## CONTENTS OF VOL. 41, No. 1.

Editorial notes:	Page.
The agricultural appropriation act. 1919-20	1
Recent work in agricultural science	10
Notes	100

## SUBJECT LIST OF ABSTRACTS.

#### AGRICULTURAL CHEMISTRY-AGROTECHNY.

Recent advances in organic chemistry, Stewart	10
Commercial oils, vegetable and animal, Laucks	10
The rancidity of palm kernel and other feeding cakes, Furlong	10
Lysin as a hydrolytic product of hordein, Johns and Finks	11
Palau and rhotanium ware platinum substitutes, Gurevich and Wichers_	11
Hydrogen-ion concentration and gelatin liquefaction, Patten and Johnson_	11
Colorimetric determination of the hydrogen-ion concentration, Haas	11
Determination of iodid in mineral waters, Baughman and Skinner	12
Application of Benedict method to levulose and inulin, Okey	12
A system of blood analysis, Folin and Wu	13
Determination of urea in urine by nesslerization, Folin and Youngburg	13
Rapid method for estimation of urea in urine, Sumner and Bodansky	14

<sup>1</sup>On leave of absence for military service.

	Page.
The proximate analysis of wood, Dore	14
Nitrating of woodpulp cellulose, Wells and Edwardes	14
Studies on canning, Bovie and Bronfenbrenner	14
The bacteriology of canning	15
Saving raisins by sulphuring, Bioletti and Way	15
Potato drying, Rutishauser	15

## METEOROLOGY.

Introductory meterology, Humphreys et al	15
Evaporation and area of evaporating surface, Gallenkamp	15
Climate formula and reduced rainfall, Köppen	16
Bioclimatic law in entomological research and farm practice, Hopkins	16
A soil temperature survey of the United States and Canada	16
The climate of Utah, West and Edlefsen	17
[Weather reports for 1917], Georgeson et al	17
Meteorological observations, Stevens	17
Observations at Massachusetts Station. Ostrander and Chandler	17

## SOILS-FERTILIZERS.

Soil survey of Montgomery County, Iowa, O'Neal, jr., and Rhodes	17
Soil survey of St. Martin Parish, La., Meyer and Hendrickson	18
Soil survey of Mahoning County, Ohio, Beck and Gossard	18
Sandy soils and how to farm them, Whitson and Ullsperger	18
The "slick spots" of middle western Idaho, Peterson	18
The value of legumes on Indiana soils, Wiancko et al	19
Continuous wheat and rye with and without legume, Lipman and Blair	19
H-ion concentrations in extracts of soils and plants, Kappen and Zapfe	19
The value of ammonification test, Temple	19
Ammonification of manure in soil, Conn and Bright	20
Preservation of nitrogen in liquid manure, Vogel	20
The science and practice of manuring, Dyke	21
[Report of soil fertility work in Massachusetts], Gaskill	21
Experiments in fertilizing a crop rotation, Lyon	21
Experiments with various nitrogenous fertilizers, Mitscherlich et al	22
Availability of nitrate of soda and dried blood, Lipman and Blair	22
The present status of nitrogen fixation, White	22
The phosphate-rock industry in 1918	23
Availability of phosphorus and potassium compounds, Lipman and Blair	23
The world's supply of potash, Matignon	24
Use of lime on Iowa soils. Limestone and fertilizer dealers, Corson	24
Fertilizer analyses, Patten et al	24
Analysis of fertilizers for 1918, Curry and Smith	24
Analyses of commercial fertilizers and home mixtures, Cathcart et al	24
Analyses of commercial fertilizers, bone, and lime, Cathcart et al	24
Fertilizer registrations for 1919, Cathcart	25
	200

## AGRICULTURAL BOTANY.

[Activities of the] department of botanical research, MacDougal	25
Development of conceptions included in growth, MacDougal	25
The nature and course of growth in higher plants MacDougal	26
The growth mechanism of protonlasm MacDougal	20
Temperature and the hydration and growth of colloids MacDougal	20
Collection and the hydration and growth of conords, MacDougan	21
Salt requirements for young and mature buckwheat in cultures, Shive	27
Salt requirements in solution cultures for growth of buckwheat, Martin	27
Form of phosphorus most available for buckwheat seedlings, Bancroft	27
The toxicity of phosphates toward soy bean seedlings, Shive	27
Effect of ammonium sulphate on soy beans in sand cultures. Wolkoff	27
Absorption of sodium and calcium by wheat soddlings Bood	
Infuence of yout of maxing plants wheat securings, itel	21
inducice of root of growing plants on soil microorganisms, Neller	28
Gas interchange in Mesembryanthemum and other succulents, Richards	28
Photosynthesis and respiration, Spoehr and Long	28
The carbohydrate economy of cacti Speehr	20
and carbony arade sectionly of cach, spoem	28
Acidity of Castilleia, Ericameria, and Erigeron, Richards\_\_\_\_\_ 29 The acclimatization of plants, Sutton\_\_\_\_\_ 29

## FIELD CROPS.

Dry farming in Arizona, McOmie, Fillerup, and Bates	29
Dry farm crop rotations and cultural methods, Atkinson and Gieseker	29
Report of [field crops] work at Fairbanks, Georgeson and Snodgrass	29
Report of [field crops] work at Kodiak Station, Pratt	- 30
Report of [field crops] work at Rampart Station, Georgeson and Gasser	31
Cotton and corn: Cultural and variety tests, McClelland	31
[Report of work with field crops in Kansas, 1917–18]	32
[Variety tests with alfalfa and potatoes], Gaskill	35
[Report of work with field crops in New Jersey], App and Van Nuis	35
Progress report, substation No. 11, Nacogdoches, Tex., 1909–1915, McNess_	35
A study of environment in small grains, Halsted	36
Spring grains in western Nebraska, Zook	36
Farm pastures in Montana, Atkinson	37
A bad farm practice, Ayres	37
Napier and Merker grasses, two new forage crops for Florida, Thompson_	37
Field pea production in north Idaho, Hulbert	37
Position in pod and productiveness; seed weight, Schultz	- 38
[Work with potatoes at the Sitka Station], Georgeson	- 38
An improved method of potato seed treatment, Melhus and Gilman	- 38
Control of weeds in rice fields, Laude	- 38
Sugar beets under irrigation in Washington, Sievers and Schafer	39
Strains of White Burley tobacco resistant to root rot, Johnson and Milton_	39
The velvet bean, McClelland	39
Velvet bean varieties, Scott	39
Wheat investigations—varieties, Grantham	39
Fifth report of Montana grain inspection laboratory, Atkinson et al	39
Test your clover and timothy seed, King and Pammel	40
Results of seed tests for 1918, Taylor	40
The composition of some lawn-grass mixtures, Helyar	40
Jonnson grass as a weed in southwestern Iowa, Pammel and King	40

## HORTICULTURE.

[Horticultural investigations in Alaska], Georgeson et al	40
[Report on horticultural investigations]	41
Report of the department of horticulture, Blake and Connors	41
Studies on heredity and environment. Halsted	42
The breeding of vegetable fruits. Owen	43
Spray and practice outline for fruit growers. Eustace and Petit	19
Analyses of insecticides and fungicides during 1918. Catheart and Willis	49
Sod, tillage, and fertilizers for the apple orchard Gourley	49
Fertilizer tests for strawberries Brown	43
Currants and gooseherries Darrow	44
The avocado in Guatemala, Popence	40
Vanilla — A promising now group for Porto Pigo McClolland	45
Planting the rural general general general deligent	45
ranting the rural school grounds, rialligan	46

### FORESTRY.

Trees of Indiana, Deam	46
Geologic history of the locust and its allies. Berry	46
[Progress report on forestry investigations]	46
Waipoua Kauri Forest, its demarcation and management Hutching	46
Observations on distribution of forest tree pollen Hesselman	40
Anatomy of the union of a spruce graft on pine Romell	40
Study of frustum form factors of hard manle and vellow birch. Chandler	47
Obtaining form-class and volume of trees by use of form-point Potripi	41
Results of cutting at Ne-Ha-Sa-Ne Park in the Adirondacks Chandler	41
On the question of forest renewal. Beekman	41
The northeastern Minnesota forest fires of October 12 1018 Pickerdson	40
A contribution on the tan bark question van den Busseho	48
Charcoal hurning in Sweden Dilkmans	48
the standing in Strough, Dijamans	48

Page.

### ECONOMIC ZOOLOGY--ENTOMOLOGY.

Wild animals of Glacier National Park	55
Mammals of Australia in the Zoological Park, Le Souef	55
Our national elk herds, Graves and Nelson	56
[The mongoose in the West Indies]	56
The muskrat in Bohemia, Frickhinger	56
The birds of economic importance, Godard	56
An early experiment in keeping hummingbirds in captivity, Palmer	56
Another reference to early experiments in keeping hummingbirds, Palmer_	56
Insect fauna of bank swallows' nests in Virginia, Snyder and Shannon	56
Class book of economic entomology, Lochhead	56
A method for the preservation of insect larvæ and pupæ, Jackson	56
Plants used as insecticides, Roark	56
Fungoid and insect pests and their control, I, Mosley	56
The insect pests of maize, Gurney	56
Forest zoology, Osmaston	57
Entomology and the war, Howard	57
Seventeenth report State entomologist of Minnesota, Ruggles	57
Third biennial report of the Montana State Board of Entomology, Cooley_	57
Sixteenth annual report of the State entomologist of Montana, Cooley	57
Report of the department of entomology, Headlee	57
[Economic insects in South Dakota]	58
Miscellaneous insects, Ballou	59
[Papers on insects and insect control]	59
Insect notes, Dupont	59
[Economic insects in Mysore]	59
On a long-winged or caudate phase of <i>Neotettix proavus</i> , Fox	59
Cacao thrips in Grenada	59
Burn the chinch bug, Flint	59
Fight the chinch bug with crops, Burlison and Flint	60

The oriental fruit moth in Virginia, Stearns	30
The Furghean corn horer (Purgusta nubilalis), Felt	30
The sugar case moth horer. Holloway and Loftin	60
Possh haver observations at Vineland Blake and Connors	81
Arauresthia illuminatella Schiitze	81
Apple bud moths and their control in Nova Scotia Sanders and Dustan	81
Apple but motins and their control in rota Scotta, Sunders and Dustan-2	82
Man showing distribution in England and Wales of anopholings Lang	62
Notes on the Negratia Nuss (Dinters Asilida) Metro	82
Notes off the NearCite Nusa (Diptera, Asinda), Mertee	62
Letomyza in North America, Alurich	62
Role on resking synonymy, Townsend	62
Concoptera Industrata, Notinal	34 09
The comparent is driving both and horizon and in Fisher	34 69
The convergent ladybird beetle and barley corn apins, Davidson	04 00
Mobilizing a lady bug army to light the apins, Thomas	02
Five new species of ptinid beerles, Fisher	03
The apiary in Quebec, Vallancourt	03
Elements of beekeeping, Niswonger	03
Unheated egg yolk media, White	03
The carpenter ant as a destroyer of sound wood, Graham	63
Three new species of Braconidæ, Muesebeck	63
New reared parasitic Hymenoptera, with some notes on synonymy, Gahan_	63
The rice worm ( <i>Tylenchus angustus</i> ) and its control, Butler	64
Some significant structural modifications in Nearctic termites, Snyder	64

## FOODS-HUMAN NUTRITION.

Experiments on the digestibility of wheat bran, Holmes 64
Milling grain sorghums64
How to prepare banana meal 64
The utilization of yeast in the animal organism, Schill65
Digestibility of certain miscellaneous animal fats, Holmes6
Whale meat as food, Stubbins68
Whale meat in the diet65
Food values and dairy products, Overman63
[Miscellaneous food topics], Ladd and Johnson66
The Chinese petsai as a salad vegetable, Fairchild66
Food sauces of Europeans and Indo-Chinese compared, Rosé 66
[Food inspection], Soule66
[Food inspection]66
Report of fifteenth convention of Association of German Food Chemists66
Ten lessons in thrift66
Cold storage reports, season 1917–1918, Bell66
Food surveys66
Europe's larder.—Record American exports66
Food supply manual revised to July 31, 191867
Food regulations67
The food supply of our allies, Lusk6'
Food situation in Austria during the summer of 1918 6'
Diet, nutrition, and excretion of Asiatic races in Singapore, Campbell 6'
Dietaries suitable for schools, hotels, etc., Moore and Hecht 63
Hot lunches in rural schools, Laird6
Health without meat, Miles6
Study of intestinal contents of newly born infants, Hymanson and Kahn_ 68
Influence of phlorizin on the energy metabolism, Hari and Aszódi
The hospital metabolic laboratory, Ford63

# ANIMAL PRODUCTION.

Analysis of feeding stuffs, Curry and Smith	68
Cattle feeding.—XIV, Winter steer feeding 1917-18, Skinner and Starr	68
Cattle feeding investigations	69
Utilization of Yucca for the maintenance of cattle, Jones and Conner	70
Sheep feeding.—VIII, Fattening lambs, 1917–18, Skinner and Starr	70
Feeding western lambs	71
Production of goats on far western ranges, Chapline	71
The utilization of irrigated field crops for hog pasturing, Farrell	72
[Feeding experiments with swine], Hunter	73

Page.

# CONTENTS.

[Mineral nutrients and corn in swine feeding]	73
Feeding value of skim milk for swine, Norton, jr	74
Velvet bean meal, tankage, and soy bean meal for hogs, Good and Mann	74
Inheritance investigations in swine	74
Experimental work [with poultry], Lewis	75
Effect of certain grain rations on growth of chick, Buckner et al	75
Protective feeds for poultry, Lewis	76
[Inheritance of color in Andalusian fowl]	76
Improvement and conservation of farm poultry	76
The Vineland international egg-laying and breeding contest, Lewis	76
Report of the second (yearling) year of the Vineland contest, Hannas	- 76
Lessons to be learned by keeping records, Aubry	77
The incubator egg, Hannas	77
Marketing of dressed poultry	77

# DAIRY FARMING-DAIRYING.

Winter rations for dairy heifers, Eckles	77
Dairy cattle feeding experiments, Ewing, Ridgway, and Doubt	78
Some aspects of the physiology of mammary secretion, Hill	79
An exceptional case of milk secretion and its bearing, Hill	79
A new and powerful galactagogue, Duncan	80
Milk as a galactagogue, Palmer and Eckles	80
Principles and practise of milk hygiene, Klein	80
The utilization of dairy by-products, Kelly	80
Practical cultivation of green mold for making blue cheese, Chavastelon	80
Buttermilk cheese, Rudnick	81
The manufacture of condensed milk	81

# VETERINARY MEDICINE.

Textbook of meat hygiene. Edelmann, trans, by Mohler and Eichhorn	81
Live stock laws and regulations of State Board of Agriculture	81
Report of New York State Veterinary College for 1917–18, Moore	81
First biennial report of [Utah] Live Stock Board, 1918, Hoggan et al	- 82
[Diseases of live stock]. Corv	82
The physiological action of nitrobenzene vapor on animals. Chandler	82
Iodized chloroform in war surgery, Chassevant	- 83
Acriflavin emulsion as a wound dressing, Stowell	- 88
Treatment of wounds by paraffin, Pratt	88
Extract of autolyzed yeast as a culture medium, Dienert and Guillerd	- 88
On a new accessory factor in bacterial infections, Bullock and Cramer	- 83
The proteus group of organisms, Bengtson	- 83
A study of Abderhalden's polarimetric method, Sordelli	84
Problems in anthrax control, Frey	84
Specificity of complement fixation method, Fontaine and Lütje	84
The detection of anaphylaxis in horses affected with glanders, Waldmann	84
Habronemic conjunctivitis, Lewis and Seddon	84
The histology of the lesions of Johne's disease, M'Fadyean	84
The spirochete of infectious jaundice, Otteraaen	85
Scrapie, M'Fadyean	85
Attenuation of human, bovine, and avian tubercle bacilli, Raw	- 85
Bovine tuberculosis in children, Austin	8
Localization of Bacillus abortus in the bovine fetal membranes, Smith	85
Report of committee on bovine diseases, Roadhouse	- 86
A new disease of bovines and ovines, de Figueiredo Parreiras Horta	86
Sheep-maggot flies, IV, W. W. and J. L. Froggatt	86
Are camels susceptible to blackquarter, etc.? Cross	- 86
Paralysis of sow due to kidney worm, Pickens and Shivers	86
Observations in regard to immunizing young pigs, Birch	- 86
So-called medicinal hog cholera remedies and cures, Clink and Clark	87
Necrobacillosis, Fitch	87
Atlas of the anatomy and physiology of the horse, Bradley and Browne	87
The normal blood of the horse, Bonard	87
Castor seed (Ricinus communis) poisoning in horses, Wooldridge	87
Poisoning of horses with castor seeds, White	87
Strongylidæ in horses, Yorke and Macfie	87
Ulcerative lymphangitis in horses of the A. E. F., Straus and Wight	87
Prevalence and distribution of poultry diseases in New Jersey, Lewis	88

## CONTENTS.

	Page.
The intradermal test for Bacterium pullorum, Scherago and Benson	88
Gapes in chickens, Atwood and Lueder	88
Tuberculosis in farm poultry, Dimock and Willey	88

# EXPERIMENT STATION RECORD.

Vol. 41.

JULY, 1919.

No. 1.

1

Beginning with its second volume in 1892, the *Record* has been publishing year by year summaries of the annual acts making appropriations for the support of the Federal Department of Agriculture. These acts, authorizing expenditures for the Department's work for the ensuing fiscal year, prescribe the scope of most of its activities in considerable detail, and thus have afforded a convenient means of forecasting its program for several months to come. They have also permitted of comparisons with previous years, revealing changes in problems and policies and reflecting current public opinion as to the most urgent needs of American agriculture and the ways in which an institution like the Department can render the most effective service to the Nation.

It has seemed desirable to summarize the latest of these acts in much the same way as in previous years, although direct comparison with earlier legislation is somewhat more complicated than usual. It will be recalled that after the declaration of a state of war with Germany the regular appropriation act for the fiscal year ended June 30, 1918, was supplemented by emergency legislation, known as the Food Production Act and carrying additional appropriations of \$11,346,400 for the year. The same policy as to agricultural legislation was continued the following year, what may be termed the normal activities of the Department without special reference to war conditions being provided for in an appropriation act carrying \$27,875,353 for the fiscal year ended June 30, 1919, and a supplementary act passed November 21, 1918, carrying \$11,031,863 for the emergency activities of the year. The latest appropriation act, however, makes provision for both the normal activities and such of those previously carried as emergency legislation as are to be continued. Mainly because of the curtailment or discontinuance of many of the emergency activities, the aggregate appropriations in the act of \$33,900,211, while \$6,024,858 larger than those of the previous appropriation act, in reality constitute a decrease of \$5,007,005 from the amount carried in the two acts of the previous year. Comparison as regards individual items must likewise be made on the combined basis of the two acts.

An estimate of the relative resources of the Department is further complicated by the increasingly large sums of money now available to it through permanent appropriations and provisions carried in other appropriation acts. Formerly what are termed the permanent appropriations of the Department were comparatively minor sources of income, but for the present fiscal year they are estimated at \$28,235,000. The largest sources are the Federal Aid Road Act, carrying \$21,000,000; the Agricultural Extension Act, with \$3,080,000; and the meat inspection provision, with \$3,000,000.

Of the annual allotments to the Department carried in other appropriation acts, the largest specific sum is \$600,000 for printing and binding. There is also an indefinite appropriation which continues the granting of a salary bonus to most of the employees of the Department, in common with other branches of the Government, the conditions under which this bonus is granted being substantially as for the previous year but with the maximum amount per employee increased from \$120 to \$240 per annum. In addition considerable expenditures may be made by the Department from a revolving fund derived from an appropriation of \$6,500,000 for the purchase and sale of seeds. This appropriation is available until "the National emergency resulting from the existing state of war shall have passed," but not later than the beginning of the next fiscal year after the termination of the war as declared by the President. The aggregate from these various appropriations can not be definitely estimated, but it seems likely that from them and the permanent appropriations funds will be derived at least equivalent to those carried in the agricultural appropriation act itself.

For various reasons the appropriation act did not become law for several weeks after the termination of the preceding fiscal year. Following extended hearings, a bill carrying \$31,691,562 was reported from the House Committee on Agriculture on January 24, 1919, and passed by the House February 1. It was reported by the Senate Committee on Agriculture and Forestry February 22, but was among the group of appropriation acts which failed of enactment prior to the adjournment of the Sixty-fifth Congress on March 4.

Upon the reassembling of the Sixty-sixth Congress, the committees were reorganized, Hon. G. N. Haugen of Iowa succeeding Hon. A. F. Lever of South Carolina as chairman of the House committee, and Hon. A. J. Gronna of North Dakota succeeding Hon. T. P. Gore of Oklahoma as chairman of the Senate committee. On May 26, the new Agricultural Committee of the House reported **a** bill, identical in text with that formed by its predecessor except for some twenty amendments, most of which were of a minor nature. This bill was passed by the House June 4, and after further amend-

### EDITORIAL.

ment, by the Senate June 27. On July 1 it was presented at the White House, but on July 11 vetoed by the President because of an amendment which had been inserted repealing the so-called Daylightsaving Law. The veto was sustained by the House, and a third bill was introduced which became a law July 24. This act was identical with the vetoed measure except for the omission of the legislation regarding daylight saving and the inclusion of a clause amending the public land laws to assist settlers driven from their holdings in 1919 by drouth. Subsequently, a joint resolution was also enacted which validated obligations incurred by the Department during the interval between July 1 and the passage of the appropriation act.

Taking up the allotments of the various bureaus and offices in turn, by far the largest increase to any bureau is accorded the Bureau of Animal Industry, whose direct allotments rise from \$4,079,588 to \$5,783,231. Some of this increase is in lieu of emergency allotments of \$1,058,975, and the remainder is mainly for work with animal diseases and meat inspection. The usual additional appropriation of \$1,000,000, plus any unexpended balance remaining from the fiscal year 1916, to combat outbreaks of foot-and-mouth disease, rinderpest, and other infectious and contagious diseases of animals is also continued and supplements the total accordingly.

The largest single item of increase for the bureau is one of \$1,000,000 for payment of indemnities to owners of tuberculous animals in connection with the tuberculosis campaign, for which \$1,500,000 will be available. Cooperation is now under way with about forty States in this campaign, both the "accredited-herd" and "circumscribed area" systems of control being used. A slight change is made in the phraseology of the item to permit Federal payments for animals condemned in one State but shipped elsewhere for slaughter.

The fund available for tick eradication is \$741,980. The highwater mark of progress reached in 1917 was exceeded in 1918 with 79,600 square miles of territory released from quarantine, freeing the entire State of South Carolina and leaving under quarantine only 269,653 square miles. The subappropriation of \$50,000 for live stock and dairy demonstration work in cooperation with the States Relations Service is continued.

The allotment for inspection and quarantine work is increased from \$503,662 to \$525,000 because of an outbreak of sheep scabies in the Western States. On the other hand, the fund for dourine eradication is decreased by \$7,800 because of the progress obtained in the campaign against this disease. An apparent increase of \$194,195 for hog cholera work is in lieu of funds derived from the emergency act. There is an apparent increase from \$308,680 to \$327,680 for animal husbandry investigations, but actually a large reduction since \$544,-600 was carried in the emergency act. The allotment for the work of the Dairy Division, likewise somewhat curtailed, is \$350,370. The special appropriations of \$60,000 for experiments and demonstration with live stock production in cane-sugar and cotton districts, and \$40,000 for experiments in dairying and live stock production in semiarid and irrigated districts are continued unchanged.

The supplementary fund for meat inspection is increased from \$477,200 to \$903,960, making with the permanent appropriation already mentioned \$3,903,960 available for the purpose. Opportunity is given to increase the salaries of about 3,000 employees of the service and provision is made for over-time pay, the Governmentto be reimbursed for this by establishments receiving the inspection. Legislation is incorporated extending the meat inspection to equine meat and meat products, and authority is given to use \$100,000 in the inspection of this commodity. The Food and Drugs Act is also amended by specifically extending its net-weight provisions to wrapped meats included in papers or other materials as prepared by manufacturers for sale.

The appropriations for the Bureau of Plant Industry aggregate \$3,379,638 as compared with \$3,137,038 in the previous appropriation act and \$459,300 in the emergency act. The principal item to be increased is the Congressional seed distribution. This is continued under the usual plan, with an enlargement of funds from \$242,320 to \$358,980.

Provision is made for the establishment of a plant inspection and detention station of not to exceed fifty acres near Washington, in connection with the foreign seed and plant introduction, with an appropriation of \$50,000 for the purchase of land and erection of buildings. The allotment for horticultural investigations is increased from \$60,540 to \$73,340, this representing a transfer of a portion of the work carried on under the emergency act to stimulate the production in the South of second-crop potatoes. The studies of nut growing and utilization are segregated with an allotment of \$20,000. Authority is given to expend \$20,000 of the funds for pomological work in developing new grape industries and methods of utilizing grapes heretofore used for the production of alcoholic beverages.

Several increases are made for combating plant diseases. A new item allots \$50,000 for cooperation with the plant disease survey and inspection and control authorities of the States to combat flag smut of wheat, take-all, helminthosporium, and other soil and seed diseases of wheat and other cereals. Allotments of \$10,000 to combat sugar beet nematodes and \$20,000 for studies of the mottling disease of sugar cane discovered in Porto Rico are made in lieu of funds derived from the emergency act. An increase of \$5,000 is provided for studies of diseases of orchards and other fruits. On the other hand, the funds for the eradication of citrus canker are decreased from \$250,000 to \$196,320 because of the completion of the campaign in Georgia and South Carolina.

Several notable increases are made in the fund for combating insect pests. The Bureau of Entomology receives \$1,371,360 as compared with \$986,680 in the previous act, but a portion of this increase is in lieu of \$247,000 allotted the Bureau under the emergency act. The salary of the chief is increased from \$4,500 to \$5,000. Special allotments of \$250,000 and \$5,000, respectively, are made for two new pests, the European corn borer and the camphor thrip. The European corn borer, deemed the most dangerous insect pest of corn which has ever appeared in this country, is spreading very rapidly from the original point of discovery near Boston, Mass., and now occurs in dangerous numbers in an area of over 1,000 square miles. The campaign for its control is made cooperatively with the States concerned, Massachusetts having appropriated \$120,000, and New York \$100,000, for the purpose. Other increases are made in the allotments for studies of several other insect pests, including the sweet potato weevil, recently become a serious menace in portions of Georgia, Alabama, Mississippi, Louisiana, and Texas, the oriental fruit moth, and the Japanese beetle.

Additional provision for combating insect pests and diseases is made through the allotments to the Federal Horticultural Board, which receives \$129,000, an increase of \$54,200 over the previous year. This increase is mainly for the cooperative campaign against the very serious potato wart disease discovered in three counties of Pennsylvania. Legislation providing a Plant Quarantine Act for the District of Columbia was favorably recommended by both the House and Senate Committees, but eliminated in each house on a point of order.

The funds for the campaign against the pink bollworm of cotton are enlarged by \$100,000, to provide for the disinfection in specially constructed fumigation sheds on the Texas-Mexican border of freight, baggage, and other materials entering the United States from Mexico. A method has been worked out under which whole trains of cars may be effectively fumigated in these sheds, the cost of materials and labor being eventually defrayed by charges against the shipments disinfected.

The appropriation for the Bureau of Biological Survey is \$742,170 as compared with \$586,350 plus \$225,000 under the emergency act. The largest item of increase is \$75,000 for the enforcement of the Migratory Bird Treaty Act. The salary of the chief is increased from \$3,500 to \$4,000. The clause authorizing experiments and demonstrations in destroying wolves, coyotes, prairie dogs, and other animals injurious to agriculture and animal husbandry is amended to include gophers, and the appropriation enlarged to \$464,440. An allotment of \$34,600 is continued for the maintenance of the Montana National Bison Range and other game reservations, and a special appropriation of \$5,000 granted to improve the game preserve in Sullys Hill National Park in North Dakota. A new item in the act authorizes the Department to transfer surplus bison to municipalities and public institutions, and for purposes of propagation to make loans or exchanges with other owners of bison.

The appropriations for the Forest Service aggregate \$5,966,869, with \$600,000 additional for further purchases under the Appalachian Forest Reserve Act, and \$100,000 for cooperation with the States in fire protection under that act. The bulk of the appropriation is to be used in the administration, protection, and development of the National Forests, which it is of interest to note returned in receipts for the fiscal year 1918, \$3,574,930.07. Considerable readjustment is made in the allotments of the individual National Forests, including an aggregate increase of \$225,568 for additional fire protection. Net decreases of \$11,000 and \$20,000, respectively, are made in the allotments for land classification and the reconnoissance of forest resources, the former by reason of the completion of some of this work, and the latter because of difficulty in securing the necessary trained personnel.

The Bureau of Chemistry receives \$1,391,571. This includes several small increases in allotments, including \$50,000 additional for the enforcement of the Food and Drugs Act; \$29,280 to complete the equipment of the laboratory at the Arlington Experimental Farm for color investigations; \$5,000 for extending the studies with dressed poultry; and \$1,000 for those with fish, but several of these allotments are in lieu of considerably larger appropriations under the emergency act. Provision is made to continue the studies of utilizing wool waste and the manufacture of sweet sirups undertaken under that act, with allotments of \$9,000 and \$5,000, respectively. The cooperative food dehydration studies instituted last year are definitely assigned to the bureau, with \$50,000 appropriated to study and devise methods of dehydration and disseminate information as to the value and suitability of such products as food.

The aggregate appropriation for the States Relations Service is \$4,905,820, this including as usual \$1,440,000 for payments to the States under the Hatch and Adams Acts. In the preceding act \$3,150,820 was granted the Service, but this was well-nigh tripled

## EDITORIAL.

by \$6,100,000 from the emergency act, so that there is an actual decrease of \$4,345,000. This decrease is almost entirely in the allotment for demonstration and extension work, although there is also a net reduction of \$5,000 for the Office of Home Economics, which will receive \$46,280. The allotment of \$20,600 for the work with farmers' institutes and agricultural schools is continued unchanged.

The insular experiment stations are allotted \$215,000. This is an increase of \$25,000, of which \$10,000 is granted to the Alaska Stations, and \$5,000 each to those in Hawaii, Porto Rico, and Guam. In Alaska the increased funds will be used for the erection of cattle barns on the island of Kodiak, and the construction of a stock barn, clearing land for pasture, and purchase of breeding stock to undertake studies in dairying and pig raising at Matanuska; in Hawaii, for the further development of the demonstration and extension work; in Porto Rico, to stimulate the increased local production of many foods now largely imported from the mainland; and in Guam, to repair the ravages caused by a serious typhoon in July, 1918.

No change is made in the usual allotment of \$645,040 for farmers' cooperative demonstration work within the cotton belt, while that for the corresponding work in the remainder of the country is increased from \$554,800 to \$751,280. As a new item, an appropriation is made of \$1,500,000 for cooperative extension work to be allotted and expended under the same terms and with the same supervision as the funds derived from the Agricultural Extension Act of 1914. The funds thus provided represent an amount equivalent to that which will be available under the Extension Act at its maximum in 1922, and are to be expended in accordance with plans mutually agreed upon by the Department and the college officials.

By legislation contained elsewhere in the act, all moneys contributed for cooperative work by the Department must henceforward be paid only through the Secretary of Agriculture, or through State, county, or municipal agencies, local farm bureaus, or like organizations cooperating for the purpose with the Department. This provision was enacted because of previous legislation prohibiting after July 1, 1919, contributions to the salaries of any Government employee from non-Government sources for services performed by him for the Government. The Forest Service, however, is specifically exempted from the entire legislation on this subject.

The appropriations for the Bureau of Public Roads are continued without substantial modifications, the principal change being an increase in the salary of the chief from \$4,500 to \$6,000. The various lines of engineering activities are continued, including \$82,440 and \$73,760, respectively, for farm irrigation and drainage investigations,

125597°-19-2

and \$25,000 for studies of farm water supplies, drainage disposal, farm building construction, and similar problems. The total carried by the act is \$594,320, or slightly less than the \$600,000 now allowed the Bureau in the Federal Aid Road Act for administrative expenses under that act.

The funds for the Bureau of Markets, consisting last year of \$2,023,255 under the appropriation act and \$2,004,608 under the emergency act, are reduced to \$2,811,365. For general marketing and distribution studies there will be available \$317,520, a net increase of \$14,100 for cotton handling and marketing work. The market news service is continued with allotments of \$250,000 for fruits and vegetables; \$105,320 for live stock and meats; \$80,600 for dairy and poultry products; \$50,000 for grain, hay, feeds, and seeds; and \$12,000 for peanuts. The market inspection service is extended to include poultry, butter, and hay, \$150,000 being allowed for the purpose; and for investigations of the transportation, storage, preparation, marketing, manufacturing, and distribution of agricultural food products, \$48,800 is granted. There is a net increase of \$17,210 to extend cooperation with the States in marketing work, now under way in twenty-five States. For studies of cotton standards and marketing methods \$45,920 is again allotted, and \$86,050 is granted for the studies of grain handling, grading, and transportation. The allotment for studies of cooperation among farmers is decreased from \$28,280 to \$15,780.

Increased funds are provided to enforce the U. S. Cotton Futures and the U. S. Grain Standards Acts, the respective allotments being \$131,780 and \$598,600. For the enforcement of the Standard Container Act \$3,800 is granted, and for the U. S. Warehouse Act \$35,000. The latter act is amended in several particulars, with a view to securing its more general utilization.

A new section appropriates \$35,000 to enable the bureau to complete the work of the Domestic Wool Section of the War Industries Board. There is also an appropriation of \$75,000 to enforce the proclamations of the President in 1918 establishing a licensing system for the stockyards industry.

The Office of the Secretary receives \$803,110. Of this, \$302,590 is for the Office of Farm Management, substantially the amount carried in the preceding act for this Office. The salary of the chief is increased from \$4,000 to \$5,000, and a specific allotment of \$23,873 is made for use in ascertaining the cost of production of the principal staple agricultural products.

The work of the remaining branches of the Department is continued on substantially the present basis, both as to funds and as to lines of work. There is a reduction from \$1,912,930 to \$1,880,210 for the Weather Bureau, but this is due mainly to the completion of certain repairs to equipment and the termination of the frost protection studies in progress for several years.

The Bureau of Crop Estimates receives \$371,102, in lieu of \$346,-232 in the previous act and \$234,540 from the emergency act; the Bureau of Soils, \$491,235; the Division of Accounts and Disbursements, \$44,620; the Division of Publications, \$240,590, an increase of \$25,850; and the Library, \$50,160. For the enforcement of the Insecticide Act the Department is granted \$123,940; for demonstration work on reclamation projects, \$48,600; and for miscellaneous expenses, \$175,500. For rent of buildings in the District of Columbia \$100,000 is provided, in addition to \$41,509 allotted in the Sundry Civil Act. This is a reduction of \$17,180 from the previous year, because of the occupancy by the Department of space in some of the temporary buildings erected by the Government for the war emergency.

A specific appropriation of \$100,000 is granted to enable the Department to make exhibits at State, interstate, and international fairs. Of this amount not to exceed \$25,000 may be used in connection with the National Dairy Show at Chicago, and not over \$5,000 for any other one fair. The President is authorized to extend invitations to other nations to appoint delegates to the International Farm Congress at Kansas City in September, 1919, and the World Cotton Conference at New Orleans, October 13–16, 1919.

From the foregoing exposition it is hoped that a general idea of the prospective major activities of the Department during the present fiscal year may be obtained. It may be said, by way of summary, that provision has been made for most of what may be termed the routine activities of the Department; for the continuance, although in most instances on a reduced basis, of many of the projects instituted under the Food Production Act and supplementary legislation: and for notable increases in expenditures in several of the regulatory functions of the Department and in the combating of injurious insects and plant diseases. Attention should again be directed to the fact that the new appropriation act, though finally passed late in July, was originally formulated in January, and probably reflects as a whole conditions then prevailing rather than those operative today. None the less, it constitutes the first expression by Congress regarding the work of the Department since the cessation of hostilities, and in view of the universal desire for retrenchment in the enormous expenditures of the Government the action taken may well be regarded as significant of the country's appreciation of the Department and its proposed lines of development.

9

# **RECENT WORK IN AGRICULTURAL SCIENCE.**

# AGRICULTURAL CHEMISTRY-AGROTECHNY.

Recent advances in organic chemistry, A. W. STEWART (London and New York: Longmans, Green & Co., 1918, 3. ed., pp. XIX+350; rev. in Jour. Soc. Chem. Indus., 38 (1919), No. 5, p. 95R).—In the third edition of this book the author has adhered to the purpose of the earlier editions "to illustrate the principles upon which modern chemistry moves—not stands—and to undermine the conservatism which exists in all but strikingly original minds." The advances in organic chemistry since the last edition in 1910 have necessitated many changes and considerable additional material in the text. Among the new subjects are Willstätter's researches on chlorophyll and the anthocyanins, the recent processes for the synthesis of rubber, and certain theories bearing upon the synthesis of compounds in vegetable and animal organisms.

Commercial oils, vegetable and animal, with special reference to oriental oils, I. F. LAUCKS (*New York: John Wiley & Sons, Inc., 1919, pp. VIII+188*).— This book contains the technical data and information required in everyday dealings in the oil trade. Special attention has been given to the characteristics or constants of oriental oils which are now being imported at Pacific coast ports. Data on these, for the most part results of work in the author's laboratory, have been given separately from the average characteristics on account of variations in the same oil from different parts of the world.

The subject matter includes general properties of and tests for oils, descriptions with characteristics of a large number of vegetable and animal oils, a brief discussion of the uses of oils, and descriptions of various methods of sampling oils.

The rancidity of palm kernel and other feeding cakes, J. R. FURLONG (Jour. Agr. Sci. [England], 9 (1919), No. 2, pp. 137-142).—The amount of acidity developed under certain conditions in palm kernels, and in cake and meal made from them has been determined in comparison with other common feeding cakes, and the nature of the action investigated.

The results indicate that all of the feeding cakes studied contain a lipase which, under suitable conditions of moisture, acts on the fat liberating fatty acids. The degree of acidity, however, can not be taken as a measure of rancidity or as an index to the palatability of the cake. The rancidity which develops in the palm kernel and coconut cakes is thought to be due to the fact that the acids yielded on hydrolysis are the volatile acids of low molecular weight and unpleasant odor.

Contrary to the results of Calder (E. S. R., 35, p. 770), the author has found palm kernel lipase to be very resistant to heat, being capable of surviving to an appreciable extent four hours' exposure to a temperature of  $97^{\circ}$  C. in a moist state, or two hours' exposure at 120° in a dry condition. It is therefore considered impracticable to render the lipase inactive before leaving the factory, and the necessity is urged of keeping the palm kernel and other feeding cakes in a dry condition, in which state the lipase is unable to act. Lysin as a hydrolytic product of hordein, C. O. JOHNS and A. J. FINKS (Jour. Biol. Chem., 38 (1919), No. 1, pp. 63-66).—Analyses of hordein by the Van Slyke method are reported from the Bureau of Chemistry, U. S. Department of Agriculture. The average distribution of nitrogen corrected for solubility of bases was as follows: Amid N 23.85 per cent, humin N absorbed by lime 0.84, humin N in amyl alcohol extract 0.28, cystin N 0.81, arginin N 5.37, histidin N 3.63, lysin N 1.01, amino N of filtrate 49.35, and nonamino N of filtrate 14.20 per cent. The basic amino acids in percentage of total protein were cystin 1.18, arginin 2.82, histidin 2.27, and lysin 0.89. These results agree quite closely with those obtained by Osborne et al. on gliadin (E. S. R., 33, p. 867), but differ considerably from the earlier analyses of hordein reported by Osborne and Clapp (E. S. R., 19, p. 611) and Kleinschmitt (E. S. R., 20, p. 907), who isolated the basic amino acids by the direct method of Kossel and found no evidence that hordein contained lysin.

Comparative tests of palau and rhotanium ware as substitutes for platinum laboratory utensils, L. J. GUREVICH and E. WICHERS (*Jour. Indus. and Engin. Chem.*, 11 (1919), No. 6, pp. 570-573).—A detailed report is given of a series of tests conducted at the Bureau of Standards, U. S. Department of Commerce, to determine the suitability of "palau" and "rhotanium" (alloys of gold and palladium) as substitutes for platinum in laboratory ware.

"These tests indicate that rhotanium A ware is superior to platinum ware both of high (2.4 per cent) and low (0.6 per cent) iridium content in respect to its resistance to loss on heating. The losses on treatment with acid, after heating, are about equal. Grade A ware compares favorably with platinum in resistance to boiling hydrochloric acid, to boiling 20 per cent sodium hydroxid, and to fusion with sodium carbonate in a muffle, and with potassium pyrosulphate. It is superior to platinum in resistance to the action of boiling sulphuric acid, and inferior in its resistance toward boiling concentrated and dilute nitric acid, boiling 10 per cent ferric chlorid solution, and for fusions with sodium hydroxid. The only objection that may be raised to its use is the rather low melting point of the alloy, which makes it impossible to blast or strongly heat the ware without melting it.

"As far as resistance to loss in weight on heating to 1,200° C. is concerned, rhotanium C and palau wares are about equal, if not slightly superior, to platinum ware containing 0.6 per cent iridium... Palau and rhotanium C behave toward reagents in about the same way as rhotanium A, except that they are not suitable for potassium pyrosulphate fusions and are inferior to grade A for sodium hydroxid fusions....

"Palau and both grades of rhotanium may all be used to advantage in the electrolysis of chemical solutions, but only as cathodes. As anodes the alloys are worthless."

The effect of hydrogen-ion concentration on the liquefaction of gelatin, H. E. PATTEN and A. J. JOHNSON (Jour. Biol. Chem. 38 (1919), No. 1, pp. 179– 190, figs. 7).—Chemical and physical data, obtained at the Bureau of Chemistry, U. S. Department of Agriculture, are reported which indicate that "the setting of gelatin is influenced by the hydrogen-ion concentration of the medium, and unless the gelatin is destroyed this effect is probably reversible. Gelatin in the concentrations used is not without effect upon the buffer solutions, displacing the pH in such a manner as one would expect from an aggregate of amino acids acting amphoterically."

Colorimetric determination of the hydrogen-ion concentration in small quantities of solution, A. R. C. HAAS (Jour. Biol. Chem., 38 (1919), No. 1, pp. 49-55).—The preparation is described of a number of indicator papers covering the usual working range of pH and which can be used to determine rapidly and

with considerable accuracy the H-ion concentration of small quantities of solution. The indicators described are blue and red lacmoid papers, methyl orange paper with a range of pH of from 2.4 to 3.8, bromophenol (pH 3.4 to 4.6), alizarin sodium sulphonate (pH 4 to 6), neutral red (pH 7 to 9), and azolitmin (pH 6.2 to 8). It is considered advisable when dealing with very small volumes of solution to check the indicator paper determinations by the supplementary use of the spot plate method, in which the H-ion concentration is determined in a drop or two of the solution by comparison of the color produced by a certain indicator in the same quantity of buffer solution of known pH value.

With the described methods, it is considered possible to obtain a pH value differing 0.4 to 0.02 pH or even less from those obtained by the more exact methods.

The determination of iodid in mineral waters and brines, W. F. BAUGHMAN and W. W. SKINNER (*Jour. Indus. and Engin. Chem.*, 11 (1919), No. 6, pp. 563– 568).—The authors at the Bureau of Chemistry, U. S. Department of Agriculture, report an investigation of various methods for the determination of iodin in the presence of chlorid and bromid as a result of which the permanganate method is recommended as the most satisfactory, provided certain directions which are given in detail are observed. In regard to other methods the following conclusions are drawn:

"Distillation with potassium bichromate will not completely liberate iodin from iodids. Iodid in the presence of as much as 10 gm. sodium chlorid can be determined with satisfactory results by distilling with ferric sulphate.

"Iodid can be determined quite accurately in the presence of bromid by a single distillation with ferric sulphate if the quantity of bromid present in the sample does not greatly exceed 0.4 gm. This method is especially recommended for removing iodin from the sample which is to be used for the bromid determination.

"Iodin may be determined in the presence of large amounts of bromid by making a double distillation with ferric sulphate. However, this method is more tedious and time-consuming than the permanganate method, and the results obtained not quite so accurate."

Studies on the behavior of inulin in the animal body.—Application of the Benedict method to the estimation of levulose and inulin, R. OKEY (Jour. Biol. Chem., 38 (1919), No. 1, pp. 33-42).—The author reports a series of tests on the application to the estimation of levulose and inulin of the modification of the Lewis-Benedict method for sugar determination developed by Benedict and Osterberg (E. S. R., 39, p. 112). The method was found satisfactory for the determination of levulose and of levulose in the presence of inulin. Attempts to determine inulin quantitatively by hydrolysis with the picratepicric acid and colorimetric determination of the levulose in the same solution proved unsuccessful, owing to the formation of products which on heating, after the addition of the carbonate, gave colors increasing in depth with the time of heating in the acid solution and becoming more intense than those from equivalent quantities of levulose. An increase in depth of color was also produced when glucose and levulose solutions were heated with the acid picrate before the addition of the carbonate,

Hydrolysis of the levulin with hydrochloric acid led to a retardation of the rate of color development which was proved to be due to the salts formed by the neutralization of the acid. It was found that this interference may be avoided by increasing the time of heating with the carbonate to 15 minutes, or by using the higher concentration of the picrate-picric acid recommended by Benedict (E. S. R., 39, p. 112) for the determination of blood sugar. It is pointed out that this precaution must be taken in estimating the monosaccharids formed by acid hydrolysis of the more complex carbohydrates.

A system of blood analysis, O. FOLIN and H. WU (Jour. Biol. Chem., 38 (1919), No. 1, pp. 81-110 figs. 2).—A system of blood analysis, the starting point for which is a protein-free blood filtrate, is described in detail. The determinations, which include nonprotein nitrogen, urea, creatinin, creatin, uric acid, and sugar, are all conducted on the filtrate from 10 cc. of the blood.

The precipitation of the blood proteins is brought about by a new protein precipitant, tungstic acid, in the following manner: A measured amount of blood is transferred into a flask having a capacity of 15 to 20 times that of the volume taken and diluted with seven volumes of water. To this are added, by means of pipettes, one volume of 10 per cent sodium tungstate ( $Na_2WO_22H_2O$ ) and one volume of 2N/3 H<sub>2</sub>SO<sub>4</sub>. On shaking, the precipitation is complete within a few seconds. The precipitate can be removed by filtering or, if heated on a water bath for two or three minutes, by centrifuging. Filtration is recommended as safer for ordinary work. This precipitation process is said to work equally well with any kind of blood, and is considered by the authors to be superior to all former methods.

The nonprotein nitrogen determination is made with 5 cc. of the protein-free filtrate by the nesslerization process of Folin and Denis (E. S. R., 36, p. 316), with certain modifications in method of procedure and preparation of reagents.

In the urea determination direct nesslerization has been abandoned. For the hydrolysis of the urea, use has been made of jack bean urease or the autoclave, and for the isolation of ammonia, aeration or distillation. Any of the four combinations is said to give satisfactory results, using 5 cc. of the protein-free blood filtrate. The autoclave process is recommended chiefly when a large series of determinations is to be made, or when creatin is to be determined also, as the hydrolysis of the urea can then be accomplished simultaneously with the conversion of creatin into creatinin.

Folin's colorimetric method is employed for the determination of creatin and creatinin, using 10 cc. of the blood filtrate for preformed creatinin and 5 cc. for creatinin and creatin. One standard creatinin solution suitable both for creatinin and creatin determinations is made by transferring to a liter flask 6 cc. of the standard creatinin solution used for urine analysis, adding 10 cc. of normal hydrochloric acid, and making up to the mark with distilled water.

For determining uric acid a modification of the Folin-Denis-Benedict method has been developed which requires only 20 cc. of the blood filtrate (equivalent to 2 cc. of blood), and which is considered to be more dependable as well as more simple and convenient than the original method. The technique of the process is described in full, including the preparation of a new standard uric acid solution, the keeping quality of which is considered superior to any other as yet devised. The solvent is 10 per cent sodium sulphite, which tends to keep the solution free from dissolved oxygen.

Sugar is determined in 2 cc. of the blood filtrate by a new colorimetric method, involving the application of the phenol reagent of Folin and Denis to cuprous oxid obtained by the action of a weakly alkaline copper tartrate solution on the blood sugar. The color produced is said to be intense and stable.

Note on the determination of urea in urine by direct nesslerization, O. FOLIN and G. E. YOUNGBURG (*Jour. Biol. Chem.*, 38 (1919), No. 1, pp. 111, 112).— The authors state that, by using a urease preparation sufficiently free from nitrogenous materials, the urea nitrogen can be nesslerized without any charcoal treatment. The urease solution is prepared by washing 3 gm. of permutit once with 2 per cent acetic acid and twice with water, adding 5 gm. of fine jack bean meal and 100 cc. of 30 per cent alcohol, shaking gently but continuously for ten minutes, and filtering. The filtrate, which is said to contain practically the whole of the urease and but little other material, is used in amounts of 1 cc. for 1 cc. of diluted urine (1:10) and the digestion and nesslerization conducted as usual, employing the Nessler reagent described in the article noted above.

A rapid method for the estimation of urea in urine, J. B. SUMNER and A. BODANSKY (Jour. Biol. Chem., 38 (1919), No. 1, pp. 57-61).—The method, which is said to be rapid, accurate, and simple, consists essentially in treating a small quantity of urine in a centrifuge tube with an approximately neutral phosphate solution and with urease. After the urea has been decomposed a protein precipitant (acidified potassiomercuric iodid solution) is added, the tube centrifuged, and an aliquot of the clear supernatant liquid nesslerized and compared wth a standard. The preparation of reagents and method of procedure are described in detail.

The proximate analysis of wood, W. H. DORE (Jour. Indus. and Engin. Chem., 11 (1919), No. 6, pp. 556-563).—This preliminary report of a study conducted at the California Experiment Station on the chemistry of certain California woods from the standpoint of their chemical utilization, deals with the analytical methods employed and results obtained in a complete proximate analysis of these woods. The analyses included determination of loss on drying, extractives soluble in benzene, extractives soluble in alcohol, substances soluble in water, substances soluble in 1 per cent sodium hydroxid solution, cellulose, and lignin. The woods studied were redwood, yellow pine, live oak, and blue gum.

Sawdust was found to be the most satisfactory mechanical condition of wood for analytical purposes. Cellulose was determined by a modification of the Cross and Bevan method involving chlorination in vacuo, and lignin by König's method with 72 per cent sulphuric acid.

In the analysis of coniferous woods by these methods 96 to 97 per cent of the wood constituents were accounted for, while in the case of the hardwood examined the lignin determinations failed and only from 83 to 91 per cent of the wood constituents were obtained.

Nitrating of woodpulp cellulose, S. D. WELLS and V. P. EDWARDES (*Paper*, 23 (1919), No. 23, pp. 180-185, fig. 1).—The authors report an investigation conducted at the Forest Products laboratory, U. S. Department of Agriculture, on the utilization of woodpulp as a source of nitrocellulose. The determination of yields from laboratory nitrations indicated that under favorable conditions a yield of 150 per cent nitrocellulose would be obtained from woodpulp, with a corresponding yield of from 160 to 165 per cent from cotton. The pyro grains from both soda and sulphate pulps prepared from jack pine were dark brown, but the nitrocellulose from unbleached sulphite was as light colored as that from cotton, having lost the yellow coloration from nitration in the boiling and poaching treatments. The products from all the pulps studied met the laboratory tests for completeness of washing, stability, and purity of product.

The factory runs on the woodpulps seem to indicate the suitability of woodpulp properly manufactured for the production of nitrocellulose.

Studies on canning.—An apparatus for measuring the rate of heat penetration, W. T. BOVIE and J. BRONFENBRENNER (Jour. Indus. and Engin. Chem., 11 (1919), No. 6, pp. 568-570, figs. 5).—The apparatus described was devised to find the rate of transfer of heat from the outside toward the center of cans of food during the process of cooking and sterilization, as affected by the variations of the autoclave temperature, size of can, viscosity of the food, etc., such as are encountered by the commercial canner.

The apparatus consists of a constant thermojunction, which is maintained at the temperature of the autoclave and is located just outside the can. The actual temperature of this junction is obtained from the readings of a thermograph, the bulb of which is placed close to the constant junction. Connecting the thermograph bulb with the recording clock is a capillary tube which is led out of the autoclave through a suitable steam-tight joint. Connected with the constant junction is a series of variable junctions located in different parts of the cells and joined through a cable of wires to a galvanometer outside of the autoclave, which records all differences in temperature. The apparatus, which is illustrated diagrammatically and described in detail, is said to give very satisfactory results.

The bacteriology of canning (*Kansas Sta. Rpt. 1918, p. 49*).—An investigation of methods of canning vegetables is reported, the results of which indicate that blanching does not aid in the sterilizing process, proper sealing aids greatly in preventing spoilage of canned foods, salt, except in amounts too large to be allowable, is of little value, and small amounts of acetic acid (vinegar) are of value in preserving canned vegetables.

Saving raisins by sulphuring, F. T. BIOLETTI and A. E. WAY (California Sta. Circ. 211 (1919), pp. 4, figs. 3).—This circular describes a sulphuring hood to be used in sulphuring raisins as soon as they are stacked after rain. The hood, consisting of a wooden frame covered with building paper, when made from the specifications given will cover about 26 trays in two stacks and is said to be easily handled by two men. A pan containing about 0.5 lb. of sulphur is placed on the ground between the two stacks. After igniting the sulphur, the hood is placed over the stacks and a little soil is shoveled around the base to make it air-tight. The time during which the grapes must be subjected to the fumes of sulphur dioxid has not been determined, but is thought to be between 5 and 35 minutes.

It is said that by the use of this method the cost of stacking is much reduced, and that even in the wettest and most unfavorable season the crops are not lost.

**Potato drying**, J. RUTISHAUSER (*Die Kartoffeltrocknung. Bern*, *Switzerland: Ferd. Wyss*, 1918, pp. 51).—A brief description is given of the potato-drying industry in Germany, and suggestions are made for the establishment of such industries in Switzerland.

# METEOROLOGY.

Introductory meteorology, W. J. HUMPHREYS ET AL. (New Haven: Yale Univ. Press, 1918, pp. XII+150, pls. 19, figs. 50; rev. in Nature [London], 103 (1919), No. 2581, pp. 123, 124).—This book was prepared and issued under the auspices of the Division of Geology and Geography, National Research Council, for use in "the course of study outlined by the Committee on Education and Special Training of the War Department for Students' Army Training Units." The plan "involves an intensive study of the elements of the subject," but "the book is not intended to be elementary in the sense that it needs no study on the part of students or elaboration and explanation by the instructor."

The relation between evaporation and the area of the evaporating surface, W. GALLENKAMP (*Met. Ztschr. [Brunswick*], 36 (1919), No. 1-2, pp. 16-22, fig. 1).—Observations are recorded which show that in all cases the rate of evaporation decreased with an increase in the extent of the evaporating area. The decrease in evaporation, however, was not directly proportional to the increase in surface, being greatest with the first increase in surface and declining with subsequent increases.

Climate formula and reduced rainfall, W. KÖPPEN (*Met. Ztschr.* [*Brunswick*], 36 (1919), No. 1-2, pp. 1-7).—The author explains a formula which is proposed as a convenient method of briefly designating the climate of a particular place.

The bioclimatic law as applied to entomological research and farm practice, A. D. HOPKINS (*Sci. Mo.*, 8 (1919), No. 6, pp. 496-513, figs. 3).—This law, as explained in an article previously noted (E. S. R., 39, p. 317), is defined and certain of its applications discussed.

It is stated that "we have in the so-called bioclimatic law of latitude, longitude, and altitude an example of a natural law which represents the general laws of climate as affecting the seasonal activities and geographical distribution of land-inhabiting species of plants and animals, periodical practice in agriculture, and the adaptation of farm crops to the requirements of climatic conditions. The law is founded on the determined country-wide average rate of variation in the time at which periodical events occur in the seasonal development and habits of plants and animals at different geographical positions within the range of their distribution. Other things being equal, this variation is at the rate of four days for each degree of latitude, 5° of longitude, and 400 ft. of altitude." Isophanal maps of the United States, constructed on this basis, are shown and discussed.

It is claimed that having "the date of a periodical event or practice at an established base in any given season we can, by means of the time constants of the law and their equivalents in latitude, longitude, and altitude, compute a corresponding date constant of the same event for any other place within the range of the species or periodical practice involved. Or, having determined for any section of the country the upper or northern limit in the geographical distribution of a native or introduced species or variety of animal or plant, the corresponding limit constants for altitude or latitude can be computed for any other section; and having determined also the lower or southern limit, the altitude and latitude constants can be worked out for the possible geographical range in which the species or variety, under its other environmental requirements, would survive and thrive."

The applications of the law to entomological research are illustrated in the cases of the southern pine bettle, the western pine beetle, the mountain pine beetle, the pine bark louse, the hatching of Chermes on Pike's Peak, and the Hessian fly.

Among the problems in farm practice which have a direct relation to the bioclimatic law, the following are briefly discussed: "(1) Seedtime and harvest, as applied to a wide range of farm, garden, and truck crops, and as adapted to the varying climatic conditions which prevail from the lowest to the highest latitudes and altitudes and from eastern to western longitudes of the United States, (2) the application of remedies against insect pests and plant and animal diseases, [and] (3) the selection of varieties of domestic animals and cultivated plants and the types of agriculture best adapted to regional and local conditions of soil, climate, etc."

A soil temperature survey of the United States and Canada (Sci. Amer., 120 (1919), No. 19, p. 481).—It is announced that a committee of the Ecological Society of America has organized a soil temperature survey of the United States and Canada.

"The present plan is to carry on observations at various places for a number of years under identical conditions. Upwards of 30 stations are now in operation. Thermograph records are obtained for thermometer bubbs placed at the same depth (3 in, below the ground at all stations with additional readings at 12 in, at certain stations), in level, well-drained soil, free from the shade of trees or buildings, and under a ground surface kept free from sod or weeds, but without continuous cultivation. It is hoped that the data obtained will make it possible eventually to draw isotherms for the soil of the United States and Canada analogous to those that have been drawn for the air over the same ccuntries."

The climate of Utah, F. L. WEST and N. E. EDLEFSEN (Utah Sta. Bul. 166 (1919), pp. 3-66, figs. 48).—Weather and climate are defined and the various influences and effects of climate are discussed. How weather observations are recorded and forecasts are made are also explained. "The type of climate peculiar to Utah and the configuration of its land surface are discussed; also the areas devoted to the different kinds of agriculture and to the leading industries of the State. The State is divided into climatic zones and a general discussion of each made. Charts showing the distribution of population, the value of the farm land in different sections, and the areas that are irrigated, are inserted. . . . For the principal town of each county, the following data are presented by means of a chart: The precipitation for each year of the record, the mean monthly amount of precipitation, the duration of the growing season for each year, the occurrence of summer rains, and the leading agricultural products. . . . The means and extremes are [also] given with a very brief discussion. A table containing data on precipitation, temperature, and frost for the entire State by towns is inserted."

[Weather reports for 1917], C. C. GEORGESON ET AL. (Alaska Stas. Rpt. 1917, pp. 5, 34, 35, 59-61, 72, 73, 90-96).—Tabular summaries are given of observations on temperature, precipitation, and cloudiness at 25 Weather Bureau stations in Alaska, and the character of the season, with special reference to crop growth and agricultural operations, at the Sitka, Rampart, Fairbanks, and Kodiak Stations is discussed.

Meteorological observations, J. S. STEVENS (*Maine Sta. Bul.* 275 (1918), pp. 235, 236).—A monthly and annual summary of observations at the University of Maine on temperature, precipitation, cloudiness, and wind movement during 1918 is given. The mean temperature for the year was  $42.99^{\circ}$  F., as compared with an average of  $42.75^{\circ}$  for 50 years; the total precipitation was 37.97 in., the snowfall 95.75 in., the number of clear days 210, the number of cloudy days 73, and the total movement of wind 45,013 miles.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. OSTRANDER and A. L. CHANDLER (*Massachusetts Sta. Met. Buls. 363-364* (1919), pp. 4 each).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during March and April, 1919, are presented. The data are briefly discussed in general notes on the weather of each month.

# SOILS-FERTILIZERS.

Soil survey of Montgomery County, Iowa, A. M. O'NEAL, JR., and L. L. RHODES (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1917, pp. 30, fig. 1, map 1).—This survey, made in cooperation with the Iowa Experiment Station, deals with the soils of an area of 271,360 acres situated in the southwestern part of the State. The topography is prevailingly rolling, with conspicuous broad, nearly level bottoms along the streams. The elevations range from 1,000 to 1,260 ft. above sea level, and the area is said to possess excellent natural drainage.

The soils of the county are largely derived from the Missouri loess and are quite uniform in both color and texture. Six soil types, representing 5 series, are mapped. Marshall silt loam and Wabash silt loam, occupying 66.1 and 27.1 per cent of the total area, respectively, predominate.

Soil survey of St. Martin Parish, La., A. H. MEYER and B. H. HENDRICKSON (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1917, pp. 32, fig. 1, map 1).—This survey deals with the soils of an area of 442,880 acres situated in the southern part of the State and lying wholly within the region of alluvial soils. The topography is prevailingly flat and natural drainage is rather sluggish.

The soils of the region comprise upland, low terrace, and first bottom alluvial deposits, the latter comprising about 70 per cent of the whole. Exclusive of peat, 11 soil types of 6 series are mapped, Sharkey clay, occupying 71.8 per cent of the total area, predominating.

Soil survey of Mahoning County, Ohio, M. W. BECK and O. P. GOSSARD (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1917, pp. 41, fig. 1, map 1).—This survey, made in cooperation with the Ohio Experiment Station, deals with the soils of an area of 273,280 acres situated in the northeastern part of the State, bordering the State of Pennsylvania. The topography of the region is gently undulating to rolling, and the average elevation is about 1,000 ft. above sea level. Natural drainage is fairly well established, but is said to be insufficient in many localities for the best results in farming.

The soils of the county include upland soils composed of reworked glacial material, terrace or old alluvial soils laid down as glacial outwash plains or old stream flood plains, and first-bottom or recent alluvial soils. In addition to muck, 19 soil types representing 12 series are mapped. Volusia silt loam, Canfield silt loam, and Mahoning silt loam, occupying 26.8, 20, and 19.8 per cent of the total area, respectively, predominate.

Sandy soils and how to farm them, A. R. WHITSON and H. W. ULLSPERGER (*Wisconsin Sta. Bul. 299 (1919), pp. 26, figs. 8*).—This describes in a rather popular manner approved methods of crop production on the sandy soils of Wisconsin. It is stated that approximately one-fifth of the area of the State (6,000,000 acres) is classed as sandy loam, fine sand, and sand. The correction of acidity, the addition of humus, and the judicious use of fertilizers are regarded as the principal factors in the improvement of these soils, while spring plowing, the planting of windbreaks, the growing of cover crops, and the use of a corrugated roller tend to protect the soil. Soy beans and clover seed are regarded as the best cash crops, while alfalfa, vetch, buckwheat, sweet clover, serradella, wheat, barley, oats, cowpeas, potatoes, and corn require special consideration when grown on sand. Garden crops are said to give good results.

The "slick spots" of middle western Idaho with suggestions for their elimination, P. P. PETERSON (*Idaho Sta. Bul. 114* (1919), pp. 3-11, figs. 3).— The nature of these spots is briefly described and studies of their chemical and physical properties discussed in an effort to ascertain the factors underlying their formation. It is stated that the characteristics which render these areas unproductive are their impermeability to water and their impenetrability to plant roots. The conclusion is reached that this condition is due largely to the cementing action of calcium carbonate which is present in greater quantities than in adjacent good soils, this cementing action having occurred when calcium was deposited from solutions in the soil.

Heavy applications of barnyard manure are held to be the most effective means for overcoming the physical defects of these spots, through the solvent action on the calcium compounds of the decomposing humus with a consequent flocculation of the soil particles. The use of green manure crops is also recommended. Gypsum applied at the rate of from 300 to 400 lbs. per acre before fall plowing is deemed worthy of trial as a mineral flocculent, while burned lime is regarded as of value for small areas.

The value of legumes on Indiana soils, A. T. WIANCKO, S. D. CONNEE, and S. C. JONES (Indiana Sta. Bul. 226 (1919), pp. 19, figs. 6):—Based on results secured on the station farm and on outlying experiment fields, it is concluded that from 25 to 50 per cent of the nitrogen and humus of the soil of the State has been used up or lost by the cropping systems employed, and that the increased growth of legumes is the easiest and most economical method of restoring nitrogen and organic matter to run-down soils. As an average for 61 crops grown on 8 experiment fields during the last 12 years, crop rotations containing legumes produced 4.6 bu. of corn and 4.7 bu. of wheat per acre more than rotations in which no legumes were grown. Factors contributing to successful clover production are indicated and the use of soy beans or cowpeas recommended when clover fails.

The continuous growing of wheat and rye with and without a legume as green manure, 1917, J. G. LIPMAN and A. W. BLAIR (*New Jersey Stas. Rpt.* 1917, pp. 350-352).—In the continuation of work previously noted (E. S. R., 39, p. 725), further observations have been made upon the effect upon the nitrogen supply of the soil of growing a legume between the main crops of a rotation.

Wheat and rye grown alone have produced at the rate of 7.33 and 13.67 bu. of grain and 780 and 1,720 lbs. of straw per acre, containing 14.44 and 24.94 lbs. of nitrogen, respectively. Wheat followed by soy beans as a green manure crop produced 12.33 bu. of grain and 1,420 lbs. of straw, containing 28.78 lbs. total nitrogen. Under similar conditions rye produced 14.33 bu. of grain and 2,760 lbs. of straw, containing 34.7 lbs. total nitrogen.

H-ion concentrations in extracts of peat soils and of peat- and humusforming plants, H. KAFPEN and M. ZAFFE (Zentbl. Agr. Chem., 47 (1918), No. 7, pp. 193-197; abs. in Physiol. Abs., 3 (1919), No. 11, p. 583; Chem. Abs., 12 (1918), No. 19, p. 2035).—Continuing work previously noted (E. S. R., 37, p. 623), observations are described on samples of soils taken at different depths ranging from 0 to 165 cm. (about 64.4 in.), of the subsoil below 165 cm., and of cultivated peat soil receiving different fertilizer treatments, together with samples of fresh sphagnum, and pine and spruce needles. Extracts were prepared by treating 10 gm. of the material for 2 hours with 200 cc. of either water, normal potassium chlorid solution, or a 10 per cent calcium acetate solution. The water extracts were slightly yellowish in color, while the other extracts were colorless. The titratable acidity and the H-ion concentration were determined in each case. Observations were also made on the conductivity of the aqueous solutions and the air-dry and the ignited residues determined.

It is concluded that soluble acids were present in the peat soil in traces only, since the H-ion concentration but slightly exceeded that corresponding to the neutral point. The power of these soils to decompose neutral salts is thought to be due to an exchange of ions rather than to the liberation of free acid. The H-ion concentration of aqueous extracts of peat- and humus-forming plants was generally high and the true acidity marked.

The value of ammonification test, J. C. TEMPLE (Georgia Sta. Bul. 126 (1919), pp. 3-18).—Observations on the ammonifying efficiency, ammonifying inoculating power, and ammonifying capacity of different soils subjected to various treatments have led to the conclusion that the ammonification test is of little value in ascertaining the nature of the soil microflora, because (a) the rate of ammonia production is largely controlled by the soil medium, (b) all soils are well supplied with bacteria capable of changing nitrogen into

ammonia if the soil is made a suitable medium, and (c) the test as usually conducted fails to account for considerable amounts of ammonia which may escape into the atmosphere or are converted into nitrate or nitrite. It is stated, however, that the test can probably be employed by the soil chemist or physicist to determine soil fitness.

Ammonification of manure in soil, H. J. CONN and J. W. BRIGHT (Jour. Agr. Research [U. S.], 16 (1919), No. 12, pp. 313-350).—This contribution, from the New York State Agricultural Experiment Station, supplements previously reported investigations (E. S. R., 37, pp. 516, 517) and deals mainly with the results of a detailed laboratory study of two of the most easily recognized types of nonspore-forming organisms which are especially active as ammonifiers in freshly manured soil, namely, *Pseudomonas fluorescens* and *Bacillus caudatus*, renamed *P. caudatus*. The first part of the paper "shows the predominance of these two organisms in manured soil and gives the results of an investigation of their function in soil. The second gives a detailed description of the two organisms to aid in their identification by others."

The results confirmed previous conclusions that the nonspore-forming bacteria are the most active ammonifiers in manured soil. "Pure cultures of *P. fluorescens* and *P. caudatus* multiply much more rapidly in sterilized manured soil than do pure cultures of *B. cereus* (selected as a typical spore former). When sterilized manured soil is inoculated with a mixture of these three organisms in pure culture, the two nonspore formers immediately gain the ascendency, *B. cereus* occurring in too small numbers for detection by the ordinary methods of study.

