in five, that is, in three cases of pneumonia, in one of continued fever, and in the case of injury to the spine. Of course, it might be said that had these persons lived longer, they would have all become anæmic after a time, but why were they absent in thirty-two of the undoubted anæmia cases if the disease was really caused by its presence in the intestines? Might it not be considered with greater reason that whatever induced the disease in the latter, that is, in cases in which the anchylostoma was absent, was also the cause of the former, and that the presence of anchylostoma in these was of no more import in its causation than that of the lumbrici found in common with it in a large majority of the cases? Uncomplicated cases of anæmia were by no means difficult to cure, and he had treated successfully, as the Kandy Hospital records would show, scores of cases occurring among estate Malabars as well as Singhalese villagers, without thymol or any other specific treatment, and only with good nourishing food and remedies calculated to improve the general health; and the success which attended Mr. Gratiaen's cases, in his (Dr. Attygalle's) opinion, was due more to the treatment on general principles, which he adopted after the exhibition of thymol, than to the expulsion of the parasite by the latter. With regard to cases of anæmia that occurred in epidemic form among the workmen employed in the construction of the St. Gothard Tunnel some years ago, if he (Dr. Attygalle) recollected aright, it was attributed by several of the Swiss physicians to their having been ill-fed and ill-housed; in other words, to defective diet and defective sanitary arrangements in respect of their dwellings. It would not, he thought, be denied as a rule, that the disease occurred mostly, if not entirely, among the poorer classes of people, whether in Ceylon, Egypt, Brazil, or South of Europe—countries where it is chiefly met with—who were ill-fed and ill-housed, and not infrequently living in malarious districts. He was inclined to the belief that the cases of anæmia met with in Ceylon, at any rate, were caused by the deficiency in certain of the essential elementary principles, probably albuminates, of which the dietary of the poorer classes of natives (both Singhalese and Malabars) was particularly deficient, aided to a considerable extent no doubt by other secondary causes, such as living in malarious districts and ill-ventilated houses. It must be borne in mind that the anchylostoma did not reproduce itself in the human intestines; its number depended entirely on the number of ova swallowed by each individual, and it was also so small in size that one would hardly think it possible, without further proof, even if it were found in large numbers, which was not the case as a rule, that it would consume such a quantity of blood as to cause anæmia.—Dr. BRITO hoped he would not be considered egotistical if he stated that the first discovery of the anchylostoma duodenale in Ceylon was made by him, when he was

pathologist of the General Hospital, in Dr. Driberg's presence, who was acting at the time for the Medical Superintendent, and who commenced the treatment of cases with reference especially to the expulsion of the worm. It struck him very forcibly that in deaths from other diseases, such as pneumonia, fevers, etc., anchylostoma had been met with. Although they were not found quite so frequently as round worms, yet, in some cases where round worms did not occur, anchylostoma did. After the statistics and assertions of Dr. Attygalle in regard to many cases of anæmia in Ceylon in which he did not find the anchylostoma present, he (Dr. Brito) would say that he agreed with him. In the St. Gothard Tunnel operations a peculiar kind of anæmia was associated with the presence of the anchylostoma, he admitted; but the parasite was so frequent in the *post-mortem* examination of cases that did not die of anæmia, that he had his doubts as to whether its presence invariably gave rise to anæmia with all its train of symptoms. Thymol expelled the worm, and he found this to be so whenever the ova was found beforehand; but one of the greatest dangers in this treatment was its tendency to cause intestinal irritation, and this was a danger to guard against. In several of the deaths after the administration of thymol, he found marked congestion of the intestinal canal.—Mr. SCHOKMAN quite agreed with Dr. Attygalle that, in the generality of cases, anæmia was due to bad diet and malnutrition. He said that, in his experience, such cases were successfully treated by ferruginous tonics and nutritious diet; but the patients, after they returned to their homes and resorted to their usual poor diet, after some time again sought admission into hospital on account of relapse. Thanks were due to Mr. Gratiaen for the report of a number of cases of anæmia in the Kandy Hospital, which he stated were successfully treated by him with thymol, according to Dr. Lutz's method. It would be interesting to know if those cases ever returned to hospital with a relapse of the disease, for, if they did, Mr. Schokman thought the theory that anæmia was due to anchylostoma duodenale failed.—Mr. ELEVATAMBY said that when Mr. Brito suggested the theory, the treatment adopted was by *felix mas*, *santonine*, etc.; but more cases were lost than by the expectant treatment. He was the house-physician of the General Hospital at the time, and he found in three-fourths of the cases of anæmia that the expectant treatment answered. It was evident the patients could not stand the diarrhoea. The active treatment had increased the rate of mortality. In very few cases was iron used—ammonia seemed to answer better. As regards the parasite, he found in cases he had examined medico-legally that the anchylostoma was often present without there being any anæmia. In two of the cases recorded by Mr. Gratiaen there was a history of malarial fever, and, considering the food of the estate cooly, there would be no difficulty in tracing the cause. In this anæmia, the liver and spleen were often diseased, and this diseased state tended to keep up the anæmia. There was no reason why the round worm should be absolved from all blame for causing the anæmia by absorbing all the nutritious material from the food, whereas the anchylostoma was said to suck up the blood.—Dr. Loos said that he had seen some of the cases of anæmia which were under treatment in the Kandy Hospital, and had also seen the ova and parasites passed by the patients. The disease called "panduwa" by the natives—a form of progressive pernicious anæmia—might be regarded as a mystery. It was a disease not amenable to treatment; and iron, bark, and other tonics had been given without much effect. In 1870, the Straits Government wished for some information regarding beri-beri from the Government of Ceylon, and on that occasion he (Dr. Loos) wrote a letter to the Principal Civil Medical Officer, in which he suggested that panduwa and beri-beri might in some way be connected. The latter disease was not now known in Ceylon; but was it possible that the same causes which produced the panduwa, operating in an intenser degree, might have caused beri-beri in times when the climate was more malarious and sanitary defects more common? Ordinary forms of anæmia arose from hæmorrhage, chronic discharges, and other well-known causes; but the anæmia now referred to was a special disease, the cause of which had not been ascertained.—Dr. Rockwood said that he could corroborate the observations of the previous speaker that certain cases of anæmia were not amenable to treatment, especially cases of pernicious anæmia. (Dr. Loos here said that he referred in his remarks to cases of progressive pernicious anæmia of the country.) Dr. Rockwood, continuing, said that in his experience the cases of anæmia that resisted ordinary treatment were not those resulting from mal-nutrition or malaria,

but where the anæmic state was associated with a fair condition of body and considerable development of fat, His colleague, Dr. Macdonald, who had worked with such enthusiasm in bringing the subject of anchylostomiasis to the notice of the profession in Ceylon, and who was now absent in Europe, often drew his attention to the association of anæmia with a certain amount of obesity, and he would look upon this feature as a means of differentiating ordinary anæmia and chlorosis from anæmia due to anchylostoma. Through the courtesy of Dr. Macdonald he had the opportunity of witnessing *post-mortem* examinations in cases of anæmia associated with anchylostoma, and he was particularly struck with the amount of fat deposited in the skin, abdominal wall, and omentum, in cases where quantities of the worm and ova had been passed under the influence of thymol. It was easy to understand how a process of abstraction of blood, a fluid rich in oxygen, by the anchylostoma, would lead to the conversion of albuminoid tissue into fat. He had also noticed a greater liability to retinal hæmorrhage in cases of anchylostomiasis than in simple anæmia.—The CHAIRMAN said that he considered Mr. Gratiaen deserving of a special vote of thanks for having evoked so interesting a discussion. He had himself no personal observations of the disease to contribute to those which had just fallen from the various speakers who took part in the discussion, but would merely mention with reference to a remark made by Dr. Attygalle that the anæmia of the miners of St. Gothard Tunnel was believed to be due to other causes than anchylostoma, that his recollection of the discussion on the subject when it was first brought to the notice of the International Medical Congress in 1881 by Dr. Lang, of Geneva, was that all the speakers were agreed that it was undoubtedly due to this cause and this alone. At the same time he was much struck with the fact that in not one of the three cases so elaborately reported by Mr. Gratiaen were any of those symptoms noticed which characterised the anæmia of the St. Gothard miners, namely—digestive troubles, abdominal pains, diarrhoea, and intestinal hæmorrhage. It would appear from the remarks made by some of the speakers, as well as from Mr. Gratiaen's report, that there were no diagnostic or characteristic symptoms by which the pernicious anæmia due to anchylostoma could be distinguished from similar anæmia due to other causes or other entozoa.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, MAY 18TH, 1888.

W. H. RANSOM, M.D., F.R.S., President, in the Chair.

Electrolysis in the Treatment of Uterine Disease.—Dr. ELDER read a paper on this subject. Mention was made of the points of difference between the method of Apostoli and that of other workers in the same direction, and the mode of application in the different varieties of myomata was described. Several cases illustrating the beneficial effects of electrolysis were given, and reference made in general terms to the results obtained in over forty cases. Dr. Elder believed that in suitable cases this remedy was far in advance of any other purely medical remedy, and in the vast majority of cases would do away with the necessity for hysterectomy or removal of the uterine appendages.

Abdominal Abscess following Enteric Fever.—Dr. MICHIE read notes of a case of abdominal abscess following enteric fever treated by abdominal section and drainage. The patient complained of pain and tenderness a little to the left and below the umbilicus during the fourth week of enteric fever. Towards the end of the seventh week there appeared a hard and tender lump in the same situation; the patient had shiverings and night sweats. At the end of the tenth week Dr. Michie saw the case in consultation with Dr. Brown Sim. At that time the swelling was about twice the size of a cocoa-nut, hard, slightly tender, movable; there was no discoloration of the skin. No fluctuation could be made out; there was nothing unusual in the pelvis, temperature 100° F., pulse slightly accelerated. The diagnosis was, "Abdominal abscess having its origin in a suppurating gland of the mesentery." On February 1st abdominal section was performed, the abscess opened and washed out with plain warm water, and a large rubber drainage tube inserted. The patient was dismissed on the twenty-first day after operation, all discharge having ceased and the wound healed. Dr. Michie attributed the speedy progress of the case to (1) the equable intra-abdominal pressure, (2) the large-sized drainage tube, (3) the absence of any washing or syringing out of the cavity after the first time. He deprecated this practice in the treatment of abscesses or wounds generally.

Cerebral Atrophy in Hemiplegia.—Mr. E. POWELL showed a specimen of brain atrophy from an imbecile woman, aged 46, who had been epileptic and hemiplegic on the left side, since she was 3½ years of age. At that age she had a "fit," was totally blind, and more or less helpless for seven weeks, when she gradually recovered her sight, but remained hemiplegic. She had also internal squint of the left eye, and anæsthesia of the left side. The other special senses were normal. She had a cousin who was epileptic. The brain, on *post-mortem* examination, presented the following appearances in the right hemisphere: there was complete atrophy of the occipital lobe, also considerable atrophy of the ascending convolutions, the fusiform lobule, and the lingual lobule. The angular gyrus was apparently healthy. The left hemisphere and remaining parts of the brain were also apparently normal. The right hemisphere weighed two ounces and three-quarters less than the left.

Specimens.—Dr. HANDFORD: (1) Intestinal Lesions in Enteric Fever from a Child; (2) Subacute Aortitis.—Mr. ANDERSON: Fibroid Tumour removed from Uterus.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

THURSDAY, JUNE 7TH, 1888.

FREDERICK ABELL HUMPHRY, F.R.C.S., in the Chair.

CLINICAL MEETING.

Blood Cyst in Neck.—Dr. BLACK showed for Mr. BLAKER a large blood cyst in a boy's neck. He regarded it as a degenerated nevus. A small quantity of bloody fluid had been extracted by an exploring syringe, and it was proposed to treat the cyst by tapping.—Mr. W. TURNER was in favour of free opening.—Dr. WHITTLE referred to a case of congenital blood cyst under the gluteus maximus, which was cured by free opening and removal of a portion of the cyst wall.

Supernumerary Digits and Deformity of Mouth.—Dr. BLACK showed a case of supernumerary thumbs, or fingers (?), on both hands, associated with a deformity in the mouth like a lateral hare-lip. The child was mentally deficient.

Double Hare-Lip.—W. HARRISON, L.D.S. Eng., showed a cast of an unusual case of double hare-lip. The child, a boy, aged 5 weeks, was admitted into the Royal Alexandra Hospital under Dr. Whittle. The premaxillary bone was firmly attached to the nasal septum and was very prominent, the columella being at the tip of the nose. There was an unusually wide gap in the lip, but no opening in the palate, only a slight depression. Dr. Whittle removed the premaxillary bone with forceps, but utilised the columella. The child was discharged well, but was readmitted a few weeks later with acute diarrhoea, and died within forty-eight hours.

Sarcoma of Femur.—Mr. HUMPHRY narrated the case of a girl, aged 20, who suffered from a burning pain in one thigh, but was otherwise apparently in good health. She fell in the street, and was admitted into the county hospital with fractured femur. She had no pain in hospital, but the limb swelled and no union took place. A sarcomatous tumour was diagnosed. Mr. Humphry amputated at the hip-joint. The specimen showed the tumour growing from within the bone, destroying the shaft.—Mr. W. TURNER spoke of the probable recurrence of the growth, local and distant. He considered it a mixed-cell sarcoma. He referred to a case of myeloid tumour of the humerus, where, a year after amputation, there was local recurrence treated by ligature of axillary artery.—Mr. VERRALL and Dr. UTHOFF referred to a case of myeloid tumour of humerus, in which fracture occurred just before operation in bringing the patient from the ward. The clinical diagnosis was confirmed by examining the fluid withdrawn from the tumour by puncture. Myeloid cells were detected. Mr. Verrall referred to a case of sarcoma in a boy's tibia treated by amputation, where, after a year, there were no signs of recurrence.

Chian Turpentine in Uterine Cancer.—Mr. GEO. MORGAN read notes for Mr. SANDERSON of a case of uterine cancer treated by Chian turpentine, with relief to pain and hæmorrhage, apparent restoration of health, and extensive disappearance of growth.

Prolapse of Ovary.—Mr. HUMPHRY described a case of tumour in the inguinal ring of an infant, with vomiting and collapse, but no obstruction. On operating, it was found to be a prolapse of the ovary and Fallopian tube.—Mr. MORGAN mentioned a case of congenital prolapse of the ovary into the inguinal canal removed by operation.

REVIEWS AND NOTICES.

A MANUAL OF ZOOLOGY. By H. ALLEYNE NICHOLSON, M.D., F.L.S., etc. Edinburgh: William Blackwood and Son. Seventh Edition. 1887.

The new edition of this manual is considerably enlarged, and, in many respects, an improvement upon the previous editions. But it is not easy to decide for what class of students the book is intended: certainly not for beginners, as the description of "types" is not sufficiently detailed; not for advanced students, as the treatment of the subject is not nearly full enough, nor is adequate attention paid to the comparison of organs, or to embryology and other points. Probably, therefore, it is intended for more popular use, and in this respect it will prove of some value, provided that a thorough knowledge of a few animals has been previously acquired.

At the end of each group of animals a fairly extensive bibliography is given; but this loses much of its value from being arranged neither chronologically nor alphabetically, and there is no reference in the text to this bibliography. Moreover, in some cases the references are wrong (a matter which it is rather difficult to avoid), or the same work is quoted twice—for example, see page 317, where Nos. 19 and 28 are identical. In many points the book is not up to date; for instance, no mention is made of Balfour's and Sedgwick's works on *Peripatus*, nor to Vajdovsky's work on *Oligochæta*; and other instances will occur to anyone looking through the bibliography.

A good deal of exception might be taken to the classification, which is rather antique; for instance, the flat worms and nematodes are grouped together as "Scolecida" in the sub-kingdom "Annulosa." Again, it seems to us that the three groups, Hirudinea, Oligochæta, and Polychæta, are not, by a long way, of equal value.

Turning now to the descriptive part, we notice that the author neglects to point out that the "ectosarc" and "endosarc" of *Amœba* are continually interchangeable, but leads one to imagine that they are permanently separate, and proceeds to state that the "ectosarc" is the layer of which the pseudopodia are mainly composed; while, in the figures, the latter are evidently and correctly represented by endosarc surrounded by a thin layer of ectosarc. The figure of *Paramecium* (p. 97) is not a very accurate representation of the animal.

The statement (p. 99) that the contractile vacuoles "are now usually regarded as corresponding with the water-vessels of various of the higher animals (such as Rotifers)," scarcely puts the matter in its true light; of course, the word *analogous* should have found a place in the sentence.

In the description of the *Acinetæ*, no mention is made of the fact that a mouth, such as is found in the Ciliata, is here absent; nor is the interesting fact pointed out that the embryos pass through a ciliated stage during development.

On page 124, we read that the cavity of Cœlenterate animals "represents the body cavity of higher animals;" it represents more, as it includes, in reality, both "body cavity" (coelom) and digestive tract. The characteristic ciliated pits of Nemertines are not even mentioned.

From his manner of speaking of the earthworms, a reader might imagine that the only ones existing are similar to Lumbricus, for the author writes, "the terrestrial forms are the earthworms (Lumbricidae)," totally disregarding the numerous genera of Perrier and others, such as *Perichæta*, *Acanthodrilus*, etc. We should like to know what is his authority for regarding the so-called "capsulogenous glands" as the organs which secrete the cocoon.

In dealing with the Crustacea, he writes (p. 320): "The number of pairs of articulated limbs is generally five to seven." Surely some slip of the pen must have occurred here. So, again, on page 358, the Schizopods are said to differ from Decapods in having a "larger number of thoracic limbs," whereas, doubtless, the author means that a larger number of limbs are used for progression.

In regard to the pericardium of Mollusca (p. 446), he says that it "is not normally filled with blood;" as a matter of fact the presence of blood in this cavity is extremely rare, if, indeed, it ever occurs; since recent researches tend to prove that the vascular system is completely separated from the pericardium.

In his description of *Amphioxus*, we are astonished to read that "the water" (having entered at the mouth) "passes through the slits in the branchial sac, and thus gains the abdominal

cavity (C), from which it escapes by means of.....the abdominal pore." The cavity here referred to has nothing whatever to do with the abdominal cavity, but is a secondarily formed chamber, and is of the same nature as the branchial chamber of a lobster. The statement in regard to the "pair of rudimentary eyes" is also incorrect.

Many other similar errors mar the book. Some of the figures, however, are very good, especially those referring to fossil forms and to mammalian dentition. But, to a student of zoology, the book will be found to be of little value.

NOTES ON BOOKS.

Notes on the Origin of the Belief in the Bis-Cobra. By J. Aécacio da Gama, Knight Commander of the Order of Jesus Christ, etc.; Chief Surgeon to the Bombay Eye and Ear Infirmary. —The natives of certain parts of India believe that there exists a reptile (generally considered to be a lizard) whose bite is twice as poisonous as that of the cobra-di-capello. The general opinion among Europeans and educated natives is that this creature is as mythical and non-existent as the amphispæna of the Rev. Cotton Mather. Dr. da Gama, however, seeks in a paper, read before the Natural History Society of Bombay, to show that the bis-cobra was a real animal, and that the name was originally applied, not to a venomous reptile, but to the comparatively harmless mangoose; while its supposed poisonous qualities are rather a survival of sixteenth century beliefs than any invention of the native mind or echo of the qualities possessed by any living creature. Dr. da Gama proves from the work of Dr. Garcia de Orta, published at Goa in 1563, that an animal called "bicho" was believed by the naturalists of the sixteenth century to have the power of killing the cobra snake in single combat, having first anointed itself with its own spittle after chewing the root of the cobra tree. Engelbert Kaempfer, who visited India about 1690, describes the cobra-tree, but says the Portuguese name for it was "mungo;" he also, in the same connection, speaks of the mangoose. Other authors inform us that the mangoose was a serpent-killer, so that our author believes there is no difficulty in identifying this little creature with the bicho-de-cobra of Garcia de Orta, of whose name he considers bis-cobra as merely a native contraction. He believes that the stories told by the early Portuguese naturalists of the poisonous breath and bite of the bicho-de-cobra, are sufficient to account for the present belief in the deadliness of the poison infused by the teeth of the bis-cobra; for that when the Portuguese adopted the native name "mangús," they left a belief in the native mind that the bis-cobra, an animal which the natives had never identified, and whose identity was quickly forgotten by the Portuguese, possesses poisonous properties of extraordinary virulence—a tradition handed down through two centuries, and still accepted and imparted. We think that Dr. da Gama has completely made out his case, and that the mangoose is the original of the bis-cobra. But we suggest that the legends of the superior power of the bis-cobra poison compared with that of the cobra-di-capello are certainly partly to be explained by popular etymology, which is the father of so many myths. Just as (according to Max Müller) the title of the constellation the Great Bear arose from the mistake of people who, having forgotten the first meaning of *riksha*, its original Sanscrit title (namely, "bright," that is, the bright ones—the stars), and knowing that *riksha* meant a bear, gave the title of the "bear" to the constellation, for all time and for nearly all nations; so we believe that the prefix "bis," having lost its old Portuguese form of "bish," and meaning of "beast," instead of being accepted as an unmeaning prefix, was supposed by the Indo-Portuguese to be one with the Latin "bis," and thus the bis-cobra would easily be translated into an animal having double the properties of the cobra-di-capello.

The Metropolitan Hospital Sunday Fund on Wednesday last had reached a total of nearly £35,000.

PROFESSOR MATHILDE WEBER, in a third edition of her work on *The Ethical and Sanitary Need of Female Practitioners for the Diseases of Women*, mentions that since the second edition appeared the German "Frauenverein" has received from a friend of the cause 80,000 marks for the advancement of female study, and that a still larger sum has been left by another friend for the purpose of founding a gymnastic institute for teaching women.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS, IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

CARBON CONES AND CASES (PATENTED).

A NOVEL and ingenious idea is skilfully embodied in these cones. The use of vapours for disinfection, deodorisation, or therapeutics has always presented some practical difficulties, and these difficulties have come in to reinforce certain theoretical objections which may be urged against methods of volatilisation hitherto employed. These cones appear to us, after careful trial, entirely to do away with the practical difficulties, and to obviate some, if not all, of the theoretical objections.

The general construction of the cones can be understood from the drawings, which are of about the same dimensions as the smaller sizes made. In Fig. 1 part of the outer casing has been

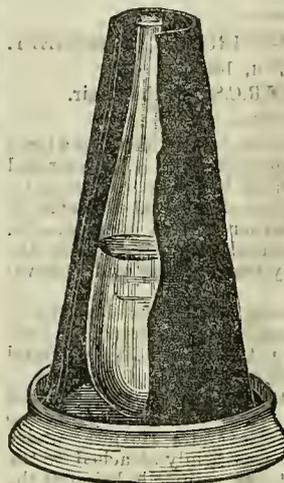

Fig. 1.

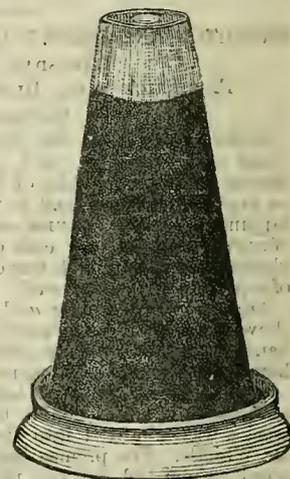

Fig. 2.

broken away to show the small glass flask in which the substance to be volatilised is placed; the flask is stoppered with a substance which melts at a low temperature; the cone proper is made of very pure carbon mixed with an oxidising substance, and is carefully constructed, so that its walls are of uniform thickness at all points; the base of the cone is fixed to a disc of incombustible material, resembling asbestos in appearance. The cone is used by lighting the top, and the carbonised casing then smoulders. Fig. 2 shows the appearance when the cone is well alight, and when the vapour is, on the average, first beginning to be emitted. The casing burns slowly and steadily, and the flask is heated from above downwards. The liquid, so soon as the heat reaches its surface, is vaporised, and rises through the narrow neck of the flask, where the temperature is still higher, and is propelled into the air with great velocity, and at a high tension. The inventors contend that as there is no tension on the mouth of the flask there can be no destruction of the active principles, that whatever is capable of being vaporised must at the given temperature escape, and that as only layer by layer of the contained substance becomes heated to the necessary vapour point, the contents of the flask never boil. It has been found possible by varying the proportion of the ingredients of the carbon shell to adjust the temperature attained to the requirements of each substance; by this means temperatures ranging up to as high as 1000° F. (537.7° C.) have been reached.

It is thus easy to understand that a large number of vapours and gases can be obtained; oxygen, chlorine, iodine, bromine, sulphurous acid, nitrous oxide, carbolic acid, terebene, creasote, camphor, the two chlorides of mercury, and ammoniac chloride are among those mentioned by the inventors; but it is a little surprising to find that eucalyptus and pine oil, and even the most delicate perfumes, such as stephanotis, white rose, and violet can be diffused through a room. The construction of the cones is so excellent that in the case of these perfumes the products of the

combustion of the carbon cone itself can be neither seen nor smelt; no doubt there is some loss with these perfumes, but the general result is that one of the smaller cones will thoroughly perfume an average sitting-room.

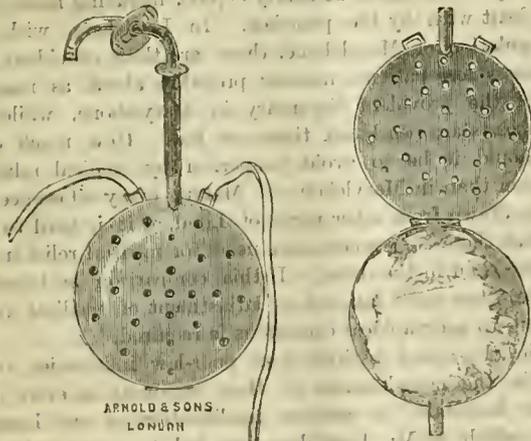

As will have been already perceived, the invention may be used for the administration of remedies, or for the deodorisation or disinfection of rooms; for the first-named purpose a cone may be burnt in the room, or—as, for example, with the ammoniac chloride cone—by adapting a suitable funnel the dense vapour may be inspired as it issues from the cone. For disinfection it is recommended to use first one or more mercuric chloride cones, and to follow with sulphurous acid cones; the iodine and bromine cones are also adapted for disinfecting rooms. The appended list of substances which are kept in readiness will speak for itself, the purpose for which each is designed being apparent; but the manufacturers invite suggestions for new formulae, and are also willing to issue the cases and flasks to medical men who may desire to use their own formulae.

Terebene	Creasote	Sulphurous Acid
Terebene et Iodum	Carbolic and Acetic Acid	Chlorine
Thymol	Thymol and Lavender	Bromine
Eucalyptus	Carbolic and Lavender	Iodine
Pinus Sylvestris	Hydrag. Subchlor.	Mercuric Chloride
Ammon. Chloride	Oxygen Gas	Perfumes
Bromo Eucalyptus	Carbolic	

The manufacturers are the Chemical Carbon Co., Limited, Basingstoke.

TRACHEA INHALER FOR USE AFTER TRACHEOTOMY.

THIS instrument is intended to overcome the dangers to tracheotomised patients from breathing cold air. It consists of a thin metal flask about four inches in diameter and half an inch in thickness, which is suspended round the neck and worn over the upper part of the sternum. The anterior surface is perforated. The flask opens like an oyster-shell, and the interior can be filled with antisepticised wool or any desired inhalants. From the upper part passes a short rubber tube with a tapering nozzle, which is fitted into the tracheotomy tube, but is easily re-

movable. The posterior surface of the flask rests against the warm chest, and the air, therefore, which is inspired is warmed as it passes through the flask and tube before it reaches the trachea, the object being to make up for the warming and moistening powers of the nasal passages on the inspired air. The rubber tube is made readily removable by the patient from the tracheotomy tube in the trachea, should urgent necessity for it arise. The instrument has been made for me by Messrs. Arnold and Sons, of West Smithfield.

T. FREDERICK PEARSE, M.D., F.R.C.S.

POISON AND MEDICINE BOTTLES.

A poison bottle has been patented by Mr. O. C. Hoit, of Faulkner Street, Manchester. It is certainly of a very striking nature. It is made of blue glass, and is shaped like a coffin.

Messrs. Kilner Bros., of King's Cross, N., the well-known bottle manufacturers, have taken a new departure, indeed, in the matter

of dispensing bottles. Nothing is sacred to the inventor, and the principle of the screw-stopper is applied by Messrs. Kilner to medicine bottles. It is manifest, that, in using bottles fitted with screw-stoppers, time would be saved in dispensing, the necessity of searching for a suitable cork being done away with. Obviously also, in opening the bottle, no cork could be broken off, and the same screw-stopper could be used for an indefinite period.

Messrs. Kilner at present are only prepared to supply six-ounce and eight-ounce bottles with this adaptation. The prices are reasonable, and the bottles can be obtained from the makers, washed, and with stoppers fitted, so as to be ready for immediate use for dispensing purposes.

PREPARATIONS OF CASCARA SAGRADA.

THE employment of the bark of rhamnus purshianus (cascara sagrada) continues to increase, and manufacturers take advantage of this fact by bringing their special preparations under the notice of medical practitioners. We have recently had submitted to us no less than four such preparations. The drug itself has a disagreeably bitter taste, and this taste is very marked in the liquid extract, the only official liquid preparation. Makers, therefore, endeavour to produce such compounds that the bitter taste is concealed while the aperient properties remain unimpaired.

Under the name of "Extractum Cascarae Sagradae Liquidum," Mr. H. Cracknell, of Craven Road, Westbourne Terrace, has brought out a preparation which is not at all unpalatable, and which will form a clear mixture with either water or spirit.

Messrs. Evans, Sons and Co., of Hanover Street, Liverpool, prepare a "Liquor Cascarae Sagradae Dulcis," half the strength of the Pharmacopoeial liquid extract. In this the nauseous bitter taste is almost entirely concealed.

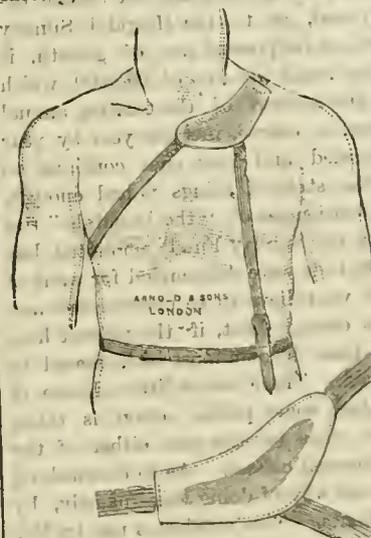

Mr. T. O. Sandell, of Baron's Court Road, West Kensington, has given the rather fanciful name of "Cascaradyne Tablets" to a kind of chocolate cream containing as a chief ingredient cascara sagrada. They are quite pleasant to the taste.

Lastly, Mr. Tompsett, of Anerley, S.E., has produced some really elegant "Cascarine Pastels." These are a kind of jujube, are very palatable, and one or two may be taken for a dose.

We have found that all the above preparations appear to possess the full laxative properties of the bark of rhamnus purshianus.

PAD FOR FRACTURED CLAVICLE.

Not finding the methods usually employed for maintaining the sternal end of clavicle *in situ* after dislocation or fracture satisfactory, I have invented an appliance (here figured) which I believe fulfils all the necessary requirements.

It consists of an irregularly shaped crescentic pad, concave on its under surface, and grooved so as to lie easily on the clavicle. A strap is attached to both ends of the pad, one of which passes over the shoulder of the injured side, to be attached to the other, which is brought out under the opposite axilla. A third strap passes down from the convex border to be buckled to a belt at the waist. This splint has the following advantages:

1. Facility of application.
2. It maintains fractures and dislocations in perfect apposition, without undue pressure.
3. Comfort is ensured, and unsightliness avoided, the patient being able to be

dressed and about, as it takes up but very little room. I have only to add that I am indebted to Messrs. Arnold, of West Smithfield, for the excellent carrying out of my ideas.

G. E. JOHNSON, Ferns, Co. Wexford.

BRITISH MEDICAL ASSOCIATION.
SUBSCRIPTIONS FOR 1888.

SUBSCRIPTIONS to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the West Central District Office, High Holborn.

The British Medical Journal.

SATURDAY, JUNE 30TH, 1888.

THE HOSPITAL QUESTION.