"In field soil to which there has been no addition of organic matter for several years, *P. fluorescens* and *P. caudatus* were rarely found, while *B. cereus* was a common organism. When this same soil was mixed with manure and potted, *P. fluorescens* and *P. caudatus* immediately multiplied rapidly, while but small numbers of *B. cereus* spores and no active forms of *B. cereus* could be found.

"All three of these organisms are vigorous ammonifiers when tested in pure culture. The activity of the nonspore formers and the absence of activity of the spore formers in unsterilized manured soil leads to the conclusion that *P. fluorescens* and *P. caudatus* are important ammonifiers of manure in soil, while there is no evidence that *B. cereus* takes part in this process.

"Detailed descriptions are given of the two ammonifying organisms studied. The culture of *P. fluorescens* studied has been compared with other fluorescent bacteria isolated from soil, and a review of the literature relating to fluorescent bacteria has been made. It has not proved possible to fix definite limits for this species. *P. caudatus* is the name now assigned to the organism previously denoted by one of the writers as the 'orange-liquefying type.' It is apparently identical with the organism described by Wright in 1895 and seems to be quite common in soil and water."

A list of 54 references to literature cited is given.

Preservation of nitrogen in liquid manure, VOGEL (Zentbl. Agr. Chem., 47 (1918), No. 7, pp. 201-203; abs. in Chem. Abs., 13 (1919), No. 3, p. 244).—It is stated that sodium acid sulphate used at the rate of 40 kg. per cubic meter (about 67.7 lbs. per cubic yard) is the best chemical agent for preventing loss of nitrogen from liquid manure, material treated in this manner having given excellent results in tests on meadow land and with rye, potatoes, and beets. To avoid the caustic effects of the acid sulphate it is recommended that an equal amount of gypsum be used in combination with it. The use of from 1 to 2 per cent of a solution containing formaldehyde and phenol resulting as a by-product of the Bakelite industry prevented the loss of nitrogen from urine without any subsequent injury to germination.

The science and practice of manuring, W. DYKE (London: The Lockwood Press (1918), rev. and enl., pp. [2]+157+[3]; rev. in Nature [London], 102 (1919), No. 2573, p. 485).—This is a revised and enlarged edition of this work, which treats the subject from the standpoint of the commercial horticulturist and is based to a large extent upon the successful practical experience of the author.

[Report of soil fertility work in Massachusetts], E. F. GASKILL (Massachusetts Sta. Rpt. 1917, pp. 21a-32a) .-- Noting the progress of work previously mentioned (E. S. R., 38, p. 218) this comprises a report on comparative tests of barnyard manure, nitrate of soda, sulphate of ammonia, and dried blood in various fertilizer combinations, with and without lime, on Green Mountain potatoes; muriate v. high-grade sulphate of potash on alfalfa, blackberries, currants, gooseberries, mangels, rhubarb, raspberries, and soy beans; manure and various combinations of chemical fertilizers on asparagus and tomatoes, and on both limed and unlimed beets and onions; different forms of potash, including kainit, high- and low-grade sulphate, muriate, nitrate, carbonate, and treater dust on Early Canada Flint corn; various kinds of phosphates, including Arkansas, South Carolina, Florida soft, and Tennessee rock phosphate, slag, dissolved bone black, raw bone, dissolved bone meal, steamed bone, and acid phosphate on Medium Green soy beans; a fertilizer mixture high in potash (160 lbs. of muriate per acre) and low in phosphoric acid v. one without potash and high in phosphoric acid for corn; various fertilizer treatments used continuously, alone and in different combinations on cabbage, both limed and unlimed; different combinations of fertilizers used continuously with lime on corn; different systems of top-dressing meadows; and sulphate of ammonia v. nitrate of soda as a top-dressing for permanent meadows.

Potatoes grown on the limed area produced scabby tubers in every case, amounting to 75 per cent in one instance, while only two of the unlimed plats showed any scab, the injury amounting to about 10 per cent in each case.

Top-dressing permanent meadow with barnyard manure has resulted in an average yield of 6,006 lbs. of hay per acre as compared with 5,824 lbs. from an application of bone and potash, and 5,496 lbs. from slag and potash (formerly wood ashes). No potash was applied in 1916 and 1917. The omission of potash on a permanent meadow usually receiving complete chemical fertilizers was accompanied by a normal crop of hay in 1916, a favorable season for hay production, but by a crop much below normal in 1917, an unfavorable season.

Experiments in fertilizing a crop rotation, T. L. LYON (New York Cornell Sta. Bul. 399 (1919), pp. 19-30).—In connection with experiments previously noted (E. S. R., 30, p. 829), in which all the farm manure or commercial fertilizers were applied to timothy in a rotation comprising three years of timothy followed by corn, oats, and wheat, a new series of tests is described, in which a comparison was made of this practice with that of fertilizing the grain alone. The soil upon which the tests were made is said to be particularly well adapted to timothy, less so to small grains, and poorly suited to corn, although its natural fertility is high. Observations were also made on the effect of withholding potash from the fertilizer mixture for grass as compared with the use of a moderate amount. The results are presented in tabular form, together with data showing the estimated value of the crops based both on prewar prices and on prices as of July 1, 1918.

It is concluded that a moderate quantity of a complete commercial fertilizer applied during each of the three years the land was in timothy was more profitable than a somewhat similar fertilizer applied to corn, oats, and wheat. The application of 5 tons of farm manure per acre to each of three timothy crops also proved to be more effective than an application of 15 tons to corn alone. Doubling the amount of manure applied to both grass and corn resulted in increased yields of crops, but not in proportion to the cost of the treatment. The use of potash in conjunction with sodium nitrate and acid phosphate on grass appeared to be profitable at prewar prices.

A brief outline of the technical procedure followed in conducting the experiments is appended.

Experiments with various nitrogenous fertilizers, E. A. MITSCHERLICH, S. VON SAUCKEN, and F. IFFLAND (*Jour. Landw.*, 66 (1918), No. 3, pp. 187–198, pl. 1, fig. 1).—Sand culture experiments with oats conducted during 1917 and 1918 are described, in which observations were made upon the relative value of different nitrogen carriers, with particular reference to urea and urea nitrate. The fertilizers were applied in varying amounts, both before seeding and onethird at the time of seeding, with the remainder as a top-dressing, one-half being applied upon the formation of the fourth leaf and one-half upon the appearance of the panicle. The yields of grain and straw are presented in tabular form.

The conclusion is reached that both urea and urea nitrate are as effective as the usual nitrogen carriers (sodium nitrate, calcium cyanamid, ammonium sulphate, and ammonium nitrate), and that urea nitrate may be used to advantage for top-dressing.

The influence of the mechanical composition of the soil on the availability of nitrate of soda and dried blood, J. G. LIPMAN and A. W. BLAIR (*New Jersey Stas. Rpt. 1917, pp. 335–350, pls. 2, figs. 3*).—Further observations (E. S. R., 39, p. 726) on the relative availability of nitrate of soda and dried blood to barley and a residual crop of buckwheat when applied in equivalent amounts to cylinders containing shale soil and different mixtures of shale and sand have led to the following conclusions:

For all soil combinations the average recovery of nitrogen from nitrate of soda by the main crop was 60.53 per cent and from dried blood 30.98 per cent. With the buckwheat the average recovery of nitrogen was 2.47 per cent for the nitrate and 10.57 per cent for the dried blood cylinders. The dried blood showed an availability of 68.2 on the basis of 100 for the nitrate.

"From these results, and likewise from the results secured for a period of years, it is quite clear that nitrate of soda can not be counted on to show much residual effect. Dried blood, on the other hand, does show some residual effect on both heavy and light soils. However, the initial effect of the nitrate is almost always sufficiently above that of the blood to place the former in first rank when the combined crops—that is, the first crop and the residual crop are taken into consideration. A pound of nitrate nitrogen produces more dry matter than a pound of dried blood nitrogen, and therefore, in most cases, is worth more.

"The nitrogen of the soil organic matter is more completely utilized in a light soil than it is in the heavier types."

The present status of nitrogen fixation, A. H. WHITE (Jour. Indus. and Engin. Chem., 11 (1919), No. 3, pp. 231-237, figs. 3; Sci. Amer. Sup., 87 (1919), No. 2264, pp. 330, 331, fig. 1).—The present status of the development of the arc, cyanamid, nitride, direct synthetic ammonia, and cyanid processes is reviewed. Diagrams are given showing the world's production and consumption of fixed inorganic nitrogen (including Chilean nitrate).

Production doubled from 1909 to 1917, largely as a result of the great demand for nitrogen compounds in munitions making. There was, however, no greater increase in production during the war than in the period immediately preceding it. "The year 1917 shows no increase from Chilean nitrate, in spite of the urgent demands of the Allies for greater supply. This was partly due to lack of ships. The greatest increase . . . for the period 1909–1913 is shown by the by-product coke ovens. In 1917 the increase was mainly due to the cyanamid and Haber processes, so that in this year the world's supply came almost equally from the three sources, Chilean nitrate, coke ovens, and synthetic, the cyanamid process being the most important in the latter group, with the Haber second."

It is thought that the rapid rate of increase indicated for the period 1909–1913 is not likely to continue. "The largest demand for fixed nitrogen in the future will probably be for fertilizers, and the use of fertilizers will be very largely a matter of price. . . If all the resources of Chile and all the facilities in the way of coke ovens now under construction and fixation plants should be utilized, the year 1920 might well see a possible production of 25 per cent more than 1917. . . .

"The cheapest source of fixed inorganic nitrogen will undoubtedly be the ammonia from by-product coke ovens because it is a by-product and the cost of collecting and putting it into marketable form is small. The coke ovens of the world can now produce more fixed nitrogen than the world used from all sources 10 years ago. It will be a powerful factor tending toward low prices. It is probable that Chilean nitrate could, if necessary, be sold at lower prices than in former years. The fixation processes will therefore have to be prepared to meet possible low prices if they are to be ranked as anything more than emergency reliances."

The phosphate-rock industry in 1918 (U. S. Geol. Survey Press Bul. 411 (1919), p. 2).—It is stated that the production of rock phosphate in the United States in 1918 was 2,490,760 long tons valued at \$2,14,463, as compared with 2,584,287 tons valued at \$7,771,084 in 1917. Florida land pebble constituted 80 per cent of the total output. There was, however, a small decrease in production of land pebble, but a considerable increase in Florida hard and soft phosphates. The production of phosphate in South Carolina increased about 11 per cent in 1918, but that of Tennessee and Kentucky was about 27 per cent less and of the Western States 20 per cent less.

Vegetation experiments on the availability of phosphorus and potassium compounds, J. G. LIPMAN and A. W. BLAIR (*New Jersey Stas. Kpt. 1917, pp.* 353-368).—In continuation of work previously noted (E. S. R., 36, p. 820) further observations made during 1916 and 1917 on the relative availability of various phosphorus carriers for soy beans grown in pot tests are recorded, together with a report on similar tests made during 1917 with greensand marl as a source of potash for different crops. The results secured may be summarized as follows:

With soy beans grown in coarse white sand, basic slag as a source of phosphorus gave about as good yields as acid phosphate, while under the same conditions blue rock phosphate yielded only slightly more than the check, and brown rock somewhat better than the blue rock. The average percentage of nitrogen in the dry matter (soy bean hay) was about the same with basic slag as with acid phosphate, but was distinctly and uniformly less with raw rock and where no phosphate was used.

On coarse white sand, with greensand marl as a source of potash, barley and buckwheat gave greatly increased yields over the checks, while on a coarse yellow sand containing 1.09 per cent total potash ( $K_2O$ ) oats and buckwheat gave very fair yields without potash treatment, and applications of marl did not appreciably increase the yields. On the same soil, barley showed a slight increase over the check for the marl treatment. On both the white and yellow

125597°-19-8

sand, soy beans, when inocculated and supplied with available phosphates and lime gave practically as good yields on the checks as on the marl-treated pots up to the time the pods were about one-half filled, although when allowed to mature there was an appreciable falling off in the yield of seed on the check pots, the yield of stalks being about the same on the check pots as on the treated pots. Dry matter (soy bean hay) from check pots and from marl-treated pots contained quite as high a percentage of nitrogen as that from pots treated with a soluble potash salt ( $K_2SO_4$ ). The amount of potash in dry matter (soy bean hay) from pots treated with soluble potash was notably higher than in that from marl-treated pots or check pots, but is said to represent a "luxury" consumption since the yield of dry matter and percentage of nitrogen are not thereby increased.

The results secured are held to indicate that there is a very close connection between the presence in the soil of soluble phosphates and the accumulation of nitrogen by the soy bean plant. It was also shown that soy beans, when inoculated and furnished with lime and soluble phosphate, can make a good growth and accumulate a high percentage of nitrogen, up to the time the pods are half filled (hay), without the aid of readily soluble potash compounds.

"The work suggests the possibility of utilizing the potash of greensand marl and the potash of natural soil materials by growing soy beans and possibly certain other crops, which could be returned to the soil and thus furnish available potash for those crops which can not so readily utilize potash from these natural sources."

The world's supply of potash, C. MATIGNON (*Rev. Sci.* [*Paris*], 57 (1919), *No.* 8, pp. 225-230).—This is a general discussion of the potash content of the earth's crust, the disintegration of potash-bearing rocks, the solution and removal of potash salts to the sea, and the formation, character, and extent of potash deposits.

The use of lime on Iowa soils. Limestone and fertilizer dealers, G. E. CORSON (*Iowa Sta. Circ. 58 (1919)*, pp. 7).—This comprises a brief popular account of the value of lime for correcting soil acidity, together with results of tests and other information relating to the form, amount, and method of applying lime. A list of limestone and fertilizer dealers is included.

Fertilizer analyses, A. J. PATTEN, C. F. BARNUM, E. F. BERGER, A. L. LEWIS, and M. L. GRETTENBERGER (*Michigan Sta. Bul.* 283 (1918), pp. 3–48).—This reports the actual and guarantied analyses of 863 samples representing 279 brands of commercial fertilizers and fertilizing materials collected during 1918. It is stated that 6.3 per cent of the samples were below the guaranty in nitrogen, 0.6 per cent in total phosphoric acid, 6.4 per cent in available phosphoric acid, and 11.4 per cent in potash.

Analysis of fertilizers for 1918, B. E. CURRY and T. O. SMITH (*New Hamp-shire Sta. Bul. 189 (1918)*, pp. 10).—This reports the results of the actual and guarantied analysis of 147 official samples of commercial fertilizers and fertilizer materials collected during 1918.

Analyses of commercial fertilizers, fertilizer supplies, and home mixtures, C. S. CATHCART ET AL. (*New Jersey Stas. Bul. 331 (1918)*, pp. 5-47).—This bulletin contains a report on the actual and guarantied analyses of 204 brands of complete fertilizers, 274 brands containing nitrogen and phosphoric acid, 5 home mixtures, and 114 samples of fertilizer materials collected during the spring months of 1918.

Analyses of commercial fertilizers and ground bone; analyses of agricultural lime, C. S. CATHCART ET AL. (*New Jersey Stas. Bul. 334* (1918), pp. 5-42).—Supplementing the report noted above, the remaining analyses of samples of commercial fertilizers and fertilizing materials collected during the 1918 inspection are presented, together with a discussion of the entire 1918 inspection. A total of 1,385 samples was received for analysis. Deficiencies in one or two plant food elements occurred in 30 per cent of the brands examined.

Analysis of 20 samples of burned lime, limestone, and lime refuse are included.

A list of brands registered for sale since January 28, 1918, for the fiscal year ended October 31, 1918, is presented.

Fertilizer registrations for 1919, C. S. CATHCART (*New Jersey Stas. Bul. 335* (1919), pp. 5-36).—This comprises a tabulated statement of all the brands of fertilizer materials and mixed fertilizers registered in New Jersey up to January 30, 1919, for the fiscal year ending October 31, 1919.

# AGRICULTURAL BOTANY.

[Activities of the] department of botanical research, D. T. MACDOUGAL (Carnegie Inst. Washington Year Book, 17 (1918), p.55).—Introducing more or less detailed reports of members of the institution, the director states that during the year 1918 the scope of experimentation has been narrowed and subordinated to the preparation of manuscripts and that exploration and field work have been reduced, as also has collaboration with workers outside the institution.

Much attention has been devoted to the study of fundamental problems in carbohydrate metabolism and to the imbibitional action of the plant colloids in growth, all of the water relations of the plant being necessarily taken into consideration. An adequate physical explanation of the origin and action of the spinose and succulent plants constituting the characteristic desert vegetation has been found. Important geographic and ecological results have been formulated, some of which are noted below or previously.

Development of conceptions included in growth, D. T. MACDOUGAL (Carnegie Inst. Washington Year Book, 17 (1918), pp. 55-57).—As preliminary to the reports and discussions which follow, it is stated that three main conceptions concerning growth and its developmental aspects in plants are to be met in the history of physiology during the last half century. The earliest, that of special substances appearing in developmental and seasonal crises and considered necessary for growth and for the origination and development of reproductive organs or of any bud, has given place to the view that formative material as such has no actual existence. From the present standpoint it is assumed that growth proceeds from and depends upon states, combinations, or accumulations in connection with living matter rather than from any differentiated substance.

The second aspect of the subject deals with the incorporation of new material in the cell and its subsequent distension. The protoplast is dealt with as a tonoplast, the center and seat of energy being the vacuole, while an indispensable organ is an ideal semipermeable membrane acting according to the conception of Pfeffer and de Vries.

The third group of inquiries has been directed toward measurements for establishing the physical constants of growth, the subject having formerly been dealt with as a unified process or as a series of successive reactions in studies of temperature effects.

It is held that the chief defect in all three groups of research is in the neglect of the fact that the metabolism upon which growth depends is a constellation, not a linear series of transformations, and that the most important part of the process lies within the realm of surface tensions in which the play of imbibition is the determining factor.

A further prerequisite to rational advance in researches on growth is a recognition of the fact that a general identity of protoplasm of plants and animals does not exist. The relative amounts of proteins, carbohydrates, lipins, and salts differ widely between these two groups. While the plant can synthesize carbohydrates, amino acids, etc., which the animal can not, the respiration and metabolism of the plant are predominantly carbohydrate, while those of the animal are proteinaceous. It is held that the fundamental and ultimate structure of protoplasm is a result of the force of surface tension, and is that of a gel in which the solid material occurs in two main\_states or phases with water. In the more liquid phase the molecules of the substance are associated with such a large proportion of water as to be in a liquid condition, while in the more solid phase the proportion of water is much less. These phases have a distinct architecture likened to that of a mesh, felt, foam, or honeycomb in which the denser phase forms the framework and the fluid fills the interstices. Under certain conditions the phases may be reversed and the solid particles may be rounded into globules entirely surrounded by the fluid.

The essential feature of an idealized growth according to the present conception is the accretion or addition of water and material to the mass of colloid constituting the cell, the end-process being the hydration of a colloid. In that type of growth in which carbohydrates or proteins are carried into the mass by water, such an accumulation would, under surface tension, result in the aggregation of new masses of material. Such formation of additional elastic gel structure might occur throughout the entire cell, but in actuality would be modified and controlled at every point by the factors which affect hydration.

The nature and course of growth in higher plants, D. T. MACDOUGAL (*Carnegie Inst. Washington Year Book, 17* (1918), pp. 58, 59.)—The results obtained following the development and employment of the auxograph are said to have shown that much of the present confusion as to the main features of growth has resulted from attempts to compare and harmonize growth in organisms presenting physical conditions not really comparable. Data obtained from growth measurements on plants mentioned have shown a decrease in growth rate with daily variations (swellings and shrinkage) corresponding to internal changes. Shrinkage becomes more marked as maturity approaches. While some portions may show continuous enlargement, older parts of the stem may take up and give off water in a manner entirely reversible, showing a very wide range of alterations. The estimation of the balance between water loss and water supply, as implied in the experimental results here referred to, is considered to have given a new and more important meaning to relative humidity as affecting plant growth.

The growth mechanism of protoplasm, D. T. MACDOUGAL (*Carnegie Inst. Washington Year Book, 17 (1918), pp. 57, 58).*—Experimental studies are said to have established the view that protoplasm in plants consists of a comparatively inert base of pentosans, which may be diffused or transformed only at a very slow rate, in colloidal combination with proteins, amino acids, lipins, and salts to form a complex mass varying from the liquid condition to that of an elastic gel. The volume and changes in volume constituting growth are determined by the proportion of water taken up, this in its turn being a resultant of the proportions of the main constituents. Other soluble carbohydrates probably do not affect directly enlargement of the protoplasmic mass, but they may exert in the vacuoles an osmotic effect additive to that of the amino acids which may accumulate in these cavities. It is to the osmotic activity of these substances in the vacuoles that turgidity is due, and it is upon this largely that the maintenance of the turgidity of organs depends. The complete conception of the cell includes its expansion by the osmotic action of electrolytes and by the swelling resulting from imbibition or hydration of its colloids, as well as the effect of such increasing changes within its mass.

Nowhere is metabolism more active than in the embryonic growing cells. Changes are mentioned which are thought to exemplify but by no means to exhaust the possibilities of modifications of the colloidal action in growth.

Temperature and the hydration and growth of colloids and of cell masses, D. T. MACDOUGAL (*Carnegie Inst. Washington Year Book, 17 (1918)*, pp. 68-70).—Recognition of the complex character of the groups of reactions which enter into the more prominent life processes is said to have brought conviction as to the futility of attempts to define physical constants, such as temperature coefficients. Results of series of experiments are tabulated.

Comparison of salt requirements for young and for mature buckwheat plants grown in sand cultures, J. W. SHIVE (*New Jersey Stas. Rpt. 1917, pp. 409-413, fig. 1*).—A brief account is given of investigations previously reported (E. S. R., 39, p. 524; 40, p. 425).

A comparative study of salt requirements in solution cultures for the growth of buckwheat to the flowering stage and to maturity, W. H. MARTIN (*New Jersey Stas. Rpt. 1917, pp. 419-422*).—This reports in condensed form the results of experiments previously noted (E. S. R., 39, p. 524).

Experiments to determine whether one form of phosphorus in a complete nutrient plant solution is more available for the growth of buckwheat seedlings than are other forms, H. L. BANCROFT (New Jersey Stas. Rpt. 1917, pp. 423, 424).---A brief report is given of studies made to determine the relative availability of different forms of phosphorus in a Tottingham nutrient solution. The original solution contains monopotassium phosphate, potassium nitrate, calcium nitrate, and magnesium sulphate. In place of the monopotassium phosphate, monosodium phosphate, monocalcium phosphate, monomagnesium phosphate, and monammonium phosphate were substituted in the different series. Buckwheat was grown in the different solutions to the flowering stage, and while the data have not been completely tabulated, it is stated that great variations in height, general growth, toxic effect, and final weights for the buckwheat plants were found. As a rule the original Tottingham solution, containing phosphorus in the form of monopotassium phosphate, produced a larger total dry weight of plant substance than did any of the other forms of phosphorus, while the series receiving monammonium phosphate produced the smallest total growth of plants.

The toxicity of phosphates toward soy bean seedlings, J. W. SHIVE (*New Jersey Stas. Rpt. 1917, pp. 405-408*).—A condensed account is given of investigations previously reported (E. S. R., 39, p. 827).

Effect of ammonium sulphate in nutrient solution on the growth of soy beans in sand cultures, M. I. WOLKOFF (*New Jersey Stas. Rpt. 1917, pp.* 416-419).—This is a summary of investigations previously reported (E. S. R., 40, p. 30).

Absorption of sodium and calcium by wheat seedlings, H. S. REED (Bot. Gaz., 66 (1918), No. 4, pp. 374-380, fig. 1).—The author has studied the effects of sodium and calcium compounds applied to wheat seedlings in lower concentrations than those commonly used. He has found that antagonism is present even under these conditions, and also that concentrations of sodium chlorid strongly toxic to wheat seedlings were rendered harmless by a

3:100,000 calcium oxid solution. Antagonism was most complete when the ratio sodium: calcium equaled 98:2. At this ratio the sodium was not excluded from the plant but was rendered harmless. The antagonism appears to be internal rather than peripheral.

The influence of the roots of growing plants upon the activity of soil microorganisms as indicated by the production of carbon dioxid from the soil, J. R. NELLER (*New Jersey Stas. Rpt. 1917, pp. 414, 415*).—The possible influence of the roots of growing plants on the rate of liberation of plant food by soil microorganisms has been investigated by growing buckwheat and barley plants in soil or sand under bell jars and noting the production of carbon dioxid which was derived from decomposing organic matter. In the case of the plants grown in sand, ground alfalfa hay was added as a source of carbon dioxid.

It was found that slightly more carbon dioxid was liberated from the bell jars containing plants than from those without plant growth. In a second series of experiments buckwheat was grown as a residual crop in the same jars of sand, and again more carbon dioxid was recovered from the bell jars containing plants than from the others.

The author concludes that under the conditions of the experiments the growing roots of barley and buckwheat do not inhibit the decay of organic matter.

Gas interchange in Mesembryanthemum and other succulents, H. M. RICH-ARDS (*Carnegie Inst. Washington Year Book, 17* (1918), pp. 63, 64).—A continuation of work previously reported (E. S. R., 40, p. 29), the problem now being to account for the low carbon dioxid: oxygen ratio. It is suggested that occlusion of carbon dioxid by the fleshy tissue may be involved. It is considered probable that the processes involved are somewhat different from those presented by the succulent tissue of the cacti. It appears to be important to select tissues of like acidity in order to obtain proper results from such work.

Photosynthesis and respiration, H. A. SPOEHR and F. LONG (*Carnegie Inst. Washington Year Book, 17 (1918), pp. 60, 61*).—It is stated that for the purpose of more adequate study of photosynthesis, for which purpose simple, thin leaves have proved to be the best material, a rather elaborate device has been constructed for accurate control of temperature, light, air supply, and water vapor. The method now used is based upon the differential determination of the amount of carbon dioxid fixed by the plant, as determined with special apparatus for estimating the carbon dioxid absorbed in barium hydroxid. The features of the general problem now under investigation are rather numerous, though closely coordinated and interdependent, comprising a study of the basic metabolism of mature leaves and the influence of such metabolism and of the varying sugar content of the leaf on photosynthesis.

It is stated that leaves of different species give enormous differences as regards rate of carbohydrate elaboration and consumption. In cacti and other plants rich in carbohydrates, increase thereof above certain limits does not result in increased carbon dioxid evolution. Photosynthesis appears to be closely related to sugar content and to the respiratory activity of the leaf. Leaves having carbohydrate supply greatly depleted show, when first exposed to light, a low rate of carbon dioxid fixation. This rises until an abundance of carbohydrates has accumulated, after which it decreases.

The carbohydrate economy of cacti, H. A. SPOEHR (*Carnegie Inst. Washing*ton Year Book, 17 (1918), pp. 61-63).—Having followed this subject through the third year (E. S. R., 40, p. 30), the author reports that the continued dry weather kept the monosaccharid content low until the cold nights of the late winter months effected a change, the monosaccharids then rising and the carbohydrate equilibrium becoming about normal after the occurrence of the late winter rains.
It appears that the water requirements of the cacti are easily satisfied. The studies on the effect of water content and temperature on carbohydrate equilibrium have substantiated and elaborated the former findings. No simple or constant relation was established between the rate of carbon dioxid elimination and the carbohydrate supply, nor was respiration very definitely associated with any group of carbohydrates, although a certain negative correspondence is pointed out. It is thought that under certain conditions cactf possess the power of utilizing polysaccharids and aplastic material. The formation of pentosans is intimately associated with this condition in ways which are noted in connection with further studies now in progress.

Acidity of mesophytic and succulent forms of Castilleia, Ericameria, and Erigeron, H. M. RICHARDS (Carnegie Inst. Washington Year Book, 17 (1918), pp. 64, 65).—Some forms of variation in succulence and acidity were determined and are discussed, this work dealing with Ericameria ericoides, C. latifolia, and Erigeron glaucus.

The acclimatization of plants, G. L. SUTTON (Advisory Council Sci. and Indus., Aust., Bul. 7 (1918), pp. 86-95).—In addition to a discussion by the author and others of the naturalization and acclimatization of plants, an account is given of plans and measures for the organized control of activities connected with the introduction of plants into portions of Australia.

# FIELD CROPS.

Dry farming in Arizona, A. M. MCOMIE, C. B. FILLERUP, and L. L. BATES (Arizona Sta. Bul. 84 (1918), pp. 491-642, figs. 47).—This bulletin comprises a rather detailed discussion of the geology and soils of the State, temperature and atmospheric movements in the region, the principal dry-farming sections of Arizona, Indian agriculture in Arizona, and farming operations of early white settlers, together with a digest of the results of several years' experimental work on the Snowflake, Prescott, and Sulphur Spring Valley dry farms, dealing with cultural methods, choice of crops, variety tests, livestock feeding, silage production, and observations on cooperative management between dry-farming and range stock interests. Results secured on another farm in the Sulphur Spring Valley have already been noted (E. S. R., 29, pp. 725, 735).

It is stated that in the southern part of the State, at an altitude of 4,000 ft. and with a long growing season, Kafir corn, Club-top sorghum, milo maize, and tepary beans gave the best results, while in the northern part, under less stringent conditions, quick growing, drought-resistant varieties of corn, Sudan grass for hay, potatoes, several varieties of beans, and even orchard fruits were also found to be suited to dry farming. The production of silage is deemed to be of considerable importance, particularly in connection with the range cattle industry, it being maintained that large areas of semiarid lands within the State might be developed to advantage in cooperation with the range stock interests.

Dry farm crop rotations and cultural methods, A. ATKINSON and L. F. GIESEKER (*Montana Sta. Circ. 81 (1918)*, *pp. 49–58*).—This comprises a brief popular account of work previously noted (E. S. R., 39, p. 131).

Report of [field crops] work at Fairbanks Station, C. C. GEORGESON and M. D. SNODGRASS (Alaska Stas. Rpt. 1917, pp. 28-30, 57-59, 61-70, 85, 86, pls. 3).—The continuation of work during 1917 along the same general lines as previously noted (E. S. R., 39, p. 125) is described. Continued dry weather resulted in poor germination at the time of seeding and led to the production of about one-half the normal grain crop. The frost-free period extended over an interval of 118 days.

Practically all the winter grains winterkilled. Varieties of spring wheat, oats, and barley were grown in the field on increase plats and in head-torow tests. Brief notes on the results secured in each case are presented. Finnish Black oats produced at the rate of 31 bu. per acre for a 21-acre tract, while Canadian produced 54 bu. on a 1-acre tract. In adaptability to climatic and soil conditions H. G. spring wheat, with an average yield of more than 12 bu. per acre for the season, is deemed superior to both Romanow and Marquis, which outyielded it. Japanese buckwheat yielded at the rate of 12 bu. per acre.

Three varieties of field peas were tested, which are said to have produced heavy yields of excellent hay but failed to mature seed.

North Swedish, Cherno, Cossack, and Semipalatinsk alfalfa came through the winter in fair condition. The latter matured some seed. Red clover seeded for soil improvement made a vigorous growth. White clover seeded in 1916 in the lawn came through the winter in fair condition and made satisfactory growth under unfavorable moisture and soil conditions.

Oats grown for hay produced about  $1\frac{1}{3}$  tons per acre and is said to constitute the principal hay crop of the region. Native bluetop (*Calamagrostis langsdorfii*) is also utilized for hay.

Of the potato varieties grown in increase plats the highest yield, 160 bu. per acre, and best quality tubers were secured from Gold Coin, while in variety tests the yields ranged from 92.2 bu. for Alaska Beauty to 162 bu. for Gold Coin, which was again first in quality. In single-row tests the yields varied from 82 to 182 lbs. per row of 155 ft. for Bliss Triumph and Million Dollar, respectively. Both blight and scab were found to be present to some extent in the region.

The Petrowski turnip is said to be a sure crop for this locality, and to be nearly immune to attacks from the root maggot found in such abundance in Alaska.

Tests with cereals conducted in cooperation with the settlers of the Matanuska and Anchorage-Knik regions are briefly noted.

Report of [field crops] work at Kodiak Live Stock and Breeding Station, H. E. PRATT (*Alaska Stas. Rpt. 1917, pp. 73–77*).—This describes the continuation during 1917 of work along the same general lines as previously noted (E. S. R., 39, p. 124). The year as a whole was characterized by a short summer and a long winter with the lowest temperature on record.

Among the cereals tested for hay production the leading varieties were Sixty Day oats, Success barley, and Russian spring wheat. Amraoti is said to have given the best results among the field pea varieties tested. Red clover and field peas responded favorably to inoculation.

Based on limited variety tests with potatoes, Burpee Superior seems to be best adapted to this locality.

Native beach grass (*Elymus mollis*) and a tall beach sedge (*Carex crypto-carpa*) are said to make excellent silage, while native bluetop (*Calamagrostis langsdorfii*) is utilized for silage to a limited extent when the season is unfavorable for hay making. Fireweed (*Epilobium angustifolium*), fast becoming established on the ash-covered flats and to a less extent on the hillsides, is described as making fair silage when mixed with beach grass. Continual cutting greatly reduced the yield of all these plants, while cutting in alternate years only has maintained the yield.

C. langsdorfii comprises the principal hay crop of the region, while mixtures of this grass with greater or less amounts of coarse blue grass (*Poa glumaris*),

Kentucky blue grass (*P. pratensis*), and wild barley (*Hordeum boreale*) also make good hay. Chemical analyses of the principal grasses used for hay and silage at Kodiak, previously noted (E. S. R., 17, p. 349), are compared with similar analyses of blue grass, redtop, and timothy. Feeding trials at the station are held to indicate that the native grasses have approximately the same digestion coefficients as similar grasses in the United States.

Report of [field crops] work at Rampart Station, C. C. GEORGESON and G. W. GASSER (Alaska Stas. Rpt. 1917, pp. 21-27, 35-54, 55, pls. 3).—This describes work conducted during 1917 similar to that previously noted (E. S. R., 39, p. 125). The season is described as generally unfavorable for crop production, having been excessively cool, cloudy, and windy, although the frostfree period, 117 days, was 20 days longer than the 10-year average.

Although *Medicago falcata* and Grimm alfalfa made a vigorous growth, practically no seed ripened. It is stated that the number of bees was markedly reduced this season, and that butterflies, fairly numerous during June, disappeared almost entirely for the rest of the summer. Grimm wintered quite satisfactorily, while Hardy Grimm and Disco have been discarded as lacking in vigor. Obb and Omsk made a rank growth, but their procumbent habit renders them unsatisfactory for hay production. An attempt to inoculate 2-year-old plants with a liquid culture mixed with soil failed to give any results, no nodules being found either on treated or untreated plants.

Vicia cracca again gave excellent results, ripening from 50 to 75 per cent of its seed. Well-developed root nodules were observed on both old and new seedings, although no culture had been applied at any time.

A strain of Alaska garden peas grown at the station for 11 years produced at the rate of 27.93 bu. per acre. Root nodules were fairly abundant although no culture had been applied. Irkutsk field peas, sprouted before planting and seeded in rows 20 in. apart, produced at the rate of 15.32 bu. Tests of two varieties of field peas received from the Tulun Experiment Station, Russia, and of several strains of chick peas (*Cicer arietinum*) received from the Office of Foreign Seed and Plant Introduction, U. S. Department of Agriculture, are noted. The field peas ripened some seed, while the chick peas were still green when killed by frost.

Red clover planted as a soiling crop produced an excellent stand, although growing slowly and in spots. Only a few plants were found having root nodules. *Trifolium lupinaster* again proved to be perfectly hardy and produced seed, but its lack of vigor is said to render it almost valueless as a hay plant.

Variety testing and hybridization work with winter wheat and rye, and spring wheat, rye, barley, and oats is noted, and the results secured with each sort briefly outlined. Japanese buckwheat and a strain designated as No. 60–2 produced at the rate of 81.3 and 68.3 bu. per acre, respectively. Millet failed to produce any seed.

A small seeding of hemp resulted in plants ranging from 12 to 40 in. in height, about 75 per cent of the crop ripening seed. Flax attained a height of about 28 in. and ripened about 40 per cent of its seed.

Potatoes grown in the field gave poor results, thought to be due chiefly to the low fertility of the soil, while plantings made on good garden soil proved to be more satisfactory. Irish Cobbler, Early Six Weeks, Netted Gem, and Gold Coin are said to be superior in quality to Burpee Superior, Lake Puritan, and Knowles Big Cropper.

Cotton and corn: Cultural tests, and variety tests of 1917 and 1918, C. K. McCLELLAND (*Georgia Sta. Bul. 128 (1919)*, pp. 61–78).—Variety, cultural, and fertilizer tests with corn and cotton are described in a continuation of work

previously noted (E. S. R., 37, p. 35). The total rainfall for the growing season (April to August, inclusive) amounted to 16.92 in. in 1917 and 15.7 in. in 1918, the distribution in the latter season being described as particularly unfavorable to corn.

The corn yields in the 1917 variety test ranged from 17.1 bu. per acre for Experiment Station Henry Grady 1009 to 30.8 bu. for Velvet Cob, and in 1918 from 16 bu, for an early planting of Station Marlboro to 20.1 bu. for Steinheimer Marlboro. Ear-to-row testing of corn is thought to be the only reliable method for determining desirable strains.

Commercial fertilizer placed under corn resulted in an average yield of 15.6 bu. per acre for a 5-year period as compared with 16.8 bu. from similar applications made later around the corn plant. Yields ranging from 20.2 bu. per acre without fertilizer to 26.1 bu. from an application of 1,200 lbs. were secured as a 3-year average, although it is stated that applications of more than 400 lbs. are not economical, while in dry seasons fertilizers in any quantity were seldom profitable.

Planting velvet beans with corn at the time of planting the corn usually reduced the yield of the latter, but the beans are believed to more than compensate for this loss. Deep spring plowing and shallow cultivation the first time appeared to give better results than other methods of cultivating corn. Applying nitrogenous top-dressings early proved to be of greater importance than the kind of nitrogen carrier employed. The residual effect of stable manure practically disappeared in two years during dry seasons.

In the cotton variety tests, the 1917 yields ranged from 1,775 lbs. of seed cotton per acre for Durango (long staple) to 2,820 lbs. for O'Bannon No-chop, and the 1918 yields from 1,237 lbs. for Webber No. 49 to 1,715 lbs. for Steinheimer Cleveland.

The use of varying amounts of commercial fertilizer on cotton resulted in yields of from 978 lbs. for the checks to 1,242 lbs. for a 1,200-lb. application. From 600 to 800 lbs. is deemed sufficient.

In a comparison of early and late chopping of cotton the latter practice resulted in a slightly earlier crop, while the average yields amounted to 1,340 and 1,248 lbs. of seed cotton per acre, respectively, for a 4-year period.

[Report of work with field crops in Kansas, 1917–18] (Kansas Sta. Rpt. 1918, pp. 19, 21–27, 30, 31, 33).—This describes the progress of work previously noted (E. S. R., 40, p. 329).

Observations on the effect of cutting alfalfa at different stages of maturity showed that the highest average yield, 4.88 tons per acre, for a 4-year period followed the practice of cutting the crop when in full bloom. Plats cut in the bud stage are said to be deteriorating rapidly, the alfalfa being replaced by grass and weeds.

Adverse weather conditions resulted in low yields of corn in 1917. Corn grown continuously since 1910 produced 22.6 bu. per acre, as compared with 44.9 bu. from that grown in rotation with wheat and alfalfa, 32.8 bu. in rotation with cowpeas and wheat, and 22.7 bu. in a rotation of wheat and corn two years. Corn grown in rotation was little affected by applications of commercial fertilizers, although marked results were obtained from their use on corn grown continuously. It is stated that phosphorus may be profitably used on Kansas soils in a low state of fertility which are grown to corn continuously without manure. An annual application of 2.5 tons of manure per acre has resulted in an average increase in yield of corn of 7.93 bu.

Severe winterkilling during January and February resulted in low wheat yields. Average yields following different cropping systems for the 7 years, 1911–1917, were 17.3 bu. in rotation with alfalfa 4 years and corn 2 years, 15.73 bu. in rotation with corn and cowpeas, 13.38 bu. in rotation with corn 2 years, and 14.88 bu. when grown continuously. Wheat grown continuously without manure produced 11.85 bu. per acre in 1917, as compared with 20.5 bu. following annual applications of 2.5 tons of manure. Wheat grown in rotation was little affected by the use of manure or commercial fertilizers. The latter resulted in higher yields for all plats continuously cropped to wheat. With phosphorus there was an increase in yield of wheat of 3.49 bu. per acre in the 3-year rotation, and with a complete fertilizer 7.07 bu. A fertilizer mixture high in phosphorus and containing some nitrogen is deemed best, while potassium has failed to prove beneficial.

While alfalfa yields were low, due to drought during the summer, that grown in rotation produced considerably more than that grown continuously. Manure applied at the rate of 5 tons per acre every 3 years resulted in an increase of about 0.5 ton of hay in 1917. The use of commercial fertilizers resulted in increased yields in every case, but the increase due to potassium is said to be negligible. An application of 180 lbs. of acid phosphate per acre on alfalfa grown in rotation resulted in an average increase of 878.9 lbs. of hay since 1911, while with a complete fertilizer there was an increase of 1,477.5 lbs.

The highest yields of cowpea hay were secured on the plats receiving a complete fertilizer and barnyard manure.

In a rotation of alfalfa, Kafir corn, corn, and oats, the highest yield of alfalfa was secured from the plat receiving manure and rock phosphate. Kafir corn on the check plat produced 18.1 bu. per acre, as compared with 23.8 bu. from the plat receiving fresh manure, 23.4 bu. from fresh manure and rock phosphate, and 25.7 bu. from leached manure.

The highest yields of wheat were secured from the earliest preparation of the seed bed, and, in the case of continuous cropping to wheat, from plats plowed 7 in. deep. Nitrification varied with the amount of moisture available in the soil during the period of seed-bed preparation, while the available moisture supply appeared to be dependent upon the amount of weed growth. Different methods of seed-bed preparation had little if any effect upon the potential efficiency of nitrate-forming organisms, differences in the rate of nitrification being due to differences in the activity of the organisms concerned in the decomposition of organic matter, these in turn being affected by environmental conditions which retard their activity rather than by any differences in bacterial flora. The principal environmental factors involved are said to be the distribution of the organic matter and the availability of the moisture supply. Nitrification was as great in the surface 3 in. of soil as in the 3- to 6-in. level, while in the 6- to 12-in. layer it was less than in the upper layers. Determinations of the amount of weed growth on late-prepared plats and of the nitrogen content of the weeds led to the conclusion that nitrification was as rapid on these plats as on those receiving early tillage. Based on the average yields, it is recommended that if wheat stubble can not be plowed at once after harvest (July 15), the land should be double disked immediately and plowed 6 or 7 in. deep when convenient, but not later than early September, with sufficient cultivation to keep down weeds, and produce a firm seed bed.

Observations were made on the effect on the moisture content and nitrate formation in clay, silt loam, and fine sandy soil of maintaining a 3-in. cultivated mulch and a bare surface. In addition, weeds were allowed to grow

[Vol. 41

throughout the season on two plats. The results obtained are given in the following table:

Effect of 3-inch mulch, bare surface, and weeds on the moisture content and nitrate formation in three types of soil.

Average determinations, Apr. 1 to Oct. 1, 1917.	Clay.		Fine sand.		Silt loam.		Weeds.	
	Mulch.	Bare surface.	Mulch.	Bare surface.	Mulch.	Bare surÍace.	Plat 1	Plat 2.
Percentage of moisture to a depth of 6 ft. Pounds of nitrate per acre-foot to a depth of 3 ft.	22. 4 74. 5	23.0 57.6	17.2 91.4	16.4 126.1	19.9 219.2	20. 4 220. 3	17.5 57.0	17. 0 1145

Observations on wheat seedlings grown in soil solutions obtained by leaching, filtering, and centrifuging are held to indicate that Kafir corn and milo maize do not exert a toxic effect upon the soil, even in seasons when Kafir corn has injured the wheat growth, as shown by comparison with corn. Nutrient solutions used in conjunction with water cultures indicated that Kafir corn soil was lacking in available nitrogen. Applications of nitrogen alone on Kafir corn soil resulted in a growth of oats exceeding that secured on untreated corn soil or corn soil with nitrogen. Less moisture and nitrates were found in the soil from the Kafir corn plats than from the corn plats at the time of planting fall wheat, thought to be due to the fact that the Kafir corn produced about twice as much dry matter as the corn.

Kanred winter wheat again demonstrated its superiority over other varieties, averaging 4.5 bu. per acre more than Turkey and 4.7 bu. more than Kharkof for a 7-year period. It also appears to be markedly resistant to cold and to certain strains of black stem rust. Kansas Nos. 2414 and 2415 also proved to be quite resistant to both cold and rust, while Nebraska Hybrid No. 34 was less winter hardy and is deemed unsuited to Kansas conditions.

In a comparison of 87 varieties of small–grain, mostly wheat, as to their susceptibility to injury from the Hessian fly, it was found that the fly seldom lays eggs on oats, barley, einkorn, spring emmer, or durum wheat, and less abundantly on soft winter wheats than on hard winter wheats. It was also observed that on certain varieties, notably Illini Chief, Dawson Golden Chaff, Beechwood Hybrid, and Currell Selection, very few flaxseeds developed, although eggs were laid on the plants in abundance.

Wheat seeded in furrows produced on the average 2 bu. per acre more than that seeded in the usual way, while north and south seeding again gave better results than east and west seeding.

The average corn yields on uncultivated plats from which the weeds were removed with a hoe were only 1.1 bu. per acre less than for plats cultivated in the usual way, while summer cultivation gave the lowest yields. Spacing corn 20 in. gave the best results on upland and 16 in. on bottom land as an average for four years.

In a 5-year test of different silage crops, Kansas Orange sorghum, Blackhull White Kafir, and corn produced average yields of 19.2, 12.6, and 12.1 tons per acre, respectively.

Experiments begun in 1915 to determine the possibilities of improving native pasture land by a deferred and rotation system of grazing are said to indicate that the vacant ground is decreasing to a marked degree, that pure grass is increasing, and that mixed weeds and grass and weeds alone are decreasing on the protected areas. All attempts to seed tame plants have failed, with the exception of sweet clover on protected fields.

Alfalfa stacked green showed a loss of 39 per cent in dry matter, some of the material being badly spoiled. An analysis of the best black silage showed that the moisture content was practically the same as when the material was placed in the stack, that the ash content was considerably increased, that the protein content was greater than in the original hay, and that the percentage of nitrogen-free extract, crude fiber, and ether extract was less. Prolongation of the drying process is said to produce proteolysis, resulting in an increase in amino acids and amids.

[Variety tests with alfalfa and potatoes], E. F. GASKILL (*Massachusetts Sta. Rpt. 1917, p. 32a*).—In variety tests with alfalfa, Grimm again failed to show any superiority over common alfalfa (E. S. R., 38, p. 231). Several seedling potatoes proved to be no better than standard varieties grown in comparison with them.

[Report of work with field crops in New Jersey], F. APP and C. S. VAN NUIS (*New Jersey Stas. Rpt. 1917, pp. 313-315, 329-331*).—In continuation of work previously noted (E. S. R., 39, p. 736), the progress of studies regarding the source of seed, time of seeding, and cultivation of alfalfa, methods of seeding sweet clover, and the selection of seed corn for silage production is briefly described, together with a report of the department of farm crops relative to the acreage and yields on the experiment station farm of corn for grain and silage, rye for grain and straw and as a soiling crop, alfalfa for hay, oats and peas for silage and hay, timothy for hay, and soy beans for green manuring.

Alfalfa seeded on April 11 with wheat as a nurse crop gave much better results than that seeded without a nurse crop. Plats seeded June 7 were more weedy than those seeded April 11 without a nurse crop, while seedings made August 14 appeared to be in fair condition for the winter but with small growth. Cultivation is deemed undesirable for alfalfa.

Seeding sweet clover with wheat as a nurse crop early in the spring (the latter part of February or early March) is said to have resulted in a vigorous erop.

Selecting silage corn seed from the standing stalk is believed to be highly desirable, results secured in the 1917 crop indicating that selected seed was superior to purchased seed in germination and that the plant could be modified to meet the dairyman's needs.

**Progress report, substation No. 11, Nacogdoches, Tex., 1909–1915, G. T.** McNESS (*Texas Sta. Bul. 237 (1918), pp. 5–27, figs.* 4).—The Nacogdoches substation, located in the east-central part of the State, was established in 1903 primarily for the purpose of conducting tobacco investigations in cooperation with the U. S. Department of Agriculture. This bulletin has to do chiefly with the progress of the work since 1911. Meteorological data are presented for the region, indicating that the growing season is comparatively long and the average annual precipitation is 48.5 in. The principal lines of work comprise fertilizer experiments with tobacco, supplementing work previously noted (E. S. R., 27, p. 37); variety and cultural tests with corn, cotton, cowpeas, soy beans, peanuts, Sudan grass, and Japanese cane; field tests with several other leguminous and nonleguminous forage crops; variety tests with seven different truck crops, and fertilizer tests with tomatoes. The results secured may be briefly summarized as follows:

Cottonseed meal with other materials and in rather large amounts seemed to be the most effective agent used in fertilizer tests with tobacco, while smaller amounts were effective for other crops than tobacco. Surcropper and Strawberry corn are recommended for uplands and the socalled prolific varieties for the bottom lands. Rate of seeding tests with corn are held to indicate that the stalks should be thinned to 3 by 3 ft. In a comparison of corn grown alone with corn and cowpeas grown together, better results were secured the later the cowpeas were planted.

The largest yields of cotton have been secured from hills spaced from 18 to 36 in. apart, containing two stalks per hill. Mebane, Rowden, and Lone Star are deemed to be the best varieties.

Clay and New Era cowpeas are said to be suitable for general use, while Chinese Red is recommended as a catch crop and Iron for forage. Wide row planting has given more cowpea hay than narrow row planting, while heavy seeding has given larger crops than light seeding.

Soy beans do not appear to be profitable.

Peanuts in 18-in. rows have not shown a profitable gain over 36-in. rows when grown for nuts. Spanish peanuts are recommended for forage. In width of row tests with this variety 36-in. rows produced more forage than 18-in. rows. It was not found profitable to crack the shells of peanuts before planting.

Sumac sorghum is recommended as a silage crop. Among new forage crops tested each year, Kulthi moth bean, Florida beggar weed, Japanese sword bean, and frijole bean are of little importance, while mung bean and *Dolichos lablab* proved to be of some value.

Sudan grass, newly introduced, is of considerable importance as an annual hay and pasture crop. In date and rate of planting tests with Sudan grass the results are held to indicate that rather late spring planting is necessary or that early planting after oats is practical. It is advised that the crop be planted in rows at from 5 to 15 lbs. of seed to the acre.

Japanese sugar cane gives promise as a silage crop.

The largest yield of tomatoes has been obtained from plats receiving 20 loads of stable manure per acre.

A study of environment in small grains, B. D. HALSTED (New Jersey Stas. Rpt. 1917, pp. 394, 395).—This comprises a brief preliminary report on work with wheat, oats, barley, and buckwheat, comprising a study of the influence of the position of the grain on the plant upon the viability of the grain and the vigor of the seedling, of the effect of the depth of planting upon the viability of the seed and the weight of the plants produced, and the effect of the number of plants per hill upon the weight of the plant.

Seedings were made 1, 2, 3, 4, and 5 in. deep and the average weight of the plants and the percentage of plants harvested at each depth ascertained. The highest average weight per plant for wheat and oats was secured at the 5 in. depth and amounted to 99.5 and 280 gm., respectively, while the maximum weight for barley, 144 gm., and for buckwheat, 68.1 gm., was secured at the 4 in. level. The viability of wheat and oats increased from the 1 to the 3 in. depth and then declined, while barley attained its maximum at the 1 in. depth, and buckwheat at the 4 in. depth.

Planting 1, 3, 5, 10, and 20 grains per hill resulted in maximum average weights per plant of 85.3 gm. for wheat at the 5 grain rate, 410.6 gm. for oats at the 1 grain rate, 149.3 gm. for barley at the 1 grain rate, and 98.8 gm. for buckwheat at the 20 grain rate.

Spring grains in western Nebraska, L. L. ZOOK (*Nebraska Sta. Bul. 172* (1919), pp. 16, figs. 4).—Experimental work is described in which observations were made on the effects of different dates of seeding and on the relative yields of spring grains, including wheat, oats, barley, and emmer, at the North Platte substation for the 10 years, 1909 to 1918, inclusive. A previous report on this work has already been noted (E. S. R., 29, p. 225).

The average seeding dates were March 25, April 6, 18, and 30. The average precipitation for the 10-year period was 18.77 in., or slightly less than the 44-year average for the substation. A comparison of the monthly precipitation for each year of the experiment with the crop yields is held to indicate that the distribution of the rainfall, together with the moisture condition of the soil in the spring, is sometimes of greater importance than the total amount of precipitation in determining yields. The results obtained may be summarized as follows:

With the exception of two years, early seedings produced the best yields, while the average yields of all crops were materially higher with early than with late seeding. Differences between early and late seedings of barley and oats were less marked than with wheat and emmer. Barley outyielded all other crops, and on account of the length of the season in which it can be successfully seeded, its high feeding value, and high yields, it is recommended for more general planting. The lowest yields were secured from emmer, and the growing of this crop in the western part of the State is said to be scarcely justifiable. There appeared to be little difference between spring wheat and early oats, either as feed or cash crops. It is stated that weed growth usually proved to be less troublesome in early than in late seedings.

Farm pastures in Montana, A. ATKINSON (Montana Sta. Circ. 82 (1919), pp. 61-67).—Methods of seeding both dry-land and irrigated pastures in the State for summer pasture and feed are briefly described and suitable seed mixtures recommended.

A bad farm practice, W. E. ATRES (Arkansas Sta. Circ. 47 (1919), pp. 4, fig. 1).—Observations made at the Scotts Branch substation in 1918 on the effect of delayed harvesting on the yield and quality of three varieties of cotton are said to indicate that an average loss was sustained amounting to 11.1 per cent in yield and 33.6 per cent in the value of lint and seed. It is estimated that the total annual loss in the State due to late harvesting varies from  $3\frac{3}{4}$  to  $5\frac{1}{2}$ million dollars. Increased production of food and feed crops in the South, accompanied by a limitation of the acreage planted to cotton to that which can be harvested at the proper time, is urged.

Napier and Merker grasses, two new forage crops for Florida, J. B. THOMP-SON (Florida Sta. Bul. 153 (1919), pp. 237-249, figs. 7).—Napier grass (Pennisetum purpureum), also known as elephant grass, Napier fodder grass, Zinyamunga, Carter grass, and bamboo grass; and Merker grass (P. merkeri), recently introduced into Florida, are briefly described and their production and utilization in the State discussed. Napier grass is said to be indigenous to tropical Africa and Merker grass to South Africa, and to have been introduced into this country by the U. S. Department of Agriculture in 1913 and 1916, respectively.

Napier grass is described as a rank, vigorous grower, attaining a height of from 6 to 12 ft. or more; growing readily from seed, root divisions, or cuttings of mature cane; and giving promise for the region embracing all of Florida, the southern portion of Mississippi, Louisiana, and Texas, southwestern Arizona including the Salt River Valley, and certain portions of California. The green feed is said to be highly palatable if harvested at the proper time and to contain a relatively large amount of protein. The best results have been secured with Napier grass on a moist, fertile soil, although it has proved fairly successful on rather poor land as well and is quite drought resistant.

Merker grass is said to be similar to Napier grass in general character and agricultural value.

Field pea production in north Idaho, H. W. HULBERT (Idaho Sta. Bul. 115 (1919), pp. 3-27, figs. 3).—Field practices and cultural methods deemed best for

growing the crop in the northern part of the State are indicated from observations at the station and elsewhere, and the comparative yields of different varieties and results of cultural tests are reported. It is stated that 24,722 acres were devoted to field pea production in 1918, an increase of 15.5 per cent over the 1917 crop. About 50 per cent of the crop was grown in two northern counties in place of the summer fallow.

Blue Prussian has given the highest returns in market value and White Canada the highest yield per acre. Inoculation was found to be essential. Wheat following peak is said to yield equally as well as that after summer fallow. Important insect pests of the crop are briefly described.

Position in the pod and productiveness; seed weight and abortiveness: Peanuts, O. C. SCHULTZ (*New Jersey Stas. Rpt. 1917, pp. 401-404*).—Further observations with peanuts (E. S. R., 39, p. 739) on the effect of the position of the seed in the pod upon the type of pod produced, the average weight of seeds for different positions in the pod, and the amount of abortiveness for each type of pod are briefly described.

The results are held to suggest that seeds from 1-seeded pods may yield the largest number of pods and those from 4-seeded pods the smallest crop. Seeds from 1-seeded pods also produced the largest percentage of 1-seeded pods, this percentage decreasing as the number of seeds in the parent pods increased, indicating a possible inheritance of pod type. The seeds of 1-ovuled pods were the heaviest, while the basal halves of all other pods contained heavier seeds than the upper halves. The seeds of the 4-ovuled pods were on the average the lightest, the number of 5-ovuled pods being too few for consideration. All basal seeds averaged much heavier than the tip seeds.

Abortiveness was lowest in the 1-ovuled pods, 11.61 per cent, and highest at the base of all other pods, the percentage increasing from 36.95 for the 2-ovuled pods to 60 per cent in the 5-ovuled pods. There was a positive correlation between the size of the seeds and the amount of abortiveness, the basal position in all pods yielding the larger seeds and the greater amount of abortiveness, both of these results depending upon the position of the ovules.

[Work with potatoes at the Sitka Station], C. C. GEORGESON (Alaska Stas. Rpt. 1917, pp. 6-8).—This describes the progress of variety tests with potatoes and efforts to develop new sorts from seed, as previously noted (E. S. R., 39, p. 137). It is stated that by selecting early varieties, sprouting the seed potatoes in the light before planting, and planting on elevated ground, preferably with a southern slope, excellent crops of good quality potatoes can always be secured in Alaska, even north of the Arctic Circle.

An improved method of potato seed treatment, I. E. MELHUS and J. C. GILMAN (*Iowa Sta. Circ.* 57 (1919), pp. 8, figs. 10).—A modification of the formaldehyde treatment for seed potatoes is described whereby the tubers are immersed for 2 minutes in a solution of 2 pints of formaldehyde to 30 gal. of water maintained at a temperature of from 118 to  $122^{\circ}$  F. The hot solution is said to have had no deleterious effect upon germination, as indicated by field tests made during the past 3 years.

Control of weeds in rice fields, H. H. LAUDE (*Texas Sta. Bul. 239* (1918), pp. 5-11, figs. 2).—Tests conducted at the Beaumont substation from 1914 to 1917, inclusive, have led to the conclusion that planting rice in rows and cultivating the crop before irrigating will effectively control the weeds, increase yields, result in cleaner land with each succeeding crop, and lengthen the period of profitable rice production. It is also recommended that narrow, steep levees be replaced by broad, sloping ones, and that only pure seed be employed for planting purposes.

Sugar beets under irrigation in Washington, F. J. SIEVERS and E. G. SCHAFER (*Washington Sta. Bul. 154 (1919)*, pp. 41, figs. 11).—This comprises a general discussion of the principal factors affecting the successful production of the crop in the State, together with information relating to diseases and insect pests.

Strains of White Burley tobacco resistant to root rot, J. JOHNSON and R. H. MILTON (U. S. Dept. Agr. Bul. 765 (1919), pp. 11, figs. 4).—This comprises a rather popular account of the nature of the root-rot disease of tobacco, said to be due to *Thielavia basicola*, together with a brief discussion of the development and testing of resistant strains of White Burley. It is stated that two or three resistant strains of the drooping-leaf type are suitable for use on "sick" soils, while promising results have also been secured with the stand-up type.

The velvet bean, C. K. McCLELLAND (Georgia Sta. Bul. 129 (1919), pp. 81-98, figs. 6).—Directions are given for growing, harvesting, and utilizing velvet beans as a companion crop with corn in Georgia, together with the results of limited variety tests, including agronomic data on the different varieties. It is stated that the crop is valuable for pasture, grain, feed, roughage, smothering weeds, silage, and soil improvement, especially on sandy soil, and that the feeding and fertilizing value of velvet bean meal is equivalent to about onehalf of a like weight of cottonseed meal. The Florida, Georgia or Early Speckled, Alabama or Medium Early Speckled, Chinese, Osceola, Yokohama, and Lyon are said to be the best known varieties.

Velvet bean varieties, J. M. Scorr (*Florida Sta. Bul. 152* (1919), pp. 213–233, figs. 10).—Varieties of velvet beans grown in Florida are briefly described and illustrated including the Florida, Lyon, Yokohama, Chinese, Georgia or Early Speckled, Wakulla, Osceola, and Alachua. Directions are also presented for the production and utilization of the crop in the State.

Velvet beans grown continuously for 6 years showed a decrease in yield of from 25 bu. of shelled beans per acre in 1907 to 10 bu. in 1912, or an average of 15 bu. (for 5 crops), as compared with a similar average of 23 bu. per acre for the general crop.

Wheat investigations—varieties, A. E. GRANTHAM (*Delaware Sta. Bul. 121* (1919), pp. 3-49, figs. 2).—This describes a study of winter wheat varieties conducted from 1908 to 1917, inclusive, the results of which may be summarized as follows:

Of 56 varieties grown in drill plats for 9 years the leading sorts were Auburn Red with 37.2 bu. per acre, Red Wonder with 32.54 bu., Sibley New Golden with 31.75 bu., Valley with 31.32 bu., and Mediterranean with 30.81 bu., while of 53 varieties grown by the hill-plat method for 3 years the best results were secured from Lebanon with 32.05 bu., Auburn Red with 31.5 bu., Dietz Amber with 31.13 bu., Poole with 31.05 bu., and Fulcaster with 30.9 bu. The best yielding varieties of smooth wheats were Golden Bronze, California Red, and Dawson Golden Chaff with 28.68, 28.46, and 28.23 bu. per acre, respectively. Based on the yields of bearded and smooth wheats for 26 tests, including 1,986 varieties and strains the former outyielded the latter by 3.31 bu. per acre. Grown both with and without fertilizer the bearded kinds produced better than the smooth. The shrinkage in yield of the bearded wheats when grown without fertilizer was 30 per cent, and of the smooth wheats 41 per cent.

Fifth annual report of the Montana grain inspection laboratory, A. ATKIN-SON, E. W. JAHNKE, and C. R. HALLER (*Montana Sta. Bul. 127 (1918)*, pp. 45-59, figs. 8).—The activities of the laboratory for the year ended October 1, 1918, are briefly described. A total of 635 samples of wheat were tested for

125597°-19-4

grade, dockage, moisture, etc., during the year ended July 1, 1918, while 12,604 samples of various kinds of seeds were tested for germination and purity.

Test your clover and timothy seed, C. M. KING and L. H. PAMMEL (*Iowa Sta. Circ. 59 (1919)*, pp. 2).—Legal standards of purity and germination for alfalfa, alsike and red clover, and timothy seed in Iowa are presented and the value of good seed emphasized. Germination tests of timothy and alsike clover seed alone and in alsike and timothy mixtures are held to indicate that inferior seed is often employed in such mixtures.

Results of seed tests for 1918, F. W. TAYLOR (*New Hampshire Sta. Bul. 188* (1918), pp. 15).—This bulletin contains a report on the purity and germination of 280 official samples of agricultural seed collected during the year ended July 1, 1918. It is stated that of the samples guarantied for purity 95 per cent were up to or above the guaranty while only 63 per cent of those guarantied for germination equaled or surpassed the guaranty. Alfalfa, alsike clover, corn, peas, oats, red clover, timothy, and wheat were found to be on the average above the standard for purity, while Barley, buckwheat, millet, redtop, and white clover were below the standard. With regard to germination, all seeds were up to standard except corn, millet, peas, and red and white clover.

The amended text of the New Hampshire seed law is included.

The composition of some lawn-grass mixtures, J. P. HELYAR (*New Jersey Stas. Rpt. 1917, pp. 208, 209).*—A tabulated statement is presented showing the composition of 40 different mixtures of grasses and clovers recommended for seeding lawns and examined in connection with the regular seed inspection (E. S. R., 39, p. 842). It is stated that little uniformity exists, either in the kind or the proportions of seed employed in such mixtures by various dealers and that the mixtures sometimes consist of medium or low grade lots of seed.

Johnson grass as a weed in southwestern Iowa, L. H. PAMMEL and C. M. KING (*Iowa Sta. Circ. 55 (1919)*, pp. 4, figs. 3).—The appearance of the weed in the southwestern part of the State is noted, brief descriptions of the plant and seed presented, and its distribution and methods of eradication indicated. Converting infested fields into close-cropped meadows or pastures for one year, followed by shallow cultivation during midsummer and clean culture until frost, is deemed to be the best means of exterminating the pest.

### HORTICULTURE.

[Horticultural investigations in Alaska], C. C. GEORGESON, G. W. GASSER, and M. D. SNODGRASS (*Alaska Stas. Rpt. 1917, pp. 8-21, 27, 28, 54, 55-57, 70, 71, 86-90, pls. 2*).—A progress report on varietal and cultural experiments with fruits, vegetables, and ornamentals at the Sitka Station and at the branch stations, together with the usual extracts from letters of settlers and others regarding results obtained from the seed and plant distribution and other plantings.

Orchard fruits have thus far failed to make much headway. So far no variety of apples has been discovered that can be said to be at home in the climate. A number of apples of several varieties matured at Sitka in 1915, a favorable season, the Yellow Transparent and the Livland Rasberry being the leaders. Several small trees have been grown from scions received from Finland, which it is hoped will do well in southeastern Alaska.

Notes are given on recently tested ornamentals, shrubs, and perennials, including a selected list of perennials which have proved hardy and dependable for the coast region.

40

The breeding work with strawberries was continued at the Sitka Station, although the season was unfavorable for determining the value of the seedlings. Two hybrid strawberries originated at the Sitka Station have proved entirely hardy at Rampart with no protection other than that afforded by the snow. They fruited abundantly for a period of six weeks, producing large, luscious berries.

The first two apples ever matured in interior Alaska were grown on a Siberian crab at Rampart during the past season. Of a lot of a dozen of these trees and other hardy apples sent to the Rampart Station about 12 years ago only three trees are now alive, all Siberian crab. The tops are killed down to snow line each winter.

[Report on horticultural investigations] (Kansas Sta. Rpt. 1918, pp. 35, 36).—A brief statement of progress made during the year. Summing up the results for three seasons, the station's tests show clearly that it is impracticable to prune and stake tomatoes when growing them on a commercial scale, as increase of production does not offset the cost of pruning and staking. This season's work confirms the wisdom of using some crop, usually either wheat or corn, which makes a heavy demand on the soil, between alfalfa and potatoes. Fall plowing has proved to be helpful in the control of potato diseases. It is suggested that this may be due to the fact that the soil is in better condition and better germination is secured.

Continued experimentation in orchard soil management justifies the conclusion that alfalfa and permanent sodding must be abandoned in order to control the buffalo tree hopper (*Ceresa bubalus*). On the other hand serious washing of the glacial soils, even where cultivation is along the contour lines, indicates the need of cover crops. Cowpeas and oats are being tested for this purpose. Orchard pruning experiments continue to show the superiority of two prunings, summer and winter, over a single pruning or neglected pruning. A large number of fruit buds were produced on 5-year old and 6-year old apple trees which were pruned for the 2 years preceding.

Report of the department of horticulture, M. A. BLAKE and C. H. CONNORS (*New Jersey Stas. Rpt. 1917, pp. 79–104, pls. 2, fig. 1*).—A progress report on horticultural investigations in 1917, continuing previous work (E. S. R., 39, p. 745), and including observations on peach borers and on peach yellows and little peaches abstracted on pp. 57 and 54, respectively.

The season's results from the peach-pruning experiment in the Vineland orchard indicate that the summer pruning of the tips of the branches in late June and early July delays the maturity of the fruit. Summer pruning thus prolongs vegetative action instead of checking it, as is commonly believed. The fertilizer experiments in the Vineland orchard, which have run for 10 years, are now to be discontinued, and the results will be published.

In the peach-breeding work, additional plantings of seedling peaches from known parents were made on the recently acquired Wolpert farm, and pits from crosses made in 1916 were planted in nursery rows. A small orchard of standard varieties used in the breeding work, as well as other standard varieties and promising seedlings, was planted in 1917. An experimental grape vineyard and a new planting of apples has been started on the Wolpert farm.

Cultural and variety tests with roses and carnations were continued. In the breeding work with carnations, several seedlings producing purple flowers of good form appeared. Several red seedlings and one red and white variegated seedling also are very promising.

A strain test of Earliana tomatoes was started during the year, and the strain test of beets was continued. The usual records of blooming date of fruit

trees and ornamentals as well as weather observations for the year are reported.

Studies on heredity and environment, B. D. HALSTED (New Jersey Stas. Rpt. 1917, pp. 372-394).—Studies on heredity and environment (E. S. R., 39, p. 746) were continued with corn, beans, soy beans, peas, and tomatoes.