THOUGH the question of the finance and organisation of our hospitals is always before us, and is constantly receiving the attention of authorities both lay and medical, it is brought into greater prominence at the present season of the year by the return of Hospital Sunday. Mr. C. S. Loch's letter in the *Times* of last Monday will opportunely assist this most desirable tendency. We need hardly tell our readers that Mr. Loch's letter is worthy of their perusal and of their careful consideration. Its main conclusion, that "an investigation of the whole subject by a Royal Commission is absolutely necessary," is one which we have more than once tried to enforce; and we have no doubt that some such step would long since have been taken, had the political importance of the subject borne a greater proportion to its social urgency. For, indeed, Mr. Loch's letter shows in the plainest way that the question is not only an urgent one, but is becoming year by year more urgent. There are, as we have said, two main branches of the hospital question—finance and organisation. The finances are growing every year more deficient, as the pressure on the beds and out-patient departments grows heavier; and, as to the Hospital Sunday Fund, Mr. Loch shows that, at its present rate of growth, it would take fourteen years to reach the sum of £65,000, which is at least £25,000 below the amount of the existing annual deficit—a deficit which must, of course, increase year by year as old claims are left unsatisfied and new ones continue to grow. Even at present the state of things is bad enough, when we are told that the deficiencies of "the hospitals" (we presume those recognised by the Sunday Fund) amounted last year to £100,000, and 2,000 beds were unoccupied for want of means. These facts, which we believe to be uncontested and incontestible, prove plainly enough that, if the present hospitals are to go on, either their income must be increased or their expenditure diminished. There seems little chance of the former alternative, unless some public action is taken which will compel definite steps on the part either of the Government or of the moneyed classes. As to diminishing expenditure, there is only one way of doing this—namely, by lessening the number of patients. This number is put by Mr. Loch at a million, and, though such estimates are not perfectly trustworthy, we believe that there is a general assent to the accuracy of some such enormous total.

The magnitude of hospital-population is thus graphically

represented by Mr. Loch:—"The twelve general hospitals deal with patients who, if they were settled as a colony on the north of the river, would occupy all St. Pancras, all Islington, and all Hampstead. If we add the patients at the special hospitals, such districts as St. Marylebone, Hackney, St. Giles, Strand, and the Poor-Law Union of Westminster would have to be annexed. Thus there would be a colony of patients settled in a fan-like district, through which might be drawn a vertical line from Highgate to the river at Charing Cross, and a transverse line from Finchley on the west to Hackney Marsh and the River Lea on the east. These facts are sufficiently alarming, especially when they are boldly made the ground for appeals which are coupled with no policy of retrenchment nor with any scheme of reorganisation or reform."

Now no humane person would grudge even this enormous distribution of charity if it were necessary and if it did no harm, though even then the inequality of the supply of hospitals to different parts of London is an anomaly urgently demanding reform. But another and a most potent reason for inquiry and reformation is the "deadening of provident habits in the neighbourhoods" where "this congestion of medical relief" exists. No higher authority than Mr. Loch could be quoted on this subject, and it is thus that he speaks:—

"In Marylebone there is a provident dispensary on the northern verge of the district, away from the hospitals. It has about 3,200 patients, while those in receipt of free medical relief may be estimated at nearly 80,000, including more than 7,700 dealt with by the poor-law. In Lewisham, with half the population of Marylebone, there are three provident dispensaries whose patients number probably about as many as those of the provident dispensary in Marylebone, while the free patients are nearly six times as few. How much more easy should it be to avoid pauperism by medical relief in Lewisham than in Marylebone? Making every allowance for patients drawn from other parts of London, it is hard to believe that there is so much more need for medical relief in the one place than in the other. If this comparison be taken as evidence, some more satisfactory adjustment of medical relief according to geographical conditions is required."

Again, the recent institution of poor-law infirmaries, rivaling "in the completeness of their organisation even very efficient hospitals," is another modification of our hospital system, which, as Mr. Loch does not fail to point out, calls loudly for a full inquiry into the organisation of that system.

When our present hospitals were founded they were intended for the whole town. The Middlesex and London Hospitals still retain in their pleasure-grounds a pleasant and useful memorial of the time when they were at the very outskirts of London. St. George's, not much more than 100 years ago, was more in the country than the city. There are now miles on miles of houses with no hospital within a reasonable distance, and where accidents and urgent cases can only be attended to by a rather illegal, though perhaps necessary, misapplication of the resources (imperfect for such a purpose) of the poor-law infirmaries.

All these and many more features of our present hospital system demand public investigation; not the least one feature,

which Mr. Loch's letter passes over, but which all medical men must know to be of the highest public interest, namely, the function of the hospitals and infirmaries in medical education. The poor-law fever hospitals (to take only one example of what we refer to) have at the present time assumed so exclusively the care of the poor, when stricken by epidemic diseases, that the hospital student has little if any opportunity for learning things so essential to the success of his daily practice as the diagnosis and treatment of typhoid, typhus, small-pox, etc. He sees little of chronic disease, and has to learn all the details of home practice (so different from that of hospitals) when he begins to attend patients. But, in fact, the reasons for the proposal of a Royal Commission on Hospitals are too numerous to be set out in an article, and have been too often urged in vain to make us sanguine of any success in the attempt. It seems clear that this year's collection of the Sunday Fund, whether it exceed last year's by a few hundred pounds or no, will do as little as last year's to fill up the deficiency. Our hope is that the very magnitude of the need will compel that attention from statesmen which sound reason has hitherto failed to attract. Meanwhile, the thanks of all interested in our hospitals are due to Mr. Loch for his timely and able letter.

SCURVY IN THE MERCANTILE NAVY.

A RECENT report of the Seamen's Hospital, gives very satisfactory evidence of the progressive diminution of scurvy in the Mercantile Marine Service. "The return of the cases of scurvy admitted into the hospital in 1886 is by far the least unsatisfactory one that has yet been made in the medical records of the society." Five cases only, in all of which the scorbutic symptoms, though well marked, were not very severe, were received in the course of the year, and of the five cases, four were brought from one vessel. From 1870 to 1883 the average number of admissions for scurvy was 25; in 1884, 6 cases were admitted; and in 1885, 8 cases. In 1887, 9 cases were admitted, of which 1 was fatal; 4 came from one ship, belonging to Belfast, her last voyage being from Calcutta; 2 cases were admitted from Liverpool ships, also coming from Calcutta; 2 cases were admitted from London ships. The fatal case of 1887 was the only one occurring since 1879.

This reduced rate, the reporter, Mr. Johnson Smith, the Principal Medical Officer, states is no doubt due to some extent to the rapid substitution of steamers for sailing ships, but much more to a general improvement in the diet of seamen, and to the hygienic conditions in which they live, to which so much attention has been paid of late years by the Board of Trade, and by port medical officers.

Still a mercantile marine like that of England, the tonnage of which amounts to 3,396,516 tons, is surely vast enough to give ample scope to the development of any evil that is not vigilantly watched. "In 1865, when public attention was directed, by Dr. Robert Barnes, then Physician to the Hospital, and Mr. Harry Leach, Assistant-Physician, to the prevalence of scurvy amongst merchant seamen, as many as 101 cases were admitted, and during this and the two following years there were 10 deaths from this disease."

Scurvy may now be regarded as of very rare occurrence in British ships. Early notice of every case of scurvy admitted

into the hospital is given to the Board of Trade, and the circumstances under which the scorbutic symptoms were developed are made the subject of official inquiry. As medical referee to the Board of Trade, the late Mr. Leach rendered service which was directly influential in improving the diet and general care of seamen.

Amongst the most effective measures taken by Dr. Barnes to turn the light of public observation upon the prevalence of scurvy, was the appeal to the Coroner's Court. When a death from scurvy occurred in the hospital, it was made the subject of an inquest. The captain and officers of the ship from which the case came, were called upon to give evidence. Two pertinent questions were asked: "Did scurvy occur in the cabin?" "No." "It was only known in the fore-castle?" "Yes." The conclusion was irresistible, that if preventable in the cabin it was preventable in the fore-castle, and the responsibility for the occurrence of the disease fell upon the captain and the owners. It was simply a question of supplying the crew with proper food.

Another very useful impetus to official inspection and enforcement of preventive measures was the Report on Scurvy by Dr. Barnes, made to the Privy Council in 1863 at the request of Mr.—now Sir—John Simon.

The severe suffering of the crews of the *Alert* and *Discovery* during the Arctic expedition in 1875 was the occasion of the appointment of a Committee consisting of Admiral Sir James Hope, Admiral Sir R. Collinson, Vice-Admiral Inglefield, Dr. Donnet, and Dr. Thomas R. Fraser. This Committee sat in January and February, 1877. The inquiry carried out was minute and thorough. The witnesses included many seamen who had had experience of Arctic voyages, as well as physicians qualified to throw light upon the subject. Amongst these were Mr. Busk, Dr. Pavy, Dr. Buzzard, Dr. Dickson, Dr. Barnes, Mr. Leach, and Sir Alexander Armstrong. The report of this Committee, embodying the evidence, gives probably the most complete account of the history, causes of, and means of preventing scurvy to be found. With this report before the nautical, military, and medical world, the occasion for instituting such another inquiry ought never to arise.

The prevention of scurvy is emphatically an object that demands incessant vigilance. Scurvy need not occur—it ought not to occur; and the most searching inquiry must be made into all the circumstances under which it may occur.

Scurvy may be taken as a test or index not alone of the dietary of ships, but also in some measure of their general hygienic and disciplinary condition. Where scurvy occurs the presumption is strong that general negligence prevails. Lloyd's and the marine insurance offices might exercise valuable practical influence by steady observation directed to this subject. It is worthy of consideration whether, scurvy being shown to have prevailed on board a ship which has been lost, the insurance should not thereby be invalidated. If half an ordinary ship's crew is partially disabled by scurvy, it is certain that in rough weather the ship is in danger. No rule obtains more favour amongst owners and captains than that of "not carrying more cats than can catch mice." It follows that not a hand can be spared.

It is impossible to exaggerate the importance to the nation, in its mercantile and imperial interests, of guarding the health

of our seamen. It is not one of the least claims of the Seamen's Hospital to the gratitude and support of the country that it has done and is doing so much to throw the light of scientific observation upon the hygiene of the sea. This point was eloquently enforced by Lord Charles Beresford when presiding over the last annual meeting of the governors and friends of the hospital.

SCIENTIFIC CLINICAL DESCRIPTIONS.

In all scientific work accurate observations and descriptions are necessary before proceeding to make inferences, and clinical study is no exception to this rule. Many contributions to the literature of medicine are less valuable than they should be, and less potent in advancing scientific medicine, because terms which do not indicate facts observed are used as essential parts of the descriptions given. Descriptions of various conditions seen in practice may be founded on a large experience, they may be accurate as to facts, and accompanied by able generalisations and expressions of personal opinion, but they partially miss their purpose if they do not at all points indicate to the reader points observable by him when he meets with similar conditions. These remarks on current literature apply rather to clinical medicine than to descriptions in pathology, and herein we see the reason why pathology is a more definite science than clinical medicine. It is a matter of great importance in recording clinical facts for the purposes of summary and comparison, that such terms only be used as are understood to indicate the facts observed. There are two very distinct kinds of terms commonly employed in giving clinical descriptions which may be conveniently classed as "abstract or general terms" and "physical signs." Among the former class we may instance the terms, healthiness, fatigue, sleep, spontaneous movements, consciousness, depths of coma, etc., convenient terms, but such as do not indicate actual physical signs. When put before the student such terms do not lead him to look for physical signs, but rather to try and observe a general condition, without taking the trouble to describe the actual facts as he sees them. It is common for a clinical clerk to write in his case-book that the patient was comatose or delirious, thereby expressing his own general opinion, instead of describing the detailed physical signs that might be observed; he might better describe the dorsal decubitus, the absence of movement to light or sound, the absence of movement in the limbs, etc., the relative movements of the thorax and epigastrium, at the same time noting whether the eyelids and mouth were closed or open, and describing the kind of sounds made by the patient, if any, and whether he detected any twitchings of the fingers. Of course such descriptions of physical signs, involve much labour, but such analytical work alone gives accuracy, and supplies the only true basis for correct thinking. We think that both for the advance of medical science, and sound clinical teaching, it would be well if clinicians would spend more labour in defining general conditions in terms of physical signs. Have we good descriptions of the physical facts which indicate intelligence, fatigue, nervousness, etc.?

When a general condition has been thus defined, and its physical signs are well known, it is, of course, convenient to name that condition by a general term; then such term is an

abbreviation, correctly employed, for the sake of brevity, in place of a collection of observable signs, and for such purpose only.

These remarks apply to all clinical descriptions, but particularly to the department of neurology, where advance has been rapid, and where the use of many hypotheses is necessary. Students are taught that an epileptic attack may be followed by "depths of coma." What is much wanted is a body of recognised and well-defined physical signs indicating that state. We submit that all these terms imply immensely complex conditions, while such terms as "purposive" or "voluntary" also imply an hypothesis, and so the description of the clinical state becomes most complex, and we drift away from all physical signs observable in the patient. Accuracy and the means of comparing facts can only be obtained by analysis of general observations into the physical facts observed, upon which generalisations may be founded. In teaching those untrained in clinical work and correct thinking, descriptions given in general terms seem likely to arrest rather than stimulate further thinking and observing; such knowledge is wordy. Movements are said sometimes to be purposive, voluntary, automatic, spontaneous; but authors using such terms do not usually tell us how we may know by what we see if a certain movement is voluntary or not.

At the recent Junior Medical Examination held by the Punjab University, Miss Amelia Connor, of the Lahore Medical College, was the only candidate who stood in the first division.

The next meeting of the Royal Commission on University Education in London will be held this day (Saturday), when evidence will be given by Sir Andrew Clark, President, and Sir Henry Pitman, Registrar, of the Royal College of Physicians; and by Mr. Savory, President, and Mr. Thomas Bryant, Vice-President, of the Royal College of Surgeons.

As the 8th clause of the Local Government Bill transfers to the Local Government Board, among other powers now exercised by the Home Secretary, those relating to the Burial Acts, it is, it is stated, the intention of Mr. Osborne Morgan, before the clause is passed, to call attention to the effect of this and other proposals in the Bill, upon Burial Law Administration.

THE SOCIETY OF APOTHECARIES "AND ALLEGED ILLEGAL PRACTICE."

In reference to a report forwarded to us of an inquest held at Moor Street, Birmingham, on June 20th, on a child named Margaret Hart, which is published at page 1414, we understand that the Society of Apothecaries have required the person who, it was stated in evidence, had attended the child, to answer the statements made as to his practising as a medical man, and unless they can be proved to be incorrect, will at once institute proceedings against him.

THE LATE GERMAN EMPEROR.

We are informed that the German physicians and surgeons who were in attendance on the late Emperor Frederick have drawn up a memorandum dealing with the whole subject of his illness, the measures which were at various times proposed, and the treatment which was actually adopted. The necessary permission for the publication of this important document has just been obtained, and it will probably see the light in a few days. We cannot help thinking that it was a mistake on the part of the German Court to forbid the publication of the report of the post-

mortem examination. Apart from its scientific interest, which would have been exceptionally great, such an authoritative statement would have finally silenced the absurd and scandalous rumours as to the nature of the disease, which we regret to see are once more finding expression in some disreputable journals.

THE CLAIMS OF THE MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

A REPORT of Mr. W. H. Smith's answer to Lord Randolph Churchill's question as to whether the grant of a supplementary charter to the Royal College of Surgeons could be delayed until a Royal Commission had been appointed to inquire into the constitution of the College and the position of its Members will be found on page 1415.

THE MASTERSHIP OF DOWNING COLLEGE, CAMBRIDGE.

THE election of Dr. Alexander Hill to the Mastership of Downing College, Cambridge, is a striking proof of the increased estimation in which science is held at the universities, and of the importance which now belongs to the Medical School of Cambridge. Not since Harvey, who was at one time a Fellow of Caius, was elected Warden of Merton College, Oxford, has an anatomist been chosen the head of a college, and it is probably the first time in the present century that such an office has fallen to a member of the medical profession.

INTERNATIONAL CONGRESS OF DERMATOLOGY.

AMONGST those who have already accepted office in connection with the International Congress of Dermatology to be held in Paris in August, 1889, are: Dr. Ricord, Honorary President; Professor Hardy, President; MM. Emile Vidal, Ernest Besnier, Alfred Fournier, Hallopeau, Quinquaud, Tenneson, Henri Feulard, members of the Initiative Committee. Mr. Malcolm Morris, 8 Harley Street, and Dr. T. Colcott Fox, 14, Harley Street, have been appointed secretaries for this country, to whom all communications should be sent.

ELECTROLYSIS OF FIBROIDS: LIVELY DEBATE AT THE OBSTETRICAL SOCIETY.

WE publish this week a full report of the adjourned debate on Electrolysis in the Treatment of Diseases of Women. The proceedings fully occupied two meetings of the Society, and were very animated, the advocates and opponents of the method speaking with great warmth. In some instances the speakers showed considerable sensitiveness, taking the general observations of those who argued on the other side as direct personalities. This discussion appears to have caused some considerable displacement of parties in the obstetric world, and there were distinct indications in the course of the evening of the establishment of some new and unexpected alliances.

CHILDREN'S COUNTRY HOLIDAYS.

WHEN Midsummer Day has come it is time that London children should go the country. The light and air aid their growth as nothing else will, and the pleasant scenes of the country expand the mental powers. The country is clean, the town is not so; different sights, sounds, and smells then impress the senses, and the whole being of the child is changed thereby, so that dirt becomes hateful, and the music of Nature more pleasing than the street cries. A good work is being done by the Children's Country Holidays Fund (10, Buckingham Street, Strand); 14,043 children were sent away last year to 366 country centres at a cost of £9,178 7s. 9d., of which the parents contributed £2,819 16s. 11d. Most of the children were sent to cottages in the country for a fortnight each, some for three weeks. Local committees select the children in town, and receive their payments, while friends in

the country look after their well-being in the homes to which they are sent. No mishaps appear to have occurred from infectious diseases or other cause. We have nothing but praise for such work, and wish it all success. Money thus spent produces much good and more lasting results than day trips to the country, good as they may be when no better can be had.

EXHIBITION OF LIFE-SAVING FIRE APPARATUS.

THE strong public feeling aroused by the recent calamitous fire in Edgware Road as to the urgent necessity of all houses, especially large business premises where the higher rooms are occupied as sleeping apartments, being provided with ample and suitable appliances for securing the speedy escape of the inmates in case of fire, has led Dr. George Danford Thomas, coroner for Middlesex, to arrange for a display of life-saving apparatus and the various methods of preventing and extinguishing fires. This exhibition will be held at the Portman Rooms, Baker Street, W., at the end of July next, where the public will have an opportunity of being instructed in the use of fire-escape appliances and of testing their value.

A NEW ALKALOID IN TEA.

AT the meeting of the Berlin Physiological Society on June 8th, Professor Kossel reported on a new base, discovered by him, in extract of tea. Caffein is the only definite chemical base hitherto isolated from tea, and to it are ascribed many of the effects of tea. Professor Kossel has found another base in very small quantity, having the composition $C_8H_9N_3O_2$, upon which he has bestowed the name "theophyllin." It is isomeric with the base obtained from cacao (theobromin), and with paraxanthin obtained from urine by Salomon, but differs from these substances by its reactions. The introduction of a methyl group into theophyllin converted it into caffein, and as the latter is proved by E. Fischer to be a trimethylxanthin, the former is evidently a dimethylxanthin. Investigations into its physiological effects will be made.

MICROKINESIS.

A PAPER by Dr. Francis Warner, on muscular movements in man and their evolution in the infant, was read at the meeting of the Royal Society on June 12th. In the newborn infant constant movement may be observed in all parts during the waking state; these spontaneous movements, to which Dr. Warner proposes to apply the term "microkinesis," cannot be stopped by external stimuli. This condition becomes gradually modified during the growth and development of the child, and the movements are gradually more and more controlled by external stimuli, while the phenomena termed memory and imitation are evolved. The paper also contained a study of the modes of action of nerve-centres in adult age, and it was suggested that when a co-ordinated movement followed a slight stimulus, temporary unions are produced among the centres, and that the brain-action corresponding to thought is the formation of functional union among cells; the outcome of such functional unions is seen in the movements which express the thought. Dr. Warner described a number of special postures and movements associated with certain states of the brain, and in fact affording physical signs by which those states might be recognised.

ALLEGED VIOLENCE IN A LUNATIC ASYLUM.

AN inquest on a male patient dying in the asylum has resulted in the verdict: "That the deceased died from the effects of exhaustion following melancholia and inflammation of the lungs, accelerated by a severe fracture of the jaw and bruises to the shoulder caused by violence." The jury were of opinion that the said injuries occurred after the deceased was delivered into the charge of the asylum authorities, and they further added that they were of opinion that there was no evidence forthcoming to show how the injuries were

caused, which they considered most unsatisfactory. It is highly desirable that so serious a charge may not rest here, but that the Commissioners in Lunacy will cause a thorough investigation to be made into the circumstances attending the death of this unfortunate man. In large asylums, in which attendants may assault patients without any blame attaching to the medical superintendent, it is most important that he should be assisted in tracing abuses, if they exist, to the guilty parties. Such assistance can be best rendered by an impartial investigation by the Lunacy Board. Unpleasant rumours have for long been abroad in regard to the condition of the institution in question, and it would be a satisfaction to have them dispersed by an extended inquiry, in which the public and the profession would feel confidence.

A MEDICO-LEGAL CASE.

THE following case of suicide which recently occurred in Jamaica presents features of considerable interest and no little importance. A coloured man, after murdering his sweetheart, entered his house, and cut his throat with a razor. Some of the neighbours who had witnessed both deeds rushed into the house, but were unable to find him. After a search, his dead body was found under the house, which was a small one, built on supports, raising it about two feet from the ground. After cutting his throat, the man must have walked or run to the back entrance, a distance of sixteen feet, and then have crept through a hole in the partition, and have crawled on all fours to the spot where his body was found, exactly beneath the room where he cut his throat, and, therefore, a further distance of sixteen feet. The throat was cut from ear to ear by a clean sweep, both carotids and jugulars being severed, as well as the trachea and œsophagus, the wound reaching back to the anterior portions of the bodies of the cervical vertebrae. A blood-stained razor, which was deeply notched, was found in the room, and marks of blood were traced from the room to the back entrance by which the man must have gone out. Dr. Cargill, who examined the body soon after death, and to whom we are indebted for a report of the case, was asked by the coroner if it was possible for a man to have traversed the thirty-two feet after inflicting such wounds on himself; to which he replied by declining to controvert, as a mere matter of medical opinion, facts that had been sworn to by reliable eye-witnesses. Remarkable instances of the retention of voluntary power after wounds of the carotid artery have been occasionally recorded, but we know of no occasion on which the vessels on both sides of the neck were divided, where so much power was retained by the subject of the injuries as in the present instance. The case should serve as a perpetual warning to medical men not to be too dogmatic as to what is, and what is not, possible even in the presence of the most rapidly fatal wound.

THE MEDICAL OFFICERS OF HEALTH AT GLOUCESTER.

THE circumstances under which the Gloucestershire Combination of Sanitary Districts has been dissolved is further evidence of the uncertainty attaching to public health appointments. One of these districts—that of Dursley—desired to “handle its own money,” and appears to have used as an argument for the attainment of that end the fact that Dr. Bond held the office of honorary secretary to the Gloucester Dairy Association, which had grown out of the “model dairy” established three years ago by him, and which in its turn was one of the results of the “Milk Conference” held in Gloucester in 1884. The objects of this Association are to promote the interests of dairy-farming by showing how to produce good milk, butter, and cheese, and by giving assistance to those who wish to learn how to do so. Exception was in the first instance taken to Dr. Bond holding shares in this Association and in the Sanitary and Economic Association, which

had as its object the promotion of house sanitation; but subsequently this was dropped, and the objection was limited to Dr. Bond's connection with these Associations “by name or work.” Dr. Bond at once expressed to the Local Government Board his willingness to concede this point, if it could be shown that his position in relation to them was incompatible with his official duties, but not otherwise. No attempt, however, was made to ascertain this point, but Dursley was permitted to have its own way and withdraw from a combination which is thus dissolved. Dr. Bond not unnaturally claimed the protection of the Local Government Board, and asked for an inquiry into any case the Dursley authority could bring in support of their desire for separation, for he argued that they must have some better ground for their conduct than that which they had put forward. This request has, however, not been complied with, and Dr. Bond loses his office and a part of Gloucestershire his services. These occurrences will, we fear, do much harm in further shaking the confidence of the profession in the public health service. The public will be the sufferers if medical men of ability refuse to risk their careers by accepting public offices, but this must inevitably be the case if no reasonable prospect is offered of continued tenure of office. The readiness with which an authority can dispense with its officer by appointing him for a short term of years is direct encouragement to them to raise some trivial objection to him at the end of this period, and the risk of loss of office must inevitably tend to indifferent service.

PHYSICAL EDUCATION.

PHYSICAL education is now taking a place in public estimation and popular feeling that raises much hope for the wellbeing of the rising generation. It is a great thing to find the question popular and to see a general desire for improvement; in this particular instance it seems almost as if the demand were in advance of the skill and intelligence of the majority of school teachers. The public demand for some physical training of children finds expression in the desire to provide manual and technical instruction, as well as in the support given to new gymnasia and swimming baths. Physical training is required for children of all ages and conditions of life. Athletics and gymnastic competitions are useful for older lads, but well-adapted exercises in schools, such as can be practised by large numbers in playgrounds and in schoolrooms, are necessary for the younger children; and our rapidly increasing town population makes the matter an urgent one. Most schools have a certain amount of military drill, and such is necessary for marshalling the children in their classes, but this is very different from exercises designed to aid growth and development. It is found in the army that gymnastic exercises to produce development are needed before the military drill of the recruit can be satisfactorily undertaken. It may be that the habit of leaving drill in private schools to a drill-sergeant has helped to deter those persons of good education, who could best conduct the work, from taking a due position in this important mode of training; in America and on the Continent physical exercises are conducted by medical men of good standing. Military drill in schools is comparatively worthless for aiding physical development; it is not so much individual muscles that we want brought into action, as certain well-defined groups of muscles which act physiologically together. The physiologist, rather than the anatomist, should give counsel as to the methods of calisthenics best suited to stimulate muscle and nerve growth; and in the case of delicate children the general physician should also be called upon to advise; such training needs much care in many practical details. Great discretion is required in the teacher in advancing from one set of exercises to another, and care must always be taken to see that the strain imposed on any part is never beyond that justified by conditions of present nutrition;

exhaustion should always be avoided, especially in young and delicate children. Physical training, like mental training, should be progressive and carefully adapted to the ends in view.

QUACK ADVERTISEMENTS.

A Society for the Suppression of Quackery has been in existence in Holland for several years. The chief object of this truly philanthropic association appears to be not so much the "stamping out" of unqualified practice, as the enlightenment of the public mind as to the real value of too many of the nostrums which are so widely advertised in the lay press as certain remedies for all the ills that flesh is heir to. The Society numbers more than a thousand members, of whom rather more than half are medical men or pharmaceutical chemists. The yearly subscription is only six francs—a sum hardly sufficient to furnish the sinews of war in a campaign which is, to a large extent, conducted in the law-courts. We are not surprised, therefore, to learn that the Society is hampered in its good work by want of funds. Still the crusade has been fairly successful, and several "shams" (mostly, as we are sorry to observe, of English origin) have been triumphantly exposed. We fear that such a Society would not find much support in this "free and enlightened" country, where "caveat emptor" is still, in spite of much well-meant legislation, an accepted axiom of commercial morality. Moreover, our wonderful law of libel would paralyse any organised attempt to open the eyes of confiding purchasers to the humbug of which they are the victims. Even in Holland it does not seem to be an easy matter to unmask imposture without coming within the clutches of the law. In a case in which the Society ultimately came off victorious, though at an almost ruinous cost, the judge delivered himself of the following remarkable pronouncement: "If facts which have been thoroughly proved are published, and if this be done solely with the view of warning the public, the expressions used must be carefully chosen, so that they may not be offensive to the quack in question, for he would have a right to damage for the injury done to his *honour and reputation*." This means, we presume, that you may call the "quack's" wares worthless, but the vendor himself must be spoken of as a gentleman of the strictest integrity, who labours under an unfortunate delusion as to the quality of his stock-in-trade. After all, a large part of the blame for the harm wrought by lying advertisements must be laid to the newspapers which give them publicity. If the public requires to be educated as to the value of patent remedies, the press stands just as much in need of instruction in the ethical aspects of advertising.

THE MEDICAL OFFICERSHIP OF HEALTH AT BRADFORD.

MEMBERS of the medical profession who may contemplate applying for the vacant health-officership at Bradford should learn carefully the circumstances under which the Town Council have lost the services of Dr. Hime, for Bradford affords an excellent illustration of the insecurity attaching to an election of a medical officer of health for a limited period. Dr. Hime was elected for five years, and naturally anticipated that at the conclusion of this period he would be reappointed; but he appears to have wounded the tender susceptibilities of a few members of his committee by the zealous performance of his duties, and these have so far influenced their colleagues that they have not hesitated to sacrifice the interests of the town as well as those of Dr. Hime to their own personal feelings. There are few officers who could bring such striking testimony to the esteem in which they are held as Dr. Hime, for the Town Council received no fewer than five memorials representing the strongest possible desire that Dr. Hime should be continued in office. These memorials came from all classes of the community—from ratepayers, from the working

men, the medical profession, the Trades Council, and the Women's Liberal Association, the first being so largely signed as to make it representative of the greater part of the rateable value of the borough. In view of this very strong feeling it might have been anticipated that the Town Council would have yielded to the desire of the memorialists, but they have preferred to adopt the report of their committee, who could find no better reason for the course they pursued than that they had not worked harmoniously with Dr. Hime. It is deplorable to think of the position in which an able officer is thus placed, who has abandoned practice and all other remunerative occupation except that of a health-officership, and who is deprived of this at the caprice of a few members of the committee. The result is discredit to Bradford, and certainly should deter other medical men from trusting to so uncertain an appointment. The testimonial which the people of Bradford are about to present to Dr. Hime, and in which his friends will doubtless desire to share, is a proper protest against the action of the Town Council.

CANCER OF THE LARYNX.

At the meeting of the Société Française d'Otologie et de Laryngologie on April 26th Dr. J. Charazac, of Toulouse, related a case of cancer of the larynx and made some remarks on the treatment of that disease. The patient, a healthy man, aged 60, had for years been subject to frequent attacks of hoarseness, and he had besides been an immoderate smoker. He had never had syphilis, but it may be worth mentioning that his wife had died some years before of cancer of the breast. For eighteen months before he came under the notice of Dr. Charazac he had suffered from persistent aphonia. On October 1st, 1887, the epiglottis and the left side of the larynx showed the ordinary signs of chronic laryngitis; on the right side there was a deep ulcer with greyish base occupying the centre of a swelling which involved the ventricular band and reduced the glottis to half its natural size. Dr. Charazac diagnosed the affection to be malignant, and proposed laryngectomy, which was declined. On February 19th tracheotomy became necessary, and the disease has since made steady progress. The most troublesome symptom at the date of the report was the passage of food into the larynx; this was found to be due to the fact that the tumour, as it increased in size, pushed up the epiglottis so as to interfere with its action in swallowing. In discussing the treatment Dr. Charazac compared the results of simple tracheotomy with those of extirpation of the larynx for cancer. Statistics showed that the former increased the average duration of life by six or eight months, while after laryngectomy two-thirds of the patients died either from the immediate effects of the operation or from rapid recurrence of the disease. This discouraging result is, however, in Dr. Charazac's opinion, due rather to the want of a proper selection of cases than to any inherent fatality in the operation. He thinks that as a rule it should not be performed in patients over 70, and he looks upon it as absolutely contra-indicated in all cases in which the glands are affected or the general health impaired. It should never be done unless the disease is strictly limited to the interior of the larynx, but in suitable cases early operation is imperative. If these rules are adhered to, Dr. Charazac believes that laryngectomy will prove much more successful in the future than it has been up to the present time.

THE ANATOMICAL SOCIETY OF GREAT BRITAIN.

The Anatomical Society of Great Britain and Ireland brought its first session to a close with a most successful meeting at Cambridge on June 23rd. There was a large gathering of members and visitors in the anatomical department to listen to a number of interesting and important papers. Cambridge was particularly well represented. Professor Macalister showed a number of speci-

mens which he had obtained from the dissecting-room, and mentioned incidentally a point of some importance, namely, that when the twelfth rib was long the pleura descended further than usual. The new Master of Downing, Dr. Alexander Hill, also drew attention to the subcallosal convolution, a structure which has hardly had the attention which its interest deserves. Dr. Gaskell followed with an endeavour to claim greater morphological importance for the neuroglia of the cord and brain, but, by far the most important part of his communication was an account of a canal which he has discovered behind the tuber cinereum, and which he believes to correspond with the cephalic stomach of the crustaceans. However, Professor Howse did not allow these views to pass unchallenged. Amongst visitors from a distance who contributed to the success of the meeting were Dr. Johnson Synnington and Dr. A. M. Patterson, the former with some instructive sections of the head and pelvis and the latter with a series of developmental specimens. Dr. Curnow showed a skull, which excited some discussion; and Mr. Treves described and explained an example of that very rare condition, hernia into the foramen of Winslow. After the meeting, the President of the Society, Professor Humphry, entertained sixty members and visitors at dinner in the Hall of King's College. Speeches were made by Sir George Paget, Professor Michael Foster, and others, and the Secretary, Mr. Lockwood, in replying to the toast wishing prosperity to the Society (proposed by the President) was able to say that the names of the leading teachers of the three kingdoms were upon its list of members.