Several  $F_1$  corn crosses were tested to determine the relation of ear type in the  $F_1$  to the character of the following crop. Some results are given for two crosses, but no general deductions have thus far been made from the accumulated data.

Six types of corn kernels were used in a test of the influence of depth of planting upon viability of the seeds and vigor of the plants. Samples of the corn were planted at depths ranging from 1 to 8 in. The number of kernels failing increased uniformly to 4 in., rose rapidly to nearly 50 per cent at 6 in., and still more rapidly at the maximum depth of 8 in., where the viability was only 28.7 per cent. Large kernels were more viable at great depth than small kernels, and field corn was more viable than sweet corn. The several depths did not seem to exert much influence upon the length of the stalks. Suckers were more numerous in the deeply planted rows and next in the shallow planted rows. Suckers were more numerous in rows planted with floury kernels than with rows planted with either flinty or sweet kernels. Sweet corn suckered least. Suckers were more numerous from large grains at each depth.

With five varieties of beans planted at depths of from 1 to 4 in., there was a large decrease in plants from the 3-in. depth and still more from the maximum depth. The 1-in. depth gave somewhat more plants than the 2-in. depth. Similar differences were noted in the percentage of seed viability. The number of pods per plant did not vary greatly among the four depths of planting. The Henderson Lima beans gave the greatest yield from seed planted 3 in. deep, whereas the four varieties of field beans tested declined in yield as the planting depth increased. The viability of soy beans was nearly the same for all depths excepting the 4-in. depth, where it was only 56 per cent.

Some results are given of a preliminary test conducted with soy beans to determine whether a somewhat constant relationship exists between the position of the seed in the pod and its weight, size, and value for cropping. The largest crop of pods came from the seeds borne at the tip of 3-seeded pods and the lowest yield from seeds at the base of the same pods. Seed from 2-seeded pods averaged the highest yield of pods, and seed from 1-seeded pods the lowest. A high percentage of 1-ovuled 1-seeded pods was associated with the crops from 1-seeded pods and the basal ends of 3-seeded pods. The highest percentage of 2-ovuled 2-seeded pods was associated with the crops from 2-seeded pods with both the basal and tip seeds. The highest percentage of 3-ovuled 3-seeded pods was associated with the crops from 3-seeded pods. The test indicates that, if possible, it might be well before planting to eliminate the basal seeds from the 3-seeded pods and all 1-seeded pods.

The yield of seeds was best in the 3-seeded tip crop and poorest from the 3-seeded basal crop. For pods as a whole the best average yield of seed was from the 2-seeded pods and the poorest from the 1-seeded pods. Among the full pods the heaviest seed was in the 1-seeded pods, the weight diminishing as the pods increased in number of seeds. In pods containing more than 1 seed the tip seeds were heavier than those at the base. In 3-seeded pods the middle seed was somewhat heavier than the tip seed. Abortiveness was much more frequent in the basal ovules than in the tip ovules, and was in positive correlation with weight of seed.

Some data are given on a similar study of two widely different varieties of Lima beans, the Henderson representing the type with small thin-walled pods bearing small seeds, and the Burpee having comparatively large thickwalled pods and large seeds. The seeds in the basal position were lightest in all types of pods in both varieties, while those of the middle position of 3 and 4 ovuled pods were somewhat heavier than those at the tip. The position giving the lightest seeds within a given type of pod yielded the largest number of abortive ovules. No planting tests were conducted with these seed.

A test was conducted with 100 plants of the New Wonder bean with the view of determining the relation of period of growth of plant to pods and seeds. The percentage of pods having 1 or more ovules aborted was very large and increased from the first to the last picking. Pods picked during the midseason had the greatest number of seeds, and those picked during the latter part of the season the lowest. The heaviest seeds were found in the last picking and the lightest in the midseason picking. In 4-ovuled pods seed weight gradually increased from the base to the tip of the pod. In pods with more than 4 ovules seed weight appeared to be greatest near the middle of the pod. Abortiveness was highest in the midseason pods and lowest in those of the last picking. Within the type of pod the greatest percentage is in the 3-ovuled pods and decreases with the increase in the number of ovules per pod.

Some data are given on a study of the weight of tomatoes as related to position in the cluster. With one exception the basal fruits were heaviest and the terminal fruit lightest.

A number of pea vines were examined to determine the relation between the section of plant to the character of pod and seed. The results of the test, as a whole, indicate that the first pods to form upon all vines of the Alaska type had a larger number of ovules than those formed later. The middle section of the plant produced the largest number of the pods and the heaviest seeds with far the lowest percentage of abortiveness. The abortiveness is chiefly in the basal tip position of the pod.

The breeding of vegetable fruits, E. J. OWEN (*New Jersey Stas. Rpt. 1917*, *pp. 396-401*).—In continuation of previous work (E. S. R., 39, p. 746) notes and data are given on character transmission in bean, eggplant, muskmelon, and tomato crosses.

Spray and practice outline for fruit growers, H. J. EUSTACE and R. H. PETTIT (*Michigan Sta. Spec. Bul. 93 (1919)*, pp. 32, figs. 6).—This bulletin contains general directions for the spray treatment of various orchard and small fruits and vegetables, including instructions for the preparation of sprays, dusts, and other poisonous mixtures.

Analyses of materials sold as insecticides and fungicides during 1918, C. S. CATHCART and R. L. WILLIS (*New Jersey Stas. Bul. 333 (1918)*, pp. 3-16).— The usual report on analyses of samples of insecticides and fungicides collected in the State.

Sod, tillage, and fertilizers for the apple orchard.—A 10-year summary, J. H. GOURLEY (*New Hampshire Sta. Bul. 190 (1919)*, pp. 3-40, figs. 6).—A further contribution to the long-continued orchard management investigation being conducted at the station (E. S. R., 38, p. 345), in which is presented a 10-year summary of the more practical results of various cultural and fertilizer treatments, such as yield and growth of the trees and size of fruit in the different plats.

Trees growing in sod have not yielded sufficiently well to warrant the use of the land for orcharding. They have made such inferior growth most seasons that they were less able to withstand the destructive influences of weather and parasites. Clean cultivation, without the use of cover crops, has proved to be a successful method in the reclamation of a run-down orchard, increasing the yield nearly 100 per cent and increasing the growth and general vigor of the trees. At the end of the 10-year period, however, the trees were not making as good an average growth as at the end of the 5-year period, indicating that this treatment could not be continued over a longer period of time.

Tillage with cover crops every other year resulted in decided benefit to the trees, but was less satisfactory than annual tillage either with or without cover crops. Annual tillage with cover crops has proved to be a slightly better system to follow than clean tillage, and has given practically as good results as any treatment followed. The cover crops, however, show decided evidence of the need of additional fertility, and the trees in this plat are somewhat less vigorous than during the earlier years of the experiment. Commercially the annual tillage on the cover crop plat has been the most profitable plat in the orchard, and this system is recommended for the run-down orchards throughout the State.

The fertilized plats have failed to respond to either treatment in yield of fruit, as they have made very slight gains. They have responded better in growth, which was not distinguishable, however, until after the sixth year when the larger size of trees was noticeable, and also the darker green color of the foliage. There was no preponderent difference in favor of any of the combinations of complete fertilizer used in the different plats. The combination richest in potash has given the largest apples throughout the experiment, the general quality of the apples being perhaps somewhat better than in the fertilizer plats. Lime has had no obvious effect upon this orchard.

The experiment, as a whole, shows in a most emphatic way the importance of selecting a proper site for an orchard, since the losses from frosts and freezes in a poorly located orchard are disastrous. This experiment indicates that an apple orchard receiving a good system of cultivation responds slowly to the use of chemical fertilizers. In other soils and under other conditions the response might be more marked. It is pointed out that other experiments which will shortly be reported upon show that it is usually necessary to fertilize an apple orchard which is not being cultivated, and that returns are almost immediate in that case. The author recommends that the orchardists of the State apply fertilizers at about the following rate per acre as a trial before they make general use of them: 150 lbs. nitrate of soda, from 200 to 300 lbs. acid phosphate, and from 50 to 100 lbs. sulphate or muriate of potash.

Fertilizer tests for strawberries.—Summary of results of experiments, extending over three years, on a red-shot Parkdale loam, G. G. BROWN (Oregon Sta. Bul. 159 (1919), pp. 15, figs. 3).—A series of fertilizer tests were conducted during the seasons 1916–1918, inclusive, in which nitrate of soda, superphosphate, and sulphate of potash were applied, both alone and in combination. The applications were made chiefly in the spring. A late summer application was made in 1917 to determine its value as compared with spring applications.

The results of the test, as a whole, indicate that for the particular soil involved nitrogen was more beneficial than either phosphoric acid or potash. At the same time plants receiving large quantities of nitrate during 1917 and 1918, when the weather was extremely warm during a large part of the picking season, produced berries which were inclined to be soft. Plants receiving applications of sulphate of potash produced somewhat firmer, but not more attractive berries. During 1916 when a long, cool picking season prevailed there was practically no difference between the firmness, size, or appearance of fruit from any of the plats. Applications of complete fertilizers, although showing increased yield over check plats, were less beneficial than applications of nitrate alone. It is pointed out, however, that on the lighter soils, especially where water-holding capacity and fertility are often poor on account of lack of humus, commercial fertilizers should not be used to the exclusion of green manures, stable manures, etc. Summer applications of fertilizers appear to possess considerable merit as compared with those made in the spring. Where combined fertilizers were used, late summer applications gave somewhat larger berries than spring applications of similar fertilizers.

Currants and gooseberries, G. M. DARROW (U. S. Dept. Agr., Farmers' Bul. 1024 (1919), pp. 40, figs. 26).—This discusses the essential features of currant and gooseberry culture, the selection of varieties, uses of the fruit, and the regions in which these plants may be grown. Certain restrictions on their culture due to such insect pests and diseases as the currant maggot and blister rust, have been pointed out.

In view of the fact that blister rust, so destructive to white pine trees, passes one stage of its growth on currants and gooseberries, it has been found necessary to destroy all currant and gooseberry bushes in certain areas, and to prohibit the further planting of them in certain areas representing valuable lumber interests. The laws which have been enacted by the several States to this end and the Federal quarantine regulations respecting the interstate shipment of currant and gooseberry plants and pine-tree nursery stock are here explained.

The avocado in Guatemala, W. POPENOE (U. S. Dept. Agr. Bul. 743 (1919), pp. 69, pls. 23).—An account of the avocado in Guatemala, with reference to its importance, extent of culture, popular uses, and types of avocados grown. Avocado culture in the Guatemalan highlands is discussed with reference to the origin of choice varieties, soils, growth and habits of the tree, cultural practices, regularity of bearing, yield, season, picking, ripening, and marketing the fruit, variation in fruits, climatic conditions in the principal avocado regions, hardiness of the avocado, and enemies of the avocado.

An account is also given of the coyo, a distinct species of Persea resembling the avocado, which possesses a distinctive and agreeable flavor and is considered superior to the avocado in some parts of Guatemala. Some 23 Guatemalan avocados, introduced by the Office of Foreign Seed Plant Introduction into the United States for trial in California and Florida, are described.

Vanilla.—A promising new crop for Porto Rico, T. B. McCLELLAND (*Porto Rico Sta. Bul. 26 (1919)*, pp. 32, pls. 3, figs. 4).—This bulletin embodies the results of investigations conducted by the station for several years with a view to establishing the vanilla industry in Porto Rico.

Introductory considerations deal with the general status of the vanilla industry and market prospects. The history is given of the experimental planting at the station, including directions for starting a vanillery, propagation, shading, care of plantation, methods of hand-pollinating the blossoms, picking, curing, and preparation for market.

The experiments conducted at the station have resulted in the production of vanilla beans pronounced by dealers as excellent in quality. The crop from a small plat, which was marketed at less than four years from the time the cuttings were set, averaged about  $\frac{1}{3}$  lb. cured beans per fruiting vine. The gross returns from the sale of this crop were at the rate of a little less than \$400 per acre. In the following year the yield increased to  $\frac{1}{2}$  lb. cured beans per vine, and the estimated gross returns based on samples submitted to dealers was from \$700 to \$900 per acre. In the third harvest year the crop from these

and younger vines on a one-tenth acre plat amounted to 36.44 lbs. and sold for \$109.31.

It is pointed out that vanilla growing should not be undertaken by anyone who is unwilling or unable to give the requisite attention to the crop, since the various operations require a considerable expenditure of time, care, and money.

The industry is specially recommended for such districts as are accessible only by poor roads over which bulky and more perishable products can not be carried.

Planting the rural school grounds, C. P. HALLIGAN (*Michigan Sta. Circ. 36* (1919), pp. 4, fig. 1).—Concise suggestions are given relative to the use of native plants, preparation of planting plans, where to plant, and rules for planting. A list is given of native plants that may be available in neighboring fields for improving the rural school grounds.

#### FORESTRY.

Trees of Indiana, C. C. DEAM (Indianapolis: Ind. State Bd. Forestry, 1918, 2. ed., pp. 299, figs. 126).—This is a reprint of a part of the 1911 Keport of the State Board of Forestry, to which has been added a few notes and corrections. All the woody plants of the State that usually attain a diameter of 10 to 15 cm. (4-6 in.) have been included, and also a few that rarely attain this size in Indiana. Each tree is considered under the heads of botanical description, distribution, economic uses, and horticultural value.

Geologic history of the locust and its allies, E. W. BERRY (*Plant World*, 21 (1918), No. 11, pp. 284-298, figs. 2).—This paper discusses the geologic history of the black locust (Robinia), the honey locust (Gleditsia), the Kentucky coffee tree (Gymnocladus), and the Judas-tree (Cercis).

[Progress report on forestry investigations] (Kansas Sta. Rpt. 1918, p. 36).—The station is emphasizing the desirability of increasing the planting of red cedar and black walnut, these species having shown under Kansas conditions their superiority as windbreaks, ornamentals, and shade trees. Recent investigations also show the bull pine to be a valuable ornamental tree which has heretofore received too little attention in the State.

Waipoua Kauri Forest, its demarcation and management, D. E. HUTCHINS (*Wellington, New Zealand: Dept. Lands and Survey, 1918, pp. 63, pls. 6*).—This comprises the results of a survey of the Waipoua Kauri Forest reserve in New Zealand, with special reference to the demarcation and management of kauri forests.

Observations on distribution of forest tree pollen, H. HESSELMAN (Meddel. Stat. Skogsförsöksanst., No. 16 (1919), pt. 2-3, pp. 27-60, figs. 3).—A review of the literature on this subject, including some data on observations made by the author relative to the distribution of pollen from spruce, pine, and birch trees.

Pollen was collected on prepared surfaces on two lightships, one 30 km. (18.6 miles) from land and the other 55 km. from land. Spruce pollen grains were collected at the rate of 6,961, birch 6,811, and pine 2,390 grains per square millimeter on the ship nearest shore; and at the rate of 4,089, 3,649, and 1,069 grains per square millimeter, respectively, for spruce, birch, and pine on the ship farthest from shore. Instances of even farther distribution of forest tree pollen are cited and discussed, with special reference to its influence on the question of sources of tree seed. It is pointed out that the fertilization of flowers with pollen from long distance may work against local, climatic conditions. The author is of the opinion that the presence of fossil pollen grains of certain trees in peat moors is not necessarily an index to the previous flora of these moors, inasmuch as the pollen may have been carried from long distances.

Anatomy of the union of a spruce graft on pine, L.-G. ROMELL (Meddel. Stut. Skogsförsöksanst., No. 16 (1919), pt. 2-3, pp. 61-66, figs. 2).—The author describes a case of natural grafting of spruce on pine, and discusses anatomical peculiarities observed in the region of the union. A brief bibliographical paragraph of cited literature is appended.

From a study of the graft as a whole it is concluded the foreign cells, though to a large extent autonomously reacting in a morphological sense, react physiologically with each other in a thoroughly harmonious way as parts of a single organism.

A study of the frustum form factors of hard maple and yellow birch, B. A. CHANDLER (Vermont Sta. Bul. 210 (1918), pp. 3-38, figs. 8).—During the course of timber-estimating work on the State forests of Vermont and elsewhere from 1912 to 1917, the author found that volume tables based alone on diameter and height measurements gave thoroughly unsatisfactory results. Frustum form factors were computed from measurements of a few yellow birches and hard maples and applied to a table of frustum volumes, based on a local top diameter curve. In view of the more satisfactory results obtained by this preliminary application of the frustum form factor, the work was greatly extended in 1915 and 1916, measurements being made of over 1,200 trees, principally yellow birch and hard maple. Frustum form factors were constructed from these measurements and were studied chiefly to determine the laws which govern the frustum form and methods of expressing them. The results of the study are discussed in detail, and the application of the frustum form factor to practical timber estimating is described. A bibliography of cited literature is given.

Formulas were developed from the study to find the value of the absolute diameter breast-high frustum form factor in terms of the taper ratio and form quotient; the value of the absolute diameter breast-high cylinder form factor in terms of the frustum form factor and taper ratio; the value of the cylinder form factor, when the section below diameter breast high is computed as a cylinder, in terms of the absolute diameter breast-high frustum form factor and taper ratio; and the value of the absolute diameter breast-high cylinder form factor in terms of form quotient and taper ratio.

The method of obtaining the form-class and volume of single trees by the use of form-point.—An investigation based on spruce material from Norrbotten, Sweden, S. PETRINI (Meddel. Stat. Skogsförsöksanst., No. 15 (1918), pp. 233-273, XXIX-XXII, figs. 9; Skogsvårdsför. Tidskr., No. 11-12 (1918), pp. 597-635, figs. 9).—In the investigation here reported, measurements were made of spruce material from forests differing in age, height, density, quality of soil, etc., in order to determine the degree of accuracy of the form-point method in determining the volume of individual standing trees.

It is concluded that the form-point method can not be used with sufficient accuracy for single trees, because the form-class is determined only as an average value applicable to the whole material.

Results of cutting at Ne-Ha-Sa-Ne Park, in the Adirondacks, B. A. CHANDLER (*Jour. Forestry*, 17 (1919), No. 4, pp. 378-385, figs. 3).—Data are given of spruce growth and reproduction on lands cut over for spruce some 15 to 20 years ago.

The results of the study as a whole indicate that, on hardwood lands managed for spruce, as much of the hardwoods should be cut as market conditions will allow, and the maximum number of small and medium, well-topped, free spruce consistent with lumbering conditions and danger from windfall should be left. It is concluded that possibly no satisfactory system of management for spruce can be found short of clear cutting and planting. In the area studied the spruce is being crowded out by the hardwoods which have taken advantage of the openings and are spreading out over the unused spaces every time that a conifer is removed.

On the question of forest renewal, H. BEEKMAN (Boschbouwk. Tijdschr. Tectona, 12 (1919), No. 1-2, pp. 1-129).—An exposition on forest regeneration in Netherlands Indies, with special reference to the reproduction of teak. An outline is given of investigations dealing with forest renewal conducted at the Forest Experiment Station, together with a bibliography of cited literature.

The northeastern Minnesota forest fires of October 12, 1918, H. W. RICH-ARDSON (Geogr. Rev., 7 (1919), No. 4, pp. 220-232, figs. 5).—A historical record of this disastrous fire, including a detailed map of the region burned over.

A contribution on the tan bark question, VAN DEN BUSSCHE (Boschbouwk. Tidjschr. Tectona, 12 (1919), No. 3, pp. 217-251).—A review of the present status of the tan bark industry in Java, including suggestions relative to its future development.

Charcoal burning in Sweden, M. A. F. DIJKMANS (Cultura, 31 (1919), No. 368, pp. 115-145, pls. 5, figs. 19).—A descriptive account of methods used in producing charcoal in Sweden.

### DISEASES OF PLANTS.

Plant disease investigations (*Kansas Sta. Rpt. 1918, pp. 36-38*).—The principal investigations in plant diseases carried on by the station were studies of wheat stem rust and corn smut and the resistance of sorghums to kernel smut.

More than 150 varieties of winter wheat were tested for their resistance to the stem rust (*Puccinia graminis tritici*), the experiments being undertaken both in the field and in the greenhouse. Three hard winter wheats were found remarkably resistant to the stem rust. Various selections have been made of these varieties, which are being propagated, as they appear to be of great commercial value. Hybrids between some of these forms and some spring wheats have been produced and the  $F_1$  generation grown to maturity.

In connection with the rust investigations a biologic form was observed, an account of which has already been given (E. S. R., 39, p. 454).

In the smut investigations it was found that the smut organism is carried from the soil by the wind to the axils of the corn plant, from which cultures were readily obtained. A virulent culture in the topmost leaf axil was found to be a source for infecting the several nodes below. In an attempt to control the corn smut by the use of Bordeaux mixture and formaldehyde spray, the treatments under Kansas conditions were found to be neither practical nor effective. While the percentage of corn smut was in some cases reduced, there was also a reduction in the yield. Some resistance to smut was reported in case of certain varieties.

A test was made of 38 varieties of sorghums to determine their resistance to kernel smut, and infection was found to vary from 0 per cent in case of milo, feterita, White durra, and Brown kaoliang to 38 per cent in the sorgo group. Attention is called to the fact that, while milo and feterita are usually classed as immune to smut, experiments have shown that infection can be secured by artificially injuring the seed and dusting them with smut spores.

Report of the department of plant pathology, M. T. Cook (New Jersey Stas. Rpt. 1917, pp. 523-535, pls. 5).—The author briefly refers to work that has been in progress during the year. A list is given of the most common diseases that were observed during the year.

The control of plant diseases due to fungi in Great Britain, A. S. HORNE (*Jour. Roy. Hort. Soc.*, 42 (1916), No. 1, pp. 13-26, pls. 4).—This is a review of studies, requirements, and measures related to plant diseases in Great Britain and some other countries.

Investigations [on plant diseases] at the National Fruit and Cider Institute (Jour. Bd. Agr. [London], 25 (1918), No. 3, pp. 316-320).—This is a summary of portions of the work done during the year ended September 30, 1917, in connection with plant diseases and injuries. Portions of this work as reported by Barker and Bastin (E. S. R., 40, pp. 844, 847), have been noted.

Phytopathological report, 1916 and 1917, P. MARCHAL and G. ARNAUD (Min. Agr. [France], Ann. Serv. Épiphytics, 5 (1916–17), pp. 6, 7, 20–35).—In this portion of the general report of the Phytopathological Station of Paris are noted the recent outbreak or extension of black canker of chestnut, American gooseberry mildew (Spærotheca mors uvw), and black rot of grapes. A somewhat systematic account is given also of injurious agents affecting plants of different classes, chiefly during the period under discussion.

Summary reports of entomological and pathological laboratories (*Min. Agr.* [France], Ann. Serv. Épiphytics, 5 (1916-17), pp. 253-272).—This report deals mainly with activities of the years 1916 and 1917 connected with injury by insects and fungi as reported from stations dealing with entomology or plant pathology or both, at Paris, Blois, Bordeaux, Montpellier, Saint-Genis-Laval, and Cadillac (Gironde). Lists of related contributions are also given.

The disinfection of the soil, E. MIÈGE (*Min. Agr.* [France], Ann. Serv. Épiphytics, 5 (1916-17), pp. 83-114, figs. 3).—The present contribution (E. S. R., 28, p. 623; 36, p. 623) deals with soil treatments to increase fertility and to give control of plant diseases attacking by way of the soil.

Gum formation with special reference to cankers and decays of woody plants, B. B. HIGGINS (Georgia Sta. Bul. 127 (1919), pp. 23-59, figs. 17).—In a previous publication (E. S. R., 34, p. 747), the author suggested that gummosis was probably caused by the action of an enzym, and as an enzym is usually found in freshly formed gum the author carried on a series of experiments in the artificial production of gummosis under partially controlled conditions.

It was found that gum formation, although affected to some extent by variations in temperature, moisture, etc., is not dependent upon or always associated with growth activity. This behavior, together with the fact that a pectin-dissolving enzym is always found in freshly exuded gum, is held to indicate that gum formation is brought about by enzym activity.

Studies on the crown rust of oats, I. E. MELHUS and L. W. DURRELL (*Iowa Sta. Research Bul. 49* (1919), pp. 115-144, figs. 6).—The data presented in this bulletin, obtained in cooperation with the Bureau of Plant Industry of the U. S. Department of Agriculture, constitute a progress report dealing largely with the factors influencing the growth and reaction of crown rust (*Puccinia coronata*) of oats and different species of Rhamnus, the data having been accumulated during a period of three years. The temperature relations and the moisture requirements of the uredospores were investigated.

It was found that the minimum temperature for the germination of the uredospores of crown rust is  $1^{\circ}$  C., the optimum 17 to  $22^{\circ}$ , and the maximum  $35^{\circ}$  (95° F.). Direct contact with water is essential for the germination of the crown rust uredospores, a saturated atmosphere not furnishing sufficient moisture for germination. The environment under which the uredospores were produced is said to influence their germination to some degree, spores

borne on heavily infested seedlings not germinating so well as those produced on plants approaching maturity. A still, humid atmosphere favored the rapid maturity of the spores, and spores detached from the host plant and stored in dry capsules at 13 to  $20^{\circ}$  showed increasing germination after six or seven days.

The biologic form of crown rust occurring on oats uses *R. cathartica* and *R. lanceolata* as alternate hosts. *R. frangula*, *R. caroliniana*, and *R. alnifolia*, other species occurring within the State, were not found to harbor the alternate stage of the strain of crown rust occurring on oats.

Data concerning the dissemination of wheat rust, F. U. G. AGRELIUS (*Trans. Kans. Acad. Sci.*, 28 (1916–17), pp. 115–117).—It is believed that the persistence and succession of wheat rust (*Puccinia graminis*) without the æcidial stage in the neighborhood of Oswego, Kans., are due to the presence of many native (and mostly perennial) grasses, in some cases intimately associated with cultivated grains. The grasses retain their green color and are evidently infected with the fungus. *Panicum virgatum* appeared to harbor *Puccinia graminis*.

Report of celery investigation, R. F. POOLE (New Jersey Stas. Rpt. 1917, pp. 536-539).—Field and greenhouse experiments have been carried on for the control of celery diseases, the principal of which were the crown rot due to Bacterium sp., damping-off or stem rot (Sclerotinia libertiana), root knot caused by nematodes, early blight (Cercospora apii), and late blight (Septoria petroselini apii). Damping-off due to Rhizoctonia sp. is reported to have given trouble in one greenhouse during the spring.

For the control of the crown rot due to *Bacterium* sp., a series of experiments in sterilization of the soil with various chemicals was carried out, and while the disease was not controlled the results indicate some promise for hydrochloric acid and calcium carbonate. The author believes that plant breeding offers the best solution of the problem of control of crown rot, as some varieties seem to possess considerable immunity.

For the control of the damping-of. due to *Sclerotinia libertiana*, an experiment was carried out in which beds were divided into sections, one of which was thinned, the diseased plants being removed, and sodium nitrate added to the soil; the second was not thinned, but sodium nitrate was added to the soil; the third was thinned, the diseased plants being removed, but no sodium nitrate was added; and the fourth, which was given no treatment, was used as a check. Where the diseased plants were removed and the fertilizer added the best growth was made, very few plants dying. Where all diseased plants were removed and no fertilizer added only a few dead plants were observed. In the other plats many plants succumbed.

For the control of early blight and late blight, both of which did considerable damage, spraying with Bordeaux mixture is recommended.

The angular leaf spot of cotton, R. C. FAULWETTER (South Carolina Sta. Bul. 198 (1919), pp. 41, figs. 11).—In continuation of previous studies on the physiology of Bacterium malvacearum (E. S. R., 36, p. 648) and rain as a factor in disease dissemination (E. S. R., 38, p. 47) the author brings together the data obtained by him in the course of his investigations, which have covered a period of several years.

The disease caused by *B. malvacearum*, while most noticeable on the foliage of cotton, may also be found on the cotyledons, stalks, petioles, bracts, and bolls. The factors most probably concerned in the hibernation and appearance of the disease are said to be the presence of bacteria in the soil, their survival in decaying cotton plants and plant parts, contamination of fuzz or short lint on the seed, internal seed infection, hibernation upon or in insects, and susceptibility of plants closely related to the cotton plant. Wind-blown rain is considered an important agent of dissemination, both local and general. Little evidence of insect dissemination has been found.

Sterilization of the seed coat by the use of sulphuric acid and bichlorid of mercury has been found the most efficient means of control.

Attack of peas in Gironde by Heterodera schachtii, J. CAPUS (Min. Agr. [France], Ann. Serv. Épiphytics, 5 (1916–17), pp. 239–244).—The author notes a severe outbreak of nematodes occurring in Gironde during 1915, but not since that time in sufficient severity to attract attention. The effects of the attack on the plants are described. The plants also showed the presence of a fungus, the characters of which are said to correspond closely to those of Fusarium vasinfectum pisi, considered as the conidial form of Neocosmospora vasinfecta. The fungus usually attacked the plants near the base of the stem, the nematodes attacking the roots, which showed the presence in large numbers of the brown cysts, which are simply the bodies of the females distended with eggs. The fungus is thought to be unable to attack vigorous plants.

Common potato diseases and their control, A. V. OSMUN (Agr. of Mass., 1917, pt. 2, pp. 125-133, figs. 8).—This is a discussion of early blight (Macrosporium solani), late blight (Phytophthora infestans), scurf or Rhizoctonia, scab, blackleg, and dry rot and wilt, with precautionary and other preventive measures, including sprays.

Studies on potato leaf roll, E. BLANCHARD and C. PERRET (*Min. Agr.* [*France*], *Ann. Serv. Épiphytics*, 5 (1916-17), pp. 245-252, pl. 1).—This is a more extended account than that previously noted (E. S. R., 40, p. 347) of potato leaf roll, which is said to exist in various degrees of severity in different areas indicated.

Potato spraying experiments in 1917, M. T. COOK (New Jersey Stas. Rpt. 1917, pp. 561-563).—A brief account is given of potato spraying experiments carried on in cooperation with some growers, in which Bordeaux mixture, Kil-Tone, and arsenate of lead were used as fungicides, some plats being sprayed with a combination of Bordeaux and arsenate of lead.

The highest yield in one instance was obtained where the plats received **a** spray of arsenate of lead, but the average of the plats receiving Bordeaux mixture and arsenate of lead was several bushels higher than that of the plats receiving no Bordeaux. On another farm the highest yield was obtained where Kil-Tone was used, the lowest yield being from the plat which had been sprayed with the combination of Bordeaux and arsenate of lead.

The author considers that not very much dependence can be placed in these results, as the crop was exceptionally free from disease in the early part of the season and the growth was unusually good.

Smuts of jowar (sorghum) in the Bombay Presidency, G. S. KULKARNI (*Agr. Research Inst.*\**Pusa Bul.* 78 (1918). *pp.* 26, *pls.* 6).—This report embodies the results of observations, which are still in progress, made by the author during 5 years in the Bombay Presidency on the smuts of jowar.

This name applies to all cultivated varieties of *Andropogon sorghum*, which occupies third place as regards acreage among cultivated crops of this region. The smuts, which are the most important among the fungus diseases of sorghums, are classed as loose, long, whole-head, and grain smuts, each of which is described. Experiments are cited to prove that infection with seed-borne spores occurs only in case of loose and grain smuts, and that copper sulphate checks the disease in both cases. Soil infection is apparently absent in case of these smuts, spores of which, however, may retain vitality from 2 to 6½ years under suitable conditions of dryness. Whole-head smut seems to attack chiefly by way of the soil and is not checked by seed treatment. Long

smut has not been adequately studied as to its life history, and its mode and habit of attack are not settled.

The nonneclature of these smuts is discussed in connection with descriptions of diseases and fungi.

The copper sulphate remedy is the only one considered applicable under local conditions, concentrations of from 0.5 to 3 per cent being considered as both safe and effective.

On the mode of infection and prevention of the smut disease of sugar cane, S. L. AJREKAR (Agr. Jour. India, 11 (1916), No. 3, pp. 288–295, pl. 1).—The author has carried out studies suggested by remarks made by Butler in a paper previously noted (E. S. R., 18, p. 450), attempting to ascertain how infection usually takes place in the field in case of sugar-cane smut and testing the efficacy of copper-sulphate treatment of sugar-cane sets before planting. These experiments were carried through 3 years in the neighborhood of Poona, where smut had appeared sporadically for some years, particularly on some thin varieties.

The results show that the disease may be carried by canes not obviously diseased if taken from stools some portions of which are affected. The fungus may be demonstrated in a side shoot not over 6 in. in length from an infected shoot; also in the tissues of the dormant buds in a diseased cane. Smut originating in diseased sets usually appears within 3 to 5 months after planting. Infection by spores adhering to sets does not usually become apparent until the crop is approaching maturity. No direct proof was obtained regarding probable infection of shoots by aerial transmission of spores and the formation of dormant mycelium in such shoots.

Steeping in copper-sulphate solutions is useless and does not check the disease. The practical control methods suggested are destruction of diseased canes and careful avoidance of infected stools for propagation purposes.

Tomato spraying experiments at Riverton, N. J., W. H. MARTIN (*New Jersey Stas. Rpt. 1917, pp. 540–561, pl. 1*).—A report is given of spraying experiments for the control of the late blight of tomatoes carried on in 1917 in cooperation with the U. S. Department of Agriculture and a prominent tomato grower. The fungicides used consisted of Bordeaux mixture, the formula of manufacture of which was varied and to which in some cases resin fish-oil soap was added, a copper-sulphate mixture with the fish-oil soap, and a copper-sulphate soap mixture.

As a result of the investigation, it is claimed that late blight of tomatoes, caused by *Septoria lycopersici*, can be controlled by thorough spraying at the proper time. All of the fungicides used gave increased yields over the check plats and controlled the late blight. Standard Bordeaux mixture, while not giving the best control, gave the greatest increase in yield over the check plats. The copper-soap mixture gave good results, and, on account of its low cost and ease of preparation, it is thought that it should be given serious consideration. As a result of the season's work it is believed that spraying tomato plants in the seed bed in New Jersey is unnecessary but that the first application should be made not later than July 1. It was also ascertained that if all the leaves are held on the plants until frost a large part of the fruit formed will not ripen. In connection with these experiments different forms of spray machines were tested and while there was little difference in the two types compared, the traction sprayer, due to its low cost of upkeep, is considered the better.

The effect of late applications on the yield and ripening of tomatoes was investigated. From the results obtained, it is considered that the value of spraying late tomatoes is questionable.

The apple tree anthracnose and how to control it, L. CHILDS (*Better Fruit*, 13 (1918), No. 5, pp. 7–9, figs. 3).—This canker disease of the apple is said to be confined chiefly to sections west of the Cascade Mountains, and its development reaches its height in sections of abundant rainfall. Burgundy mixture, properly made up to 3:3:100, has given the best results as regards control.

Brown rot of apples, H. WORMALD (Jour. Bd. Agr. [London], 25 (1918), No. 3, pp. 299-302, pls. 2).—The progress of the causal fungus, Monilia (Sclerotinia) fructigena, after its inoculation into sound apples is here described. Discussion is given also of spur canker.

Infection and immunity in apple rust, N. J. GIDDINGS (West Virginia Sta. Bul. 170 (1918), pp. 71, figs. 50).—The author reviews the results of investigations undertaken for the purpose of securing definite and reliable information regarding the apple rust due to Gymnosporangium juniperi virginianx, and the factors which result in the infection of the apple or cedar in some instances while in others there is apparent immunity. A previous account of some of the investigations included in this bulletin has already been noted (E. S. R., 35, p. 49).

Leaves of the variety York Imperial have been found usually susceptible to rust from 15 to 25 days after they unroll from the bud, the length of the period being closely associated with growth conditions. Infection data based on periods of rainfall, discharge of sporidia, etc., are considered to offer little definite proof that infection has taken place, since abundant sporidia discharge has been observed without any infection. Sporidia are not discharged in appreciable numbers at a temperature below 50° F. Under optimum conditions a fairly abundant discharge of sporidia may be observed in less than three hours after first moistening a mature sorus, slight evaporation apparently favoring the discharge.

The greatest injury to apple trees is said to be due to foliage infection. A severe rust infection may result in deformed fruit, general reduction in size of fruit, and great loss of vigor in the tree, and the results of severe infection may apparently persist for more than one season. A large percentage of fruit may show "ust if the infection occurs about the time the blossoms fall.

The author has observed marked variation in susceptibility of red cedar trees to this disease.

On the apple, rust may be controlled by the use of sprays, but this method is not considered practical in commercial orchards. The destruction of cedar trees for a radius of two miles about susceptible orchards is recommended, and the cost of removing the cedar trees has not been found excessive under West Virginia conditions.

Winter injury to cherry blossom buds, R. H. ROBERTS (*Proc. Amer. Soc. Hort. Sci., 14 (1917), pp. 105-110, figs. 2).*—A study was made in the spring of 1917 of severe winter injury to cherry trees of several varieties occurring in Door County, Wis., near Sturgeon Bay; also of injury in the Bayfield district. A large number of blossom buds was present. There was no die-back. Frequently only 1 or 2 of the 4 or 5 blossoms within a bud were killed. In 1917 the injury, while less severe than the previous year, followed the same relative lines as regards varieties. Exposure did not appear to have any influence as regards degree of injury. Trees partially defoliated by shot-hole fungus the previous year and young trees suffered less than other trees of the same variety, being also later in blossoming. In old Richmond trees, spurs of medium length suffered most injury; also along the terminal growth the injury to the lateral buds was more noticeable through the central part of the growth than at the base and the tip. The larger buds showed more injury. The last lateral bud showed less injury than the lower buds. On young trees injury was less severe where less growth was made, so that immaturity does not appear to have favored frost injury. Bud killing does not appear to be due to second growth following high temperatures. A relation was noted between injury and size of buds or relative development, which is supposed to bear an important relation to the size of the leaf subtending the bud. These observations are regarded as preliminary.

**Brown rot on peaches**, M. A. BLAKE and C. H. CONNORS (*New Jersey Stas. Rpt. 1917, pp. 81, 82, pl. 1*).—The authors report the occurrence of brown rot of peaches in central and southern New Jersey, from 25 to 50 per cent of the blossoms being destroyed in some instances. In addition to the attack on the blossoms, the twigs were killed in numerous cases, the trees having the appearance of being affected by twig blight.

**Peach leaf curl and how to control it**, J. T. BREGGER (*Better Fruit*, 13 (1918), No. 5, pp. 16, 17).—The author states that Bordeaux mixture at winter strength (6:6:50) is satisfactory for control of peach leaf curl, and that lime-sulphur (1:8) will control leaf curl and San José scale when that pest is present.

**Peach yellows and little peach at Vineland**, M. A. BLAKE and C. H. CONNORS (*New Jersey Stas. Rpt. 1917, pp. 88–92, pl. 1*).—A report is given of the number of trees lost in some test orchards from 1909 to 1917. The authors state that no tree has yet become diseased that had been planted in the spot from which a diseased tree had been removed, and trees replanted in the earlier years are now bearing. The immediate removal of any tree as soon as the first symptoms of the disease appear is strongly advised.

[Grape disease control and weather, 1917 and 1918] L. RAVAZ (Prog. Agr. et Vit. (Ed. VEst-Centre), 39 (1918), No. 18, pp. 409-418, figs. 3; abs. in Rev. Sci. [Paris], 56 (1918), No. 15, p. 467).—Noting principally observations made during the mildew outbreaks of 1917 and 1918, the author states that the almost perfect constancy of the time period between a given precipitation and the consequent appearance of infecting mildew spores (exactly seven days at Montpellier in 1917), permitting practically perfect control of this disease, is due to the well-established relations which obtain between atmospheric temperature and humidity. Brief notes are given on other subjects, as lime-sulphur mixtures and a sulphuric acid solution found effective against black rot.

Outbreaks of grape downy mildew in the southwest of France in 1916, J. CAPUS (*Min. Agr.* [France], Ann. Serv. Épiphytics, 5 (1916–17), pp. 193–200).—This account, which is in much more condensed form than that previously employed by the author (E. S. R., 36, p. 650), gives briefly data as to atmospheric conditions and other influences in connection with grape downy mildew and describes the 1916 outbreaks of this disease.

Comparative value of acid and alkaline copper sprays for the treatment of grape downy mildew, J. CAPUS (*Min. Agr.* [*France*], *Ann. Serv. Épiphytics*, 5 (1916-17), pp. 201-209).—This work, previously noted (E. S. R., 40, p. 158), showed that acid sprays are equally efficacious and immediate in effects as those of alkaline sprays under different atmospheric conditions. Bordeaux mixture having 2 per cent copper and 8 per cent lime was equal to standard Bordeaux in all respects. Conidia deposited on surfaces which had been sprayed but afterwards deprived by rainfall of copper deposits gave rise to zoospores. The basic sprays were more lasting in their effects than the acid sprays. The durability of acid or of alkaline sprays appears to be due not to the composition so much as to the degree of spreading or the degree of covering the surface, the deposit in case of alkaline sprays remaining practically continuous longer than in case of acid sprays. The characteristics of citrus canker and its eradication, E. M. DOIDGE (Union So. Africa, Dept. Agr. Bul. 3 (1918), pp. 9, pls. 10).—The purpose of this bulletin is to familiarize growers and handlers of citrus fruits with the appearance of citrus canker, which is the most serious of citrus diseases.

So far as known, all outbreaks have originated in *Citrus trifoliata* stock from Japan. The disease is said to have been noted in the Philippines, Australia, South Africa, and the United States. A discussion is given of its characteristics, dissemination, and possible eradication. A list is given of places where citrus canker is found in South Africa, three of these occurring in the Cape Province and the others in five districts of the Transvaal.

Sixteenth annual report of the [Massachusetts] State nursery inspector, H. T. FERNALD (Agr. of Mass., 1917, pt. 1, pp. 61-73, pls. 2).—An account is given of work done on white pine blister rust to December 12, 1917, by the State nursery inspector in cooperation with the U. S. Bureau of Plant Industry, including the planning, prosecution, difficulties, and results of that work.

The author considers it unwise at this time to attempt a State-wide control of the disease. It is thought that the best policy would be to select the best pine areas and remove all Ribes within 1 mile of such areas for at least a 5-year period.

Disease of the Carolina poplar, A. BERTIN (Vie Agr. et Rurale, 8 (1918), No. 17, p. 292; abs. in Rev. Sci. [Paris], 56 (1918), No. 14, p. 436). — Mention is made of insect enemies of the Carolina poplar, the chief fungus disease of which is said to be caused by *Pleococcum populinum*. This usually attacks plants not over two or three years old and finds ready entrance at wounds. It is recommended that young trees be sprayed with 3 per cent Bordeaux mixture.

A disease of Dalbergia latifolia, H. BEEKMAN (Boschbouwk. Tijdschr. Tectona, 11 (1918), No. 4, pp. 290-293, pls. 2).—A descriptive discussion is given of a canker affecting branches of Dalbergia latifolia noted in 1916 and earlier in several portions of the Dutch Indies, which are named. Suggestions are also given regarding the surgical and sanitary treatment which is recommended.

Fungus diseases of rubber in Southern India, W. MACRAE (*Planters' Chron.*, 13 (1918), No. 23, pp. 395-401).—In an address before the Rubber Planters' Conference at Cochin, the author dealt in a preliminary paper with the relations of Phytophthora to Hevea and cacao and with measures looking to control of the fungus, the complete classification of which appears to be not yet fully settled. Preventive measures are said to be still in the experimental stage, though results of tests appear to show that removal of fruit and dead branches will prevent the disease. The Phytophthora that attacks cacao was found able to cause a fruit rot of Hevea. See also previous notes (E. S. R., 40, p. 852).

## ECONOMIC ZOOLOGY-ENTOMOLOGY.

Wild animals of Glacier National Park (*Washington: U. S. Dept. Int.*, 1918, pp. 210, pls. 37, figs. 94).—Following a discussion of the general features governing life in Glacier National Park under the headings of physiography and life zones, by V. Bailey (pp. 15–24), the mammals are dealt with by V. Bailey (pp. 25–102) and the birds by F. M. Bailey (pp. 103–199). A colored map showing the life zones of the park, prepared by V. Bailey from a topographic base map of the U. S. Geological Survey, is attached.

Mammals of Australia in the Zoological Park, W. H. D. LE SOUEF (Zoologica [N. Y.], 2 (1919), No. 6, pp. 163-201, pls. 30).—A discussion of Australian mammals found in the New York Zoological Park.

125597°-19-5

Our national elk herds, H. S. GRAVES and E. W. NELSON (In The Open, 9 (1919), Nos. 1, pp. 33-38; 2, pp. 26-34, pl. 1, figs. 2).

[The mongoose in the West Indies] (Bul. Dept. Agr. Trinidad and Tobago, 17 (1918), No. 4, pp. 167-192).—A paper by C. B. Williams on The Food of the Mongoose in Trinidad (pp. 167-186), which records the stomach contents of 180 mongooses collected during the year October, 1917, to September, 1918, is followed by a paper on Rats and Mongoose in the West Indies (pp. 187-190) and the text of the mongoose ordinance, 1918 (pp. 190-192).

The muskrat in Bohemia, H. W. FRICKHINGER (*Naturw. Wchnschr., 33* (1918), Nos. 5, pp. 65-72; 6, pp. 73-81, figs. 26).—A discussion of the occurrence and economic importance of the muskrat, control measures, etc. A bibliography of 43 titles is appended.

The birds of economic importance, A. GODARD (Les Oiseaux Nécessaires a l'Agriculture, a la Sylviculture, a la Viticulture, a l'Arboriculture, et a l'Hygiène Publique. Paris: Perrin & Co., 1917, pp. II+121, figs. 18).—A small handbook.

An early experiment in keeping hummingbirds in captivity, T. S. PALMER (Condor, 19 (1917), No. 5, p. 168).

Another reference to early experiments in keeping hummingbirds in captivity, T. S. PALMER (Condor, 20 (1918), No. 3, pp. 123, 124).

Notes on the insect fauna of bank swallows' nests in Virginia, T. E. SNYDER and R. C. SHANNON (*Proc. Ent. Soc. Wash., 21 (1919), No. 5, pp. 110-112*).

Class book of economic entomology, with special reference to the economic insects of the northern United States and Canada, W. LOCHHEAD (*Philadelphia: P. Blakiston's Son & Co., 1919, pp. XIV*+436, figs. 265).—This work consists of four parts, the first of which (pp. 1–69) deals with the structure, growth, and economics of insects; the second (pp. 71–92), with the identification of insects injurious to farm, garden, and orchard crops, etc.; the third (pp. 93–371), with the classification and description of common insects; and the fourth (pp. 373–413), with the control of injurious insects.

A method for the preservation of insect larvæ and pupæ, F. S. JACKSON (*Canad. Ent.*, 51 (1919), No. 5, pp. 117, 118).—The author describes a method that may be used in the preservation of insects of all stages, including lepidopterous larvæ, by which both the form and color are preserved.

After the specimens are killed in the cyanid bottle or by means of chloroform vapor they are allowed to relax, and then placed in a fluid consisting of cane sugar 10 parts, glacial acetic acid 5 parts, formalin 2 parts, and distilled water 100 parts. The sugar is dissolved in the water and the acetic acid and formalin subsequently added. The specimens are allowed to remain in this fluid for about 24 hours, when they are transferred directly to a fluid identical in composition except that the acetic acid is omitted. After remaining in the second fluid for about 24 hours the fluid should be changed, and in case of large specimens a further renewal after the lapse of a week or ten days is advisable, since traces of acetic acid tend in some instances to destroy the color.

Plants used as insecticides, R. C. ROARK (Amer. Jour. Pharm., 91 (1919), Nos. 1, pp. 25-37; 2, pp. 91-107).—An annotated list which calls attention to promising insecticidal plants.

Fungoid and insect pests and their control.—I, Vegetable and pulse crops, F. O. Mosley (*Reading*, [*Eng.*]: *Author*, 1918, pp. 26, figs. 52).—Brief descriptions are given of several of the more important insect enemies of vegetable and pulse crops.

The insect pests of maize, W. B. GURNEY (Agr. Gaz. N. S. Wales, 30 (1919), No. 3, pp. 196-202, pl. 1, figs. 4).--In addition to the species dealt with in the first part of this paper (E. S. R., 40, p. 453) the author gives information on the yellow Monolepta beetle (*Monolepta rosæ*), the yellow maize or peach moth (*Conogethes punctiferalis*), and the bollworm which attack Indian corn in New South Wales. Two additional species of cutworms now recorded as maize pests in New South Wales, namely, *Agrotis radians* and *Prodenia litura*, are also described.

Forest zoology, B. B. OSMASTON (*Rpt. Forest Research Inst.* [Dehra Dun], 1917-18, pp. 6, 7).—The notes here presented relate to economic insects, particularly those attacking sal and teak.

Entomology and the war, L. O. HOWARD (Sci. Mo., 8 (1919), No. 2, pp. 109-117).—A brief discussion of some of the entomological problems dealt with during the war.

Seventeenth report State entomologist of Minnesota, A. G. RUGGLES (*Rpt. State Ent. Minn.*, 17 (1918), pp. 240, pls. 3, figs. 231).—Following brief notes on the insects of the year, by A. G. Ruggles (pp. 3–8), papers are presented on Life History of an Oak Twig Girdler (*Agrilus arcuatus torquatus*), by A. G. Ruggles (pp. 15–20); Potato Spraying in Minnesota, by S. A. Graham (pp. 21–31); The Carpenter Ant as a Destroyer of Sound Wood, by S. A. Graham (pp. 32–40); Drosophila in Bottled Certified Milk, by W. A. Riley (pp. 41–45); Contribution to Knowledge of the Tribes and Higher Groups of the Family Aphididæ, by O. W. Oestlund (pp. 46–72); The Confused Flour Beetle (*Tribolium confusum*), by R. N. Chapman (pp. 73–94); The Clover Seed Chalcid (*Bruchophagus funebris*), by W. Williamson (pp. 95–110); A Preliminary Report on the Trombidiidæ of Minnesota, by C. W. Howard (pp. 111–144); and The Hymenoptera of Minnesota, by F. L. Washburn (pp. 145–237).

Third biennial report of the Montana State Board of Entomology, R. A. COOLEY (*Bien. Rpt. Mont. Bd. Ent.*, 3 (1917–18), pp. 60, pls. 5).—This report deals particularly with the investigational and eradication work with the Rocky Mountain spotted fever tick (*Dermacentor venustus*).

The following papers are included: Report of Tick Control Operations in the Bitter Root Valley during the Season of 1918, Facts in Connection Therewith; Recommendations for the Further Prosecution of the Work, by R. R. Parker (pp. 25-40); Second Report on Investigations of the Rocky Mountain Spotted Fever Tick in Eastern Montana, by R. R. Parker (pp. 41-54); and Rocky Mountain Spotted Fever, Pathology and Etiology; Progress, by S. B. Wolbach (pp. 55-60).

In his second report, on biological studies of *D. venustus* (E. S. R., 37, p. 560), Parker deals at length with wild animals as hosts of immature ticks, presenting tabular data on the results of examination of wild animals for larvæ, nymphs, and adults, examination of domestic animals for adult ticks, etc.

Sixteenth annual report of the State entomologist of Montana, R. A. COOLEY (Montana Sta. Bul. 126 (1918), pp. 21-44, fig. 1).—The author presents notes on the occurrence of the more important insect pests of the year, including grass-hoppers; cutworms, which were particularly abundant; the Colorado potato beetle; Hylemyia cerealis, a maggot which occurred in stems of young winter wheat plants at widely separated points in the State; the sugar beet webworm (Loxostege sticticalis); the false chinch bug (Nysius ericæ); the alfalfa weevil (Phytonomus posticus); etc.

Report of the department of entomology, T. J. HEADLEE (New Jersey Stas. Rpt. 1917, pp. 425-520, pl. 1, figs. 4).—A list of the insects received and identified during the year, which includes the locality and date of receipt, is followed by a brief discussion of the occurrence of the more important forms and references to species introduced from abroad.

[Vol. 41

In investigations of the effect of climate upon the life and seasonal cycles of insects, in continuation of those of the previous year (E. S. R., 39, p. 761), work with the Angoumois grain moth and the bean weevil led to the following conclusions: "For at least two widely divergent species of the stored grain insect group, one a beetle and the other a moth, increase in atmospheric humidity means increase in speed of metabolism as measured by length of life cycle. The optimum percentage of atmospheric humidity is the highest which will not encourage a heavy growth of fungi. One hundred per cent atmospheric humidity destroys by encouraging the growth of fungi and low atmospheric moisture destroys directly, probably by the abstraction of water. While the egg stage of the bean weevil at least is most sensitive to the effect of low atmospheric humidity, other stages are unfavorably affected. Low atmospheric moisture might be developed into an efficient insecticide for certain species of stored grain insects."

The progress of work with the pear psylla, which was continued during the year in three orchards, is briefly reported upon.

A report of experiments on the adults and eggs of the peach tree borer, by A. Peterson (pp. 449–463), is summarized as follows: "The results in the above experiments are largely negative, so far as they may help to develop a muchneeded control measure for the peach tree borer. In brief, they show the improbability of developing a poison bait for the adult, the partial repellent effect of certain chemicals on the female while ovipositing, and the partial destruction of eggs when certain substances are applied as a spray. A number of experiments have been started and are now in operation on the use of various chemical and mechanical tree protectors, but the evidence obtained thus far is insufficient to warrant a statement at this time. The author is of the opinion that the peach tree borer problem will be solved by a mechanical or chemical barrier which will kill the larva before it enters the tree or prevent it from getting into the tree. The development of any control measure along the line of killing the larva after it enters the tree is not advisable."

Investigations of the destruction of early seedlings of Lima beans along the Delaware Bay coast has shown it to be due to the seed corn maggot (*Pegomyia fusciceps*). An early spring brood emerges and lays eggs in the soil upon or in the vicinity of the bean seed and maggots which hatch out concentrate upon the bean seed and destroy it. Control appears to consist in the prevention of injury to the early planted seed, and experiments indicate that much is to be expected from the continuous wide band of tarred sand or strip of tarred paper.

The results of greenhouse fumigation work briefly outlined are to be issued as a bulletin.

A paper on soil-infesting insect investigations by A. Peterson (pp. 469–479) reports upon laboratory and field experiments with sodium cyanid and other chemicals against wireworms in the soil. The results show that while wireworms can be killed with large quantities of sodium cyanid the amount necessary to bring about a satisfactory control makes this method of soil treatment too expensive for ordinary use in the field.

House fly control investigations at Beach Haven are reported upon by A. Peterson (pp. 479-484).

A detailed report on mosquito work, including a map of New Jersey, showing the drainage and mosquito conditions in 1917 follows.

[Economic insects in South Dakota] (Off. State Ent. S. Dak., 1918, Circs. 1, pp. 8; 2, pp. 2, fig. 1; 3, pp. 2, fig. 1; 4, pp. 2, fig. 1; 5, pp. 3, figs. 2; 6, pp. 2, fig. 1; 7, pp. 4, figs. 2; 8, pp. 7, figs. 3).—These circulars relate, respectively, to the Nursery Inspection Law of South Dakota; and The Buffalo Tree-hopper, The

Plum Tree Borer [Synanthedon pictipes], The Leaf Crumpler, The Plum Webspinning Sawfly [Neurotoma inconspicua], The Mealy and Rusty Brown Plum Lice [Hylopterus arundinis and Aphis seteriæ], The Plum Curculio and The Plum Gouger, and Scale Insects: The Oyster-shell Scale, Putnam's Scale, The Poplar and Willow Scale [Chionaspius salicis-nigræ], The San José Scale, and The Scurfy Scale, all by H. C. Severin.

Miscellaneous insects, H. A. BALLOU (Agr. News [Barbados], 18 (1919), No. 440, p. 74).—Brief notes are presented upon several insects of economic importance in the West Indies.

[Papers on insects and insect control] (*Min. Agr.* [France], *Ann. Serv.* Épiphyties, 4 (1915), pp. 145-161, 218-336, pls. 2, figs. 26; 5 (1916-17), pp. 36-192, 210-244, figs. 24).—These volumes contain the following papers relating to economic entomology:

Vol. 4.—Notes on the Biology of the Black Alfalfa Leaf Beetle (*Colaspidema atra*), the Elm Leaf Beetle (*Galerucella luteola*), and the Alder Beetle (*Agelastica alni*), by A. Lécaillon (pp. 145–161); Investigations on the Eudemis and Cochylis Moths in Bordeaux in 1914 (pp. 218–265) and in 1915 (pp. 266–276), by J. Feytaud; Notes on the Root Aphids, by J. Péneau (pp. 277–285); An Enemy of Cacao in New Hebrides (*Promecotheca opacicollis*), by J. Kowalski (pp. 286–328); Observations and Experiments on the Fungus Parasites of Insects, by A. Paillot (pp. 329–334); and Note on the Asparagus Beetle and Its Parasites [*Tetrastichus asparagi* and *Meigenia floralis*], by A. Paillot (pp. 335, 336).

Vol. 5.—Experimental Application of Arsenicals in the Control of the Codling Moth, by J. Feytaud (pp. 36–48); The Use of Arsenical Insecticides in Combating the Codling Moth on Apples and Pears, by A. Lécaillon (pp. 49–53); Application of the Arsenical Method to Fruit Culture in the Lyonnaise Region, by E. Massonnat (pp. 54–59); Use of Arsenicals Against Fruit Tree Insects, Particularly the Codling Moth, by J. Péneau (pp. 60–68); Experiments with Arsenical Insecticides, by E. Rabaté (pp. 69–73); Winter Fight Against the Vine Pyralid (*Enophthira pilleriana*) by the Use of Arsenicals, by P. Marchal (pp. 74–82); The Disinfection of the Soil, by E. Miège (pp. 83–144); Study of the Vine Otiorhynchus (*Otiorhynchus sulcatus*), by J. Feytaud (pp. 145–192); Researches on the Bionomy of Birds of the Vineyard, by P. Paris (pp. 210–229); Notes on the Eudemis and Cochylis Moths in Bordeaux in 1916 and 1917, by J. Feytaud (pp. 230–238); and Invasions of Pea Culture in Gironde by *Heterodera schachti*, by J. Capus (pp. 239–244).

Insect notes, P. R. DUPONT (Ann. Rpt. Agr. and Crown Lands Seychelles, 1917, pp. 20, 21).—A list is presented of 14 insects which attack the coconut in Seychelles, followed by notes on other insects of economic importance presented under the plants they attack.

[Economic insects in Mysore] (Mysore Agr. Calendar, 1918, pp. 7-14, 27-34, 43-49, figs. 10).—The papers here presented relate to the coffee borer, a serious pest found in more or less abundance in all localities and elevations in the coffee-growing areas in Mysore; sericulture in Mysore; and the fungus enemies of the green bug on coffee, of which the two most important are the white fungus (Cephalosporium lecanii) and the black fungus (Empusa lecanii).

On a long-winged or caudate phase of Neotettix proavus, H. Fox (Ent. News, 29 (1918), No. 9, pp. 347-349, fig. 1).

Cacao thrips in Grenada (Agr. News [Barbados], 18 (1919), No. 443, p. 122).— A further report on the status of the cacao thrips in Grenada (E. S. R., 40, p. 856.)

Burn the chinch bug, W. P. FLINT (Univ. Ill., Col. Agr. Ext. Circ. 28 (1919), pp. 8, figs. 6).—A map is given showing the chinch bug infested area of Illinois, which includes 26 counties, with directions for burning over to destroy the pest.

Fight the chinch bug with crops, W. L. BURLISON and W. P. FLINT (Univ. Ill., Col. Agr. Ext. Circ. 30 (1919), pp. 14, figs. 7).—A discussion of the crops which may be grown in combating the chinch bug.

The oriental fruit moth in Virginia, L. A. STEARNS (Quart. Bul. Va. State Crop Pest Com., 1 (1919), No. 1, pp. 3-7, figs. 5).—A thorough inspection of Alexandria and Fairfax Counties indicates that Laspeyresia molesta has become generally established in home orchards south and west of the Potomac River to a line drawn through the points Great Falls, Herndon, Fairfax, Annandale, and Alexandria. A similar inspection of Loudoun County located an "outpost" of infestation in a single commercial orchard at Leesburg. Both twigs and fruits showing suspicious typical injury have been collected in orchards along the railway from Leesburg to Bluemont.

The European corn borer (Pyrausta nubilalis), E. P. FELT (N. Y. State Col. Agr., Cornell Ext. Bul. 31 (1919), pp. 35-42, pls. 2, figs. 5).—A popular summary of information on this pest which has appeared in New York State in the vicinity of Scotia. The infestation covers about 400 square miles, extending west to Fort Hunter and east of Schenectady.

The sugar cane moth borer, T. E. HOLLOWAY and U. C. LOFTIN (U. S. Dept. Agr. Bul. 746 (1919), pp. 74, pls. 10, figs. 12).—This is a report of the present status of knowledge of Diatræa saccharalis crambidoides, based upon a review of the literature and investigations conducted by the authors over a period of years, together with technical descriptions of the larva and pupa stages by C. Heinrich.

It is shown that this form occurs in Florida as far north as Gainesville, in southwestern Mississippi, in southern Louisiana, and in the Rio Grande Valley in Texas in the vicinity of Brownsville.

Its only parasite of importance in the United States is *Trichogramma minuta*, which attacks the egg and is universally distributed in the sugar-cane fields of Louisiana and also in the Rio Grande Valley in Texas. Mention is made of a number of natural enemies which occur in foreign countries, including a Cuban tachinid (*Euzenilliopsis diatrax*), introductions of which are being made into Louisiana. Experiments and observations on artificial control, which are presented in detail, have led to the following recommendations:

"Scraps of cane left about the factories and derricks, after the grinding season, should be destroyed by burning or otherwise. Cars in which cane is shipped, especially if they go into noninfested territory, should be kept free of such scraps. Seed cane should be planted in the fall, if possible, and kept as deeply covered as practicable. Extraordinarily deep planting is not advocated, but as borer moths fail to emerge from cane under more than 0.5 in. of compact soil, care should be taken to keep the seed cane well covered to that depth as a minimum. A heavy rain will sometimes wash the earth from the seed cane from one end of the row to the other, and in this case it is important to cover the cane again as soon as possible, especially in the spring, when the moths are emerging.

"Cane for shipment to points beyond the infested area should be selected so as to obtain it sound and free of borers, or, if this is impossible, it should be soaked, previous to shipment, for at least an hour in Bordeaux mixture or a solution of nicotin sulphate.

"The 'trash,' leaves, or 'shucks' left on the fields after cutting should not be burned, but should be lightly covered with earth in the fall and plowed out in the spring. This practice has never been found to increase the borer infestation, and it has often diminished it. The soil is fertilized by the buried trash and its mechanical condition is greatly improved. Cutting out 'dead hearts' or dead plants and destroying them is theoretically sound, and with an abundance of cheap labor it might be recommended.

"The introduction of parasites of the moth borer from Cuba and other tropical countries is recommended."

A bibliography of 185 titles is appended.

**Peach** borer observations at Vineland, M. A. BLAKE and C. H. CONNORS (*New Jersey Stas. Rpt. 1917, pp. 83–88, fig. 1*).—The borers removed from each tree in three orchards, in continuation of records of previous years (E. S. R., 39, p. 765), are recorded in tabular form, charted, and discussed.

The infestation by borers during the year was apparently more general and more evenly distributed. It was observed in one of the orchards that three rows, which had been set in holes made with dynamite, had the lowest percentage of trees infested and the smallest number of borers found in 1917. As a possible explanation, it is pointed out that the trees planted by the use of dynamite made a much more rapid average growth during the first few years, and it is possible that they presented a more unbroken surface of bark, which, in the author's experience, tends to make them resistant to borer attack.

Argyresthia illuminatella, K. T. SCHÜTZE (Deut. Ent. Ztschr. "Iris," 31 (1917), No. 1-2, pp. 4-23; abs. in Rev. Appl. Ent., Ser. A, 6 (1918), No. 11, p. 479).—The caterpillar of A. illuminatella infests the ends of the twigs of Abies alba and lives exclusively on this tree, the attacked branches being recognized in the autumn by the slightly yellowish-green color of the needles. The eggs are laid on the buds at the tip of the twigs, the buds are eaten, and the whole twig is completely hollowed out. Pupation takes place in these hollowed twigs.

The apple bud moths and their control in Nova Scotia, G. E. SANDERS and A. G. DUSTAN (*Canada Dept. Agr., Ent. Branch Bul. 16 (1919), pp. 39, figs. 14*).— This reports investigations of bud moths, the most important insects generally affecting orchards in Nova Scotia, which have been conducted since 1912. While the recommendations as to control measures are based upon local conditions, the general features of the life history and habits are applicable to the insect in other Provinces.

The four most common and injurious species of bud moths in Nova Scotia are the eye-spotted bud moth, the oblique banded leaf roller (*Cacacia rosaceana*), the lesser bud moth (*Recurvaria nanella*), and the green bud worm (*Argyroploce consanguinana*). In general, their life histories and the injuries inflicted are similar in all four species. All are small winged moths which fly during June and July and deposit their eggs on the leaves of the apple. "Three of the four species injure the apple in the fall by occasionally attaching the leaf on which they are feeding to the fruit, and under the attached leaf eating through the skin of the apple, marring the surface, and injuring the appearance and keeping qualities.

"All species pass the winter as partly grown larvæ under bits of bark or in crevices about the fruit spurs. In the spring the larvæ merge from their hibernating quarters as the buds swell and eat into the opening buds, where they feed on the expanding flowers, thus affecting the set of the fruit. It is estimated that the bud moths reduce the crop in unsprayed or poorly sprayed apple orchards in Nova Scotia about 30 per cent. About 75 per cent of the bud moths can be destroyed and the crops increased about 22.5 per cent by two thorough applications of poisoned spray applied before the blossoms open, with a nozzle throwing a coarse, driving spray."

Technical descriptions are given of the several stages of these species, together with notes on their life history and habits in Nova Scotia and a report of control work.

Cutworms, R. W. JACK (*Rhodesia Agr. Jour.*, 15 (1918), Nos. 3, pp. 225-237, pls. 3, fig. 1; 4, pp. 344-348).—Four species of cutworms are recorded from Rhodesia, namely, *Euxoa segetis*, E. longidentifera, E. spinifera, and the black cutworm, of which E. segetis and the black cutworm are of real importance. In a search for an effective remedy for E. segetis, the species occurring most commonly in Rhodesia, 124 experiments were carried out at Salisbury.

"While the results obtained with arsenite of soda against E. segetis are unsatisfactory, the use of Paris green on green foliage was almost uniformly successful against all species tested. [The black cutworm] and E. longidentifera yield more readily to arsenite of soda than E. segetis. An even more striking disparity of tastes is shown in connection with the use of bran in making the bait, this carrier failing in every instance against E. segetis while the other two species apparently eat it readily."

A map showing the known distribution in England and Wales of the anopheline mosquitoes, with explanatory text and notes, W. D. LANG (London: Brit. Mus. (Nat. Hist.), 1918, pp. 63, pl. 1; rev. in Nature [London], 101 (1918), No. 2546, p. 463).—This map shows the known distribution in England and Wales of three species of anopheline mosquitoes, namely, Anopheles maculipennis, A. bifurcatus, and A. plumbeus, the first two of which are known to be carriers of malaria. In the accompanying text the localities are arranged alphabetically under each of the three species, primarily according to the counties and secondarily according to the place names. A brief résumé of what is known of the life history of each species is also included.

Notes on the Nearctic Nusa (Diptera, Asilidæ), W. L. MCATEE (Ohio Jour. Sci., 19 (1919), No. 4, pp. 244-248, figs. 5).

Leiomyza in North America, J. M. ALDRICH (Ent. News, 30 (1919), No. 5, pp. 137-141, fig. 1).

Note on leskiine synonymy, C. H. T. TOWNSEND (Proc. Ent. Soc. Wash., 21 (1919), No. 1, p. 20).

Coleoptera illustrata, H. NOTMAN (Brooklyn, N. Y.: Author [1915-1917], vol. 1, pts. 1-4, pp. [14], pls. 200).—This volume contains 200 illustrations of species of Carabidæ.

Chrysobothris tranquebarica Gmel. versus impressa Fabr. (Coleoptera; Buprestidæ), W. S. FISHER (*Proc. Ent. Soc. Wash., 20 (1918), No. 8, pp. 173–177).*—*C. tranquebarica* is of considerable economic importance, due to its attacks upon the so-called Australian pine (*Casuarina equisetifolia*), which has been planted quite extensively for ornamental and shade purposes in some parts of Florida.

The convergent ladybird beetle (Hippodamia convergens) and the barley corn aphis (Aphis maidis), W. M. DAVIDSON (Mo. Bul. Cal. Com. Hort., 8 (1919), No. 1, pp. 23-26, figs. 2).—This is a report of progress of a project relating to the natural control of A. maidis by the convergent ladybird beetle, started in the Imperial Valley of California in the spring of 1918.

Mobilizing a ladybug army to fight the aphis, H. E. THOMAS (*Sci. Amer.*, 120 (1919), No. 20, pp. 507, 522, 524, figs. 3).—Attention is called to the fact that 100,000,000 ladybird beetles will be distributed in the State of Washington in the spring of 1919, more than 25,000,000 having been stored ready for release. The work is being carried on by the county agricultural agents in cooperation with the Forest Service of the U. S. Department of Agriculture, the forest ranger of which service has exceptional opportunities to find the caches of the

ladybird beetles, and with the Bureau of Entomology of the same Department through its station at Forest Grove, Oreg.

Five new species of ptinid beetles, W. S. FISHER (Proc. U. S. Nat. Mus., 55 (1919), pp. 295-299).—The species here considered are Pitnus hucsanus n. sp., collected on Ichthyomethia piscipula at Key West, Fla.; Oligomerus arbuti n. sp., on dead manzanita (Arbutus sp.) at Placerville, Cal.; Ernobius conicola n. sp., reared from cones of Cupressus macrocarpa and from larvæ feeding on scales and tissues of green and dry cones of C. macrocarpa at Pacific Grove and Point Lobos, Cal.; E. californicus n. sp., reared from bark and outer wood of branches of recently killed Pinus jeffrcyi in Ventura County, Cal.; and E. champlaini n. sp., collected on dead limbs of P. flexilis in Waldo Canyon, Colo.

The apiary in Quebec, C. VAILLANCOURT (Min. Agr. Prov. Quebec Bul. 61 (1919), pp. 78, figs. 48).—A popular account.

Elements of beekeeping, H. R. NISWONGER (Univ. Ky., Col. Agr. Ext. Div. Circ. 69 (1919), pp. 22, figs. 8).-A popular account.

Unheated egg-yolk media, G. F. WHITE (Science, n. ser., 49 (1919), No. 1267, p. 362.)—The author has for several years made use of unheated egg-yolk media and found them specially valuable in studying *Bacillus larvæ*, which offers considerable difficulty in its cultivation. The technique employed in its preparation is described.

The carpenter ant as a destroyer of sound wood, S. A. GRAHAM (*Rpt. State* Ent. Minn., 17 (1918), pp. 32-40, figs. 8).—" Large black ants commonly known as carpenter ants [*Componotus pennsylvanicus*] are doing considerable damage to standing white cedar in Minnesota, at least 20 per cent of the trees cut showing ant injury on the stump. The colonies are started in a wound, knot hole, or decayed spot, usually near the butt of the tree. The ants hollow out a nest in the heart of the tree, sometimes leaving only a thin shell of wood around it, thus seriously weakening the tree at that point. From this nest the ants cut openings to the outside, called windows, and to locate a nest it is only necessary to look for the windows.

"Much unavoidable loss is occasioned by ant injury, but there is also an immense amount of loss through careless cutting of poles. Culling heavily for ant injury has meant leaving in the woods anything that looks suspiciously like a cull. The grading rules regarding ant injury should be made more lenient so as to encourage more careful trimming of ant-infested poles."

Three new species of Braconidæ, C. F. W. MUESEBECK (Canad. Ent., 51 (1919), No. 5, pp. 113-116).—Among the species here described as new is Apanteles phigaliæ, which parasitizes Phigalia titea at Melrose Highlands, Mass.

New reared parasitic Hymenoptera, with some notes on synonymy, A. B. GAHAN (Proc. U. S. Nat. Mus., 55 (1919) pp. 113-128, figs. 2).—This paper contains descriptions of 2 genera and 12 species of Ichneumonoidea and Chalcidoidea, including Phaeogenes (Centeterus) ineptifrons n. sp., reared from the oriental peach moth (Laspeyresia molesta) at Washington, D. C.; Dacnusa iridicola n. sp., reared from Agromyza laterella at Middleburg, Pa.; Trioxys cupressicola n. sp., from Cerosipha n. sp., at Riverside, Cal.; Chelonus (Chelonella) proteus n. sp., and Apanteles stagmatophoræ n. sp., both from Stagmatophora gleditschiæella at Williamsport, Md.; Bassus immaculatus n. sp., reared in connection with and possibly parasitic on Phthorimæa striatella at Baton Rouge, La.; B. usitatus n. sp., reared in cages with the cranberry fruit worm and probably parasitic on it at East Wareham, Mass.; Orgilus dioryctriæ n. sp., from Dioryctria xanthaenobares on Pinus attenuata, Patricks Creek, Cal.; Pseuderimerus mayetiolæ n. g. and n. sp., from the Hessian fly at Altamont, Cal.; Heteroschema prima n. g. and n. sp. and Habrocytus simillimus n. sp., both from Agromyza gibsoni at Tempe, Ariz.; and Eutelus mayetiolæ n. sp., from the Hessian fly at Salinas, Cal.

The rice worm (Tylenchus angustus) and its control, E. J. BUTLER (Mem. Dept. Agr. India, Bot. Ser., 10. (1919), No. 1, pp. 37, pls. 2, figs. 3).—This reports further studies (E. S. R., 30, p. 540) of the life history and habits of T. angustus, a nematode which causes the "ufra" disease of rice in the great rice-growing deltic tract at the head of the Bay of Bengal, means for its control, etc.

Some significant structural modifications in Nearctic termites, T. E. SNYDER (Proc. Ent. Soc. Wash., 21 (1919), No. 5, pp. 97-104, pl. 1).

## FOODS-HUMAN NUTRITION.

Experiments on the digestibility of wheat bran in a diet without wheat flour, A. D. HOLMES (U. S. Dept. Agr. Bul. 751 (1919), pp. 18).—In connection with studies of grains for food purposes, supplementing earlier work (E. S. R., 17, p. 481), the digestibility of coarse (unground) and finely ground wheat bran was determined, with healthy young men as subjects. The bran was fed in each case in the form of a simple bread and the remainder of the diet consisted of potatoes, fruit, butter, and sugar—that is, foods which supplied little besides fat and carbohydrate.

The results indicate that of the protein supplied by the fine bran 44.7 per cent and of the bran carbohydrate 56.6 per cent was digested, while the results of the tests with coarse bran indicate a digestibility of 28 per cent for the bran protein and 55.5 per cent for the bran carbohydrate.

The coefficients of digestibility of the diet as a whole (37 per cent for protein, 88.5 per cent for fat, and 79.8 per cent for carbohydrate, in the series in which fine bran was eaten, and 35.8 per cent for protein, 93.1 per cent for fat, and 82.8 per cent for carbohydrate, in the series in which coarse bran was eaten) are lower than those found in other experiments of the Department with a mixed diet. "This indicates the way in which the rough, relatively indigestible bran influenced the digestibility of the entire diet. It is also possible that the bran stimulated peristaltic action to such an extent that the food materials were not as completely absorbed as is normally the case when they pass through the alimentary tract without increased peristalsis.

"In general the amount of feces voided by the subjects during the tests with bran was larger than normal. This condition was noted by all the subjects, regardless as to whether they were of active, athletic, or sedentary habits. Some of the subjects found the bran diets decidedly laxative. Little, if any, difference was noted by the subjects as a whole between the laxative effects of the fine and coarse brans."

Milling grain sorghums (*Kansas Sta. Rpt. 1918*, *pp. 34*, *35*).—In continuation of the milling and baking tests with Kafir corn previously noted (E. S. R., 40, p. 361), it was found that a rather fine meal could be prepared which made a quite satisfactory substitute for corn meal, although somewhat darker in color and having a characteristic slightly bitter taste. A product corresponding to whole-wheat flour was made by grinding a blend of 35 per cent of Kafir corn and 65 per cent of wheat. It is said that less shortening should be used with Kafir-corn mixtures than with pure wheat.

How to prepare banana meal (So. African Jour. Indus., 1 (1918), No. 15, pp. 1381, 1382).—A method for the preparation of banana meal described by J. de Verteuil, in the Port of Spain Gazette, of February 7, 1918, is given.

"Peel and slice the bananas thinly with a nickel or fruit knife. Spread on wooden trays in the sun to dry. When dry crush in an ordinary mill or pound
in a mortar and sift through fine muslin. The meal may be used in bread and cakes by mixing with an equal portion of wheaten flour, or it may be cooked and eaten as oatmeal porridge or rice pudding.

"Dasheen, sweet potato, tannia, and yam meals can all be made in the same way as advised for banana meal, i. e., peeling, washing, slicing, and milling the drier chips. Excellent bread, etc., can also be made from equal parts of wheaten flour and any of the above meals."

The utilization of yeast in the animal organism, E. SCHILL (*Biochem. Ztschr.*, 87 (1918), *No.* 3-4, *pp.* 163-175).—Feeding experiments with laboratory animals (dogs) in which the food value of yeast was studied indicate, in the author's opinion, that the protein of yeast is well utilized.

Digestibility of certain miscellaneous animal fats, A. D. HOLMES (U. S. Dept. Agr. Bul. 613 (1919), pp. 25).—Continuing earlier work (E. S. R., 36, p. 860) the digestibility of 9 animal fats was studied, with young men as subjects.

The coefficients of digestibility were found to be 98.4 per cent for goat's butter, 95.3 for kid fat, 93.7 for hard-palate fat, 93.9 for horse fat, 96.8 for oleo oil, 80.1 for oleo stearin, 93.5 for ox-marrow fat, 96.6 for ox-tail fat, and 98.6 per cent for turtle fat.

"In the reports of their physical condition during the test periods, the subjects did not note any physiological disturbances except in the case of oxmarrow fat, which seemed to have a slightly laxative effect. No evidence was secured as to whether this condition resulted from the nature of the fat or from the fairly large amount [74.5 gm.] ingested daily."

On the basis of the experiments reported, it is concluded that these fats, when eaten in amounts equivalent to the amount of butter eaten in the normal dietary, are well assimilated, and that judged by this and what is known of their use as food fats they should prove wholesome sources of fat for human consumption.

Whale meat as food, V. STUBBINS (Food and Cookery and Catering World [London], 23 (1919), No. 247, pp. 16, 17).—It is calculated that many of the whales caught average about 50 tons in weight and that after the removal of the bone and blubber between 5 and 6 tons of flesh available for human food remains. This flesh is said to be very tender, agreeable in taste, and richer than beef in protein by 2 per cent.

Whale meat in the diet (Jour. Agr. and Hort. [Canada], 22, 1919, No. 9, p. 159).—Some data on the extent of shipping whale meat as food from the Canadian Pacific coast are given. "Whales taken on the Pacific coast yield from 3 to 12 tons each of prime meat, and this only is used for canning and freezing. ... Analysis of the flesh shows it somewhat to resemble corned beef or mutton. It contains 34 per cent of protein, the principal tissue-forming material of food, as compared with from 13 to 14 per cent in mutton or pork. Sales of whale meat are not yet large in Canada or the United States, but a good deal has been shipped to Samoa and Fiji."

Food values and dairy products, O. R. OVERMAN (Illinois Sta. Circ. 235 (1919), pp. 3-28, fig. 1).—The author summarizes a large amount of data in this comparison of dairy products (milk, skim milk, cottage cheese, and American cheddar cheese) with other foods. His conclusion is that these are to be regarded as among the cheapest foods of animal origin, both as to protein and total energy.

"Milk containing 4 per cent of fat is a more economical source of both protein and energy than are meats, eggs, poultry, or fresh fish.... Skim milk at 15 cts. a gallon is far cheaper as a source of protein and energy than are other foods of animal origin. It is, at this price, cheaper as a source of protein than are dry beans and peas at 15 cts. a pound. On the basis of energy the cost of skim milk and dry beans and peas is nearly the same. Cottage cheese is a much more economical source of protein than are other animal foods. It is an excellent meat substitute. On the basis of energy cottage cheese and meats cost nearly the same. It is cheaper than fresh fish, and at 15 cts. a pound is cheaper than eggs at 30 cts. a dozen. American cheddar cheese costs very much less than meat, poultry, eggs, or fish sufficient to furnish an equal amount of protein or of total energy and is an excellent substitute for these foods."

[Miscellaneous food topics], E. F. LADD and ALMA K. JOHNSON (North Dadota Sta. Spec. Bul., 5 (1919), No. 9, pp. 191, 192, 208-218).—The authors note that when butter contains over 16 per cent of water it is liable to taxation, and give information regarding adulterated and misbranded butter. It is stated that a tendency has been observed in some places to sell butter short weight and adulterated by the addition of excessive amounts of water.

An article on so-called egg substitutes by La Wall (E. S. R., 40, p. 558) is reprinted.

The Chinese petsai as a salad vegetable, D. FAIRCHILD (Jour. Heredity, 9 (1918), No. 7, pp. 291-295, figs. 2).—The author believes that the Chinese petsai, a leaf vegetable of pleasant taste, might well be used to supplement lettuce.

Food sauces of Europeans and Indo-Chinese compared, Rosé (Bul. Écon. Indochine, n. ser., 21 (1918), No. 131, pp. 525-532).—Analyses of nuoc-mam (a product similar to soy sauce) and other sauces are reported. The uses and value of such products are discussed.

[Food inspection], A. M. G. SOULE (Agr. of Maine, 1917, pp. 78-89).—A report of the chief of the bureau of inspection on the enforcement of the pure food law in Maine for the year 1917.

[Food inspection] (*Brit. Food Jour., 20 (1918), No. 241, pp. 127–136*).—An abstract from the annual report of the Principal of the Customs and Excise Laboratory on the work of the laboratory for the year ended March 31, 1918.

Report of the fifteenth convention of the Association of German Food Chemists (*Ztschr. Untersuch, Nahr. u. Genussmtl., 35 (1918), No. 1-3, pp. 152).*— This report includes, among other addresses and discussions, the following: Food Substitutes and Their Regulation, by A. Beythien; Food Substitutes and Their Valuation, by S. Rothenfusser; Beer Substitutes, by K. Windisch; Coffee Substitutes, by M. Klassert; Fruit Juices and Their Substitution, and Marmalades and Artificial Marmalades, by P. Buttenberg; The Use of Mineral Matter in Baking Powder, by L. Grünhut; Baking Powder, by F. Wirthle; Soup and Broth Cubes, by C. Mai; Calculation of Food Value of Foods, by E. Seel; and Ascertaining the Food Value of Mushrooms, by M. Klostermann.

Ten lessons in thrift (*Washington: War Loan Organ., U. S. Treas. Dept.,* 1919, pp. 16).—This outline includes thrift in the household, the household budget, family accounting, and similar topics.

Cold storage reports, season 1917–1918.—Apples, butter, American cheese, eggs, and poultry, J. O. BELL (U. S. Dept. Agr. Bul. 776 (1919), pp. 44, figs. 19).—This publication, designed particularly for trade uses, reports statistical data containing earlier work (E. S. R., 40, p. 68).

Food surveys (U. S. Dept. Agr., Food Surveys, 2 (1919), Nos. 25, 26, pp. 8 each).—Data are reported as to commercial stocks of grain, flour, and miscellaneous food products in the United States on April 1 and May 1, 1919, respectively.

Europe's larder.—Record American exports (*Nat. Food Jour. [London], 2* (1919), *No. 34, p. 266*).—A tentative record of the quantity and value of the food exported from the United States to England during the year 1918.

Food supply manual revised to July 31, 1918 (London: Govt., 1918, pp. 701).—This comprises a classified and indexed compilation of the British food controller's powers and orders, and also orders of other departments ancillary thereto.

Food regulations (*Pub. R. Accad. Lincei, Comitato Sci. Aliment.* [Rome], Nos. 3 (1918), pp. 6; 4, pp. 3; 6, pp. 12; No. 8 (1919), pp. 18).—No. 3 of these papers deals with statistics on the food consumption of Italy; No. 4 with the standards regarding the meat consumption of the civil population; No. 6 with the regulations pertaining to the slaughter of young animals; and No. 8 gives a summary of the work of the committee in charge.

The food supply of our allies, G. LUSK (Amer. Mus. Jour., 18 (1918), No. 8, pp. 629-635).—This article explains how the estimates of the amounts of imported meats, fats, sugar, and cereals needed during 1919 by Great Britain, France, and Italy were obtained.

Food situation in Austria during the summer of 1918 (U. S. Dept. Labor, Bur. Labor Statis., Mo. Labor Rev., 7 (1918), No. 6, pp. 168-196).—This article has been compiled from various Austrian daily papers in the form of translations and digests.

Diet, nutrition, and excretion of the Asiatic races in Singapore, I-II, J. A. CAMPBELL (*Reprinted from Jour. Straits Branch Roy. Asiatic Soc., 1917. Nos. 76, pp. 57-65; 79, pp. 107-112*).—This study, which is in two parts, was undertaken in order to supply the local medical students with necessary information.

In part 1, the diets of one Chinese, one Brahmin, and one Tamil, all medical students, were under observation for 6 months, while one Malay was studied for 2 weeks. The weights of the subjects was 92 lbs. for the Chinese, 110 for the Brahmin, 125 for the Malay, and 143 for the Tamil.

The average values of the diets were for the Chinese 1,577, Tamil 1,672, Malay 1,502, and Brahmin 2,493 calories. The protein intake per day was for the Chinese 60, Tamil 58, Malay 57, and Brahmin 83 gm. [Computed on the basis of 150 lbs. body weight the energy values become—Chinese 2,571, Brahmin 3,399, Malay, 1,802, and Tamil 1,754 calories, and for protein intake, Chinese 98, Brahmin 113, Malay 68, and Tamil 61 gm.]

The author draws the following conclusions:

"The results obtained from examination of the kidney excretion of local students indicate that the European figures are of no value when dealing with Asiatic patients. The total nitrogen varies from 6.64 gm. in the Brahmin to 9.25 in the Chinese. The urea varies from 11.08 gm. in the Brahmin to 16 in the Chinese. The ammonia varies from 0.57 gm. in the Brahmin to 0.66 in the Malay. The ammonia coefficient varies from 5.4 per cent in the Chinese to 7.1 in the Brahmin. The chlorids vary from 5.2 in the Tamil to 8 in the Malay." Corresponding values for an European in Singapore were found to be for total nitrogen 15.3 gm., urea 25, ammonia 1.06, and chlorids 8.1 gm., and ammonia coefficient 5.6.

"The Singapore student partakes of a smaller amount of food than the Philippine or Bengali student. This seems to be due directly or indirectly to the climatic conditions of Singapore."

Part 2 takes up similar studies made with 2 Chinese bakers, 2 Tamil gardeners, a Malay gardener, a Chinese rickshaw runner, 5 Chinese rubber-estate coolies, and 6 Chinese prisoners. It is concluded that the kidney excretions for these laborers differ considerably from the standard amounts given for Europeans in Europe. The total nitrogen varied from 7.2 to 11.4 gm., the urea from 13.4 to 21 gm., the uric acid from 0.43 to 0.65 gm., the ammonia from 0.61 to 1.09 gm., the chlorids from 2 to 7 gm., and the phosphates from 1.25 to 1.8 gm. "The local laborer uses less protein and fat but more carbohydrate than the European. The metabolized food of the former has a smaller calorific value."

Dietaries suitable for secondary schools, colleges, hostels, clubs, etc., D. C. MOORE and C. E. HECHT (London: Nat. Food Reform Assoc., 1919, pp. 54).—The recipes, food quantities, and menus, and the general suggestions given conform to a weekly expenditure of approximately 8s. (\$2) per person.

Hot lunches in rural schools, S. LAIRD (Jour. Agr. and Hort., 22 (1919), No. 9, pp. 144, 145, figs. 3).—A plea for the hot lunch in rural schools, with suggestions for necessary equipment and supplies. Some account is given of such school lunch work in Canada.

Health without meat, H. E. MILES (London: Methuen & Co., Ltd., 1918, 5. ed., pp. 134, figs. 5).—Essentially a cook book for an egg-lacto-vegetarian diet, with assertions and statements from this standpoint as to methods of saving food and of providing substitutes for meat.

Study of the intestinal contents of newly born infants, A. HYMANSON and M. KAHN (*Amer. Jour. Diseases Children, 17 (1919), No. 2, pp. 112–117).*—From the analyses of the meconium of 5 infants voided during the first 24 hours of extrauterine life, it was found that the iron and calcium contents were similar to those obtained in hunger feces, while the phosphorus was less and the sulphur more. Traces of ammonia and amylase were found, but lactase, trypsin, erepsin, and lipase were absent.

Influence of phlorizin on the energy metabolism, P. HÁRI and Z. AszóDI (*Biochem. Ztschr.*, 87 (1918), No. 3-4, pp. 176-216).—Experiments on laboratory animals (dogs and rats) indicate, in the opinion of the authors, that the body temperature and energy metabolism are noticeably increased in the case of dogs and decreased in the case of rats by subcutaneous injections of small amounts of phlorizin. The destruction of protein is greatly increased in both cases. As the increased protein diet, in the case of rats, is accompanied by lowered heat production, the increased heat production in the case of dogs can not be due to the increased protein destruction. Further investigation is needed to explain this difference.

The hospital metabolic laboratory, F. A. FORD (*Candle of Phi Upsilon Omicron, 4 (1918), No. 1, pp. 26–29*).—A discussion of the hospital metabolic laboratory, with reference to the advantages it offers to persons interested in hospital dietetics.

### ANIMAL PRODUCTION.

Analysis of feeding stuffs, B. E. CURRY and T. O. SMITH (New Hampshire Sta. Bul. 187 (1918), pp. 20).—Report is made on 288 samples of feeding stuffs collected during the 1918 inspection. Proximate analyses—mostly without crude fiber determinations—are reported of wheat bran, middlings, shorts, red dog, wheat mixed feed, corn gluten feed, hominy feed, oat feed, oat hulls, barley screenings, linseed meal, ground oil cake, cottonseed meal, cottonseed feed, peanut oil meal, unhulled peanut oil feed, peanut meal and hulls, dried beet pulp, alfalfa meal, meat scrap, and numerous proprietary stock feeds, calf meals, and poultry feeds. A compilation of the manufacturers' statements as to the ingredients in a number of these proprietary feeds is also given.

Cattle feeding.—XIV, Winter steer feeding, 1917–18, J. H. SKINNER and C. G. STARR (Indiana Sta. Bul. 220 (1918), pp. 26, fig. 1; popular ed., pp. 7, fig. 1).—To make a further study of limited corn rations for fattening cattle in continuation of work previously noted (E. S. R., 38, p. 873), and to compare the feeding value of silage made from corn and soy beans with that of ordinary corn silage, 69 two-year-old steers divided into 7 lots were included in a 120day feeding trial beginning December 13, 1917. Lot 4 was given what was considered a medium corn ration, 12 lbs. per head daily except during the first few weeks. Lot 3 received half this amount, lot 2 no corn, and lot 1 corn only during the last third of the trial. In addition these animals received cottonseed meal (2.5 lbs. per 1,000 lbs. live weight, daily), good corn silage, and clover hay. The 3 other lots were kept on a medium corn ration. Two were fed corn-and-soy bean silage, and the third corn silage. The latter lot and one of the mixed-silage lots received no concentrates other than shelled corn. As to the character of the mixed silage, the following remark is made: "The corn and soy beans were grown separately and the two crops were mixed at the cutter in the proportion of two parts by weight of green corn and one part green soy beans. The corn used was similar in yield and stage of maturity to that used for the straight corn silage. The soy beans were still green, no pods having turned brown, but the beans were well formed in the pods and the leaves were turning yellow."

The results are summarized in the following table:

Tests of corn ration, kind of silage, and use of protein supplements in steer feeding.

Lot.	Average daily corn ration.	Initial weight per head.	Average daily gain per head.	Fee	d consum	Esti-	Profit per			
				Corn.	Cotton- seed meal.	Corn silage.	Mixed silage.	Clover hay.	selling price per hundred.	head ex- cluding pork.

#### 1 Received no corn first 80 days.

Corn was charged at \$1.12 per bushel and cottonseed meal at \$53.50, clover hay \$25, and both kinds of silage \$7.50 a ton. At these prices lot 2 produced a pound of gain most cheaply and lot 4 next, but owing to low total gains and decreased finish, lot 2 was not as profitable as lot 4. A table gives the necessary selling prices per hundred pounds of lots 1 to 4 under changing corn prices. In this table the price of a ton of silage is put at \$1 more than five times the cost of a bushel of corn.

No conclusive differences were found between the two kinds of silage. Comparing lots 4 and 5 with lots 7 and 6, respectively, it appears that the omission of a protein supplement decreased the economy of gain, the finish of the animals, and the profits per head.

Hogs ran with each lot and the data on pork produced, grain consumed by the hogs, and the profits from pork are included. Since varied amounts of corn were given the hogs of different lots and in some cases shorts and tankage, exact comparison of the lots with respect to amounts of pork can not be made.

Cattle feeding investigations (Kansas Sta. Rpt. 1918, pp. 40-42).—Continuing past practice (E. S. R., 40, p. 369) calves from the Fort Hays substation were fattened for baby beef at Manhattan during the winter. Five lots, each consisting of 6 steers and 4 spayed heifers, were fed for five months. The check lot received the following approximate daily ration: Shelled corn 10 lbs., linseed meal 1.7 lbs., immature corn and Kafir corn silage 10 lbs., and alfalfa hay 4.5 lbs.; the others, some variant of this. A ration in which the corn was ground produced slightly greater gains and more finish than the check ration and the added profit more than offset the cost of grinding. A lot receiving cottonseed meal instead of linseed meal showed inferior finish, although the gains were only slightly decreased. "Until the end of the third month the calves receiving cottonseed meal had gained more than any other lot and showed as much finish, but from that time on cottonseed meal did not seem to stimulate the appetite as did linseed meal with the result that they would not eat as much feed and could not make the gains."

A lot receiving no silage, but nearly doubling the alfalfa consumption of the check lot, made the least profit per calf of any lot; due partly to the difference in prices charged for alfalfa and silage, and partly to lower gains. A lot receiving neither silage nor supplement but over twice the check ration of alfalfa made the slowest gains of any lot and next to the lowest profits.

The utilization of Yucca for the maintenance of cattle, J. M. JONES and A. B. CONNEE (*Texas Sta. Bul. 240 (1918)*, pp. 5–23, figs. 9).—This bulletin includes descriptions of nine species of plants of the Yucca family occurring on the southwestern cattle ranges in large enough numbers to be of importance as emergency feed for cattle, proximate chemical analyses made at the Texas and New Mexico Stations of the heads, stems, leaves, etc., of soapweed (Y. elata), Spanish dagger (Y. macrocarpa), bear grass (Y. glauca), and sotol (*Dasylirion* sp.), statements as to successful methods of cutting and feeding the material, particularly those developed on the Jornada Range Reserve (E. S. R., 40, p. 471), and a reprint of a press bulletin account of feeding experiments with Yucca and sotol at the New Mexico Station, since reported in greater detail (E. S. R., 40, p. 277).

Sheep feeding.-VIII, Fattening western lambs, 1917-18, J. H. SKINNER and C. G. STARE (Indiana Sta. Bul. 221 (1918), pp. 20; popular ed., pp. 7, fig. 1).-To study (1) the effect of shearing lambs a short time before marketing, (2)the possibility of confining grain feeding to the end of the fattening period, (3) the use of hominy feed as a substitute for corn, and (4) the value of linseed meal as a protein supplement, as well as to secure data in addition to those reported in the preceding number of this series (E. S. R., 38, p. 670) on soy beans as a protein supplement, and the effect of restricting the dry roughage and increasing the silage, 7 lots of 25 lambs and one of 24 lambs were fed for 90 days beginning October 28, 1917. The check lot received shelled corn and cottonseed meal (7:1), with corn silage and clover hay twice daily, and was sold unshorn. The modifications of this treatment accorded the other lots and the more important results secured are shown in the following table. Grain and supplement were fed mixed in the same proportions to all except the lot with initial no-grain period which always received its cottonseed meal (0.25)lb. per head per day) with the silage. During the first few days all the lambs, barring those in the last named lot, were given a certain amount of oats, totaling about 11 lbs. per head, to accustom them to grain feeding.

Lot.	Variation in tractment	Initial weight per head.	Average daily gain per head.	Feed o	Profit or loss			
	variation in treatment.			Grain.	Supple- ment.	Silage.	Hay.	per head.
723458 16	Check lot. Clipped after 75 days. Hominy feed in place of corn. No grain first 40 days. Linseed meal as supplement. Ground soy beans as supplement Hay first 3 weeks only Hay every fifth day.	$\begin{array}{c} Lbs. \\ 55.9 \\ 56.2 \\ 56.0 \\ 56.0 \\ 56.3 \\ 56.2 \\ 56.2 \\ 56.0 \\ 56.0 \\ 56.0 \end{array}$	$\begin{array}{c} Lb.\\ 0.281\\ .238\\ .281\\ .278\\ .283\\ .283\\ .280\\ .231\\ .260\end{array}$	Lbs. 2.97 3.51 2.93 2.45 2.94 2.97 3.61 3.21	$\begin{array}{c} Lb.\\ 0.52\\ .62\\ .52\\ .81\\ .52\\ .52\\ .52\\ .52\\ .64\\ .57\end{array}$	Lbs. 5.48 6.27 5.20 6.34 5.38 5.52 8.59 7.15	Lbs. 2.28 2.70 2.27 2.69 2.26 2.29 .86 1.24	$ \begin{array}{r} +\$0.10 \\ -1.19 \\ +.23 \\ +.06 \\ +.29 \\ +.03 \\40 \\10 \end{array} $

Results of a 90-day lamb feeding trial.

Owing to market conditions current at the time, these feeding operations were conducted without margin. The selling price assigned the check lot was \$17 per hundred pounds. The low average gains of the clipped lambs resulted directly from decreased consumption of silage following shearing; they were greatly discriminated against in selling.

In spite of the fact that corn was charged at 2 cts, and hominy feed at 3 cts. a pound, the lambs fed the latter showed greater profit due to more economical gains and an increased selling price of 10 cts. a hundred. Part-time grain feeding resulted in a feed cost lower than the check lot by about 12 cts. a head, but the smaller gains and a 15-ct. decrease per hundred in selling price produced less profit.

Linseed meal and ground soy beans were each charged at \$60 per ton as against \$53.50, the purchase price of cottonseed meal. Soy beans were identical with the latter in feeding value, and the selling prices of the two lots were the same. The difference in profits reflects the difference in cost of feeds. The increased profit from the linseed meal lot was due partly to an added selling price of 25 cts. per hundred and partly to more economical gains.

Clover hay was valued at \$25 and corn silage at \$7.50 per ton, but neither the feeding of hay every fifth day only, thereby cutting the consumption in half, nor the complete elimination of hay after the animals were on full feed was profitable, because of reduced gains.

Feeding western lambs (*Kansas Sta. Rpt. 1918*, *pp. 42*, *43*).—Five lots of 60 lambs each were fed for 60 days during January and February, 1918. Comparisons were made between shelled corn and whole Kafir corn, alfalfa hay and sweet clover hay, silage and no silage. One lot was crowded. Results from the others are summarized as follows:

Lot num- ber.	Kind of grain and hay fed.	Initial weight F <b>er</b> head.	Average daily gain per head.	Feed consumed per pound gain.			Feed cost per	Profit	Market
				Grain.	Нау.	Silage.	pound of gain.	per lamb.	grade.
16 17 18 19	Corn, alfalfa Corn, sweet clover Corn, alfalfa Kafir corn, alfalfa	$\begin{array}{c} Lbs_{\bullet} \\ 61.2 \\ 61.2 \\ 60.4 \\ 59.9 \end{array}$	$\begin{array}{c} Lb. \\ 0.44 \\ .37 \\ .39 \\ .41 \end{array}$	<i>Lbs.</i> 3.2 3.7 3.5 3.4	Lbs. 4.0 2.7 2.4 4.2	Lbs.	$\begin{array}{c} Cts. \\ 14.6 \\ 15.2 \\ 14.4 \\ 17.0 \end{array}$	+ \$0.40 + .02 + .23 50	Prime. Choice. Do. Good.

Results of a 60-day lamb feeding experiment.

The following prices were charged for feeds: Corn 3 cts. and Kafir corn 3.5 cts. per pound, hay \$25 and silage \$8 per ton. It is computed that the value of Kafir corn as feed for lambs was only 2.9 cts. per pound, while corn in lot 16 was worth nearly 3.5 cts.

**Production of goats on far western ranges**, W. R. CHAPLINE (U. S. Dept. Agr. Bul. 749 (1919), pp. 35, pls. 12, figs. 2).—A number of problems associated with range goats are considered in some detail, particularly with reference to (1) character of the range, (2) methods of management that will insure profits from goats without interference with sheep and cattle raising, timber reproduction, watershed protection, or other uses of the range, and (3) increasing the amount of mohair and goat meat by reducing death losses and by exercising greater care in the selection and management of the herd. The publication constitutes a general treatise on the management of goats on the range.

125597°-19-6

The utilization of irrigated field crops for hog pasturing, F. D. FARRELL (U. S. Dept. Agr. Bul, 752 (1919), pp 37, figs. 6).-This bulletin reviews 149 tests with hogs on irrigated pastures, involving a total of 3,795 animals, conducted by the Bureau of Plant Industry on various western reclamation projects. Most of these tests were made during the years indicated at experimental farms on (1) the North Platte project at Scottsbluff, Nebr. (1913-1916); (2) the Huntley, Mont. project (1913-1916); (3) the Belle Fourche, S. Dak. project (1914-1916); and (4) the Truckee-Carson, Nev. project (1915-Less comprehensive experiments at the experimental farms of the 1918). Umatilla, Oreg. and Yuma, Ariz. projects are also reported. Practically all the tests conducted on the experimental farms have been previously noted from the annual reports of each farm and a summary of the Scottsbluff results through 1915 has been published separately (E. S. R., 36, p. 767). Additional details of the tests are given in the present compilation and in some cases different and, presumably, revised data. The other tests summarized were conducted in cooperation with farmers located on the North Platte, Tieton, Uncompangre, Boise, and Minidoka projects.

Pasturing alfalfa without supplementary feed seldom proved satisfactory. Hogs on alfalfa pasture with a 2 per cent grain ration produced about 2,500 lbs. of pork per acre in a season and consumed from 2.5 to 3 lbs. of grain per pound of gain.

"The feeding values of corn, barley, shorts, and milo [maize] as supplements to alfalfa pasture differ from one another so little that the choice among these supplements should depend on prices, cultural adaptability, and general economic conditions. When the grain supplement is to be produced by the swine grower, preference usually should be given to corn, barley, and the grain sorghums, depending on the adaptability of each of these crops to local conditions in each instance.

"An acre of good alfalfa pasture supplemented with as much as a 2 per cent ration of grain has an average hog-carrying capacity of about 2,500 lbs. of live weight for the growing season. Carrying capacity increases rapidly with increased grain allowance, and it varies somewhat during the growing season with the rate of crop growth.

"An acre of good alfalfa pasture, if supplemented with a 2 per cent ration of corn or barley, will support 6 to 8 sows and 50 to 70 suckling spring pigs for a period of about 60 days in early summer, during which time the pigs should gain 25 to 30 lbs. each. At the close of this period the pigs should be ready to go into alfalfa pasture by themselves for the remainder of the growing season. The few tests so far conducted indicate that white sweet clover is not to be regarded as a rival of alfalfa as hog pasture.

"The gains made in the tests of hogging corn reported in this bulletin ranged from 183 to 1,048 lbs. per acre of corn when no supplementary feed was given and from 335 to 1,377 lbs. per acre where the corn was supplemented. It is estimated that in these tests an average of about 450 lbs. of corn was required to produce 100 lbs. of gain when no supplement was used, as compared with an average of 409 lbs. when the corn was supplemented with tankage, late alfalfa pasture, or rape. Alfalfa pasture is to be preferred as a supplement to corn in hogging off enterprises on irrigated lands because of its cheapness and reliability.

"The tests reported show that field peas have a high value as an irrigated crop to be hogged off. The gains in live weight per acre of peas in 17 tests ranged from 250 to 949 lbs., averaging in the neighborhood of 600 lbs. These results compare not unfavorably with those obtained by hogging corn, when the costs of production of these crops are considered."

[Feeding experiments with swine] J. M. HUNTER (New Jersey Stas. Rpt. 1917, pp. 107-121).—Summaries of 4 swine feeding experiments are presented, mostly in continuation of work previously noted (E. S. R., 39, p. 777).

A comparison of self-feeding and hand-feeding of concentrates when forage crops were also fed was made with two groups of 24 weanling pigs, averaging 49 lbs. in weight, from June 14 to October 1, 1916. Each group was divided into 4 equal lots, treated similarly. One group had free choice of shelled corn, wheat middlings, and tankage (60 per cent), the other was fed a 2 per cent ration made up of these feeds in proportions that varied somewhat from lot to lot. The self-fed group made a total average gain per pig of 106 lbs. at a cost per pound of 3.2 lbs. of feed. The hand-fed group gained only 70.4 lbs. per pig and consumed 1.8 lbs. of feed per pound of gain. There were considerable differences between lots within a group. On October 2, when the forage season was over, certain pigs of both groups that had not attained a weight of 200 lbs. were given free choice of corn and tankage. By December 12, the continuously self-fed pigs averaged 56.6 lbs. increased weight and had consumed 5.2 lbs. of feed per pound of gain. The pigs previously hand-fed had gained an average of 41.25 lbs. by the same date at a cost of 7.5 lbs. of feed per pound of gain.

A second trial with blackstrap molasses as a substitute in whole or in part for corn in a ration for brood sows is reported, 4 lots of 6 sows, 2 to  $4\frac{1}{2}$  years old, being used. The lots fed corn meal and molasses and hominy feed and molasses did about as well as the lot fed corn without molasses. A lot not receiving any corn but a larger amount of molasses and with the proportions of other feeding stuffs altered to secure the same nutritive ratio and the same amount of digestible nutrients in the rations, gained at a much slower rate, and showed a tendency to scour.

A single test with 7 sows and their pigs seems to indicate that young growing pigs can not make satisfactory gains when fed out of doors during the winter and housed in an A-shaped colony house.

Forty fall pigs averaging 42 lbs. in weight were divided into 4 equal lots for a test of fattening rations fed free choice. Apparently the length of trial varied in the different lots, and the exact basis of comparison is not altogether evident. In the order of increasing time estimated as necessary for the pigs to attain a weight of about 200 lbs., the rations tested ranked as follows: (1) Shelled corn, wheat middlings, tankage, and skim milk, (2) corn, middlings, and tankage, (3) corn and tankage, and (4) corn, middlings, tankage, and ground alfalfa. The low average gains on the last-named rations are attributed partly to the influence of a single pig that remained stunted throughout, "yet the fact remains that ground alfalfa is not relished by young fattening pigs having access to the self-feeder containing the above-mentioned feeds. When 2 lbs. of ground alfalfa is all that pigs at 100 to 150 lbs. will consume per day it is not likely that such a small amount would effect any considerable saving or tend to cheapen the ration. It may be possible that ground alfalfa lessens the appetites of pigs on the self-feeders."

[Mineral nutrients and corn in swine feeding] (Kansas Sta. Rpt. 1918, pp. 13-17).—The two lines of work already noted (E. S. R., 40, p. 371) have been continued.

Study of the influence of low-ash rations on pregnant sows was made with 14 animals, 10 being survivors of the preceding year's work. Eight sows fed ground corn alone with either tap or distilled water produced 14 dead pigs and 39 living ones, of which only 6 lived for 2 months. Three sows fed corn, corn gluten meal, and blood meal produced 21 dead pigs and no living ones.

Three sows fed corn, shorts, and tankage produced 1 dead pig and 21 living ones, all still alive at weaning, 60 days afterwards.

Study of the effect of protein and ash supplements to corn in the fattening ration was made with 66 Duroc-Jersey pigs weighing at the start about 54 lbs. a head and divided into lots of 6 each. The feeding methods are judged largely by the time necessary for the pigs to gain 150 lbs. Seven lots were fed on alfalfa pasture, and 4 in dry lots. Of the former, the 3 lots in which corn was the only concentrate took longest (104 to 107 days) to attain the desired weight. Additional ash had no apparent influence. The most rapid gains (97 days) were made by a lot in which 6 per cent of the concentrate was tankage and which had access to extra mineral nutrients. A lot in which shorts and tankage (4:1) formed 20 per cent of the grain ration gained 150 lbs. per head in 99 days. Two self-fed lots, one with corn, shorts, and tankage and the other with corn, tankage, and additional ash, required 100 and 101 days, respectively. Three of the lots not on pasture received shorts and tankage (4:1) as supplement to corn. A feeding period of 112 days was required for two whose grain rations were 70 and 60 per cent corn, respectively, and a period of 105 days for the other in whose ration the proportion of corn was gradually changed from 40 to 80 per cent. The fourth lot not on pasture had free choice of corn, shorts, and tankage and needed 104 days' feeding. Shorts and tankage were consumed approximately in the proportion of 8:1 and formed about 30 per cent of the ration.

Feeding value of skim milk for swine, H. W. NORTON, J.B. (Michigan Sta. Spec. Bul. 92 (1918), pp. 9).—This is an amplification of an earlier study (E. S. R., 40, p. 75) of the combined results of numerous swine feeding trials at various experiment stations. It is computed that a pound of any of the following-named supplements would replace the designated amount of grain: Skim milk 0.28 lb., tankage 2.53 lbs., middlings 1.05 lbs., linseed meal 2.62 lbs., and soy-bean meal 3 lbs. A table gives the change in money value for swine feeding of skim milk as the prices of the other supplements vary. Buttermilk is considered to be equal in feeding value to skim milk, and whey about half as efficient.

An experiment comparing velvet bean meal, tankage, and soy bean meal as supplements to corn meal in feeding hogs, E. S. GOOD and L. B. MANN (Kentucky Sta. Circ. 20 (1918), pp. 4).-A lot of 8 Duroc-Jersey and Berkshire shotes, each weighing originally about 125 lbs., was fed on corn meal and velvet bean-and-hull meal (5:1), another on corn meal and tankage (9:1), and a third on corn meal and soy bean meal (7:1), for 89 days. The average daily gains were, respectively, 0.8, 1.52, and 1.42 lbs. per pig, and the corresponding amounts of feed consumed per pound of gain were 6.5, 4.2, and 4.5 lbs. Although the velvet beans were much cheaper than tankage or soy beans, they were fed at a distinct loss. The velvet bean ration had a wider nutritive ratio than the others, but it was impracticable to increase the proportion of velvet beans since the mixture as it stood was unpalatable, due presumably to the high crude fiber content. It is suggested that a velvet bean meal made from the kernels only would be a more useful feeding stuff to place on the market. The value of soy beans as a supplement to corn is pointed out, and analyses of velvet bean meal and tankage are reported.

Inheritance investigations in swine (Kansas Sta. Rpt. 1918, pp. 42, 43).— The following results are claimed from cross breeding experiments with swine, the details not being given: (1) Wide forehead (Berkshire) dominant to medium forehead (Duroc-Jersey) and to narrow forehead (Tamworth, wild hog), (2) straight face (Tamworth, wild hog) dominant to dish (Berkshire), (3) long face (Tamworth) completely dominant to short face (Berkshire), and (4) erect ear (Berkshire) dominant to drooping ear (Duroc-Jersey).

Experimental work [with poultry] H. R. LEWIS (New Jersey Stas. Rpt. 1917, pp. 135-175, fig. 1).—The following research projects with poultry are briefly outlined but without the presentation of results other than general progress reports similar to those previously noted (E. S. R., 39, pp. 780, 781). Distribution and inheritance of fecundity, inheritance of plumage color, variation and inheritance of eggshell color, sequence of sex, strain test of Single Comb White Leghorns, nutrition studies with concentrates of animal origin, effect of time of hatching upon the molt and seasonal distribution of egg production, the elaboration of growth and production standards, and the home preservation of eggs. A section on the amount and causes of embryo mortality presents detailed results which have been previously noted from another source (E. S. R., 38, p. 876).

A survey of 14 of the large commercial poultry breeding farms in New Jersey during the year 1915-16 is reported. These farms apparently did not form part of a larger survey with which the author was connected (E. S. R., 40, p. 570). The labor incomes of farms maintaining less than 1,000 birds averaged \$660, of those maintaining 1,000 to 2,000 birds, \$3,191, and of those with more than 2,000 birds, \$9,606. The annual production per bird for the three classes of farms were, respectively, 134, 145, and 125 eggs.

A study is undertaken of the errors incident to the use of production records of pens of laying birds in experimental work. Data are presented showing how differences between groups due to inherent differences in capacity might be attributed to the experimental procedure. A numerical method differing considerably from usual statistical practice is proposed for the correction of such errors. It is also suggested that many errors could be avoided by doing the experimental work with second-year birds, assignments to lots being based upon the trap nest records of the pullet year.

A tabulation is presented by months during the year 1916-17 of prices of eggs and market fowl in New York City. To some extent this is a continuation of data previously furnished by the author (E. S. R., 38, p. 373).

Effect of certain grain rations on the growth of the White Leghorn chick, G. D. BUCKNER, E. H. NOLLAU, R. H. WILKINS, and J. H. KASTLE (Jour. Agr. Research [U. S.], 16 (1919), No. 12, pp. 305-311, pl. 1).—Some unexplained results from feeding grain mixtures containing soy beans to growing White Leghorn chicks at the Kentucky Experiment Station are reported. The experiments originated from an observation that 1-day-old chicks failed to grow when fed ground soy beans and ground oats (1:2), protein-free milk, sprouted oats, cabbage leaves, grit, oyster shell, and sour skim milk.

A group of 11 chicks fed equal parts of soy beans, oats, wheat, shipstuff, sunflower seed, and cracked corn, with the addition of some skim milk, sprouted oats, shredded cabbage, grit, and oyster shell, grew from an average weight of 48 gm. to 490 gm. in 9 weeks, approximately a normal growth, but the animals were subnormal in vigor. Two died during this period. A similar group of 12 chicks were fed at the same time on the same ration except that the grain had been baked at 420° F. Eight died in 9 weeks, but the average weight of the survivors was 566 gm.

In a more elaborate experiment, 3 lots of 60 chicks each were used. The control (lot 3) received the so-called Cornell ration (E. S. R., 29, p. 273) and attained an average weight of 1.36 kg. (3 lbs.) at the end of 28 weeks. Lot 1 was fed the growth-promoting high-lysin ration previously studied by three of the authors (E. S. R., 34, p. 871) with the addition of soy beans in the mash and scratch. The chicks averaged 1.24 kg. at 28 weeks and the cockerels particularly were consistently somewhat less vigorous than the controls. Secondary sexual characters and sexual instincts developed normally. Lot 2 had access to dry mash of ground barley, rice, hominy, and oats (in equal parts), and was given a scratch of barley, rice, and hominy. Enough butter fat and gluten flour were added to the mash and scratch to make them equal in protein and fat content to the mash and scratch fed lot 1. Once a day a wet mash composed of the grain mixture and protein-free milk was fed. This lot made much less than normal growth, the average weight at 28 weeks being only 809 gm. The external sexual characteristics were rudimentary and the feather tracts were not properly developed. Only 19 survived the 28 weeks. "The chicks of lot 2 seemed to have a good appetite, and while they ate with apparent avidity, yet they always seemed to be in search of something in their feed which they could not find. Regarding their ration, it will be seen that it is satisfactory with respect to every necessary dietary factor except the quality of protein. We are unable at this time to show wherein these proteins are limited, but hope to be able to prove this by experiments which are now in progress."

Protective feeds for poultry, H. R. LEWIS (*New Jersey Stas.*, *Hints to Poultrymen*, 7 (1919), No. 7, pp. 4).—Average weights in successive weeks until the twenty-fourth after hatching are given for two groups of chicks, one grown at New Brunswick, N. J., under customary "normal" conditions without milk products in the diet, the other at Vineland, N. J., for contest purposes, with dried buttermilk in the mash, infertile incubator eggs to eat, fluid buttermilk to drink, and an alfalfa pasture as range. Breeds of the American class and Leghorns are treated separately in each group.

The Vineland chicks in both cases made distinctly the better growth, were for a considerable period during the second and third months at least 50 per cent heavier than the New Brunswick chicks, and attained the last recorded weights of the latter about a month earlier. The success of the Vineland group is attributed to the generous supply of vitamins in their feed. Poultrymen are advised to consider recent discoveries as to the dietary needs of growing animals.

[Inheritance of color in Andalusian fowl] (Kansas Sta. Rpt. 1918, p. 45).— It is stated that further study of the genetics of Andalusian blue in continuation of work already noted (E. S. R., 39, p. 877) makes it desirable to postulate a fourth factor for feather color, namely, a factor responsible for black lacing on the contour feathers.

Improvement and conservation of farm poultry (Kansas Sta. Rpt. 1918, pp. 43-45, fig. 1).—The annual egg records of mongrel pullets and of their pullet descendants after three generations of top crossing with pure-bred males are compared. The records of Barred Plymouth Rock grades averaged 207.3 eggs, of Single Comb White Leghorn grades 198 eggs, and of White Orpington grades 111.25 eggs. The average records of the great granddams were 104.5, 74.5, and 123.5 eggs, respectively. A check lot of mongrels not crossed with improved stock increased their average record in three years from 101.7 to 129.6 eggs.

The Vineland international egg-laying and breeding contest, H. R. LEWIS (*New Jersey Stas. Rpt. 1917, pp. 177–184, 185–187*).—This is a statement of the first year's results of the Vineland contest, presenting certain material not given in a previously noted publication (E. S. R., 38, p. 677), including the individual annual egg records of the 10 hens in each of the 100 pens.

Report of the second (yearling) year of the Vineland international egglaying and breeding contest, R. R. HANNAS (*New Jersey Stas.*, *Hints to Poultrymen*, 7 (1919), No. 4, pp. 4).—This is a preliminary report of the second year

76

of a three-year contest. A similar report of the first year has been noted (E. S. R., 38, p. 677). A list of 99 pens classified as to breeds is given, together with the egg production of each pen during both years and the name of the exhibitor. General notes on feeds consumed, mortality, hatching, and brooding are included. "The data obtained this year show that a hen eats practically as much feed as does a pullet, but she requires a different balancing of the food materials to maintain a high production, requiring nearly twice as much mash, the real egg food, as grain."

The ratio of weight of eggs to weight of feed was 1:4.35 in the case of Leghorns and 1:5.65 in the case of the heavy breeds (Plymouth Rocks, Wyandottes, and Rhode Island Reds).

Lessons to be learned by keeping records, V. G. AUBRY (*New Jersey Stas.*, *Hints to Poultrymen*, 7 (1919), No. 5, pp. 4).—Tabulations are given by months of the average results secured by 32 poultrymen who by agreement handled their flocks for a year substantially according to the methods advocated by the station. Data on amounts and costs of feeds, production percentage, prices received for eggs, and profits are included. It is thought that these figures provide a normal standard whereby any poultryman who keeps records can discover whether he is securing satisfactory returns from his efforts.

The incubator egg, R. R. HANNAS (New Jersey Stas., Hints to Poultrymen, 7 (1919), No. 6, pp. 4).—Directions are given for caring for eggs before and during incubation. The importance of individual differences in hens with respect to hatching percentage of their eggs is recognized.

Marketing of dressed poultry (*Kansas Sta. Rpt. 1918, p. 46*).—Progress in this investigation during the year, in continuation of work previously noted (E. S. R., 40, p. 372), is said to warrant the following conclusions:

"(1) Quantitative bacteriological determinations are not an index to spoilage. (2) The most important accumulations of bacteria are in the intestinal tract and the skin. There is evidence that the skin flora plays a more important rôle than was formerly considered. (3) The intestinal tract gives rise to bad odors and volatile products most rapidly; the liver next, the skin next, if kept moist, and the muscles last. Nothing has been found to keep down the development of bad odors without injuring the appearance and texture of the skin."

## DAIRY FARMING-DAIRYING.

Winter rations for dairy heifers, C. H. ECKLES (Missouri Sta. Bul. 158 (1918), pp. 3-54, figs. 16).—This bulletin compares 15 rations with reference to their value and economy in promoting growth of dairy heifers during the winter months, and is based upon 76 individual feed and growth records of heifers. Seventeen of the animals were included in the light-fed group of heifers forming a part of a previous investigation (E. S. R., 34, p. 378). The others were used in a series of feeding experiments conducted annually each winter from 1913-14 to 1917-18 and not hitherto reported in detail. Of the total number of heifers, 31 were Jerseys, 34 Holsteins, and 9 Ayrshires. One of the Jerseys and one of the Holsteins were used two seasons. For each of these animals the following data are published: Age at the beginning of winter feeding, the average daily consumption of each feeding stuff offered, the digestible crude protein, and the net available energy of the daily rations (based respectively upon the average figures published by Henry and Morrison and by Armsby), the initial weight and height at withers, the normal weight and height for animals of the same breed and age, the daily gain in weight, the total gain in height, and the gains in weight and height to be expected of similar heifers under normal conditions. The Jerseys varied in age at the start from 6 to

20 months, the Holsteins from 7 to 21 months, and the Ayrshires from 9 to 15 months. The feeding periods were mostly 5 months. The data on normal growth are taken from those accumulated at the Missouri Station; they are still incomplete for animals approaching maturity and have been published only in part (E. S. R., 40, p. 877). Difficulties arising from differences in age and condition were largely overcome by using these normal figures as the basis of comparison.

The combinations of feeding stuffs compared include (1) alfalfa hay alone, (2) alfalfa and silage, (3) alfalfa and corn, (4) clover hay and corn, (5) silage, alfalfa, and corn, (6) silage, timothy hay, and corn, (7) silage, corn, and cotonseed meal, and (8) silage, timothy, corn, and cottonseed meal. A variety of different proportions of grain and roughage were tested. It was found that animals fed a ration which resulted in heavy gain during the winter made only small gains the following summer on pasture. When the winter ration was so meager that the animals were low in vitality in the spring fairly large gains were produced on summer pasture, but in most cases they were not large enough to compensate for the small winter gain. Neither extreme in winter feeding is considered economical. The best results, it is held, follow a winter ration that keeps the animal in moderate flesh and produces growth as nearly normal as possible. It was found that normal growth may be obtained from rations furnishing considerably less protein than that prescribed by the Wolff-Lehmann standard.

Of the 17 heifers wintered on alfalfa alone, only 2, both rather mature, made a gain in weight equal to normal. "Although alfalfa is probably the most palatable roughage used for cattle in this country and the quality fed was of the highest, still animals did not consume enough to supply sufficient energy to allow for a greater growth."

The 15 heifers fed both silage and alfalfa made better gains than those fed alfalfa alone. The best gains occurred when both roughages were fed at will. On this ration animals more than 9 months old made practically normal gains. They consumed the silage and alfalfa in the proportion of 2:1. Younger calves needed grain in addition in order to grow normally.

"The most satisfactory ration of all those tried was silage at will, legume hay limited to about 6 lbs. daily, and 2 lbs. of corn daily. On this ration heifers of all ages thrived and made gains somewhat above the normal.

"Fair results may be obtained from silage alone for roughage, if legume hay is not available. In this case about 2 lbs. of concentrates should be supplied daily, of which one-half should be a high protein feed such as linseed or cottonseed meal, the remainder corn, or other grains if the cost is less a pound than for corn." The animals made better gains and seemed to be more contented if about 2 lbs. of timothy hay per day was added to a ration of silage and grain.

Alfalfa or clover hay fed at will with 2 or 3 lbs. of corn daily made a satisfactory ration for heifers of any age from 6 months to within a few weeks of freshening.

It is considered best to continue feeding grain to all heifers for a few months after the cessation of milk feeding. At a later age they can be fed exclusively on roughage if necessary without greatly retarding their growth. It appears that Holsteins are able to make more nearly normal gains on a ration composed mostly of roughage than are Jerseys.

Dairy cattle feeding experiments, P. V. EWING, J. W. RIDGWAY, and W. A. DOUBT (*Texas Sta. Bul. 238 (1918)*, pp. 5-14).—Results of two studies are presented.

1. Cottonseed meal v. peanut feed for milk production (pp. 5-9).—Two lots of 6 cows each were fed alternately by the reversal method during four 3-week

periods on two grain rations, corn chop and peanut feed (1:1) and corn chop and cottonseed meal (3:2). The cows when on the peanut ration produced 178.7 lbs. more milk and 8.85 lbs. more butter fat than they did on the cottonseed meal ration, but owing to the fact that about 50 per cent more protein supplement was consumed, the increased production was not profitable, since peanut feed and cottonseed meal were purchased at almost exactly the same price. A third lot of 6 cows fed during the entire 12 weeks on corn chop, peanut feed, and cottonseed meal (6:3:2) produced 583 lbs. of milk and 1.08 lbs. of butter fat more than the other cows when on the cottonseed meal ration. The third ration is considered the most economical of those tested. In assigning the cows to lots, care was taken "to divide them as equally as possible with respect to age, production, size, feeding capacity, stage of lactation, and natural productive capacity."

Proximate analyses of the samples of peanut feed and cottonseed meal used are reported.

It is held that under Texas conditions, where proteins are generally cheaper than carbohydrates, the proper basis for comparing feeds is the percentage of total digestible nutrients, and not the protein content.

2. Comparison of methods of preparation of velvet beans for dairy cows (pp. 10–14). The grain mixture used in this experiment consisted of corn bran, cottonseed meal, and velvet beans (2:1:3), and the roughage of pasture. Each of four different ways of preparing the beans was tested in rotation with 4 lots of 3 cows, each lot receiving beans prepared by a particular method for 20 days. The amount of grain fed in each period was the same. The milk produced by the cows when the beans were fed whole totaled 6,337 lbs., when the beans were cracked 6,345 lbs., when cracked and soaked in water 6,398 lbs., and when ground 6,690 lbs. The feeding of cracked beans soaked, and of ground beans, was accompanied by an increase of 7 or 8 lbs. of butter fat. The increase in milk resulting from grinding was about 57 gal. for a ton of beans, which at 40 cts. a gallon is worth \$22.80. Since mills will often grind the beans for \$2.50 a ton, and the grinding can be done on many farms for \$5, the operation is deemed distinctly profitable. No differences in palatability apparently resulted from the various methods of preparation.

Proximate analyses of the samples of corn bran, cottonseed meal, and velvet bean feed used are presented. The milk and butter fat records of each lot by 5-day intervals are also tabulated.

Some aspects of the physiology of mammary secretion, R. L. HILL (Jour. Amer. Vet. Med. Assoc., 51 (1917). No. 5, pp. 642-654).—This paper repeats to some extent data already published (E. S. R., 32, p. 871) showing increased milk flow and fat yield in a goat as the immediate result of pituitrin injections, and includes confirmatory data from three other goats. Milk analyses which are published show that pituitrin has no influence on any of the milk solids except the fat.

An exceptional case of milk secretion and its bearing on the theories concerning mammary development, R. L. HILL (Jour. Dairy Sci., 2 (1919), No. 1, pp. 19-27, figs. 3).—The case is described of a doe kid at the Maryland Experiment Station, which was found to have well-developed mammae and an udder full of milk before she was 4 months old. The fluid had the normal composition of goat's milk. The animal was milked at intervals for about 6 months. That the lactation differed from a normal post-partum one is indicated by the fact that relatively long intervals, even 19 days, between milkings did not result in cessation of flow.

"This kid had not reached sexual maturity, so any theory of mammary growth or milk secretion involving the ovaries, corpora lutea, fetus, or placenta is not applicable. The udder of this kid had not been massaged, suckled, or treated in any way to stimulate its growth or secretion. It is possible that some other of the internal secreting glands have a prominent part in regulating the growth and secretory activity of the mammary glands. There is some evidence [as noted above and in another publication of the author (E. S. R., 36, p. 573)] in favor of the theory that the pituitary body (hypophysis cerebri) may function in this way."

The milk analyses and the author's theory of colostrum formation are repeated from another paper (E. S. R., 38, p. 780). The literature on the physiology of milk secretion is reviewed.

A new and powerful galactagogue, C. H. DUNCAN (N. Y. Med. Jour., 105 (1917), No. 1, pp. 22, 23).—Several cases are cited in which the milk flow of the nursing mother (human) was apparently increased by subcutaneous injection of 1 cc. of her own milk. The statement is made that veterinarians have successfully treated cows by similar methods. "This treatment should be brought to the attention of the cattle raisers, stockmen, farmers, dairymen, etc., for if this treatment is judiciously given it will insure the animal giving the maximum amount of milk of which she is capable. . . The writer suggests that practically every cow be treated as indicated to insure her doing her duty toward supplying milk."

Milk as a galactagogue, L. S. PALMER and C. H. ECKLES (N. Y. Med. Jour., 108 (1918), No. 9, pp. 375, 376).—The authors have attempted to verify the above-noted theory using cows of the Missouri Experiment Station herd. Two experiments were performed in which 20 cc. of milk from fresh heavy milking cows was injected subcutaneously on three successive days into the shoulders of cows advanced in lactation. The results were entirely negative. In a third experiment, after a cow was milked dry 20 cc. of milk was injected and the cow milked again in an hour, when 85 gm. of milk was secured. On the previous day the same procedure without injection resulted in 200 gm. of milk.

Since Duncan's treatment seems to have been most effective in cases of sudden cessation of milk flow the authors suggest that the injected milk served as a counterdepressant and not as a galactagogue.

Principles and practice of milk hygiene, L. A. KLEIN (*Philadelphia: J. B. Lippincott Co., 1917, pp. 320, figs. 40*).—This book is intended primarily as a text for students pursuing a course in milk hygiene.

The utilization of dairy by-products, E. KELLY (Jour. Dairy Sci., 2 (1919), No. 1, pp. 46-49).—Attention is called to the food lost to the people of the United States by the waste of skim milk, buttermilk, and whey, and general suggestions made regarding methods of utilization. It appears that only six States have laws requiring pasteurization of skim milk and whey destined for human consumption.

The practical cultivation of the green mold (Penicillium glaucum) for making blue cheese, R. CHAVASTELON (Compt. Rend. Acad. Agr. France, 4 (1918), No. 18, pp. 564–566).—By the method proposed very thin slices of bread (wheat or rye) are soaked in a 35 per cent solution of tartaric acid, inoculated on both sides with Penicillium spores, kept on screens or straw mats (previously sterilized) in a moist atmosphere for a day or two, and then, when colored a uniform green, dried in the air and pulverized. Practically nothing is left by this time of the original bread and the residue consists almost exclusively of spores suitable for use in cheese making.

The method commonly used by makers of Roquefort cheese is to steep large pieces of rye bread in vinegar to which spores have been added, but this is considered undesirable aside from the waste of material since acetic acid is not so favorable a culture medium for Penicillium as for some other molds. 1919]

Buttermilk cheese, A. W. RUDNICK (*Jour. Dairy Sci.*, 2 (1919), No. 1, pp. 41-45, fig. 1).—The author, working at the Iowa Experiment Station, finds that a satisfactory cheese can be made from pasteurized sour cream buttermilk by running the heated buttermilk through one of the commercial centrifugal machines now available for the extraction of curd from skim milk in the manufacture of cottage cheese.

The machine consists of a hollow cylinder open at the top except for a rim one-eighth of the diameter, supported by a spindle, and inclosed in an iron frame. The curd lodges under the rim. The casein content of the whey depends upon the acidity, temperature of heating, and duration of heating. When sour pasteurized buttermilk with a casein percentage of 2.69 was held one hour at 170° F. the whey tested 0.266 per cent. When it was held one hour at 140° F. the test was 0.319 per cent, and when heated to  $170^{\circ}$  F. but not held 0.397 per cent. The curd had the best grain after the buttermilk was held for one hour at 140°. Sour pasteurized buttermilk cheese prepared by the centrifugal method does not have the disagreeable taste resulting from the customary method of neutralization with sodium hydroxid and reacidulation with hydrochloric acid.

It is stated that the centrifugal machine will leave only 0.15 per cent of casein in the whey when buttermilk from pasteurized sweet cream is used. Such buttermilk held at 95 to 115° F. for an hour after the acidity has reached 0.65 per cent produces a cheese equal to cottage cheese in flavor and texture.

The manufacture of condensed milk (So. African Jour. Indus., 1 (1918), No. 15, pp. 1447-1449).—The preparation of condensed milk and milk powder is outlined.

## VETERINARY MEDICINE.

Textbook of meat hygiene, with special consideration of ante-mortem and post-mortem inspection of food-producing animals, R. EDELMANN, trans. by J. R. MOHLER and A. EICHHORN (*Philadelphia: Lea & Febiger, 1919, 4. rev. ed., pp. VI+17-472, pls. 5, figs. 161*).—The fourth revised edition of the work previously noted (E. S. R., 35, p. 678).

This work is based on the rules and regulations of the Bureau of Animal Industry of the U. S. Department of Agriculture, the latest regulations under Order 211 of this Bureau being incorporated. Throughout the book references are made to these regulations, especially with regard to the disposition of carcasses.

Live stock sanitary laws and regulations of the State Board of Agriculture. Laws regulating the practice of veterinary medicine ([Baltimore]: Md. State Bd. Agr., 1918, pp. 39).—The text of the laws is here brought together.

Report of the New York State Veterinary College at Cornell University for the year 1917-18, V. A. MOORE (*Rpt. N. Y. State Vet. Col., 1917-18, pp. 184, pls. 11*).—In addition to the report of the director of the college and others on the work during the year 1917-18, the following papers are presented: Researches in the Diseases of Breeding Cattle, by W. L. Williams and C. M. Carpenter (pp. 51-108); Handling an Outbreak of Calf Scours and Pneumonia, by C. M. Carpenter (pp. 109-118); The Paranasal or Facial Sinuses of Sheep, by G. S. Hopkins (pp. 119-121); The Anatomy of the Digestive Tract of Sheep, by E. Sunderville (pp. 122-127); Foreign Bodies in the Tissues with a Report of Six Cases, by S. A. Goldberg (pp. 128-137); Orokinase and Salivary Digestion in the Horse, Cow, and Pig, by B. J. Finkelstein (pp. 138-144); Certain Aspects of the Pathology of Spavin (E. S. R., 39, p. 686), by S. A. Goldberg (pp. 145–148); A Preliminary Report on the Urine Analysis of the Dairy Cow, by C. E. Hayden (pp. 149–155); Horseshoes of Interest to Veterinarians, by H. Asmus (pp. 156–168); and The Strongylidæ Infesting the Horse, by W. A. Hagan (pp. 169–179).

First biennial report of the [Utah] Live Stock Board for the period ending November 30, 1918, R. W. HOGGAN ET AL. (*Bien. Rpt. Live Stock Bd. Utah*, 1 (1917-18), pp. 23).—This includes a discussion of the occurrence of and work with the more important diseases of live stock for the period ended November 30, 1918.

[Diseases of live stock], A. H. CORY (Ann. Rpt. Dept. Agr. and Stock [Queensland], 1917-18, pp. 64-67, pls. 6).—A discussion of the occurrence of and work with ticks and tick fever and other diseases of cattle, including sheep, swine, etc.

The physiological action of nitrobenzene vapor on animals, W. L. CHAND-LER (*New York Cornell Sta. Mem. 20 (1919)*, pp. 411-472, pl. 1).—This is a report of investigations of the effect of nitrobenzene upon the host, conducted in continuation of the parasiticide investigations previously noted (E. S. R., 38, p. 760).

The work reported has confirmed the findings of previous investigators that (1) nitrobenzene exhibits toxic properties, whether it is ingested, applied to the skin, inhaled, or administered by subcutaneous injection; (2) the size of the lethal dose is extremely variable; (3) the symptoms of poisoning are inconstant; (4) an interval of time (the latent period) often elapses between the administration of the poison and the onset of the symptoms; (5) nitrobenzene is not necessarily converted in the body into anilin, hydrocyanic acid, or any other substance before it exerts a toxic action; and (6) nitrobenzene forms methemoglobin in the blood. It has also led to the following conclusions:

"Aside from the possible disturbance of digestive functions and a possible asphyxia due to a direct action of nitrobenzene on the blood, most, if not all, of the observed symptoms of nitrobenzene poisoning may be explained on the basis of disturbances in the cerebellum or the cerebellar paths.

"Toxic doses of nitrobenzene, when administered by vapor inhalation, exert a direct action on the Purkinje cells in the cerebellum, causing chromatolytic degeneration of these cells. Histological examinations have failed to reveal any definite changes in any of the organs of the body except the blood (presence of methemoglobin and morphological alterations of erythrocytes) and the cerebellum (chromatolytic degenerations of the Purkinje cells).

"The size of the lethal dose probably depends on conditions such as the amount and the kind of fats in the blood, which favor or disfavor a concentration of the drug in the vicinity of the nerve cells. The latent period (the time elapsing between the administration of the poison and the onset of the symptoms) is undoubtedly due to the absorption of the nitrobenzene from the blood, and its retention by the liquid fats of the body in which it is easily soluble. . . .

"Nitrobenzene can not be used, with any degree of safety, for the fumigation of animals to destroy their external parasites... Because of the extreme toxic properties and the subtle action of nitrobenzene, the following uses of this drug should be prohibited by legislation: For perfuming soaps, lotions, and pomades; as a solvent in shoe polish, floor wax, and the like; and especially as an ingredient of flavoring extracts, confections, and liqueurs. The drug should be regarded as one of the most dangerous of poisons, and its sale and use should be regulated by law just as in the case of any other deadly poison."

A list of the literature cited consisting of 27 titles is included.