SCOTLAND.

EDINBURGH UNIVERSITY: FINAL EXAMINATION IN MEDICINE.

THE final examination for graduation in medicine at Edinburgh University is in progress. The number of candidates is larger than in previous years. The new arrangement, whereby the clinical portion of the examination in medicine is compressed into a much shorter term, has been found to work admirably, both by examiners and by candidates. The latter feel their labours materially lightened, while the prolonged state of anxiety which the old arrangement necessitated has been considerably curtailed.

THE UNIVERSITIES (SCOTLAND) BILL.

It is matter for congratulation on all sides here that, at last, the Universities Bill has been read a third time in the House of Lords. The fresh nominations to the Commission have been eagerly scrutinised, and satisfaction is expressed over the selection of Sir Henry Roscoe and Lord Elgin. But the list is generally thought too long and the proportions of the Commission too cumbrous to admit of a really efficient executive.

ECZEMA AND LEPROSY.

A REMARKABLE suit has just been raised in the Court of Session, and of considerable interest to the profession. Michael Christison Piggott, clerk, Glasgow, sues the Governors of Fettes' College, Edinburgh, for £500, as damages for unlawful dismissal and breach of contract. He states that in July, 1884, after examination, he was admitted a foundationer of the college, by which he was entitled to receive free board and education, valued at £130 a year, for six years. In the spring of 1887 eczema, he says, broke out in the college, and he was one of the last to be affected. His leg suppurated, and, about three weeks after that, occurred he was ordered to leave. He maintains that defenders acted illegally and in violation of his rights as a foundationer, after his having been admitted, examined and tested by them as to his physical health, and declared to be duly qualified. Defenders say that one

of the questions asked the applicants before being admitted is—“Is there any peculiarity of constitution which requires to be considered?” and that the pursuer falsely answered “No.” There was nothing apparently the matter with pursuer when he was admitted, but that shortly after admission they found he was suffering from leprosy, which was incurable. Inasmuch, however, as leprosy was not transmissible by mere personal contact, the medical officers did not consider it imperative to disclose to anyone the nature of the disease, as such a disclosure would have a disastrous effect on the boy's prospects. Active periods of the disease occurred more than once, but it was only in the spring of 1887, when a skin disease broke out in the college, that the medical officers considered it no longer safe to keep the boy, because it was within the range of possibility that he might communicate the leprosy through the medium of the other disease. They therefore informed the head master, and he told the boy to leave. The defenders maintain that under the rules of the college the head master has power summarily to dismiss any boy, when, in his judgment, it is necessary to do so in the interests of the school.

ST. ANDREW AMBULANCE ASSOCIATION.

THE annual report of this Association, just issued, shows a record of excellent work. It states that in 1882, when the Association was formed, there was not a proper ambulance waggon in all Scotland, loss of life and unnecessary suffering being caused by the removal of serious cases in unsuitable vehicles. Now, in various parts of Scotland, properly equipped waggons are to be found. Since March 1st, 1887, new waggons have been stationed at Falkirk, Johnstone, Motherwell, and Aberdeen, two are being built for Blantyre and Morsend, and wheeled litters have been supplied to Harthill and Lesmahagow. During the past fifteen months 1,483 calls have been made on the waggons of the Association, and since the formation of the Association 4,049 patients have been safely carried. Last year 6,655 pupils received instruction in first aid, an increase of 742 on the numbers of the previous report. The total number trained since 1882 now amounts to 19,969. The Association has had a stretcher constructed for use in fits; a cover strapped to the stretcher poles binds down the patient's trunk, legs, and arms independently, and the stretcher is hinged, so that the patient may be brought up to the surface in a horizontal, vertical, or sitting position. A stretcher for police use has also been designed and constructed, in which a canvas cover, secured all along one side and fastened on the other by three strong straps, forms, when in use, an elongated straight waistcoat. The Association has now a total of nineteen centres, Dunfermline, Grangemouth, and Perth having been added in the past year, and detached classes have been held in 96 towns. Ambulance corps have been formed in many important manufacturing centres. The financial statement shows a satisfactory balance in hand.

THE SANITARY ASSOCIATION OF SCOTLAND.

THE fourteenth annual meeting of the Sanitary Association of Scotland has been fixed to be held in Glasgow on Wednesday and Thursday, July 4th and 5th. On Wednesday the proceedings will be opened by an address from Sir James King, Lord Provost of Glasgow, after which the President's address will be delivered by Dr. John C. McVail, medical officer of health, Kilmarnock. Dr. J. B. Russell, medical officer for Glasgow, will read a paper on “The Sanitary Enfranchisement of the Rural Population of Scotland.” Dr. Eben. Duncan, Crosshill, on “The Dissemination of Infectious Particles by Air Currents;” and Dr. Maitland Moir will also give a paper. On the second day the proceedings will be opened by Ex-Bailie Crawford (Glasgow), and papers will be read by Mr. Thomas Walley, Principal of the Royal Veterinary College, Edin-

burgh, on "The Inspection of Meat in Relation to our Food Supply, with special Reference to Tuberculosis in Cattle;" and by Mr. W. B. Buchan (Glasgow) on "Late Improvements in House Drainage;" while Mr. Fyfe, sanitary inspector (Glasgow), will explain the new smoke-testing apparatus. The members will afterwards visit the Glasgow refuse despatch works, under the guidance of Mr. Young, superintendent of the cleansing department, Glasgow.

PUBLIC MORTUARIES.

Dr. J. B. RUSSELL has reported to the Glasgow Town Council in favour of the provision of public mortuaries, the question having been referred to him for consideration. He states that under the Public Health (Scotland) Act, Section 43, the provision of mortuaries by local authorities bears the same relation to the prevention of disease, in so far as it could be spread by the dead, as the erection of hospitals bears to the prevention of disease by the living. In each case compulsory power to remove the source of danger was conferred, and in the one case the exercise of this power depended upon the provision by the local authority of a "proper place for the reception of dead bodies," in the other of an hospital. They were in the position of not having made the necessary provision for the cases described in the words of the Act, namely, "dead body of one who has died of any infectious disease, retained in a room in which persons live or sleep, or any dead body which is in such a state as to endanger the health of the inmates of the same house or room." It was not creditable to the local authority that they could not deal with such a case. He observed further that just as hospitals were most successful by encouraging voluntary resort to their accommodation, so mortuaries were intended to educate and entice the occupants of small houses to send their dead thither. In neither case was the compulsory use of such places a measure of their necessity or utility.

IRELAND.

IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.

At the Council meeting of the above Association, held at Cambridge on June 21st, Professor Alexander Macalister, F.R.S., President, in the chair, the Honorary Provincial Secretary (Dr. Stewart) reported that the proposal to restrict appointments on the honorary staff of the Bristol Royal Infirmary to those holding certain specified London diplomas had been abandoned as a result of the action of representatives of the Association. In view of the possibility of a similar proposal being brought forward, either at Bristol or elsewhere, at a future time, a statement (to be placed in the hands of lay governors of hospitals) was submitted, setting forth the objections to such exclusive action. On the motion of the President, seconded by Sir George E. Paget, K.C.B. (Vice-President), this statement was adopted and ordered to be printed for circulation. Dr. Macnaughton Jones was elected Chairman of Council, to succeed Professor Gerald F. Yeo at the expiration, in July, of the latter's term of office. The summer dinner of the Association took place the same evening in the Hall of Gonville and Caius College, Professor Alexander Macalister, President, in the chair. Amongst the members and guests present were Sir George E. Paget, K.C.B. (Vice-President); Sir Thomas Crawford, K.C.B., and Dr. Macnaughton Jones, Ex-Presidents; the Master of Peterhouse; the Master of Downing; Professor Humphry, F.R.S.; Dr. Richard Fegan (President-elect), Professor apother; Professor Latham; Professor Roy, Brigade-Surgeons W. Alexander (Hon. Treasurer), and Thomas Wright; Surgeon-Major W. Nash, Dr. Bradbury, Rev. Dr. Sheilds, Dr. Ingle, Dr. Gilbert Smith.

Dr. Lea, Mr. Percy Dunn, Mr. Keetley, Dr. Connellan (Gt.ernsey), and the two Hon. Secretaries (Drs. Stewart and Abraham). The loyal toasts were duly honoured. In proposing the health of "The Guests" the President observed that the hall in which they were assembled was that of a college of which the immortal Harvey was first a student and subsequently a Fellow, and within whose walls some of his greatest experiments were performed. The toast was responded to by Professor Latham. Professor Humphry proposed "Success to the Irish Schools' and Graduates' Association." The President, in responding, referred to their recent success at Bristol as an instance of the value of such an organisation as theirs in protecting the interests of Irish medical graduates and diplomates. In proposing the toast of "The University of Cambridge," Sir Thomas Crawford alluded to the fact that the oldest college of the university, Peterhouse, had now an Irishman (the Rev. Dr. Porter) as master. He referred also to the rapid rise within recent years of the Cambridge Medical School, much of which, it was acknowledged, was due to the indefatigable energy and ability of Professor Macalister. The toast was responded to by the Master of Peterhouse and by Dr. Hill (Master of Downing). The health of the outgoing Chairman of Council, Professor Gerald F. Yeo, was proposed by Dr. Gilbert Smith. In the absence of Dr. Yeo, the toast was responded to by Dr. Macnaughton Jones, who said he considered it a high honour to be called on to succeed one who, during his three years' tenure of office, had been so constant in his attendance, and had exercised such a vigilant and wise oversight of the detail working of the Association. Dr. Fegan proposed "The health of the Master and Fellows of Gonville and Caius College," by whose courtesy they had been allowed to meet in a hall of such historic interest. The toast was responded to by two of the Fellows present, Sir George Paget and Professor Ridgeway (Queen's College, Cork). The proceedings were enlivened by the singing of several Irish and other melodies by Mr. Groome and Drs. Lea, Gilbert Smith, and Abraham.

PROPOSED MAIN DRAINAGE SCHEME FOR CORK.

An efficient system of main drainage for the city of Cork has long been required, but the expensive nature of the schemes proposed prevented their adoption. The Public Health Committee of the corporation have at present under consideration a scheme proposed by the city engineer, which appears to present many advantages. The plan proposed is to drain the northern parts of the city by a sewer, and the southern parts by another sewer, the two to meet near the Old Passage railway. It is then intended to project the main to within a distance of the park, and the entire sewerage having been collected in two reservoirs with alternative action, pumping works will be constructed to pump the sewage to lands close to the Skahabeg Road. Here it is proposed that the corporation shall purchase 300 acres of land, and utilise them as a sewage farm, over which the sewage, after precipitation, would flow by gravitation, and the effluent would pass into the Tramore river. The estimated cost is £94,708, and the annual cost £800, which, capitalised, represents £16,000, so that the estimated capital cost of the proposed scheme would be close on £110,700. The present sewers cost annually about £2,700, and deducting this and the annual profits from the utilisation of the sewage, the proposed scheme would ultimately cost the rate-payers £58,708.

CONVERSAZIONE AT THE ROYAL COLLEGE OF PHYSICIANS.—At the *soirée* of the Royal College of Physicians given on Wednesday evening last, the President, Sir Andrew Clark, Sir Edward Sieveking, Sir Alfred Garrod, Sir Dyce Duckworth, Sir Henry Pitman, and Dr. C. Handfield-Jones, members of Council, received a large and distinguished gathering in the hall of the College in Pall Mall East. An interesting collection of works of art and curiosities was on view for the entertainment of visitors.

THE METROPOLITAN COUNTIES BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

THE annual dinner of the Metropolitan Counties Branch of the British Medical Association on Wednesday evening was marked by some incidents of considerable interest. The company assembled, under the presidency of Dr. BRODIE SEWELL, was numerous and distinguished. The Directors-General of the Army and Navy were both present, and their speeches excited considerable interest.

In proposing the toast of "The Medical Services," Mr. ERNEST HART pointed out that it could not be fairly said, as sometimes stated, that the officers of the public services were by habit grumblers and disposed to obtrude their grievances, inasmuch as in respect to the Naval Medical Service he was happy to say that since the Warrant of 1881, which conferred satisfactory conditions of rank, pay, and general service regulations, he could not call to mind having received from any single member of the service a single word of complaint during the whole seven years, throughout the reign of the late Director-General, Sir John Watt Reid, who had just retired loaded with honours and followed by the universal affection and confidence of his department. The work of the Naval Medical Service had, he believed, during that time been carried on without a hitch of any sort and without the slightest friction, so that it might fairly be inferred that when the medical officers of the public services were treated with courtesy and fairness, they were even more readily contented than any other body of men that could be named. The recent accession of Dr. Dick to the office of Director-General of the Navy had been warmly welcomed throughout the whole service, and he trusted that his term of office might be marked by equally auspicious conditions. He referred also in eulogistic terms to the high personal regard which was entertained towards Sir Thomas Crawford, and regretted that the present condition of the Army Medical Service was not one of equal contentment.

Dr. DICK, Director-General of the Naval Medical Department, who was very warmly received, expressed the deep sense of himself and of the Naval Medical Department generally, of the highly important services which had been rendered to that Department during a long series of years by the efforts of the British Medical Association and of its Parliamentary Bills Committee, to the efforts of which were mainly due the successive warrants which had brought his department into the state of contentment—and he hoped he might add, of high efficiency—which it had now reached. He expressed his profound satisfaction on being the guest of the Association on that occasion, and he trusted that throughout his term of office the same contentment might prevail in the service as had endured now for so many years. The besom of reform was, however, sweeping over both the naval and military medical services in the hands of the Select Committee of the House of Commons now sitting, and it could hardly be expected but that some reductions would be effected in view of the urgent desire for economy which that Committee of the House of Commons generally were shewing in respect to the military and naval services.

Sir THOMAS CRAWFORD, who spoke with much earnestness and feeling, expressed also his deep sense of the services which the Parliamentary Bills Committee of the Association, and the Association generally, had rendered on so many occasions to the service over which he presided, and his most earnest desire that the Medical Department of the army should enter into closer relationship with the civil branch of the profession. He had seen with the greatest satisfaction that increasing numbers of the members of his department were entering the Association, and he had had occasion, when his advice had been asked, to counsel them rather to associate themselves with the civil branches of the Association than to form, as had once been suggested, a separate military Branch. He desired in all things to see the civil and military medical men of the country associated in a common bond of brotherhood and with common interests.

Dr. BRIDGWATER (President of Council), replying to the toast of "The British Medical Association," eloquently proposed by Dr. ORD, ably epitomised the present position of the Association, and referred with satisfaction to its world-wide extension, to the service which it was rendering to medical science, and to the financial and literary success which it had attained through the influential character of its JOURNAL and the ability with which its finances were conducted. Alluding to the recent communication from the Secretary of State for War, he observed that the day could not be

far distant when it would be impossible to speak of the military medical service and of the British Medical Association as being in any way distinct bodies, inasmuch as by far the greater number of members of the Army Medical Service were now members of the British Medical Association, which was therefore substantially in every way entitled to speak for them.

Dr. HOLMAN (Treasurer) in proposing the toast of "The Metropolitan Counties Branch" and its new President, Dr. Brodie Sewell, referred to the great success with which the Association was carrying out its original main object, that of uniting the general practitioners of the country in powerful and extended union, and giving them their rightful place in the councils of the profession. He referred to the interesting fact that the office of President of Council of the Association, of Treasurership of the Association, and the Presidency of the Metropolitan Counties Branch—the most numerous of all the Branches—were at the present moment held by Dr. Bridgwater, Dr. Sewell, and himself, all belonging to the class of general practitioners. He referred especially, with pride, to the new home of the Association, which was in every way worthy of the importance and extended operations of the Society, and expressed a hope that the Library, which was in course of formation, would be well remembered by the members, and that they would make use of the accommodation now afforded them in the library and reading room.

The toast of "The Visitors" was proposed by Dr. DICKSON, and responded to by Dr. FORDYCE BARKER, of New York, who received a very hearty welcome from the assembled guests.

IMPROVEMENTS IN THE BELGRAVE HOSPITAL.—The Belgrave Hospital for Children, at 79, Gloucester Street, Pimlico, is one that is busily engaged in supplying the wants of a poor neighbourhood, and, though almost entirely without endowment, it does not often press itself upon the notice of the public. A week ago was held there an afternoon meeting of the governors and those interested in its work to acknowledge and return thanks for the generous gifts of the Honourable Mrs. W. le Poer Trench, all the more generous that they were eminently practical. A complete new hot-water system had been provided by her, which extended all over the hospital, and made a great difference in the labour of the nurses and the comfort of the children; a fire-hose had been added, which was shown to be amply sufficient to command all the building; and last, but not least, a bath-room had been established on the ground floor, whose walls are of smooth dark-olive tiles, on which is impressed most appropriately, in Greek letters of gold, the Hellenic far-famed axiom, the first words of Pindar: "Best of all things is water." Mr. Bottomley, of Messrs. Laing and Son, by whom the whole had been carried out in a thoroughly satisfactory manner, was in attendance to show the arrangement and competence of the fire-extinguishing apparatus. After the Honourable Mrs. W. le Poer Trench had declared the additions at the service of the hospital, and when the wards and their occupants had been duly inspected, the company were invited to tea by Mrs. Munro, the Lady Superintendent.

HYDROPHOBIA IN PARIS.—In the first five months of 1888 there were no fewer than 280 applicants at M. Pasteur's laboratory from the department of the Seine alone, all of whom had been bitten by dogs either known to be rabid or suspected of being so. This number is almost equal to the corresponding total for the whole year 1887, which amounted to 306. The Prefect of Police has, therefore, issued an order that for six weeks no dog shall be allowed to go about the streets of Paris, unless led by a string. The owner of two dogs, which had been in contact with a rabid cur, was recently sent to prison for six days and fined 200 francs (£8) for refusing to have them destroyed.

MR. ELLIS, L.R.C.P., of Liverpool, the winner of the Queen's Jubilee Prize, given by the Royal Botanic Society, Regent's Park, for the best essay upon the plants and vegetable products introduced into the United Kingdom for use in the arts, manufactures, and for food, during Her Majesty's reign, was presented on June 23rd, at a meeting of the Society (the Duke of Teck in the chair), with a gold medal and purse of fifty guineas.

AN OVERDOSE OF CHLOROFORM.—Mr. Edmund Gurney, joint secretary of the Psychological Society, and author of numerous works, has met his death at Brighton by incautiously inhaling an overdose of chloroform, which he was in the habit of taking as a remedy for obstinate sleeplessness and occasional neuralgia.

ASSOCIATION INTELLIGENCE.

COUNCIL.
NOTICE OF MEETING.

A MEETING of the Council will be held at the Offices of the Association, No. 429, Strand (corner of Agor Street), London, on Wednesday, the 18th day of July next, at 2 o'clock in the afternoon.

FRANCIS FOWKE, *General Secretary.*

June 14th, 1888.

NOTICE OF QUARTERLY MEETINGS FOR 1888.
ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Meetings of the Council will be held on July 18th, and October 17th, 1888. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before each meeting, namely, June 27th, September 26th, and December 28th, 1888.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No member can be elected by a Branch Council unless his name has been inserted in the circular summoning the meeting at which he seeks election.

FRANCIS FOWKE, *General Secretary.*

GRANTS FOR SCIENTIFIC RESEARCH.

THE Scientific Grants Committee of the British Medical Association desire to remind members of the profession engaged in researches for the advancement of medicine and the allied sciences, that they are empowered to receive applications for grants in aid of such research. Applications for sums to be granted at the next annual meeting should be made without delay to the General Secretary, at the office of the Association, 429, Strand, W.C. Applications must include details of the precise character and objects of the research which is proposed.

Reports of work done by the assistance of Association grants belong to the Association.

Instruments purchased by means of grants must be returned to the General Secretary on the conclusion of the research in furtherance of which the grant was made.

COLLECTIVE INVESTIGATION OF DISEASE.

REPORTS upon the two remaining inquiries, namely, that into DIPHTHERIA, and that into the GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES, are in preparation, and will be published as soon as ready.

The following inquiry only of the first series remains open, namely, that on the ETIOLOGY OF PHTHISIS.

A fresh inquiry into the ORIGIN AND MODE OF PROPAGATION OF EPIDEMICS OF DIPHTHERIA has been issued.

Memoranda upon these subjects, and forms for recording observations, may be had on application to the Secretary of the Collective Investigation Committee, 429, Strand, W.C.

BRANCH MEETINGS TO BE HELD.

BORDER COUNTIES BRANCH.—The twenty-first annual meeting of this Branch will be held at Perth on Friday, July 13th. The chair will be taken by Dr. McLeod at 1.30 p.m. The usual election of office-bearers for the year will be held. Dr. Robertson, Perth, will deliver his presidential address. Intimations of papers for reading or communications of any kind should be sent to the Secretary as soon as possible.—H. A. LEDIARD, 41, Lowther Street, Carlisle, Honorary Secretary.

CAMBRIDGESHIRE AND HUNTINGDONSHIRE BRANCH.—The annual meeting of this Branch is appointed to be held at Ely on Friday, July 8th. Members wishing to make communications, to exhibit specimens, or to propose new members are requested to signify their intention to Dr. Annington, Cambridge, for insertion in the order of proceedings.—BUSHELL ANNINGTON, Honorary Secretary.

NORTH OF IRELAND BRANCH.—The annual meeting of this Branch will be held in the Belfast Royal Hospital, on Wednesday, July 11th, at 4 p.m. Business: 1. To receive the Secretary's report and the Treasurer's statement for the past year. 2. To elect office-bearers for the ensuing year. 3. To elect two members as representatives of the Branch on the Council of the Association, and also the

representatives on the Parliamentary Bills Committee. 4. The President (Dr. J. M. Palmer) will deliver an Address. 5. Dr. O'Neill will show a Patient operated on for Extensive Disease of Foot, and also a Patient operated on for Cleft Palate, and will read notes of each case. 6. Dr. W. A. McKeown will show a New Apparatus for Intra-ocular Irrigation in the Extraction of Cataract. He will also show some cases in which Senile Cataract has been extracted without Iridectomy. 7. Mr. Fagan will show a Patient on whom he recently performed Resection of the Wrist-Joint. He will also show a Portion of Bowel, the Seat of Cancerous Stricture removed for Intestinal Obstruction, and give notes of the case; and a Portion of the Saphena Vein removed and presenting some features of pathological interest. 8. Dr. E. C. Thompson (Omagh) will read Notes of a Successful Case of Ovariectomy. 9. Dr. Barden will show a Series of Microscopic Sections of Tumours. 10. Dr. Byers will show the Instruments employed for the Electrical Treatment of Fibroid Tumours of the Uterus after the Method of Apostoli. He will also show a specimen of Cystic Vesicular or Hydatid Degeneration of the Chorion. The annual dinner will be held on the same evening at 7.30 p.m. in the Royal Avenue Hotel; tickets, 5s. 6d. (exclusive of wine).—JOHN W. BYERS, M.D., Lower Crescent, Belfast, Honorary Secretary.

NORTH WALES BRANCH.—The annual meeting will be held at Dolgelly on July 9th. Members having any communications to bring before the meeting are requested to intimate the same before June 30th to W. JONES-MORRIS, Honorary Secretary, Portmadoc.

NORTHERN COUNTIES OF SCOTLAND BRANCH.—The annual meeting of this Branch will be held at the Spa Hotel, Strathpeffer, on Thursday, July 5th, at 1.50 p.m. Papers will be read by Dr. Fortescue Fox, Strathpeffer, Cases of Venesection, and Dr. Leslie H. Milne, Forre, Notes on the Weir-Mitchell Treatment. A visit will also be paid to the Spa.—J. W. NORRIS MACKAY, M.D., Honorary Secretary, Elgin.

READING AND UPPER THAMES BRANCH.—The annual meeting of this Branch will be held in the Library of the Royal Berkshire Hospital, Reading, on Wednesday, July 11th, at 4.15 p.m. The chair will be taken by the President (Dr. C. H. Teuch), who will introduce the President for the coming year (W. B. Holderness, Esq., of Windsor), who will then take the chair. Members willing to read short papers or bring forward cases of clinical interest are requested to communicate with the Honorary Secretary without delay. The annual dinner will take place on the same evening at 6.15 p.m. at the Queen's Hotel, Reading. Dinner tickets (5s. without wine, or 10s. including wine) should be obtained from the Honorary Secretary on or before Saturday, July 7th.—H. HEYGATE PHILLIPS, 43A, London Road, Reading, Honorary Secretary.

SHROPSHIRE AND MID-WALES BRANCH.—The annual general meeting of the Branch will be held at the Salop Infirmary, Shrewsbury, on Tuesday, July 3rd, at 2 p.m. The annual dinner will take place at the Raven Hotel after the meeting. Members desirous of contributing papers, notes of cases, etc., are requested to communicate with the undersigned.—EDWARD CURETON, Honorary Secretary, Shrewsbury.

OXFORD AND DISTRICT BRANCH.—The annual meeting will be held at the Radcliffe Infirmary, Oxford, on Friday, July 27th, at 3.30 p.m. Members wishing to read papers or show cases or specimens are requested to give notice to the Honorary Secretary, W. Lewis Morgan, 42, Broad Street, Oxford, on or before July 13th.—S. D. DARBYSHIRE and W. LEWIS MORGAN, Honorary Secretaries.

NEW SOUTH WALES BRANCH.

THE seventieth general meeting of this Branch was held in the Royal Society's Room, Sydney, on Friday, May 4th, at 8 p.m. Dr. CHAMBERS, President, in the chair. The following gentlemen were present: Drs. Sydney Jones, Crago, Roth, Macdonald, Marshall, Martin, Knaggs, Parker, Brady, Worrall, Fiaschi, Garrett, Kendall, Clubbe, West, Twynan, and Scot Skirving.

The minutes of the previous meeting were read and confirmed.

Morphine Poisoning.—Dr. CRAGO read some notes on a case of morphine poisoning.—THE PRESIDENT said that the great difficulty in the case mentioned by Dr. Crago was that there was no knowledge as to whether the man really had taken morphine. Goltz's experiments in this connection were interesting, demonstrating very clearly that exactly the same stages of loss of function were found in morphine poisoning as were seen in removing successive portions of the brain of animals from above downwards.—Dr. BRADY remembered a case in which a patient took two ounces of opium. The patient was paralysed, but artificial respiration was kept up by the late Dr. Fortescue and himself, and large doses of atropine were administered. The patient recovered.—Dr. SCOT SKIRVING said that at the Prince Alfred Hospital he saw a patient who had tried to hang herself. First, a partial recovery took place, lasting some hours, followed by relapse into unconsciousness and death. The conditions of opium poisoning and strangulation were somewhat analogous. He would ask what was the mechanism of death in such cases of partial recovery followed by relapse. Several explanations might be given.—Dr. KNAGGS said he had been attending the Criminal Court all day as an expert in a case of morphine poisoning, and he had been particularly struck with the great diversity of opinion amongst the medical experts in this matter. The patient mentioned in Dr. Crago's paper did not seem to have been used to taking morphine. The secondary symptoms mentioned by Dr.

Scot Skirving were no doubt brought about by the congestion of the nerve-centres, leading to a subsequent serous effusion. He (Dr. Knaggs) mentioned a case of a young woman who was partially drowned and brought round, and went on well for a time, but relapsed and died. Upon examination it was found that there was a large effusion on the brain. The mechanical conditions were certainly somewhat the same in morphine poisoning, strangulation, and drowning. He had had several *post-mortem* examinations of cases of morphine poisoning, and had always found a great deal of effusion.—Dr. SYDNEY JONES did not quite see that there was sufficient evidence to justify the diagnosis of morphine poisoning, as the man's statement as to taking morphine pills could not quite be relied upon, especially as he was in such a confused condition. The results of a limited hæmorrhage into the pons Varolii were wide-spread and more in keeping with the symptoms described, and he should think that the cause of death had been some subsequent inflammatory mischief. In support of this view of the case there was the total absence of that coldness and clamminess mentioned by the authorities as distinctive of opium poisoning.—Drs. WEST, MACDONALD, WORRALL, and TWYNAM also took part in the discussion, and Dr. CRAIG replied.

Anæmic Sore Throat.—Dr. SCOT SKIRVING read some notes on a form of sore throat seen in anæmic persons.

Perforation of Vermiform Appendix.—Dr. TWYNAM exhibited and made some remarks upon a specimen of perforation of the vermiform appendix.

Subject of Discussion at Next Meeting.—Dr. KNAGGS stated that he would open a discussion on the administration of chloroform at the next meeting of the Branch.

JAMAICA BRANCH.

THE bi-monthly meeting of this Branch was held at the public library on May 30th, the Hon. J. C. PHILLIPPO, President, in the chair.

Papers.—Dr. BRONSTORPH read a paper on Tetanus following Abortion.—Dr. PLAXTON read a paper on a case of Shrinkage of a Hemisphere and subsequent Pachymeningitis. The brain and its coverings were shown.

LANCASHIRE AND CHESHIRE BRANCH.

THE fifty-second annual meeting of this Branch was held at the Medical Institution, Hope Street, Liverpool, on Wednesday, June 13th, at 2.30 P.M.

The minutes of the last annual meeting were read and confirmed.

New President's Address.—Dr. BALL, the retiring President, then introduced his successor, Dr. WATKINS (Newton-le-Willows), who, after thanking the members for the honour conferred upon him, delivered his presidential address. At its conclusion, on the motion of Dr. A. T. H. WATERS, seconded by Dr. EYTON JONES, a hearty vote of thanks was carried by acclamation.

Report of Council.—The report showed that the Branch had lost fifty-two members by death and removal from the district. The reduction had, however, been made good by the election of fifty-four new members. The financial condition of the Branch was highly satisfactory, while the expenses of the year had been a few shillings under that of last year. The receipts had increased, and there was now a balance of £231 4s. 1d. as against £229 16s. 11d. at the end of the previous year. It was proposed at the council meeting held before the last annual meeting to make a donation from the funds of the Branch to the Epsom Medical Benevolent College; but as some members considered this step to be *ultra vires*, the Council submitted the question to Mr. Upton, the solicitor to the Association, who was of opinion that it came within the powers of the Council to vote the amount, but that it would be better to have an expression of feeling on the point from a general meeting. Notice had therefore been duly given that a proposition to make a donation of twenty-five guineas to the Epsom Medical Benevolent College would be brought before the meeting. The Council had during the past year appointed subcommittees to consider the best steps to take to secure an increase of fees to medical witnesses, and to obtain more consideration for them at sessions and assizes. The subcommittee, after considerable deliberation, had drawn up a similar inquiry into the scale of fees payable in different parts of the country, and asking if any grievances existed, and, if so, for suggestions for their removal. It was intended to send this circular to every Branch within the United Kingdom, to collate the replies, and take steps to memorialise the Government on the subject. Another

subcommittee had been engaged in revising the proposed amendments of the Lunacy Acts Amendment Bill, and, after lengthy consideration, had proposed certain amendments in the interest of the profession which would be submitted to the meeting. The whole subject of annual and intermediate meetings had received the attention of the Council, which had drawn up a scheme whereby it is unanimously recommended that Liverpool, Manchester, Lancaster, and Chester be considered as the principal points for annual meetings of the Branch, and that in future annual meetings be held in these places on alternate years in rotation, unless special circumstances rendered a different arrangement desirable in any particular year. That in the intervening years the annual meetings be held at one of the following towns—Preston, Wigan, Warrington, Crewe, Barrow, Ulverstone, Blackpool, Southport, Burnley, Blackburn, Rochdale, Macclesfield, Clitheroe, St. Helens, Bolton, Bury, Stockport, Birkenhead, Runcorn, Knutsford, Northwich, and Nantwich—the place of meeting to be fixed on at the preceding annual meeting each year. That it is desirable that an intermediate meeting be held in the autumn of each year in one of the above mentioned towns to be selected by the Council. These recommendations had been adopted with a view of holding more frequent meetings throughout the district without waiting for specific invitations from places which were often made at inconvenient dates, and proceeded from places inaccessible to the bulk of the members. It was intended to defray the cost of all meetings from the funds of the Branch, thus relieving the local practitioners from what might have been felt somewhat of a tax upon their generosity, especially in sparsely inhabited districts. The adoption of the report and financial statement was proposed by Dr. A. T. H. WATERS, seconded by Dr. CARTER, and carried.