Iodized chloroform in war surgery, A. CHASSEVANT (Schweiz. Apoth. Ztg., 56 (1918), No. 44, pp. 581-583; abs. in Chem. Abs., 13 (1919), No. 7, p. 770).— A solution of iodin in chloroform in the proportion of 1 gm. of iodin to 30 of chloroform has been used by the author with success as an antiseptic in the treatment of furunculosis, anthrax, suppurating wounds, and varicose ulcers. As a protective dressing for wounds an ointment made of equal parts of paraffin, white wax, and spermaceti is recommended.

Acriflavin emulsion as a wound dressing, T. E. A. STOWELL (*Brit. Med. Jour., No. 3035 (1919), pp. 244, 245).*—The formula is given of an emulsified preparation of acriflavin developed by G. Humphreys, which is said to have given better results than the 1 in 1,000 solution in normal saline. The proportions to give a stable emulsion are as follows: Acriflavin 0.1, thymol 0.005, white wax 4, liquid paraffin 76, and distilled water 20 parts.

Treatment of wounds by paraffin, E. F. PRATT (*Brit. Med. Jour., No. 3035* (1919), pp. 243, 244).—Several case reports are given of the successful treatment of burns and lacerated wounds with ambrin or paraffin. The method of procedure is first to clean the wound thoroughly with sterilized water and then spray or paint the melted paraffin over the affected area. A layer of gauze is then placed over the paraffin and another layer of melted paraffin sprayed or painted over the gauze. This is covered with a cotton pad and bandaged. The dressings should be changed daily, from 3 to 4 dressings being usually required.

The author refers to the "bipp" treatment of wounds (bismuth, iodoform, and parafiin), and suggests that the paraffin is the most important of the three ingredients.

Extract of autolyzed yeast as a culture medium for B. coli, F. DIÉNERT and A. GUILLERD (*Compt. Rend. Acad. Sci.* [*Paris*], 168 (1919), No. 4, pp. 256, 257).—The authors have found autolyzed yeast to be a satisfactory substitute for peptone in culture media. The composition is said to be much more constant than that of peptone and the cost much less.

On a new accessory factor in bacterial infections.—Preliminary communication, W. E. BULLOCK and W. CRAMER (Jour. Physiol., 52 (1919), No. 5, pp. XLV, XLVI).—The authors state that suspensions of Bacillus welchii and of Vibrion septique do not produce gas gangrene or any symptoms of illness when injected into mice, rats, or guinea pigs, but that if a small quantity of a soluble ionizable calcium salt is injected, together with a suspension of these bacteria, a violent gas gangrene is produced which kills the animal within 20 hours. A similar phenomenon is observed with B. tetani, an animal injected with tetanus spores remaining perfectly well unless calcium chlorid is given. The chlorids of sodium, potassium, ammonium, strontium, and magnesium are not capable of releasing the pathogenic properties of B. welchii, and the action of the Ca ions can be antagonized by Na or Mg ions.

The conclusion is drawn that "calcium ions have the property of disturbing the relationship between the offensive mechanism of these bacteria and the defensive mechanism of the normal animal by which the bacteria are normally kept under control. The disturbance of this relationship leads eventually to a breaking down of this defensive mechanism. The term 'kataphylaxis' is proposed to designate this new phenomenon."

The proteus group of organisms with special reference to agglutination and fermentation reactions and to classification, I. A. BENGTSON (*Jour. Infect. Diseases*, 24 (1919), No. 5, pp. 428-481).—This paper embodies the results obtained in a study of the cultural and agglutination properties of a number of organisms of the proteus group isolated from various sources. The characteristics of the group as a whole and the differential characteristics of the various members have been determined by this study and by a review of the more important literature.

Food-poisoning epidemics in which the organism has been considered to bear a causal relationship are described in the literature. "Such epidemics are relatively few in comparison with similar epidemics ascribed to *Bacillus paratyphosus* B, and are not established on as firm a basis. As in the case of the latter organism the harmful effects produced may be due to the multiplication of the organism as well as to the formation of toxic substances, these toxins being very low in potency as contrasted with those produced by tetanus and diphtheria organisms.

"A number of local infections, including wound infections in which *Proteus* vulgaris have been concerned as the primary agent or as secondary agent, are described in the literature. Infections of the urinary tract due to this organism have been noted a number of times. Occasional general infections are also described."

An extensive bibliography is appended.

A study of Abderhalden's polarimetric method, A. SORDELLI (An. Soc. Quim. Argentina, 6 (1918), No. 23, pp. 31-34).—Polarimetric readings obtained in the examination by the Abderhalden method of samples of the placenta peptone and of sera from cases of cancer, tuberculosis, and typhus were found to be of the same order as those obtained with sera of pregnancy. As a result of this the conclusion is drawn that the Abderhalden method is lacking in specificity and its diagnostic value is to be doubted.

**Problems in anthrax control, J. J. FREY** (Jour. Amer. Vet. Med. Assoc., 55 (1919), No. 2, pp. 192-198).—A brief discussion is given of the rôle of various agencies in the spread of anthrax, of the relative value of methods of immunization with emphasis on the superiority of the double-spore vaccine, and of the most suitable ways of sending specimens for laboratory diagnosis.

Contribution to the question of specificity of the complement fixation method for diagnosing glanders, FONTAINE and LÜTJE (Ztschr. Veterinärk., 31 (1919), No. 1, pp. 1-36).—An extensive investigation of the influence of various factors on the reliability of the complement fixation test for glanders is reported, from which the conclusion is drawn that the effect upon the test of other diseases is practically negligible. An explanation of occasional positive reactions in glanders-free animals is given, and the recommendation is made that the test be checked by the use of multiple aspecific extracts.

Experiments on the detection of anaphylaxis in horses affected with glanders, O. WALDMANN (Arch. Wiss. u. Prakt. Tierheilk., 44 (1918), No. 3-4, pp. 253-289).—The effects of intravenous injections of various preparations of glanders bacilli into 31 glandered and 11 glanders-free horses were studied for the purpose of determining whether the introduction of such antigens causes a state of anaphylaxis in glandered horses.

The sensitiveness produced was shown to be of the nature of the reaction produced in the mallein test rather than a phenomenon of anaphylaxis, as the reaction in sick and well horses differed only in degree and no subsequent state of antianaphylaxis was produced. The conclusion is drawn that the reaction can not be used with certainty for the purpose of diagnosing glanders.

Habronemic conjunctivitis, J. C. LEWIS and H. R. SEDDON (Jour. Compar. Path. and Ther., 31 (1918), No. 2, pp. 87-94, figs. 2).—Four cases are reported and discussed.

The histology of the lesions of Johne's disease, J. M'FADYEAN (Jour. Compar. Path. and Ther., 31 (1918), No. 2, pp. 73-87, figs. 16).—A report of a histopathological study.

The spirochete of infectious jaundice (Spirochæta icterohæmorrhagiæ, Inada; Leptospira, Noguchi) in house rats in Chicago, A. OTTEBAAEN (Jour. Infect. Diseases, 24 (1919), No. 5, pp. 485-488).—" Spirochetes resembling those described as the cause of acute infectious jaundice were demonstrated in only two Chicago house rats of 30 examined (or 6.6 per cent), indicating that the spirochetes probably are not present in a high percentage of such rats. The spirochetes were demonstrated in material from the mouth and in tissue from the kidney.

"Because of the presence of spirochetes in the mouth of rats it is possible that at the time of the bite organisms may be carried into the wound by the saliva or teeth, and disease in this manner transferred directly from the rat to man."

Scrapie, J. M'FADYEAN (Jour. Compar. Path. and Ther., 31 (1918), No. 2, pp. 102-131, figs. 2).—The author here records experiments with scrapie which have been carried out at the Royal Veterinary College at London during the last seven years.

Attenuation of human, bovine, and avain tubercle bacilli, N. RAW (Lancet [London], 1919, I, No. 10, pp. 376, 377).—Pure cultures of human, bovine, and avian tubercle bacilli subjected for 12 years to continuous subculture on artificial media containing glycerin are said to have retained all their characteristic and selective appearances but to have undergone a gradual decrease in virulence, becoming almost nonpathogenic to animals. Reports are given of several cases of active glandular and pulmonary tuberculosis which have been apparently cured by injections of mixed attenuated bacilli, the cultures being raised to a temperature of  $220^{\circ}$  F. for two minutes before injection.

It is the opinion of the author that the careful use of such attenuated bacilli may have the effect of controlling and probably preventing tuberculous infections in the human body.

Bovine tuberculosis in children, R. S. AUSTIN (Amer. Jour. Discusses Children, 17 (1919), No. 4, pp. 264-269).—A study is reported of 24 cases of tuberculosis in children, ranging in age from  $2\frac{1}{2}$  months to 11 years, all but 3 cases of which ended fatally. Clinical, bacteriological, and post-mortem findings indicated that 7 of the cases were of bovine origin. The importance of this variety of the tubercle bacillus in tuberculosis of children and the necessity of home pasteurization of cow's milk are emphasized.

A characteristic localization of Bacillus abortus in the bovine fetal membranes, T. SMITH (*Jour. Expt. Med.*, 29 (1919), No. 5, pp. 451-456, pls. 3).—The author reports a characteristic localization of *B. abortus* in the epithelial covering of the chorion, the cells of which in cases of infectious abortion have been found to be densely filled with minute bacilli. Fetal membranes at the end of the normal period of gestation which are macroscopically without pathological changes have been found uniformly free from such cell contents.

The author concludes that "the significance of this invasion of the chorionic epithelium from the standpoint of pathogenesis can not be properly evaluated until a more complete history of the successive localizations of *B. abortus* has been obtained. It is safe to assume that this particular cell parasitism is but one of a series of localizations and centers of multiplication in the fetal membranes, although evidence points to it as perhaps the earliest stage in which-the organism gains by rapid, unchecked multiplication a considerable advantage over the host. The local destruction of an epithelial covering by an infectious agent when other miscellaneous infectious agents are absent may or may not be of much importance, for it would depend on the regenerative activity of the epithelium, the tendency to the gathering of injurious transudates, and the toxic substances associated with the bacilli." Report of committee on bovine diseases.—Their relation to the milk supply and to the public health, C. L. ROADHOUSE (Ann. Rpt. Internat. Assoc. Dairy and Milk Insp., 7 (1918), pp. 49-53).—A carefully kept record of the cause of losses of animals in two large certified herds is presented.

A new disease of bovines and ovines, P. DE FIGUEIREDO PARREIRAS HORTA (*Rev. Vet. e Zootech., 8 (1918), No. 2, pp. 3–32).*—This discussion relates to a gastroenteritis hemorrhagica found in cattle and sheep in the States of Minas-Geraes and Rio de Janeiro, Brazil.

Sheep-maggot flies, IV, W. W. and J. L. FROGGATT (Dept. Agr. N. S. Wales, Farmers' Bul. 122 (1918), pp. 24, figs. 11).—This is a report, in continuation of that previously noted (E. S. R., 38, p. 466), of work carried on during 1917–1918 at the government sheep-fly experiment station, at Kooroogama, Moree.

Are camels susceptible to blackquarter, hemorrhagic septicemia, and rinderpest? H. E. CROSS (Agr. Research Inst. Pusa Bul. 80 (1918), pp. 17, pl. 1, fig. 16).—The conclusions drawn from the investigations are that camels are as susceptible to blackquarter as cattle, that they are not very susceptible to hemorrhagic septicemia, and that they develop severe lesions of rinderpest, and are more susceptible to the disease than some cattle.

**Paralysis** in the hind quarters of a sow due to kidney worms, E. M. PICKENS and C. C. SHIVERS (*Cornell Vet.*, 9 (1919), No. 2, pp. 124–126).—**The** authors record a case of paralysis in a grade 6-year-old sow, reared at the Maryland Experiment Station, which was caused by *Stephanurus dentatus*.

Observations in regard to immunizing young pigs, R. R. BIRCH (Cornell Vet., 9 (1919), No. 2, pp. 75-92, figs. 15).—The author discusses the problem of establishing immunity to hog cholera in young pigs by the use of the simultaneous treatment following serum alone, and reports investigations conducted upon young pigs to determine whether passive immunity produced by serum alone interferes with the production of active lasting immunity by the simultaneous treatment, and what influence is exerted by the interval beween the two treatments. The general plan was to give follow-up treatment to several groups of pigs, litter mates of known susceptibility, at various ages and with various intervals elapsing between serum-alone and simultaneous treatment. Other groups were given simultaneous treatment only and were used aschecks. In the experiments reported none of the pigs showed any physical reaction, all acquired a lasting immunity, and individual differences in temperature reaction were not such as to indicate that the passive immunity produced by serum alone prevents the establishment of active immunity by subsequent simultaneous treatment. This principle appeared to hold good regardless of the interval elapsing between the two treatments.

The observation is made that there is apparently a distinct difference between natal immunity and serum-alone immunity in young pigs, in that if virus and serum are given while natal immunity still persists active immunity is not conferred; but virus and serum administered during the existence of passive immunity due to serum alone usually produces active immunity.

In conclusion the author recommends that in garbage-fed herds, and in other herds where there is constant danger of infection, serum alone should be administered when the pigs are from 4 to 6 weeks of age, or earlier if hog cholera should develop. This should be followed by simultaneous treatment when the pigs are from 9 to 12 weeks of age. If it is necessary to administer serum when the pigs are 2 or 3 weeks of age, a second dose of serum should be given 4 weeks later, followed in the usual manner and length of time by the simultaneous treatment. In immunizing herds less seriously threatened, the first serum-alone treatment may be omitted entirely. So-called medicinal hog-cholera remedies and cures, C. H. CLINK and D. B. CLARK (Indiana Sta. Bul. 223 (1918), pp. 3–24, figs. 2).—It is stated that the great loss of hogs resulting from outbreaks of hog cholera makes it important that the farmers of the State should appreciate the fact that the so-called medicinal hog-cholera remedies and cures have not been successful in controlling the disease in herds under test. In compliance with the provisions of the swine-disease law 20 different preparations have been tested and are here reported upon. Of 235 treated hogs 187 died of cholera and of 227 untreated hogs 179 died, thus showing that the preparations did not control the disease.

Necrobacillosis, C. P. FITCH (Cornell Vet., 9 (1919), No. 2, pp. 93-103).—A contribution from the Minnesota Experiment Station in which the author draws the following conclusions:

"Necrobacillosis of swine is becoming more prevalent in certain sections of the country and is assuming considerable economic importance. It is in no sense a new disease. The five principal forms of this infection as occurring among swine are necrotic stomatitis, necrotic rhinitis, necrotic gastritis and enteritis, necrotic dermatitis, and necrotic pneumonia.

"Oftentimes necrobacillosis and hog cholera occur in the same animal. These cases of mixed infection require great care in making a correct diagnosis. If the neucrotic lesions are not too extensive or the herd too widely involved it may be wise to use antihog cholera serum. Some types of necrobacillosis lend themselves to treatment, but the keynote in the control of this disease is prevention, based especially on the proper disposal of the manure." A list of ten references to the literature is included.

Atlas of the anatomy and physiology of the horse, O. C. BRADLEY and T. G. BROWNE (London: Baillière, Tindall & Cox, 1918, pp. 38, pls. 13).—Of the 13 original plates containing 105 figures, by G. Dupuy, 5 are in color.

The normal blood of the horse, H. BONARD (Schweiz. Arch. Tierheilk., 61 (1919), Nos. 3, pp. 113-137, figs. 3; 4, pp. 160-174).—This reports upon the specific gravity of the blood of the horse and its hemoglobin content as measured by Sahli's hemometer.

Castor seed (Ricinus communis) poisoning in horses, G. H. WOOLDRIDGE (Jour. Compar. Path. and Ther., 31 (1918), No. 2, pp. 94–98).—A report upon the poisoning of horses from having fed upon a mixed feed which contained castor seed. Five of the affected animals died and the services of others were lost for several weeks.

Poisoning of horses with castor seeds, M. E. WHITE (Jour. Compar. Path. and Ther., 31 (1918), No. 2, pp. 98–100).—A report of poisoning in several horses that had fed on castor beans.

Strongylidæ in horses, W. YORKE and J. W. S. MACFIE (Ann. Trop. Med. and Par., 12 (1919), No. 3-4, pp. 273-278, figs. 9).—In continuation of previous papers (E. S. R., 39, p. 892) the authors describe a sixth new species to which the name Cylicostomum pseudo-catinatum is given.

Preliminary report on ulcerative lymphangitis in horses of the A. E. F., A. H. STRAUS and A. C. WIGHT (*Jour. Amer. Vet. Med. Assoc., 55* (1919), No. 2, pp. 180–186).—A bacteriological study is reported of 36 cases diagnosed as ulcerative lymphangitis. The streptococcus was found to be the most frequent cause of the disease, being isolated in almost pure culture from 22 of the cases. The cryptococcus was found in 5 cases, the bacillus of Preisz and Nocard in 4, and *Staphylococcus aureus* in 1. Four cases proved to be glanders, a fact which shows the importance in making the diagnosis of first excluding glanders by use of the mallein and complement fixation tests.

125597°-19-7

In the treatment of cases of streptococcic and staphylococcic infection, the method employed has been the routine local treatment followed by the use of an autogenous vaccine or a stock vaccine containing from 4 to 10 strains of streptococci. The latter vaccine was prepared by growing the streptococci in dextrose bouillon for 24 hours, killing by heat, and diluting with physiological salt solution to approximately one billion per cubic centimeter. This was preserved in a 0.5 per cent solution of carbolic acid and injected daily in increasing doses from 1.5 billion to 4 billion organisms on the seventh day. This method of treatment has proved successful in the cases studied.

Investigations concerning the prevalence and distribution of poultry diseases in New Jersey, H. R. LEWIS (*New Jersey Stas. Rpt. 1917, pp. 175-177*).— Of 140 diseased fowls sent to the poultry department from various parts of the State during the year, 58 were suffering from diseases of the reproductive system. Several that had never laid an egg were found to be suffering from nuiscarriage and reabsorption of the ova, and it is suggested that this may be one of the causes in some pedigree laying flocks for the low production by some individuals which have every external appearance of high production.

Experiments on the intradermal test for Bacterium pullorum, M. SCHERAGO and J. P. BENSON (Cornell Vet., 9 (1919), No. 2, pp. 111-119).—A comparative study is reported of the agglutination test for the presence of *B. pul*lorum infection in fowls and the intradermal test proposed by Ward and Gallagher (E. S. R., 36, p. 884). Both tests were used on 134 fowls, and the most typical reactors to either or both tests were used in retests to check the results obtained at first and to observe the influence of previous injections with the intradermal test fluid on subsequent agglutination and intradermal tests.

From results which are summarized in tabular form, the authors conclude that the intradermal test is so inconsistent as to be worthless as a diagnostic agent for *B. pullorum* infection in adult fowls. As possible reasons for the inconsistency of the test, it is suggested that edema is likely to develop and persist for some time after injection even with the introduction of sterile water, the introduction of any foreign protein is likely to give the same results, and hematomes are very apt to develop after injection and interfere with the reading.

The experiments also indicated that a previous injection of the intradermal fluid caused at least 85 per cent of the birds retested to react to the agglutination test, regardless of their reaction in the original test.

Gapes in chickens, H. ATWOOD and C. A. LUEDER (West Virginia Sta. Circ. 30 (1919), pp. 4).—A brief summary of information on this affection, means for its prevention, and remedial measures. An outbreak of the affection at the station farm in 1900 and 1901 was eradicated through the practice of burning all chickens that died of the disease, and keeping the young chickens shut up until after the dew had dried off in the morning.

In a study made of recently hatched gape worms the junior author found them to be extremely susceptible to a very dilute solution of creolin or carbolic acid. A solution of 3 drops of creolin in a pint of water killed the newly hatched worms in from 30 to 60 seconds. This led to the conclusion that creolin added to the drinking water would serve as a remedy, since the medicated water would necessarily flush the surfaces to which the worms had just become attached and so kill them, and experiments were conducted that proved the correctness of this hypothesis.

Tuberculosis in farm poultry, W. W. DIMOCK and L. E. WILLEY (*Iowa Sta. Circ. 56* (1919), pp. 3-12, figs. 6).—A popular summary of information relative to tuberculosis in fowls.

It is pointed out that the disease is somewhat prevalent here and there among poultry flocks in the State of Iowa. Of 255 fowls examined at the pathological laboratory of the Iowa State College from July 1, 1912, to September 11, 1915, tuberculosis was the cause of sickness or death in 43. Of 227 fowls similarly examined between September 11, 1915, and June 1, 1918, 83 were affected with tuberculosis.

#### RURAL ENGINEERING.

Softening hard water with permutit, R. HULBERT (North Dakota Sta. Spec. Bul., 5 (1919), No. 9, pp. 193-208, figs. 3).—Continuing the series previously noted (E. S. R., 40, p. 588) tests of a small-sized permutit water softener on water from the city supply of Fargo, N. Dak., are reported.

"The plant consists of a hollow steel cylindrical shell, 9 in. in diameter by 5 ft. in height. The cylinder is closed at the top with removable, water-tight head, to operate under pressure. For these tests the softener was charged with 40 lbs. of new permutit mineral, resting on a 5-in. layer of coarse gravel. This charge is supported on a perforated steel plate some 6 in. above the bottom of the tank. Above the bed of permutit is placed an upper screen-plate holding a 5-in. layer of coarse, screened, washed marble, the purpose of which is to remove carbon dioxid from the raw water before it passes through the permutit. Supported on brackets at the right and on a level with the top of the cylinder is the brine tank holding about 10 gal., in which is prepared the salt solution for regenerating the permutit. A water meter is placed in the hard water intake pipe for controlling the rate of softening and backwashing, and to indicate the total volume of water passed through the plant in either of these operations. . .

"The zero water capacity of the permutit softener operated in these tests was five times its rated capacity, as stated by the manufacturers. This very considerable underrating, if carried out in commercial practice, should guaranty that this type of softener would always furnish at least its rated capacity of completely softened water even under adverse operating conditions, which in practice might result from (1) abnormal increases in the hardness of the raw water, (2) incomplete regeneration, (3) allowing the softener to exceed its specified maximum rate, or to exceed its rated capacity between regenerations through careless operation, and (4) any possible depreciation in the quantity of zeolite over a number of years.

"The permutit content of the softener is only about one-third completely exhausted when the filter has delivered its full capacity of zero water. Remembering that its full capacity in these tests was five times more than its rated capacity, it follows that in normal operation the zeolite is only slightly exhausted between regenerations. Permutit may be fully regenerated even from complete exhaustion. This requires, however, a disproportionately large volume of brine with a much higher concentration of salt, and a longer period of time than is feasible under practical operating conditions. A permutit installation will easily furnish double its rated capacity of zero water when operated intermittently, and without exhausting the zeolite beyond the point where it may be restored by a normal regeneration.

"Under any operating conditions the cost of salt for regeneration will not exceed 0.7 ct. per thousand gallons of soft water for each grain per gallon of hardness removed. Fargo city water can be softened completely by permutit at a total cost not exceeding 20 cts. per thousand gallons. This estimate includes all fixed and operating charges. The soap consuming power of Fargo tap water averages 12 lbs. per thousand gallons. This is equivalent to a money waste of about \$2.50 at the present price of soap."

Coal stove brooder and colony brooder house, W. F. SCHOPPE (*Montana Sta. Circ. 80 (1918)*, *pp. 33–46*, *figs. 7*).—This circular describes the construction and operation of the coal stove brooder and colony brooder house under Montana conditions.

"The principal advantage of the coal stove brooder is that a large number of chicks can be handled in one flock under one hover. . . .

"Experience for the past two years indicates that the heat can be better controlled with these coal brooders than with oil lamps. The source of heat is larger and consequently more uniform. The greatest difficulty arises from allowing the ashes to clog the fire-bed or to accumulate in the ash pit so as to cover the drafts and kill the fire. To overcome this the fire should be shaken down twice each day and the ashes removed. The temperature under the hover should vary with the age of the chicks. The brood should be started at about  $110^{\circ}$  F., gradually dropping this about  $10^{\circ}$  each week for the first four weeks. . . .

"Although the coal-stove brooders are constructed for the use of hard coal, soft coal can be used with equally satisfactory results, provided a little more care and attention are given the fire. Fine coal and very large lumps are to be avoided... On an average about 20 lbs. of soft coal a day will run the brooder during mild weather; in extremely cold weather it requires at least 30 lbs. of soft coal to operate for the 24 hours."

## RURAL ECONOMICS.

War prices and farm profits, H. C. TAYLOR and S. W. MENDUM (Wisconsin Sta. Bul. 300 (1919), pp. 18, figs. 10; Hoard's Dairyman, 57 (1919), No. 21, pp. 1052, 1053, figs. 6).—The discussion is based on records of 60 farms in Verona Township, Dane County, Wis., for the period of 1913–1917. This community is fairly typical of southern Wisconsin. Corn, oats, and hay are the staple crops, and dairy products, cattle, and hogs are the main sources of income.

In 1914 and 1915 the gross receipts and farm profits fell below the level of 1913. Farm receipts increased appreciably in 1916 and even more in 1917. "In both of these years the expenses increased, but not so rapidly as the income; hence, there was an increasing proportion of the gross income left for the farmers' profits or labor income."

It is shown that "the higher profits of 1916 were due in part to better crops but more largely to higher prices, and that the relatively high returns in 1917 must be attributed entirely to high prices, because the crops were poorer.... Even with such high prices as those of 1916 and 1917 the average labor income for the five years stands at \$408....

"On the average for the five years one out of every six farmers netted a loss ranging from \$20 to \$598, omitting what the family received from the farm... Yet... more than half the farmers made labor incomes which, when combined with what the farm furnished the family, put them in a position to get ahead financially year after year. The future of American agriculture demands that the road be kept open to the top.... Prices should be high enough to give at least five out of six a labor income."

The study is graphically illustrated, and tables are given showing a summary of the farm business over a period of five years, 1913–1917, and labor incomes arranged according to size of the 5-year average.

The cost of producing Minnesota field crops, 1913-1917, F. W. PECK (Minnesota Sta. Bul. 179 (1918), pp. 42, figs. 4).—This study follows the plan of one previously noted (E. S. R., 32, p. 688).

Among the principal results noted are that the average monthly cost of board for the period 1913–1917 at Halstad amounted to \$14.96 and at Cokato to \$16.02. The average wage rate per hour for labor hired by the month for 1913–1917 for the seven crop months (April to October) was 15.3 cts. at Halstad and 15.7 cts. at Cokato. This was an increase of 12 per cent over the previous 5-year period. The cost of labor was 21 per cent higher in 1917 than in 1912.

The 5-year average annual cost of maintaining a farm work horse at Halstad was \$110.50 and at Cokato \$113.36. In 1917 the cost was \$151.56 at Halstad and \$128 at Cokato. The average cost per hour was slightly more than 11 cts. in each locality. In 1917 the rate per hour was 17 cts. at Halstad and 13.6 cts. at Cokato. For the period 1913–1917 the average annual depreciation of machinery was 7.3 per cent for all machines.

By comparing the cost per acre for the 5-year period 1908–1912 with the cost during 1913–1917, it was found that there was an increase in cost of the principal crops, as follows: Wheat 40 per cent, oats 28, barley 31, corn 25, silage 16, tame hay 49, wild hay 19, and clover seed 15.

The report contains a number of statistical tables showing complete details.

Live stock and other factors for profitable farming in northern Kentucky, J. B. HUTSON (*Kentucky Sta. Circ. 21 (1918*), pp. 6-20).—Conclusions arrived at from a farm management study of 80 representative farms in Kenton County, Ky., in the summer of 1917, are set forth here. The average farmer's earnings for the 80 farms was \$871, and for the most profitable 10 farms, \$1,866. Comparisons are made between the averages for the 80 farms and for the most profitable 10 farms, in actual values and on a percentage basis, in matters of amount of live stock kept, production per cow (in pounds of milk), crop yields, and size of business.

Studies are also made of the relation of the above factors to the farmer's earnings, and it is shown that the quality and quantity of live stock kept and the size of the business very materially affect the income.

**Report of the State Land Settlement Board of the State of California, E.** MEAD ET AL. (*Rpt. State Land Settlement Bd. Cal., 1918, pp. 30, pls. 2*).—The commission appointed to administer the State land settlement act makes its first report of operations and expenditures.

Suggestions to the settler in California, T. F. HUNT ET AL. (*California Sta. Circ. 210 (1919), pp. 80, figs. 9*).—This circular contains statistics of the average, probable, and possible yields of important California crops, also general information regarding capital, land settlement, selection, and organization of farms, need of water, soil characteristics, marketing advantages, climate, and other features. It is similar to one previously noted (E. S. R., 32, p. 193).

Brief articles by specialists on the staff of the College of Agriculture on the production of certain typical crops and of meat, dairy products, poultry, and bees are included.

Experiences of northern Minnesota settlers, F. W. PECK (*Minnesota Sta. Bul. 180 (1918)*, *pp. 43, figs. 10*).—This bulletin is based on information gained by forest rangers from testimony of personal experience of settlers in northern Minnesota. One hundred forty-one records were taken and tabulated under the direction of the division of agronomy and farm management. The crop seasons reported on are those for 1914, 1915, 1916, and a few for 1917.

Part 1 includes a tabulation of detailed information, by counties, and number of farms surveyed, of township and range areas covered in each county, general

[Vol. 41

facts concerning settling on the land, cash required, crop statistics, live-stock statistics, total receipts per farm and distribution of income, and principal complaints of settlers. Part 2 contains maps of each county concerned and presents the records of individual farms that make up the averages presented in Part 1.

Some of the conclusions are that a soil survey and land utilization survey should be made, that small grain crops, potatoes, garden produce, and hay may be made profitable crops in this section, that a constructive program of State aid in clearing the land and draining it is necessary and would eliminate the settler's need of working away from his farm, that live stock, especially dairy stock, is a prime essential to a good income, and that it is desirable to develop the woods as an annual cash crop. Furthermore, real estate licenses under safe regulations should be adopted, and investigations as to cost and methods of clearing land, profitable marketing practices, types of farming, land colonization schemes, and like problems should become a part of the State's program of land reclamation and settlement.

First steps for bringing into use the idle lands of Oregon, T. T. MUNGER (Commonwcalth Rev., Univ. Oreg., 3 (1918), No. 3, pp. 52-62).—In this article the author urges careful classification of the cut-over lands and rough, hilly lands of Oregon as the first step in inducing colonization in that State.

[Agricultural phases of political economy], T. N. CARVER (In *Principles of Political Economy*. Boston and London: Ginn & Co., 1919, pp. 142–154, 208–220, 318–328, 409–417, 563–571, fig. 1).—The author includes in this examination of economic principles chapters on land, the genetic industries, marketing, the rent of land, and the single tax.

Scientific agriculture and the nation's food, [H. G. WELLS] (In *The Elements of Reconstruction. London: Nisbet & Co., Ltd., 1916, pp. 45–56*).—The author's point of view is that the State should function as a buyer and distributor of food, that a tariff must not be merely protective but subsidize the grower in the form of a bonus price at the expense of the community benefiting from a prosperous agriculture, and that nationalization of public services will spread and make effectual the scientific education.

Conservation and regulation in the United States during the world war, C. R. VAN HISE (Washington: U. S. Food Admin. [pt. 1] (1917), pp. 63; pt. 2 (1918), pp. VII+64-233).—Part 1 consists of an outline for a course of lectures to be given in higher educational institutions on the economic principles involved in conservation and Government regulation, the conditions antecedent to the world war, economic effects of the world war, measures taken for fruit production and conservation, and Federal regulatory legislation. Part 2 describes in detail the work accomplished under the various laws and boards. The outline was prepared for the U. S. Food Administration.

The food crisis and Americanism, W. STULL (*New York: The Macmillan Co.,* 1919, pp. VIII+135).—The author discusses the increase of farm mortgages, also school systems, organized labor, mills and elevators, methods of packers, and many others as factors in the food shortage and low farm profits.

The farmer's problem and the remedy, E. F. LADD (North Dakota Sta. Spec. Bul., 5 (1919), No. 8, pp. 177-190).—In this address before the Tri-State Grain Growers' Convention at Fargo, N. Dak., January 16, 1919, the author emphasizes the farmer's responsibility in matters of improved methods of production, grading, and marketing of products, also of cooperation and diversified agriculture for North Dakota.

The place of agriculture in industry, C. S. ORWIN (In Some Problems of Urban and Rural Industry. Oxford: Ruskin Col., 1917, pp. 60-75).—This paper is a part of the report on The Reorganization of Industry, Series II. The

points enlarged upon by the author are, first, that the nation, as a whole, must consider questions relating to the increase of home-grown food supply, and second, that a complete reorganization of the industry itself is necessary. He favors industrialization for large-scale production.

The position of the rural worker in industry, A. W. ASHBY (In Some Problems of Urban and Rural Industry. Oxford: Ruskin Col., 1917, pp. 76–97).— This paper appears in the series noted above. The author says here that the agricultural worker must be assured an adequate income and some leisure time. He discusses the disadvantages of small holdings, the rate of wages, competition of unskilled labor, housing, and related topics.

How the laborer lives: A study of the rural labor problem, B. S. ROWNTREE and M. KENDALL (London and New York: Thomas Nelson & Sons, Ltd., 1917, pp. 342, pl. 1).—This book, first published in 1913, showing that the agricultural wages then paid were below the efficiency minimum, is republished with the aim of showing that correspondingly the wage of 25s. (60.08) provided under the Corn Production Act of 1917 must prove inadequate. It contains a chapter on wages based on figures found in volume 5 of the Report on Earnings and Hours of Labor in 1907. In addition, it gives accounts of investigations and figures obtained by cross-questioning housewives in 42 rural families in counties of England and Wales regarding their household budgets, covering weekly money earnings, extra earnings, charitable gifts, rent, percentage of standard requirements of food consumed, etc.

The economic future of agriculture, V. A. MALCOLMSON (Jour. Farmers' Club [London], 1919, Apr., pp. 39–57).—A sliding scale of duties imposed on imported wheat and flour is advocated in this paper. It is suggested that import duties should begin to operate at the level of 60s. (\$14.60) a quarter, and that principles of empire preference be incorporated in the policy of taxation in the form of a 50 per cent rebate on importations from empire sources. There are included cost of production data in the form of several typical balance sheets giving the approximate cost of wheat per acre in 1913–14, and in 1917–18, also family budgets from the study noted above illustrating the cost of living of the agricultural laborer.

Farm tenancy and leases, A. H. BENTON (*Minnesota Sta. Bul. 178* (1918), pp. 33, figs. 2).—In this are discussed questions of the increase in farm tenancy in the United States and particularly in Minnesota, and of types of farm leases, namely, the one-third crop share lease, the one-half crop share lease, the crop and stock share lease, the one-third crop and stock share lease, and the cash lease. Suggested forms for several of these leases are given.

It is indicated here that data collected by the division of agronomy and farm management of the University of Minnesota, including that from a farm management survey previously noted (E. S. R., 39, p. 394), show that the advantages, both to the landlord and tenant, under the share lease system, are greater than under either the cash or mixed share and cash system.

Several tables are given to show the shares that landlord and tenant should bear in the cost of production of wheat, oats, barley, hay, and corn, and the cost of maintaining a dairy cow, and to indicate the landlord's and the tenant's expense under the one-half share system and the one-third share system. These tables are based upon recent data of the cost accounting section and results of investigations previously noted (E. S. R., 32, p. 688; 35, p. 691).

The function of the farm bureau, B. H. CROCHERON (*California Sta. Circ.* 209 (1919), pp. 16).—The speaker addresses the annual farm bureau conference on the beginning of the farm bureau organization in California, its functions, and its relationships with the farm advisor, members of the community, the U. S. Department of Agriculture, the agricultural college, and the experiment station.

The Federal Farm Loan System, G. E. PUTNAM (Amer. Econ. Rev., 9 (1919), No. 1, pp. 57-78).—In this article there are reviewed the establishment of the system, difficulties that required adjustment before any loans were made, difficulties encountered in matters of making loans, especially in the war crisis, and the position of joint stock land banks and proposed amendments pertaining to them. The author suggests that part of the system will need readjustment before American needs can be adequately met.

The Jewish Agricultural and Industrial Aid Society annual report for the year 1918 (*Jewish Agr. and Indus. Aid Soc. Ann. Rpt. 1918, pp. 49*).—This report continues information previously noted (E. S. R., 39, p. 89).

Remarks upon the function of agricultural cooperative associations in Egypt, S. B. HENEIN (*L'Egypte Contemporaine*, 10 (1919), No. 45, pp. 297–323).—This paper reports on cooperative associations operating in provinces of Egypt, describes their legal status, criticises them, and offers suggestions for their closer organization.

Reports on the working of the cooperative societies in the Punjab for the years ending July, 1916, 1917, and 1918 (*Rpt. Work Coop. Soc. Punjab*, 1916, pp. 9+14; 1917, pp. 10+19; 1918, pp. 12+15).—These reports continue the information previously noted (E. S. R., 34, p. 894).

Farmers' Market Bulletin (North Carolina Sta., Farmers' Market Bul., 6 (1919), No. 26, pp. 7).—In addition to the usual partial list of products which farmers have for sale, this number contains articles on the soy bean market and the demand for North Carolina corn.

Our sister Italy: Her agricultural production and her trade with France, B. RAMBAUD (Ann. Ecole Nat. Agr. Grignon, 6 (1915-16), pp. 75-138, figs. 8).— Part 1 of this article discusses the changes in Italian agriculture during the past 50 years, and contains comparative data on the production of the principal crops, together with a forecast with reference to the future of Italian agriculture. Part 2 covers the trade between France and Italy for a series of years, showing the principal products of exchange and comparing French and German methods in competing for Italian markets.

Agricultural statistics of Denmark (*Statis. Aarbog Danmark, 23* (1918), pp. XXIV+264+[4]).—This number continues the information previously noted (E. S. R., 39, p. 91), and adds statistics relating to land values taken in 1916 to serve as a basis for rental.

Annual report on reforms and progress in Chosen (Korea), 1916–17 (Ann. Rpt. Reforms and Prog. Chosen (Korea), 1916–17, pp. XIII+188, pls. 16).— This report adds later information to that previously noted (E. S. R., 39, p. 192).

## AGRICULTURAL EDUCATION.

Report of the development commissioners on their proceedings during the year ended March 31, 1918, R. F. CAVENDISH ET AL (*Rpt. Develop. Comrs.* [*Gt. Brit.*], 8 (1918), pp. [2]+16).—This is a report of the procedures of the development commissioners of Great Britain for the year 1917–18, which were in continuation of the policy adopted since the beginning of the war, as noted in the previous report (E. S. R., 38, p. 794). The total of recommended expenditures during the year for agriculture, rural industries, and forestry was \$876,948, including loans amounting to \$24,908. The sum total of advances recommended for these purposes up to March 31, 1918, was \$9,993,900, including loans amounting to \$1,394,995.

War work of women in colleges, I-II (*Washington: Committee Pub. Inform*, [U. S.], 1918, [pts. 1], pp. 11; 2, pp. 21).—The first of these publications gives a description of how the colleges for women met the war emergency, college war courses, student war activities, and the employment of college-trained women. The second contains supplementary information. It is not intended to be a "complete survey of the college war work of the country, but is a reportorial account of news which has been sent to The Division on Woman's War Work of the Committee on Public Information."

Report of the division of extension in agriculture and home economics, A. AGEE ET AL. (*New Jersey Stas. Rpt. 1917, pp. 211-309; N. J. Agr. Col. Ext. Bul., 1 (1917), No. 13, pp. 94*).—This is a report on the organization and progress of the extension activities in New Jersey for 1917, including farm and home demonstration work and boys' and girls' club work. Attention is called to the reorganization of the county boards of agriculture on a community basis, according to the plan originated last year, and their assumption of all local responsibility for farm demonstration work. A suggested constitution and program of work for county boards of agriculture are included.

The essential features of a cooperative plan adopted in the boys' and girls' club work between the State department of public instruction and the extension division of the agricultural college are outlined. It is provided that the extension division is to direct and supervise all project work from the agricultural and home economics point of view, and the department of public instruction is to have within its jurisdiction everything that pertains to the place that club work shall have in the schools. All projects are to be outlined by the extension division in cooperation with the county farm demonstrator and the county superintendent of schools.

Wisconsin wins: Annual report of the agricultural extension service for 1917–18, H. L. RUSSELL and K. L. HATCH (Wisconsin Sta. Bul. 301 (1919), pp. 24, figs. 19).—This is a brief report on the activities of the extension service in the 1917–18 food production campaign to achieve the production of more of the essential vegetable foods, an increase of the supply of fats and animal foods, a greater production of feed for animals and of food for man, and the bringing of more acres under cultivation through drainage, land clearing, and control of weeds, plant diseases, and insect pests.

Agricultural training for returned soldiers: Preparatory and field instruction, W. J. BLACK (*Agr. Gaz. Canada, 5 (1918), No. 12, pp. 1123–1126*).— An outline is given of a course of instruction, adopted by the Soldier Settlement Board of Canada, to enable men without experience who desire to farm to secure at least a general working knowledge of farming operations on training farms in Great Britain in the interval between the signing of peace and the return of the men to Canada.

Outline studies on the school garden, home garden, and vegetable growing projects, O. J. KERN (*California Sta.* [*Pub.*], 1919, pp. 64, figs. 32).—This is a reprint of part of the syllabi the author has worked out in his course for teachers on the elements of agricultural nature study and school and home gardening in the University of California.

Agricultural laboratory exercises and home projects adapted to secondary schools, H. J. WATERS and J. D. ELLIFF (Boston: Ginn & Co., 1919, pp. VI+218, figs. 160).—This manual contains outlines of 96 laboratory exercises dealing with plant life and growth, the soil and its management, field and orchard crops, insects and plant diseases and their control, breeds and types of farm animals, feeding farm animals, and farm equipment and machinery, together with outlines of five production projects and two soil, demonstration, and

improvement projects, respectively. The authors have endeavored to make the exercises and projects "cover as completely as is possible the important, interesting, and practical farm problems of the country... Each exercise and home project has been tried out." Tables showing digestible nutrients and fertilizing constitutents in common American foodstuffs, plant food contained in common fertilizers, feeding standards, and a suggested list of typical home projects are appended.

Manual for the teaching of agriculture, home economics, and manual training in the sixth grade, T. E. BROWNE (State Bd. Ed. [N. C.], Agr. Bul. 1 (1918), pp. 42, figs. 5).—Instructions are given for carrying out projects in Irish potato growing, poultry raising, tomato growing, and gardening, one of which the pupil is to select as his laboratory work. Of the possible 100 points, a weight of 70 is given to the production phase, and 30 points to each to the manual training and domestic science or cooking phase. This makes it possible for the boy to meet his 100 points by completing the production and manual training phases and for the girl by completing the production and cooking phases. A weight of 60 for the textbook work and 40 for the project is considered a fair distribution.

Manual for the teaching of agriculture, home economics, and manual training in the seventh grade, T. E. BROWNE (*State Bd. Ed. [N. C.], Agr. Bul.* 2 (1918), pp. 30, figs. 4).—This is the second of a series of bulletins to be issued in accordance with the requirements of the law of 1917. It gives directions for carrying out manual training, growing and cooking projects with corn, peanuts, and vegetables, and raising a pig.

Soils and crops, J. G. MOSIER (*Chicago: Rand, McNally & Co., 1919, pp.* VIII+412, figs. 179).—This text for schools includes a study of the factors of crop production and of the following crops, together with some of the underlying principles and practices involved in their improvement: Cereals, legumes, forage, fiber, tuber, root, and sugar crops, and broom corn, rape, and field beans. A study outline and problems, practice work, and references for supplementary reading follow each chapter. Tables giving the legal weights of seed per bushel and plant food requirements for crops are appended.

Botany for agricultural students, J. N. MARTIN (*New York: John Wiley & Sons, 1919, pp. X*+585, *figs.* 488).—This book is intended for elementary courses in botany, covering a year's work, in colleges and universities.

In its preparation the aim has been to present the fundamental principles of botany, with emphasis upon their practical application. The author holds that in an elementary course in botany, regardless of the education the student desires to obtain, the guiding aim of both recitation and laboratory work should be to give the student a notion of the fundamental principles of botany. A secondary aim should be to relate the subject to the student's major line of work.

The subject matter in this text consists of two parts, part 1 being devoted to the study of structures and functions, chiefly of flowering plants, relating them to such agricultural subjects as farm crops, forestry, and horticulture and to the more advanced courses in botany. Part 2 consists of a study of the kinds of plants, with emphasis upon their evolutionary relationships and their economic importance, and evolution, heredity, and plant breeding as related to the improvement of plants.

Farm horticulture, G. W. Hoop (New York: Lea & Febiger, 1919, pp. VI+339, figs. 142).—This book has been written primarily as an elementary text to meet the needs of the undergraduate collegiate students as well as those who are studying agriculture in the secondary agricultural schools. It

should also serve as a guide to the farmer and city man practicing horticulture about the home, as it treats the subject from the standpoint of production of horticultural products as well as improvements for the home. The following subjects are dealt with: Planning the home garden, the seed, hotbed and cold frame, cultivation and tillage, plant propagation, budding, grafting, and pruning, plant pests, spray machinery and materials, harvesting and marketing, the winter protection of plants, the strawberry, bush fruits, the brambles, the grape, pome fruits, stone fruits, citrus fruits, and beautifying the home grounds. Lists of shrubs which can be used as guides for the various geographical regions in this country are appended.

Productive sheep husbandry, W. C. CoFFEY (*Philadelphia and London: J. B. Lippincott Co., 1918, pp. X*+479, *pl. 1, figs. 262*).—This manual of sheep husbandry comprises seven parts dealing respectively with the history of sheep raising and breeding, structure and judging, breeds, the management of the flock, sheep feeding, sheep management on the ranges in the Western States and buildings and equipment for farm flocks, and preparing mutton on the farm.

Vocational agriculture in high schools. Animal husbandry series No. 1: Some suggestions as to the subject of dairy husbandry, T. H. EATON (*State Bd. Ed. Conn. Bul. 19* [1919], pp. 28).—This bulletin deals with the content, organization, and method of instruction in dairying in the high schools in Connecticut. The suggestions are designed for a treatment of dairy husbandry to make use of at least one-half of the total time given to the agricultural course for the year.

Trees, stars, and birds: A book of outdoor science, E. L. MOSELEY (Yonkerson-Hudson, N. Y.: World Book Co., 1919, pp. X+404, pls. 16, figs. 244).—This is a nature-study book written in language simple enough for students in the sixth or seventh grades.

Housewifery: A manual and textbook of practical housekeeping, L. R. BALDERSTON (Philadelphia: J. B. Lippincott Co., 1919, pp. [VII]+353, pl. 1, figs. 175).—This book is the outgrowth of many years of experience in housekeeping and in teaching housewifery to groups of practical housekeepers, with emphasis upon the technical processes of the home. Its purpose is to help the individual homewoman and to serve as a text for study groups of rural extension and other clubwomen and in the housekeepers' courses given by schools and colleges. Among the subjects discussed are housewifery as a business, plumbing, heating and lighting, equipment and labor-saving appliances, household supplies and furnishings, storage, cleaning and care of rooms, beds, bathroom, kitchen, and metals, cleaning and renovation, disinfectants and fumigants, and household pests. Each chapter is followed by references to helpful Suggestions for teachers with reference to methods of teaching, literature. including practice work, an outline of a course of lessons in housewifery as given in a regular high school with a practice department, and a more detailed outline of lessons for use in schools, settlements, or other special classes or in rural-extension work are included.

Industrial work for boys, A. E. PICKARD (St. Paul, Minn.: Webb Pub. Co., 1917, pp. 145, figs. 113).—This book includes, among others, chapters on home projects in woodwork; home credit for work in agriculture, including soil study, a miniature farm with suggestive rotations, germination tests, garden work, weed, insect, and wood collections, study of birds and rodents, study of machinery, stock and grain judging, apple-tree grafting, and strawberry raising; and contests and club work, including corn, potato, tomato, poultry, and pig contests, canning as club work, savings banks, keeping accounts, and an industrial exhibit. The work suggested has been done successfully for a number of years in the teachers' training department in the intermediate and upper grades and in the rural schools in Minnesota that were under the supervision of the author.

Industrial work for girls, A. E. PICKARD and M. C. HENEGREN (St. Paul, Minn.: Webb Pub. Co., 1916, pp. 145, figs. 62).—This book contains chapters on course and equipment, general industrial work, sewing in the rural school, principles of home science, the hot lunch, industrial club work, and home credit exercises. Practically all the exercises suggested have been successfully done in several rural associated schools, as well as in the grades and the teachers' training department at the central school under the supervision of the authors.

## MISCELLANEOUS.

**Report of Alaska Stations, 1917** (*Alaska Stas. Rpt. 1917, pp. 96, pls. 9*).— This contains the organization list and a report of the several lines of work carried on during the fiscal year ended June 30, 1917. Meteorological data and accounts of the extensive tests with field and garden crops and other lines of work are abstracted elsewhere in this issue.

Thirty-first Annual Report of Colorado Station, 1918 (*Colorado Sta. Rpt.* 1918, pp. 47).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1918, a report of the director on the work of the station, and departmental reports.

**Report of Kansas Station**, **1918** (*Kansas Sta. Rpt. 1918*, *pp. 63*, *figs. 5*).— This contains the organization list, a financial statement for the fiscal year ended June 30, 1918, and a report of the director summarizing the work and publications of the station. The experimental work recorded is for the most part abstracted elsewhere in this issue.

Thirtieth Annual Report of Massachusetts Station, 1917 (*Massachusetts Stat. Rpt. 1917, pts. 1–2, pp. IX*+63a+348, *pls. 11, figs. 5*).—This contains the organization list, reports of the director and heads of departments, a financial statement for the fiscal year ended June 30, 1917, and reprints of Bulletins 178–181, previously noted. The experimental work recorded is for the most part abstracted elsewhere in this issue.

Annual Report of New Jersey Stations, 1917 (*New Jersey Stas. Rpt. 1917*, *pp. XXVIII*+563, *pls. 14, figs. 10*).—This contains the organization list of the stations, a financial statement for the State Station for the fiscal year ended October 31, 1917, and for the College Station for the fiscal year ended June 30, 1917, a report by the director (E. S. R., 40, p. 198), and departmental reports. the experimental features of which are for the most part abstracted elsewhere in this issue.

Abstracts of papers not included in bulletins, finances, meteorology, index (*Maine Sta. Bul.* 275 (1918), pp. 227-244+XII).—This contains the organization list of the station; abstracts of three papers previously noted; meteorological observations noted on page 17; a financial statement for the fiscal year ended June 30, 1918; an index to Bulletins 269-275, inclusive, which collectively constitute the thirty-fourth report of the station; and announcements as to the work, publications, and equipment of the station.

Quarterly bulletin of the Michigan Experiment Station (Michigan Sta. Quart. Bul. 1 (1919), No. 3, pp. 147, figs. 16).—This contains the usual list of available bulleins and the following articles: Michigan Live Stock Improvement; Beef and Pork Production Prospects, by G. A. Brown; Use of the Overshot Stacker in Michigan, by A. B. Cook; The Future of the Horse Market, by

R. S. Hudson; Where Sheep Should be Raised, by V. A. Freeman; Pasture Crops for Swine, by W. E. J. Edwards; Spring Inoculation of Legumes, by C. Nobles; Vinegar Making and Its Troubles.-Vinegar Bees, by Z. Northrup; Pure Seed for Spring Sowing, by B. A. Hollister; Michigan Experiments on Bean Disease Control, by G. H. Coons; The Dairy Outlook, by A. C. Anderson; Roundworms of Swine, Ascarids, by W. L. Chandler; New Pests Which Have Established Themselves in the United States and for Which We Should be on the Lookout, by R. H. Pettit; Selecting the Tractor, and Multiple Hitches, both by H. H. Musselman; Stock Poisoning from Bad Silage, by W. Giltner; M. A. C. Exhibit at the 1918 Inernational; Pedigreed Oats, and Pedigreed Alfalfa Seed, both by F. A. Spragg; Does it Pay to Test Seed Corn? by C. R. Megee: Notes on Maple Sirup Making, and Planting Trees for Ornament and Profit, both by A. K. Chittenden; Progress in Blow Sand Control, by F. H. Sanford; Most Called-for Varieties of Apples, Horticultural Notes, and Small Peach Crop in 1918, all by H. J. Eustace; Culling the Poultry Flock, by C. H. Burgess; Commercial Fertilizers for 1919, by A. J. Patten; Phosphorus for Spring Crops, and Let Us Preserve our Muck Soils, both by M. M. McCool; and Sterility in Cattle as a Complication of Infectious Abortion, by E. T. Hallman.

Address of D. F. Houston, Secretary of Agriculture, before the Governors' Conference, Annapolis, Md., December 16, 1918 (U. S. Dept. Agr., Off. Scc. Circ. 133 (1919), pp. 15).—This deals with such matters as Federal and State cooperation, the need of clear thinking in agricultural matters, the Government and guarantied wheat prices, land and the returning soldiers, recent helpful legislation in agriculture, improving rural health, the functions of State departments of agriculture, etc.

Laws applicable to the United States Department of Agriculture, compiled by O. H. GATES (U. S. Dept. Agr., Off. Solicitor, 1917, 4. Sup., pp. 137).— This publication represents a revision of that previously noted (E. S. R., 33, p. 698), embracing legislation enacted from December 6, 1915, to September 8, 1916, inclusive.

# NOTES.

Maryland Station.—Dr. A. G. McCall has returned from service with the Army Educational Corps in France, and has resumed his duties in charge of soil investigations.

Mississippi Station.—The substation located at McNeill will henceforth be conducted in cooperation with the Bureau of Animal Industry of the U. S. Department of Agriculture. Special attention will be given to live stock, notably sheep and hogs, with reference to conditions in southern Mississippi. S. W. Greene of the Department has been appointed in charge of the substation.

The work formerly carried on at McNeill has been transferred to Poplarville, where E. B. Ferris, as assistant director in charge, is engaged in experiments with forage crops and fertilizers.

Missouri University and Station.—H. O. Allison, associate professor of animal husbandry and animal husbandman, has been appointed farm adviser for the Soil and Crop Improvement Association of Livingston County, Ill.

Montana College.—President James M. Hamilton resigned July 7, and has been succeeded by Alfred Atkinson, professor of agronomy and agronomist.

**Cornell University.**—The semi-centennial of the university was observed June 20 to 22, the elaborate ceremonies including the unveiling of a statue of the founder, Ezra Cornell.

A new chemistry building is to be built to cost about a million and a half dollars. The name of the donor has not yet been announced.

Tennessee University and Station.—It is announced that President H. A. Morgan is to continue as dean of the college of agriculture and director of the station. J. D. Hoskins, dean of the college of liberal arts, has been appointed assistant to the president; C. A. Willson, assistant dean of the college of agriculture; and C. A. Mooers, assistant director of the station.

A gift of \$25,000, by Miss Mary Boyce Temple, for conducting special agricultural tests by the division of agricultural extension, has been made public.

**Vermont University.**—President Guy Potter Benton, for some time educational director of the American Army of Occupation in Germany, has tendered his resignation as president of the university, effective July 1.

Washington College and Station.—J. P. Fairbank, assistant professor and acting head of the department of agricultural engineering, has been made professor and head of the department. E. H. Steffen of the Forest Service of the U. S. Department of Agriculture has been appointed associate professor and head of the department of forestry. Roy O. Westley, instructor in agriculture at the School of Agriculture at Crookston, Minn., has been appointed instructor in farm crops. Joseph Passonneau, assistant in the office of markets, has been appointed director of that office vice Asher Hobson resigned.

West Virginia Station.—The legislature has converted into a regular permanent grant the appropriation which two years ago was made as a special emergency fund on account of war conditions. In addition, \$30,000 has been granted for farm buildings, roads, fences, and other improvements at Morgantown, and \$15,000 for the special needs of the Reymann Memorial Farms. It is expected to proceed with the building of additional barns immediately and the furnishing of the additional equipment needed.

Director J. L. Coulter has returned from six months' service in Army educational work in Europe.

#### SUBJECT LIST OF ABSTRACTS.

#### AGRICULTURAL CHEMISTRY-AGROTECHNY.

The production and treatment of vegetable oils. Chalmers	110
Vegetable fats and oils. Andés, trans, by Salter	110
Gums and resins their occurrence, properties and uses. Parry	110
The natural organic coloring matters. Perkin and Everest	110
Chemical analyses of Logan blackberry (loganberry) juices. Hollingshead	111
The distribution of urease in the seeds of cereals. Němec	111
Agglutination, Buchanan	111
The oxidation of ammonia, Landis	111
Commercial oxidation of ammonia to nitric acid. Parsons	111
Manual of the chemical analysis of rocks. Washington	112
A new indicator for acids and bases. Chauvierre	112
The volumetric determination of sulphurous acid. Craig	112
Separation [and estimation] of formic, acetic, and lactic acids. Onodera	112
separation [and estimation] of terms, weeks, and weak with one detail	

<sup>1</sup> On leave of absence for military service,

Page.

	Page.
Sodium sulphite analyses, Van Heurn and Bertels	112
Estimation of cyanogen in ammonia liquor, Spielmann and Wood	113
Fat extraction apparatus, Griffiths-Jones	113
Acidimetric titration of grain extracts and amino acids, Birckner	113
Meat extracts, their composition and identification, Emery and Henley	113
New method for vanillin in vanilla extract, Dox and Plaisance	114
Evaluation of coconut and palm oils, Vizern and Guillot	115
Revision of copper phosphate method for sugar, Folin and Peck	115
Analysis of commercial saccharin, I–II, Richmond and Hill	115
Determination of the amylolytic power of saliva, Grimbert	115
Colorimetric determination of nonprotein nitrogen, Grigaut and Guérin	116
Determination of small quantities of urea in blood, Grigaut and Guérin	116
Procedure for the volumetric micro determination of lipoids, Bang	116
The micro determination of blood lipoids, Bang	116
The evaporation of vegetables, Cruess	116
The sun drying of vegetables, Howard	116
Sirup from sugar beets, Parsons	117
Utilization of Arum as food, for starch, alcohol, etc., Pantanelli	117
The preparation of xylose from corncobs, Monroe	117
Salvaging rain-damaged prunes, Cruess	117
Evaporators for prune dryisg, Cruess	117
Scientific production, classification, and manufacture of rubber, Van Pelt_	118

# EXPERIMENT STATION RECORD.

Vol. 41.

AUGUST, 1919.

No. 2.

Within the past few months there has been organized, developed, and brought to successful completion one of the most remarkable educational projects of years. This project was the establishment and operation of a comprehensive educational system for the American Expeditionary Forces in Europe. Of great interest to every American citizen, its achievements have been of special significance to educators, and in particular, because of the large place assigned to instruction in agriculture, to those associated with agricultural education.

The bulk of the actual instruction provided was given in the spring of 1919, but efforts to formulate an educational program began much earlier. Toward the close of 1917, or soon after American troops began arriving in force in Europe, studies were commenced by Dr. Anson Phelps Stokes, secretary of Yale University, working under the auspices of the American University Union, to ascertain the conditions and the need and desire for educational work on the part of the soldiers and their commanding officers. Dr. Stokes reported after several months' inquiries that there was a general desire for the promotion of educational opportunities, embracing common school studies, industrial and vocational work, agricultural education, and general university training, and with particular emphasis upon industrial, vocational, and agricultural lines.

In April, 1918, announcement was made of the sanction by General Pershing of a broad educational movement, sponsored by the Y. M. C. A. but eventually to constitute a Department of Education as a component part of the Army. The purpose of this project was set forth as not only to increase the efficiency of the men while engaged in war but at the same time to prepare them for vocational usefulness after the war.

Subsequently the Army Educational Commission of the Y. M. C. A. was appointed to organize the new undertaking. This commission consisted of Dr. John Erskine of Columbia University, chairman and in charge of general collegiate instruction; Mr. F. E. Spaulding, superintendent of schools in Cleveland, Ohio, in charge of general

101

education of sub-collegiate grade; and President K. L. Butterfield, of the Massachusetts Agricultural College, in charge of agricultural, vocational, and general technical education. A budget of fifteen million dollars was drawn up, of which several million dollars was estimated as needed for textbooks alone. Four-fifths of the funds were to be provided by the Y. M. C. A., and the remainder by the American Library Association.

The organization of so vast an enterprise at top speed in a foreign land and under war conditions has been aptly described as a veritable "adventure in education." It was not, however, entirely a pioneer undertaking. Quite early in the war a system of instruction had been developed, apparently somewhat informally, in one of the Canadian divisions in France, and known as the University of Vimy Ridge. The object was announced as to equip men in active service for "greater efficiency in business, agriculture, and other great industries of the Dominion." The instruction included lectures for large groups of men, class work with smaller groups, and individual instruction for advanced students.

Late in 1917 what was known as Khaki College was organized by the Canadian Expeditionary Forces farther back of the lines, on a somewhat more formal basis with a chancellor, a senate, and an executive faculty. One of the eight departments of instruction was agriculture, with lecturers, drawn mainly from the ranks, in animal husbandry, field husbandry, horticulture, farm bookkeeping, agricultural English, and poultry. A system of credit in Canadian institutions for work of college grade was arranged, and instruction through short practical courses was also provided at some twenty lecture centers in France and England. About five hundred thousand dollars was allotted by the Dominion Government for the maintenance of this work, supplemented by about an equal amount from the Y. M. C. A. From October, 1917, to July, 1918, about nine thousand men had been enrolled in the various departments.

Some attention had also been given to agricultural instruction in the British Army. In August, 1918, through the joint efforts of the Training Branch of the General Staff and the Directorate of Agricultural Production, the British Government located at Etrun, just outside the devastated area surrounding Arras, the First Army School of Agriculture. Here a farm of three hundred acres was fitted up, and demonstrations and other instruction provided through the winter to officers and men awaiting demobilization. This school was one of the first of a series of British educational enterprises.

The suspension of hostilities on November 11, 1918, altered the purposes and plans of the American educational system to some extent, but intensified the demand for instruction on a comprehensive basis

#### EDITORIAL.

during the many months before the return of the overseas men to this country could be completed. Efforts were accordingly increased to recruit from civil life the large administrative and supervisory force necessary and to provide the huge amount of textbooks, lectures, and illustrative material required. In this work educational institutions in this country heartily cooperated. For instance, nearly every agricultural college granted leaves of absence to one or more members of its instruction, research, or extension staffs and assisted in other ways. The Federal Department of Agriculture contributed, through the States Relations Service, a large amount of bibliographical material for use in preparing courses of study, as well as thousands of copies of Department publications, many of its lantern slides, sets of agricultural exhibits, and other matter.

Organization in Europe proceeded along the main lines originally projected. Special provisions were also made for embarkation points, leave areas, the occupied region of Germany, and other localities at which large groups of men were assembled.

The underlying purpose of the educational program was well set forth in the opening paragraph of a General Order of February 13, 1919, instituting the instruction: "The commander-in-chief invites the attention of the organization commanders and of all officers in the American Expeditionary Forces to the importance of national education. This citizen army must return to the United States prepared to take an active and intelligent part in the future progress of our country. Educational and occupational training should, therefore, be provided to meet the needs of the members of the American Expeditionary Forces in order that they may become better equipped for their future responsibility."

Provision was made for the detail of officers and men to participate in the instruction, and authorizing the Army Educational Commission of the Y. M. C. A. to assist in every way possible in the development of the educational system. On April 16, 1919, the Army assumed full responsibility for the enterprise, enrolling the commission and its workers as the Army Educational Corps. This action placed the project on a definite military basis, and greatly facilitated its rapid development.

The instruction afforded was of various grades, the intention being to meet the diverse needs of the Army as adequately as possible. The apex of the system was the A. E. F. University at Beaune. The bulk of the men, however, receiving instruction were of course enrolled for sub-collegiate instruction, chiefly at the many post and divisional schools. In addition numerous special agencies were developed. For instance, some of the most striking work in agriculture was done at the School of Agriculture at Allerey and the innumerable "farmers' institutes" and "farmers' clubs." It has been stated

#### 1919]

that there was probably not a single regiment among the hundreds of the American Expeditionary Forces which was not reached by some of these means.

Mention should also be made of the arrangements for advanced instruction at the leading institutions of learning of the nations associated with this country in the war. Opportunity was afforded for details from the Army for the spring term of 1919 of about two thousand students at English universities, while the number enrolled in France has been estimated at four thousand. Some of these students were in agriculture, though the proportion of these is understood to have been comparatively small.

In order to provide "college and technical training beyond that offered at divisional educational centers" there was established the A. E. F. University. This institution was located at Beaune, some twenty-five miles from Dijon and in the Cote-d'Or vineyard district of east central France. The site had been previously utilized as an American hospital center, so that a number of buildings were immediately available. An immense amount of additional construction was still necessary, however, at the beginning of active operations in March, 1919, much of which was carried on by the soldierstudents themselves. Ultimately approximately five hundred buildings were completed, mainly one-story structures of the barracks type 150 ft. long by 30 ft. wide, and some of the ready-made "quick erection" wooden type devised for general army use. One of the largest buildings was required for the library, this housing nearly five hundred thousand volumes supplied by the American Library Association, and comprising a surprising range of subjects and a wealth of bibliographical material.

The university was organized into fourteen colleges, including agriculture, fine and applied arts, business, vocations, education, engineering, correspondence, journalism, law, letters and science, medicine and chemistry, music, and citizenship. The combined faculty numbered approximately five hundred, and the student enrollment reached a maximum of nearly eight thousand.

The college of agriculture was among the largest and most completely organized in the institution. The courses of instruction were arranged under four departments, animal husbandry, agronomy, horticulture and forestry, and rural economics and sociology. These were further subdivided into about forty courses. The animal husbandry courses covered the feeding and breeding of animals, dairying, poultry husbandry, and animal hygiene, and those in agronomy included farm crops, soils, fertilizers, and farm machinery. There were seven courses in horticulture and forestry, dealing with forestry, vegetable gardening, orcharding, greenhouse man-

#### EDITORIAL.

agement, and floriculture. The courses in rural economics and sociology dealt with farm management, agricultural economics, rural organization and sociology, and comparative agriculture. There was also a general course in agriculture offered as an elective for students in other colleges of the university.

The college was headed by Dean Hayward of the Delaware College as director, with Capt. E. N. Wentworth, formerly of the Iowa and Kansas colleges, as assistant director. The faculty numbered about fifty, nearly all of whom were originally from the instruction and extension forces of the agricultural colleges. A partial list of its members shows sixteen of these institutions represented, and might easily have been mistaken a few years ago for a roster of the staff of the Graduate School of Agriculture.

The student body varied at different times, but reached a maximum enrollment of over fifteen hundred and was even more composite than the faculty. Former agricultural college seniors from the Middle West rubbed elbows with prospective freshmen from New England or the South, and a captain from the Pacific coast sometimes found himself under instruction in stock judging or fruit growing or rural sociology by a sergeant from New York or Pennsylvania. This diversity of training and experience complicated the arranging of courses, but greatly added to the interest and value of recitations, conferences, club work, etc.

A high school education or its equivalent, together with some farm or agricultural college experience, was required for admission to the college. In order to give an opportunity for advanced work, instruction in most subjects was divided into what were known as A, B, and C courses, corresponding to beginners', intermediate, and more advanced grades. Certain prerequisites were set up for enrollment in B and C courses, such as a minimum amount of chemistry for advanced soils work or of elementary genetics for some of the instruction in animal breeding.

In quality, the student body ranked notably high. The average age of the students was probably not very much greater than in most colleges, but they appeared considerably more mature and manifested a distinctive seriousness of purpose. Evidence of this is shown by the fact that in numerous instances where their military units were returned to this country during the spring students voluntarily elected to remain to complete their courses. It is stated that the mid-term reports showed less than twenty-five men in the entire college doing unsatisfactory work.

In a general way the instruction was given much as in the agricultural colleges at home. Perhaps the most serious handicap encountered was the absence of laboratories. Considerable equipment was available, however, in farm machinery, and French illustrative

#### 1919]

[Vol. 41

material as to live stock, horticulture, soils, and other lines was utilized as far as possible. Trips to farms, vineyards and gardens, cheese factories, and other rural enterprises were a distinctive and exceptionally valuable feature of the work. Opportunity was thus afford to observe at first hand the intensive farming and other special methods used in France. One trip of particular interest was to the district of La Perche, the home of the Percheron horse, and another to the grape-growing sections of Burgundy.

Closely coordinated with the college of agriculture was the university farm school at Allerey. This school was developed shortly after the opening of the university to provide instruction for soldiers who could not meet the college requirements for admission. It was located some fifteen miles from Beaune and, like the university, at the site of a former hospital center. Several hundred buildings, mostly of wooden construction, were hastily erected and instruction begun early in April.

The school faculty numbered about ninety, supplied in part by the American Educational Commission, but mainly by details from the Army. Supervision of its operations was vested in the college of agriculture, with Mr. H. J. Baker, director of extension work in Connecticut, as principal.