Election of Office-bearers.—*President-elect*, Dr. Davidson; *Vice-presidents*, Mr. Hardie and Mr. Chauncy Puzey; *Honorary Secretary*, Dr. Glascott.

Representatives in the Council of the Association.—Geo. B. Barron, M.D., Southport; Alex. Davidson, M.D., Liverpool; Charles E. Glascott, M.D., Manchester, *General Secretary*; James Hardie, Esq., Manchester; James Taylor, Esq., Chester, *Local Secretary*.

Council of the Branch.—W. Alexander, M.D., Liverpool; F. J. Bailey, Liverpool; J. A. Ball, M.B., Wantage; W. C. Barnish, Wigan; J. Barr, M.D., Liverpool; William Bell, New Brighton; W. Berry, Wigan; P. M. Braidwood, M.D., Birkenhead; J. J. Bride, Wilmslow; S. Buckley, M.B., Manchester; J. E. Burton, Liverpool; A. F. H. Cameron, Liverpool; W. M. Campbell, M.D., Liverpool; W. Carter, M.D., Liverpool; J. Corns, M.D., Oldham; E. H. Dickinson, Liverpool; J. Dreschfeld, M.D., Manchester; A. M. Eason, Lytham; H. M. Fernie, Macclesfield; W. H. Fitzpatrick, M.D., Liverpool; T. R. Glynn, M.D., Liverpool; A. Godson, M.B., Cheadle; F. Granger, Chester; W. Hall, jun., Lancaster, *Local Secretary*; C. E. Harris, M.D., Birkenhead; W. H. Hughes, Ashton; J. H. Hammond, M.D., Preston; Leslie Jones, M.D., Manchester; T. Jones, M.B., Manchester; J. Lambert, M.D., Birkenhead; W. McAfee, M.D., West Kirby; E. D. McNICOLL, Southport; Edwin Rayner, M.D., Stockport; C. J. Renshaw, M.D., Ashton-on-Mersey; D. Lloyd Roberts, M.D., Manchester; John Robinson, Frodsham; T. L. Rogers, Rainhill; J. Ross, M.D., Manchester; G. E. Shuttleworth, M.D., Lancaster; Starkie Smith, M.D., Warrington; F. Southam, Manchester; G. Thomson, M.D., Oldham; C. Thorp, Todmorden; F. Vacher, Birkenhead; E. Waters, M.D., Chester; Wm. Walter, M.D., Manchester; H. Welch, Blackpool; R. Williams, Liverpool; G. A. Woods, Southport; A. H. Young, M.D., Manchester.

Representatives on Parliamentary Bills Committee.—Dr. Barron and Dr. Carter.

Next Annual Meeting.—It was resolved that the next annual meeting should be held at Blackpool.

Donation to Epsom College.—It was resolved that a donation of twenty-five guineas be made from the funds of the Branch to the Epsom Benevolent Medical College.

Reports of Subcommittees.—The report of the Medical Witnesses Subcommittee was read and adopted.

Lunacy Acts Amendment Bill.—It was resolved that the following report of the Lunacy Acts Amendment Bill be adopted:—

“Your Committee, having carefully examined the proposed amendments to the Lunacy Acts Amendment Bill, would suggest that Section 4, Subsections 1, 2, and 9, be retained, with the modification of three clear days instead of seven days, line 8, Subsection 1, page 3. Your Committee suggests the retention of Section 4 with the above modification, as it is frequently impossible to

obtain the services of a magistrate so as to get the patient at once admitted to an asylum, and on this head beg to remind your Council of the recent case of a patient who was driven about in a vehicle for twelve hours during most inclement weather in search of a magistrate, who was expected to examine the lunatic. Section 54, page 33, line 14, insert "shall" instead of "may," lines 20 and 21, omit words, "as the Committee may think fit," thus putting hospital officers in the same category as county asylum officers. With the exception of the above alteration and amendments, your Committee recommend the acceptance of the amendments suggested by the Subcommittee of the Parliamentary Bills Committee of the Association."

Medical and Surgical Communications.—Owing to the large number of papers it was found necessary to divide the meeting into two sections, the following being a list of communications: Dr. WALTER: Notes of a Case of Total Extirpation of the Uterus *per Vaginam*.—Dr. GLYNN: A Note on a new Method of treating Chlorosis.—Mr. R. HARRISON showed the Electric Endoscope.—Dr. JOHNSON MARTIN: How to prevent Small-pox and how to spread it.—Dr. ALEXANDER: Hysterectomy for Uterine Cancer (patient).—Mr. SHEARS: Xerosis of the Conjunctiva with Night Blindness.—Dr. IMLACH: The Use of Stimulants and Narcotics by Women.—Mr. G. WALKER: Treatment of Closed Pupils, with cases.—Dr. BURTON: Short Notes of Cases of Uterine Fibroma treated by the Apostoli Method.—Dr. W. MITCHELL BANKS: Abdominal Section for Chronic Suppurative Peritonitis, and for Retro-peritoneal Cyst.—Mr. E. STANMORE BISHOP: Case of Nephrectomy.—Dr. R. WILLIAMS: Two Cases of Conical Cornea treated by Actual Caution.

Exhibits.—A small museum of drawings, photographs, and selected pathological specimens was shown.

Dinner.—In the evening fifty-four members dined together at the Adelphi Hotel, under the presidency of Dr. Watkins, President of the Branch.

NORTH OF ENGLAND BRANCH.

Visit to Durham County Asylum.—On Friday, June 22nd, by the kind invitation of Dr. Smith, the Medical Superintendent, the members of the North of England Branch visited the Durham County Asylum at Sedgfield, which contains twelve hundred patients. Between sixty and seventy members were present.

Amongst many typical cases demonstrated by Dr. SMITH was one of myxœdema, in which he took a special interest, as he has only had two cases of the kind. The first patient died, and a series of microscopical preparations of the thyroid gland, kidneys, etc., were shown.

A remarkable group of general paralytics excited much attention; and, in conversing with them, Dr. Smith brought out their exaggerated ideas of wealth, power, etc. A good discussion took place with reference to a man who had been trephined for convulsions, consequent upon an injury to the head; he improved considerably after the operation, then relapsed, but it was hoped that he would ultimately be benefited.

The general arrangements of the asylum were much admired, and every one was struck by the good order, brightness, and cleanliness of the whole institution. At two o'clock Dr. Smith entertained his visitors at lunch with generous hospitality, and his health was drunk with much enthusiasm.

The members generally were very grateful to Dr. Smith for enabling them to see so many patients of a class not often met with in ordinary practice.

METROPOLITAN COUNTIES BRANCH: NORTH LONDON DISTRICT.

THE annual meeting of this district was held at the Zoological Gardens on Wednesday, June 14th, when the following officers were re-elected: *Vice-President*: Dr. Bridgwater; *Representative Member of Council*: Dr. E. Hooper May; *Committee*: Dr. Wynn Westcott, Dr. Sykes, Dr. H. Goude, Dr. W. Smith, Dr. Plaister, and Dr. Crabb; *Honorary Secretary*: Dr. G. Henty.

Many of the members attended the lecture on Deinosauria, by Mr. E. Boddard, M.A., and others visited the lion-house, the new reptile-house, and many other interesting objects of these well-conducted gardens.

The dinner was presided over by the President, A. G. Durham, Esq., supported by Dr. Brodie Sewell, Dr. Bridgwater, Dr. Dickson, and upwards of twenty members, one and all expressing great satisfaction at so good a reception.

BRITISH MEDICAL ASSOCIATION.

FIFTY-SIXTH ANNUAL MEETING.

THE fifty-sixth Annual Meeting of the British Medical Association will be held at Glasgow, on Tuesday, Wednesday, Thursday, and Friday, August 7th, 8th, 9th, and 10th, 1888.

President: John T. Banks, M.D., D.Sc.(Hon.), F.R.C.S.P., Regius Professor of Physic in the University of Dublin.

President-Elect: Professor W. T. Gairdner, M.D., LL.D., Professor of Medicine in the University of Glasgow.

President of the Council: Thomas Bridgwater, M.B., J.P., Harrow-on-the-Hill.

Treasurer: Constantine Holman, M.D., J.P., Reigate.

An Address in Medicine will be delivered by Thomas Clifford Allbutt, M.D., F.R.S., Consulting Physician, Leeds General Infirmary.

An Address in Surgery will be delivered by Sir George H. B. Macleod, M.D., Surgeon in Ordinary to Her Majesty in Scotland.

An Address on his "Recent Investigations in Surgery" will be given by William Macewen, M.D., Lecturer on Clinical Surgery, Glasgow Royal Infirmary.

An Address in Physiology will be delivered by John Gray McKendrick, M.D., LL.D., F.R.S., Professor of Institutes of Medicine, University of Glasgow.

All the rooms required for the purposes of the meeting will, by the kindness of the authorities, be provided in the University of Glasgow.

PROGRAMME OF PROCEEDINGS.

TUESDAY, AUGUST 7TH, 1888.

9.30 A.M.—Meeting of 1887-1888 Council. Randolph Hall.

11.30 A.M.—First General Meeting. Report of Council. Reports of Committees. Bute Hall.

4 P.M.—Service in the Cathedral. Sermon by the Very Rev. John Caird, D.D., LL.D., Principal and Vice-Chancellor of the University of Glasgow.

8.30 P.M.—Adjourned General Meeting from 11.30 A.M. President's Address. Bute Hall.

WEDNESDAY, AUGUST 8TH, 1888.

9.30 A.M.—Meeting of 1888-89 Council. Randolph Hall.

10.30 A.M. to 2 P.M.—Sectional Meetings.

3 P.M.—Second General Meeting. Address in Medicine by Thomas Clifford Allbutt, M.D., F.R.S. Bute Hall.

9 P.M.—*Conversazione* given by the Professors of the University.

THURSDAY, AUGUST 9TH, 1888.

9.30 A.M.—Address on his Recent Surgical Investigations by William Macewen, M.D. Bute Hall.

11 A.M.—Meeting of Council. Randolph Hall.

10.30 A.M. to 2 P.M.—Sectional Meetings.

3 P.M.—Third General Meeting. Address in Surgery by Sir George H. B. Macleod, M.D. Bute Hall.

7 P.M.—Public Dinner. St. Andrew's Hall.

FRIDAY, AUGUST 10TH, 1888.

10.30 A.M. to 1.30 P.M.—Sectional Meetings.

3 P.M.—Concluding General Meeting. Address in Physiology by John G. McKendrick, M.D., F.R.S. Natural Philosophy Class-room.

9 P.M.—*Conversazione* given by the Corporation of Glasgow at St. Andrew's Hall.

Garden Party given by the Faculty of Physicians and Surgeons at the Botanic Gardens.

SATURDAY, AUGUST 11TH, 1888.

Excursions:—(1) Lanark and Falls of Clyde; (2) Ayr and the Land of Burns; (3) the Perthshire Highlands, Lochearnhead and Crieff; (4) Callender and the Trossachs (Loch Katrine); (5) Ayr; (6) Stirling, Bridge of Allan and Dunblane Cathedral; (7) Rothesay and the Kyles of Bute; (8) Loch Lomond.

The following discussions and papers are promised up to the present time.

SECTION A.—MEDICINE.

Humanity Class Room.

A. MEDICINE.—*President*, Professor T. McCall Anderson, M.D. *Vice-Presidents*, R. L. Bowles, M.D.; George F. Duffey, M.D. *Honorary Secretaries*, J. McGregor Robertson, M.A., M.B., 400, Great Western Road, Glasgow; Robert M. Simon, M.D., 27, Newhall Street, Birmingham.

The President will open the proceedings by introducing a discussion on the Diagnosis and Treatment of Syphilitic Disease of the Nervous System. Dr. Thomas Buzzard, Dr. T. S. Clouston, Dr. William Moore, Dr. Ross, Professor Grainger Stewart, Professor Julius Dreschfeld, Dr. J. G. Sinclair Coghill, Dr. Francis Warner, Dr. Frederick Bateman, Dr. C. R. Drysdale, Dr. C. W. Suckling, and Dr. Alex. Robertson (Glasgow) will take part in the discussion.

On the third day of the sectional proceedings, the Value of Inhalations in the Treatment of Lung Disease is set down for discussion, to be opened by Dr. C. Theodore Williams. The following gentlemen have already indicated their intention to engage in this

discussion: Dr. Burney Yeo, Dr. W. W. Ireland, Dr. C. F. Knight, Dr. J. A. Lindsay, Dr. J. G. Sinclair Coghill, and Dr. E. Markham Skerritt.

Drs. Byrom Bramwell and Milne Murray will give a demonstration of their Method of Graphically Recording the Exact Time Relations of Cardiac Sounds and Murmurs.

The following papers have been promised.

- COGHILL, J. G. S., M.D., Ventnor. The Treatment of Phthisical Pyrexia.
 COUPLAND, Sidney, M.D. A Case of Subphrenic Abscess.
 FINLAY, David W., B.A., M.D. Bronchiectasis treated by Incision and Drainage.
 FREW, W., M.D., Kilmarnock. Prevalence of Cerebro-spinal Fever in Scotland.
 GARRY, T. Gerald, M.D., M.Ch. Massage: When and How to Use it.
 GREENE, G. E. P., L.K.Q.C.P. A Note on a Recent Epidemic of Erysipelas.
 HANFORD, H., M.D. The Influence and Position on Cardiac Murmurs and the Condition of the Heart in Anæmia (Chlorosis).
 HARRISON, A. J., M.B. Further Researches on the Treatment of Tinea Tonsurans. Illustrated with photographs.
 JONES, A. Orlando, M.D. A New Remedy for Some Forms of Heart Disease.
 MYRTLE, A. S., M.D., Harrogate. Neurasthenia, True and False: Diagnosis and Management.
 STRACHAN, John, M.D. (Dollar). A Case of Pernicious Anæmia Successfully Treated by Arsenic.
 STRAHAN, John, M.D. (Belfast). (*Title not received.*)
 SUCKLING, C. W., M.D. Notes on Peripheral Neuritis and on its occurrence in Brassworkers.
 TOMORY, J. K., M.B. East African Fever, with special reference to Climatic Conditions.
 WARNER, Francis, M.D. 1. Methods of Studying and Examining the Nerve System. 2. Imbecility in Children from Chronic Meningitis.
 Sir W. Roberts, Dr. Lauder Brunton, Dr. Russell Reynolds, and Dr. F. W. Pavy have also intimated their intention to take part in the proceedings of the Section.

SECTION B.—SURGERY. Chemistry Class Room.

B. SURGERY.—*President*, George Buchanan, M.D. *Vice-Presidents*, James Dunlop, M.D.; Charles Robert Bell Keetley, F.R.C.S. *Honorary Secretaries*, David Neilson Knox, M.B., 8, India Street, Glasgow; Walter Pye, F.R.C.S., 4, Sackville Street, Piccadilly, London, W.

As already announced, in this Section discussions have been arranged for on the following subjects:

1. The Surgical Treatment of Abscess of the Lung and of Empyema. To be introduced and supported by Mr. T. Pridgin Teale (Leeds), Sir Spencer Wells (London), Mr. A. Pearce Gould (London), Mr. R. J. Godlee (London), Dr. J. Ward Cousins, Portsmouth, and Mr. W. Thomas (Birmingham).
2. The Operative Treatment of Club-Foot. To be introduced and supported by Sir William Stokes (Dublin), Mr. E. Lund (Manchester), Dr. Alexander Ogston (Aberdeen), Mr. R. W. Parker (London), Mr. E. M. Little (London), Mr. John Chiene (Edinburgh), Mr. W. J. Walsham (London), and others.

The following papers have also been promised.

- BENTON, Samuel, Esq., London. On the Treatment of Stricture of the Rectum by Electrolysis.
 BISHOP, E. Stanmore, Esq., Manchester. Some Cases of Osteotomy, with an Apparatus for fixing the Lower Limbs after Division of the Bones.
 BROWNE, G. Buckston, Esq., London. An Explanation of the way in which Calculi in the Male Urinary Bladder sometimes escape Detection by the Sound, with a description of a New Form of Sound.
 BROWNE, Lennox, Esq., London. Tubage of the Larynx.
 CARMICHAEL, Alexander, M.D., Barrow-in-Furness. A Case of Gastrostomy, with Exhibition of Patient.
 CLARK, Sir Andrew, London. The History of a Case of Catheter Fever.
 CLARKE, W. Bruce, Esq., London. Prostatic Abscess and its Consequences.
 COUSINS, J. Ward, M.D., Portsmouth. (1) New Apparatus for Treatment of Fractures of Lower Jaw; (2) New Evacuator for Litholapaxy and other Bladder Operations.
 FEWICK, E. Hury, Esq., London. Notes from the Experience of 450 Cases of Organic Stricture of the Urethra.
 FLEMING, W. J., M.D., Glasgow. 1. On Continuous Extension in Spinal Curvature. 2. On the Treatment of Perineal Fistula.
 HARRISON, Reginald, Esq., Liverpool. On an Improvement in the Construction of Slips' Berths, relative to the Treatment of some Surgical Injuries and Diseases at Sea (with models).
 KETLEY, C. B., Esq., London. Plastic Amputations of the Foot.
 LOYD, Jordan, Esq., Birmingham. Inflammatory Disease of the Seminal Vesicles.
 McINTYRE, John, Esq., Glasgow. The Electric Illumination of the Cavities of the Body.
 MURPHY, James, M.D., Sunderland. (1) A Case of Gastrostomy, with Exhibition of Patient Eleven Months after Operation. (2) Hysterectomy per Vaginum for Uterine Fibroids, *morcellément* as practised by M. Péan.
 OWEN, Edmund, Esq., London. A Case of Intra-cranial (Subdural) Hemorrhage; Localisation; Trephining; Recovery.
 PEARSE, F. Frederick, Esq., M.D., London. (1) On Puncture of the Bladder; (2) On Gonorrhœa in Women.
 RAKE, Beaven, M.D., Trinidad. The Value of Nerve Stretching in Leprosy, based on One Hundred Cases.
 RENTON, J. Crawford, Esq., M.D., Glasgow. A Case of Severe Deformity of Lower Lip restored by Mr. Teale's operation six years ago.
 ROBSON, A. W. Mayo, Esq., Leeds. (1) Prostatectomy, a Sequel of the Opera-

tion of Suprapubic Lithotomy in cases of Prostatic Enlargement. With Cases. (2) A Series of Cases of Macewen's Operation for Genu Valgum.
 ROTH, Bernard, Esq., London. On Scoliosimetry, or an Accurate and Practical Method of Recording Cases of Lateral Curvature of the Spine.
 SMITH, Noble, Esq. Demonstration of the Reduction of Fractured Vertebrae, and the application of Apparatus to Control the Spine.
 STOKES, Sir William, Dublin. Modification of Gritti's Amputation; and will show Casts of Stumps.
 TAIT, Lawson, Esq., Birmingham. A Second Series of One Thousand Consecutive Abdominal Sections.
 THOMSON, Wm., Esq., M.D., Dublin. On Excision of the Knee-joint.
 THORBUERN, Wm., Esq., Manchester. The Distribution of Paralysis and Anæsthesia in Injuries of the Cervical Region of the Spinal Cord.
 VALCOURT, Th. de, Esq., M.D., Cannes. Winter Sea-baths at Cannes in cases of Scrofulous Disease.

SECTION C.—OBSTETRIC MEDICINE. Medical Jurisprudence Class Room.

C. OBSTETRIC MEDICINE.—*President*, Thomas More Madden, M.D. *Vice-Presidents*, William Leishman, M.D.; J. Halliday Croom, M.D. *Honorary Secretaries*, William Walter, M.D., 20, St. John Street, Manchester; W. L. Reid, M.D., 7, Royal Crescent, Glasgow.

The following two special discussions will take place:—

1. On Intra-uterine Death; its Pathology and Preventive Treatment. To be opened by Professor Simpson. The following gentlemen will take part in the discussion:—Drs. R. Barnes, Graily Hewitt, More Madden, W. O. Priestley, John W. Byers, and A. D. Leith Napier.
2. On Obstructive Dysmenorrhœa and Sterility. To be opened by Dr. Halliday Croom. The following gentlemen will take part in the discussion:—Drs. Aveling, Bantock, F. Barnes, R. Barnes, Cranny, Duke, Edis, Graily Hewitt, Macan, More Madden, Professor Stephenson, J. W. Taylor, W. Walter, and J. W. Byers.

Dr. Samuel Sloan (Glasgow) will show his Antero-posterior Compression Forceps, and will explain their use in Flat Pelves.

Wm. Walter, M.D., Manchester, will exhibit his instruments for Securing the Broad Ligaments during Extirpation of the Uterus per Vaginam.

The following papers are promised.

- APOSTOLI, G., M.D., Paris. On Some Novelties in the Electro-Therapeutics of Gynaecology.
 AVELING, J., M.D. The Treatment of Uterine Tumours by Electricity.
 BARNES, R., M.D. Analogies between Menstruation and Gestation and Puerperia in their Physiological and Pathological Relations.
 CAMERON, Murdoch, M.D., Glasgow. 1. On Cesarean Section, with Notes of a Successful Case. 2. On the Thermostatic Nurse, with Cases.
 CROOM, J. Halliday, M.D., Edinburgh. (1) On the Remote Effects of Removal of the Uterine Appendages. (2) On Some Points in the Pathological Anatomy of Incarceration of the Retroflexed Gravid Uterus.
 DUKE, A., F.K.Q.C.P., Dublin. (1) On the Rapid Expansion of the Cervical Canal by a New Method. (2) Tractors and Belt for Additional Power in Forceps Cases, as an Alternative to Craniotomy.
 HART, D. Berry, M.D., Edinburgh. Successful Case of Cesarean Section (Porro's modification).
 IMLACH, Francis, M.D., Liverpool. The Function of Anæmia in Gynaecology.
 KENNEDY, Hugh, M.D., Dublin. Notes on the Treatment of Lacerations of the Cervix Uteri.
 McDONALD, A. D., M.D., Liverpool. A Case of Extra-uterine Pregnancy.
 MADDEN, More, M.D., Dublin. On the Causes and Treatment of Pseudocystitis.
 MARTIN, J. M., M.D. On Some Points in the Pathology of Carcinoma of the Uterus.
 NAPIER, A. D. Leith, M. D., London. The Treatment of Habitual Abortion.
 ROUTH, A., M.D. Headaches of Pelvic Origin.
 STEPHENSON, William, M.D., Aberdeen. On the Influence of Permanganate of Potass on Menstruation.
 TAIT, Lawson, Esq., Birmingham. The Treatment of Uterine Myoma.

SECTION D.—PUBLIC MEDICINE. Greek Class Room.

D. PUBLIC MEDICINE.—*President*, Henry Duncan Littlejohn, M.D. *Vice-Presidents*, James Christie, M.D.; D. Page, M.D. *Honorary Secretaries*, Ebenezer Duncan, M.D., 4, Royal Crescent, Crosshill, Glasgow; John C. McVail, M.D., Holmhead, Kilmarnock.

1. Sanitary Legislation. This discussion will be introduced by the Opening Address of the President of the Section.
2. The Communicable Diseases Common to Man and Animals, and their Relationships. Discussion to be opened on the second day of the sectional meetings by George Fleming, LL.D., F.R.C.V.S., Chief of the Veterinary Department of the Army. Professor Edgar Crookshank, King's College, will take part in the discussion.
3. The Disposal of Sewage (a) in Large Towns; (b) in Small Towns and Country Districts. Discussion will be opened on the third day by Dr. James B. Russell, Medical Officer of Health, Glasgow.

The following papers are promised.

- BROWN, William, M.D., Carlisle. Report on Outbreak of Typhoid Fever, Associated with an Infective Fever among Cows.
 CARPENTER, Dr. Alfred, Croydon. On Disposal of Sewage.

June 30, 1888.]

- CHURTON, T., M.D., Leeds. On Some Researches in the Homes of Hospital Patients and of Holiday Children.
- DRYSDALE, Charles R., M.D. 1. On Indigence as a Main Cause of High Death-rates. 2. The Berlin and Parisian Sewage Farms.
- HIME, T. W., M.B. Milk Scarlet Fever.
- HOPE, E. W., M.D., Liverpool. On the More Recent Phases in the Decline of the Liverpool Death-rate.
- JAMES, J., Brindley, Esq., London. On a Minister of Public Health.
- KERR, Norman, M.D. Some Risks of Sanitation.
- LITTLEJOHN, Dr., Edinburgh. On Disposal of Sewage.
- MUNRAT, Dr., Forfar. On Disposal of Sewage.
- NASMYTH, T. G., F.R.S. A Report on the Chemical and Biological Conditions of the Air of Coal Mines, together with Mortality Statistics of a Mining District, being a report to the Scientific Grants Committee of the British Medical Association.
- PRINGLE, Surgeon-Major Robert, M.D., late of the Sanitary Department Her Majesty's Bengal Army. (1) On Sheffield and Leicester Compared as Regards Small-pox Prevalence. (2) The Condition of Water-Supply for Drinking Purposes in Public Fountains, Railway Stations, etc.
- SEATON, Edward, M.D., London. On Epidemic of Ephemeral Fever.
- SIMPSON, —, M.D., Medical Officer of Health, Calcutta. On Cholera and its Fostering Conditions in the Endemic Area.
- SUTHERLAND, J. Francis, M.D. National Sanatoria.
- TOMKINS, H., M.D., M.O.H., Leicester. Some Bacteriological Researches in connection with Summer Diarrhoea.
- WHITELAW, Dr., Kirkintilloch. On Disposal of Sewage.

SECTION E.—PSYCHOLOGY.

Natural History Class Room.

E. PSYCHOLOGY.—President, James C. Howden, M.D. *Vice-Presidents*, James Rutherford, M.D.; Julius Mickle, M.D. *Honorary Secretaries*, A. R. Urquhart, M.D., Murray House, Perth; Alex. Newington, M.D., Titchhurst, Sussex.

Dr. J. C. Howden, the President of the Section, will deliver an Address.

Dr. C. M. Campbell will introduce a discussion on the Uniform Recording of *Post-Mortem* Examinations in Asylum Reports.

Drs. A. Yellowlees and A. Campbell Clark will introduce the following subject: The Sexual and Reproductive Functions—Normal and Perverted—in Relation to Insanity. 1. Menstruation: its Commencement, Irregularities, and Cessation; 2. The Sexual Instinct and its Abuse; 3. Pregnancy, Parturition, the Puerperal Period, and Lactation.

Dr. Clouston will initiate a discussion on the Principle of Construction and Arrangement of an Asylum for Private Patients of the Higher Classes.

The following have promised papers: Drs. Savage, Hack Tuke, Fletcher Beach, Charles Mercier, W. J. Mickle, and Turnbull.

SECTION F.—ANATOMY AND PHYSIOLOGY.

Anatomy Class Room.

F. ANATOMY AND PHYSIOLOGY.—President, John Cleland, M.D., LL.D., F.R.S. *Vice-Presidents*, R. J. Anderson, M.D.; Henry Edward Clark, F.F.P.S.G. *Honorary Secretaries*, John Barlow, M.D., 27, Elmbank Crescent, Glasgow; Charles Barrett Lockwood, F.R.C.S., 19, Upper Berkeley Street, Portman Square, W.

C. B. Lockwood, F.R.C.S., will introduce a discussion on the Teaching of Anatomy; and will show sections illustrating the Development of the Organs of Circulation and Respiration.

The following papers are promised.

BROOKS, Henry St. John, M.D. On the Morphology of the Epitrochleo-anconeus or Anconeus Sextus (Gruber).

BROWN, J. Macdonald, M.B., F.R.C.S. The Construction of the Cardiac Ventricles in the Mammalia.

CLELAND, Professor, M.D., F.R.S. On the Nature of Certain Forms of Double Monstrosity.

COLLIER, Mark P. Mayo, M.B., F.R.C.S. On the Mechanism of the Heart and Pulse.

LANE, W. Arbuthnot, M.B., F.R.C.S. The Influence Produced by Excessive Strain upon Muscles and Ligaments (to be illustrated by specimens).

MURRAY, R. Milne, M.B., F.R.C.P.E. Will Show an Arrangement for the Investigation of the Action of Measured Galvanic and Faradic Currents on Tissues.

PATERSON, A. M., M.D. On the Position of the Vertebrate Limb, considered in the Light of its Innervation and Development.

SECTION G.—PATHOLOGY.

Law Class Room.

G. PATHOLOGY.—President, Sir William Aitken, M.D., LL.D., F.R.S. *Vice-Presidents*, Alexander Davidson, M.D.; Joseph Coats, M.D.; Charles Roy, M.D., F.R.S. *Honorary Secretaries*, G. Sims Woodhead, M.D., 6, Marchhall Crescent, Edinburgh; J. Lindsay Steven, M.D., 34, Berkeley Terrace, Glasgow.

Arrangements are being made to hold a discussion on Cancer originating apart from Epithelial Structures, in which Mr. Lawson Tait (Birmingham), Dr. Joseph Coats, Dr. John Carlyle (Greenock), and others are expected to take part.

The following papers have been promised.

BRUCE, Alex., M.B., F.R.C.P. Edin. On Disseminated Sclerosis,

COATS, Joseph, M.D. On a Case of Lipæmia in Diabetes, with Suggestions as to the Source of the Fat.

CROOKE, G. F., M.D., Birmingham. (1) Histological Examination of Organs in Two Cases of Purpura Haemorrhagica. (2) Cancrum Oris Terminating Fatally with Hemorrhagic Myocarditis.

CROOKE, G. F., Professor Edgar, M.B. (1) On Anthrax in Swine. (2) On Tuberculous Infection in Swine. (3) On Tubercular Cows Milk. (4) On Human and Bovine Actinomycoses.

GREVES, E. Hyla, M.D., Bournemouth. Notes on the Pathology of a case of Pseudo-hypertrophic Paralysis.

DELEPINE, Sheridan, Esq. A Few Uncommon Forms of Sarcoma. (Specimens to be shown.)

HUNTER, W., M.D. On the Pathology of Pernicious Anæmia.

KENNEDY, —. On Case of Cystic Kidneys and Liver.

MAPOTHER, E. D., M.D., Dublin. An Anomalous Form of Eczema.

MAYLARD, A. E., M.B., B.S. Lond. The Results of some Bacteriological Cultivation Experiments with Iodoform.

NUNN, T. W., Esq., F.R.C.S. Exhibition of a Selection of Microscopic Sections of Cancerous Tissues.

O'CONNOR, Bernard, M.D., M.R.C.P. Hydatids of the Spleen, Liver, and Brain.

RAKE, Beaven, M.D. Lond., Medical Superintendent of the Trinidad Leprosy Asylum. The Percentage of Fibrin in the Blood of Lepers.

RUSSELL, William, M.D. The Pathology of Pernicious Anæmia.

The following gentlemen have also intimated their intention of contributing to the business of the Section by reading papers or otherwise: Professor Greenfield, Professor Roy, Professor D. J. Hamilton, Dr. William Hunter, Dr. Barrett (Edinburgh). Dr. McFadyean (Edinburgh), Alex. Edington, M.B. (Edinburgh), etc.

Demonstrations.—Dr. Alexander Bruce (Edinburgh) will give a Magic Lantern Demonstration on Diseases of the Spinal Cord; and Alexander Edington, M.B. (Edinburgh), a Bacteriological Demonstration. Arrangements are also being made for a series of Microscopical Demonstrations illustrative of Tumours, Tuberculosis etc.

Pathological Section of the Annual Museum.—Intimation has been received of the following exhibits for this Section of the Annual Museum: 1. Calculi removed by Lithotomy, by Professor George Buchanan. 2. Calculi removed by Lithotripsy or by Scoop, by Professor George Buchanan. 3. Miscellaneous Objects removed from the Body, by Professor George Buchanan, namely: Bullets, Needles, Cases of Teeth, Impacted Pessaries, etc., also Isolated Bones of the Tarsus Excised. 4. Rhinoplasty; Wax Cast, by Professor George Buchanan. 5. Bladder and Urethra showing False Passages. 6. Selected Specimens from the Private Collection of Professor W. T. Gairdner. 7. A Series of Specimens of Tumours of the Brain, by Dr. Joseph Coats. 8. A Series of Specimens illustrative of Diseases of the Kidneys, by Dr. David Newman. 9. A Series of Specimens illustrative of Leprosy, by Dr. Beaven Rake (Trinidad). 10. A Series of Large Sections illustrating Malignant Tumours of the Lung; and a Series of Specimens illustrating Deformities of the Liver, by Drs. Woodhead and Bruce. 11. Drawings and Sections to illustrate Diseases of Bone and Joints, by Mr. F. M. Caird (Edinburgh). 12. A Series of Specimens illustrative of Diseases of the Heart, by Dr. John Lindsay Steven. 13. A Series of Myomata of the Uterus, by Dr. Joseph Coats. 14. A Series of Bacteriological Cultivations. By Mr. A. E. Maylard, B.S. 15. Sections of Primary Growths of the Pleura and Lungs, by Dr. George F. Croke, Birmingham.