The instruction provided in the school was restricted to subjects dealing directly with agriculture and country life, except for a practical course in English. Animal husbandry, agronomy, horticulture, rural economics and sociology, and farm engineering comprised the principal courses. About half of the students were without previous farm experience, and a farm of about one hundred and fifty acres constituted an important asset of the school, providing two-hour practicums for each student in actual farm and garden practice.

No fewer than eight thousand applications were received for enrollment in the school. Accommodations were available, however, for only about three thousand students, making necessary a rigid selection of candidates.

It is estimated that from five thousand to ten thousand men received agricultural instruction in the post and divisional schools of the Army, and this number would doubtless have been considerably larger but for the inability to obtain sufficient instructors. These schools offered elementary courses of six to twelve weeks, usually enrolling from fifty to four hundred men each. They were held wherever available space could be obtained. In the occupied portion of Germany, abandoned agricultural schools were taken over in some instances and the surrounding land used for practical instruction. Live stock was sometimes secured for judging, and visits of observation to nearby farms were of frequent occurrence. Of the special forms of instruction developed by the educational forces particular mention should be made of the "farmers' institutes." These, as the name implies, represented an adaptation of the well known farmers' institutes of this country. This form of instruction was found to be peculiarly well suited to the conditions and was one of the first means to be employed.

Early in January farmers' institute teams were organized at several embarkation points, notably Bordeaux and Brest, and the campaign was subsequently extended throughout the forces. By April a corps of twenty-six specialists was at work from the American Educational Commission, supplemented by scores of speakers drawn from the Army. In the Bordeaux region alone a staff of thirty-five workers was recruited. The number of men reached was correspondingly large. For the month of May it is estimated that four hundred institutes were held of from one to three days each, with an aggregate attendance of at least one hundred and fifty thousand. Some of these were doubtless attracted to the sessions by way of diversion, but it is reported that many even of this class became greatly interested. For thousands it was their first contact with educational work in agriculture.

The special advantage of the institutes was of course their adaptability to a wide variety of conditions. Meetings were held at all hours of the day, even the mess hour. The aim was to deal with all phases of agriculture, but special emphasis was put on the relations of the returning farmer-soldier to his work and to the rural community, and these discussions like the other instruction in rural economics and sociology are reported to have made particular appeal.

Scarcely less noteworthy were the "farmers' clubs." More than five hundred of these clubs were organized throughout the forces, including units at the college and school of agriculture and with an estimated aggregate enrollment of fully twenty thousand men. In a single division a membership of one thousand three hundred is reported. These clubs provided convenient units for group study and for arranging institutes and observation trips, in addition to their marked educational and social value in drawing together men of greatly varied experience for this common purpose. In some cases these clubs were even continued on shipboard and in demobilization camps in this country.

Under the auspices of the farmers' club of the college of agriculture, a permanent organization has also been perfected called the American E. F. Farmers' Club, including a Committee on International Agriculture. Among other activities it is planned to establish this fall a periodical, to be known as *World Agriculture* and to be of interest to professional agricultural workers, farmers, and the gen-

130002°-19-2

eral public. It is announced that the cooperation of several men of world-wide reputation in agricultural leadership has already been

Early in May, 1919, the entire educational system was well under way, with arrangements perfected for an indefinite continuance and the extension of activities. So rapid, however, had been the withdrawal of the troops to this country that by June the situation was radically changed. The completion of the first term's work on June 7 marked the virtual close of the undertaking.

An interallied rural life conference, including a rural life pageant, was held at Beaune early in June and brought together a group of educators of international reputation for the discussion of agricultural problems. The addresses of these leaders constituted an impressive and appropriate termination of the work of the college and school of agriculture. Soon afterward the Army Educational Corps was disbanded, instructors and students alike were on their way homeward, and the A. E. F. University and its associated activities were added to the other memories of the war.

It is difficult to believe, however, that the results of this great project will be wholly ephemeral or unimportant. Leaving aside the great gain to the Nation in helping to keep up the morale of the troops through many long months of waiting, the mental stimulation afforded by instruction from a new corps of men in an unusual environment, and the great pedagogic value of the experiment to the Army and to educators generally, it would seem that the benefits to agriculture alone would have amply justified the enterprise. Who can estimate, for example, the number of men from agricultural colleges whose intentions to resume their education this fall have been thus crystallized into action? Or the much larger number previously unfamiliar with agriculture and its educational system whose interest has been aroused and whose whole life work has been redirected? Or the intangible but no less vital reaction upon the agricultural colleges themselves as instructors and students return from this novel undertaking?

By way of conclusion attention may be drawn, though perhaps needlessly, to one or two significant facts. The first is the tacit acceptance by all concerned of agricultural education as an integral component in this elaborate educational program. Since at least twenty-five per cent of the American Expeditionary Forces were from farm homes this may not seem surprising, yet it may be seriously questioned whether the same prominence would have been so readily conceded a generation ago.

In any case, it seems certain that nothing like the same success would have been secured under the conditions then prevailing. With-

assured.

#### EDITORIAL.

out the substantial body of agricultural knowledge acquired by the slow but fundamental labors of the experiment stations, the U. S. Department of Agriculture, and other research agencies; the development of strong faculties and sound pedagogic methods in the colleges of agriculture and associated institutions of learning; and the training and experience of a vast corps of extension workers, county agents, and others in man-to-man instruction of a type readily adaptable to the emergency conditions, the accomplishments in agricultural education overseas would necessarily have been seriously retarded and restricted. As in our food production campaign, it was primarily because these institutions had been developed and strengthened year after year that agricultural education was ready when the call came, and was able to play so worthy a part in this great enterprise.

# **RECENT WORK IN AGRICULTURAL SCIENCE.**

## AGRICULTURAL CHEMISTRY-AGROTECHNY.

The production and treatment of vegetable oils, T. W. CHALMERS (London: Constable & Company Ltd., 1918, pp. XI+152, pls. 9, figs. 97).—This volume deals with the production and treatment of vegetable oils, primarily from the engineer's point of view. The material presented includes descriptions with accompanying plates and diagrams of machinery for the various stages in the production of oils, and chapters on the refining of oils, the hydrogenation of oils, the generation of hydrogen, soap making, the recovery and refining of glycerin, and the splitting of oils.

In the chapter on extraction of oils by chemical solvents the relative merits of the pressure and solvent extraction processes are discussed, with reference particularly to the value of the resulting residue as a cattle feeding stuff and as a fertilizer. The author is of the opinion that with modern methods the earlier objections to the solvent process as yielding both cake and oils unfit for consumption are unfounded, and that the residue from the solvent extraction process can be used to better advantage than the press-cake as a fertilizer and, with proper control of the amount of oil left in the residue, equally well as a feeding stuff.

Vegetable fats and oils, L. E. ANDÉS, trans. by C. SALTER (London: Scott, Greenwood & Son, 1917, 3. ed., rev. and enl., pp. XI+351, figs. 93).—In the third English edition of this book, the preceding edition of which has been previously noted (E. S. R., 25, p. 801), the subject matter has been revised and enlarged by H. B. Stocks to include modern methods for the extraction and purification of vegetable fats and oils.

Gums and resins, their occurrence, properties, and uses, E. J. PAREY (London: Sir Isaac Pitman & Sons, Ltd., 1918, pp. VI+106, pl. 1, figs. 6).—This is a reference handbook on the occurrence, properties including analytical constants, and uses of the more important true resins, gum resins, true gums, balsams, and medicinal resins.

The natural organic coloring matters, A. G. PERKIN and A. E. EVEREST (London and New York: Longmans, Green & Co., 1918, pp. XXII+655; rev. in Analyst, 44 (1919), No. 516, pp. 119, 120).—This volume of the series of monographs on industrial chemistry edited by E. Thorpe deals with the properties of the natural coloring matters, including a discussion of the facts which have led to a determination of their constitutions. The history of the employment of natural dyestuffs is traced in an introductory chapter. In the succeeding chapters the natural dyestuffs are grouped according to the constitution, where known, of their main tinctorial constituents. Where members of two widely distinct groups are present in the same plant, the description of the plant is given under the heading which from its present or past uses appears the more suitable.

An appendix contains lists from various sources of Indian natural dyestuffs, natural dyes of the Philippines, British plants capable of dyeing mordanted wool, and leaves and flowers of wild and cultivated British plants capable of dyeing aluminum-mordanted cotton.

Chemical analyses of Logan blackberry (loganberry) juices, R. S. HOL-LINGSHEAD (U. S. Dept. Agr. Bul. 773 (1919), pp. 12).—The uses of the loganberry, the manufacture of the juice for commercial purposes, and the results of a number of analyses are reported.

It is pointed out that because of its pleasant flavor, loganberry juice is popular as a beverage, while the berry is also used for making jams, jellies, and for soda fountain service. The juice is naturally so sour that it is considered necessary to dilute and sweeten it when used as a beverage, since the addition of sufficient sugar to mask the acid makes the product too sirupy to drink unless diluted. "The flavor and color of Logan blackberry juice permit a dilution with from 2 to 3 parts of water, and the addition of 1 part of sugar. As a rule, the sirups prepared for soda-fountain use are made by adding sugar to undiluted juices, the composition running from about 1 part of juice and 1 part of sugar to, roughly, 3 parts of juice and 1 part of sugar."

In discussing the analyses it is stated that the Washington and Oregon juices differ considerably from those from California-grown berries.

Tentative limits are proposed for Washington and Oregon-grown juice of minimum and maximum nonsugar solids of 2.8 and 3.92 per cent, ash 0.25 and 0.43 per cent, and acids, as citric, of 1.42 and 2.33 per cent. For California juice the corresponding limits suggested are 3.06 and 3.74 per cent for nonsugar solids, 0.43 and 0.63 per cent for ash, and 1.06 and 1.96 per cent for acids, as citric.

The distribution of urease in the seeds of cereals, A. NĚMEC (Biochem. Ztschr., 91 (1918), No. 1-2, pp. 126-130).—Analytical data are given to prove the presence of the enzym urease in grains such as wheat, rye, barley, and oats, and the connection between the presence of urease and proteins yielding arginin on hydrolysis is pointed out.

Agglutination, R. E. BUCHANAN (Jour. Bact., 4 (1919), No. 2, pp. 73-105, figs. 3).—In this address delivered before the Society of American Bacteriologists, December 27, 1918, the author discusses bacterial agglutination as essentially a colloidal phenomenon that can best be studied in the light of the modern work on colloidal and physical chemistry. An extensive list of literature references is appended.

The oxidation of ammonia, W. S. LANDIS (*Chem. and Metallurg. Engin., 20* (1919), No. 9, pp. 470-477, figs. 5).—A résumé is given of the early investigations on the commercial oxidation of ammonia, followed by a discussion of the development of the cyanamid process as adopted in the Government nitrate plant at Muscle Shoals, Ala.

Commercial oxidation of ammonia to nitric acid, C. L. PARSONS (Jour. Indus. and Engin. Chem., 11 (1919), No. 6, pp. 541-552, figs. 13).—This paper deals with past and present methods and apparatus for the oxidation of ammonia to nitric oxid for the production of nitric acid, including references to the method noted above. In particular the development of the U. S. Bureau of Mines converter is discussed, and tables are given showing its efficiency. The principle of the converter is the catalytic action of four cylindrical superimposed layers of platinum gauze so arranged inside the fire-brick lining of the converter that the inside surface is always reflecting against another red hot surface, no outside heat being required except that generated by the reaction itself. The results obtained in 160 determinations indicate that a 92 per cent efficiency with 10.5 per cent ammonia and with 200 cu. ft. per minute capacity can be easily reached with this converter, In conclusion the author discusses certain factors influencing the yield in all forms of apparatus using platinum as a catalytic agent for the oxidation of ammonia.

Manual of the chemical analysis of rocks, H. S. WASHINGTON (New York: John Wiley & Sons, Inc., 1919, S. ed., rev. and enl., pp. XII+271, pl. 1).—For the third edition of this manual (E. S. R., 16, p. 638), the subject matter has been thoroughly revised and considerably enlarged by introducing some changes in details of procedure, including new methods, treating in much greater detail the methods previously described and placing more stress on the sources of error both in operations and in methods.

A new indicator for acids and bases, M. CHAUVIERRE (Bul. Soc. Chim. France, 4. ser., 25 (1919), No. 3, pp. 118, 119).—A filtered aqueous extract of red beets is said to be a very sensitive indicator for acids and bases. The extract, which is a violet-red, opalescent liquid, retains its color in the presence of acids and turns a deep yellow in the presence of alkalis. Test paper can not be prepared from it as the color is not taken up by the paper.

The volumetric determination of sulphurous acid, T. J. I. CRAIG (Jour. Soc. Chem. Indus., 38 (1919), No. 8, p. 96T).—The method described consists in treating a water solution of the sulphurous acid, sulphite, or bisulphite to be tested with a known excess of acidified hydrogen peroxid and determining the residual hydrogen peroxid by titration with N/2 potassium permanganate.

A method for the separation [and estimation] of formic, acetic, and lactic acids, I. ONODERA (Ber. Ohara Inst. Landw. Forsch., 1 (1917), No. 2, pp. 231-259; abs. in Jour. Chem. Soc. [London], 114 (1918), No. 674, II, pp. 461, 462).— The literature on the separation of the volatile fatty acids and lactic acid from mixed solutions is reviewed, and a new method is described which is said to be more satisfactory than previous methods and to lend itself equally well to the separation of the three acids from the fermentation products of organic fertilizers and to the determination of lactic acid alone.

The essential features of the method are as follows:

An aqueous solution of the sample is extracted with ether, neutralized with alkali, acidified with phosphoric acid, and distilled with steam. The distillate is conducted into alkali, partially evaporated in a vacuum, and neutralized with sulphuric acid. The resulting sample is divided into three portions, each of which is oxidized with alkaline potassium permanganate. In one portion the excess of permanganate is, titrated with sodium thiosulphate, the amount of permanganate used determining the formic and lactic acids together. In another portion the lactic acid alone is determined by precipitation of the oxalic acid formed from it on oxidation as calcium oxalate. Acetic acid is estimated in the third oxidized portion by extracting the ether, diluting the extracted acid to 100 cc., and distilling the solution until 95 cc. of distillate has collected.

Sodium sulphite analyses, F. C. VAN HEURN and W. BERTELS (Arch. Rubbercult. Nederland. Indië, 3 (1919), No. 1, pp. 16; Meded. Alg. Proefstat. Alg. Ver. Rubberplanters Oostkust Sumatra, Rubber Ser., No. 16 (1919), pp. 10).—The results are reported of analyses of 19 samples of sodium sulphite used as an anticoagulant for rubber latex. The analyses included the reaction on phenolphthalein and content of sodium sulphate, sodium sulphite, and inclosed water and dirt. The methods employed have been noted from a previous communication (E. S. R., 39, p. 413).

The purest of the samples of crystallized sodium sulphite tested averaged 40 per cent of pure sulphite (theoretical 50 per cent), while the best sample of the anhydrous salt contained only 80 per cent sodium sulphite (theoretical 100 per cent). The necessity for control of the material sold as pure sodium sulphite is pointed out.

Estimation of cyanogen compounds in concentrated ammonia liquor, P. E. SPIELMANN and H. WOOD (*Jour. Soc. Chem. Indus.*, 38 (1919), No. 4, pp. 43T-45T).—The basis of the scheme of analysis outlined is (1) the conversion of the ammonium thiocyanate into ferric thiocyanate and measurement in a tintometer of the depth of color obtained, and (2) the interaction of a further quantity of the original liquid with ammonium polysulphid, which converts the ammonium cyanid originally present into ammonium thiocyanate, and the estimation of the total ammonium thiocyanate as ferric thiocyanate. The difference between the results obtained in (1) and (2) is a measure of the quantity of cyanid originally present.

The method is described in detail, including the preparation of standard colors and the use of the Lovibond tintometer.

Fat extraction apparatus, E. GRIFFITHS-JONES (Analyst, 44 (1919), No. 515, pp. 45-47, fig. 1).—The apparatus, which was designed for use when the ordinary Soxhlet apparatus is not available, consists of an ordinary vertical condenser, the lower end of which passes through two corks, the upper one to serve as a connection for the extraction flask and the lower one for the reception of the extraction thimble. A side tube passes just through the upper cork, upward and parallel with the condenser, and then down the condenser tube to approximately the level of the water intake. The material to be extracted is placed in an ordinary extraction thimble covered with a plug of cotton wool and fitted over the lower cork. The condenser is then connected with an extraction flask containing the solvent and the extraction carried out over an electrically heated sand bath.

The extraction is said to be more rapid than with the ordinary type of Soxhlet and to require less of the solvent.

Acidimetric titration of grain extracts and amino acids in the presence of alcohol, V. BIRCKNER (Jour. Biol. Chem., 38 (1919), No. 2, pp. 245-254, figs. 2).— A study at the Bureau of Chemistry, U. S. Department of Agriculture, of the cause of the change in acidity of grain extracts on the addition of alcohol led to the conclusion that the increased acidity noted is due to the fact that amino acids, which in aqueous solution are nearly neutral to phenolphthalein, react distinctly acid in the presence of alcohol. It is pointed out that this fact should be taken into account when making acidimetric titrations in alcoholic liquids containing amino compounds, such as various animal or vegetable extracts.

Meat extracts, their composition and identification, J. A. EMERY and R. R. HENLEY (Jour. Agr. Research [U. S.], 17 (1919), No. 1, pp. 1–17).—This investigation was conducted at the Bureau of Animal Industry, U. S. Department of Agriculture, to obtain information regarding differences in composition of meat extracts prepared from muscle tissue, livers, spleens, hearts, cured-meat cook water, roast-beef soak water, and bones, all of which materials have been used in recent years in the commercial manufacture of beef-extract.

The extracts used in the investigation were prepared in the meat extract department of a large commercial establishment according to the method ordinarily used, and also in the laboratory on a smaller scale but as far as possible in the same way. The extracts prepared in the laboratory were identical in physical appearance and organoleptic properties with those obtained by the commercial process. The methods employed in the analysis of the extracts were essentially those of Street et al. previously noted (E. S. R., 20, p. 959).

The quantitative results, which are presented in tabular form, show the following characteristic differences depending upon the nature of the extract:

"Liver extracts are low both in total nitrogen and 'meat-base' nitrogen,

1919]

have a low inorganic phosphorus to total phosphorus ratio, are very low in total creatinin, and as a rule are very high in nonnitrogenous organic matter.

"Spleen extracts are high in total nitrogen, low in 'meat-base' nitrogen, very low in creatinin, and lower than other extracts, liver excepted, in the inorganic-phosphorus to total-phosphorus ratio.

"Heart extracts are low in total nitrogen as compared with chuck and plate extracts, but much higher than liver. They contain considerable nonnitrogenous organic matter, being next to liver extracts in this respect. Heart extracts differ from liver and spleen extracts in total creatinin and in 'meatbase' nitrogen, the latter comprising at least 50 per cent of the total nitrogen in heart extracts.

"Pickle and cured-meat extracts are readily identified by the invariable presence of nitrates.... The quantity of total phosphorus present in such extracts is very small. In other respects cured-meat extracts are found to resemble true-meat extracts. Pickle extracts contain rather less creatinin than true-meat extracts.

"Chuck and plate extracts run high in total nitrogen, 'meat-base' nitrogen, and total creatinin and have a high inorganic-phosphorus to total-phosphorus ratio.

"The bone extracts prepared commercially and the extract prepared from roast-beef soak water resemble chuck and plate extracts."

Marked differences were also noted in the physical properties of color, texture, and "shortness," (an extract being termed "short" when it breaks quickly and easily upon testing its elasticity). Liver extracts are very dark brown, forming a red solution with a trace of fluorescence, and are gummy. Spleen and bone extracts are light chocolate or yellow-brown and are very "short." The other extracts are lighter than the liver extract but darker than the spleen extract and are usually very "short." Their solutions are dark but are not fluorescent.

In addition to the quantitative differences qualitative differences have been noted and made the basis of tests for the identification of liver and spleen extracts either when pure or in the absence of any considerable proportions of true meat extracts. These include an acetic-acid test suggested by R. M. Chapin for distinguishing spleen extract by the bulky yellowish-white precipitate formed; the Molisch test, which indicates the presence of liver extract; and the copper test, applied to the ash, a positive result indicating liver extract. The presence of copper is also indicated by the greenish tint of the ash.

It is stated in conclusion that complete identification of an extract can be made by the following determinations: Total solids, ash, sodium chlorid, total  $P_2O_5$  inorganic  $P_2O_5$ , total nitrogen, "meat-base" nitrogen, preformed creatinin, creatin, Molisch test, acetic-acid test, test for starch and sugar if the Molisch test is positive, test for nitrates, and test of ash for copper.

A new method for the determination of vanillin in vanilla extract, A. W. Dox and G. P. PLAISANCE (*Amer. Jour. Pharm.*, 91 (1919), No. 3, pp. 167-170).— The authors at the Iowa Experiment Station have applied the methods previously noted (E. S. R., 36, p. 318) for the determination of furfural to the determination of vanillin in vanilla extract.

Thiobarbituric acid in the presence of 12 per cent hydrochloric acid was found to give with vanillin a vermillion-colored precipitate. The method is not applicable to artificial extracts containing caramel as a coloring matter. Caramel is said to be easily detected by the brown precipitate formed on addition of phloroglucinol to the clarified extract containing 12 per cent hydrochloric acid. The use of lead acetate as a clarifying agent was found not to interfere with the determination.

114

Evaluation of coconut and palm oils, VIZERN and GUILLOT (Ann. Chim. Analyt., 2. ser., 1 (1919), No. 4, pp. 117-119).—The authors point out that it is irrational to calculate the acidity of coconut and palm oils in terms of oleic acid, and suggest that the evaluation of the acidity of these oils should be made on the basis of the mean molecular weights of their acids, 208 for coconut oil and 222 for palm oil.

A revision of the copper phosphate method for the titration of sugar, O. FOLIN and E. C. PECK (*Jour. Biol. Chem.*, 38 (1919), No. 2, pp. 287–291).—On account of divergent results obtained in the copper phosphate method of Folin and McEllroy (E. S. R., 38, p. 614) for determining sugar, due to variations introduced by different individuals in the manner of preparing the salt mixtures, the exact technique for preparing the mixture in order to obtain concordant results is described. This involves first mixing the phosphate and thiocyanate thoroughly in a mortar until the thiocyanate has abstracted enough water from the phosphate to give a solution, to which the sodium carbonate is then gradually added.

A slight modification of the method is described which is said to eliminate the small loss of copper due to reduction by the thiocyanate. This is accomplished by adding 1 cc. of saturated sodium carbonate to 5 cc. of the copper sulphate solution before adding the salt mixture (4 or 5 gm.). This requires the use of a 5.9 per cent solution of copper sulphate in place of the 6 per cent solution previously employed.

A few observations of value in connection with the titration are given, including certain time restrictions. The modification described is said to be applicable also to the determination of lactose in milk.

Analysis of commercial saccharin, I-II, H. D. RICHMOND and C. A. HILL (Jour. Soc. Chem. Indus., 37 (1918), No. 14, pp. 246T-249T; 38 (1919), No. 2, pp. 8T-10T).—Two papers are given.

I. The estimation of o-benzoylsulphonimid from the ammonia produced by acid hydrolysis.—The methods commonly employed for estimating commercial saccharin are discussed, and a method developed as the result of a study of the defects of the present methods is described, the technique of which is as follows:

Ten cc. of 7.5 N NaOH is boiled for 2 minutes with 0.6104 gm. of saccharin. Fifteen cc. of 10 N HCl is then added and the solution boiled for 50 minutes under a reflux condenser. After the heating is completed, 75 cc. of cold water is added and a current of air passed through the upper part of the flask to remove any acid vapor. Fifteen cc. of 7.5 N NaOH is added carefully and the ammonia distilled into an absorption flask, in which is placed 20 cc. of N/5 HCl. After about 70 cc. is distilled, the solution is titrated with N/10 alkali, using methyl red as indicator.

The method is said to be rapid, convenient, and accurate.

II. The detection and estimation of impurities.—A discussion is given of the tests in use for determining the impurities of most common occurrence in saccharin, including moisture, mineral matter, *p*-sulphonaminobenzoic acid, *o*-sulphonaminobenzoic acid, *o*-toluenesulphonamid, lead and arsenic, melting point, ammonia, easily carbonizable organic matter, sweetness, and the French Codex identification test.

Determination of the amylolytic power of saliva, L. GRIMBERT (Jour. Pharm. et Chim., 7. ser., 19 (1919), No. 8, pp. 244-250; Compt. Rend. Soc. Biol. [Paris], 82' (1919), No. 9, pp. 312-315).—The author recommends a standardization of the experimental conditions to be observed in determining the amylolytic power of saliva in order that results obtained may have a comparative value, and outlines the proposed technique.

1919]

Colorimetric determination of the nonprotein nitrogen of the blood by Nessler's reagent, A. GRIGAUT and F. GUÉRIN (*Compt. Rend. Soc. Biol.* [*Paris*], 81 (1918), No. 22, pp. 1139-1142).—The method employed is essentially that of Folin and Denis (E. S. R., 36, p. 316). Trichloracetic acid is used in place of metaphosphoric acid as the protein precipitant. The preparation of the reagents employed is described in detail.

A precise method for the determination of small quantities of urea in blood, A. GRIGAUT and F. GUÉRIN (*Compt. Rend. Soc. Biol.* [*Paris*], 82 (1919), *No. 1, pp.* 25–27).—The process described is one of direct nesslerization, but is said to differ from that of Folin and Denis (E. S. R., 36, p. 317) by a more energetic action of the urease, a more simple and rapid process of clarification, and the use of a more concentrated Nessler's reagent. The urease preparation consists of a suspension of 1 gm. soy bean flour and 0.4 gm. acid sodium phosphate in 100 cc. of distilled water. Trichloracetic acid is used as the precipitating agent. The reagents are prepared as described in the article noted above.

**Procedure for the volumetric micro determination of lipoids, I.** BANG (*Biochem. Ztschr., 91 (1918), No. 1-2, pp. 86-103).*—A method of determining fats and other lipoids is described which depends upon the fact that such substances reduce chromic acid quantitatively. The excess chromic acid is determined by titration with thiosulphate after addition of potassium iodid. The paper discusses with accompanying data the application of the method to the determination of fats and soaps, cholesterins, cholesterin esters, and phosphatids.

To determine cholesterin in the presence of fat, use is made of the fact that on the addition of a digitonin solution cholesterin digitonid is formed, which is insoluble in petroleum ether and can be separated from the fat which remains in solution. Cholesterin esters can be separated from neutral fats or phosphatids through the greater resistance of the former to hydrolysis and the insolubility in petroleum ether of the soaps formed by the hydrolysis of the fats. A similar method is used to separate cholesterin esters from phosphatids.

The micro determination of blood lipoids, I. BANG (*Biochem. Ztschr.*, 91 (1918), No. 3-4, pp. 235-256).—This paper discusses in detail the application of the method noted above to the determination of the blood lipoids, including neutral fats, cholesterin, cholesterin esters, and phosphatids. The method is said to give very accurate results for total lipoids, neutral fat, and cholesterin, but not so exact results for cholesterin esters, and phosphatids.

The evaporation of vegetables, W. V. CRUESS (Mo. Bul. Cal. State Com. Hort., 8 (1919), No. 3, pp. 93-100, figs. 8).—This is a general article on the subject, including a discussion of the advantages and disadvantages of evaporated vegetables; descriptions of types of evaporators for industrial production, for community operation, and for home use; and directions for the preparation of vegetables for evaporation, temperature and air control during the process, and packing and storing of the dried vegetables.

The sun drying of vegetables, G. L. C. HOWARD (Fruit Expt. Sta. Quetta [India] Bul. 8 (1918), pp. 20, fig. 1).—This bulletin, which presents the results of an investigation of methods for the sun drying of vegetables in the arid climate of Quetta, India, contains information of general interest in connection with the dehydration of vegetables. The main principles of successful drying are considered to be rapidity of drying, and treatment of the fresh material by some form of heat, upon which depends the toughness or tenderness of the resulting product.

General directions are given for the preparation of the material, for the heating processes of steeping, scalding, or steaming, for drying, and for storage and transportation of the dried product. Compression of the dried vegetables into bricks is recommended in the case of the more bulky vegetables and a simple hand press for the purpose is described and illustrated.

Special directions are given for the drying of French beans, cabbage, eggplant, carrots, peas, kohl-rabi, onions, potatoes, spinach, tomatoes, turnips, and several native vegetables. General and special directions are included for cooking the dried products. It is emphasized that all the vegetables, even those which are ordinarily fried, must be boiled after soaking.

Sirup from sugar beets, T. S. PARSONS (Wyo. Farm Bul., 8 (1918), No. 5, pp. 67, 68).—It is stated that a satisfactory sirup can be made on a small scale by boiling thinly sliced sugar beets for four hours in sufficient water to cover, to which has been added one tablespoonful of white wine vinegar for each beet. The liquid is then strained off and evaporated to a sirup. It is estimated that 10 sugar beets will make sirup equivalent in sweetening power to 1 lb. of sugar. In Scotland the beet sirup is used quite extensively in jam making. The fruit is added to the liquid after straining and the mixture boiled down until the required consistency of the jam is reached.

Utilization of Arum as a food and for the manufacture of starch, glucose, and alcohol, E. PANTANELLI (Staz. Sper. Agr. Ital., 51 (1918), No. 1-2, pp. 69-82, pl. 1).—The possibility is suggested of utilizing the rhizomes of Arum maculatum and A. italicum, two species of Arum growing wild in Italy, as a food for man and for domestic animals, or as a commercial source of starch. From laboratory tests it was estimated that a yield of 20 per cent starch, 20 per cent glucose, or 11 per cent ethyl alcohol could be obtained on a commercial scale.

The preparation of xylose from corncobs, K. P. MONROE (*Jour. Amer. Chem.* Soc., 41 (1919), No. 6, pp. 1002, 1003).—The method of preparing xylose from corncobs, as described by Hudson and Harding (E. S. R., 40, p. 17), has been improved by removing the adhesive gum by digestion with dilute alkali at 100° C. The residue yields on acid hydrolysis from 8 to 10 per cent of crystalline xylose of a quality superior to that obtained by the previous methods. The technique of the method is described in detail.

Salvaging rain-damaged prunes, W. V. CRUESS (*California Sta. Circ. 212* (1919), pp. 11, figs. 3).—The purpose of this circular is to call attention to the damage to the California prune crop by the September rains of 1918, which destroyed at least 50 per cent of the value of the prune crop, causing a loss of probably not less than \$5,000,000, and to offer suggestions for avoiding such a loss in the future.

Sulphuring the fruit on the trays for two or three hours, using hoods similar to thee one described by Bioletti (E. S. R., 41, p. 15), was found to check the mold and yeast growth which caused most of the damage, and to make it possible to dry the fruit without artificial heat. Fruit dried in this way is said to be of a lighter color than fruit dried in the usual way but to be salable and of excellent flavor.

Investigations of the utilization of damaged fruit for alcohol, vinegar, and sirup manufacture, and for hog feed are reported which indicate that in no case would the returns be very large. Good results were obtained in the use of damaged prunes in hog feed, provided no more than 15 per cent was incorporated in the feed.

Evaporators for prune drying, W. V. CRUESS (*California Sta. Circ. 213* (1919), pp. 30, figs. 18).—This circular gives the results of a study of the principal evaporators in California, with a view to their more extended use in supplementing sun drying during such emergencies as noted above. Better

results are said to be obtained with the evaporators than with sulphuring, although the initial cost of an evaporator is much greater. It is pointed out, however, that the initial cost of an evaporator is only a fraction of the loss during one rainy season such as that of 1918.

A short discussion is given of the theory of evaporation and general principles and defects of some present evaporators, followed by detailed descriptions with specifications of the Oregon tunnel evaporator, an air-blast evaporator for wooden trays, and the small Young stack evaporator. General descriptions are given of the kiln evaporator, Watsonville stack evaporator, and the Anderson tunnel evaporator.

Attention is called to the necessity in designing an evaporator of making provision for sufficient heat production and radiating surface, good air circulation, and control of temperature. For the small dry-yard, the Young type of small stack evaporator is recommended, and for the average-size yard, the Oregon tunnel evaporator. Where wooden trays are to be used the airblast evaporator is considered best.

Scientific methods in the production, classification, and manufacture of rubber, G. VAN PELT, (Inst. Colon. Marseille, Bul. Caoutchoucs, No. 1, (1919), pp. 51).—This bulletin discusses the principal operations connected with the exploitation of rubber from the production to the manufactured objects, with a view to introducing a more scientific control of the various processes. As a means to this end, the author recommends the establishment of laboratories on the plantations, the collaboration of the scientific staff of the plantation with the special laboratories, both nonofficial and official, in the producing countries, the establishment of scientific standards for estimating the value of rubber, the creation of a scientific organization for the study of questions applying to the rubber industry, and the collaboration of this organization with the technical service of the rubber factories.

#### METEOROLOGY.

Relation between vegetative and frostless periods, J. B. KINCER (U. S. Mo. Weather Rev., 47 (1919), No. 2, pp. 106-110, pls. 8, figs. 5).—The relation between the frostless period and the length of the period during which the mean daily temperature is  $43^{\circ}$  F. or above is discussed on the basis of a series of eight charts showing (1) the average dates in spring when the daily mean temperature rises to  $43^{\circ}$ , (2) the dates in autumn when it falls below that value, (3) the average number of days when the mean daily temperature is  $43^{\circ}$ or higher in different sections of the country, (4) the normal mean daily temperature on the average date of the last killing frost in spring for all regular Weather Bureau stations in the United States, (5) similar data for fall frosts, (6) and (7) the average number of days in spring and fall, respectively, by which the potential growing season is shortened by frost, and (8) the total number of days that the average frostless season is shorter than the vegetative period.

It is shown that the advent of the vegetative period in the average year ranges from February 1 in the northern part of the Gulf States to May 1 in extreme upper Michigan and northern New England, and that this period comes to an end, on the average, about the middle of October in the extreme northern districts, but continues till the end of the year in the South. The length of the period ranges from less than 180 days in the extreme north and in the central and northern portions of the Rocky Mountain region, to 365 days in the South Atlantic and Gulf districts, and also in the central and southern Pacific coast sections.

[Vol. 41

The normal daily march of temperature is closely allied with the annual march in establishing the vegetative period. In most of the country the average frost-free date in spring corresponds to a mean daily temperature of from 52 to 66°, except along the central and north Pacific coast, the region of the Great Lakes, and along the middle and north Atlantic seaboard, where the temperatures are lower. Similar data for fall frosts are in close agreement with those for spring frosts. In limited areas, however, the first fall frost occurs on the average while the mean daily temperature is a degree or two higher than is necessary to cause a cessation in spring frosts in an average year. "Considering the records for all stations throughout the country the mean daily temperature on the average date of the last killing frost in spring is  $52.1^\circ$ , and on the average date of the first in fall it is  $52.6^\circ$ ... Owing to the fact that these temperatures corresponding to the average frost dates are so uniform, it is possible to determine very closely the average frost dates from the mean daily temperatures...

"The only locality in which the frostless season is longer than the vegetative period is comprised in a small area along the north Pacific coast. In most of Washington, portions of upper Michigan and much of Minnesota, as well as along the north Atlantic seaboard, killing frost shortens the vegetative period by less than 20 days, but in much of the central portion of the country the difference in the two periods ranges from 40 to 60 days. From Virginia, Kentucky, Missouri, and Oklahoma southward this difference increases rapidly from 60 to more than 100 days in the northern portions of the Gulf States. Southward from the upper Mississippi Valley to southern Arkansas the difference increases from 20 to 100 days, or from less than one to more than three months."

Increase of precipitation with altitude, A. J. HENRY (U. S. Mo. Weather Rev., 47 (1919), No. 1, pp. 33-41, figs. 2).—Reviewing observations bearing upon this subject in different parts of the world, the author concludes that "the main features of the precipitation-altitude relation are essentially as follows:

"The trend of the mountains must be in such a direction as to cause an ascent of the air masses which encounter them. Mountain systems whose axes are parallel, or nearly so, with the direction of the rain winds cause little or no increase in precipitation.

"The inclination of the slope of the mountain is of great importance; the steeper the slope, other things being equal, the greater the precipitation. The quantity of rain or snow which falls anywhere is also conditioned upon the initial temperature and relative humidity of the air at the beginning of the ascent. Obviously, it also depends, in no small degree, upon the duration of the winds from the rain quarter, or, in other words, upon the rate of movements of the atmospheric disturbance with which the rain winds are associated.

"The altitude of the zone of maximum precipitation appears to vary slightly with latitude, being lowest in the Tropics—a little less than 1,000 meters—and highest in temperate latitudes, say, between 1,400 meters and 1,500 meters. It has also a seasonal variation, being highest in summer and lowest in winter."

The rainfall of France: Variations with altitude, E. MATHIAS (Compt. Rend. Acad. Sci. [Paris], 168 (1919), Nos. 2, pp. 105-108; 4, pp. 239-242; 7, pp. 358-360, fig. 1; abs. in Rev. Sci. [Paris], 57 (1919), No. 2, pp. 61, 62; U. S. Mo. Weather Rev., 47 (1919), No. 1, p. 41).—The author concludes from observations at different places and altitudes that "the precipitation-altitude relation in France may be expressed closely with the formula,  $R=R_1+kA-k'A^2$ , in which R represents the rainfall in millimeters at altitude A (in meters),  $R_1$  the rainfall at a lowland station, k the coefficient of increase with altitude, and k' A<sup>2</sup> a

[Vol. 41

term to take care of the decrease of rainfall above a certain elevation. For

the Puy du Dome, and probably for the rest of France, k' is 1/20,000; thus, the formula becomes,  $R=R_1+kA-\frac{1}{2}$   $(A/100)^2$ ."

On a map of France the author shows the values of k for each Department. " k varies uniformly with latitude, ranging from 0.5 in the Pyrenees (latitude 43°) to 1.2 in the north (latitude 50°)."

The rainfall may vary widely with the position and altitude of the rain gauge on a given parallel of latitude, but if the gauges are sufficiently numerous the algebraic sum of the variations is zero.

Urban v. suburban temperatures, J. W. REDWAY (U. S. Mo. Weather Rev., 47 (1919), No. 1, pp. 28, 29).—Reviewing briefly records made at Battery Park, New York City, and Mount Vernon, N. Y., the author reaches the general conclusion that "suburban days are somewhat warmer and suburban nights are somewhat cooler than urban days and nights." He agrees with Kimball's view that "the blanket of moisture, smoke, and dust over a city tends to prevent radiation of heat at night, and during the day arrests much of the heat which reaches the suburban station."

Classification of clouds (U. S. Dept. Agr., Weather Bur. [1919], pp. [15], pls. 12).—This is a series of colored plates with brief explanatory matter to aid observers in the identification of the several cloud forms, namely, cirrus, cirrostratus, cirro-cumulus, alto-cumulus, alto-stratus, strato-cumulus, nimbus, cumulus, cumulo-nimbus, stratus, fracto-stratus, and fracto-cumulus, according to the international system of classification. A table of measurements of heights of clouds at different places, namely, Potsdam 1896–97, Blue Hill 1890–91 and 1896–97, Toronto 1896–97, Washington 1896–97, Allahabad (India) 1896–97, and Manila 1896–97, is also given.

Monthly Weather Review (U. S. Mo. Weather Rev., 47 (1919), Nos. 1, pp. 64, pls. 17, figs. 19; 2, pp. 65–142, pls. 17, figs. 33).—In addition to weather forecasts, river and flood observations, halo phenomena, and seismological reports for January and February, 1919; lists of additions to the Weather Bureau Library and of recent papers on meteorology and seismology; notes on the weather of the months; solar and sky radiation measurements at Washington, D. C., during January and February, 1919; condensed climatological summaries; and the usual climatological tables and charts, these numbers contain the following articles:

No. 1.—Work of the Smithsonian Astrophysical Observatory at Calama, Chile, by C. G. Abbot; Terrestrial Weather and Solar Activities, by C. F. Marvin; Influence of the Solar Eclipse of June 8, 1918, upon Radiation and Other Meteorological Elements (illus.), by H. H. Kimball and S. P. Fergusson; Proposed Magnetic and Allied Observations During the Total Solar Eclipse of May 29, 1919, by L. A. Bauer; Simultaneous Occurrences of Lunar Halos and Coronas, by C. F. Brooks; Lunar Halo and Paraselenic Circle Observed at Colony, Wyo.; Notes on the Comparison of Anemometers Under Open-air Conditions, by A. N. Shaw; Southern California Windstorm of November 24-26, 1918 (illus.), by F. A. Carpenter; The Terrific Windstorm on Mount Wilson, Cal., November 24-26, 1918 (illus.), by W. P. Hoge; A New Altitude Record (reprinted); Urban v. Suburban Temperatures, by J. W. Redway (see above); Evaporation in the Canal Zone (illus.), by H. G. Cornthwaite; Evaporation Compared With Vapor Pressure Deficit and Wind Velocity (illus.), by E. S. Johnston; Increase of Precipitation with Altitude (illus.), by A. J. Henry (see p. 119); Altitude Relations of Rainfall in France, by E. Pettersson; Notes on the Fluctuations of Mean Sea Level in Relation to Variations in Barometric Pressure, by T. B. Franklin (abs.); The Effect of Wind on Sea Level (extract); An Instrument for Accurate and Kapid Density Measurements on Board Ship, by A. L. Thuras (abs.); An Electrical Instrument for Recording Sea Water Salinity, by E. E. Weibel and A. L. Thuras (abs.); William Allingham (reprinted); Captain Melville Willis Campbell Hepworth (reprinted); Relation between Vegetative and Frostless Periods (ilus.), by J. B. Kincer (see p. 118); and Weather Control of the Periodical Cicada, by W. E. Hurd.

Climatological data for the United States by sections (U. S. Dept. Agr., Weather Bur. Climat. Data, 6 (1919), Nos. 1, pp. 211, pls. 4, figs. 2; 2, pp. 211, pls. 4, figs. 2).—These volumes contain brief summaries and detailed tabular statements of climatological data for each State for January and February, 1919, respectively.

General classification of meteorological literature, C. F. BROOKS (U. S. Mo. Weather Rev., 47 (1919), No. 1, pp. 42, 43).—A general classification designed to furnish a logical, simple, and easily remembered system for filing notes, pamphlets, and references is given.

#### SOILS-FERTILIZERS.

Studies in the reversibility of the colloidal condition of soils, A. B. BEAU-MONT (New York Cornell Sta. Mem. 21 (1919), pp. 479-524).—Investigations with artificially prepared colloids, including colloidal silica, alumina, and ferric oxids, and humus, together with Dunkirk and Clyde surface soils and Dunkirk and Vergennes subsoils are described in an effort "to throw some light on the physical changes, and their effects, which a soil undergoes with variations in its moisture content, especially on being wetted and dried. ... It has resolved itself into a study of the reversibility of the colloidal condition of soils." The reversibility of the colloidal state of soils is believed to include "all cases brought about by physical, chemical, and biological agencies or a combination of these," and is represented as follows:

Noncolloidal state 
$$\rightleftharpoons$$
 Collodial state  $\begin{cases} Sol \\ \uparrow \\ Gel \end{cases}$ 

Evidence bearing on the occurrence of various colloidal materials in the soil is presented, and investigations dealing with the effect of moisture changes on soil properties are reviewed. Most of these studies are said to deal with soil properties other than colloidal, and with methods other than those employed in colloid chemistry. The results of a rather critical study of different methods for measuring colloidality and of certain difficulties encountered in attempting to apply various methods are also presented and the details of the methods finally developed for use in these investigations described. The methods comprise a modification of Mitscherlich's water-vapor-adsorption method (E. S. R., 17, p. 838), a modification of Ashley's dye-adsorption method,<sup>r</sup> and the so-called suspension method.

Observations were made on the effect of drying upon the adsorption of dyes by artificial preparations of the principal colloidal materials found in the soil; the effect of different factors on hygroscopicity in the soils studied by the water-vapor-adsorption method including time, remoistening, the permanency of the effect of drying, alternate wetting and drying, drying at high temperatures, long immersion in water, and leaching; the adsorption of various dyes by differently treated soils; the amount of Clyde soil subjected to different moisture treatments remaining in suspension in distilled water and in 4 per cent ammonia 30 minutes after shaking; the effect of alternate wetting and drying on the amount of humus extracted from a Clyde soil; the relative intensities of water extracts of Dunkirk and Clyde surface soils; and the chemical nature of soil colloids. The results of the experimental work may be summarized as follows:

The adsorption of water vapor was not materially affected by variations of from 5 to 10° between 15 and 40° C. The chemical composition of certain soil-forming minerals affected the adsorption of dyes, acid dyes as a rule being more strongly adsorbed by basic minerals than were basic dyes, while the latter were more strongly adsorbed by acid minerals. Diamin sky-blue, one of the few dyes strongly adsorbed by colloidal ferric oxid, was adsorbed the most strongly of all those examined. It was also adsorbed by alumina, but not by silica. An alga and a fungus adsorbed considerable amounts of the dyes used, indicating that the growth of lower forms of plant life in the soil affects its adsorptive capacity. Both air-dried and oven-dried colloidal silica, alumina, ferric oxid, and humus, immersed in dye solutions, showed a reversal of their capacity to adsorb dyes, and also adsorbed water vapor rapidly.

The difference in hygroscopicity between a moist and an air-dried soil was found to persist for three months at least, while remoistening air-dried soils to a moisture content above that originally held did not cause a reversal of hygroscopicity immediately nor within three months. The alternate wetting and drying of soils did not affect the hygroscopicity after the first drying. Subsoils that had been wetted and dried 32 times showed a significant cumulative decrease in hygroscopicity. Hygroscopicity decreased successively with airdrying, oven-drying, and ignition, the change from the moist to the air-dry condition producing a greater change than that from the air-dry to the ovendry, while the change from the oven-dry to the ignited condition was greater than from the air-dry to the oven-dry condition. Some ignited soils had comparatively high hygroscopic values. Long immersion under water increased the hygroscopicity of a soil poor in organic matter, and decreased it in one rich in organic matter. Leaching a soil increased its capacity for adsorbing water vapor.

Oven-drying and ignition reduced the adsorption of methylene blue. Clyde soil, rich in organic matter, showed less effect due to drying than did the other soils, this being contrary to the results secured with water-vapor-adsorption.

<sup>1</sup> U. S. Geol. Survey Bul. 388 (1909) pp. 1-65.

122
Effects of air-drying and alternate wetting and drying were so irregular, as measured by dye adsorption, as to be deemed inconclusive. The immersion of a soil in water for 2 years increased its adsorptive capacity for methylene blue. Leaching a soil also increased its adsorption of methylene blue. Less diamin sky-blue was adsorbed than of methylene blue. Ignition decreased the adsorption of this dye.

Drying decreased the amount of soil that would go into suspension in distilled water and in 4 per cent ammonium hydroxid. Drying 32 times as compared with one drying decreased the amount of suspended matter.

Extractions of humus with 4 per cent ammonium hydroxid showed no effect on humus due to drying, while extractions with distilled water showed an increase in the solubility of the coloring matter of humus due to drying.

Oven-drying soils previous to their standing in an excess of water increased the amount of iron soluble in weak hydrochloric acid, while sterilization checked the formation of this easily soluble colloidal material.

The water-vapor-adsorption method is deemed better than the dye-adsorption method for measuring the total surface of soils. Finally, it is concluded that "drying a surface soil once produces as much effect on the colloidal material as repeated dryings alternated with moistenings. With a subsoil there is a cumulative effect due to alternate drying and wetting. Drying a soil once or many times produces a change in the colloidal material from which it does not immediately recover on being wetted. Drying soil affects indirectly the reversibility of its colloidal condition, the changes being directly produced through biological and chemical action."

A bibliography of 58 titles is appended.

H-ion concentration—soil type—common potato scab, L. J. GILLESPIE and L. A. HURST (Soil Sci., 6 (1918), No. 3, pp. 219–236, figs. 3).—In this paper, a contribution from the Bureau of Plant Industry, U. S. Department of Agriculture, the authors describe observations made on a number of soil samples representing both Caribou and Washburn loam from northern Maine. These are held to indicate that an excellent correlation exists between the H-ion concentration of the soil and the occurrence of common scab (actinomycosis) of potatoes, soils having an H-ion exponent of as low as 5.2 being found to rarely produce scabby potatoes. Similar results were also secured with a few soils of different origin and type. The limiting zone of the H-ion exponent for the potato scab organism appeared to be approximately the same for soil as for culture media as previously determined (E. S. R., 40, p. 644).

The characteristic difference of the H-ion exponent found to exist between the Caribou and Washburn loams in earlier experiments (E. S. R., 38, p. 620) has been confirmed, typical Caribou loam having an H-ion exponent of about 4.8 and being free from scab, while Washburn loam was generally less acid and usually produced scabby potatoes. It is stated, further, that a considerable number of soils having the exponent 5 may be successfully grown to potatoes and truck crops without liming. This indicates that exponent 7 (representing physico-chemical neutrality) can scarcely be regarded in general as the socalled rational end-point in lime requirement tests, no such standard end-point being deemed justified without further experimental work with specific crops.

Satisfactory methods of determining the H-ion concentration of soils both colorimetrically and electrometrically are also described. The results secured in applying the two methods to a large number of soils are said to have agreed within the limits of experimental error.

A list of 23 titles comprising the literature cited is appended.

130002°-19-3

Variability in soils and its significance to past and future soil investigations.—II, Variations in nitrogen and carbon in field soils and their relation to the accuracy of field trials, D. D. WAYNICK and L. T. SHARP (Univ. Cal. Pubs. Agr. Sci., 4 (1919), No. 5, pp. 120–139, pl. 1).—In a further contribution to the subject (E. S. R., 39, p. 815) the authors present data showing the amount of variation found in total nitrogen and total carbon in silty clay loam soil at Davis and in blow sand at Oakley (Cal.). The total area sampled at each point was a little more than 1.3 acres, the fields being selected for their apparent uniformity. Altogether 100 soil samples were taken from each area, 80 samples being distributed uniformly at 30-ft. intervals over the entire area, 40 samples at 15-ft. intervals in 5 different parts of the field, and 12 samples taken within an area of approximately  $\frac{1}{45}$  acre in the center of the field. Statistical methods have been applied to the interpretation of the data secured, and the limits of accuracy of the method employed in the nitrogen determinations are discussed at some length. The results obtained may be summarized as follows:

The extreme range for nitrogen in the Davis soil was from 0.077 to 0.124 per cent, and in the Oakley soil from 0.022 to 0.063 per cent, while for carbon the determinations varied from 0.903 to 1.383 per cent in the Davis soil, and from 0.252 to 0.947 per cent in the Oakley soil, indicating that results secured with one or a few samples would probably be unreliable. A study of the relation of soil samples taken from small areas and at short distances apart to those from a larger area and to the whole number of samples taken is held to indicte that "it is unwise to attempt to apply the statistical constants calculated for one area to other areas even though in themselves apparently uniform, since the respective variabilities may be very different." When the variations in the area to be sampled are known, the making of a composite sample is deemed to be fully justified. The relation of variations in a small area to differences between soil types is discussed, and the conclusion reached that only after very careful sampling can such differences be determined with certainty. The advantages of estimating the number of soil samples necessary to secure any given degree of accuracy are indicated.

[Report of] soil investigations (North Dakota Sta. Rpt. 1917, pp. 15, 16).— Extraction with ammonium sulphate solution and with plain distilled water of both the surface and subsurface 6 in. of limed and unlimed soil grown to wheat continuously for about 40 years, and of a virgin sod resulted in the removal of varying amounts of soluble materials from the differently cropped soils by means of the ammonium sulphate solution. A greater amount of soluble calcium was removed from the virgin soil than from the wheat soil, while the amount of soluble magnesium was practically the same for both soils by extraction with ammonium sulphate but greater by aqueous extraction from the wheat soil. There appeared to be little, if any, difference between the two soils in the amount of soluble iron and aluminum.

With the addition of lime to these soils an increase in soluble calcium and a decrease in soluble iron and aluminum was observed. The amount of soluble magnesium increased slightly in all cases, but the proportion of this ingredient to soluble calcium was much less in all the limed samples. Aqueous extracts of the limed soils showed a much smaller content of soluble calcium and magnesium for the virgin soil than for the wheat soil.

These results are held to indicate that continuous cropping to wheat has caused a loss of calcium carbonate in this soil, and that the proportion of soluble magnesium to soluble calcium has undergone a change. No definite results have thus far been secured regarding soluble iron and aluminum.

Azofication, J. E. GREAVES (Soil Sci., 6 (1918), No. 3, pp. 163-217, figs. 2).--This paper, a contribution from the Utah Experiment Station, comprises a comprehensive review of the literature dealing with nonsymbiotic nitrogen fixation in the soil. Briefly tracing early studies concerning nitrogen fixation by soil organisms, the author then deals with the distribution and food requirements of the azofiers; the reaction of the media; the effect upon azofication of volatile and nonvolatile antiseptics, organic soil constituents, colloids, manure, water, temperature, light and other rays, aeration, season, crop, and climate; sources of energy for Azotobacter; metabolism and 'pigment production in Azotobacter; morphology of the nitrogen-fixing organisms; the relation of Azotobacter to other organisms and to nitrate accumulations; the action of azofiers on plant food; soil inoculation; and soil gains in nitrogen.

A bibliography of 211 titles is appended.

Studies on nitrification in natural soils and its importance from an ecological point of view, H. HESSELMAN (Meddel. Stat. Skogsförsöksanst., No. 13-14 (1916-17), pt. 1, pp. 297-528, XXXIII-LVIII, figs. 30).—This paper, in addition to a lengthy discussion of the investigation already noted from another source (E. S. R., 40, p. 418), embraces a detailed presentation of the experimental results obtained, together with a bibliography of 87 titles.

The effect of regeneration measures on the formation of nitrates in the soil and its importance in the regeneration of coniferous forests, H. HESSELMAN (Meddel. Stat. Skogsförsöksanst., No. 13-14 (1916-17), pt. 2, pp. 923-1076, XCI-CXXVI, figs. 48).—The author describes investigations having to do with nitrification in forest soils and with the effect upon nitrification of measures usually employed in the care of the forest. The more important results secured in coniferous forests may be summarized as follows:

Little or no nitrification was observed to occur in the humus covering of mossy coniferous forests, the organic nitrogen present not being transformed beyond ammonia, even in the best and most productive forests. Fellings which permitted a strong access of light exerted a marked influence on the transformation of nitrogen. Where the humus covering was rather thin and loose, being composed chiefly of mosses and fallen needles, felling sometimes resulted in an active transformation of humus nitrogen into nitrate, said to be due, among other things, to a radical alteration in the bacterial flora of the humus covering. An active transformation of humus nitrogen appeared to take place in raw humus but without nitrate formation.

The covering vegetation was thought to be an index to the nature of the nitrogen changes taking place, nitrification being indicated by the presence of the raspberry, *Epilobium angustifolium*, *Arenaria trinervia*, *Galeopsis bifida*, *Senecio silvaticus*, *Rumex acetodella*, etc., while *Aira flexuosa* predominated where nitrification was lacking. Thorough mixing of the humus with the mineral soil and decaying brushwood and timber and burning over the area resulted in the formation of nitrates even in markedly raw humus. It is stated that a close correlation appeared to exist between nitrification and the regenerative possibilities of the soil. Raw humus solls without nitrification were found to be difficult of regeneration. Experiments and observations in the field are held to indicate that young pine trees develop to better advantage in the presence of nitrification than without it, as is also thought to be the case with spruce.

In herbaceous spruce forests nitrification was usually observed, and felling resulted in such an increase of nitrates that nitratophilous vegetation became troublesome to the coniferous plants. In such instances the spruce developed in the small areas which did not lend themselves to any very marked development of the covering vegetation, and it was often found necessary to check the growth of this vegetation, the competition of which would otherwise prove fatal to the tree plants. A bibliography of 51 titles is appended. See also a previous note (E. S. R., 40, p. 418).

The solubility of the soil potash in various salt solutions, D. K. TRESSLEE (Soil Sci., 6 (1918), No. 3, pp. 237-257, figs. 2).—This paper, a thesis submitted to the faculty of the Graduate School of Cornell University, describes investigations in which a study was made of the effect upon the solubility of the potash contained in several soils of allowing them to remain in contact with various salt solutions of different concentrations until the systems reached Dunkirk silt loam and Genessee humus loam secured near equilibrium. Ithaca, N. Y., Whiteland clay subsoil and Yamhill silt loam from the vicinity of Corvallis, Oreg., Porters sandy loam and Durham sandy loam from North Carolina, and Merrimac fine sandy loam from the experimental plats of the Massachusetts Experiment Station comprised the soils examined. The salts employed included the component parts of commercial acid phosphate, viz. calcium sulphate and tri-, di-, and monocalcium phosphate, calcium carbonate, sodium nitrate, sodium chlorid, and sodium carbonate. About 125 gm. of dry soil, or its equivalent in moist soil, was placed in a liter of water, various amounts of the salts added, and the solutions allowed to stand for three weeks. The amount of  $K_2O$  in parts per million of the solution was then determined. The results secured may be summarized as follows:

When commercial acid phosphate liberated potash in the soils used in this investigation the effect was found to be due to the gypsum which it contained. Calcium sulphate in solution increased the solubility of the potash compounds in some soils, this effect being much more marked in clay than in silt or sand and offering a possible explanation of the fact that only certain soils are benefited by applications of gypsum. Calcium sulphate solutions did not seem to be particularly active in dissolving the potash of silt and sands containing mica. It is deemed probable that on some, if not all fertile clay loam and clay soils, some potash is made soluble by the application of gypsum. In Dunkirk clay loam and silt loam, only a small amount of calcium suphate was required in the solution in order to affect materially the solubility of the potash, this possibly indicating why small applications of gypsum are quite beneficial on some soils.

The soil potash of Dunkirk silt loam was found to be somewhat more soluble in solutions of carbon dioxid and calcium bicarbonate than in a solution of carbonic acid containing the same amount of carbon dioxid. It is stated that soils high in organic matter may derive some soluble potash from the effect of the calcium bicarbonate in the soil water after the addition of a large amount of lime.

Sodium salts were quite active in dissolving potash from soils. The fact that sodium chlorid solutions were active in dissolving potash and that beets require sodium for proper growth is believed to explain why beets derive benefit from applications of salt, since they are very resistant to the tonic action of sodium chlorid.

A list of 29 titles comprising the literature cited is appended.

**Relation of fluorin in soils, plants, and animals, L. A. STEINKOENIG** (Jour. Indus. and Engin. Chem., 11 (1919), No. 5, pp. 463-465).—The author briefly reviews the work of other investigators, together with observations made by himself on the amount of fluorin present in both surface and subsoil samples of 9 different types of soil. He concludes that the original source of fluorin in the soil is such minerals as biotite, tourmalin, muscovite, apatite, fluorite, and phlogopite. In the soils examined fluorin occurred in amounts averaging 0.03 per cent, but a higher content may be expected in soils carrying larger amounts of mica. The roots of plants absorb fluorin and transmit it to the animals which consume them, and animals may also obtain fluorin from spring water.

Report upon the extent and character of the saline lands of the Madras Presidency, W. H. HARRISON (*Madras Agr. Dept. Yearbook, 1918, pp. 13-25, pl.* 1).—Studies of the nature of the soluble salts present are reported, as are the results of tests of various native methods of improving the lands, such as adding organic matter, adding substances which produce acid on decomposition, mixing and washing the soil, and growing resistant plants.

A peculiar alkaline tract in South Arcot district, M. R. RAMASWAMI SIVAN (*Madras Agr. Dept. Yearbook, 1918, pp. 25–33*).—Scattered patches of soil made sterile by excessive amounts of sodium carbonate, soluble organic matter, and clay are described. A peculiarity of the soils is that they become friable and heave when dried out. This is attributed in part to the gas resulting from the decomposition of organic matter in the presence of the large amount of lime (3.5 per cent) which the soil contains.

The alkali content of soils as related to crop growth, F. T. SHUTT and E. A. SMITH (*Agr. Gaz. Canada, 6 (1919), No. 1, pp. 8-15*).—This paper has already been noted from another source (E. S. R., 40, p. 719).

Soil survey of Faulkner County, Ark., E. B. DEETER and H. I. COHN (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1917, pp. 35, fig. 1, map 1).—This survey deals with the soils of an area of 416,640 acres situated slightly north of the geographical center of the State and lying entirely within the Quachita Mountain belt of the Appalachian Mountain province. Topographically, the northern part of the county comprises tillable plateaus with intervening, rather narrow, lowland areas, while the southern part consists of alternating belts of ridges and narrow valleys with wide valleys of important farming land lying between these belts. In general, natural drainage is well established.

The upland soils of the county are of residual origin from Pennsylvanian sandstones and shales. Soils of alluvial origin also occur along the stream bottoms. In addition to rough stony land and riverwash, 17 soil types of 8 series are mapped. Conway silt loam, Hanceville gravelly fine sandy loam, Hanceville loam, and Hanceville stony loam, predominate, occupying 30.1, 18, 17.4, and 13 per cent of the total area, respectively.

Soil survey of the Anaheim area, Cal., E. C. ECKMANN, A. T. STRAHORN, L. C. HOLMES, and J. E. GUERNSEY (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1916, pp. 79, pls. 3, fig. 1. map 1).—This survey, made in cooperation with the University of California, deals with the soils of an area of 317,440 acres lying southeast of Los Angeles and fronting on the Pacific Ocean. The region comprises the most important agricultural sections of Orange County, together with small portions of Los Angeles and San Bernardino Counties, including the entire area covered by the Santa Ana survey (E. S. R., 13, p. 926), and a part of the survey of the Los Angeles area (E. S. R., 16, p. 1060). These earlier surveys have been revised in the classification and mapping of the soils in the present survey.

Most of the area consists of smoothly sloping plains, including alluvial fans and river flood plains, while broken hills occur on the north and east together with remnants of somewhat elevated old valley surfaces or marine terraces lying along the base of the hills or bordering the ocean front. The elevations range from sea level to 1,600 ft. above. It is estimated that from 50 to 60 per cent of the region has good natural drainage.

The soils of the area have been derived from residual, old valley filling or coastal plain, and alluvial material. In addition to such miscellaneous material

#### 1919]

as rough broken and stony land, tidal marsh, riverwash, coastal beach and dunesand, and muck and peat, 28 soil types of 9 series are mapped. Hanford fine sandy loam, Hanford sandy loam, rough broken and stony land, and Yolo loam, occupying 14.9, 9.2, 8.9, and 8.6 per cent of the total area, respectively, are the prevailing types.

Soil survey of Shelby County, Ky., C. VAN DUYNE, L. R. SCHOENMANN, and S. D. AVERITT (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1916, pp. 67, pl. 1, fig. 1, map 1).—This survey, made in cooperation with the Kentucky Experiment Station, deals with the soils of an area of 244,480 acres situated in the north-central part of the State and lying within the Lexington Plain. The topography varies from undulating to rolling and hilly. Natural drainage is well established.

The upland soils of the county are residual from limestones and shales, while alluvial soils occur on the stream terraces and bottom lands. Eight soil types of 6 series are mapped. Shelbyville silt loam, Cincinnati silt loam, and Eden clay, occupying 45.4, 26.8, and 17.7 per cent of the total area, respectively, predominate.

S. D. Averitt briefly discusses the fertility of the different types of soils found in the county as indicated by chemical analyses of the surface and subsoil.

Soil survey of Calhoun County, Mich., R. F. ROGERS and W. G. SMITH (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1916, pp. 54, figs. 2, map 1).—This survey deals with the soils of an area of 443,520 acres situated in the south-central part of the State. The topography is said to be typical of a glaciated region, comprising rolling to hilly morainic belts with intervening strips having a level to gently undulating surface. Natural drainage is generally well established in the upland, although many swamps, ponds, and lakes occur throughout the region.

The soils of the county are largely of glacial origin, having been derived from ingneous and metamorphic rocks, while part of the material has come from sedimentary limestone, sandstone, and shale. In addition to muck and peat, which occupy 12.5 per cent of the total area, 22 soil types of 11 series are mapped. Coloma loam, Fox loam, and Bellefontaine loam, occupying 16.6, 15.2, and 11.3 per cent of the area, respectively, are the prevailing types.

Soil survey of Amite County, Miss., A. L. GOODMAN, A. H. MEYER, R. W. MCCLURE, and B. H. HENDRICKSON (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1917, pp. 38, fig. 1, map 1).—This survey deals with the soils of an area of 456,960 acres situated in the southwestern part of the State. The topography varies from almost level to hilly but is prevailingly rolling. Natural drainage is generally well established throughout the region.

The upland soils of the county have been derived from loessial material overlying Coastal Plain beds of sandy clay and gravel. The second bottom lands comprise old alluvium which has undergone considerable change through the influence of varying drainage conditions, while the first bottoms consist of recent alluvium and are still subject to overflow. The loessial soils prevail over most of the area. Seventeen soil types representing 14 series are mapped. Ruston fine sandy loam, Grenada silt loam, and Ruston very fine sandy loam, occupying 40.3, 20.4, and 12.6 per cent of the total area, respectively, predominate.

Soil survey of Callaway County, Mo., H. H. KRUSEKOPF, J. H. AGEE, and R. H. HALL (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1916, pp. 38, fig. 1, map 1).—This survey, made in cooperation with the Agricultural Experiment Station of Missouri, deals with the soils of an area of 517,120 acres situated in the central part of the State and on the north side of the Missouri River. Approximately the northern half of the county is comprised of glacial plains characterized by level prairies and gently rolling areas, while the southern portion consists of timbered, rolling to hilly uplands representative of the Ozark region. In general, natural drainage is well established.

The upland soils of the county are glacial, loessial, and residual in origin, with the first two predominating in the northern part and the last in the southern part of the county. Gray soils with heavy subsoils characterize the region generally. Areas of alluvial soil also occur. In addition to rough stony land, 21 soil types of 16 series are mapped. Putnam silt loam, Lindley silt loam, and Union silt loam predominate, occupying 41.8, 19.2, and 12 per cent of the total area, respectively.

Soil survey of Oswego County, N. Y., C. N. MOONEY, E. T. MAXON, R. J. MORGAN, and J. H. BROMLEY (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1917, pp. 43, fig. 1, map 1).—This survey, made in cooperation with the New York State College of Agriculture, deals with the soils of an area of 606,720 acres situated in the north-central part of the State at the eastern end of Lake Ontario. The topography varies from undulating to hilly with a range in elevation of from 246 to 1,750 ft. above sea level. Except in certain boggy and swampy areas in the central and eastern part of the county, natural drainage is generally adequate.

The soils of the region consist of glacial till derived chiefly from sandstone and sandy shale and comprise glacial drift, water-deposited, and cumulose material. In addition to muck, meadow, and beach sand, 18 soil types of 8 series are mapped. Worth stony fine sandy loam, including the poorly drained phase, occupying 37.1 per cent of the total area, is the largest single type.

Soil survey of Benton County, Wash., A. E. KOCHER and A. T. STRAHORN (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1916, pp. 72, pls. 3, figs. 2, map 1).—This survey deals with the soils of an area of 1,100,800 acres situated in the southeastern part of the State and separated from the State of Oregon by the Columbia River, which also bounds the county on the north, east, and south. The elevations range from 240 ft. above sea level in the river valleys to 3,500 ft. in the Rattlesnake Hills and Yakima Range. Rather extensive areas in the Columbia River Plains lack adequate natural drainage.

Benton County lies wholly within the Northwest Intermountain soil province, and is underlain by a succession of basaltic sheets of the Columbia River lava, which has entered little into the formation of the soils. The soils of the region have been derived from loessial, eolian, old valley filling, and stream-laid material. In addition to scabland, dunesand, and riverwash, 26 soil types of 12 series are mapped. Ritzville loam and Sagemoor silt loam, occupying 30.9 and 10.7 per cent of the total area, respectively, are the prevailing types.

[Cultivation and soil moisture], M. RINGELMANN (Compt. Rend. Acad. Agr. France, 4 (1918), No. 27, pp. 746-748; abs. in Rev. Sci. [Paris], 57 (1919), No. 9, pp. 280, 281).—This article discusses briefly the relation of plowing to the water content of soils. According to the author's tests the best results with the least expenditure of energy will be obtained in plowing when the soil contains from 11 to 17 per cent of moisture, depending upon the physical character of the soil. This necessarily narrowly limits the time in which plowing can be most effectively done, and hence increases the value of tractors in expediting the work.

It was found that traction increases with decrease of moisture in the soil. With 15.4 per cent of moisture in the soil, the traction per square decimeter was 47.4 kg., with 11.1 per cent of moisture, 46.1 kg.; with 5.1 per cent of moisture 70.7 kg.; and with 3.8 per cent of moisture 78.2 kg. The washed lands of Indiana: A preliminary study, M. L. FISHER (Indiana Sta. Circ. 90 (1919), pp. 24, figs. 18).—The nature and causes of soil erosion in the State are discussed and various methods for its prevention and for reclaiming washed areas are brifly described. The principal preventive measures are said to comprise strip farming, mulching the brow of steep slopes, skip plowing, diverting the run-off, and keeping the land in permanent vegetation; while the recovery of badly eroded land includes filling in the gullies with straw, cornstalks, weeds, brush, tree tops, logs, and trees; the seeding of alfalfa or other hay and pasture plants or the growing of wheat or corn; and liming and preparing the seed bed for grasses, particularly redtop and Kentucky blue grass, on denuded surfaces.