As space for the Museum is somewhat limited, gentlemen intending to send specimens should intimate their intention without delay to John Lindsay Steven, M.D., 34, Berkeley Terrace, Glasgow, Honorary Secretary of the Section of Pathology of the Annual Museum.

SECTION H.—OPHTHALMOLOGY.

Midwifery Class Room.

H. OPHTHALMOLOGY.—President, Thomas Reid, M.D. *Vice-Presidents*, J. R. Wolfe, M.D.; C. E. Glascock, M.D. *Honorary Secretaries*, Henry Bendelack Hewetson, M.R.C.S., 11, Hanover Square, Leeds; A. Freeland Fergus, M.B., 41, Elmbank Street, Glasgow. Mr. Brudenell Carter will open a discussion on the Treatment of Senile Cataract. Drs. Prichard, Meighan, Mason, Teale, G. Anderson Critchett, Dr. C. Lloyd Owen, Charles G. Lee, H. Bendelack Hewetson, Esq., and others have promised to take part in the discussion.

The President of the Section intends to give a Demonstration of several Instruments of Use in Ophthalmic Diagnosis.

The following papers are promised.

BICKERTON, T. H., M.D., Liverpool. Sallors and their Eyesight.

CRITCHETT, G. Anderson, Esq. Iridectomy and Sclerotomy in Chronic Glaucoma.

GROSSMANN, K. A., M.D. Colour-blindness, with a Demonstration of New Tests.

HEWETSON, H. Bendelack, Esq. General Neuroses having an Ophthalmic Origin.

JESSOP, W. H., M.D. Ocular Headaches.

LEE, C. G., Esq. Two Cases of Foreign Bodies.

MACKAY, George, M.D., Edinburgh. A Contribution to the Study of Hemianopsia of Central Origin, with special reference to Acquired Colour Blindness.
 McHUGH, T. S., M.D., Glasgow. On the Treatment of Symbplepharon by Transplantation of Mucous Membrane from the Lip.
 RENTON, J. C., M.D., Glasgow. The Value of the Cautey in the Treatment of Elevation of the Cornea

SECTION I.—OTOLOGY.

Biblical Criticism Class Room.

I. OTOLOGY.—*President*, Thomas Barr, M.D. *Vice-Presidents*, John Astley Bloxam, F.R.C.S.; J. J. K. Duncanson, M.D. *Honorary Secretaries*, Johnstone Macfie, M.D., 23, Ashton Terrace, Glasgow; James Black, F.R.C.S., 16, Wimpole Street, London.

The following special subjects have been proposed for formal discussion:

1. The Conditions calling for Perforation of the Mastoid Portion of the Temporal Bone, and the Best Methods of Operating; to be opened by Dr. F. M. Pierce, of Manchester. Mr. Peter McBride has promised a paper on this subject. Dr. D. Stewart, of Nottingham, hopes to take part in the discussion.

2. The True Value of those Aids to Hearing usually termed "Artificial Tympanic Membranes." Dr. W. L. Purves has promised a paper on this subject.

3. Adenoid Growths in the Naso-Pharynx; their Influence on the Middle Ear, and their Treatment. To be opened by Mr. Lennox Browne, F.R.C.S.Ed.

The following have promised papers.

BROWNE, Lennox, Esq. (*Title not received*).
 TORRANCE, R., Esq. On Syphilitic Cochleitis.
 WARDEN, Charles, M.D. (*Title not received*).

Dr. Samuel Sexton, of New York, hopes to be present, and will give a communication on Excision of the Drumhead and Ossicles.

SECTION J.—DISEASES OF CHILDREN.

English Literature Class Room.

J. DISEASES OF CHILDREN.—*President*, Walter Butler Cheadle, M.D. *Vice-Presidents*, James Finlayson, M.D.; Henry Ashby, M.D. *Honorary Secretaries*, George S. Middleton, M.D., 23, Sandyford Place, Glasgow; W. Arbuthnot Lane, M.S., F.R.C.S., 14, St. Thomas's Street, S.E.

The following two discussions will take place:

1. Diphtheria: (a) Etiology. (b) Relationship to other Infectious Diseases, and to other Forms of Sore Throat; Occurrence on Open Wounds and on Mucous Membranes other than those of the Throat. (c) Diagnosis. What are the Distinctive Features, especially those Distinguishing the Lesion in the Throat from other Forms of Sore Throat? Does Membranous Croup occur apart from Diphtheria? (d) Pathology and Sequelae. (e) Medical Treatment. (f) Surgical Treatment; Tracheotomy; Tubage. The medical and general aspects of the subject will be introduced by Dr. A. Jacobi (New York), and the surgical aspect by Mr. R. W. Parker (London). Messrs. E. Owen, H. R. Hutton, Lennox Browne, R. N. Pugh, and Drs. W. T. Gairdner, George Buchanan, James Finlayson, Henry Ashby, H. C. Cameron, D. Newman, Thos. Buzzard, John Macintyre, Alex. Robertson, and J. S. Cameron will take part in the discussion.

2. Rickets: (a) Etiology and Prevention. (b) Its Connection with Syphilis and Scurvy. Is Enlargement of the Liver and the Spleen always present, more or less, in Rickets; or only in Cases of Syphilitic Origin? (c) Medical Treatment. (d) Surgical Treatment; at what Stage, and in what Way? Drs. Macewen, A. Ogston, L. W. Marshall, H. Ranke (Munich), Thos. Buzzard, Henry Ashby, and Messrs. R. W. Parker, H. R. Hutton, R. Haggard, E. L. Freer, John Gordon, R. N. Pugh, and W. A. Lane will take part in the discussion.

Drs. Jacobi (New York), Keating (Philadelphia), Ranke (Munich), and Sanné (Paris), and other members of the profession on the Continent have been invited.

The following have promised papers.

BROWNE, Lennox, F.R.C.S. Anatomical Facts in support of Intubation in Diphtheria.
 CAMERON, J. S., M.D. Etiology of Diphtheria. (1) Predisposition from Recent or Existing Disease, especially Scarlet Fever; (2) Influence of Insanitary Surroundings, especially Rise and Fall of Subsoil Water.
 FINLAYSON, James, M.D. Evidence of the Occurrence of Laryngeal Diphtheria in Glasgow, in the Early Part of this Century.
 HAGGARD, Robert, M.R.C.S. The Effects of Sunlight on Rickets in Children and in the Lower Animals.
 LANE, W. A., F.R.C.S. The Deformity of Rickets.

SECTION K.—PHARMACOLOGY AND THERAPEUTICS.

Conveyancing Class Room.

K. PHARMACOLOGY AND THERAPEUTICS.—*President*, James Morton, M.D. *Vice-Presidents*, John Dougall, M.D.; Theodore

Cash, M.D., F.R.S. *Honorary Secretaries*, Alexander Napier, M.D., 3, Royal Terrace, Crosshill, Glasgow; Sidney Harris Cox Martin, M.D., 60, Gower Street, London, W.C.

A special discussion will be opened by Professor Theodore Cash, M.D., F.R.S., on Carbolic Acid, Antipyrin, Antifebrin, and their Allies, especially as regards their Antipyretic, Analgesic, and Antiseptic Actions. Drs. Walter G. Smith (Dublin), A. D. Macdonald, and Prosser James will take part in the discussion.

Dr. W. Allan Jamieson (Edinburgh) will show two cases of Xeroderma Pigmentosum.

It is expected that Professors Liebreich and Dujardin-Beaumetz will be present at the meeting. Dr. Dujardin-Beaumetz will contribute a paper on Phenacetin.

The following have promised papers.

DAVISON, James, M.D. The Pine Treatment.
 DOUGALL, J., M.D., Glasgow. (*Title not received*).
 DRYSDALE, C. R., M.D. 1. On the Therapeutic Value of Alcohol. 2. The so-called Abortive Treatment of Syphilis.
 JAMES, J. Brindley, Esq. Scavies and its Treatment.
 KERR, J. G. Douglas, M.B. Thermal Treatment of Acute Rheumatism, with a Short Outline of the System pursued at Bath
 MACDONALD, A. D., M.D. Three Cases of Poisoning.
 PEARSE, T. F., M.D. The Treatment of Eczema.
 SHOEMAKER, John V., M.D., Philadelphia. An Investigation of the Action of Naphthol β.

SECTION L.—LARYNGOLOGY AND RHINOLOGY.

Divinity Class Room.

L. LARYNGOLOGY AND RHINOLOGY.—*President*, Felix Semon, M.D. *Vice-Presidents*, George Hunter Mackenzie, M.D.; Peter McBride, M.D. *Honorary Secretaries*, D. Newman, M.D., 18, Woodside Place, Glasgow; A. E. Garrod, M.D., 9, Chandos Street, Cavendish Square.

The following subjects are proposed for special discussion:

1. The Use and Abuse of Local Treatment in Diseases of the Upper Air Passages. To be opened by Dr. de Havilland Hall (London) and Mr. Stoker (London).

2. The Causes, Effects, and Treatment of Nasal Stenosis. To be opened by Dr. Macintyre (Glasgow) and Mr. Creswell Baber (Brighton).

3. Hæmorrhages from the Pharynx and Larynx, and other Hæmorrhages which simulate these. To be opened by Dr. Percy Kidd (London) and Dr. Hodgkinson (Manchester) (probably).

The following gentlemen hope to take part in the discussions: Dr. Prosser James (London), Dr. McBride (Edinburgh), Dr. Charles Warden (Birmingham), Dr. Cartaz (Paris), and Mr. Richard Ellis (Newcastle-on-Tyne).

The following papers have been promised.

JOHNSTONE, R. Mackenzie, M.D. Account of a Case of Tumour of the Naso-Pharynx.
 MCBRIDE, P., M.D., Edinburgh. On Hay-Fever and Allied Conditions.
 MACINTYRE, J., M.D. Anatomical Demonstration of the Larynx.
 MACINTYRE, John, M.D., Glasgow. The Use of Electricity in Diseases of the Throat.
 NEWMAN, D., M.D. Two Cases of Complete Laryngeal Stenosis produced by Wounds of the Larynx in Attempted Suicides.
 SPICER, R. H. Scanes, M.D. (1) Clinical and Pathological Observations on Affections of the Tonsils (Faucial, Lingual, and Pharyngeal) in the Light of Recent Views as to their Functions. (2) A Case of Lupus Vulgaris of the Upper Respiratory Tract—with Polyypus (Lupous) of the Larynx.
 WARDEN, C., M.D. (*Title of paper not yet received*).

ANNUAL MUSEUM.

THE Annual Museum will be held on August 7th, 8th, 9th, and 10th, in the Examination Hall, Hebrew Class Room, and Chemistry Tutorial Class Room, of the University of Glasgow, and will be arranged in the following six Sections:

SECTION A.—Food and Drugs, including Antiseptic Dressings, and other Chemical and Pharmaceutical Preparations. (Honorary Secretary, R. S. Thomson, B.Sc., M.B., C.M., 3, Melrose Street.)

SECTION B.—Pathology, comprising Casts, Models, Diagrams, Microscopical Preparations, and Micro-organisms. (Honorary Secretary, J. Lindsay Steven, M.D., 34, Berkeley Terrace.)

SECTION C.—Anatomy, comprising Special Dissections, Methods of Mounting, Abnormalities, Drawings, Medals, etc. (Honorary Secretary, J. Yule Mackay, M.D., 34, Elmbank Crescent.)

SECTION D.—Physiology, consisting of Apparatus, Microscopes, Microtomes, and Microscopical Preparations of Normal Histology. (Honorary Secretary, J. McGregor Robertson, M.A., M.B., C.M., 400, Great Western Road.)

SECTION E.—Instruments and Books, including Appliances—Medical, Surgical, and Electrical. (Honorary Secretary, J. Macintyre, M.B., C.M., 173, Bath Street.)

SECTION F.—Sanitation (I) Domestic Sanitary Appliances, em-

June 30, 1888.]

bracing all Improvements applicable to the Treatment of the Sick in Private Dwellings. (2) Personal Hygiene, including Dress and Gymnastic Appliances. (3) Ambulances, Carriages, and all other Appliances used for the Conveyance and Treatment of the Sick and Wounded, either in Civil, Naval, or Military Practice. (4) Drawings, Models, and Apparatus illustrative of the Ventilation, Lighting, and Draining of Hospitals. (5) Hospital Furniture. (6) Sanitary Appliances in connection with Educational Institutions and Public Buildings. (Honorary Secretary, 1, 2, 3, Robert Pollok, M.B., C.M., Pollokshields; Honorary Secretary, 4, 5, and 6, A. W. Russell, M.A., M.B., C.M., Western Infirmary.)

Intending exhibitors should communicate as early as possible with the Secretary of the Section in which they propose to exhibit, as the Museum Catalogue must be complete one month before the date of meeting. Inquiries as to advertisements in the Catalogue should be sent without delay to Dr. Thomson, 3, Melrose Street, Glasgow.

Honorary General Secretaries of Museum Committee, A. Ernest Maylard, B.S., M.B., 4, Berkeley Terrace; R. S. Thomson, B.Sc., M.B., C.M., 3, Melrose Terrace.

Honorary Local Treasurers, Joseph Coats, M.D.; Jas. B. Russell, M.D.

Honorary Local Secretaries, John G. McKendrick, M.D., F.R.S., 45, Westbourne Gardens, Glasgow; James Christie, M.D., Hillhead, Glasgow; John Glaister, M.D., 4, Grafton Place, Glasgow.

FRANCIS FOWKE, General Secretary.

SPECIAL CORRESPONDENCE.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

Physiological Action of Onobaio.—*Intestinal Myiasis.*

MM. HENRY DE VARIGNY and Paul Langlois have investigated the physiological action of onobaio. The natives of Obock fix this poison, in the form of a small ball of hard, resinous, brown substance behind the barbed point of their arrows. MM. Varigny and Langlois made a watery 1 per cent. solution with some of these balls. Injections of 5 or 10 milligrammes of this solution kills rabbits and guinea-pigs very quickly. The animal is bent double; it leaps about, then falls over on its side making efforts to breathe, and dies with well-marked symptoms of asphyxia. If the animal is then opened the heart will be found to be perfectly still. The ventricles no longer beat; a slight action is still observed in the auricles. The lungs are pale and anæmic. During life no disturbance of motor power or of sensibility is observed. One or two milligrammes were injected under the skin of a frog in which the heart had been laid bare. After a few minutes it was found that the ventricle became contracted after auricular systole; this phenomenon increased; four or five minutes after the injection the quantity of blood entering the ventricle at each auricular systole became infinitesimal, and finally none passed in. The ventricle ceased to act; the auricles continued to contract for ten to fifty minutes. The following experiments were made upon dogs which had been subjected to the action of chloral and curare. In one case a large dose (1 centigramme of onobaio in 1 cubic centimetre of water, injected in about a minute) caused cardiac disturbance, without any definite respiratory symptoms. To avoid the direct action of the poison on the endocardium a solution of 1 milligramme in 1 cubic centimetre of water was injected into the veins at intervals. In the case of weak doses (4 milligrammes to 13 pounds of the animal's weight) the breathing became much slower a minute or two after the injections. This phenomenon, which was not accompanied by notable cardiac disturbance, lasted one or two minutes, and then ceased. Larger doses (8 milligrammes to 11 pounds of weight, administered in four injections in about half an hour) quickened the breathing for a few instants. The breathing then became gradually slower, and at the end of two or three minutes entirely ceased. The heart continued to beat, but subsequently became slower, and finally ceased. In an experiment with 6 milligrammes to 11 pounds of the weight the cessation of the respiration did not arrest the action of the heart. Artificial respiration was practised; the heart continued to beat, and at the end of a few minutes the respiration became natural. Onobaio sometimes causes vomiting in animals which have not been previously brought under the influence of chloral.

M. Joannes Chattin has made some researches on myiasis, an

affection caused by the larva of diptera. It occurs in two principal forms—1, cutaneous; and, 2, intestinal myiasis. The existence of cutaneous myiasis is universally admitted, but that of the intestinal form has frequently been questioned. M. Chatin lately showed at the Académie de Médecine some larvæ of the *teichomyza fusca*, found in the dejecta and in the matter vomited by one of his patients. The larvæ of *teichomyza fusca*, by its peculiar organisation, is especially adapted to live in the intestine. It is able to collect a considerable quantity of fluid in which to breathe, owing to its unusually capacious tracheal system. It has only two pairs of stigmata, peculiarly arranged; the animal can instantly shut its posterior stigmata, which are attached to long caudal extremities. The anterior stigmata resemble the pseudo-branchia of the ephemerides larva. Some regard this arrangement as intended to allow of aquatic respiration, when aerial respiration is prevented. The *teichomyza fusca* larvæ are remarkably refractory to asphyxia. They will live for several days in water, oil, etc., or in the stomach of different mammals, when introduced for purposes of experiment. Foreign bodies, however, of similar aspect found in the organism are often mistaken for the larva of *teichomyza fusca*. M. Chatin relates the following example. A whitish, elongated body was recently sent to him, as a larva of *teichomyza fusca*, for examination. M. Chatin examined it microscopically, and found that the tracheæ it presented were vegetable and not animal. When dissected under a lens, the pseudo-larva proved to be a fragment of fruit incompletely digested. The ovarian chamber still contained a grain; the double extremity was formed by the remains of the style.

VIENNA.

[FROM OUR OWN CORRESPONDENT.]

Tubercle of the Iris.—*Xeroderma Pigmentosum.*

PROFESSOR FUCHS recently brought forward a case of tuberculosis of the iris before the Imperial Royal Society of Physicians of Vienna. The patient, a girl aged 6½, had previously suffered from measles, whooping-cough, and small-pox. She had some time before been admitted into the Children's Hospital. After remaining there for four weeks she became affected with inflammation of the eyes, for which she was admitted into the clinic of Professor Fuchs. The child had lived under very bad hygienic conditions in a room on the ground floor, into which the sun's rays never penetrated. She was fairly well nourished, and her parents were healthy. Her grandmother, however, had died of pulmonary phthisis, and three of her sisters had died of "convulsions," which may possibly have been due to tuberculous meningitis. The patient herself looked well, and was free from tuberculosis. The cornea was dim, and on its posterior surface there were signs of irido-cyclitis. The pupils were distorted. At the internal and lower part of the iris there was a tumour the larger end of which reached as far as the cornea. It was composed of numerous small nodules of a yellowish-red colour. There were numerous blood-vessels on the surface. The tumour was not sharply limited, but was prolonged into several other small nodules; some disseminated the nodules were also to be seen over the front part of the lenticular capsule. Professor Fuchs believed the case to be one of tubercular disease of the iris. It was a rare form of the affection which he had never before met with. Tubercle of the iris ordinarily occurred under one of two forms, namely, disseminated or conglobate. In the former there was always iritis, which was produced by the nodules. In such a case the nodules might disappear, while others developed anew; the iritis might complete its course, and the power of vision might be regained. In other instances, however, pupillary occlusion and atrophy of the eyeball supervened. This process usually affected both eyes, and was seen only in young individuals. The conglobate form had another course. The symptoms of inflammation were absent, but a tumour developed only on one place. This varied in appearance, and it was impossible to say whether it was a tubercle, or a syphilitic neoplasm, or a sarcoma. The tumour penetrated the cornea, so that it might be mistaken for a malignant neoplasm. Later it underwent caseous degeneration, and the eye shrank to a small stump. Von Graefe, who was the first to observe such a case, enucleated the eye, and Virchow called the tumour a "granuloma." It was not until recently that such tumours were recognised to be conglobated tubercles. The case shown to the Society occupied a place between these two forms. The iritis was a characteristic feature of the disseminated

form. In many such cases tuberculosis was also met with in other organs; in others only the eye was affected, while the submaxillary lymphatic glands might also be enlarged. Professor Fuchs knew a case in which after enucleation no further tuberculosis developed. He thought that enucleation was indicated in his patient, as otherwise the affected eye might be a focus of further infection.

Docens Dr. Riehl showed to the same Society a case of xeroderma pigmentosum. The patient, a woman, aged 61 years, had been affected from childhood with patches resembling summer rashes on the face and the arms. Eighteen years since the patches became more numerous and darker, and a warty tumour developed on the nose. The patient stated that her grandfather had suffered from very marked general pigmentation. The woman now presented the usual symptoms of xeroderma pigmentosum. Dark and irregular pigmentations with numerous white scars were to be seen on the face, the neck, the chest, and the arms. The hands were affected only on their dorsal aspect, whereas the thighs and the feet were almost free from pigmentation. Some angiomas and telangiectasias were noticed on the face. The atrophy of the skin of the hands and the forearms, and the dryness of the epidermis were very striking. The neoplasms which were characteristic of this disease, such as an ulcerating epithelioma on the nose and several tumours of the same nature on the cheeks, were also present. The process set in at an early period, when pigmented patches and small angiomas developed. At the age of from 6 to 12 years, epitheliomata began to develop out of the pigmentations, which gradually increased in number and caused death. Fifty cases of xeroderma pigmentosum had already been reported by various authors, but the anatomy and etiology of the affection were not sufficiently known. The clinical symptoms were very well known since Kaposi's work, published in 1870. Kaposi laid much stress on the dryness and atrophy of the skin, whereas Geber, using the term "nævus," attributed most importance to the fact that the abnormality of pigmentation was congenital. Taylor ascribed a greater importance to the presence of the angiomas, and, therefore, gave the disease the name of "angioma pigmentosum et atrophicum." Pick called the affection "melanosis lenticularis progressiva;" Neisser, "liodermia cum melanosi et telangiectasiâ;" Vidal, "dermatose de Kaposi." The fact that the disease was frequently met with in children of the same family rendered the suggestion very probable that the affection was due to a congenital abnormality in the structure of the skin. The epitheliomata were not of the usual type, sometimes epithelial carcinomata, and on other occasions pigmented sarcomata were observed. Dr. Riehl's patient was the oldest one affected with "xeroderma pigmentosum." Professor Kaposi remarked that the oldest case of "xeroderma pigmentosum" known to him was a boy, aged from 18 to 20 years. He happened to have at present under his care a girl who had suffered from the disease since the age of 12. Her face was now much deformed. The chief feature of this affection was the melanosis. In such cases the papillary body also underwent an atrophic process, and the atrophy was so severe that it gave origin to the development of severe ectropion, so that the mouth became distorted, etc. When the author published his first cases of "xeroderma pigmentosum" he did not know that carcinomata supervened in such cases. As to this, he had only observed it in the third child under his care. The girl now under his treatment scarcely presented any trace of carcinoma three years ago, but at present the whole left part of her nose had disappeared, and moreover, Professor Kaposi had removed from her about thirty carcinomata with the sharp spoon. The patient was moreover affected with a papillary carcinoma on the right cheek, which had in the meanwhile been allowed to remain. The process in question was quite different from the usual melanosis, and little was therefore gained by the term "angioma" or "melanosis." The term "xeroderma" was not indeed the best one, but the atrophic character of the process was expressed by it, and when the adjective "pigmentosum" was added the whole character of the disease was clearly indicated.

SWITZERLAND.

[FROM OUR OWN CORRESPONDENT.]

Perforation of Vermiform Appendix caused by Intestinal Concretions.—A New Surgical Soap.

At a recent meeting of the Société de Médecine du Canton de Fribourg, Dr. Buman read a paper on ulceration of the vermi-

form appendix, based on two cases which had been under his own care. The first was that of a boy, aged 8, who was suddenly attacked with a sloughing abscess in the right groin, to die eight days later. At the necropsy, a perforating ulcer of the vermiform appendix was found, which had been caused by a hard concretion consisting of magnesia coated with mucus. Upon inquiry it was discovered that the boy had been suffering from habitual constipation, which his parents had treated by daily administration of magnesia in ever-increasing doses. The other patient, a boy of 6, who occasionally suffered from passing attacks of colic, but was otherwise in the best of health, was suddenly seized with agonising abdominal pain, vomiting, and hiccough. There was slight tenderness with distension in the right iliac fossa, and a slight degree of pyrexia: The bowels did not act. Three days later the boy died collapsed. The *post-mortem* examination revealed a perforation of the vermiform appendix by a hard and gritty stone ovoid in shape. In neither of the cases had the actual state of things been suspected during life. Dr. Buman dwells on the great difficulty sometimes met with in the differential diagnosis of such cases; but, strange to say, he does not say a word about laparotomy, either as an exploratory or a therapeutic measure. It is true that for this great step forward surgery is mainly indebted to Great Britain and the United States—benighted countries whose medical practitioners are so notoriously "inferior" that it requires some stretch of condensation for well-regulated Swiss minds to recognise their scientific existence (see the JOURNAL, March 31st, 1888, p. 717). Still, Dr. Buman might, perhaps, with advantage have strained a point in the present instance, and might have taken the trouble to show that he had at any rate heard of a method which has already given such brilliant results in countries less favoured—academically speaking—than his own. Even in Switzerland such men as Kocher, of Berne, Kroenlein, of Zurich, or Senn, of Milwaukee (originally of St. Gall), might have taught him better.

In the *Revue Médicale de la Suisse Romande*, No. 5, 1888, page 285, Professor Auguste Reverdin, of Geneva, speaks highly of a "surgical soap" prepared after the following formula:—R. Oil of sweet almonds, 72 parts; lye (*lessive*) of soda, 24 parts; lye of potash, 12 parts; sulpho-carbulate of zinc, 2 parts; essential oil of roses, 9.5 parts. (Mem.—The preparation consists in slowly adding to and carefully mixing with the almond oil the lyes and the sulpho-carbulate part by part until an intimate and homogeneous mixture is obtained.) The latter is kept for several days at 20° C. The mass, which gradually acquires the consistence of soft paste, is then divided into any number of portions that may be desired; these are placed in suitable moulds, where they are kept till they are completely solidified. Professor Reverdin has been using this antiseptic soap since the summer of 1887, when he visited Professor Bottini's clinic at Milan, where it is extensively employed for various purposes. The soap is said to possess wonderful cleansing, as well as antiseptic, properties, and it does not irritate the skin, however sensitive or irritable it may be. Moreover, as the soap contains an excessive proportion of fatty substances, it does not dry the skin. The presence of potash makes the soap by far more active comparatively than a pure sodic soap, since, as Dr. Unna has proved, potash has a more energetic solvent action on the horny layer of the cuticle than soda. Professor Reverdin recommends this soap not only for general use in hospital and private practice, but also for washing the hands in dissecting-rooms and everywhere where the hands come in contact with decomposing substances. Further, he urges that barbers should universally adopt this disinfecting soap for their purposes, and thus protect their customers from various infectious diseases, to which they are exposed in their shops. Dr. Reverdin has also obtained good results from this soap in various cutaneous affections. Finally, it is a very pleasant toilette soap, as he himself and many of his patients and friends have found.

EGYPT.

[FROM OUR OWN CORRESPONDENT.]

Lunatic Asylum.—Ramadan.—Sickness at Damietta.—English Nursing Sisters for Kasr-el-Aini.—Cairo Jubilee Memorial.

There is but one lunatic asylum for the whole of Egypt. It is situated at Abassieh, near Cairo, and seldom contains more than 300 patients. This speaks well for the general condition of the country as regards lunacy; but there are probably many people in the towns and villages of the interior who are afflicted with disorders of the intellect, chiefly idiocy. The other forms of in-

sanity are undoubtedly rare; this is probably due to education being in its infancy. At Abassieh, during the past year, 459 patients were admitted. The deaths amounted to 67; the number of non-dangerous lunatics returned to their friends was 55; and 302 were discharged cured. The asylum was lately visited by General Dormer, C.B., who, having seen it in 1882, was able to judge of the vast improvement that had taken place lately. So pleased was the General with his visit, that he very kindly sent a large package of cigarettes for the lunatics, with a letter of thanks to the medical officer in charge (a native).

The fast of Ramadan happily ended last Sunday (June 10th), before the great heats which have since set in had commenced. It is really pitiable to see the poor creatures who fast, and yet are obliged to work during a hot season. A conscientious Mussulman—and most of the lower orders are such—will not only not drink anything from sunrise to sunset during a fast, but will not even swallow his spittle should his mouth water from any cause. It is not, therefore, astonishing that in Ramadan the death-rate invariably increases enormously. Fortunately, being a lunar month, it does not always occur in the summer, and is now steadily working its way back every year towards cooler weather. A rich man who can afford to sleep all day, and have his meals at night, may keep Ramadan with impunity, but the poor "fellah" who has his daily task to perform must inevitably suffer.

There has been rather a serious epidemic of fever lately in a village not far from Damietta. The very name of Damietta in connection with sickness seems to strike terror in Egypt, but on this occasion fortunately there is no danger to apprehend anything worse than typhus. The Sanitary Department has sent down an ambulance for the sick, and not only medical aid, but also a detachment of their corps of sweepers under an English inspector, in order that Damietta, as well as the village where the malady exists, may be cleaned up and put into a sanitary condition. This, of course, is only a palliative measure, for once the sweepers' backs are turned the town will rapidly relapse into its normal state of filth. Dr. Greene Pacha, however, seems to hope that under the enlightened rule of the new President of Council, Riaz Pacha, a system of scavenging may eventually be established in the larger towns, including the important port above mentioned.

Two English ladies, trained nurses, are at present on their way out in one of the Orient liners to join Kasr-el-Aini Hospital, where, under the direction of Dr. Milton, they will be invaluable, not only for the nursing of the sick, but also as trainers and instructors of the native female pupils and nursing staff. The Sanitary Department is empowered to allow £300 a year towards the expenses of these ladies, and of any others whose services may eventually be obtained, and a committee has been formed to administer this sum and regulate everything in connection with this nucleus of a nursing institution. The committee is composed as follows: President: Sir Evelyn Baring. Members: Sir Sydney Waterlow, Dr. Greene Pacha, Dr. Milton. Secretary and Treasurer: Dr. Sandwith.

The Cairo Jubilee Memorial Committee have held a final meeting, at which it was decided that the amount subscribed, namely, £827, should be handed over to the Victoria Deaconesses' Hospital, for the purpose of erecting infectious wards in connection with that establishment. There are to be six wards, including one for an insane patient, and the building will be so arranged that at any future time it will be practicable to add another storey. It is to be regretted that the amount subscribed was not sufficient to found an independent hospital, which should have served as a model of what an institution of the kind ought to be in Egypt. The Deaconesses' Hospital is administered by a German society, and leaves much to be desired from a sanitary point of view. As an example, I may mention that the drainage is effected through untrapped pipes into a percolating cesspit partly within the foundations of the building, in accordance with the vicious system which obtains almost universally in the country. Any hospital in Egypt, as elsewhere, should be perfect as regards sanitary arrangements, and *a fortiori* an infectious ward subscribed for by English subjects. The building has been designed by Mr. Price, C.E., of the Sanitary Department, but he is not responsible for its sanitation, as his ideas were not accepted by the committee.

THE *Berliner Klinik* is a new medical periodical, under the editorship of Herren Fürbringer and Hahn. The first number contains two articles by Professor Senator, one being on The Aims and Means of Medical Activity, the other on Icterus, its Origin and Treatment. It is published by Fischer, of Berlin.

CORRESPONDENCE.

THE MEDICAL OFFICERSHIP OF HEALTH AT BRADFORD

SIR,—The circumstances under which an advertisement for a successor to myself in the above office appears in the JOURNAL are of sufficient public importance to warrant me addressing your readers thereon. The questions involved include the conditions of tenure of office, the possibility of a medical officer against whom no charge can be brought being deprived of his income through the personal enmity of the chairman of his committee; the position which the medical officer of Bradford is to occupy towards his committee and the inspector of nuisances, in a word the possibility of any medical man of integrity and independence, and with any self-respect, ever being able to hold the appointment, except for a very brief period, and with the certainty of disaster before him. When I came here, five years ago from Sheffield, I gave up a good practice, an appointment of £300 per annum, hospital appointments, a lectureship in the School of Medicine, and other offices indicative of the good-will of my fellow citizens—all the fruits of sixteen years hard work. I accepted the appointment here for five years, with the belief that re-election was certain if I did my duty; I have honestly striven to do so, no charge of any kind has been preferred against me; but now I am deprived of my office, and of my income, and obliged to commence life once more after receiving such a wound. I forward you the account of the meeting of the Town Council, at which the Sanitary Committee's resolution not to re-appoint me was adopted. You will see that the chairman of that Committee eulogised my private and professional character, my devotion to my work, and ventured to make no charge or insinuate anything against me.