[Report of soil work in Georgia] (Georgia Sta. Rpts. 1917–18, pp. 15, 16).— Continuing observations previously noted (E. S. R., 37, p. 23), it is stated that the rapid increase in numbers of bacteria in soil receiving stable manure, sterilized manure, or green manure persisted for several months, and was due largely to the addition of fermentable material. A study of bacteria picked from plates inoculated with variously treated soils is held to show that the increase in numbers was due to the multiplication of small sporeless forms, with but little increase in the number of Actinomyces. A large number of gasproducing forms are said to have followed the addition of sterilized manure, but to have disappeared in two or three weeks.

A strain of *Bacillus radicicola* isolated from vetch and at that time unable to inoculate alfalfa is said to have acquired this power after growing with alfalfa meal in heated soil for two years. The same strain grown on nitrogen-poor agar for two years remained specific for vetch. Soy beans and velvet beans were found to be inoculated with the same strain of *B. radicicola*. Most of the native legumes appeared to be well inoculated, while redbud (*Cercis canadensis*), wild coffee bean (*Cassia tora*), honey locust (*Gleditsia triacanthos*), and mimosa, although abundant and well established in the State, are said to be entirely lacking in nodule formation.

[Report of soils work at the Delaware Experiment Station, 1918], T. F. MANNS (*Delaware Sta. Bul. 122 (1918), pp. 28, 29*).—Observations on crop yields and changes in the bacterial flora in 10 different types of soil subjected to various fertilizer, lime, and manurial treatments in a continuation of similar work previously noted (E. S. R., 39, p. 116), are held to indicate that applications of manure, phosphorus, and lime have resulted in the highest crop yields on most of the soils, and that additions of manure produced the greatest changes in the soil flora.

**Results of fertilizer experiments in Arkansas,** DEF. HUNGERFORD (*Arkansas Sta. Bul. 155 (1918), pp. 3-27, figs. 4*).—Fertilizer experiments with cotton and corn begun in 1909 and conducted for different lengths of time at the station, on outlying experiment fields, and in cooperation with farmers and district agricultural schools in the State are reported on in some detail, the more important results having already been noted from another source (E. S. R., 39, p. 21).

Nitrogenous fertilizers such as nitrate of soda, cottonseed meal, and barnyard manure produced decided increases in crop yields in most of the experiments, while both acid and rock phosphate used in conjunction with them also proved to be beneficial. Acid phosphate used alone was not profitable except where the soil had been previously well manured or where legumes had been plowed under. Ground limestone gave profitable returns in practically every instance.

Soil test experiment at Aroostook farm [1918], C. D. Woods (Maine Sta. Bul. 278 (1919), pp. 33-56, figs. 3).—This describes the progress of soil fertility work on Caribou loam on Aroostook farm (E. S. R., 39, p. 327). Clover yields are said to have been too uneven to justify any conclusions, while the following tentative deductions with regard to oats and potatoes are presented: Nitrogen appears to be the limiting factor on this soil for both oats and potatoes. Neither phosphoric acid nor potash affected the yields of oat grain. Small amounts of potash increased the yield of potatoes, while phosphoric acid had no effect.

[The progress of soil investigations in India, 1917-18] (*Rpt. Prog. Agr. India, 1917-18, pp. 66-73, 101-104*).—Soil fertility investigations conducted in various parts of India are rather briefly summarized.

Some notes on manures in southern India, W H. HARRISON (Madras Agr. Dept. Yearbook, 1918, pp. 52-66).—It is noted that the fertilizer resources of this region are limited. Small amounts of lime and gypsum are available. The supply of branyard manure is limited and poor. A certain amount of Tri-chinopoly phosphates, oil cakes, and fish manures can be had.

The influence of farmyard manure on the clover crop, E. J. RUSSELL (Jour. Bd. Agr. [London], 26 (1919), No. 2, pp. 124–130).—Results of experiments at Rothamsted, the Ohio Experiment Station, and elsewhere are cited to show that "farmyard manure may have an important residual effect on clover which should be taken into account in estimating its effect on the rotation." In all of the cases cited except one, manure was more effective than other fertilizers in increasing the growth of clover in rotations with other crops.

[American peat industry in 1918] (U. S. Geol. Survey Press Bul. 412 (1919), p. 2).—The production of crude peat in 1918 was 151,521 short tons as compared with 97,363 tons in 1917. The amount of refined peat marketed was 107,261 tons worth \$1,049,493. Of this amount 79,573 tons was used for fertilizer purposes, 7,096 in the manufacture of stock food, 20,567 for fuel, and 25 tons for miscellaneous purposes. The increase during the year in the use of peat for fuel was especially noteworthy. The total number of plants engaged in commercial production of peat was 25. New York and New Jersey had 4 plants each, Massachusetts 3, Georgia, Illinois, Indiana, and California, 2 each, and Maine, New Hampshire, Connecticut, Pennsylvania, North Carolina, and Florida 1 each.

The Bucher cyanid process for the fixation of nitrogen, E. POSNJAK and H. E. MERWIN (Jour. Wash. Acad. Sci., 9 (1919), No. 2, pp. 28-30; abs. in Sci. Abs., Sect. B—Elect. Engin., 22 (1919), No. 255, p. 90).—In the investigations here briefly reported, "it was found by means of microscopical examinations that the nitrogen-bearing constituent of some of the crude technical products manufactured by this process [i. e., heating a mixture of sodium carbonate, charcoal, and iron powder in a stream of nitrogen at a temperature above 900°] consisted principally of some other substance than ordinary sodium cyanid."

The question of phosphatic fertilizers, E. Miège (*Rev. Sci.* [*Paris*], 57 (1919), *No.* 7, *pp.* 202-210).—Investigations relating to physical, chemical, and biological methods of making phosphates available as plant food are quite fully reviewed with numerous references to literature, including the recent American work of Lipman, McLean, Brown, and others on the action of sulphur and bacteria in rendering mineral phosphates available, and the fertilizing value of the products obtained by various methods is discussed. The author considers the American work of great interest and practical significance and promise.

Phosphatic nodules of Trichinopoly and their availability as manure, M. R. RAMASWAMI SIVAN (*Madras Agr. Dept. Yearbook, 1918, pp. 34–51, pls. 2, figs.* 4).—The results of a Government survey of the district in which the phosphate is found are reviewed and the phosphatic nodules are described. An analysis is

reported which showed 55.95 per cent of tricalcium phosphate, 2.44 per cent of magnesium carbonate, and 7.1 per cent of iron oxid and aluminum. Since the phosphates are evidently not suited to the manufacture of superphosphate it has been recommended that they be used in fine ground condition. They are being tested in this form as fertilizer for rice.

Analyses of inspection samples of fertilizers, 1917, J. T. WILLARD, C. O. SWANSON, and R. C. WILEY (*Kansas Sta. Insp. Circ.* 7 (1918), pp. 16).—This reports the results of the actual and guarantied analyses of official samples of commercial fertilizers and fertilizing materials collected during 1917.

# AGRICULTURAL BOTANY.

Report of plant physiologist, E. M. R. LAMKEY (Delaware Sta. Bul. 122 (1918), pp. 30, 31).—A summary is given of investigations carried on in changing permeability and its relation to availability and the reactions of enzyms to solutions within the plant. Work on these projects has not progressed very far, but preliminary investigation has shown the necessity of considering temperature, shade, sunlight, and moisture content of the soil in conjunction with the permeability of the tissues and the availability of plant food. It has been found that peach tissues may be equally permeable to certain salts under one system of management while under another system they will be unequally permeable. In the study of the reactions of enzyms, the author has designed and used apparatus for the determination of peroxidase and oxidase.activities under known and controlled conditions. By use of the methods devised by him, the peroxidizing, oxidizing, diastatic, and inverting enzyms of variously fertilized trees have been studied throughout a single season.

Growth in organisms, D. T. MACDOUGAL (Science, n. ser., 49 (1919), No. 1278, pp. 599-605).—In an address before the Pacific Division of the American Association for the Advancement of Science, the author discussed growth as based on the conception that living matter is composed mainly of pentosans and albumins or albumin derivatives with lipins as a minor component and that growth of living matter consists of hydration with accompanying swelling and of accretion of solid matter, the two processes being actually independent. Enlargement of cells is considered almost entirely due to the swelling which results from hydration in their earlier stages, and later the enlargement of the syneretic cavities in the colloidal structure is followed by the distending or stretching action of osmotic pressures in the vacuoles thus formed.

Root growth in desert plants and the oxygen supply of the soil, W. A. CANNON (Carnegie Inst. Washington Year Book, 17 (1918), pp. 81-83).—It is said that roots of Prosopis continue growth for a longer time in a soil atmosphere poor in oxygen, with no carbon dioxid, than is the case with Opuntia. The oxygen, as well as the carbon dioxid, response thus appears to be specific, at least as far as these two plants are concerned, and is thought, therefore, to be a matter of ecological importance. The relative indifference of the roots of Prosopis to soil aeration permits either deep or shallow growth and enables the species to range widely as regards soils, while the relative dependence of the roots of O. versicolor on good soil aeration prevents their striking to any considerable depth and also excludes the species from soils of fine texture.

Root absorption from solutions at minimum concentrations, R. B. HARVEY and R. H. TRUE (Amer. Jour. Bot., 5 (1918), No. 10, pp. 516-521, figs. 2).—Following up the studies of True and Bartlett (E. S. R., 34, p. 224) with investigations of equilibrium points as regards gain or loss of electrolytes by plants, the authors found that in case of squash, peanut, soy bean, and sweet corn growing in water culture the equilibrium concentration was specific for each plant. It is stated that if the concentration is below that which is toxic for the plant, yet meets growth requirement thereof, the equilibrium concentration value is independent of the kind of nutrient salt used, the concentration of the electrolyte, or the volume of the solution.

At the point of equilibrium between the plant and the solution, the electrolyte content of the solution is determined (1) by certain factors which are constant for different plants under the same conditions, such as carbon dioxid equilibrium with the air, and (2) by the rate of cleavage of ion-producing compounds of the cell and reabsorption of the ions produced.

The influence of certain added solids upon the composition and efficiency of Knop's nutrient solution, E. H. TOOLE and W. E. TOTTINGHAM (*Amer. Jour. Bot., 5 (1918), No. 9, pp. 452–461*).—Results of experimental tests regarding the effects upon the physiological balance of a nutrient solution produced by adding solids offering relatively large surface to the action of solvents and solutes are given.

The authors state that when barley and pea plants were grown for 21 days in Knop's nutrient solution plus ferric hydrate, silicic acid, and carbon black, each upon two planes of application, it was found that the first increased the dry weight of the barley tops about 50 per cent, the second had no effect, and the third depressed growth appreciably. The weight and the length of the roots were not markedly affected in any case. The dry weights of barley tops were inversely proportional to the hydrogen-ion concentration of the solution, but the total range in the acidity of the cultures was comparatively small. In all cases the growing barley plants exerted a neutralizing effect upon the reaction of the solution. Over 90 per cent of the phosphorus of Knop's solution was removed by the higher application of ferric hydrate, presumably owing to the formation of insoluble ferric phosphate. This culture was by far the best, as regards both appearance and yield. Treatment with ferric hydrate (producing neutrality of the nutrient medium) may have contributed to the higher yield. No clear evidence was obtained regarding adsorption of nutrient ions.

A simple method of demonstrating the production of aldehyde by chlorophyll and by anilin dyes in the presence of sunlight, W. J. V. OSTERHOUT (*Amer. Jour. Bot.*, 5 (1918), No. 10, pp. 511-513).—A method is described by which relatively large quantities of aldehyde free from contamination by nonvolatile substances is obtained in sunlight from chlorophyll or from certain anilin dyes.

The origin and physical basis of succulence in plants, D. T. MACDOUGAL and H. A. SPOEHE (*Carnegie Inst. Washington Year Book*, 17 (1918), pp. 85, 86).—The discovery that Castilleja and Erigeron each included some individuals which were thick leafed and some which were thin leafed, and that these leaf characters were correlated with water supply, has furnished a starting point for the study of succulence. An analysis of the carbohydrates of desert plants has shown that when cells containing polysaccharids undergo depletion of water content these sugars are reduced to the pentosans, of which the mucilages are largely composed. This and other facts lead to the conclusion that aridity, by causing undue loss of water, induces a change in the cell by which the amount of water it may hold is greatly increased. This results in giving the cell mass a storage capacity which is permanent, as the pentosans are not reconvertible into the polysaccharids. The change from a thin-leafed condition to that of succulence is not a simple one, and it appears that the resulting biocolloidal complex of the succulent leaf has taken on new characters. The index of transpiring power of plants, E. B. SHREVE (*Carnegie Inst. Washington Year Book, 17 (1918), pp. 72–74*).—Having noted previously (E. S. R., 40, p. 27) a large opening for error in the assumption that the tripartite cobalt paper slips for determining index of transpiring power are at the same temperature as the surrounding air, the author has employed an adaptation of the thermocouple referred to below to test the temperature of the cobalt paper slip as it rests upon the leaf under its grass cover. This work has established the fact that the temperature of the air may be safely taken as the temperature of the cobalt slip. It is also shown that if cobalt slips are standardized at within 2 or 3° of 20° C., the error introduced is smaller than that obtained from consecutive readings on the same slip at any given temperature.

Modification of root habits by experimental means, W. A. CANNON (*Carnegie Inst. Washington Year Book, 17 (1918), pp. 83–85*).—These observations appear to show that roots which penetrate deeply, or which ordinarily grow in soils of fine texture, are less responsive to relatively small changes in soil aeration and may be less dependent on temperature than is the case with roots which are essentially superficial and which occur only in relatively well-drained soils. Exceptions are noted. Cultural experiments with species whose roots remain close to the surface and which have well-fixed characters show a surprising plasticity in root development. It is claimed that in certain cacti the distinctive root characters do not result from inherited tendencies, but are probably expressions of the response of the species to the distinctive aeration and temperature conditions of the soil environment.

Water content and abscission in the nuts of Juglans californica quercina, F. E. LLOYD (*Carnegie Inst. Washington Year Book, 17* (1918), p. 76).—A record having been kept on numerous fruits of *J. californica quercina* of such as ultimately became separated from the twig by abscission, it is stated that a daily net gain was made which decreased until an uncompensated loss occurred. Inadequate water supply is thought to be the exciting cause of abscission, which closely resembles that occurring in the cotton plant (Gossypium).

Calcium oxalate in the dasheen, O. F. BLACK (Amer. Jour. Bot., 5 (1918), No. 9, pp. 447-451).—Investigation of tubers and leaves of the dasheen is considered to show that the calcium oxalate crystals are the sole cause of the acrid taste, which is supposed to be due directly to mechanical irritation by the needles coming in contact with the mucous membrane of the mouth. It is stated that proper cooking will remove the crystals and render the plant useful as a vegetable.

Sterility and self and cross incompatibility in shepherd's purse, G. H. SHULL (Abs. in Science, n. ser., 49 (1919), No. 1275, p. 547).—An abstract is given of a paper read before the American Philosophical Society in which the author describes the result of crossing the common shepherd's purse of the eastern United States with a form that occurs on the Pacific coast. The form from eastern America is characterized by sterility of the lower flowers of the main axis, while the western species does not show this condition. As a result of study of the crosses made, there was found to be a rhythmatic succession of sterile and fertile flowers, and there seemed to be some evidence that this arrangement was under the control of two genetic factors.

Culture of a potato hybrid, Solanum fendleri $\times$ S. tuberosum ("Salinas"), D. T. MACDOUGAL (Carnegie Inst. Washington Year Book, 17 (1918), pp. 87, 88).—Cultures of the hybrid between the wild potato of Arizona and the domestic variety have been carried on at the Coastal Laboratory and on a ranch in the Carmel River Valley, resulting in the separation of a number of elements of different value. Studies are being made on about a dozen strains of possible economic importance.

#### FIELD CROPS.

Uredinales of Guatemala based on collections by E. W. D. Holway, II-IV, J. C. ARTHUR (Amer. Jour. Bot., 5 (1918), Nos. 8, pp. 420-446; 9, pp. 462-489; 10, pp. 522-550).—The present series, which is consecutive with the contribution previously noted (E. S. R., 40, p. 327), deals with the Æcidiacaæ (Pucciniaceæ), some genera having been placed out of their usual order to express the author's conception of their affinities.

## FIELD CROPS.

The influence of crop plants on those which follow, II, B. L. HARTWELL, F. R. PEMBER, and G. E. MERKLE (Rhode Island Sta. Bul. 176 (1919), pp. 4-48, figs. 7) .- Supplementing experimental work conducted in the field (E. S. R., 40, p. 623), pot experiments begun in 1911 are described in which further observations were made on the effect of different crops on those grown subsequently. The investigations were divided into two parts, one conducted in Wiley pots in the greenhouse to study the effect of onions, buckwheat, rye, and redtop on onions and buckwheat when grown with an optimum supply of nutrients; with nitrogen, phosphorus, and potassium each omitted; and with half more than the optimum supply of nutrients; and the other made in ash cans sunk in the ground out of doors in which observations were made on the effect of onions, buckwheat, rye, redtop, and mangels on onions and buckwheat when the crops were grown with different amounts of nitrogen. Applications of lime were made to all pots at the beginning of the experiment and again 3 or 4 years later. Data showing the crop yields and the amount of nutrients removed in the different crops are presented in tabular form with full discussion and may be summarized as follows:

When onions were grown after the different crops had occupied the soil 2 or 3 successive seasons, the yields increased after the crops in about the following order: Buckwheat, mangels, rye, onions, and redtop. When buckwheat was grown uniformly, the yield increased in order after redtop, buckwheat, mangels, rye, and onions. With the different fertilizer treatments the relative effect of the several crops varied somewhat, depending upon the treatment, but not so much as generally expected. Chemical analyses of the crops are held to indicate that changes in the percentage composition of a crop brought about by a given application of a nutrient depended not only upon its effect upon the rate of growth but also upon the abundance of the other nutrients in relation to the needs of the crop. In general it appeared that the nutrients actually required for the normal growth of the crops need not exceed in dry material 2 per cent nitrogen, 1.5 per cent potassium oxid, and 0.5 per cent phosphoric oxid, providing an adequate supply of other ingredients is available to furnish the indifferent ash. As indicated by the field experiments, "the divergent effect of crops on those which follow seems not to be attributable, at least principally, to differences in the amount of nutrients removed by the crops grown previously-that is, the smallest yield may not occur after the crop which removed the largest amount of even the most-needed nutrient."

The soil acidity was affected differently by the various crops. Onions, said to be sensitive to conditions accompanying acidity, showed the best yields after crops giving rise to the least acidity. The effects of the crops on those which followed were observed to be much less divergent when the soil acidity was reduced by liming. Even the preceding crop effects may prove to be relatively unimportant on neutralized soil. It is suggested that for practical purposes the potent influences observed in these investigations should receive careful attention, since many soils exhibit a higher degree of acidity than existed in the

#### 1919]

experimental soil and it is regarded as doubtful whether they would ever be limed sufficiently to maintain them in a neutral condition.

[Crop rotations for northeastern Ohio], C. W. MONTGOMERY (Mo. Bul. Ohio Sta., 4 (1919), No. 4, pp. 117-120, fig. 1).—Results secured on the Northeastern Test Farm, Cuyahoga County, with 3- and 5-year rotations for the period of 1915 to 1918, inclusive, together with a study of crop costs and net receipts per acre in the 5-year rotation for 1917 and 1918, have led to the conclusion that under present conditions a rotation of corn, oats, wheat, and clover would be most profitable in a majority of cases for this section of the State. It is suggested that the fertilizer treatment comprise an application of 6 tons of phosphated manure on the corn, 160 lbs. of acid phosphate on the wheat with 4 tons of phosphated manure as a top-dressing, and 2 tons of ground limestone applied before either the corn or the wheat. A mixture of 5 lbs. of red clover and 3 lbs, each of alsike clover and alfalfa is recommended for seeding with the wheat.

[Report of field crops work at the Delaware Experiment Station, 1918], A. E. GRANTHAM (*Delaware Sta. Bul. 122* (1918), pp. 10-20.)—This describes the progress of soil and crop investigations in continuation of similar work previously noted (E. S. R., 39, p. 127).

Observations on the effect of commercial fertilizers, green manure, and stable manure used with and without lime in a rotation of corn, soy beans, wheat, and clover showed marked results from liming, the hay yield being increased nearly 40 per cent and the corn yields from 6 to 8 bu. per acre over the untreated or unlimed areas. Wheat did not respond readily to liming, while soy beans made a more vigorous growth of vines where lime was applied. Liming also appeared to hasten the maturity of corn. Little effect from the use of lime was noted on wheat and corn grown continuously.

With regard to the application of single plant food elements, phosphorus exerted a marked effect on wheat during the earlier years of the experiment, while later potash appeared to be more important. Wheat receiving phosphorus ripened from 3 to 5 days earlier than when it was omitted. Phosphorus and potassium in combination gave the greatest net profit per acre. Commercial nitrogen applied in conjunction with phosphorus and potassium failed to show any consistent profit with either wheat or corn. Potassium proved to be the most important element for both corn and soy beans. The number of nodules on the roots of the soy beans was found to be considerably greater where potash was used than with any other fertilizer treatment. Potash also effected the fullest development of the ear and grain in corn.

A number of crop rotation experiments were begun in 1910 to study the value of green manures for maintaining crop yields. The principal crops in the rotations were corn, wheat, potatoes, red clover, timothy, winter oats, and soy beans, while the green manure crops included crimson clover, red clover, vetch, rye, and cowpeas. Except on the potato crop only green manure and mineral fertilizers other than nitrogen were used. The results secured indicate that red clover requires considerable potash for the best results. Corn produced much better in rotation with red clover than in rotation with soy beans and timothy, the difference amounting to as much as 25 bu. per acre. Soy beans were found to exhaust the soil to a marked extent. Wheat after soy beans gave good results, but the best wheat yields were secured after potatoes. The corn yields obtained in a rotation of corn, wheat, and alfalfa two years were larger than where 700 lbs, of commercial fertilizer was used in a rotation of corn, soy beans, wheat, and red clover, while the wheat yields averaged about 30 bu. per acre. Observations on the relative value of various forms of lime and phosphorus in maintaining soil fertility are held to indicate that carbonate of lime is practically as efficient as the burned forms of lime for correcting soil acidity; that raw rock phosphate can be used to fair advantage when employed in rotations where considerable amounts of organic matter are turned under; that lime alone has not resulted in a better stand of clover; that phosphorus carriers vary to a marked extent in their effect on the crop, their value decreasing in the following order: Acid phosphate, basic slag, sodium phosphate, bone meal, and raw rock phosphate; that with applications of raw rock phosphate wheat yields have increased as the experiment progressed; and that high magnesium lime has given as good results as high calcium lime.

Extensive variety tests with wheat have been described elsewhere (E. S. R., 41, p. 39), the results for the past year corresponding very closely with those of the previous tests. A study of the performance of different varieties and types of wheat grown under various fertilizer treatments, ranging from many times the optimum requirements of the plant to the minimum quantity of plant food required for a 25-bu. yield, is noted. The results indicate that the amount of potash taken up during growth and the proportion of phosphorus, potassium, and calcium vary somewhat with the different varieties.

Johnson County White corn is deemed to be best for Delaware conditions, in many cases producing more than 100 bu. per acre. Reid Yellow Dent and Leaming appeared to be the best yellow sorts, although they yielded from 8 to 10 bu. per acre less than Johnson County White. Observations on seed of hybrid origin, as compared with pure seed, indicated that the former outyielded the latter on both poor and fertile soil. Smooth ears of Johnson County White also gave better results than rough ears on poor land, there being little difference when the two were planted on fertile soil. A study of the effect of variations in the physical characters and the chemical composition of the kernel on the vigor and yield of the plant has not as yet revealed any wide differences in yield from corn of different physical characters when grown under good environmental conditions, although noticeable differences in the degree of vigor of the plant were observed under slightly unfavorable circumstances. The study has also shown a wide range in the physical characters of ears in the same variety.

Silver Mine and Swedish Select Oats have given somewhat better results than the other varieties of spring oats tested, although the crop in general is regarded as unprofitable. Limited tests with winter oats are said to have given promising results.

The Wilson, Peking, and related strains of soy beans are deemed best for general farm purposes, while Cloud is said to be one of the best varieties for hay.

[Report of field crops work in Hawaii, 1918], F. G. KRAUSS, C. A. SAHR, and R. A. Gorr (*Hawaii Sta. Rpt. 1918, pp. 33, 45-51, 51-53, fig. 1*).—This describes the continuation of work previously noted (E. S. R., 38, pp. 826, 827, 828).

In a comparative test of the relative resistance to blight of three standard varieties of potatoes and of the new Hamakua Hybrid made at the forage crop station near Castner (Oahu), Early Rose and Burbank succumbed about 11 weeks after planting and Portuguese Purple and Hamakua Hybrid about 3 weeks later.

Kukiruki and Okabu rice grown in rotation with taro at Waiau (Oahu) produced increases in yield favoring rotation which amounted to 872 and 944 lbs. per acre, representing 17 and 17.7 per cent, respectively.

Work with corn consisted chiefly of testing different varieties for resistance to the leaf hopper (*Peregrinus maidis*). Native Guam corn received from the Guam Experiment Station is said to have shown considerable resistance. Several standard varieties of corn received from the Bureau of Plant Industry, U. S. Department of Agriculture, failed to produce any grain, while certain other varieties varied in yield from 10.9 bu. per acre of shelled corn for Northwestern Dent to 39.2 bu. for Creole, as compared with 46.7 bu. for Native Guam. Cuban Red, introduced by the College of Hawaii, also showed marked resistance to leaf-hopper attack but possessed somewhat inferior drought-resistant qualities.

Of six varieties of button clover tested, Medicago scutellata and M. orbicularis alone made promising growth. M. scutellata, although attaining considerable size, was killed off by aphids, while M. orbicularis gave the best results when the trailing stems were supported and partially shaded by Bermuda grass. Plantings of annual types of white sweet clover, received from the U. S. Department of Agriculture and from the Iowa Experiment Station, have made favorable growth. Duplicate plantings of so-called Prolifikeeno grass received from Fabens, Tex., produced at the rate of 15.35 tons of green forage per acre from 55 to 60 days after planting. It is said to resemble Johnson grass closely in the appearance of underground suckers shortly after cutting.

In fertilizer and manurial experiments with edible canna (*Canna edulis*) the maximum yield of tubers, 42.83 tons per acre, followed an application of 250 pounds each of ammonium sulphate, superphosphate, and sulphate of potash, as compared with a yield of 28.43 tons from the check. Observations on the utilization of spherical and cylindrical types of tubers for sets resulted in yields amounting to 32.02 and 37.13 tons per acre, respectively.

Further observations of the effect on the yields of different forage crops of soil heating and manuring at Castner again demonstrated the high value of stable manure on manganese soils, crop yields being considerably increased over all other methods of handling. Spraying Peruvian alfalfa with copperas the first and second week after each cutting resulted in increases in yield in the succeeding cuttings ranging from 4.9 to 228.4 per cent over the unsprayed crop. Japanese cane sprayed every 2 weeks for a period of 6 months showed an increase in yield of 43.5 per cent when harvested 6 months after the spraying was discontinued. Spraying alfalfa with copperas and fertilizer compounds, including lime, sulphate of potash, and superphosphate, resulted in decided increases in yield in almost every case over drilling in the fertilizer.

Hill selection of potatoes both to increase the yield and to secure a blightresistant type at the Haiku (Maui) substation is said to have given some success. Dibble Russett produced 180 bu. of marketable tubers as compared with 100 bu, from unselected seed. The potato industry is reported to be increasingly affected by the potato mite. Lime-sulphur spray or sulphur alone has proved to be an effective remedy.

Work with alfalfa on the Glenwood (Hawaii) substation indicates that seeding may be done in the field instead of in seed plats or nursery seed beds, as was formerly deemed essential to successful alfalfa production, providing care is exercised to plant when cutworms are not plentiful. In variety tests with potatoes, yields have been secured amounting to from 35.7 bags (100 lbs. each) per acre for Vermont Gold Coin to 108 bags for Hamakua Hybrid (light variety). In an effort to develop a fiber industry for areas near Glenwood which can not be used for sugar-cane production, trials have been made with sisal, New Zealand flax, hemp, flax, and Manila hemp, all but the last giving some promise for the future.

[Report of field crops work in New Mexico, 1917-18] (New Mexico Sta. Rpt. 1918, pp. 27-29, 32, 33, 44-47, figs. 3).—The progress of work previously noted (E. S. R., 38, p. 633) is briefly described, including observations on Johnson grass eradication; irrigation experiments with alfalfa; irrigation, cultural, and manurial tests with potatoes; and trials with Giant Russian sunflowers for forage.

Medium deep plowing on soils free from an excess of moisture is said to have resulted in a material decrease in the stand of Johnson grass, while plowing wet soil served to stimulate it. San Luis Valley peas and wheat gave good results as smother crops.

Giant Russian sunflowers seeded in rows and cultivated the same as corn produced at the rate of 25 tons of silage per acre when cut in full bloom. It is stated that the crop is of doubtful value as a seed crop owing to ravages from birds.

The alfalfa plats receiving 5-in. applications of water and cultivated once after each irrigation produced the heaviest yields in 1917, followed closely by plats seeded broadcast receiving the same amount of water. Two-in. applications produced the greatest amount of hay per inch of water, 333 lbs., as compared with 285.7 lbs. for the 5-in. application. Observations made in root penetration again indicated that alfalfa roots increase in length with an increase in the amount of water applied.

A tabular statement is presented showing the potato yields for individual plats, together with a diagram of the plat arrangement and a graphic representation of the results secured during 1918. Plats receiving no winter irrigation but 1, 2, and 3 summer irrigations produced at the rate of 2,006, 3,178, 3,644, and 2,396 lbs. per acre, respectively, while those receiving winter irrigations totaling 5 and 10 in., respectively, produced 2,512 and 3,585 lbs. of potatoes as ecompared with 2,709 lbs. for no winter irrigation. In a similar manner, plats receiving no summer irrigation and 1, 2, and 3 irrigations during the summer produced 2,372, 2,265, 4,115, and 3,791 lbs., respectively. In a comparison of level, ridge, and Greeley cultivation respective yields of 3,388, 3,172, and 1,967 lbs. per acre were obtained. Stable manure applied in 1916 resulted in a yield of 3,259 lbs. in 1918, as compared with 2,942 lbs. for the unmanured plats.

[Report of field crops work in North Dakota] (North Dakota Sta. Rpt. 1917, pp. 5, 6, 9, 10, 12-14, 16).—In the tests here reported, Minnesota No. 13, Rustlers White Dent, and Mercer corn produced the largest yield of silage. Seed harvested in the glazed stage gave about as good a stand and yield as ripe seed, while that harvested in the dough and milk stages produced a fair stand but low yields. Manuring appeared to hasten maturity in corn, while corn grown in rotation with clover is said to have been of better quality than that grown in rotation with timothy.

Where wheat has been grown continuously for 30 years the soil was found to contain from one-fourth to one-third less nitrogen and one-fifth less phosphorus than virgin soil of the same type. For the last 8 years the wheat yield was 28 per cent less than for the first 8 years of the period. Manuring brome grass is said to have increased the yield of hay 72 per cent, together with a marked increase in the nitrogen and phosphorus content of the soil.

Clover proved to be more profitable in the rotation than timothy or peas, while alfalfa was also quite profitable. A rotation of corn, wheat, barley, clover, and wheat produced the maximum return, the average annual value of the crops produced from 1910 to 1916, inclusive, amounting to \$24.49 per acre, as compared with \$12.06 for wheat grown continuously.

One-ton applications of fresh and rotted manure resulted in average increases in the value of the crops of \$1.13 and \$1.22, respectively. In view of the loss from rotting and the extra labor involved the trial is held to indicate that it is more profitable to haul manure directly to the field than to compost it.

130002°--19---4

In a comparison of live stock and crop farming an application of manure and phosphorus produced a slight increase in the yield of corn, oats, and barley, while clover has failed to respond either to manure or fertilizer. Increased yields due to the use of mineral fertilizers have not yet been sufficient to cover their cost.

Medium red clover gave satisfactory results when sown at the rate of 5 lbs. per acre with northern-grown seed. *Melilotus alba* appeared to be unable to withstand wet conditions and flooding, being almost entirely killed where red clover survived. Cutting the first crop of sweet clover at different heights resulted in almost no second growth with a stubble of 4 in., a 50 per cent stand with the stubble left at 12 in., and a full stand with the stubble cut to 16 in. Observations on the preparation of silage from sweet clover and alfalfa are said to have led to encouraging results, an excellent grade of silage having been obtained under varying conditions, such as differences in maturity, length of curing, the addition of water, and admixture with other crops. Spoilage almost invariably occurred when the dry matter was less than 25 per cent. Good results were secured even with very dry material providing it was well cut and tightly packed.

A total of 5,933 samples of seeds were analyzed by the seed laboratory during the fiscal year, of which 2,776 were wheat. It was concluded that seed wheat more than a year old should be tested for viability unless it had been kept free from moisture effects during storage. Observations on wilt and canker-resistant strains of flax and on the influence of the imperfect fungi upon the seed and seedling of different crops are mentioned.

Fertilizing the corn crop, C. E. THORNE (Mo. Bul. Ohio Sta., 4 (1919), No. 4, pp. 99, 100, fig. 1).—Briefly reviewing soil fertility work conducted at Wooster and on outlying experiment fields, it is advised that from 150 to 200 lbs. per acre of acid phosphate or steamed bone meal be applied to corn, "with the expectation that while the first year's increase may be small, the systematic repetition of the treatment will be profitable." It is recommended, further, that the fertilizer be applied broadcast, and not only in the hill or drill, in order that succeeding crops may benefit more fully from the unexhausted fertilizer residues.

Cultural experiments with cotton, 1918, W. E. AYRES (Arkansas Sta. Bul. 161 (1919), pp. 3-14, pl. 1, figs. 4).—This describes the continuation of work similar to that previously noted (E. S. R., 39, p. 739).

Planting cotton in check rows 3, 3.5, and 4 ft. apart, with the hills 36 in. apart in the row and with from 1 to 5 plants per hill, resulted in an average yield for 3 varieties of 1,182.8 lbs. of seed cotton per acre. The highest average yield, 1,232.1 lbs., was secured with 2 plants per hill. The 4-ft. rows gave better results than narrower rows, thought to be due to droughty conditions. A comparison of check-row spacing with ordinary spacing resulted in a total average yield of 1,089 lbs. from an average of 10,361 plants per acre for the former method of planting and 1,052.2 lbs. from 12,514 plants for the latter method.

Cotton seeded in drills in the usual manner and unthinned, seeded in hills 12 in. apart and thinned to 1 plant per hill, and seeded in hills 12 in. apart and left unthinned, produced at the rate of 1,036.2, 1,070.9, and 1,184.3 lbs. of seed cotton per acre, respectively. These results are held to indicate that profitable crops may be produced on the more fertile soils without thinning.

Seeding cotton in hills about 15 in. apart with one plant per hill resulted in a total average yield amounting to 1,115.9 lbs. of seed cotton per acre, as compared with 1,112.4 lbs. from a planting rate of 2 plants per hill with the hills about 30 in. apart. Varying the number of plants per hill in hills spaced 18 in. apart resulted in average yields ranging from 1,096.4 lbs, per acre for 1 plant

per hill to 1,323.5 lbs. for 5 plants per hill. Spacing cotton different distances in drill rows 3.5 ft. apart resulted in average yields ranging from 1,011.9 lbs. per acre for plants spaced 36 in. apart to 1,150.1 lbs. for those spaced 3 in. apart. Observations on spacing and time of thinning showed little difference in yield between 6 and 12 in. spacings, while late thinning (with the plants 10 to 12 in. high) produced only 984.6 lbs. of seed cotton per acre, as compared with 1,042.4 lbs. from early thinning. With the plants spaced at a constant distance in the row and with the rows 3, 3.5, and 4 ft. apart, yields of 1,071.2, 1,112.3, and 1,114.8 lbs. per acre, respectively, were secured. With a constant number of plants per acre (8,750), rows spaced 3, 4, 5, and 6 ft. apart, produced 1,264.7, 1,234.2. 1,299.2, and 1,235.5 lbs., respectively. It is stated that replanting with cotton where two-thirds of a stand was secured was not profitable, while replanting with corn practically ruined the cotton.

Planting cotton on ridges or beds resulted in a total average yield of 1,398.4 lbs. of seed cotton per acre, as compared with 1,236 lbs. for level planting.

In 1918 the best results were secured from plantings made the latter part of May, although as a general practice late planting is deemed undesirable. Little difference in yield was observed between deep and shallow cultivated plats. Tests on the value of topping cotton are noted, but the results are deemed inconclusive.

Varieties of cotton, 1918, W. E. AYRES (*Arkansas Sta. Bul. 159 (1919)*, pp. 16, fig. 1).—This reports the continuation of work previously noted (E. S. R., 40, p. 437).

Of 109 varieties grown on small plats at the Scotts substation the three leading sorts both in total yield of lint and in value of seed and lint included Dixie, Lewis No. 63, and Toole, with 723.7, 629, and 618.6 lbs. of lint per acre, respectively. Experiments conducted at Scotts, Van Buren, Burdette, and Monticello with 25 standard varieties of cotton resulted in average returns per acre for seed and lint ranging from \$137.74 for Webber 49 to \$195.24 for Boykin 202. The average length of lint was from  $\frac{1}{32}$  to  $\frac{1}{3}$  in. below the 1917 average, thought to be due to adverse weather conditions. In a comparison of seed of promising strains from different sources, Lone Star 1, valued at \$187.18 per acre, was first at Scotts, and Trice 1, with a total value of \$165.54, first at Burdette. Boykin 202, Express 28–350, and Station Trice, tested on a field scale at Scotts, produced returns valued at \$180.21, \$170.78, and \$145.04 per acre, respectively. Cooperative tests with farmers to study the local adaptation of promising varieties are also noted.

The irrigation of oats, F. S. HARRIS and D. W. PITTMAN (*Utah Sta. Bul. 167* (1919), pp. 3-20, figs. 15).—Irrigation experiments with oats conducted during the period of 1916 to 1918, inclusive, on the Greenville experiment farm, are described in which observations were made on the effect of 5-in. irrigations applied at different stages of growth including the five-leaf, the early boot, the blooming, and the dough stages, respectively, together with weekly irrigations of either 1, 2.5, 5, or 7.5 in. beginning when the crop was 5 or 6 in. high and continuing until it began to turn yellow. During 1916 and 1917 three plats were manured at the rate of 5, 15, and 40 tons per acre, respectively, each plat also receiving an application of 2.5 in. of water. Natural precipitation during the years of the experiment averaged slightly more than 18 in. The results secured are depicted graphically and briefly discussed, and may be summarized as follows:

Of the plats irrigated weekly that receiving 5 in. per week for 6 weeks gave the highest average yield, 79.9 bu. per acre, this also being the maximum yield secured in the experiment. The next highest yield, 79 bu., was obtained with an application of only 15 in. of water applied in 5-in. incremeents at the first three stages of growth. An average yield of 45.6 bu, per acre was secured without irrigation. Where only one irrigation was given the best results were secured from an application made at the five-leaf stage and where two irrigations were given at the five-leaf and boot stages. Where only one irrigation was omitted during the different stages of growth, that made at the dough stage was omitted to the best advantage. Omitting irrigations at either the bloom or the dough stage or both resulted in higher yields of grain than when applications of water were made at all four stages. In general the first irrigations were found to be of most value to the crop, and the second next in order. Applications of water made after seeding but before the grain was up decreased the yield.

The ratio of grain to straw, the height of the plant, the amount of tillering, the weight of the kernels, and the size of head were all affected by the irrigation treatment. Irrigation, especially at the later stages of growth, always retarded maturity. Small applications of manure increased the yield of both grain and straw, but large amounts caused excessive loss of grain through lodging. Twenty acre-in. of water spread over 4 acres of land produced more than three times as much grain as where it was all used on one acre. Under climatic conditions prevailing at Logan, the natural precipitation is said to have been sufficient to produce over 70 per cent of the maximum yield. Finally, these experiments are held to indicate that under the conditions described the best practice in irrigating oats is to make 3 applications of water of about 5 in. each, beginning when the plants are from 6 to 8 in. high and terminating with the blooming period.

Potato studies, C. D. Woons (*Maine Sta. Bul. 277 (1919), pp. 17-32*).—This bulletin comprises a discussion of the food value and mineral content of Maine grown potatoes, the utilization of potato pomace, ridge and level culture for potatoes previously noted (E. S. R., 25, p. 529), and a continuation of observations on nitrogenous fertilizers for potatoes on Aroostook farm and on the effect upon the potato crop of omitting potash fertilization (E. S. R., 39, p. 334).

A comparison of analyses of Maine grown potatoes with similar analyses of potatoes from other American sources is held to indicate that Maine potatoes contain approximately 1.5 per cent more dry matter than all other American potatoes. Spraying potatoes with Bordeaux mixture has resulted in an increase both in the yield of marketable tubers and in the starch content. Steaming potatoes appeared to have little effect on the composition of the dry matter. In feeding experiments with sheep in which raw and cooked potatoes were compared, the dry matter, organic matter, and the starch of the nitrogenfree extract were found to be somewhat more completely digested in the cooked than in the raw material. Similar tests with pigs resulted in a gain of 60 lbs. each in 44 days for pigs fed raw potatoes as compared with a gain of 67 lbs. for those fed steamed potatoes.

Based on the results of an analysis of the ash of Maine grown potatoes, it is estimated that a 250-bu. crop weighing 150 cwt. would remove 56 lbs. of ammonia, 20 lbs. of phosphoric acid, 72 lbs. of potash, and 1.5 lbs. of lime from the soil.

The composition of potato pomace, left as a residue from the manufacture of potato starch, is compared with that of potatoes and the conclusion reached that under present conditions its profitable utilization in this country is not possible.

Fertilizer tests begun in 1914 to determine the best source of nitrogen for potatoes in Aroostook County were discontinued with the 1918 experiments, the results of which confirmed the earlier findings. It is stated that there is apparently little choice in the form of nitrogen to be used on potatoes in this region, and it is suggested that in the fertilizer employed one-third of the nitrogen be supplied from nitrate, one-third from ammonium sulphate, and one-third from high-grade organic matter.

Further observations on the omission of potash in fertilizer tests with potatoes begun on Aroostook farm in 1915 have led to the following conclusions: Good yields were secured without potash. The application of 300 lbs. of common salt per acre resulted in a small but uniform increase in yield over the untreated plat. The application of 45 lbs. of potash per acre (equivalent to 1,500 lbs. of 3 per cent goods) produced a uniform and profitable increase in yield on Caribou loam, while larger applications were not proportionately more profitable. Finally, nitrogen and not potash appeared to be the limiting factor in potato production on this soil.

How to control potato enemies (*Maine Sta. Doc. 535 (1918*), *pp. 16, fig. 1*).— Brief popular descriptions of the insects and diseases affecting potatoes and the nature of the injury produced by each are presented, together with recommendations for their control. Directions as to the time and manner of spraying and formulas for the preparation of insecticidal and fungicidal sprays are included.

Fertilizer experiments with tobacco, W. W. GARNER and D. E. BROWN (Maryland Sta. Bul. 225 (1919), pp. 157-183, figs. 4).—This bulletin describes rather extensive fertilizer tests with tobacco conducted in cooperation with the U. S. Department of Agriculture in Prince George County (southern Maryland). Observations were made on the effect upon the yield and quality of tobacco of applying different combinations and amounts of commercial fertilizers and on the use of lime. The results secured may be summarized as follows:

An analysis of the leaves and stalks of tobacco grown on the experiment field showed that a crop ranging from 1,300 to 1,600 lbs. per acre removed from the soil approximately 35 to 55 lbs. of nitrogen, 10 to 12 lbs. of phosphoric acid. and 55 to 70 lbs. of potash, about one-third of which was contained in the stalks and should be returned to the soil. Nitrogen appeared to be the limiting factor on these soils, inorganic forms such as nitrate of soda and sulphate of ammonia giving better yields than organic forms such as cottonseed meal and tankage, although the latter resulted in a better quality of tobacco than the Phosphates failed to increase the yield of tobacco but stimulated former. growth and promoted the proper ripening of the crop to a marked extent, resulting in a lighter color in the cured leaf. Wheat and other crops following tobacco showed a decided residual benefit from phosphate fertilizing. Potash gave only small increases in yield on "rested" land, while under continuous cropping to tobacco the soil showed a decided need of potash.

The proper ratio between the nitrogen and phosphoric acid in tobacco fertilizers is deemed to be most important, a nitrogen content amounting to from one-half to two-thirds of the phosphoric acid content being recommended for all except quite fertile soil or where a legume has been plowed under. For average soil conditions it is suggested that a fertilizer containing 4 or 5 per cent nitrogen, 8 per cent available phosphoric acid, and 4 per cent potash be applied at the rate of 600 lbs. per acre. Somewhat increased yields resulted from applying the fertilizer in the drill over broadcasting, while the crop also secured an earlier start and usually matured earlier.

Liming produced increased yields of tobacco only when nitrogen was not liberally supplied in the fertilizer through the liberation of nitrogen from the reserve supply in the soil. The darker color of tobacco following liming is said to be due to the excess nitrogen made available to the plant. It is suggested that lime, when used on tobacco soils, be applied to the crop immediately following tobacco in the rotation rather than to the tobacco crop itself. Root-rot diseases of tobacco as a cause of uneven growth (especially on soil cropped continuously or too frequently to tobacco), late maturity, and reduced yields are briefly discussed in connection with investigations by Johnson (E. S. R., 36, p. 349). See also a previous note (E. S. R., 41, p. 39).

## HORTICULTURE.

Adaptation in relation to hardiness, M. J. DORSEY (*Minn. Hort.*, 46 (1918), No. 12, pp. 456-469, fig. 1).—A contribution of the Minnesota Experiment Station, discussing seasonal response, or reaction, of varieties to growing condition as a basis for a clear understanding of what is ordinarily meant, in horticulture, by adaptation and hardiness.

Data are given on experiments conducted by J. C. Whitten at the Missouri Experiment Station and described to the author in a letter, which indicate that there is a fundamental distinction between a variety, or a clone, and a species in respect to differences brought about as a result of reaction or adaptation to their environment. In these experiments seed of native forest trees secured from the northern tier of States so far as possible and from each intervening State to Texas and the Gulf tier were sown at the Missouri Station over 20 years ago. The northern seed came up first generally. The seedlings from the extreme northern seed made far less height growth at first than those from seed obtained in the center of the natural distribution of the species. The northern seed produced trees which, for the first few years, took a much shorter growing period, starting later in the spring and shedding their leaves much earlier in the fall. Some of the seedlings from the South killed back to the ground the first season. The extreme southern seedlings had a relatively brief rest period, pushing out into growth with the first warm days of late winter or early spring and shedding their leaves very much later in the fall. At the end of 10 years practically all the specimens had reached a common habit of growth and seemed essentially equal in their hardiness.

Elberta and Old Mixon Free peach trees, propagated from Michigan and Ontario southward to the Gulf States, were planted out at the Missouri Experiment Station at 1 year of age. Whitten reports that "we have never been able to detect any differences in hardiness, in phenology, or in habit of growth or characteristics of these introduced trees. Evidently if there was any difference in the trees as propagated in these different States that difference was overcome by their first summer's growth here in the orchard."

In order to determine something of the season of maturity in Minnesota of plants from the southern and northern range of a species, 3-eye cuttings were obtained from the wild grape (*Vitis vulpina*) from Arkansas, Missouri, Iowa, and different sections of Minnesota. These were all planted in the same cold frame at the fruit breeding farm at Zumbra Heights. In the fall of 1916 the first killing frost killed the leaves completely on those from Arkansas and Missouri, while those from Iowa north were uninjured. Although the difference in frost resistance was striking, there was no marked difference in maturity between the several lots in the nursery bed, since the leaves were not green on each lot. The author also cites from the experience of Macoun, who found at the Central Farm, Ottawa, Canada, that with apples there is not only a relation between hardiness and early ripening of fruit, but also that in hardy varieties both fruit and wood ripen early.

The field testing of copper-spray coatings, J. R. WINSTON and H. R. FULTON (U. S. Dept. Agr. Bul. 785 (1919), pp. 9, figs. 4).—This bulletin describes a practical method of testing copper-spray coatings that has been used during two

seasons and has been found to be reasonably satisfactory in field practice. Some representative results secured in field trials are given, together with directions for using the method.

In making the test "a 200 gm. fresh weight sample of leaves is washed at least 3 minutes, with occasional stirring, in 1,000 cc. of a 0.2 per cent solution of chemically pure nitric acid in water, either distilled or sufficiently pure to give correct results. A convenient amount of this acidulated wash water is treated with a few drops of 2 per cent solution of potassium-ferrocyanid solution, sufficient to precipitate the copper. A color comparison is then made with a series of known dilutions of a standard copper solution, similarly treated with the potassium-ferrocyanid solution. From this comparison the copper content of the wash water is determined. For more exact readings a colorimeter may be used."

The test promises to be of value to pathological investigators, agricultural experts, and commercial growers, "to secure data showing the persistence of copper-containing sprays as it may be influenced by method of preparation, weathering, or other factors; to determine the minimum and maximum limits of working safety zones, as measured by evenly distributed residues, effective for the practical control of specific diseases; to secure prompt correction of faulty spraying practices, either in the preparation of mixtures or in the times or modes of application, with a view to insuring more effective and economical protection of crops; and to serve as a practical guide in timing new applications, especially after rainy periods."

Report of horticulturist, C. A. McCUE (Delaware Sta. Bul. 122 (1918), pp. 25-28).—A brief statement of progress made in various lines of work.

Variety tests of orchard and small fruits were continued. A list is given of peach varieties recommended for commercial plantings and those which have been rejected as having no value as commercial varieties. In the variety test of cherries Montmorency and various strains of this variety have proved most valuable for Delaware. It appears doubtful whether the sweet cherry will be valuable in Delaware orcharding.

Cover-crop studies in peach orchards have been completed. The results indicate that under Delaware conditions the cowpea is one of the best, if not the best, cover crop for peaches, but that no one cover crop is always best in a given peach orchard. The light and shade factor has an important bearing upon cover cropping. The soy bean is a valuable cover crop and oats is also recommended. Rape and cowhorn turnips may be used for the first three years, but not afterwards. Winter vetch is not a good cover crop for northern Delaware. It is concluded that in most cases sufficient nitrogen for good growth and yield of peaches can be supplied by proper cover cropping with leguminous plants, providing the cover crop is begun early in the life of the orchard and is continuous.

[Report on horticultural investigations] (Georgia Sta. Rpts. 1917-18, pp. 11-13).—Brief statements of progress made with various projects.

As a result of the collard breeding work a new commercial type has been established and the seed introduced to the trade. In the work of breeding and selection for a tomato resistant to blossom-end rot,  $F_6$  generation plants resulting from a cross between the Red Cherry and the Greater Baltimore varieties proved to be susceptible to the blossom-end rot. Since previous filial generations of these plants, partaking more of the Cherry type, were immune to the blossom-end rot it appears that susceptibility has returned with increased size in the process of selection.

A considerable number of hybrids secured in the grape-breeding investigations produced their first fruit in 1918. It was observed that one white staminate vine was decidedly prepotent in stamping good qualities of fruit characters on practically all of its progeny. A certain type of foliage variation was found to be closely correlated with sweetness of fruit. Four new varieties of muscadine hybrids were introduced in 1917, and named by the Georgie State Horticultural Society. Efforts to cross Vitis rotundifolia and V. vinifera failed.

Report of the horticultural division, J. E. HIGGINS (*Hawaii Sta. Rpt. 1918*, *pp. 13-21*, *pls. 2*).—A brief report on extension activities, experimental work, and distribution of plants.

In the fall of 1917 a variety test of garden beans was conducted by J. H. Cowan. It was found that an important factor in successful bean production lies in the susceptibility of the different varieties to the attacks of the melon fly. Twenty-one per cent of the Stringless Green Pod was stung, and varying degrees of susceptibility were shown by the other varieties. Early Refugee and Refugee Wax received no injury whatever from the fly, and the Stringless Refugee and Ventura Wonder Wax suffered less than 1 per cent injury. There was uniformly a very much higher percentage of infestation in the first picking than in the second. After careful tests of cooking qualities, flavor, texture, and absence of strings, it was concluded that the Stringless Green Pod, the Early Refugee, and the Stringless Refugee beans were of most promise both for canning and for table use under the conditions existing at the station.

Tomato crosses were made by J. H. Cowan, with special reference to developing the fly-resistant character of certain small-fruited sorts with the greater size of some of the standard kinds. Flowers of the Earliana were crossed with pollen from the small wild form.  $F_1$  fruits were variable and intermediate in size between the two parents, but they all appeared to be free from infestation, except where otherwise injured. The second generation also is recorded as having been free from attack at the station and many thousands of seeds and seedlings were distributed for further trial. In a cross between Red Pear and John Baer the first generation was practically free from attack of the melon fly, but the second has shown some degree of infestation. Observations thus far made indicate that any tomato to be bred for resistance to the fly must combine both evenness and smoothness of surface. The skin must be tough, with a degree of smoothness amounting almost to slipperiness. A tomato with a slight depression about the stem end is subject to attack, especially if the circle protected by a tightly fitting calyx is not greater in diameter than the length of the ovipositor.

The work with seedling pineapples (E. S. R., 38, p. 841) was continued during the year.

[Report on horticultural investigations in Illinois] (*Illinois Sta. Rpt. 1918*, *pp. 17-19*).—Brief statements are given of progress made in various lines of work.

The orchard fertilizer experiments have shown a progressively increasing yield in nitrogen-fertilized plats over plats not thus fertilized.

Apple blotch was effectively controlled by making applications of either limesulphur or Bordeaux three weeks and five weeks after the fall of the petals. Dusting controlled codling moth and curculio as effectively as spraying, but failed to control the fungus diseases. Calcium arsenate was satisfactory as a stomach poison, and did not injure fruit or foliage. Nicotin sulphate was only of value in controlling aphids. Acid or hydrogen lead arsenate reduced scab infection from 30 to 60 per cent when used without the usual fungicides. Standard commercial lime-sulphur diluted 1: 50 was as effective as a 1:40 dilution. Other conditions being favorable, moderate pruning of winter-injured peach trees gave better results as to form, growth, and fruit buds than severe pruning. Experiments on pear blight showed that infection may be carried by other agencies than insects.

Among the results secured in olericulture, tomato strains have been developed which have proved highly wilt-resistant as compared with commercial strains when grown on badly infected soil. A disease organism causing the rotting of onion sets in storage has been isolated and described. Experiments with greenhouse lettuce and tomatoes have shown that rich garden loam is not inferior to rotted sod as a basic soil for these crops, that large amounts of manure in the soil mixture greatly increase the yield, but that large amounts of sand decrease the yield, since the extra sand displaces a certain amount of fertilizer.

[Report on horticultural investigations in New Mexico] (*New Mexico Sta. Rpt. 1918, pp. 35-41, 44, fig. 1*).—Brief statements of progress made in cultural and varietal tests of orchard and small fruits, nuts, and vegetables.

[Report on horticultural investigations in North Dakota] (North Dakota Sta. Rpt. 1917, pp. 14, 15).—A brief statement of progress.

The station's work in tomato selection has progressed sufficiently to establish definitely the fact that early enough strains are available to make the production of tomatoes practical in that climate. The most promising varieties of celery, sweet corn, cauliflower, and strawberries under test are listed. Pedigreed strawberries have proved to be in most instances the poorest strains grown.

Experiments on the supposed deterioration of varieties of vegetables in Porto Rico, with suggestions for seed preservation, C. F. KINMAN and T. B. MCCLELLAND (*Porto Rico Sta. Bul. 20 (1919)*, *Spanish Ed.*, *pp. 32*, *figs. 11*).—An English edition of this bulletin has been previously noted (E. S. R., 36, p. 340).

Simple methods of celery culture, W. J. GREEN (Mo. Bul. Ohio Sta., 4 (1919), No. 4, pp. 129-134, figs. 4).—Methods of fertilizing, growing, blanching, and harvesting best suited to the home garden are described.

Muskmelon culture in Michigan, C. W. WAID (*Michigan Sta. Spec. Bul. 95* (1919), pp. 13, figs. 10).—Popular instructions are given for growing, harvesting, and marketing muskmelons, including a descriptive list of varieties.

Grafting and budding fruit trees, W. J. GREEN (Mo. Bul. Ohio Sta., 4 (1919), No. 4, pp. 101-105, figs. 5).—Methods of top-working and bridge-grafting fruit trees are described.

The pruning of winter-injured peach trees, A. J. GUNDERSON (Illinois Sta. Bul. 218 (1919), pp. 383-394, figs. 13).—The station conducted experiments in 1918 to determine the best pruning treatment for peach trees seriously injured during the winter of 1917-18. The results, which are here presented in detail, have been summarized in a previous paper by the author (E. S. R., 40, p. 835).

The financial history of a 12-year-old peach orchard, H. J. EUSTACE and F. M. BARDEN (*Michigan Sta. Spec. Bul. 94* (1919), pp. 15, fig. 1).—In continuation of a previous report (E. S. R., 30, p. 443), the annual records are given of a 15-acre peach orchard located near South Haven, Mich.

The net profit from the orchard for the whole 12-year period was \$11,263.05, or a net profit of \$938.58 per year, \$62.57 per acre per year, and 66 cts. per bushel. The orchard yielded a revenue from the interplanted corn crop the first year, but was managed at a loss the three following years, after which it yielded a profit every year.

Description of hybrid plums and other new fruits, C. HARALSON (Minn. Hort., 47 (1919), No. 4, p. 152).—Several plums, a seedling blackberry, and an ornamental cherry sent out for testing in 1919 from the Minnesota State Fruit-Breeding Farm are described.

**Raspberry culture,** R. E. LOREE (*Michigan Sta. Circ. 37* (1919), pp. 16, figs. 11).—Practical instructions are given for the culture and care of raspberries, including a descriptive list of varieties.

The culture of currants and gooseberries, R. E. LOREE (*Michigan Sta. Circ.* 38 (1919), pp. 18, figs. 9).—A circular similar to the above on currant and gooseberry culture.

Almond pollination, W. P. TUFTS (*California Sta. Bul. 306* (1919), pp. 337– 366, figs. 15).—A progress report on a study of the California varieties of almonds with reference to relative sterility or fertility, and the selection of suitable cross-pollinizers for commercial varieties. The data given cover observations and pollinating studies conducted by the author and others at the station for several years.

The results thus far secured indicate that for all practical purposes the cultivated almond is self-sterile, and orchards must be inter-planted with pollinizing varieties if they are to prove commercially profitable. Certain almond varieties are also inter-sterile. A list is given of varieties cross-pollinating satisfactorily. The California at present seems to be the one best pollinizer for all varieties thus far tested which have a coincident period of bloom. With regard to the length of their effective full bloom, the varieties tested are divided into two classes, early bloomers and late bloomers.

In making recommendations of varieties for inter-planting the author has aimed to keep in mind the date of blooming, abundance of pollen, and, to a limited extent, the productiveness and commercial value of the pollinizer. It is advised that care be taken in the arrangement of varieties in the orchard to facilitate cross-pollination and convenience in harvesting. Also, one colony of bees should be provided for each acre of orchard, since pollinizing agencies, such as the honeybee, are necessary to the set of a good crop of fruit.

Fertilizer experiments with rice, bananas, and pineapples, M. O. JOHNSON (Hawaii Sta. Rpt. 1918, pp. 23–25, pl. 1).—In these experiments dilute solutions of fertilizing salts were applied in the form of sprays to rice, banana, and pineapple plants. Ammonium sulphate was the only treatment to give any noticeable increase of yield of rice. Both ammonium sulphate and potassium sulphate solutions stimulated the growth of bananas. With pineapples, ammonium sulphate solution gave good results on manganese soils. Nitrate of lime produced very good results with pineapples on windward Oahu. Inasmuch as only a small amount of fertilizer can be supplied in a single spraying, this method of application does not appear practical except in certain special cases, as on manganese soils where ammonium sulphate can be added to the iron sulphate solution which is already being extensively used for spraying.

A small fertilizer experiment with pineapples was started in the fall of 1917, in the Waipio district of Oahu. Several insoluble fertilizers were applied singly and in mixtures directly in the heart of young plants. Up to the present time, dried blood at the rate of 250 lbs. per acre has given quite striking results. As the result of demonstration experiments conducted at the station this method of top feeding the pineapple with cottonseed meal or dried blood, commonly used in Porto Rico, is now being quite extensively adopted by the Hawaiian growers.

The iron sulphate spraying treatment developed by the station as a practical means for overcoming the various injurious effects of highly manganiferous soils on pineapples (E. S. R., 36, p. 850) has met with continued success and is being used extensively by commercial planters. In practice it has been ob-

#### FORESTRY.

served that iron must be frequently supplied to the plant during the periods of rapid growth, but that comparatively few sprayings are necessary during quiescent periods. Methods of treating manganese soil before planting to supply iron to the plant have thus far given no success, except where stable manure was used, in which case the pineapple is grown on the manure rather than on the soil.

Series of experiments were made with rice grown in nutrient solutions to determine the effect of additions of manganese dioxid and manganous sulphate in the presence of different amounts of ferrous sulphate, preliminary experiments having indicated that the effect of manganese depends largely on the amount of iron supplied by the solution. With the smallest amount of iron supplied, 5 mg. per liter, which was sufficient for the normal growth of the checks, manganese dioxid and manganous sulphate caused an extreme depression in growth, the plants in these solutions being light yellow in color with brownish spots. As the amounts of iron were increased up to the very excessive amount of 80 mg, per liter the injurious effects of the manganese were overcome and growth approached that of the checks. Dipping the leaves of the plants at intervals in a dilute solution of ferrous sulphate was also partially effective in overcoming the injurious effects of manganese dioxid. The experiment was repeated with ferric chlorid and with ferric citrate as sources of iron and gave similar results. The beneficial effect on growth of adding manganese to nutrient solutions claimed by several investigators is believed to be due to the facts that in most cases the effect on growth was determined only by rough measurements of the increase in the height of the plants and that the iron content of the nutrient solutions used was not only sufficient for normal growth but was so excessive as to mask the injurious effects of manganese.

## FORESTRY.

A national lumber and forest policy, H. S. GRAVES (U. S. Dept. Agr., Off. Sec. Circ. 134 (1919), pp. 14; Jour. Forestry, 17 (1919), No. 4, pp. 351-363).— An address delivered before the American Lumber Congress at Chicago, Ill., April 16, 1919, in which the author discusses the problems causing the present unstable condition of the lumber industry, and makes an appeal for cooperation in laying the groundwork for a national policy in carrying out and administering the great private resources of timber so as to prevent the present waste and uneconomic overproduction and at the same time to insure forest renewal. Some of the principles, aims, and problems of such a national policy are briefly outlined. Among other points the acquisition on the part of the Federal Government and the States and municipalities of cut-over and nonagricultural lands, especially those bordered by watersheds, with the object of reforesting them is advocated.

Vacation days in the Battlement National Forest (U. S. Dept. Agr., Forest Serv., 1919, pp. 13, pl. 1, figs. 4).—A popular document describing the recreational features of the Battlement National Forest in Colorado.

Report of the superintendent of forestry, C. S. JUDD ([Bien.] Rpt. Bd. Comrs. Agr. and Forestry Hawaii, 1917-18, pp. 19-46, pls. 9).—A report for the calendar years 1917 and 1918 relative to the work of forest protection and extension, including operations on the Government reserves and nurseries and private planting work.

The work of examining, surveying, and setting aside the main forest reserve system has been concluded. The reserves which are shown on maps now include 814,926 acres, 68 per cent of which is Government land. The results of experi-

#### 1919]

mental planting on Haleakala, Maui, show that temperature zone coniferous trees, such as the Jeffrey pine of California, do well at an elevation of 6,700 ft., with a height growth in 8 years of 11 ft. and a diameter of 3.5 in. Of 18 different kinds of Eucalyptus trees set out in Nuuanu Valley, the Blackbutt shows up best, with a yield of 4.5 cords per acre after 5 years' growth.

Report of the forest nurseryman, D. HAUGHS ([Bien.] Rpt. Bd. Comrs. Agr. and Forestry Hawaii, 1917–18, pp. 47–50).—A brief report for the years 1917 and 1918 relative to collection and exchange of seed, trees distributed from the Government nurseries, and miscellaneous work.

Annual progress report on forest administration in the Presidency of Bengal for the year 1916–17, H. A. FARRINGTON (*Rpt. Forest Admin. Bengal, 1916–17, pp. II+53+4*).—The usual progress report on the constitution and management of the State forests of Bengal. Detailed data relative to alterations in forest areas, forest settlements, forest surveys, working plans, forest protection, silvicultural operations, yields in major and minor forest products, revenue, expenditures, etc., are appended.

Progress report on forest administration in the Northwest Frontier Province for the year 1917–18, R. PARNELL (*Rpt. Forest Admin. Northwest Frontier Prov., 1917–18, pp.* [21]+XXI).—A report similar to the above relative to the administration of the State forests in the Northwest Frontier Province for 1917–18.

Annual progress report on forest administration in the Province of Bihar and Orissa for the year 1917-18, F. TRAFFORD (Ann. Rpt. Forest Admin. Bihar and Orissa, 1917-18, pp. [64]).—A report similar to the above relative to the administration of the State forests in the Province of Bihar and Orissa for 1917-18.

The resources of our colonial forests, H. BOUTTEVILLE (Bul. Soc. Encour. Indus. Nat. [Paris], 118 (1919), I, No. 2, pp. 258-283).—A report on the extent and economic importance of French colonial forests, including a review of the causes which have thus far prevented their exploitation and recommendations relative to means of promoting a greater utilization of colonial woods.

Official note on the colonial woods (*Bul. Soc. Encour. Indus. Nat.* [*Paris*], 118 (1919), I, No. 2, pp. 284–298).—A tabular inventory of exploitable woods of the Ivory Coast and Gabon, Africa, prepared under the direction of the French Colonial Ministry. The woods are grouped into seven different categories, with special reference to European and American woods which they might replace to advantage. Each wood is considered with reference to its botanical and native names, color, texture and general appearance, relative durability, and uses.

Selection and thinning, A. A. L. RUTGERS (Arch. Rubbercult. Nederland. Indië, 3 (1919), No. 3, pp. 105-115, 119-123, pls. 8).—A summary of a lecture on this subject, in which the author reviews the results of a number of selection and thinning experiments to show the importance of these factors in reducing the cost price of raw rubber.

The structure of the lactiferous vessel system of Hevea, W. H. ARISZ (Arch. Rubbercult. Nederland. Indië, 3 (1919), No. 3, pp. 139–155, figs. 12).—In contradiction to results which have been obtained by other experimenters the author found that the various concentric layers of latex vessels in the stem are connected with each other. The greater number of layers at the base of a tree is caused by the existence of communication layers, and only to a very limited extent is due to a few short layers which are connected with the adjacent layers. The lactiferous vessels of the stem have their continuation in the same way in the main root. The number of lactiferous layers in the lateral branches depend upon the age of the branch.

150

In consequence of the existence of communications between adjacent latex vessels, it is concluded that lactiferous layers not opened by the tapping operation can nevertheless in the long run have some influence on the latex yield. Latex obtained from a tapping cut made at the base of the stem can have proceeded from the stem, the main root, or the larger lateral branches and roots. The latex of the leaves and secondary or tertiary lateral branches can not proceed to the cut in view of the fact that a sufficient number of continuous lactiferous vessels has not been developed.

The effect of time intervals in rubber tapping, T. PETCH (*Dept. Agr. Ceylon Bul.* 42 (1919), pp. 8).—Results are given of experiments begun in 1912 to determine the effect on yield of latex of tapping rubber trees at varying intervals.

The experiment, as a whole, shows that the yield of latex per tapping in twice per week tapping is greater than that in thrice per week tapping, but that tapping once per week does not give a greater yield than tapping twice per week. The greatest quantity of rubber was obtained from the most frequent tapping, but the total yield obtained by tapping 3 times per week has been only about 12 per cent greater than that obtained by tapping twice per week. The percentage of rubber in the latex increased as the time interval increased. The difference between the percentages of scrap obtained in tapping twice per week and 3 times a week, respectively, is very small.

Influence of a change in tapping surface on latex and rubber, O. DE VRIES (Arch. Rubbercult. Nederland. Indië, 3 (1919), No. 3, pp. 130-138).—Experiments conducted by the author indicate that when a change of tapping surface is accompanied by a change of tapping system the properties of the rubber may be expected to be affected to some extent. The difference is more marked when changing to heavier tapping than when changing to milder tapping. It is pointed out, however, that the change of tapping surface in ordinary estate routine need not be regarded as a cause of variability, such as undoubtedly is formed by the opening of a new cut or the reopening of a cut after a period of rest.