But, your readers will say, there must be some grounds for my losing my appointment, my treatment being nothing different from that which would have been meted out to a thoroughly incompetent person? The only reason suggested is "want of tact" in dealing with the Committee, my tact in dealing with all others, the public and the medical profession, being cordially admitted. No case is specified, no opportunity is given me of refuting any alleged complaint. Such a charge is, I protest, utterly inadequate and the manner of making it unjust, not to say ungenerous; 3,000 ratepayers have memorialised for my reappointment; they have not found me defective in tact, and express themselves as highly satisfied with my official and private conduct. These included many of the leading citizens—Sir Henry Mitchell, Sir Jacob Behrens among them—and represented over one-half the rateable value of the borough. The Bradford and District Tradesmen's Association, a powerful organisation, memorialised the council also; the whole medical profession of the town have warmly supported me, and publicly expressed their desire for my reappointment, although this is a notification town. They have also paid me the compliment of appointing me president of the Medico-Chirurgical Society this year. Last year I was president of the Association of Medical Officers of Health of Yorkshire, and a couple of years ago I held the presidency of the North-Western Association of Medical Officers of Health. Other medical, scientific, literary, and social societies have honoured me similarly. I venture to argue that these facts afford strong evidence that I am not a person devoid of "tact" so utterly as to warrant deprivation of my appointment, or of such general incompetence or unfitness as to call for my rejection. My real "want of tact" has been that I have failed to conceal the sanitary defects and requirements of the town. I have reported on them to the sanitary authority as I am bound to do. My published reports are evidence whether, so far as they go, I have reported with courtesy and "tact." These reports have been most favourably noticed in the medical papers when they appeared. I have several times reported against the pernicious custom of allowing excrement and filth of every kind, infected with fever and otherwise, to be used for forming roads and levelling-up for building purposes. My views on this subject have given great offence. Is this not the cheapest plan for the moment, however many lives it cost in the long run?

I have had to report that we have no proper provision for small-pox, though it is very prevalent around us; and the three cases now in the town are obliged to be put in a ward intended for scarlet fever, lying within twenty yards of another ward occupied by scarlet fever patients; but up to to-day no proper hospital accommodation has been provided. I have had to report that the disinfecting apparatus is practically useless, but no other has

been got. I have had to report on a good deal of property unfit for human habitation, but which is still occupied. These and similar things have been the undoing of me. My requirements would cost money, and hence were hateful. This was my real "want of tact;" but I have shown still less of that quality in actually condemning piggeries belonging to one member of my own Committee, and a slaughter-house in which another was "interested." These things led to the bitter, unceasing, personal hostility of the chairman and certain members of the Committee. The former has long since declared that if "yon man" (myself) were re-elected he would resign. That such an attitude should be adopted towards any official is bad enough; but when the feeling exists, as explained to me by a "friend" on the Committee, that if one of the two must go he would support the chairman, then no medical officer's post is tenable.

As an illustration of how the department is worked here, I may say that I was but a few months here when I was told that none of the inspectors were to be considered under my control, and that the chief inspector alone had any control over them. If I wished anything done by them, I must address the chief inspector. That official, I soon learned, was the confidant of the chairman, who regularly frequented his office. The establishment of a staff of inspectors independent of the medical officer naturally has rendered his work most difficult, and his position in every respect unsatisfactory. It led to the nuisance office being a rival establishment for the criticism of the medical officer, and the propagation of opinions for the use of the chairman and any other ill-disposed person. That the medical officer should be obliged to depend on the wishes of the nuisance inspector for the services of the *employé* of the department is sufficient to paralyse his hands. These services, permitted with unwillingness, ceased practically to be available at all for the purpose of investigation of the sources of the disease and its propagation, and to the multitudinous other requirements of a medical officer giving his whole energies and time to the work of his department in a large town. The inspectors have, therefore, been solely occupied in the nuisance department, and the medical officer has had no assistance whatever in his work, save a boy in the office at a salary of a few shillings a week. The success of this manoeuvre in detailing the "nuisance" from the "medical" department quickly led to the demand by the Committee that I should personally do such work as inspecting all dairies, cow-sheds, milk-shops, new houses (under a local Act), also every house where an infectious case was notified, besides the numerous inspections of market nuisances, unheathy trades, etc., called for urgently by ratepayers every day. This I have done single-handed, and the Committee has publicly declared that my work has been thoroughly done.

When I accidentally heard that the Committee had specially met to decide the question of my reappointment, I addressed a letter to the members, in which, among other things, I expressed a wish to appear before them and face to face hear and answer anything which might be alleged against me or need explanation. That letter, addressed to the Committee, was not brought to the knowledge of the Committee by the chairman.

No other officer of the corporation is appointed on the same precarious terms as the medical officer, and yet Parliament thinks him so necessary as an adviser that one must be appointed by every local board and corporation. Is it reasonable the appointment should be for the brief term of one or a few years, and that the medical officer should live in continual dread of disaster, if by discharging his duty faithfully he shall offend some member of his committee? Ought there not to be some authority to which a medical officer of health can appeal when unjustly or cruelly treated? Can the present system continue to work to the benefit of the public when it may operate so disastrously to the medical officer of health? Mine is not an isolated or exceptional case. Unfortunately there are other medical officers of health who have received treatment of a similar kind.

No doubt many young men will eagerly seek for my post, with the confidence of youth believing they can avoid every mistake made, and that they will be secure in their office. I believed so when I came here, and I had had five years' experience of municipal work in Sheffield before coming here. I trust their hopes may not be disappointed, but would say to any candidate once in office here, You have burned your boats; reflect well before giving up practice, however modest, with independence, before surrendering yourself completely in the hands of men who will deliberately turn you off after receiving your best services.—I am, etc.,

THOMAS WHITESIDE HIME.

THE DEBATE ON ELECTROLYSIS AT THE OBSTETRICAL SOCIETY.

SIR,—As a non-speaker during the recent debate, I crave space for a few remarks I would have made had time permitted. I listened attentively, hoping to learn something, but the strong bias of most of the speakers, either *pro* or *con.*, rendered the speeches less profitable than they might have been.

From all sides it is agreed that the action of the anodal pole is antihæmorrhagic; at times a simple application to the mucous membrane suffices, at times galvano-puncture, which is made by the cathodal pole, and the subsequent introduction of the positive needle is necessary. Admitting this hæmostatic action, let us think of allied hæmostasis, and understand, if we can, how the effect is produced. In aneurysmal tumours we have records of several cases of solidification and cure after electro-puncture. The blood is coagulated, the through current is thereby arrested, fibrin is deposited, and more or less shrinkage and absorption results; but the introduction of watch springs, of horsehair, etc., effects the same results, and the question arises whether it is a mechanical or an electrolytic action. I am aware that I now expose myself to the too frequently iterated accusation of ignorance, or of comparing dissimilar things. It may be said that in aneurysm small plates are used, both needles are introduced, that an unmeasured strength of from ten to thirty cells is employed, and that there is a continuous action, lasting twenty or thirty minutes, so that this must be regarded as wholly different from the *technique* of Apostoli, of Keith, or Steavenson. So it is, and when we hear of 250, 500, or 1,000 milliampères being used, we are ready to concede a probably total different result; yet that, in but a different degree, the theoretical explanation must needs occupy much the same platform is also true. We must freely admit Dr. Steavenson's contention that in electrolysis we have a cleanly and elegant though tedious caustic.

The action of the negative pole as an actual destroyer or remover of tissue is unquestionably the point on which depends the future of the electrical treatment of fibroids. If fibroids decrease under its use—and I for one admit that in some measure they do, as the authority of Dr. Keith, of Sir Spencer Wells, and of others is enough to convince me that certain fibroids are lessened—it is needful to know something more of this action than we now do. Some assert that only the soft, that is, the muscular or other non-fibrinized elements of fibro-myomata are resolved by the electrical treatment; others allege that diminutions of muscular elements occur alternately with increases in the absence of all treatment, and no one who has had a case of fibroid under observation for some years can deny this latter statement; but the negative pole is supposed by others to convert the fibrinous material into a softer and more readily-absorbable substance without causing actual necrosis or sloughing. Well, if this could be proved, we should have a very distinct pathological basis for electrical therapeutics; but is it so? Can this be demonstrated? Some patients are doubtless greatly benefited, others are very little better, and that only temporarily; yet after all an ounce of practice is worth a pound of theory; if we can derive benefit without knowing why, is it wise to reject it?

Now it is readily conceivable that inter-mural fibroids may derive good from electricity, but this is not the class requiring new methods. It is in intra-mural or interstitial or in extra-mural tumours—in which the uterus lies fixed low down in the pelvis, and in which severe pressure or hæmorrhagic symptoms occur, in many of which cases no reasonable operation can be employed—that we look to electricity for aid. Although we may not be able to cure, if we can relieve symptoms, if we can even temporarily lessen certain tumours—although the procedure may be tedious, expensive, and in some perchance difficult and, beyond all, uncertain—in these cases there will exist a future for electrolysis. But to adopt as proved all that has been alleged for this method, to accept as permanent certain ameliorated conditions, we require time and experience, as yet deeply hidden in the future. Dr. Champneys's plea for extended consideration was amply justified by all we have yet learned.

It is no question of this man's bias or that man's interest, of this man's apathy or that man's enthusiasm, of this man's skill as an electrician or that man's abilities as a surgeon. It is simply a question of the worth or worthlessness of powerful but regulated currents of electricity as a reliable controllable curative measure in treating fibroid tumours. We ought, from the history of gynæcology, to be very indulgent to new methods, to wait

patiently, to work quietly, or to watch others carefully, ere we determine to accept or reject what none of us know very much about. This done, let us calculate the difficulties and dangers, weigh them well against the clearly-acknowledged benefits, if such there be, and remember that what is good will remain, and what is false or redundant will unquestionably be swept away.—
I am, etc.,
A. D. LEITH NAPIER, M.D.

Beaufort Gardens, S.W., June 22nd.

PAROXYSMAL SNEEZING.

SIR,—I have read the very interesting remarks on this affection by Drs. Ringer and Murrell, and have long considered that the terms "hay-fever" and "hay-asthma" were very misleading as applied to a complaint depending on so many diverse conditions. Some time ago I had under observation a very peculiar and remarkable case of this description. The patient was a single lady, aged 38. About eighteen years ago she had a cold bath during a menstrual period, and since then had suffered from "perpetual colds," always aggravated in winter by the most trifling cause. There was a small tender spot over the right lung, and she at one time coughed up a little blood, but attached no importance to it. There was a sense of fulness over frontal sinus and the upper eyelids, which was always intensified by colds, and momentarily relieved by the free discharge that invariably succeeded. The voice was of a nasal character, the feces were relaxed, and the right Eustachian tube was chronically inflamed. The sense of smell was much impaired, but was always more acute after daily discharge had ceased. On rising in the morning there was a free watery discharge from the nostrils, often sufficient to saturate a dozen handkerchiefs, and on one occasion as many as two dozen. The discharge was not usually preceded by sneezing; it came on without any apparent cause, and was only materially influenced by low and damp situations, when it was usually much more than usual. The patient was very seldom troubled during the day, and the discharge nearly always came on whilst rising from bed.

It is very hard to say what the exciting cause was in this case—possibly dust; but at all events, whatever it may have been, it simply reacted on the extremely sensitive nerve filaments supplying the nasal mucous membrane.

This lady consulted a great many eminent specialists, but without deriving any benefit, and ultimately was virtually cured by the systematic employment of compressed air. She was placed under pressure of seven pounds (nearly one atmosphere and a half) to commence with. After a fortnight the pressure was raised to ten pounds, but never exceeded that amount. On the fifteenth day there was a decided improvement, the discharge was much less and thicker, or, to use her own words, "like towards the end of a cold." At the end of a month (twenty-first time) she was practically well; there had been no discharge whatever for some days, and she felt for the first time as if "conscious of the existence of a brain." At no time did she experience any inconvenience, except during the first two days, when she complained of slight pain and fulness in the right Eustachian tube.

I have not heard of any cases of this nature similarly treated, and believe that the method now employed deserves more extended trial. Compressed air has a powerful sedative influence on the nervous system, and especially on the nerves supplying the mucous membrane of the air passages. In addition to this it exercises very important mechanical effects, which act very beneficially in chronic catarrhal conditions of the mucous membrane especially that lining the Eustachian tubes.

Massage was also employed in this case, but more on account of its general tonic effects than anything else.

The patient writes, two months after all treatment has ceased: "I feared that the distress and anxiety (alluding to domestic troubles) would bring back my running cold, but happily it has not done so, and I feel how much I have been strengthened to bear it all as I have done."—I am, etc.,

Liverpool.

T. GERALD GARRY, M.D., M.Ch.

THE NEW SYDENHAM SOCIETY.

SIR,—I shall be much obliged if you will allow me a few lines, in order to explain to members of the New Sydenham Society the present state of our year's issue. We shall be (for the first time) a little behind-hand. The year's series ought to be complete by the end of June, but from unavoidable circumstances, it will not be so this year till the end of July, or it may be a week or two later. Two volumes are yet to come. They will be sent out to-

gether almost immediately. Our members have received for this year the first volume of Spiegelberg's work on *Midwifery*, and a fasciculus of the *Lexicon of Medical Terms*. The two works which are not yet out, but which are nearly ready, are a fasciculus of the *Atlas of Pathology* and a volume of selected essays. In the latter are comprised Raynaud's two memoirs on the disease which now bears his name, translated by Dr. Thomas Barlow; two essays on Malaria and Melanemia translated by Dr. Drummond from Italian sources; and Neugebauer's last memoir on Spondylolisthesis, translated by Dr. F. Barnes. Thus the year's issue for 1887 will be complete in four works. As regards the preparations for next year, it will be satisfactory for our members to know, that the second volume of Spiegelberg's *Midwifery* is almost finished printing; and that a volume of Charcot's *Clinical Lectures* and a fasciculus of the *Lexicon* are also well advanced.

Our annual meeting will be held at Glasgow during the meetings of the British Medical Association. I am at all times glad, on behalf of the Council, to receive suggestions for new works, to be submitted to its consideration, and especially so in anticipation of the annual meeting.—I am, etc.,

Cavendish Square.

JONATHAN HUTCHINSON,
Honorary Secretary.

MODERATE DRINKING.

SIR,—Dr. Isambard Owen, in Appendix C to the Report of the Inquiry into Disease and Intemperance, says he believes no detailed report has been published of the remarkable statistics of the United Kingdom Temperance and General Provident Institution. Will you permit me to somewhat supply Dr. Owen's omission by giving the figures that have been issued, which form an unimpeachable testimony to the superior healthfulness of abstinence over moderate drinking. The period is 22 years, 1866 to 1887 inclusive. There are two sections of the assured, one for abstainers, the other for the general public, drunkards being excluded.

	Temperance Expected Deaths.	Section. Actual Deaths.	General Section. Expected Deaths.	Actual Deaths.
1866-70 (5 years) ...	549	411	1,008	944
1871-75 " ...	723	511	1,268	1,330
1876-80 " ...	933	651	1,485	1,480
1881-85 " ...	1,179	835	1,670	1,530
1886-87 (2 years) ...	553	390	713	700
	3,937	2,796	6,144	5,984

I am, etc.,
June 23rd.

NORMAN KERR, M.D.

RESECTION OF THE TARSUS.

SIR,—A case of resection of part of the tarsus for disease by Sir Wm. Mac Cormac, published in the JOURNAL for May 8th, with the remarks that have been made upon the operation, lead me to make the following comments upon the best method of treating such cases by operation. In Sir W. Mac Cormac's case the condition of the parts removed is not recorded. It may be taken for granted that disease of the tarsus is very commonly met with in two positions: First, disease of the os calcis, which may extend to the posterior calcaneo-astragaloid, or more rarely to the calcaneo-cuboid joint; and, secondly, disease involving the anterior calcaneo-astragaloid and its prolongation, the astragalo-scapoid joints. In this second case, the mischief may spread over the astragalus and attack the ankle-joint, or, travelling in the opposite direction, may reach beyond the scaphoid and involve the common tarsal sac. These are probably the conditions of disease most often met with. Where the os calcis alone is involved, removal of that bone is an excellent and successful operation. Where the astragaloid joints and common tarsal sac are diseased most surgeons amputate by Syme's method or remove the whole foot. The Mikulicz-Wladimiroff operation is no doubt an advance upon this, but better still. I think, is the plan of making a transverse incision across the dorsum of the foot (Holmes), dissecting out all the tarsal bones with the exception of the back of the os calcis, removing the bases of the metatarsal bones, and, if necessary, the lower ends of the tibia and fibula together with all tuberculous material. The cut tendons are then sutured together, the foot fixed in its natural position, and when healing has taken place, a foot small and short, it is true, but still a foot both in shape and function, remains. It is more sightly than an "equinus foot," and infinitely better than the stump of a Syme. The exact amount of

bone taken away varies with the case, but it is far better to take away all than to leave any disease. In none of my cases have I taken away the whole of the os calcis together with the rest of the tarsus; but since, after subperiosteal resection of the os calcis alone, we usually get a very perfect reformation of the heel, I should not hesitate to do so rather than amputate. In a paper in the *Medical Chronicle* for 1886, p. 460, I have already discussed the question and published some cases with illustrations, and since then I have operated on other patients. One of my colleagues, Mr. Thomas Jones, has also operated in this way, and I have had much reason to be satisfied with tarsectomy for disease. There is no occasion to attempt any adjustment of the bony surfaces. They may be left to themselves, and as repair takes place a firm, mobile foot results. It must be very rarely that the operation described by the Russian surgeon exactly meets the case, for it does not follow the lines most frequently mapped out by disease.—I am, etc.,
G. A. WRIGHT, M.B. Oxon, F.R.C.S.
Manchester.

LIABILITY FOR DEFECTIVE DRAINS.

SIR,—With reference to your paragraph on the case of *Butler v. Goundry* in the *JOURNAL* of June 23rd, it seems to me that it ought not to be necessary for a special declaration to be made as to the condition of the drains. When a house is let to anyone, it would be just as reasonable to expect a guarantee to be given as to the condition of any other part of the house—for example, the gas pipes, the stability of the chimney stacks, and the perfect fitting of the doors and windows, etc. When a landlord of his agent lets a house, he ought to be responsible for the consequences of all structural defects, and he should not be allowed to plead ignorance; he ought to make it his business to see that everything is in perfect order. He lets the house for purposes of gain, and he ought to see that no harm can affect the tenant from anything that is under his (the landlord's) control. This applies very specially with regard to drains. They are an essential part of the house, and it ought to be a crime for a landlord to let a house with the drains in a bad state, or who pleads ignorance of their condition.

I would go further. I think that local sanitary authorities should see that the drains of all new property are constructed in the most perfect manner. This should not be left to the fancy of the builder or the owner. They should be examined and tested by the sanitary authority and a certificate given, and all new additions should be similarly certified to. The owner should still be the responsible party, because drains require to be kept in good order, and he is the party to see that this is done.—Yours, etc.,

F. W. JORDAN, Medical Officer of Health to the
Heaton Norris Local Board.

ON THE ADMINISTRATION OF ANÆSTHETICS.

SIR,—Sir Spencer Wells, in his paper on "Methylene and other Anæsthetics" (in the *BRITISH MEDICAL JOURNAL* of June 9th, 1888), remarks that, on trying some samples of methylenchloride, manufactured by Riedel in Berlin, the tube of my apparatus, with which it was administered, speedily became closed by a sort of snow, thus rendering impossible the continuation of the narcosis.

When I first devised, twenty years ago, my apparatus for the administration of bichloride of methylene (which is manufactured by Messrs. Krohne and Sescmann, 8, Duke Street, Manchester Square, W., the original makers), I also tried other anæsthetics. I signally failed with ether, on several occasions, in the Samaritan Hospital, from the same cause as Sir Spencer with Riedel's preparation. I had scarcely commenced when the tube became closed by an icicle protruding into the face-piece, and the side-holes of the top-ventilator were likewise covered with a thick layer of ice. I explained this phenomenon in a similar way as Professor Bardeleben did in his letter to Sir Spencer. The aqueous vapour with which the breath is always more or less charged was converted into ice by the freezing action of the rapidly evaporating ether. My apparatus is, therefore, utterly unfit for ether and similar too volatile preparations.

It is, however, perfectly suitable for chloroform, and has been used for this purpose in the Samaritan Free Hospital, and in many surgical clinics in Germany—namely, in Berlin, and especially in Leipzig, by Professor Thiersch, where the bellows are worked, as also those of the spray and similar apparatuses, by hydraulic pressure fitted up in the amphitheatre.

Professor Rose, formerly in Zürich, at present at the Bethania

Hospital in Berlin, who, in all operations in the face and in the throat in which there is danger of blood passing into the trachea, always places the patient on his back with the head hanging down over the edge of the table, states that he was only enabled to continue an uninterrupted narcosis during the whole operation by the aid of my apparatus. After the patient has been brought under the full influence of chloroform, the face-piece is removed, and the tube is introduced through the nostrils into the fauces, and in that manner the anæsthesia is kept up. He latterly devised a bifurcated piece of india-rubber tubing, which is joined to the original tube, and its two branches are inserted into both nostrils.

Dr. E. Field, of Bath, writes in the *JOURNAL* of June 16th, that he once failed to bring a strong man under the full influence of methylene by using my apparatus. That must have been an exceptional case, which never happened either to Dr. Day or to me. Many years ago I gave methylene with this apparatus for Sir Spencer to a publican and ex-prizefighter. I brought him without any difficulty into deep narcosis. I mention this case because I consider it a fair test. Prizefighters surely are strong men, and publicans, as a rule, not abstemious. This patient, at any rate, was not. It is a well-known fact how difficult it is to narcotise individuals addicted to strong drink.—I am, etc.,

J. A. JUNKER, M.D.

30, Hyde Park Place, W., June 16th.

SETTING-UP DRILL AND HEART DISEASE.

SIR,—In reference to Surgeon-General Maclean's letter, with the labours of Surgeon-Major F. A. Davy the name of Surgeon-Major W. E. Riordan should be coupled. In the latter officer's work on "Heart Disease and Aneurysm in the Army, Dublin, 1878," the effects of setting-up drill and gymnastics are frequently alluded to, especially at page 35.

This book, if not published before, was anyway in the press when Dr. Davy's observations appeared in the *Blue-book*. The most accurate clinical observations and the most valuable will be found in Brigade-Surgeon Veale's paper in the *A. M. D. Report*, 1880.—I am, etc.,

A. M. S.

June 26th, 1888.

ON HYDROPHOBIA AND ITS TREATMENT.

SIR,—Mr. V. Horsey, in the *JOURNAL* of June 9th, relates some experiments, in cases of rabies, with the hot-bath. In his paper he says, "There is no single case of reputed cure of developed hydrophobia, by drugs or other means, that will bear investigation." I suppose that statement cannot be gainsaid; but are any cases published in which the symptoms were thought to be due to the poison of rabies, such symptoms being only the incipient signs of hydrophobia, in which recovery took place? If such cases have been met with, it would lead us to believe that hydrophobia may be recovered from, although there is no recovery when the worst symptoms are fully developed. It must be remembered that it is only a small percentage of those bitten by rabid dogs who exhibit signs of hydrophobia, while cases are recorded in which hydrophobia followed bites inflicted by dogs which showed no signs of rabies. While practising in Lancashire I treated a good few bites inflicted both by rabid and healthy dogs, only one of which gave me any anxiety afterwards. I had given up applying nitrate of silver to bites, having come to the conclusion that it did nothing but harm, and was in the habit of merely encouraging the bleeding, and healing the part as quickly as possible by the help of carbolic acid. The case which gave me some anxiety was that of a boy; while playing in a field with other boys, a retriever dog, which was enjoying the fun, bit him on the thigh through the trousers. Hardly any blood came from it, and no dressing was needed.

Some time afterwards, early one morning, a message came for me to visit the house where the boy was. No particulars were given, but I had some suspicion that it might be the boy, and before going I turned up my day-book to ascertain the exact date on which he had been bitten. It was exactly that day six weeks, which did not allay my suspicion. When I reached the house I inquired who was ill, and found it was the boy. He complained of pain in the bite, which had kept him from sleeping. The place was quite visible, and it was tender to the touch. I could detect nothing else wrong with the boy. I ordered him to be put into a hot bath and to be kept in bed till I saw him again. The pain left the bite that day, and he had no other symptoms. Is it possible that there may be cases which show other symptoms

more marked than mere pain in the part bitten, and which nevertheless recover?

The resemblance between hydrophobia and tetanus is so marked that a closer study of particular wounds, as to their nature, locality, and effects upon the nervous system, may assist in arriving at the true pathology of hydrophobia.—I am, etc.
MELROSE, N.B., June 15th.
JOHN HADDON.

NAVAL AND MILITARY MEDICAL SERVICES.

THE "NON-EFFECTIVE" LIST.

A "NON-EFFECTIVE" correspondent affirms that in the June *Army List* there are no less than 164 medical officers on the retired list, of whom a considerable number are now actually employed at brigade depôts and elsewhere, and the rest are "liable to be recalled to service" in any national emergency; yet these *bonâ fide* reservists are ignored and counted among those entirely "non-effective" by the Estimates Committee and other critics of the medical vote. He asks, "Why should they be classed as non-effective?" "Why, in the face of such a reserve, should a misleading cry be raised about '38 per cent. being non-effective charges?'" "Perhaps," he suggests, "it is to harrow the feelings of the taxpayers!"

We will not go into probable motives, but we have already pointed out that the attitude of hostile critics in suppressing all mention of the only real reserve of medical officers is very suspicious. We hope the friends of the department in the House will not lose sight of this when the medical vote comes up.

VOLUNTEER MEDICAL RESERVE.

SURGEON A. writes: I think your answer to the third portion of "Surgeon-Major's" question, in the *JOURNAL* of June 15th, is not quite correct. Section 355, Part III, of the *Manual for the Medical Staff Corps* refers to a bearer company, and not to regimental stretcher bearers, who are differently organised, and who I believe march past in rear of their battalion, with folded stretchers in close order; this has always been the custom in my neighbourhood, and if I am wrong I shall be very glad to be set right.

Can you inform me whether the cocked hat is abolished or not?

* * * I. There are no instructions for the guidance of regimental stretcher bearers except those contained in the *Manual for the Medical Staff Corps*. The present custom of marching past with stretchers will continue until regimental transport is provided for volunteers.

2. Medical officers of volunteer corps will wear the uniform of their respective corps with the exception of sword belt, pouch belt, and field pouch. Medical officers of volunteer corps are permitted to wear the cocked hats, belts, and pouches at present in possession, until they require to be replaced (Vol. Reg. 1887, Part IV, Section III, para. 1044). It is not stated definitely that the helmet is to be worn, but such is the conclusion to be drawn.

GRIEVANCES OF OFFICERS OF THE A.M.D.

I. I. writes: I observe in the *Homeward Mail* that "a weighty memorial to Parliament in favour of the existing rules for cantonment sanitation has already been signed by more than one hundred doctors," in India. Suppose officers of the A.M.D., taking this as a precedent, signed a "weighty memorial to Parliament," setting forth their grievances, would this be permitted by the powers that be, as the former must have been? I trow not. The aggrieved officers would very speedily be told that such action savoured of insubordination, and it would be put down at once. Yet in the one case the Indian memorial is against a decision of the highest authority in the land; on the other the appeal is made against a mere department which is subject to Parliament. Why should a memorial to Parliament, signed by a number of medical officers, be allowable in the one case and not in the other?

STATION HOSPITALS IN INDIA.

A CORRESPONDENT sends us the following Circular Memorandum, issued by the Commander-in-Chief in India, expressing his gratification at the success which has been achieved, chiefly through the exertions of the medical officers, in increasing the amenity of station hospitals, and thereby mitigating the terrible monotony of the sick soldier's life in India. We are heartily glad such endeavours find due recognition in high quarters. But why should "funds, however small," for such objects come from station sources? Have the Government of India no duties and responsibilities in humane exertions of this kind?

No. 1930
Office of the Adjutant-General in India,
Headquarters,
Simla, May 14th, 1888.
B.
From the Adjutant-General in India to General Officers commanding Divisions and Districts and Officers commanding Stations, which include British Troops in Garrison.
Circular Memorandum.

The Commander-in-Chief, at his inspection of station hospitals, was glad to observe that very much has been done to increase the comforts of the sick by making the hospitals cheerful in a manner which is not, and cannot be, provided for by regulations. There is, however, still great inequality in the comfort of hospital buildings, and His Excellency has observed that without cordial co-operation between station and regimental commanding officers on

the one hand, and medical officers in charge on the other, there is a liability to failure. The buildings cannot be made comfortable without some extra expenditure, and, however small the requirements in this respect may be, the funds must come from station sources. There are many means of providing these; and His Excellency's experience is that there is no lack of willingness to furnish the means of raising those funds when the authorities work together and give facilities.

His Excellency commends the improvement of hospitals to all concerned, and hopes that the very great success which has been achieved in not a few stations may soon become universal. Kindness and attention to the wants of the sick are so much a part of the nature of Englishmen and English women of all ranks, that Sir F. Roberts feels it is sufficient simply to bring the subject before those who are in close association with sick soldiers in India to insure the hearty co-operation of all. It is requested that this Circular may be made generally known in all stations where British troops are quartered.—By order, W. K. ELLES, Major-General, Adjutant-General in India.

PROTEST BY RETIREMENT.

JUSTITIA writes: Allusions have recently been made in the columns of the *JOURNAL* to the injustice of the decision which resulted in the retirement of a surgeon-general from the service, but it does not appear to be generally known how unprecedented were the means adopted to bring about that end. The officer in question was ordered to Bermuda, an appointment always before and now held by a deputy surgeon-general. To such an insult he could not submit, and accordingly he retired. That the head of the Medical Department should lend himself to such a course of action (for his worst enemies cannot believe that he originated it) will be the subject of universal regret. A parallel case in the combatant branch of the service would be the removal of a major-general from his command and the appointing him to a colonel's command on the grounds that a lieutenant-colonel in his district had failed in his duty! How different is the treatment accorded to the two branches of the staff! While we have not infrequently seen the incompetent general rewarded, we now have an example of how a competent surgeon-general can be bullied out of the service. The authorities would seem to desire that the Medical Staff of the army should no longer be a service which a gentleman who expects fair and honourable treatment can enter. If this be their end they are going the surest way to attain it.

THE NAVY.

The following appointments have been made at the Admiralty:—Fleet-Surgeon, W. H. STEWART, M.B., and Surgeon G. A. WATERS, M.D. (dent), to *Warspite*; Fleet-Surgeon G. A. CAMPBELL and Surgeon C. J. MANSFIELD (dent) to the *Northampton*.

THE NAVAL VOLUNTEERS.

M. DAVID CAIRNS, M.D., is appointed Surgeon to the Clyde Brigade of the Royal Naval Artillery, and Messrs. E. H. BEAMAN, M.R.C.S., L.S.A., and R. F. OWEN to be Honorary Surgeons to the Liverpool Brigade.

THE MEDICAL STAFF.

SURGEON E. A. C. SMITH, who joined the service on January 31st, 1885, has resigned his commission. He has been serving in Bengal since the end of 1866.

SURGEON W. G. MACPHERSON, M.B., and R. J. S. SIMPSON, M.D., both serving in Bengal, have passed the examination in Persian by the higher standard. Brigade-Surgeon A. F. CRITCHILL, M.D., and Surgeons W. H. PINCHES and G. S. TATE, M.D., who are serving in Bengal, have passed the examination in Hindustani by the lower standard.

SURGEON G. WILSON, M.B., serving in the Bombay command, has leave of absence for six months on medical certificate. It is reported that Surgeon R. B. GENGÉ, who was serving in the Bengal command, together with six of his servants, has been buried in an avalanche in the Kainthal Mulla, in Kishitwar, Kashmir.

BRIGADE-SURGEON H. F. PATERSON, M.D., F.R.C.S. Edin., is promoted to be Deputy Surgeon-General (ranking as Colonel) vice R. Hungerford, granted retired pay. Dr. Paterson entered the service as Assistant-Surgeon, October 19th, 1857; became Surgeon, January 15th, 1873; Surgeon-Major, March 1st, 1873; and Brigade-Surgeon, April 23rd, 1883. He is at present stationed at Colchester. He has no war record.

BRIGADE-SURGEON JAMES PAXTON, M.D., is granted retired pay. His commissions bear date: Assistant-Surgeon, April 22nd, 1858; Surgeon, March 1st, 1873; Surgeon-Major, April 1st, 1873; and Brigade-Surgeon, April 28th, 1884. During the Russian war in 1855 he served with the Baltic expedition, and received the medal therefor.

SURGEON-MAJOR W. T. MARTIN, M.D., is promoted to be Brigade-Surgeon, vice H. Knaggs, granted retired pay. His previous commissions (ranking as Lieutenant-Colonel) are dated: Assistant-Surgeon, April 14th, 1863; Surgeon, March 1st, 1873; and Surgeon-Major, April 28th, 1876. Hart's *Army List* informs us that he served through the Abyssinian campaign, having been appointed to the exploring party sent to Abyssinia in September 1867, and which he accompanied through various expeditions for discovering a practicable route for troops from the sea to the highlands; was afterwards Secretary to the Principal Medical Officer of the force and present with the Headquarters Staff at the capture of Magdala (mentioned in despatches, and medal). Served with the Burmese expedition in 1887 on the personal staff of Sir Charles Arbutnot (medal with clasp).

SURGEON-MAJOR AUGUSTUS MORPHEW has been granted retired pay. He entered as Assistant-Surgeon January 18th, 1856, became Surgeon June 15th, 1861, and Surgeon-Major March 1st, 1873. He was principal medical officer throughout the operations in Quinh, Western Africa in 1860-2; was present at the capture and destruction of Massongha on December 10th, storming and destruction of the stockades and war fences at Madonkia on December 19th, capture and destruction of the stockade at Madonkia on the night of December 27th, of the Fetish town of Robea on December 28th, 1861, and of the town of Mefemba and Majohn on January 17th, 1872 (mentioned in despatches).

ARMY MEDICAL RESERVE.

The undermentioned officers to be surgeons-major (ranking as lieutenant-colonels):—Surgeon-Major MALCOLMSON, 4th Battalion the Royal Irish Fusiliers (late the Cavan Militia); Surgeon and Honorary Surgeon-Major A. H. MACKENZIE, M.D., 1st Volunteer Battalion the Seaforth Highlanders (Ross-shire

Buffs, the Duke of Albany's) (late the 1st Ross-shire); Surgeon and Honorary Surgeon-Major J. CLARK, M.D., F.R.C.S. Edin., 2nd Volunteer Battalion the South Staffordshire Regiment (late the 3rd Stafford).

The undermentioned officers to be surgeons-major (ranking as majors):—Surgeon-Major T. F. GREENWOOD, 4th Battalion the Sherwood Foresters (Derbyshire Regiment) (late the 2nd Notts); Surgeon R. R. BROWN, 3rd Volunteer (Kent) Brigade, Cinque Ports Division Royal Artillery (late the 1st Royal Artillery).

The undermentioned officers to be surgeons (ranking as captains):—Surgeon and Hon. Surgeon-Major J. A. WATSON, the London Division Volunteer Medical Staff Corps; Acting-Surgeon G. R. GILBERT, 1st Edinburgh City Artillery Volunteers; Acting-Surgeon J. S. WILSON, M.D., 2nd Volunteer Battalion the South Staffordshire Regiment (late the 3rd Stafford); Acting-Surgeon G. H. TURNBULL, M.D., 1st Roxburgh and Selkirk (the Border) Rifle Volunteers.

Surgeon HENRY TOMPKINS, M.D., 7th Lancashire Artillery Volunteers, to be Surgeon (ranking as Captain).

THE INDIAN MEDICAL SERVICE.

SURGEON A. W. DAWSON, M.B., Bengal Establishment, is appointed to the officiating medical charge of the 5th Bengal Cavalry, vice Surgeon-Major H. Hamilton, M.D., transferred temporarily to civil employ.

Surgeon J. G. JORDAN, Bengal Establishment, is appointed to the officiating medical charge of the 16th Bengal Cavalry, vice Surgeon H. C. Hudson, transferred temporarily to civil employ.

Surgeon-Major H. D. COOK, M.D., Madras Establishment, Civil Surgeon and Superintendent of the gaol at Calicut, is appointed Surgeon of the First District and Medical Inspector of Emigrants, vice Surgeon-Major D. R. Thompson, M.D., C.I.E.

Surgeon H. K. FULLER, Madras Establishment, acting Professor of Hygiene, Madras Medical College, is directed to officiate as Superintendent of the Madras Lunatic Asylum, without prejudice to his own duties, during the absence of Surgeon H. Armstrong on leave.

Surgeon-Major A. L. HACKETT, Madras Establishment, has leave of absence for 182 days on medical certificate.

Brigade-Surgeon W. S. FOX, Madras Establishment, Examiner of Medical and Fund Accounts, Madras, is permitted to proceed out of India, on medical certificate, in anticipation of the furlough which will be granted to him by the Government of India.

Surgeon T. D. C. BARRY, Bombay Establishment, is appointed to officiate in medical charge of the 4th Native Infantry during the absence of Surgeon C. Monks.

Surgeons W. H. W. ELLIOT and J. MURRAY, of the Bengal Establishment, have passed the examination in Hindustani by the lower standard.

Surgeon-Major C. J. M'KENNA, Bengal Establishment, Medical Officer 39th Native Infantry, has leave to Murree and Kashmir, on private affairs, for six months.

Surgeon S. LITTLE, M.D., Bengal Establishment, whose services have been placed temporarily at the disposal of the Punjab Government, is appointed to officiate as Civil Surgeon of Imballa, relieving Surgeon-Major G. Thomson, M.B.

Surgeon-Major G. THOMPSON, Bengal Establishment, is appointed to officiate as Medical Officer to H.H. the Maharajah of Patiala, vice Surgeon-Major J. Bennett, M.D., proceeded on furlough.

Brigade-Surgeon J. DUNCAN, M.D., Bengal Establishment, is appointed to the Civil Medical Charge of Sheikh Budeen.

Surgeon J. A. CUNNINGHAM, M.D., Bengal Establishment, is appointed to the Civil Medical Charge of Mooltan, vice Surgeon-Major W. A. C. Roe, appointed to officiate as Sanitary Commissioner, Punjab.

Surgeon-Major PETER CULLEN, M.D., of the Bengal Establishment, who entered the service as Assistant-Surgeon July 27th, 1859, has been promoted to be Brigade-Surgeon from April 18th.

Surgeon-Major WILLIAM MOIR, M.B., of the Bengal Establishment, has been promoted to be Brigade-Surgeon from April 26th. His commission as Assistant-Surgeon dates from January 20th, 1880.

The retirement of the undermentioned officers, which has been already announced in the JOURNAL, has received the approval of Her Majesty:—Deputy Surgeon-General T. G. HEWLETT, C.I.E., Bombay Establishment; Brigade-Surgeon A. GARDEN, M.D., Bengal Establishment; Brigade-Surgeon J. E. T. AITCHISON, M.D., C.I.E., Bengal Establishment.

The services of Surgeon F. O. REEVE, Madras Establishment, are placed temporarily at the disposal of the Department of Finance and Commerce.

Surgeon A. W. DAWSON, Bengal Establishment, is appointed to the officiating medical charge of the 5th Native Cavalry, vice Surgeon-Major H. Hamilton, transferred temporarily to civil employ.

Surgeon-Major D. D. CUNNINGHAM, M.D., Bengal Establishment, is appointed to be Secretary to the Committee for the management of the Zoological Gardens at Alipore, vice Mr. A. Simson, resigned.

Surgeon C. C. VAID, Bengal Establishment, a Supernumerary Civil Surgeon in the North-West Provinces, is appointed to officiate as Civil Surgeon of Jhansi during the absence on privilege leave of Surgeon C. P. Lukis.

The services of Surgeon-Major H. ALLISON, M.D., Madras Establishment, are replaced at the disposal of the Military Department.

Surgeon T. W. STEWART is admitted to the Madras Establishment from May 1st, the date of his arrival in India.

Surgeon D. S. E. BAIN, Madras Establishment, Bangalore Rifle Volunteers, is permitted to resign his appointment as Honorary Surgeon at his own request.

The services of Surgeon W. A. CORKEBY, Bombay Establishment, are placed at the disposal of the Government for employment in the Civil Department.

The services of Surgeon A. R. W. SEDGEFIELD, M.D., Surgeon-Major J. O'M. McDONNELL, M.D., and Surgeon C. J. BAMBER, all of the Bengal Establishment, are placed permanently at the disposal of the Government of the Punjab.

The services of Surgeon-Major J. MORAN, M.D., Surgeon-Major H. HAMILTON, M.D., and Surgeon H. C. HUPSON, all of the Bengal Establishment, are temporarily placed at the disposal of the Government of the N.-W. Provinces and Oudh.

The services of Surgeon P. DE CONCEIÇÃO, Bengal Establishment, are placed temporarily at the disposal of the Chief Commissioner of Assam.

THE MILITIA AND VOLUNTEERS.

SURGEON-MAJOR O. T. DUKE, formerly of the Bengal Establishment, has been

appointed Captain in the 5th Battalion of the Rifle Brigade (formerly the 2nd Tower Hamlets Militia).

Acting-Surgeon J. H. REES, M.D., of the Severn Division Submarine Miners Royal Engineers, has resigned his appointment, which was dated September 19th, 1885.

Surgeon A. BAKER, of the 1st Volunteer Battalion Yorkshire Regiment (late the 1st North Riding of Yorkshire), is granted the honorary rank of Surgeon-Major.

The undermentioned gentlemen are appointed Acting-Surgeons to the corps specified:—W. F. LOVELL, 4th Volunteer Brigade Cinque Ports Division Royal Artillery (late the 1st Cinque Ports Artillery); ROBERT JONES, Mersey Division Submarine Miners Royal Engineers; Acting-Surgeon J. R. THOMAS, M.B., from the 1st Volunteer Battalion Welsh Regiment to the 4th Volunteer Battalion Devonshire Regiment (formerly the 4th Devonshire).

Acting-Surgeon W. L. MORGAN, of the 1st (Oxford University) Volunteer Battalion Oxford Light Infantry (late the 2nd Bucks), is promoted to be Surgeon in the same corps.

Surgeon F. E. MANBY, 3rd Volunteer Battalion South Staffordshire Regiment (late the 4th Stafford), is granted the honorary rank of Surgeon-Major.

Surgeon R. E. WILLIAMSON, M.B., 3rd Volunteer Battalion West Riding Regiment (late the 9th West Riding of Yorkshire), has resigned his commission, which was dated October 3rd, 1885.

Surgeon G. BOLTON, 1st Durham Artillery, is granted the honorary rank of Surgeon-Major.

Surgeon and Honorary Surgeon-Major R. DAVY, of the 3rd Middlesex, has resigned his commission, which dates from May 16th, 1871; he is permitted to retain his rank and uniform.

The undermentioned gentlemen have been appointed Acting-Surgeons to the regiments specified:—ROBERT POLLOCK, M.B., 3rd Volunteer Battalion Highland Light Infantry (late the 8th Lanarkshire); J. W. ELLIS, 6th Volunteer Battalion King's Liverpool Regiment (late the 19th Lancashire); and G. M. LOWE, M.D., 1st Volunteer Battalion Lincoln Regiment (late the 1st Lincoln).

Mr. C. A. O. OWENS, M.D., is appointed Surgeon to the 1st Volunteer Battalion Norfolk Regiment (late the 1st Norfolk).

Acting-Surgeon THOMAS RICHARDS, M.B., who joined the 1st Volunteer Battalion Warwickshire Regiment (late the 1st Warwick) June 25th, 1884, is now made Second Lieutenant in the same corps.

VOLUNTEER MEDICAL OFFICERS.

ACTING-SURGEON writes: 1. Is a volunteer acting-surgeon entitled to use a cockade? If so, and he resigns before serving fifteen years, can he still continue to use it, or must it be given up when he resigns? 2. What are the best books to read in preparing for the proficiency examination, and over what ground does the examination extend? 3. What are the best books to use when instructing a volunteer class in ambulance work and duties.

* * * 1. Officers holding Her Majesty's commission are entitled to use a cockade. An acting-surgeon has no commission, and cannot claim the use of the cockade. 2 and 3 were answered fully in the JOURNAL, on June 4th, 1887, p. 1244, and have been several times referred to.

MEDICO-LEGAL AND MEDICO-ETHICAL.

FEES FOR VISITS BY UNQUALIFIED ASSISTANTS.

IN an action, which raised the question whether a medical practitioner was entitled to charge the same fees for the visits of his assistant (an unqualified practitioner) as for those of himself, was recently heard at the Liverpool County Court before Judge Thompson. The action was brought by Dr. Arthur Wiglesworth, of Liverpool, against Mr. Hooker, master joiner of that city, to recover £11 19s. 6d. for professional attendance upon the defendant's wife. The plaintiff said when the wife of the defendant visited him at his house he charged 2s. 6d. for the consultation, and nothing for medicine supplied. When he had visited the patient at her own house he had charged 2s. 6d. for the visit, and made an extra charge for medicine. This was according to the custom of the profession. In cross-examination it was elicited that the largest sum charged for an ordinary visit was 4s. 6d., and for consultation with a physician 10s. 6d. Mr. Coates, a former assistant of the plaintiff, not a qualified practitioner, said he had attended the defendant on several occasions on behalf of Dr. Wiglesworth. The Judge, in summing up the case, said it would be for the jury to decide as to the reasonableness of the charges, but he himself thought that the plaintiff was not entitled to charge the same fee for the visits of his assistant, an unqualified practitioner, as for his own visits. The jury found for the plaintiff for the full amount of his claim less 14s. upon the items charged in respect of the assistant's visits. Judgment accordingly.

UNQUALIFIED PRACTICE: A CASE FOR THE APOTHECARIES' SOCIETY.

ON June 20th an inquest was held at Birmingham by Deputy Coroner Weekes on the body of a child, aged 3 years, named Margaret Hart. The statement made by the mother was that on June 13th she took her child to a house (412, Monument Road) where there was a card in the window bearing the name of "Dr. McLellan," the word "Dispensary," and the hours of attendance, with the charges. Witness saw a Mr. Millership, whom she thought was Dr. McLellan. He examined the child and gave her some medicine, and witness paid him 6d. The child was worse next day, and Millership saw her at the mother's house and administered more medicine. On Friday he again saw her, and said the illness was not diphtheria as he had thought, but croup.

More medicine was again given to the child, and the mother paid him 2s. 6d. On Saturday he called in company with a Mr. Tovey, and they both saw the child, who died on the following morning. Mr. Millership promised a certificate, which the mother, after calling several times, was unable to obtain. Mr. Tovey, surgeon, said that Millership asked him to "look at the case," as it was one Dr. McLellan was attending just before his death. Accordingly he went with him on the Saturday, and on Tuesday Millership said the child was dead, and asked the witness to give a certificate. Finding Dr. McLellan had not attended the case, he declined to grant the request. The child had apparently been well treated, and died from convulsions consequent on croup.

The Deputy Coroner said the case was an extraordinary one, and from the evidence it appeared that Millership had taken money under false pretences. He evidently held himself out as a doctor, trading upon the fact that he was assistant to Dr. McLellan, who had, of course, screened him. It was certain that Millership had acted contrary to the Medical Acts in holding himself out and practising as a qualified medical man. That, however, was not for the jury to consider. It appeared that the child had not been improperly treated. Had a qualified man attended the child, an inquest might have been avoided, and in this way the jury might consider whether they should not recommend the proper authorities to take steps to prevent poor people being imposed upon by persons holding themselves out as qualified practitioners. The jury returned a verdict of "Death from natural causes," but could not arrive at any unanimous recommendation. The Deputy Coroner said he hoped the press would take notice of the case, so that it might come before the attention of the proper authorities.

CLUB PRACTICE.

THE essential part of Messrs. "A. R." and "W. T.'s" correspondence and respective statement of case (which differ in no material point whatever, but are far too lengthy for insertion in the medico-ethical columns of the JOURNAL) is the simple question whether "W. T.," by the line of conduct he pursued in respect to the club referred to, and which could hardly fail to influence adversely, in a pecuniary sense at least, the other clubs against the old medical officer, acted wrongly in; a medico-ethical sense. After a careful consideration of the whole case, there cannot, we think, be any reasonable doubt upon the subject; and, further, that in so acting he disobeyed the express injunction to do unto others as he himself would wish to be done by. We would, at the same time, venture to add, in the interest of himself and the profession at large, that any attempt to seek legal redress against "A. R." for his assumed "libellous action" in submitting their correspondence to third parties, would, in our opinion, be injudicious.

"COVERING" UNQUALIFIED PRACTITIONERS.

L.R.C.P., on referring to the JOURNAL for March 31st last, at p. 714, will see what is the power possessed by the Medical Council, in a case where unqualified persons practise under cover of qualified medical men.

A QUESTION OF RETAINING FEE.

CYMRU writes: Mrs. X. called upon me on June 1st, to engage me for her confinement, which was expected on June 21st. She, her husband and two children, have recently taken the house of some patients of mine, for six months, and I was therefore not surprised at her coming. On June 10th I was asked to see the two children, and attended them three times, leaving them apparently well after the third visit. On June 15th, towards evening, I am told by a jobbing gardener who works at Mr. X.'s, that Mrs. X. has been confined of a girl; that Dr. Y. attended her, and that the baby was born on the morning of June 14th.

On my return home about an hour later I find a note from Mr. X., enclosing £2 2s. for "retaining fee," and stating that after his wife's visit to me, he had heard that Dr. Y. was living in the neighbourhood, and had asked him to attend the accouchement which had been done. I forthwith returned the £2 2s., saying that I presumed it was sent under a misapprehension (no fee having been agreed upon) that my fee was £5 5s., which I would be obliged if he would kindly remit.

I afterwards hear from Dr. Y.'s son, also a doctor, that on being asked to attend Mrs. X., he (Dr. Y.) had said that he could not agree to do so until Mrs. X. had communicated with me, and had sent me a fee, and that the next time he heard from the X.'s, it was an urgent summons to the accouchement, which took place two days after he was first spoken to.

Will you kindly inform me: (1) Whether I am entitled to the fee of £5 5s. in law. (2) Whether the etiquette of the profession demands that Dr. Y. should communicate with me either before or after the said accouchement?

* * * In reply to our correspondent's first question, we may note that although we entertain no moral doubt of Mr. X.'s liability (which, *de facto*, was acknowledged by the remittance of £2 2s. as a "retaining fee," and which our correspondent would have acted [wisely in retaining], to pay the obstetric fee in full, it is, we think, very questionable whether, under the circumstances, and as a young practitioner moreover, "Cymro" would succeed in enforcing payment of the fee demanded. With regard to the second query, we are clearly of opinion that Dr. Y. having declined to attend Mrs. X. "until she had communicated with and sent a fee to 'Cymro,'" it was not ethically essential that he (Dr. Y.) should address himself to the letter on the subject in question, though if on terms of friendly intimacy, it would have been well to have done so.

A QUESTION OF ETIQUETTE.

M.D. writes: During a severe illness which kept me out of my practice for three months, one of my patients, Mrs. B., who had engaged me to attend her in confinement about this time, elected to be attended by a neighbouring medical friend rather than by my *locum tenens*, my friend, Dr. C., kindly attended on my behalf. Two years later I started on my annual holiday, leaving one of Mrs. B.'s children, who was convalescent after a long illness, in the hands of my *locum tenens*. Mrs. B. not being satisfied with him, called Dr. C. in, not only to see the child but also Mr. B., who had been taken ill since my absence. Dr. C. again attended for me, and on my return we saw Mr. B. (who was then convalescent) in consultation. The nature of his case

demanding very plain speaking; this however resulted in Mr. B.'s obstinate refusal to submit to any treatment at our hands. As might be anticipated, Mr. B. has just recently had another break down, and Dr. C. was called in, and is now attending on his own account. Has Dr. C. acted in a proper manner towards me in taking Mr. B. on as his own patient?

* * * Inasmuch as the right of a patient (under the usual restrictions of courtesy, and, if need be, of explanation) to change his medical adviser is unquestionable, and especially in the case of a new attack of illness, Dr. C. was, in our opinion, under the circumstance related, justified in accepting charge of the patient. Such changes are no doubt annoying to the super-seeded practitioner, but nevertheless are of very frequent occurrence, and in the instance in question may, we think, be readily be accounted for, if, from "the nature of the case the necessity of very plain speaking" devolved upon our correspondent, and not on Dr. C.

MEDICO-PARLIAMENTARY.

HOUSE OF LORDS.—Monday, June 25th.

Universities (Scotland) Bill.—The Bill was read a third time.—The Marquis of Lothian's amendment to increase the number of the members of the Commission from thirteen to fifteen, by the addition of the Earl of Elgin and Sir Henry Roscoe, was adopted.—The motion that the Bill do pass was then agreed to.

HOUSE OF COMMONS.—Thursday, June 28th.

The Royal College of Surgeons.—Lord R. CHURCHILL: I beg to ask the First Lord of the Treasury whether it is correct that Her Majesty's Privy Council has advised Her Majesty to grant a "supplemental charter" to the Royal College of Surgeons of England; and whether the said charter recognises, and if so, to what extent, the claims of the Members of the College to take part in the election of, and to representation on, the Council of the said College, as embodied, with other requests, in a petition signed by 4,665 members, and presented to the Privy Council in May, 1887; if not, whether Her Majesty's Ministers will be prepared, at the urgent request of the Members, to recommend Her Majesty to delay granting said supplemental charter until such time as a report from a Royal Commission, appointed to inquire into the constitution of the College.—Mr. W. H. SMITH: The Lords of the Council have agreed to advise Her Majesty to grant a supplementary charter to the Royal College of Surgeons of England. The charter does not in any way deal with the question of election. The Government do not consider it necessary to recommend the appointment of a Royal Commission to inquire into the constitution of the College, or the postponement of the grant of a charter, which does not affect any of the questions which have been matters of controversy.—Lord R. CHURCHILL: In consequence of the answer of the right hon. gentleman, I beg to give notice that I shall take the earliest opportunity to move an address praying Her Majesty not to grant such supplementary charter until an inquiry has been made into the constitution of the College.

Thursday, June 21st.

Alleged Illegal Dissection.—Mr. MATTHEWS, in reply to Mr. PICKERSGILL, said he had inquired into the allegations as to the *post-mortem* examination on a young man named Cornish at the Victoria Park Hospital, and was informed that it was not the fact that the father was unable to get the body. It was given to him at the customary time on the day of the death. The so-called dissection of the body was nothing more than the usual *post-mortem* examination, made in consequence of the unaccountable features of the case. The father had expressed no objection to a *post-mortem* examination, inasmuch as he did not come to the hospital until after the examination had necessarily taken place. He was unable to discover that the authorities had rendered themselves amenable to the law.

Monday, June 25th.

Shop Hours Regulation Act.—Mr. WINTERBOTHAM asked whether the attention of the Secretary of State for the Home Department had been called to the refusal of a magistrate to grant summonses applied for by the Secretary of the Shop Hours Reform League against certain shopkeepers of Hackney, whose assistants, it was stated, were kept at work eighty, ninety, and even one hundred hours per week, unless the overworked persons (whom it was proposed to subpoena to give evidence) themselves attended and supported the application; and whether he would call the attention of the magistrate to the fact that summonses under this Act were granted by other metropolitan courts.—Mr. MATTHEWS said he had

ascertained from the magistrate that he refused to grant the summons because insufficient evidence was tendered. Any person could institute proceedings. It was within the magistrate's discretion to decide whether or not a summons should be issued on the evidence brought before him.

Tuesday, June 26th.

Army Medical Officers.—Mr. E. STANHOPE, in answer to Dr. TANNER, said forty-six retired medical officers were at present employed. The question of extending the system of re-employment was at present under consideration. Such officers were re-appointed for five years, and if they continued to be required and were still efficient the term might be extended till they reached the age of sixty-five years.

Colney Hatch Asylum.—Mr. W. REDMOND asked the Secretary of State for the Home Department whether his attention had been called to the following facts in regard to the treatment of a man in Colney Hatch Asylum: "John Stickley, an old man of 68, was removed to the asylum last Saturday from Hammersmith Police Court. He was then in a feeble condition, and perfectly quiet. On Monday his friends were informed that he was seriously ill, and on Tuesday he was dead. At the time of his death he had a broken jaw, and had lost a tooth, and the jury find that his death was accelerated by these injuries;" whether there was any evidence to prove that the injuries were caused after the man entered the asylum; and whether the Government would order an inquiry to be held into the whole matter.—Mr. MATTHEWS said the facts were stated with substantial accuracy in the question. The jury found that Stickley's injuries were received after he entered the asylum. The Lunacy Commissioners informed him that the Committee of Visitors of the Colney Hatch Asylum had intimated to them their intention to hold a searching inquiry into all the circumstances attending the death of this patient. The inquiry would begin on Friday, and the Commissioners had been requested to be at once informed of the result.

OBITUARY.

THOMAS EDWARD MASON, M.D., M.R.C.S., L.S.A.

WE regret to record the sudden death of this energetic and highly popular practitioner at Deal, Kent, on the 7th instant, from heart disease. Dr. T. E. Mason was the eldest son of Mr. George Mason, surgeon, also of Deal, and was born in November, 1841. He obtained his medical education at Guy's Hospital, and graduated at St. Andrews University in 1862. In the following year he became M.R.C.S. and L.S.A., and went at once into practice at Deal, where he succeeded his father. His energy, enthusiasm, natural kindness of heart, and anxiety to promote every public undertaking of the better sort soon endeared him to all with whom he came into contact, and gave him troops of friends and an extensive practice.

He held a large number of public appointments; was formerly for many years captain of the local company of Artillery Volunteers, and lately surgeon to the same corps. In 1872 he gained the ladies' challenge cup at the Kent County shooting competition. In 1873 he was elected medical officer for the borough and port of Deal; the latter being an extensive district, comprising some fifteen or sixteen miles of seaboard. In 1875 he became Admiralty Surgeon and Agent for the district. He was to a great extent instrumental also in the establishment of the Deal Fire Brigade, of which he was captain; and he was surgeon to many provident societies.

Dr. Mason was apparently in the prime of life and unimpaired health, and just about to undertake a holiday of some three weeks' duration in Germany and Paris—in fact, a longer absence from work than he had ever before during his professional career enjoyed—when, on the morning of Wednesday, the 6th instant, he returned to his house, and sank upon his couch in a state of exhaustion. He then had great pain at his chest; and notwithstanding all the efforts made to relieve him, died on the afternoon of the following day, leaving a widow and family of several children, to whom his death has occasioned an irreparable loss.

Dr. Mason's sudden decease naturally occasioned widespread grief in the neighbourhood of Deal, which was attested by the number and character of those who on the following Monday attended the funeral, which was a public pageant. The coffin, upon which lay the Union Jack and the helmet of the deceased, was

conveyed to its last resting place upon the borough fire-engine, between rows of saddened townsfolk who lined the streets, in which all business was for the time suspended. The drum and fife band of the Royal Marines headed the long funeral procession, being followed by Volunteers, Coastguards, Foresters, Odd Fellows, and Freemasons, the fire engine and fire brigade; and then, in carriages, the mourners, the Mayor and Corporation, and political and private friends, amongst whom the medical men of the locality mustered in strong force. But it is not in the seaside Kentish town alone that Dr. Mason's loss is experienced; distant comrades will also feel for many a day that his death has indeed robbed them of a valued, staunch, and upright companion and friend.

JOHN BRICKWELL, SEN., M.R.C.S., L.S.A., OF SAWBRIDGEWORTH.

WE have to announce the death of Mr. John Brickwell, sen., of Sawbridgeworth, Herts, for many years a member of the British Medical Association, member of the Obstetrical Society, and of some other scientific and charitable associations, M.R.C.S.E., and L.S.A. The deceased was born on December 12th, 1807; commenced practice at Sawbridgeworth, in succession to his father, in the year 1829; and died there on Sunday, June 10th, at the ripe old age of eighty years and six months, respected and mourned by a large circle of friends, and in the full possession of his intellectual faculties almost to the very last. He had been a student at St. Bartholomew's Hospital medical school at the time when Dr. Abernethy was surgeon there, whose portrait occupied the place of honour in the deceased's study. His cheerful and energetic manner, fertility of resource, and ready assumption of responsibility at a crisis, had enabled him to bring comfort and relief to many a sick bed, and had endeared him to a large number of friends and patients, by whom he was much beloved, as is testified to by the fact that, in the year 1864, he was presented with a testimonial, to which no fewer than 250 signatures were attached, among which may be recognised the names of many of his humbler patients, who vied with their richer neighbours in honouring their friend. In fact, he was one of those numerous medical men who unobtrusively, by their kindness and genuine charity as well as by their skill, do so much to ennoble the grand profession to which they belong. In private life, Mr. Brickwell was a cheerful and genial companion, much given to the study of natural history with its branches. Mr. Brickwell had given up the more active duties of his profession some years ago, when he took his son, Mr. E. A. Brickwell, as working partner.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

THE SANITARY CONDITION OF BUCKINGHAM.

THE Local Government Board have just issued the report of their Inspector, Dr. H. F. Parsons, on the recent outbreak of enteric fever in the borough of Buckingham. It would appear from the annual reports of the medical officer of health, and from the statements of local medical practitioners, that cases of enteric fever occur in the borough every year. During the ten years 1877 to 1886 the average annual death-rate from fever (almost entirely enteric) was 0.36 per 1,000 (the average rate for England and Wales during the same period being 0.30), and in those years there were local groups of cases in places where defective sanitary conditions were reported to exist. In the autumn of 1887 four cases in widely-separated parts of the borough came to the knowledge of the medical officer of health, and during the first three months of the present year about 114 cases (5 fatal) occurred in 49 households. The result of Dr. Parsons's investigation is that he classes this outbreak with those which have been recorded (for example, at Caterham and Dangor) as resulting from the entrance of a relatively minute quantity of specific fever poison into a water of pure origin. It appears that the water-supply of the affected locality is almost wholly obtained from a copious stream, called the Bath Lane Spout, running some ten gallons per minute, which, coming from a spring in the hillside above, is brought down, first in a rubble-stone conduit, and then in one of socket-pipes, to an iron spout from which it issues. Some fifty feet above the spout the line of the conduit is crossed by a drain which has received the sewage

of eight houses, including (that in which the first case of fever occurred in January last. The privies, which are of very rude construction, are connected with it, and into one of them a small stream of water from a spring is led, with the view of washing away the excreta. The drain, which occupies the course of an old ditch, has been laid in the greater part of its course only with common field-pipes. Immediately over the course of the conduit above referred to Dr. Parsons found a small catchpit inlet with bottom of bare earth, and just below where the drain crosses the conduit the former runs through a larger catchpit, which has sometimes been intentionally stopped, with the result of causing sewage to well out from the drain higher up. Leakage of sewage from the drain must, in such circumstances, be the result: and, as a matter of fact, Dr. Parsons observed that the earth in which the water-pipes were lying beneath the drain was black, foetid, and sewage-sodden. The joints of the water-pipes themselves were also found to be faulty, and ground-water (and worse) could enter the conduit. There is, therefore, good reason to believe that sewage leaked out of the drain and found its way into the drinking water. The amount so entering would no doubt be very small relatively to the volume of the stream of water, and hence slight pollution may probably have been going on for a considerable time, but escaped notice until the sewage happened to become infected with the fever poison. Then an extensive outbreak of fever among the drinkers of the water was the result.

Another lesson confirmed by this outbreak is that too much importance should not be attached to the mere chemical analysis of water, seeing that typhoid fever may be produced by drinking water containing the specific poison of that disease, even though the total amount of pollution present may be so small as to be undiscoverable by chemical analysis. In illustration of this fact Dr. Parsons quotes a report which was shown him by one of the Buckingham Town Council, made by an analyst on a sample of water taken from the River Ouse at a point below where it has received the sewage of Buckingham. The analyst, after noting the presence of some excess of organic matter, says that the water "does not appear from the analysis to contain sewage matters."

The sanitary defects of Buckingham—for example, defective sewers and drains, foul privies, water-sources in danger of pollution, and houses unfit for habitation—have for the most part been frequently brought under the notice of the town council, both by the present medical officer of health, Mr. G. H. De'Ath, and by his father and predecessor in the office, the late Mr. R. De'Ath, who have also urged the desirability of adopting by-laws for the regulation of new buildings, and making some provision for the isolation of cases of infectious disease, and the Local Government Board have by correspondence repeatedly called the attention of the town council to some of these matters, but hitherto, except as regards the improvement of privies and removal of their contents, only rectification of individual nuisances appears to have been attempted, and no action of a comprehensive kind taken. Some action has, we believe, been adopted in consequence of the panic caused by the recent epidemic, but it is to be regretted that known defects should have been allowed to continue until they produced disease. This is, however, a too common practice in some districts.

INSPECTION OF MEAT.

At the last meeting of the Town Council, Glasgow, it was stated that the Market Committee had resolved at once to consider what additional arrangements could be made with a view to the detection of diseased animals and carcases in the slaughter-house. There have been many complaints on this subject, and considering its importance both from the pecuniary and public health points of view, it is most surprising to find that the inspectors of carcases in our enormous *abattoirs* are simply policemen. It is to be hoped that a highly qualified and experienced veterinary surgeon will soon be appointed to fill this most responsible post.

THE SCOTCH POLICE BILL.

THIS Bill is now being considered by a Select Committee of the House of Commons, the Lord Advocate presiding. When the health clauses were reached, Dr. Clark said he was anxious that this Bill should pass this session, and in order that it might pass he proposed that they should leave out all the clauses dealing with the mitigation and prevention of disease. At this period of the session, and with the business they had before them, it would be wholly impossible to pass the Bill with these health clauses. They

must remember that these clauses ought to apply to villages quite as much as to burghs, and therefore he thought the matter should be dealt with in such a manner as would apply to the whole country. What they really wanted was a new Public Health Act for Scotland, because in this matter they were far behind England. The Lord Advocate said this was the most important matter that had been raised as yet, and as there was a small attendance of the Committee, he proposed that all the clauses relating to public health should be postponed, promising in the interval to consider whether the Bill could stand without the clauses. This was agreed to.

HEALTH OF ENGLISH TOWNS.—During the week ending Saturday, June 23rd, 5,775 births and 2,794 deaths were registered in the twenty-eight great English towns, including London, which have an estimated population of 9,398,273 persons. The annual rate of mortality per 1,000 persons living in these towns, which had been 16.2 in each of the two preceding weeks, declined to 15.5 during the week under notice. The rates in the several towns ranged from 9.9 in Nottingham, 10.4 in Birkenhead, 11.6 in Portsmouth, and 12.4 in Bristol to 22.5 in Manchester, 23.4 in Bolton, 23.5 in Plymouth, and 24.3 in Preston. The mean death-rate in the twenty-seven provincial towns was 16.4 per 1,000, and exceeded by 1.9 the rate recorded in London, which was only 14.5 per 1,000. The 2,794 deaths registered during the week under notice in the twenty-eight towns included 248 which were referred to the principal zymotic diseases, against numbers declining from 330 to 259 in the five preceding weeks; of these, 80 resulted from whooping-cough, 48 from diarrhoea, 33 from "fever" (principally enteric), 29 from diphtheria, 25 from measles, 24 from scarlet fever, and 9 from small-pox. These 248 deaths were equal to an annual rate of 1.4 per 1,000, and ranged from 0.0 in Portsmouth, Birkenhead, and Halifax to 2.4 in Cardiff, 2.5 in Preston, 2.7 in Derby, and 3.2 in Leicester. Scarlet fever caused the highest proportional fatality in Cardiff; whooping-cough in Salford, Blackburn, Newcastle-upon-Tyne, Leicester, and Derby; and "fever" in Preston and Huddersfield. The 29 deaths from diphtheria in the twenty-eight towns included 15 in London, 2 in Leicester, 2 in Salford, and 2 in Leeds. Of the 9 fatal cases of small-pox recorded during the week under notice, 5 occurred in Sheffield, 2 in Preston, 1 in Leeds, and 1 in Manchester, but not one in any of the other provincial towns or in London. The Metropolitan Asylums Hospitals contained only one small-pox patient on Saturday, June 23rd, which had been admitted during the week. These hospitals also contained 820 scarlet fever patients on the same date, against numbers declining from 915 to 830 in the four preceding weeks; there were 72 admissions during the week, against 89 and 61 in the two previous weeks. The death-rate from diseases of the respiratory organs in London was equal to 2.3 per 1,000, and was below the average.

HEALTH OF SCOTCH TOWNS.—During the week ending Saturday, June 16th, 842 births and 505 deaths were registered in the eight principal Scotch towns. The annual rate of mortality, which had been 19.3 and 18.5 per 1,000 in the two preceding weeks, rose again to 20.0 during the week under notice, and exceeded by 3.8 per 1,000 the mean rate during the same period in the twenty-eight large English towns. Among these Scotch towns the lowest rates were recorded in Dundee and Paisley, and the highest in Edinburgh and Glasgow. The 505 deaths in these towns during the week under notice included 36 which were referred to the principal zymotic diseases, equal to an annual rate of 1.4 per 1,000, which corresponded with the mean zymotic death-rate during the same period in the large English towns. The highest zymotic death-rates were recorded in Dundee and Glasgow. Of the 42 deaths registered in Glasgow, 12 resulted from measles, 5 from whooping-cough, and 3 from "fever." Two fatal cases of scarlet fever were recorded in Edinburgh. The mortality from diseases of the respiratory organs in these Scotch towns during the week under notice was equal to 3.7 per 1,000, against 2.6 in London.—In the eight principal Scotch towns, 877 births and 466 deaths were registered during the week ending Saturday, June 23rd. The annual rate of mortality in these towns, which had been 18.5 and 20.0 per 1,000 in the two preceding weeks, declined again to 18.4 during the week under notice, but exceeded by 2.9 per 1,000 the mean rate during the same period in the twenty-eight large English towns. Among these Scotch towns the lowest rates were recorded in Greenock and Edinburgh, and the highest in Aberdeen and Glasgow. The 466 deaths in these

towns during last week included 46 which were referred to the principal zymotic diseases, equal to an annual rate of 1.8 per 1,000, which exceeded by 0.4 the mean zymotic death-rate during the same period in the large English towns. The highest zymotic death-rates were recorded in Aberdeen and Glasgow. The 230 deaths registered in Glasgow during last week included 11 from measles, 8 from whooping-cough, 9 from diarrhoea, 4 from scarlet fever, and 1 from diphtheria. The mortality from diseases of the respiratory organs in these towns was equal to 3.0 per 1,000, against 2.2 in London.

MEDICAL NEWS.

MEDICAL VACANCIES.

The following Vacancies are announced:

- BOROUGH OF BRADFORD.**—Medical Officer of Health. Salary, £500 per annum. Applications by June 30th to the Chairman of the Sanitary Committee.
- BRISTOL GENERAL HOSPITAL.** Assistant Surgeon. Applications by July 20th to the Secretary.
- CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST,** Victoria Park, E.—Assistant-Physician. Applications by July 12th to the Secretary.
- CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST,** Victoria Park, E.—Pathologist. Salary, 100 guineas per annum. Applications by July 12th to the Secretary.
- CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST,** Victoria Park, E.—Resident Clinical Assistant. Applications by July 12th to the Secretary.
- CHELSEA HOSPITAL FOR WOMEN,** Fulham Road, S.W.—Resident Medical Officer. Salary, £60 per annum, with board and residence. Applications by July 4th to the Secretary.
- DERBYSHIRE GENERAL INFIRMARY.**—Resident Assistant House-Surgeon (for six months). Board, etc., with bonus of £10. Applications by July 7th to the House-Surgeon.
- DONCASTER GENERAL INFIRMARY AND DISPENSARY.**—House Surgeon. Salary, £100 per annum, with board and residence. Applications by July 5th to the Honorary Secretary.
- EAST SUFFOLK AND IPSWICH HOSPITAL.**—House-Surgeon. Salary, £80 per annum, with board, lodging, etc. Applications by July 10th to the Secretary.
- GENERAL INFIRMARY,** Northampton.—Assistant House-Surgeon. Salary, £80 per annum, with board and residence. Applications by July 9th to the Secretary.
- GLASGOW HOSPITAL FOR SICK CHILDREN.**—Assistant House-Surgeon. Applications to M. P. Fraser, Esq., 91, West Regent Street, Glasgow.
- HOSPITAL FOR WOMEN,** Soho Square, W.C.—House-Physician. Salary, £75 per annum, with board, etc. Applications by July 12th to the Secretary.
- KENT COUNTY LUNATIC ASYLUM,** Barming Heath.—Third Assistant Medical Officer. Salary, £120 per annum, with furnished apartments, etc. Applications by July 15th to F. R. Howlett, Esq., 9, King Street, Maidstone.
- KILLYBEGS AND TRIBANE.**—Admiralty Surgeon and Agent for these Coast-guard Stations. Salary to include attendance, supply of medicines, and travelling, £50 per annum. Applications to the Admiral Superintendent of Naval Reserves, Spring Gardens, London, S.W.
- MIDDLESEX HOSPITAL,** W.—Physician for Skin Diseases. Applications by July 15th to the Secretary Superintendent.
- NORTH STAFFORDSHIRE INFIRMARY.**—Assistant House-Surgeon (for six months). Board, apartments, etc. Applications to the Secretary.
- PARISH OF EDRACHILLIS,** Sutherland.—Salary, £150 per annum, with free house. Applications by July 15th to Mr. A. R. Cowie, Inspector, Scourie by Larg, N.B.
- PARISH OF KIRKMABRECK,** Kirkenbrightshire.—Medical Officer for the Poor. Salary, £85 per annum. Applications by July 14th to Mr. J. Carson, Inspector of Poor, Creetown, N.B.
- PARISH OF KIRKMAIDEN.**—Medical Officer. Salary, £85 per annum. Applications by July 12th to Quintin Cochran, Port Logan, Stranraer, N.B.
- PARISHES OF PENNYGOWN AND TOROSAY.**—Medical Officer. Salary, £100 per annum. Applications by July 3rd to Mr. A. McDougall, Inspector of Poor, Auchnaeraig, Oban, N.B.
- PLYMOUTH PUBLIC DISPENSARY.**—Physician's Assistant. Salary, £60 per annum. Applications by July 17th to the Honorary Secretary, W. H. France, Esq., 7, Athenæum Terrace, Plymouth.
- UNIVERSITY COLLEGE HOSPITAL.**—Surgical Registrar. Applications by July 11th to the Secretary.
- WEST SUSSEX, EAST HANTS, AND CHICHESTER INFIRMARY.**—House-Surgeon. Salary, £100, with board and lodging. Applications by June 30th to the Honorary Secretary, E. Arnold, Esq., White Hall, Chichester.
- WESTERN GENERAL INFIRMARY,** Marylebone Road.—Honorary Surgeon. Applications by July 2nd to the Secretary.
- WORCESTER GENERAL INFIRMARY.**—House-Surgeon. Salary, £100 per annum, board and residence. Applications by July 24th to the Secretary, Worcester Chamber, Pierpoint Street, Worcester.

MEDICAL APPOINTMENTS.

- BINDLEY, R. A.,** M.R.C.S., L.S.A., appointed Resident Medical Officer to the North London Consumption Hospital.

- BONTOR, S.A.,** M.B., B.S. Durh., L.R.C.P., M.R.C.S., appointed House-Surgeon to the West London Hospital, *vice* P. J. F. Lush, M.B., resigned.
- BROWN, William, M.B.,** C.M.Glas., reappointed Medical Officer of Health for the Stapleton Urban Sanitary District.
- COPE, G. P.,** promoted to Senior Assistant to the Richmond District Asylum, Dublin.
- CRISP, James Ellis, M.R.C.S.,** L.S.A., appointed Medical Officer to the Corsham District of the Chippenham Union: *vice* William Kemm, M.R.C.S., L.S.A., deceased.
- DONALDSON, William Ireland, A.B.,** M.B., B.Ch. Univ. Dub., appointed Assistant Medical Officer to Cambervell House Asylum, London, S.E.
- LAWRENSEN, H. F.,** M.B., B.Ch. (T.C.D.), appointed Medical Officer to the Dunlavin District, Baltinglass Union, *vice* G. E. Howes, M.R.C.S., resigned.
- LUSH, P. J. F.,** appointed House-Physician to the West London Hospital, *vice* W. S. Colman, M.R.C.S. Eng., resigned.
- MAHOOD, Edward Allan, M.B.,** M.Ch., M.A.O., Royal University of Ireland, appointed Assistant Medical Tutor in the Queen's College, Birmingham.
- MARTIN, James P.,** M.R.C.S. Eng., L.R.C.P. Lond., appointed Medical Officer to the Colerne district of the Chippenham Union, *vice* W. Kemm, M.R.C.S., L.S.A., deceased.
- SIMPSON, Alexander, M.B.,** C.M. Aberdeen, appointed Assistant Medical Officer to the City of Newcastle-upon-Tyne Lunatic Asylum, *vice* G. N. Hurry, M.B., C.M., resigned.
- STEER, W.,** M.R.C.S. Eng., L.S.A. Lond., appointed Resident Medical Superintendent of the Infirmary, and Medical Officer to the Workhouse, Fulham Union, *vice* R. H. Scanes Spicer, M.D., resigned.

The *Medical Record* of New York states that an association of "coloured" physicians, calling itself the Lone Star Medical Association, is in existence in Texas, and recently held its second annual meeting.

SWEATING SICKNESS.—Sweating sickness has again appeared in France, at various places in the Poitiers, and Civray arrondissements, and at Chouzé-sur-Loire, in the department of Indre et Loire.

The Kidderminster guardians have increased the salary of Mr. Samuel Stretton, M.R.C.S. Eng., L.S.A. Lond., Medical Officer to the Workhouse, from £90 to £120 per annum.

Mr. NICHOLAS HARDCASTLE, M.R.C.S. Eng., L.S.A. Lond., late Medical Officer to the Workhouse, Newcastle-upon-Tyne Union, has obtained a superannuation allowance of £80 per annum.

AN epidemic of typhoid fever has broken out at Königsberg; 300 persons have been affected so far, and the epidemic increases every day in severity.

DR. LUDWIG KNORR, Privat-Dozent, and known by his preparation of antipyrin, has been named Extraordinary Professor in the University of Würzburg.

DIARY FOR NEXT WEEK.

WEDNESDAY.

OBSTETRICAL SOCIETY OF LONDON, 8 P.M.—Specimens will be shown. Dr. Boxall: On the Conditions which favour Mercurialism in Lying-in Women, with Suggestions for its Prevention. Dr. Champneys: Description of a New Operation for Vesico-Uterine Fistula. Mr. Alban Doran: On Myoma and Fibro-Myoma of the Uterus, and Allied Tumours of the Ovary.

FRIDAY.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM, 8.30 P.M.—Annual General Meeting. Papers: Dr. Bronner, 1. Spring Conjunctivitis; 2. On a Simple Method of Preventing Hæmorrhage in Iridectomy. Mr. Rockliffe: Notes on (1) Secondary Hæmorrhage after Iridectomy for Glaucoma. (2) Ophthalmoplegia. Mr. Mules: On a Case of Embolus of Branch of Arteria Centralis Retina removed by Massage, with Recovery of Visual Field. Living Cases and Card Specimens as usual at 8 P.M.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 5s. 6d., which should be forwarded in stamps with the announcement.

BIRTH.

ROBERTS.—On June 19th, at Milton-under-Wychwood, the wife of Henry Roberts, M.D. Brux., M.R.C.S.E., L.R.C.P. Lond., L.S.A. Lond., of a daughter (premature).

MARRIAGE.

HARDCASTLE—CURRIE.—At St. Michael's Church, Dumfries, N.B., on the 21st instant, by the Rev. John Paton, Hugo McCauley Hardcastle, M.D., of Newcastle-upon-Tyne, younger son of His Excellency Hardcastle Bey, Alexandria, Egypt, to Ruby, youngest daughter of the late T. D. Currie, Esq., of Clerkhill House, Dumfries.

DEATHS.

MCCULLOCH.—On June 25th, at Dumfries, N.B., James Murray McCulloch, M.D., in his eighty-fourth year.

THOM.—At Ivy Lodge, Crief, N.B., on the 21st instant, Alexander Thom, M.A. Aberd., M.R.C.S. Eng., F.R.C.S., and L.R.C.P. Ed., in the 70th year of his age.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY.....10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's (Ophthalmic Department); and Royal Westminster Ophthalmic.—2 P.M.: Metropolitan Free; St. Mark's; Central London Ophthalmic; Royal Orthopaedic; and Hospital for Women.—2.30 P.M.: Chelsea Hospital for Women.

TUESDAY.....9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's; St. Bartholomew's (Ophthalmic Department); St. Mary's; Royal Westminster Ophthalmic.—2 P.M.: Westminster; St. Mark's; Central London Ophthalmic.—2.30 P.M.: West London; Cancer Hospital; Brompton.—4 P.M.: St. Thomas's (Ophthalmic Department);

WEDNESDAY.....10 A.M.: National Orthopaedic.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: Middlesex.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: London; University College; Westminster; Great North Central; Central London Ophthalmic.—2.30 P.M.: Samaritan Free Hospital for Women and Children; St. Peter's.—3 to 4 P.M.: King's College.

THURSDAY.....10.30 A.M.: Royal London Ophthalmic.—1 P.M.: St. George's.—1.30 P.M.: St. Bartholomew's (Ophthalmic Department); Guy's (Ophthalmic Department); Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; St. Thomas's (Obstetric Department); Central London Ophthalmic; Hospital for Diseases of the Throat; Hospital for Women.—2.30 P.M.: North-West London; Chelsea Hospital for Women.

FRIDAY.....9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.15 P.M.: St. George's (Ophthalmic Department).—1.30 P.M.: Guy's; Royal Westminster Ophthalmic.—2 P.M.: King's College; St. Thomas's (Ophthalmic Department); Central London Ophthalmic; Royal South London Ophthalmic; East London Hospital for Children.—2.30 P.M.: West London.

SATURDAY.....9 A.M.: Royal Free.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: King's College.—1.30 P.M.: St. Bartholomew's; St. Thomas's Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Middlesex; Royal Free; Central London Ophthalmic.—2.30 P.M.: Cancer Hospital, Brompton.

HOURS OF ATTENDANCE AT THE LONDON HOSPITALS.

CHARING CROSS.—Medical and Surgical, daily, 1; Obstetric, Tu, F., 1.30; Skin, M, Th., 1.30; Dental, M, W, F, 9.

GUY'S.—Medical and Surgical, daily, 1.30; Obstetric, M, Tu, F., 1.30; Eye, M, Tu, Th, F., 1.30; Ear, Tu, F., 12.30; Skin, Tu, 12.30; Dental, Tu, Th, F., 12.

KING'S COLLEGE.—Medical, daily, 2; Surgical, daily, 1.30; Obstetric, Tu, Th, S., 2; o.p., M, W, F., 12.30; Eye, M, Th., 1; Ophthalmic Department, W., 1; Ear, Th., 2; Skin, Th.; Throat, Th., 3; Dental, Tu, F., 10.

LONDON.—Medical, daily, exe. S., 2; Surgical, daily, 1.30 and 2; Obstetric, M, Th., 1.30; o.p. W, S., 1.30; Eye, W, S., 9; Ear, S., 9.30; Skin, Th., 9; Dental, Tu, 9.

MIDDLESEX.—Medical and Surgical, daily, 1; Obstetric, Tu, F., 1.30; o.p. W, S., 1.30; Eye, W, S., 8.30; Ear and Throat, Tu, 9; Skin, Tu, 4; Dental, daily, 9.

ST. BARTHOLOMEW'S.—Medical and Surgical daily, 1.30; Obstetric, Tu, Th, S., 2; o.p., W, S., 9; Eye, Tu, Th, S., 2.30; Ear, Tu, F., 2; Skin, F., 1.30; Larynx, F., 2.30; Orthopaedic, M., 2.30; Dental, Tu, F., 9.

ST. GEORGE'S.—Medical and Surgical, M, T, F, S., 1; Obstetric, Tu, S., 1; o.p., Tu, 2; Eye, W, S., 2; Ear, Tu, 2; Skin, W., 2; Throat, Th., 2; Orthopaedic, W., 2; Dental, Tu, S., 9, Th., 1.

ST. MARY'S.—Medical and Surgical, daily, 1.45; Obstetric, Tu, F., 1.45; o.p., M, Th., 1.30; Eye, Tu, F, S., 9; Ear, M, Th., 3; Throat, Tu, F., 1.30; Skin, M, Th., 9.30; Electrician, Tu, F., 2; Dental, W, S., 9.30; Consultations, M., 2.30; Operations, Tu, 1.30; Ophthalmic Operations, F., 9.

ST. THOMAS'S.—Medical and Surgical, daily, except Sat., 2; Obstetric, Tu, F., 2; o.p., W., 1.30; Eye, M, Th., 2; o.p., daily, except Sat., 1.30; Ear, M., 12.30; Skin, W., 12.30; Throat, Tu, F., 1.30; Children, S., 12.30; Dental, Tu, F., 10.

UNIVERSITY COLLEGE.—Medical and Surgical, daily, 1 to 2; Obstetrics, M, Tu, Th, F., 1.30; Eye, M, Tu, Th, F., 2; Ear, S., 1.30; Skin, W., 1.45; S., 9.15; Throat, Th., 2.30; Dental, W., 10.30.

WESTMINSTER.—Medical and Surgical, daily, 1.30; Obstetric, Tu, F., 3; Eye, M, Th., 2.30; Ear, M., 9; Skin, Th., 1; Dental, W, S., 9.15.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS FOR THE CURRENT WEEK'S JOURNAL SHOULD REACH THE OFFICE NOT LATER THAN THE FIRST POST ON WEDNESDAY.

COMMUNICATIONS respecting editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

IN order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the office of the JOURNAL and not to his private house.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate beforehand with the Manager, 429, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication. CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

QUERIES.

PERSISTENT OEDEMA OF FOOT.
A MEMBER asks for advice in the treatment of the following case: A gentleman over 30, about a year ago, got suddenly an oedematous swelling on the dorsum of the right foot; he was obliged to walk on it, and in a couple of days the swelling got as hard as bone, and has remained so since; he is of rheumatic, or rather neuralgic, diathesis. Iodine ointment locally and iodide of potash internally have been tried, but no without effect. There is not much incoercible as long as a large boot is worn, but the slightest pressure causes the plantar surface to swell more. The foot is always swollen more or less, but there is no pain on pressure of finger.

MICROSCOPE WANTED.

MR. S. W. FOSTER, M.B. (Barrow, Chester) writes: Can any of your numerous readers inform me what is the most useful, simplest, and inexpensive microscope suitable for the general practitioner, chiefly for the examination of urine deposits, and tube casts, etc., and where to obtain it?

ANSWERS.

DR. H. K. HITCHCOCK (Boornemouth), Dr. Henry Bennet (Mentone).—Mr. Hart's letters on Oratava as a Health Resort have been published in pamphlet form, by Messrs. Smith, Elder and Co., London, S.W.

TREATMENT OF WOUND OF LEG.

C. R. HELLINGWORTH, M.D. (Accrington) writes: In answer to "S. H. J.," I agree with Mr. Clay that strapping is the best treatment. But I put only a single strip on, and I take the precaution to provide for drainage, by making a small hole in it, about an eighth of an inch in diameter, opposite the lower edge of the wound. Over this opening a small piece of dry boracic lint is placed every morning, and the dressing finished with an elastic-web bandage extending from foot to knee. Plaster changed every four days.

ANTISEPTIC FOR MIDWIVES.

MR. C. T. KINGZETT (96, Amhurst Park, N.) writes: In answer to "Dispensary Surgeon's" query as to the best antiseptic for use by midwives, I recommend "Sanitas fluid;" it is cheap, can be readily obtained everywhere, is reliable as an antiseptic, pleasant in use and free from all objections. It should be diluted with from five to ten times its own quantity of water. "Kingzett's thymolic bactericide" (containing 1 per cent. thymol and 5 vols peroxide of hydrogen) is equally recommendable, and should be similarly diluted before use.

NOTES, LETTERS, ETC.

SUDDEN ACCESSIONS OF HIGH TEMPERATURE IN CHILDREN.
DR. ALBERT KISCH (Sutherland Avenue, W.) writes: The interesting case recorded by Dr. Joseph Smith in the JOURNAL of June 9th, in which the temperature of a child aged 18 months was found to have suddenly risen to 110° without the occurrence of any critical condition, bears close resemblance to a case in my own practice in a girl aged 12.

On May 7th, 1887, I received an urgent summons at 9 A.M. to see C. L., a dark, bright-eyed, healthy-looking girl, aged 12. She had not yet menstruated. I found her in bed, apparently well; pulse 72; temperature in mouth, 99°. The father explained to me that he made a practice of taking the temperature of his children with a clinical thermometer on all occasions of illness, and as the child had complained of headache and some general discomfort shortly after waking, he placed his thermometer in her mouth, and found that it registered at 8 A.M. 105°. At 8.40 A.M. she seemed more uncomfortable, and, being unable to keep the bulb of the thermometer in her mouth in consequence of a rigor, he placed it in the rectum, and found that it registered 110°. When I found, only twenty minutes later, that my meter only indicated 99° in the mouth, we concluded too hastily that my friend's thermometer must have been faulty; but while we were discussing this matter the child again felt uncomfortable; her pulse was then 144; she was pale, and said she felt more ill than ever previously. A slight shiver came on. I inserted the bulb of my thermometer into the rectum and found that it registered 110°. Five minutes later it still registered the same temperature, but ten minutes later it indicated 105°.

At 5 P.M. the temperature was found to be 102.2°, and at 9.30 P.M. it was 99° both in mouth and anus, and the pulse was 84. She complained of occasional violent pains in the head, but neither pulse nor temperature was affected by them. The tongue was clean, and, but for the pains in the head and occasional slight rigors, she was fairly comfortable throughout the day. A dose of Gregory's powder administered after my first visit acted at about 7 P.M. At 10 P.M. she fell into a sound sleep, which continued with slight intermission till the morning, when pulse and temperature were normal, and she seemed to be quite well, and remained so.

I may add that the bowels had been regular, and that the urine was normal in all respects, and that, but for the fluctuations of temperature, there were no physical symptoms whatever. It is a well-known aphorism of Sir Andrew Clark that fever can exist without rise of temperature. The converse seems to be also true—that rise of temperature may exist without fever.

SELF-HELP FOR HOSPITALS.

MISERABLE DICKE writes: While in the act of reading your able article on "Self-help for Hospitals," an example of one of the consequences of indiscriminate hospital and dispensary treatment came under my personal notice. A patient who acknowledged to earning 55s. to 40s. per week, and to having a sick club allowance of 15s. per week, objected strongly to paying 2s. 6d. each time he came for medical and surgical attention, certificates, etc., thrown in, and a year's grace having been given him to pay a bill of 41. telling me that if he had known he would have paid 1s. 6d. This is a typical example of what we practitioners in the poorer parts of North-West London are reduced to as a result of competition with dispensaries, provident and private, and hospitals, that is—of competition between various classes of medical men.

In further proof of my last statement, I may mention that there is a large provident dispensary in direct competition with me. The doctors, with one exception, reside outside the district; no trouble whatsoever is taken to find

out the standing of the patients beyond their bare word; the surplus receipts divided amongst the medical men amount to over £120 each on the average, and they also personally collect in the neighbouring churches and chapels, and receive from a public fund an additional sum.

If a large number of self-qualified patients are treated for next to nothing by one set of medical men, must not the other neighbouring practitioners suffer? Is this fair or right? As regards private dispensaries; in the interests of the public and of the medical profession they should be suppressed on the following grounds.

1. Because the payments (often 1s. weekly during illness only) are, on the face of it, quite inadequate, and hence directly tend to inefficient treatment. In proof of this I may mention: a. A case of puerperal fever where the "doctor" refused to give quinine, as "Too expensive a drug to pay." b. A case of diphtheria recently under my observation, where the room was destitute of the barest necessities, while the patient had been left without any attention beyond what a half-witted mother could give. The atmosphere was foul beyond description.

2. On account of the gross ignorance, incapacity, and carelessness of the "medical men" in charge. From many instances I quote the following: a. I was called to see a young primipara, whom I found in a state of the greatest alarm, as she was told she had been seventy-two hours in labour. The "doctor" being equally frightened. The membranes had not even been ruptured. The cord was tied so carelessly that the child died in the night from hemorrhage. b. A strangulated hernia poulticed and treated as a bubo. c. A typical case of pneumonia where the patient's friends were told he had intestinal obstruction, though the bowels had recently been moved. Two dispensary men saw this patient together, with the above diagnosis.

3. The well known fact that the dispensary men keep their patient's paying by exaggerating their maladies. I saw a patient to-day who was recently informed that she had a tumour in the stomach, and that if she was not pregnant, it contained "Blood and matter." She is suffering from subacute uterine catarrh, and has no tumour whatsoever.

Is it not time that the medical profession—or in its absence the public—should take some steps to prevent such prostitution of its powers? From another point of view, does not each patient who going to hospital pays nothing, or an inadequate something really pauperise himself?

PAYING HOSPITAL PATIENTS.

A VICTIM writes: May I be allowed to suggest that the present time (when the public are being asked to contribute to the numerous hospitals and dispensaries in London) would be a suitable opportunity to ask them also to contribute to the scores of struggling metropolitan practitioners who are being driven into the Bankruptcy Court by the encroachment of these institutions on their private patients. Many of the hospitals now charge each out-patient a small fee—3d. or 6d.—thus competing with the hundreds of so-called private dispensaries which are cropping up in all parts of London and its environs; the result being that medical men daily find their patients going to the hospital and paying their 3d. rather than pay his modest fee of 2s. or 2s. 6d.

If hospitals are in debt why do they not restrict their relief to the necessitous poor, and not relieve those who are well able to pay for what they require? If there is to be a hospital fund, there should also be a bankrupt practitioners' fund.

A CASE OF DISTRESS.

MR. JOHN M. BRIGHT (Forest Hill, S.E.) writes: Will you kindly allow me to acknowledge the following donations towards the relief of the case of distress, which have been received since May 24th?

	£	s.	d.		£	s.	d.
A. M....	5	0	0	Dr. A. Roberts, Kensington ...	1	1	0
C. M....	5	0	0	E. B. Tench, Esq., Kensington 1	0	0	0
Ger. Bux Simla, India	2	2	0	Small amounts ...	5	8	6

Further donations for the relief of the family, and especially clothes, will be gratefully received by Dr. G. C. Jonson, 16, South Eaton Place, or by myself.

THE LUCE FUND.

AMOUNT already subscribed, £83 18s. 6d.; Miss Jacob, £1. Further donations in aid of Mrs. Luce will be gratefully received by Dr. Sheppard, 64, Darning Road, or by Dr. Caton, 31, Rodney Street, Liverpool.

ANTISEPTICS IN MIDWIFERY.

MR. R. H. A. HUNTER, M.R.C.S. (Clifton House, Battersea) writes: During the last few years I have at various times noticed letters in the columns of the JOURNAL respecting the use of antiseptics and ergot in midwifery. Perhaps it may interest some of your correspondents to learn that although I have attended over 2,000 cases without a death, I have never employed antiseptics except Condy's fluid, in the proportion of a drachm to a pint of water, when the lochia has been offensive. As regards ergot, I invariably give half an ounce of the liquid extract where ergot is required; when, if the child is not expelled within an hour I deliver with forceps. One point I am very careful about, which is that the placenta and membranes are completely expelled. Whenever I have the slightest doubt, I always thoroughly explore the uterus with the whole hand, and without any antiseptic precautions other than washing with clean water. In my opinion it is on the management of the third stage of labour and not on antiseptics, that success as an accoucheur depends.

COMMUNICATIONS, LETTERS, etc., have been received from:

Mr. J. Mill, Beverley; Mr. C. Lewers, London; Mr. Butler-Smythe, London; Dr. Cargill, St. Andrew, Jamaica; Messrs. Johnson, Budd, and Johnson, London; Messrs. May and Baker, London; Mr. W. SCALE OF CHARGES FOR ADVERTISEMENTS IN THE "BRITISH MEDICAL JOURNAL"

Seven lines and under	£0	3	6
Each additional line	0	0	4
A whole column	1	15	0
A page	5	0	0

An average line contains seven words.

When a series of insertions of the same advertisement is ordered, a discount is made on the above scale in the following proportions, beyond which no reduction can be allowed.

For 6 insertions, a deduction of	10 per cent.
" 12 or 13 "	20 "
" 25 "	25 "
" 52 "	30 "

Special terms for occasional change of copy during series: 30 per cent. if not less than 25 pages be taken } or their equivalent in half or quarter pages.

For these terms the series must, in each case, be completed within twelve months from the date of first insertion.

Advertisements should be delivered, addressed to the Manager at the Office, not later than noon on the Wednesday preceding publication; and, if not paid for at the time, should be accompanied by a reference.

Post-Office Orders should be made payable to the British Medical Association, at the West Central Post-Office, High Holborn. Small amounts may be paid in postage-stamps.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-Offices letters addressed to initials only.