Rubber tapping experiments: Two cuts v. one cut, T. PETCH (*Dept. Agr. Ceylon Bul.* 41 (1918), pp. 6).—Tapping experiments were started at Henaratgoda in 1916 and continued for about 21 months in which the latex yield from a single oblique cut on one quarter of the tree was compared with the yield from two cuts on the opposite quarter of the tree. In one group of trees the two cuts were made 1 ft. apart and in another group 2 ft. apart. In both groups the lower cut was made about 15 in. above the ground at the same height as the single cut on the opposite quarter.

For the group of trees on which the two cuts were 1 ft. apart, the upper cut at first appeared to stimulate a greater flow of latex from the lower cut than the flow from the single cut on the opposite quarter. This apparently stimulating effect disappeared in a few months, however, after which the flow from the lower cut was less than from the single cut. In the other group of trees with the two cuts spaced 2 ft. apart, the upper cut apparently exerted a beneficial influence on the flow of latex from the lower cut as compared with the single cut throughout the duration of the experiment. In both groups of trees the yield from the upper cut averaged about half that of the lower. The author is inclined to believe that the increased flow of the lower cut in the second group of trees is due to a possible tendency of certain trees to yield more latex on one side than on the other rather than to any stimulating influence of an upper cut. Latex and rubber from upper and lower cut, O. DE VRIES (Arch. Rubbercult. Nederland. Indië, 3 (1919), No. 3, pp. 124–129).—Analyses made by the author indicates that where two cuts are made on one quarter of a rubber tree the latex from the upper and lower cut may for practical purposes be regarded as identical in quality.

# DISEASES OF PLANTS.

**Physiological specialization of parasitic fungi**, G. M. REED (*Brooklyn Bot. Gard. Mem.*, 1 (1918), pp. 348-409).—This paper is the outcome of an attempt to bring together the results of numerous investigations bearing on specialization of fungi in connection with particular hosts. It deals extensively with the Uredineæ, the Erysiphaceæ, and other fungi in relation to other plants as normal or as bridging hosts. It is considered especially desirable to know the exact host relations of the different races, as well as to determine whether the races are stable and constant or whether they are capable of a change in virulence and consequently able to extend their host range.

Studies in the genus Gymnosporangium.—I, Notes on the distribution of the mycelium, buffer cells, and the germination of æcidiospore, B. O. Dodge (Brooklyn Bot. Gard. Mem., 1 (1918), pp. 128-140, pl. 1, figs. 5).—The author reports briefly studies designed to determine the distribution of the mycelium of Gymnosporangium in the different portions of an infected plant.

A method of obtaining abundant sporulation in cultures of Macrosporium solani, L. O. KUNKEL (Brooklyn Bot. Gard. Mem., 1 (1918), pp. 306-312, figs. 4).—Having employed in work previously noted (E. S. R., 31, p. 730) a method of retarding growth of Monilia sitophila by lowering the vapor tension of the atmosphere above the pure cultures, as a result of which the fungus was made to fruit more abundantly than in a moist atmosphere, the author employed this treatment in an effort to induce sporulation in Macrosporium solani. It was found that this fungus would fruit profusely when growing in any of the media employed under such conditions, especially if the mycelium was wounded after the culture had obtained a good start as here described. Contrasts were noted as observed between M. solani, M. tomato, and M. daturæ when these fungi are grown side by side in pure cultures.

Notes on some methods and terms employed in studying the Uredinales, H. R. ROSEN (*Phytopathology*, 8 (1918), No. 11, pp. 581-583).—The author describes the methods and terminology used by J. C. Arthur and those associated with him in preparing the data relating to rusts published in the North American Flora.

The Uredinales of Oregon, H. S. JACKSON (Brooklyn Bot. Gard. Mem., 1 (1918), pp. 198-297).—This represents work by the author and others in collecting material in several portions of Oregon. In all 220 species are recorded as occurring on 500 host plants, the number of species being considered as worthy of mention on account of their economic bearing. All the grain rusts yet recorded for North America are known to occur in the State except the corn rust (*Puccinia sorghi*). All the rusts which are troublesome to florists are represented. The Pacific coast rust of pears and quinces threatens to become of economic importance. Many partially known rusts are found in this section. Notes on distribution are given in some cases. The genera are listed alphabetically and the species thereunder with their host plants.

The relations of crown gall to other overgrowths in plants, E. F. SMITH (Brooklyn Bot. Gard. Mem., 1 (1918), pp. 448-453).—The author proceeds upon the expressed belief that all overgrowths are correlated phenomena, the response of the organism to essentially similar, but not necessarily identical

stimuli, and that visible difference in response when brought about by parasites is due to the number and location of the parasites, age and kind of tissues invaded, and volume, direction, and velocity of the stimulus exerted, every case being primarily a physical stimulus due to changed osmotic pressure rather than a direct chemical stimulus. He discusses briefly the factors governing overgrowth in crown gall, some other types of plant galls, and crown galls formed by extrusion of chemical substances and other effects of parasitic excretions. References are given to literature on the subject.

An automatic spore trap, F. D. FROMME (*Phytopathology*, 8 (1918), No. 10, pp. 542–544, fig. 1).—A description is given of a spore trap in which an alarm clock revolves a Petri dish containing nonnutrient agar, the dish being covered by a metal piece so arranged as to expose one-twelfth of the area of the dish through an hour's time. This trap is said to have been used in studying the dissemination of the basidiospores of *Gymnosporangium juniperi-virginianæ* with rather satisfactory results.

[Plant diseases and treatments], H. E. WATERBURY (*Bien. Rpt. Dept. Agr. Wash.*, 3 (1917–18), pp. 84–87).—The results of tests with a third application of iron sulphid or atomic sulphur for apple powdery mildew indicate that such an application is justified, at least where the infection is pronounced, iron sulphid being the cheaper and more effective. Some very good results were secured by the use of lime-sulphur with atomic sulphur, the results being due apparently to the more rapid volatilization, but these results were more noticeable on the fruit than on the foliage and twigs. Milled sulphur is to be tested in this connection.

Potato seed tubers treated for Rhizoctonia for  $1\frac{1}{2}$  hours with corrosive sublimate at a strength of  $\frac{1}{4}$  lb. to 30 gal. of water showed results as good as those obtained by treating for 2 hours or with a stronger solution. Apparently the same treatment was effective against potato scab.

Experiments with dust sprays applied under somewhat adverse conditions yielded results not quite so good as those with lime-sulphur.

Report of the division of plant pathology, C. W. CARPENTER (Hawaii Sta. Rpt. 1918, pp. 35-45, pls. 3).—Among the diseases reported upon, the author gives a further description of the banana freckle or black spot disease, which has been previously noted (E. S. R., 38, p. 848). This disease seems to be spreading rapidly, causing considerable loss, the infected plants producing undersized, discolored and unevenly ripened fruit. The fungus attacks both leaves and fruit, defoliating and weakening the plants and rendering the fruit so unsightly that it is worthless for market purposes. The results of investigations of the fungus are given, and since the perfect stage is unknown the organism is tentatively described as *Phoma musæ* n. sp. For the control of this disease, the author recommends sanitary measures. A fungus similar to *P. musæ* has been found associated with a black spot disease of algaroba (*Prosopis chilensis*) pods.

Considerable attention has been given to diseases of the Irish potato, some of which seem quite serious in Hawaii. The mite disease previously described (E. S. R., 40, p. 644) is said to yield to dusting with dry sulphur or to spraying with lime-sulphur spray. This trouble seems to be associated with dry weather, and it is not anticipated that it will prove a serious menace to the potato industry at elevations of 1,500 to 4,000 feet except in abnormally dry years. Spraying experiments for the control of late blight are said to have given very satisfactory results. A description is given of a potato variety which exhibits considerable resistance to the late blight.

Notes are given on coffee diseases, as well as miscellaneous insect and fungus diseases observed during the year or not hitherto reported. The author also reports having demonstrated the presence of stomata on the underside of the leaves of pineapple plants.

Pathological laboratory [notes] (Roy. Bot. Gard. Kew, Bul. Misc. Inform., No. 1 (1918), pp. 39-42).—In this portion of the 1917 report it is stated that, although American gooseberry mildew appeared to be absent and whiteheads in wheat less destructive than during the previous year, much browning and scorching of potato foliage was noted. Among the diseases most prevalent were black currant rust (Cronartium ribicola), bean pod canker, potato blackleg and scab, plum rust, die-back and sooty blotch of apples, and onion diseases (Sclerotinia and Botrytis). Notes are also given regarding American gooseberry mildew (Sphærotheca mors-uvæ), parsnip canker, potato wart disease, and apple mildew (Podosphæra leucotricha). A comparative study has been made of the morphology and parasitism of the fungus B. cinerea, particularly in Æsculus pavia and Ribes alpinum. Progress has also been made in the investigation of Thielavia basicola.

Pathological problems in the distribution of perishable plant products, C. L. SHEAR (*Brooklyn Bot. Gard. Mem.*, 1 (1918), pp. 415-422, pls. 3).—In order to indicate the variety and complexity of the problems involved in the transportation of perishable plant products, typical cases are described in connection with suggestions regarding protective measures considered as practicable.

Seed disinfection by formaldehyde vapor, C. C. THOMAS (Jour. Agr. Research [U. S.], 17 (1919), No. 1, pp. 33-39, fig. 1).—In a contribution from the Federal Horticultural Board, U. S. Department of Agriculture, a preliminary report is given of a study of methods of seed disinfection that would be applicable to the treatment of considerable quantities of seed. The author devised a form of apparatus by which formaldehyde vapor may be used, and he reports upon the effect on seeds as well as on fungi and bacteria of various strengths of the vapor employed for different periods of time.

A tabulation is given showing the effect of formaldehyde vapor on 20 different kinds of seeds, from which it appears that little or no injury followed the subjection of the seed for from 1 to 3 hours to the formaldehyde vapor. Studies of various fungi and bacteria showed that the formaldehyde solution vapor destroyed the organisms in about 1 hour if they were exposed in a thin film, but where masses of spores were used more time was required to kill them. Formaldehyde vapor and a 2 per cent formalin solution were compared, 10 different kinds of seeds being used, and in all cases the 2 per cent formalin solution sample was intermediate between the checks and those treated with formaldehyde vapor. The vapor treated samples are said to have been remarkably free from fungi and bacteria.

In conclusion, the author states that the use of liquids for disinfection is unsatisfactory for many kinds of seeds. A number of species of fungi and bacteria were killed when treated for 2 hours with 20 oz. formaldehyde vaporized in 1,000 cu. ft. without any injury to the seeds tested.

An epidemic of corn smut following hail, H. G. MACMILLAN (*Phytopathology*, 8 (1918), No. 11, pp. 584, 585).—An account is given of an epidemic of corn smut following a severe hailstorm in a small district near Greeley, Colo. Sixteen days after the storm, fields of smutted corn were observed averaging 19 per cent of infection, while other fields outside the hail area showed only 1 per cent of infection.

Varietal susceptibility of beans to strains of Collectrichum lindemuthianum, M. F. BARRUS (*Phytopathology*, 8 (1918), No. 12, pp. 589-614, pls. 5).--On account of the possible bearing on plant breeding and also as possibly offering some suggestions as to the factors responsible for resistance to disease, DI

the author has carried on inoculation experiments with about 240 varieties and species of bean and related plants to test their susceptibility to strains of *C. lindemuthianum*, the presence of which was previously reported (E. S. R., 26, p. 747). Several species of Phaseolus and also species of other genera were found to be affected with the anthracnose to some extent, but they were not favorable host plants for the parasite. Some varieties of beans were found susceptible to one strain of the fungus and others to a second. Resistance was found in many distantly related plants. The degree of susceptibility of the different varieties is indicated.

Varieties of beans susceptible to mosaic, D. REDDICK and V. B. STEWART (*Phytopathology*, 8 (1918), No. 10, pp. 530-534).—During the progress of a study of the mosaic diseases of beans, the authors tested the susceptibility to this disease of a number of the more common varieties of *Phaseolus vulgaris*. About 30 varieties showed unmistakable symptoms of mosaic as a result of inoculation, while others which did not develop mosaic as a result of a single test are under further observation.

A storage fermentation of dasheens, O. T. WILSON (*Phytopathology*, 8 (1918), No. 10, pp. 547-549, fig. 1).—From a study of a peculiar rotting of dasheens in storage, the author has found that it is due to yeasts. These under some conditions secure access to the tissues of the corms and tubers and cause a fermentation of the sugars, rendering the affected parts useless for food.

Ramularia root rots of ginseng, C. L. ZINSSMEISTER (*Phytopathology*, 8 (1918), No. 11, pp. 557-571, figs. 8).—A description is given of a disease of the roots of American ginseng popularly known as rust. The roots are said to show dark brown, dry lesions, at first small and scattered but finally becoming widespread and deep-seated. Two types of injury are recognized. In the first, the injury is merely superficial and is confined to a few layers of cells immediately beneath the epidermis. In the second, the lesion extends through the cortex, frequently involving the stele, and in many cases the rot extends throughout the entire cross section of the root. The disease is said to be widely distributed, and it is expected that it will be found in almost all ginseng regions.

A study of the cause of the disease revealed the presence of two species of Ramularia, to which the names R. destructans and R. panacicola n. spp. are given. The cultural characteristics and morphology of the organisms are described, and technical descriptions of both species are included.

Diseases of parsnips, A. D. COTTON (Roy. Bot. Gard. Kew, Bul. Misc. Inform., No. 1 (1919), pp. 8-21, pls. 2, figs. 2).—Recent study of the disease of parsnips known as canker, which does much damage in certain localities or situations (the degree of injury being affected apparently by conditions and varieties), has shown that the trouble is due primarily to physiological phenomena involving rupture not followed by renewal of the surface tissue, and not directly to invasion by fungi, although these organisms are afterwards involved. The contributory conditions are discussed. Preventive measures include rectification of certain cultural practices and the use of potash and salt to retard maturation. Other parsnip diseases are discussed.

Diseases of parsnips, A. D. COTTON (*Jour. Bd. Agr.* [London], 25 (1918), No. 1, pp. 61-71, pls. 2).—This reproduces most of the report noted above on parsnip canker, omitting notes of other diseases mentioned in that article.

Potato leaf roll: Its diagnosis and cause, E. J. WORTLEY (*Phytopathology*, 8 (1918), No. 10, pp. 507-529, figs. 16).—After an account of the losses due to leaf roll of potatoes in Bermuda, the author gives the diagnosis of leaf roll and presents the various theories regarding its cause.

130002°-19-5

Among the symptoms of leaf roll which are often overlooked, the author calls attention to the rolling and rigidity of the lower leaves. The rolling of the upper leaves in some varieties is said to be not particularly conspicuous, while the rolling of the lower leaves seems to be very typical of the disease. Leaf roll may be detected from 5 to 8 weeks after planting, and the author claims that it is safe to assume that if there is no evidence of leaf roll when the plants are 9 weeks old the disease will not develop later.

In discussing causes, the author states that there is little room for doubt that unfavorable climatic conditions in the previous season or seasons are important factors in the development of leaf roll.

Two tomato diseases, E. S. REYNOLDS (*Phytopathology*, 8 (1918), No. 10, pp. 535-542, figs. 2).—Descriptions are given of a chlorosis of the leaves and a fruit rot observed in greenhouse tomatoes in the winter of 1913-14.

The chlorosis is attributed to unknown environmental conditions surrounding the plants when the leaves were in a very young or embryonic condition. The fruit rot, which is considered the same as the blossom end rot, was studied at some length but no causative organisms were found present. The hypothesis is proposed that this disease is due to an organism, probably ultramicroscopic, which infects at pollination time only and causes the rotting area to enlarge until such time as physiological processes of the maturing of the fruit render further invasion impossible.

Tomato wilt (Georgia Sta. Rpts. 1917–18, pp. 14, 15).—A brief account is given of investigations on the tomato wilt due to Fusarium lycopersici. It is reported that the mode of infection has been studied and has been found to be through the root tips, up the water ducts, and into the stem of the plant.

Various soil treatments for the control of the disease have been investigated without any promise of success. It is considered that the breeding of wiltresistant varieties will probably prove the most satisfactory method of control.

The origin and spread of tomato fruit rots in transit, J. ROSENBAUM (*Phytopathology*, 8 (1918), No. 11, pp. 572–580, pl. 1, fig. 1).—As a result of a study of diseases occurring on tomato fruits in transit, the author states that, with the possible exception of Phoma rot and leak due to *Rhizopus* sp., tomato fruit rots found upon the arrival of the car do not originate in transit but in the field and spread from one or more infected fruits included in the pack. The transit and other conditions favoring the development of Phoma rot and leak have not been determined, but overripeness of the fruit and bruises and other injuries are considered as predisposing causes.

From their ability to spread in transit, the author divides tomato fruit rots into three groups, (1) those where the causal fungus can spread and infect adjacent uninjured fruit, (2) those where the causal organism can spread but can infect the fruit only through the stem end or through some break in the skin of the fruit, and (3) those where the fungus is unable to grow through the tomato wrappers and infect healthy tomato fruit. The buckeye rot due to *Phytophthora terrestria* is said to represent the first group. The second group includes the soil rot (*Rhizoctonia* sp.), white rot (*Sclerotium rolfsii*), and leak (*Rhizopus* sp.). Examples of the third group of rots are the nail head spot (*Macrosporium solani*), black spot (*Phoma destructiva*), and anthracnose (*Colletotrichum phomoides*).

An apple canker due to Cytospora, F. L. STEVENS (Illinois Sta. Bul. 217 (1919), pp. 367-379, pl. 1, figs. 15).—A description is given of a canker observed in 1918 on young apple trees. No abrasion or wound seemed to mark the place of the original infection. For the most part the cankered areas exhibited a tan color, the demarcation between diseased and healthy tissues being very sharp.

The disease is apparently of fungus origin. Isolations were repeatedly made, and inoculations from pure cultures on apple, pear, rose, blackberry, plum, and peach twigs kept in test tubes resulted in rapid growth and the development of conditions identical with those observed in the natural canker. No attempts were made to produce the disease on trees in the open, as it was feared from the rapid development made that the disease might occasion serious loss.

The fungus which causes the disease is said to belong to the genus Cytospora, but it has not been specifically identified owing to the confusion between the species of this and closely allied genera on various rosaceous hosts. Lists are given of about 90 species of Valsa and Cytospora which have been reported on various species of Rosaceæ.

A bibliography of the literature completes the publication.

Peach diseases, T. F. MANNS (*Delaware Sta. Bul. 122* (1918), p. 30).—A brief account is given of inoculation work with peach yellows and little peach in the experimental orchard. Natural infection through bruising and rubbing, as by harness, etc., from infected trees to healthy trees was not found to bring about a great amount of infection. The author records the complete recovery of two out of five trees which were inoculated with yellows in 1916 and showed typical symptoms of the disease in 1917, two recovering completely in 1918. Two of the trees of this series are reported as dead and another nearly so.

Placing tree protectors around trees to keep away borers has given very poor results.

Wood rots of peach trees caused by Coriolus prolificans and C. versicolor, J. A. ELLIOTT (*Phytopathology*, 8 (1918), No. 12, pp. 615–617, figs. 2).—Parasitic wood rots of peach trees due to C. prolificans and C. versicolor are described by the author as occurring near Lamar, Ark., on peach trees that had been rather severely cut back. The parasitism of the fungi was considered evident, as the trees had made a vigorous growth for one or two seasons following the cutting back and had then been checked by the destruction not only of the heartwood of the older trees but of the sapwood as well. The destructiveness of the rots is said to have been limited to certain localities, the orchard in question being on relatively low, heavy soil, while in other orchards in the vicinity, on higher ground and lighter soil, trees which had been cut back in a similar way showed no signs of the rot.

A Sterigmatocystis smut of figs, R. W. HODGSON (*Phytopathology*, 8 (1918), No. 10, pp. 545, 546).—The author states that California growers of White Adriatic figs have experienced losses due to a black discoloration of the fruit. A survey was made of some of the packing houses and a considerable quantity of infected figs was found. Cultures made from such figs have uniformly shown the presence of a Sterigmatocystis. The percentage of badly infected fruit is relatively small, but a larger percentage is infected to a slight extent. When opened, these figs show a streak or two of a black, gummy nature which greatly detracts from the appearance of the figs. The gummy masses in small quantity are said not to injure the flavor of the fruit, and such figs can be used in the manufacture of fig paste. The fungus is said to be the same as that causing the internal rot of pomegranates previously described (E. S. R., 28, p. 549).

The prevailing practice in preparing dried figs is to allow them to remain on the ground for 10 days or 2 weeks. The author believes that gathering the fruit at shorter intervals, while resulting in a much better dried fig, will also prevent at least a certain amount of black smut.

Early occurrence of citrus scab in Japan, H. A. LEE (*Phytopathology*, 8 (1918), No. 10, p. 551).—The author notes the occurrence of citrus scab lesions

on *Citrus nobilis* material collected in 1863 at Nagasaki, Japan, and now in the Hongkong Botanic Gardens herbarium.

The problem of the imported plant disease as illustrated by the white pine blister rust, H. METCALF (*Brooklyn Bot. Gard. Mem.*, 1 (1918), pp. 327-333, pls. 2).—Attention is called to the danger and the possibilities that exist in the plant disease situation as outlined and as illustrated by white pine blister rust for 3 sections of the United States. In the first of these, lying west of the Mississippi River, this disease is not known to occur; in the second, east of the Mississippi River to the Hudson River, areas are indicated as heavily infected; in the third, east of the Hudson River, the case is so desperate that only the elimination of all Ribes will save the pines.

The overwintering of Cronartium ribicola on Ribes, H. H. YORK and P. SPAULDING (*Phytopathology*, 8 (1918), No. 12, pp. 617-619).—It is claimed that *C. ribicola* may occasionally winter over on dead Ribes leaves, thus perpetuating the fungus in localities where pines are absent.

Overwintering of the æciospores of Cronartium ribicola, L. DOSDALL (*Phytopathology*, 8 (1918), No. 12, p. 619).—The author reports observing in April, 1918, a branch of white pine which was covered by a heavy infection of white pine blister rust. The branch showed many æcial scars, and a study of the material is believed to have shown that the æciospores produced in 1917 still germinated in the spring of 1918, thus indicating the overwintering of the rust in this manner.

# ECONOMIC ZOOLOGY-ENTOMOLOGY.

Eighteenth report of the State entomologist of Connecticut for the year 1918, W. E. BRITTON (Connecticut State Sta. Bul. 211 (1919), pp. 249-352, pls. 16, figs. 7).—The first part of this report relates to administrative and regulatory work, including the inspection of nurseries, of imported nursery stock, and of apiaries, with locality records of the occurrence of European and of American foul brood in the State. Papers are next presented on Suppressing the Gipsy and Brown-tail Moths in 1918, by W. E. Britton, I. W. Davis, and J. T. Ashworth (pp. 272–290) and on Record of Treatments in an Attempt to Control the Striped Cucumber Beetle (Diabrotica vittata), by W. E. Britton and M. P. Zappe (pp. 290–292) which relates to work carried on in continuation of that commenced several years ago. Of the several treatments which gave favorable results the first in the order of effectiveness is lead arsenate and powdered sulphur, equal parts, dusted on both sides of the leaves. Spraying experiments in orchards at Clintonville, by M. P. Zappe (pp. 292, 293) are in continuation of those of the previous year (E. S. R., 39, p. 760), the results of which are presented in tabular form.

Tests of Sprays to Control the Potato Aphid, by W. E. Britton and M. P. Zappe (pp. 294–297), a summarized account of which is noted on page 162, show that kerosene emulsion will destroy all lice hit, while the materials cost about half as much as nicotin and can be obtained at any grocery store. A summarized account of the oriental peach moth (pp. 298–306) here presented is based upon the papers by Wood and Selkregg (E. S. R., 39, p. 259) and by Garman (E. S. R., 39, p. 260) previously noted.

In a report of studies of the peach twig moth it is stated that attention was called to its presence in the State to an extent not before realized. The account includes a bibliography of 22 titles.

The Life History and Development of the Greenhouse Cockroach (*Pycnoscelus surinamensis*), by M. P. Zappe (pp. 311-313) supplements a detailed account previously noted (E. S. R., 39, p. 761). This paper includes descriptions of the
immature stages, observations on its life history, and effect of cold. There were found to be six molts, the average length of time for reaching the adult stage being about 7.5 months.

In a discussion of the occurrence of the European house cricket (*Gryllus domesticus*) (pp. 313-316), M. P. Zappe gives a brief summary of information relating to it and records its occurrence in the attic of a new house at Shelton where it annoyed the occupants by its nightly chirpings and by getting into the food in the pantry on the floor below. This infestation was controlled by the use of poison baits, one of which contained borax and the other bichlorid of mercury.

A summarized account of the European corn borer (*Pyrausta nubilalis*), which may occur in Connecticut (pp. 316–327), includes an annotated bibliography of 21 titles. In a brief account of the bean leaf beetle (pp. 327–329) it is stated that it was reported in 1918 as injuring beans in Connecticut for the first time for many years.

Injury by the raspberry sawfly (*Monophadnoides rubi*) (pp. 329–331) in a field of about an acre of red raspberries in New Haven is reported upon in which at the time of examination on May 29 practically all the old leaves had been eaten while the new and tender shoots were uninjured. It is pointed out that since there is only one brood each year, treatment by spraying with helebore or lead arsenate is a simple matter if applied in season. The spraying must be done soon after the plants blossom and may be applied even before they blossom to prevent defoliation.

The Iris root borer (Macronoctua onusta) (pp. 331–333) which was a source of injury to Iris beds through tunneling in the root stalks is briefly considered. A brief account of garden slugs (pp. 333-336) is followed by a report of mosquito work in 1918 (pp. 337-340) by B. H. Walden. A note on entomological features of the season is followed by miscellaneous insect notes, which deal with a larva on tartarian honeysuckle (Harpipteryx sp.), the clavate tortoise beetle (Coptocycla clavata), abundance of potato or cucumber fleabeetle, the rose chafer, salt marsh caterpillar feeding on beans, abundance of 3-lined potato beetle (Lema trilineata), birch leaf skeletonizer (Bucculatrix canadensisella), leaf tyer on rose (Tortrix albicomana), Schizura unicornis on hickory, the saddled prominent in Litchfield County (Heterocampa guttivitta), absence of tent caterpillar, an orchid weevil in Connecticut (Diorymellus lævimargo), Chamyris cerintha feeding on privet, white woolly larvæ on hickory (Erythraspides carya), the chrysanthemum gall midge (Diarthonomyia hypogea), Calosoma sycophanta, the stalk borer in corn, the poplar girdler (Saperda concolor), the elm leaf beetle, a tip borer in garden Physostegia (Olethreutes hebesana), and a rare moth (Tetralopha robustella) attacking white pine.

[Insect notes] (New Mexico Sta. Rpt. 1918, pp. 24, 25).—In work with the squash bug it was found that blackleaf 40 (1:400), with soap 4 lbs. to 100 gal. killed all up to the next to the last stages that are hit. Two applications of this spray at intervals of a week controlled a severe infestation. The chrysomelid beetle Coptocycla clavata, whose native host plant is Physalis spp., attacked chili plants to a considerable extent in limited areas. Eutettix tenella was the source of considerable destruction through its transmission of curly leaf infection.

Thirty-third report of the State entomologist on injurious and other insects of the State of New York, 1917, E. P. FELT (N. Y. State Mus. Bul. 202 (1917), pp. 240, pls. 12, figs. 82).—In his report to the director of the State Museum the author includes a discussion of the occurrence of the more important insects of the year and work carried on with them.

[Vol. 41

Under the heading of Injurious Insects, work with the codling moth in continuation of that of the previous year (E. S. R., 40, p. 162) is first discussed, the details relating to experimental work being reported in part in tabular form. The general conclusions drawn are similar to those of the previous year.

A brief summary of information on the apple and thorn skeletonizer (*Hemerophila pariana*), together with a bibliography of 17 titles, is given. An account of this insect by the author has been previously noted (E. S. R., 38, p. 60).

The potato aphis (*Macrosiphum solanifolii*), next considered, occurred in great numbers during 1917 and was a source of considerable loss, particularly in the southeren part of the State. Experiments during the year are said to have demonstrated the efficacy of the nicotin soap preparations (0.75 pint of 40 per cent nicotin to 100 gal. of water to which are added from 6 to 8 lbs. of any cheap soap).

Under the heading Notes for the Year, the author discusses the more important fruit tree insects, small fruit insects, grass and grain pests, garden insects, and gall insects. Part 6 of A Study of Gall Midges (E. S. R., 40, p. 163), which deals with the tribe Itonididinariæ, is appended (pp. 76–205).

[Experimental entomological work], H. E. WATERBURY (Ann. Rpt. Dist. Hort. Insp. Yakima County, Wash., 1917, pp. 25-54, fig. 1; Bien. Rpt. Dept. Agr. Wash., 3 (1917-18), pp. 78-87).—Experiments with paste arsenate of lead for control of the codling moth confirm the results obtained the previous year (E. S. R., 38, p. 653). Four lbs. to 50 gal. of water shows about 10 per cent more clean fruit than 2 lbs. to 50 gal., and 30 per cent more clean fruit than 1 lb. to 50 gal. The results indicate, however, that 4 lbs. to 50 gal. is not necessary throughout the season, but that the beneficial results of the stronger solution are gained in the later applications.

In the experimental work, powdered arsenate of lead gave over 14 per cent more clean fruit than paste lead of equivalent strength. The results obtained from the use of nicotin sulphate during the year failed to confirm the earlier results (E. S. R., 38, p. 653), and led to the conclusion that nicotin under lower valley conditions is not so effective against codling moth as is arsenate of lead. In one experimental plat the nicotin was as effective as the lead but no more effective.

The use of calcium arsenate as a spray was unsatisfactory, due to its effect on fruit and foliage. This effect was noted about the middle of July, and by picking time a considerable proportion of the leaves had fallen and a burned area around the stems of some of the apples was noticeable. In addition there was a larger percentage of windfalls on the plat sprayed with calcium arsenate, this doubtless being due to the burning of the stems. The author considers it probable, however, that the burning was in part due to the condition of the orchard, which was allowed to become very dry during the summer.

The use of distillate oil emulsion at the rate of 1.5 gal. to 100 gal. of water destroyed the red spider with a single spray, and there was no burning or any other injury noticeable.

A summary is given of the results obtained from banding 230 trees for the codling moth.

Insects injurious to the hop in New York, with special reference to the hop grub and the hop redbug, I. M. HAWLEY (New York Cornell Mem. 15 (1918), pp. 147-224, figs. 62).—This is a report of investigations commenced in the spring of 1913 and continued in 1914 and 1915, the greater part of the account relating to investigations of the hop vine borer or hop grub (Gortyna

*immanis*) and methods of control. Two new pests, the hop redbug (*Paracalocoris hawleyi*) and the filamented looper (*Nematocampa limbata*) were also studied, as was the hop snout moth (*Hypena humuli*), an old but little-known pest. In addition some control experiments were conducted with the hop aphis under New York conditions, and notes are presented on several pests of lesser importance, namely, the red spider or spider mite (*Tetranychus telarius*), the hop merchants (*Polygonia interrogationis* and *P. comma*), leaf hoppers (*Empoasca flavescens* and *E. flavescens birdii*), a milliped (*Julus caruleocinctus*), a leaf miner (*Agromyza* sp.), flea beetles (*Psylliodes punctulata* etc.), and leaf rollers (*Archips rosaceana* and *A. argyrospila*). A list of several others is included.

The hop vine borer is a native insect, widely distributed in the northern United States and in Canada, which is only known to reach maturity on the hop. The injury is done to the head of the hop, the inside and outside of the vines, and in the roots. The loss occasioned varies greatly in different years and in different yards in any one year. In one yard in which the author worked, there were 90 dead vines in 100 hills, or a total loss of 20 per cent from the work of this insect, which is said to be a conservative estimate for the yard.

The eggs are laid on grass in and around hop yards from the middle of August to the last of September. The winter is passed in this stage and they hatch from the last week in April to the last of May. In an examination of distended females dissected, 866, 725, 457, and 612 eggs were obtained. Upon hatching out the larvæ make their way into grass or hop plants. "In grass they eat into the stem near the surface of the ground and feed upward, killing the central blade. They leave the grass at about the time other larvæ leave the inside of the hop. In the hop the young grubs enter the part that is the most readily available and easy to penetrate, which may be the head or any part of the vine. If the larva enters the head, it drops to the ground in about two weeks and helps to increase the large number already working in the vine near the root. About the first of June, when the larva is in the third or the fourth stage, it stops inside work and either feeds on the outside of the vine, nearly or quite severing it, or makes burrows in the root. In July or the first part of August the larva pupates, and the moth emerges the last of August or early in September." There appears to be six larval stages, the entire length of which is from 9 to 12 weeks. The length of the pupal stage in the laboratory varied from 35 to 37 days.

*Microplitis gortynæ*, a braconid, is a common parasite of the larva and two tachinids (*Frontina frenchii* and *Masicera myoidea*) apparently attack it. Control work, the details of which are reported in tabular form, has led to the recommendation (1) that all extra vines be pulled and removed some distance from the yard before June 1, (2) that the hops be hilled so as to give the extra rootlets an opportunity to grow, (3) that clean cultivation be practiced by removal of grass from the yard, and (4) that a plowed border several yards wide be maintained around the field. The use of paradichlorbenzene, a few crystals in each hill and covered with about 2 in. of dirt, about the third week in May may prove to be worth while.

The hop redbug has caused conspicuous injury to the foliage by perforations of the leaves and also a stunting and deformation of the stems during the past few years in yards about Waterville. The injury which it causes may be recognized by the deformed and stunted vines and the irregular holes in the leaves. The eggs which are inserted in the bark or the wood of hop poles from the middle of August to the middle of September hatch during the following June, or an egg period of 9 to 9.5 months, There are five nymphal stages for the

[Vol. 41

development of which 28 to 31 days are required. The application of nicotin sulphate, 1 pint to 100 gal. of water with 6 lbs. of soap added, on July 17 apparently killed the bugs at once. A weaker solution (3/8 pint to 100 gal.) appears to be insufficient for control.

The hop snout moth, which so far as known feeds only on the hop, has been found by the author to strip the hop vine of its leaves occasionally, but there has not been a general outbreak during the past five years. The eggs of the first brood are deposited about the middle of May on the underside of the hop leaves and hatch in three weeks. Eggs of the second brood have been found from July 28 to August 11. The larval stage of the first brood averages 25.3 days and the pupal stage 13 days. Full-grown larvæ of the first brood have been taken from June 17 to July 21, and those of the second brood from August 15 to September 6. Two tachinid flies (*Masicera rutila* and *Exorista hypenæ*) are said to parasitize the larvæ. The application of powdered arsenate of lead mixed with the sulphur used for hop mildew, at the rate of 1:10, has been effective in its control.

The filamented looper, a general feeder widely distributed in the eastern part of this continent, while not of great economic importance at the present time, is increasing in abundance and may become a serious leaf-eating pest of the hop. It is said to have been found on the hop in large numbers near Sangerfield, N. Y. The eggs, which are deposited beneath the bark or in cracks of hop poles the latter part of August, pass the winter, and hatch from the middle of May to the last of the following June. A period of about 10 months is passed in the egg stage, an average of 28.8 days in the larval stage, and 13.5 days in the pupal. Control measurers for the hop snout beetle should hold the filamented looper in check.

The hop aphis, which in some years has caused almost total loss of the hop crop, is briefly reported upon. Control experiments have led to the recommendation that nicotin sulphate 1:2,000 with soap be applied the last week in June or the first week in July.

The spider mite occasionally appears in hop yards in New York, but has never caused any serious damage as it has on the Pacific coast.

A bibliography of 33 titles and a list of 14 references to the literature cited are included.

The Ohio wheat survey, H. A. GOSSARD and T. H. PARKS (*Jour. Econ. Ent.*, 12 (1919), No. 1, pp. 58-66).—Substantially noted from another source (E. S. R., 39, p. 863).

Insects in relation to wheat flour and wheat flour substitutes, R. N. CHAP-MAN (*Jour. Econ. Ent.*, 12 (1919), No. 1, pp. 66-70).—Substantially noted from another source (E. S. R., 40, p. 59).

Some new phases of the entomology of disease, hygiene, and sanitation brought about by the great war, W. D. PIERCE (*Jour. Econ. Ent.*, 12 (1919), No. 1, pp. 42-47).

Grasshopper control in Indiana, J. J. DAVIS (Indiana Sta. Circ. 88 (1919), pp. 8, figs. 9).—This is a brief popular account of means for grasshopper control based upon cooperative work with the Bureau of Entomology of the U. S. Department of Agriculture.

The meadow plant bug, H. OSBORN (*Maine Sta. Bul. 276 (1919), pp. 16, pl. 1, figs. 5*).—This is an account of *Miris dolabratus* based upon the more detailed paper by the author previously noted (E. S. R., 40, p. 260).

Kerosene emulsion v. nicotin solution for combating the potato aphid, W. E. BRITTON and M. P. ZAPPE (*Jour. Econ. Ent.*, 12 (1919), No. 1, pp. 71-81).— The authors found that kerosene emulsion, made at the rate of 3 cakes of laundry soap (30 oz.), 4 gal. of kerosene, and 2 gal. of hot water diluted to make 50 gal., is effective in combating the potato plant louse, all the aphids hit

make 50 gal., is effective in combating the potato plant louse, all the aprilas hit by the spray being killed. The materials used for the emulsion cost about half as much as for nicotin solution, and possessed the additional advantage of being obtainable at any grocery store.

Life history and habits of the mealy plum aphis, W. M. DAVIDSON (U. S. Dept. Agr. Bul. 774 (1919), pp. 16, pls. 2).—For many years the mealy plum aphis (Hyalopterus arundinis) has been a source of injury in California to plums and prunes, and to a lesser extent to apricots, having been specially severe in some regions since 1913, particularly where artificial control of the pear thrips was not practiced.

Though of European origin, the species is widely distributed in North America and is known to occur in Australia, New Zealand, Java, and Japan. In California plums and prunes of the *P. domestica* type are the favorite hosts, but apricots and Asiatic types of plums and rarely almonds are also attacked, while in Europe grape, peach, and nectarines are attacked. Its injury is caused in the early summer months on the lower surface of the leaves and the petioles and upper surface are frequently infested. The young fruit is less commonly attacked. The leaves become curled and discolored and the tree produces fruit of small size and an early drop. In the years 1915 and 1916 an unusual midsummer apical cracking of green prunes developed in California.

The eggs, which are almost invariably laid in the axils of lateral buds of year-old or 2-year-old wood, commenced in 1916 to hatch about March 4 and continued for about 2 weeks. The early stem mothers began reproduction about March 20. Observations made at Walnut Creek between August, 1915, and December, 1916, are summarized as follows: "It appeared that normally from 3 to 5 generations were raised on the winter hosts, but rarely series of wingless generations persisted until the fall. The aphids of the earlier generations were mostly wingless like the stem mothers, and the individuals of the later generations mostly winged, and after the middle of June virtually all the insects produced developed wings.

"Migration to the summer hosts, Phragmites and Typha, began the last week in April and continued until August, the great body traveling in early June. On these hosts about ten generations took place, continuing up to November. The vast majority of aphids to be found during the summer were wingless, but winged parthenoparous individuals were also produced on the summer host plants, and these served to distribute the species among these plants. About the middle of October and for six weeks succeeding, winged sexuparous migrants and winged males were produced, and these flew to the fruit trees, whereupon the sexuparæ proceeded to deposit sexual females. The sexes were most abundant during the forepart of November and were to be found as late as the middle of December. Oviposition took place throughout November and December, the majority of ova having been placed before December 10."

Mention is made of a number of predatory enemies, of which it has many, but internal parasitism is said to occur rarely.

"There are two specially vulnerable periods in the annual life cycle of the mealy plum aphis—one in early spring when the stem mothers are growing and the other in late fall when the sexual females are developing on the winter hosts... Contact insecticides, which have little effect on aphids of the intermediate generations, easily destroy the stem mothers and the egg-laying females."

Seventeen-year locusts due in western Ohio, H. A. GOSSARD (Mo. Bul. Ohio Sta., 4 (1919), No. 4, pp. 124–128, fig. 1).—This article calls attention to the expected appearance of the periodical cicada over the western half of Ohio

10 and gives advice as to prevention of demage and

during the summer of 1919, and gives advice as to prevention of damage and remedies.

An European scale insect becoming a menace in Pennsylvania, J. G. SANDERS (Jour. Econ. Ent., 12 (1919), No. 1, pp. 90, 91).—Lecanium prunastri, which has in recent years become established in Pennsylvania, having been recorded a number of times from various places in central Pennsylvania at rather widely scattered points, has become sufficiently abundant in a few localities in the past two or three years to cause genuine damage and alarm to fruit growers. Some branches of the peach are said to have become completely covered with the scale, badly dwarfed, and ultimately killed. In orchards where the customary winter dormant spray with lime-sulphur is practiced the scale has not assumed dangerous proportions. Peach, sweet cherry, and apricot are its principal host plants.

Recent results in the fumigation of citrus trees with liquid hydrocyanic acid, R. S. WOGLUM (*Jour. Econ. Ent.*, 12 (1919), No. 1, pp. 117-123, pl. 1).—The author describes the successful use of liquid hydrocyanic acid in California, where he has been conducting an investigation of it with special reference to dosage requirements and during 1918 closely followed the fumigation of more than 500 acres of citrus trees.

In an experiment to determine the diffusion of the gas it was found that in each of 7 tented trees scale-kill was more effective against the purple scale toward the bottom of the tree than toward the top. Similar results were obtained from 6 small trees infested with the red scale (*Chrysomphalus aurantii*) fumigated with liquid hydrocyanic acid, thus differing from pot generated gas with which the killing effect is decidedly better toward the top of the tent. In this respect liquid hydrocyanic acid fumigation is advantageous, since the infestation of scale insects on large citrus fruit trees is usually most severe on the lower or more protected part of the trees, this being especially true of the purple scale.

The other advantages in favor of liquid hydrocyanic acid indicate that this new method will displace all others. "The cost of tent mending is almost entirely done away with, as liquid hydrocyanic acid is harmless to cloth. The treatment of small trees, frequently with such poor results in the past, can be performed with greater accuracy and corresponding certainty of results. Greater speed in tree treatment can be attained than previously, and it appears possible that the quantity of hydrocyanic acid required for scale-kill can be slightly reduced over that formerly required."

[Codling moth investigations] (*New Mexico Sta. Rpt. 1918, pp. 41-43*).— This is a brief statement of investigations carried on in continuation of those reported in a bulletin previously noted (E. S. R., 39, p. 765). The spraying work is reported in tabular form.

The status of the oriental peach moth, E. N. CORY (*Jour. Econ. Ent.*, 12 (1919), No. 1, pp. 81-84).—A brief statement of the occurrence of *Laspeyresia* molesta in Maryland, an account of which pest by Garman is given in a bulletin previously noted (E. S. R., 40, p. 756).

Euclemensia bassettella, the Kermes parasite (Microlepidoptera, Tineoidea, Oeceophoridæ), A. H. HOLLINGER and H. B. PARKS (*Ent. News, 30 (1919), No. 4, pp. 91–100, pl. 1*).—The authors review the literature relating to this microlepidopteran, and report observations on its occurrence in Missouri and Texas. These are followed by an account of its biology at College Park, Tex.

The species is shown to be a Kermes parasite and not a gall feeder as previously reported. The larvæ have habits differing from those of other Kermesinfesting Lepidoptera. There appears to be but one generation a year, and no parasites are known to attack any stage of this lepidopterous parasite of Kermes. In a few cases this parasite is said to have been abundant enough to materially reduce the coccid.

Practical application of the methods recently discovered for the control of the sprinkling sewage filter fly (Psychoda alternata), T. J. HEADLEE (Jour. Econ. Ent., 12 (1919), No. 1, pp. 35-41, pls. 2, figs. 4).—A description of the application of the method recently described by the author and Beckwith (E. S. R., 40, p. 356).

The rose midge, E. R. SASSCER and A. D. BORDEN (U. S. Dept. Agr. Bul. 778 (1919), pp. 8, figs. 2).—The location of an infestation by Dasyneura rhodophaga of a rose house at Colgate, Md., in the fall of 1916, where it has caused an annual loss of from \$4,000 to \$6,000, led to the investigations here reported, which were conducted in cooperation with the Maryland Experiment Station.

The eggs of this midge, which are deposited just under the sepals of the flower buds or between the folded leaves of the leaf buds, hatch in 2 days and the larvæ immediately attack the buds, extracting the sap and eventually causing the petals and leaves to dry up and die. They reach maturity in from 5 to 7 days, and then work their way out of the buds and fall on and enter the ground, where they construct small silken cocoons in which to pupate. The adults appear in from 5 to 7 days and shortly thereafter commence oviposition. Thus under greenhouse conditions the life cycle is passed in from 12 to 16 days. At Colgate the larvæ were especially injurious from the latter part of May to early July and from early September to November 1. Roses, especially the hybrid teas, are apparently the only plants which it attacks.

Experiments are reported in which a number of formulas were tested. The results show that severe infestation can be controlled, if not entirely eliminated, in a comparatively brief period by careful application of tobacco dust on the soil and by the persistent nightly fumigation with tobacco, in the form of stems, nicotin papers, or one of the volatile nicotin preparations. Where earth walks are present it is advisable to spray the walks also with a 5 or 10 per cent kerosene emulsion. In the case of light infestations, the midge can be controlled by systematic nightly fumigations with tobacco fumes, which should be continued until all adults disappear, or by a careful application, at the proper season, of tobacco dust. "The most opportune time to apply the dust, if not accompanied with nightly fumigation, is during the latter part of October or the first three weeks of November, at which season the last generation of larvæ leaves the plants, enters the ground, and constructs overwintering cocoons. If dependence is placed on the dust alone, it is imperative that the application be so timed as to be on the soil before the larvæ seek winter quarters."

A list is given of 8 references to literature cited.

Ground beetles attacking crops in Mysore, L. C. COLEMAN and K. KUNHI-KANNAN (*Dept. Agr. Mysore, Ent. Ser. Bul. 5* (1918), pp. 16, pls. 2, figs. 2).— Two ground beetles, namely, *Gonocephalum hofmannseggi* and *G. depressum*, are common in Mysore. The larvæ usually attack the roots of grass and the adults feed on decaying vegetation, but both may attack a summer crop like the potato. "The larvæ become pests of ragi (*Eleusine coracana*) in regions of deficient rainfall when the rains are delayed after sowing and the larvæ have not sufficient moisture to pupate. Crops like the potato grown in summer are also liable to attack, mainly by the adults which are attracted to it.

"The life history usually takes a year, the larval life being confined to the hot weather. The beetles emerging after the first heavy rains remain inactive until December, following when they commence to breed. A second brood is possible in years when the first heavy showers are followed by a drought of two or three months.

"The past may be controlled by the collection of beetles in October by means of fresh weeds pulled out along with roots and spread along the bunds. There are three enemies, an acarid on the adult, **a** wasp, and an ichneumon on the larva. These are not efficient checks."

The life cycle of Lachnosterna lanceolata, W. P. HAYES (*Jour. Econ. Ent.*, 12 (1919), No. 1, pp. 109-117, figs. 2).—This is a report of studies conducted at the Kansas Experiment Station.

L. lanceolata, an important enemy of growing wheat in Kansas and Oklahoma, is regarded as most injurious in west central Texas. During the past few years grubs of this species have come into prominence every fall soon after wheat planting time in southern Kansas and northern Oklahoma, where they annually damage thousands of acres of young winter wheat. The species is practically confined to the region bounded on the west by the Rocky Mountains and on the east by the Mississippi River.

The eggs are laid singly or in small groups of three or four in clumps of soil at depths ranging from 1 to 7 in. during the months of June and July. They hatch in an average of 16 days (9 to 29) during July and August and the larvæ are present until June of the second year, giving a larval stage of slightly over 22 months. The pupæ, which occur in June and July, require an average of 13.8 days (8 to 20). Two full years are required for development, and in some cases where the larval stage is prolonged, three years may be required. The generations overlap each other so that all stages appear every season.

A list is given of 27 food plants upon which the species has been observed feeding in the fields.

Sarcophaga prohibita has been reared and is thought to be a true parasite of the pest. Rotation of crops is one of the best means of control thus far known.

Biological notes on some flat-headed bark borers of the genus Melanophila, H. E. BURKE (Jour. Econ. Ent., 12 (1919), No. 1, pp. 105–108).—This paper deals with 12 species of flat-headed bark borers of the genus Melanophila that have been most destructive to forest trees. One species, M. drummondi, is of particular interest because it attacks the Sitka spruce, used in the manufacture of aeroplanes, while M. genitilis, M. fulvoguttata, and M. californica attack and kill some of the most important coniferous forest trees. Many sugar pine, yellow pine, Douglas spruce, true firs, true spruces, hemlocks, and larches have been killed at various times past and are now being killed by these pests.

Comprehensive demonstration of Argentine ant control, R. S. WOGLUM and A. D. BORDEN (*Cal. Citrogr.*, 4 (1919), No. 6, pp. 147, 171, figs. 3).—It is pointed out that the very direct relation of the Argentine ant in the control of mealy bugs of citrus trees was demonstrated in 1915–16 in several infested orchards in the San Gabriel Valley of California during an investigation of the common mealy bug. The trees rid of this ant quickly became freed of mealy bugs and continued in a commercially clean condition, while trees frequented by ants remained severely infested.

The following formula for a poison sirup, the Barber formula (E. S. R., 35, p. 761) modified to meet arid conditions, is recommended by the authors after two years of successful use in combating the Argentine ant in more than 600 acres of citrus orchards: Granulated sugar 12 lbs., water (distilled) 10 pints, tartaric acid (crystallized) 0.25 oz. Boil 30 minutes, cool, add distilled water to allow for evaporation. Dissolve sodium arsenite (C. P. only)

0.75 oz. in hot water (distilled) 1 pint, cool. Add poison solution to sirup and stir well. Add to the poison sirup, honey (strained) 2 lbs. Mix thoroughly. The cost of treating orchards for ant control is said to be cheaper than fumigation or spraying, and so low that the owner of infested property can ill afford not to avail himself of this method. In response to a petition of the citrus fruit growers in the Upland district, control measures against the citrophilus mealy bug were instituted and a campaign started in September, 1917, in an orchard infested by both mealy bugs and the ant. An inspection of the orchard in April, 1918, showed that 98 per cent of the trees of the first half treated were free of ants, and that 62 per cent of the part treated in November were clean. "The effectiveness of the sirup in the first demonstration was so apparent within a few weeks after its distribution that control efforts were rapidly extended to neighboring orchards and by the beginning of 1918 more than 150 acres had been treated. At the present time the ants have become not merely controlled but totally eradicated over this extensive area.

"This ant work has been extended during 1918 by more than 350 acres, practically all of which is in commercial control. An area of approximately 550 acres of citrus orchards practically in a solid block has been subjected to control of the Argentine ant within 16 months following the institution of a demonstration at Upland, and stands as an example of the possibilities in control and eradication of this insect through persistent and concerted action of fruit growers."

## FOODS-HUMAN NUTRITION.

The antiscorbutic value of cabbage.—I, The antiscorbutic and growthpromoting properties of raw and heated cabbage, E. M. DELF (*Biochem. Jour.*, 12 (1918), No. 4, pp. 416-447, pls. 2, figs. 5).—The author reviews the work of Holst and Frölich (E. S. R., 27, p. 567) on the antiscorbutic value of fresh raw cabbage and of cooked cabbage, and reports an extensive study of the same subject, using guinea pigs as the experimental animals.

The standard basal diet was a mixture of rolled oats and bran ad libitum with water and, in cases where the rations of cabbage were small, with a daily supplement of 60 cc. of milk autoclaved for one hour at 120° C. The cabbage was given in the green leaf.

From the series of experiments with raw cabbage the conclusion is drawn that under the conditions of the experiment a 1 gm. ration of fresh cabbage may be regarded as the minimum for protection from the symptoms usually diagnosed as scurvy. On a 0.5 gm. ration, well-marked symptoms of scurvy were obtained. Apparently satisfactory growth and health were obtained with from 1.5 to 5 gm. when 60 cc. autoclaved milk was added daily to the diet, although suggestions of soreness during life and the histology of the bone cartilage junctions indicated a condition of incipient scurvy. With a ration of 30 gm. of fresh cabbage, normal growth took place with an increase of about 100 per cent in 90 days.

A comparative study of the antiscorbutic value of cabbage after exposure to various temperatures for different intervals of time showed that the antiscorbutic factor is exceedingly sensitive to temperatures below 100°. The rate of destruction, however, is increased only about threefold for an increase in temperature of 30 to 40°, as shown by the fact that 5 gm. of cabbage cooked for one hour at 60° was about equal in antiscorbutic value to 5 gm. of cabbage cooked at 100° for 20 minutes and to 1 gm. of raw cabbage. It is pointed out that this low temperature coefficient is in opposition to the view that the antiscorbutic factor is a complex protein or an enzym-like substance.

In applying the foregoing results to methods of cooking vegetables, the author points out that slow cooking at a low temperature is much more deleterious than more rapid cooking at a high one, and that, consequently, as far as antiscorbutic value is concerned, the longer time needed in a fireless cooker is a great disadvantage in the case of green vegetables, such as cabbage. Evidence is also given that vegetables should be steamed rather than boiled in water, and if boiled should be boiled in water only, the addition of either acid or alkali to the water increasing the loss of antiscorbutic vitamins.

In experiments in which larger rations of cabbage were given heated to temperatures from 100 to  $130^{\circ}$  for periods of one to two hours, the destruction of antiscorbutic properties, though extensive, was less complete than was to be expected from the results at lower temperatures. A suggested explanation of this discrepancy is that the antiscorbutic value of a diet may be enhanced and may show greater heat stability when the antiscorbutic factor and the growth fat-soluble factor are derived from the same foodstuff. The greater heat stability of the fat-soluble factor is also shown from the fact that heating for one to two hours at temperatures from 100 to 120° produced only a slight effect.

The article concludes with an appendix by F. M. Tozer on the histological diagnosis of experimental scurvy, with diagrammatic drawings made from histological preparations of the rib junctions of animals used in the experiments described and which demonstrate the more important histological changes observed in animals suffering from scurvy in varying degrees. The diagnosis made from the histological preparation independently of the diagnosis of the condition seen during the life of the animal or in post-mortem examination in most cases tallied closely with the latter.

The antiscorbutic value of cabbage.—II, The effect of drying on the antiscorbutic and growth-promoting properties of cabbage, E. M. DELF and R. F. SKELTON (*Biochem. Jour.*, 12 (1918), No. 4, pp. 448–463, figs. 2).—From feeding experiments similar to those noted above, it was found that there was a loss in antiscorbutic properties of more than 93 per cent when cabbage was dried at a low temperature ( $60^{\circ}$  C.) and stored subsequently for two to three weeks at laboratory temperatures. This loss increased with prolonged storage until at the end of three months nearly all the protective value of the fresh material was lost. By plunging the cabbage into boiling water before drying, the residual amount of antiscorbutic factor was distinctly greater, indicating that killing the cells by heat before drying is beneficial in lessening the amount of destruction taking place during drying.

In the drying and storing of the cabbage there was also found to be a decided destruction of the fat-soluble growth-promoting factor, which was estimated at 86 per cent after only two weeks' storage.

The results in general are thought to agree with those of Holst and Frölich (E. S. R., 27, p. 567), and of Givens and Cohen (E. S. R., 40, p. 172).

Utilization of Burma beans for human nutrition, ROTHEA (Ann. Falsif., 11 (1918), No. 121-122, pp. 361-369).—Determinations of the hydrocyanic acid content of Burma beans and of the water in which they have been soaked and cooked are reported, which indicate that in the processes of soaking and boiling usually employed about seven-eighths of the hydrocyanic acid is removed.

The author concludes that Burma beans, even those containing 0.03 per cent of hydrocyanic acid, can be consumed by adults without danger, provided the beans have been soaked in a large volume of water from 12 to 24 hours and boiled for 3 hours in a fresh quantity of water. In no case should the water in which soaking and boiling have taken place be used. The use of these beans in hospitals and for making bean broth for infants is considered inadvisable. Moisture in wheat and mill products, J. H. SHOLLENBERGER (U. S. Dept. Agr. Bul. 788 (1919), pp. 12, figs. 2).—The moisture requirements of wheats for milling purposes, the amount of moisture added during tempering, the moisture content of wheat and various streams of mill stock, and the loss of moisture during grinding, as well as related subjects, were taken into account in this experimental study. The results are summarized as follows:

"The decrease in the moisture content of the various roll streams from the head to the tail of the milling process was closely related to the amount of water added to the wheat during tempering.

"It appeared that very little of the moisture added to the wheat during tempering penetrated farther than the pericarp or outer coatings of the kernel. The moisture content of the better grades of flour milled, irrespective of the amount of water added during tempering, closely corresponded to the percentage of moisture contained in the untempered wheat. The amount of water added in tempering compensated for the evaporation of moisture during milling only in the case of one of three mills examined."

Influence of electrolytes upon the viscosity of dough, L. J. HENDERSON, W. O. FENN, and E. J. COHN (Jour. Gen. Physiol., 1 (1919), No. 4, pp. 387-397, figs. 5).—The effect of H-ion concentration and of salts upon the viscosity of dough was determined by measuring the resistance of a definite amount of dough to stirring when packed in a torsion viscosimeter. It was found that with variation in H-ion concentration viscosity passes through a minimum a little on the acid side of pH 5. The addition of a small amount of salt to dough diminished viscosity, while as the concentration of the salt increased there was commonly a later rise in viscosity. Of the salts studied, the sulphates of sodium and magnesium had the most marked effect. The influence of salts upon viscosity was found to vary with the H-ion concentration. At a more acid range of reaction sodium chlorid depressed the viscosity greatly, while calcium chlorid lowered the viscosity in a less acid range.

The results are thought to indicate that in bread making the action of acids, bases, and salts, perhaps with the exception of potassium bromate, is favorable chiefly through the effect upon viscosity, and that any influence upon the activity of yeast is apparently a matter of secondary importance.

Compressed yeast as food for the growing organism, P. B. HAWK, H. R. FISHBACK, and O. BERGEIM (*Amer. Jour. Physiol.*, 48 (1919), No. 2, pp. 211-220, figs. 2).—Feeding experiments with rats to determine the growth-promoting porperties of baker's yeast (Fleischmann) are reported.

The addition of the compressed yeast to the extent of 5 per cent of the dried yeast by weight of the total diet caused an immediate and pronounced increase in body weight. This increase was found to be more rapid and pronounced when the diet contained case in than when the protein of the diet was furnished by lean meat. Heating to 105° C. did not destroy the growth-promoting properties of the yeast."

Cheese poisoning: A toxicogenic bacillus isolated from cheese, W. LEVIN (Jour. Lab. and Clin. Med., 2 (1917), No. 11, pp. 761–784).—The morphological and cultural characteristics, pathogenicity, and toxin formation are described of an organism known to have produced several cases of cheese poisoning. The organism, while belonging to the colon group as proved by its morphological and biochemical reactions and agglutination tests, differed from the true colon bacilli in its ability to form a soluble thermostabile poison or toxin of unknown chemical composition.

Toxin formation by a variety of B. botulinus when cultivated aerobically under various conditions: Its possible production in the animal body, L. P. SHIPPEN (Arch. Int. Med., 23 (1919), No. 3, pp. 346-361).—A study conducted at the Bureau of Chemistry of the U. S. Department of Agriculture is reported of the toxin production of a strain of *Bacillus botulinus* under unfavorable conditions, such as might occur within and without the animal body in nature.

The organism, isolated from cottage cheese that had caused an epidemic diagnosed post-mortem as botulism, was found to be a distinct variety of the *B. botulinus* of van Ermengem, differing from it in the following particulars: It is more toxic for rabbits and less toxic for cats. It grows and produces toxin at 37° C, and in sugar-free media of acidity of +3. It does not lose its ability to produce toxin after being exposed to light for two and one-half months and being dried on paper for 22 days. In symbiosis with a yeast it can be cultivated aerobically on agar slants. Grown with *B. coli* and a yeast in milk or with *Micrococcus aureus* in extract broth at 38 to 39° under aerobic conditions it produces death when ingested by a rabbit.

It is thought that the toxin produced under certain conditions by this strain might cause death by embolus or hemorrhage in the brain, accompanied by but few preliminary symptoms of a minor character, but that there always remains the possibility of the organism growing in the body and producing its toxin slowly and under altered conditions, thereby causing a different syndrome from that seen when the toxin is ingested. The author is of the opinion that some cases of forage poisoning may be due to certain strains of *B. botulinus*.

Digestibility of some by-product oils, A. D. HOLMES (U. S. Dept. Agr. Bul. 781 (1919), pp. 16).—This continues the experimental study of digestibility of vegetable fats and oils previously noted (E. S. R., 39, p. 591). Digestion experiments were made with six oils, all by-products of considerable interest in connection with the oil industry in general.

The coefficients of digestibility of the oils are given as 98.4 per cent for apricot-kernel oil, 98 per cent for cherry-kernel oil, 98.2 per cent for melon-(cantaloup) seed oil, 96.6 per cent for peach-kernel oil, 98.2 per cent for pump-kin-seed oil, and 95.8 per cent for tomato-seed oil. This indicates that these oils are very well assimilated by the body and possess a nutritive value equal to that of other better-known edible oils, such as cottonseed, corn, peanut, coconut, soy bean, and olive oils. In general the experiments indicate that as far as tolerance and assimilation are concerned all six of these oils, which at present are practically unutilized, are wholesome, nutritious foods, and should prove satisfactory for edible purposes.

The twenty-third report on food products and the eleventh report on drug products, 1918, E. M. BAILEY (Connecticut State Sta. Bul. 210 (1919), pp. 177-242).—In addition to a number of proprietary remedies, toilet preparations, and other drugs, the following food products were examined and results discussed: Tea, fats and oils (cooking fats, olive oil, butter, oleomargarin, and nut margarin), cereal products (substitute flours, breakfast foods, and health foods, etc.), fruit juices, carbonated beverages, dried eggs and egg substitutes, milk, cream, sausage, vinegar, wine, nonalcoholic beverages, and sirups. A number of foods were also tested for the presence of saccharin, suspected injurious foreign substances, etc.

"Forty-four samples of market teas, mostly of cheaper grades, have been examined... Hot water extract exceeds 40 per cent in 7 cases and exceeds 35 per cent in 43 cases of the total of 44. Ether extract is lower in black tea than in green tea, as would be expected from the fact that chlorophyll, which comprises a large portion of such extract, is largely destroyed in the process by which black tea is made."

In discussing the results of the examination of margarins and nut margarins, it is stated that "nut margarins differ from oleomargarin in that they do not contain the fat of slaughtered animals. They are chiefly composed of coconut fat with admixtures of other vegetable fats or oils to give the proper consistency. Peanut or cottonseed oils are used for this purpose. The fats are ripened with milk to which a culture of lactic acid-forming bacteria has been added, in order to impart the flavor of butter. They are quite perishable products and manufacturers do not encourage jobbers to keep large quantities on hand, preferring to have them supplied with fresh material. Benzoate of soda is used as a preservative in some cases, which is legal, provided the amount does not exceed 0.1 of one per cent, and is so stated. The color dispensed with nut margarins ... [was] found to be annatto." The results of the analyses of 8 samples of nut margarin varied considerably. However, the average was found to be as follows: Moisture 10.99 per cent, protein  $(N \times 6.25)$ 1.39 per cent, fat 84.76 per cent, free fatty acids, as oleic, 0.61 per cent, ash 2.85 per cent, refractometer reading at 40° C. 38.6, and Reichert-Meissel number 6.63.

Drugs and foods, C. D. Woons (*Maine Sta. Off. Insp., 91 (1919), pp. 20*).— Data regarding examinations of butter, ice cream, molasses, opened clams and oysters, and a large number of drug products are included in this report. In commenting on the work with ice cream it is stated that the standard was placed high, and that for the most part there had been intelligent desire on the part of ice cream manufacturers to maintain the standard.

Animal calorimetry.—XV, Further experiments relative to the cause of the specific dynamic action of protein, H. V. ATKINSON and G. LUSK (*Jour. Biol. Chem.*, 36 (1918), No. 2, pp. 415–427).—In continuation of work previously noted (E. S. R., 39, p. 772), the authors have investigated further the specific dynamic action of the proteins. In the experiments reported it is shown that 200 cc. of 0.4 per cent hydrochloric acid may slightly increase the metabolism of a dog, that aspartic acid, asparagin, and succinic acid exert no specific action upon metabolism, and that acetamid is not deaminized by the dog and does not increase its heat production.

These results appear to confirm the conclusion previously drawn (E. S. R., 33, p. 755) that the processes of deamination and urea formation have nothing to do with the specific dynamic action of protein, and to refute the conclusions of Grafe,<sup>1</sup> who attributes the stimulating action of proteins to the amino groups.

The reason for the specific dynamic action of protein, W. E. BURGE (*Amer. Jour. Physiol.*, 48 (1919), No. 2, pp. 133–140, figs. 3).—Experimental evidence is given to show that the introduction of small amounts of glutamic, aspartic, and succinic acids, asparagin, and acetamid produces no increase in catalase while large amounts do produce an increase in catalase. It is pointed out that this is in keeping both with the observation of Atkinson and Lusk noted above, that small amounts of these substances do not produce an increase in catalase and with Grafe's observation <sup>1</sup> that large amounts increase oxidation.

It is also shown that the amino group in the protein molecule renders protein, or meat, a more effective stimulant to catalase production and hence to heat production than fat and that the glycerin radical in the fat molecule renders fat more effective than sugar.

Accessory factors in the nutrition of the rat, A. HARDEN and S. S. ZILVA (*Biochem. Jour.*, 12 (1918), No. 4, pp. 408-415, figs. 7).—Feeding experiments to test the adequacy for rats of diets lacking in fat-soluble A, water-soluble B, and the antiscorbutic factor, respectively, are reported from which the conclusions are drawn that an antiscorbutic does not fulfill the physiological function of

130002°-19---6

fat-soluble A when it replaces it in the diet, and that rats subsisting on a diet containing the antiscorbutic as well as the water-soluble and fat-soluble factors grow better than rats on a diet from which the antiscorbutic factor is absent.

The authors confirm the observation of McCollum and coworkers (E: S. R., 38, p. 568) and of Drummond (E. S. R., 38, p. 503) that by depriving rats of the antineuritic factor a dietetic deficiency is brought about, as a result of which neuritic lesions are produced in the animal resulting fatally if the diet is not rectified in time.

The influence of internal secretions on the formation of bile, A. W. Downs and N. B. EDDY (*Amer. Jour. Physiol.*, 48 (1919), No. 2, pp. 192–198).—Evidence is given from the use of dogs and cats as experimental animals that the amount of bile secreted is increased by secretin, decreased by adrenalin and by mammary, orchic, ovarian, pancreatic, and thymic gland substances, and is not affected in a constant or definite manner by the substances of the spleen and thyroid gland.

**Observations on the catalytic power of blood and solid tissue,** F. C. BECHT (*Amer. Jour. Physiol.*, 48 (1919), No. 2, pp. 171–191, fig. 1).—The author reports the results of investigations of the catalase content of blood and tissues under different conditions by the use of a method which in the case of blood is said to give results accurate to within 5 per cent in most cases. Accurate results could not be obtained in the case of solid tissues, the error being from 5 to 20 per cent.

The catalytic power of the blood was found to vary from 100 to 1,000 per cent in animals of the same species under the same conditions and to vary widely in the blood of animals of different species. The activity was confined to the corpuscle, and was not influenced by the oxygen-carrying power of the blood. Thyroid feeding, contrary to the findings of Burge et al. (E. S. R., 38, p. 870), decreased instead of increased the catalytic power of the blood. There was a slight increase in the catalytic activity of the blood during ether anesthesia, which is also contrary to the results of Burge.

The author concludes that since the catalytic power of the blood varies between such enormously wide limits "we do not believe that the catalases can be particularly important, and hence do not believe that a study of catalases can possibly explain the mysteries of the processes of oxidation."

Method of estimating energy expenditure by indirect calorimetry, E. P. CATHCART (Jour. Roy. Army Med. Corps, 31 (1918), No. 5, pp. 339–352, figs. 4).— This article includes a theoretical discussion of the principles underlying indirect calorimetry and a detailed description of the procedure involved in the Douglas bag method of estimating energy expenditure by indirect calorimetry. Diagrams are given of the Douglas bag and of the Haldane apparatus for analyzing the sample of air.

## ANIMAL PRODUCTION.

The endocrine organs.—An introduction to the study of internal secretion, E. A. SCHÄFER (London and New York: Longmans, Green & Co., 1916, pp. IX+156, figs. 104).—This monograph is designed for those who require a somewhat more elaborate treatment of the ductless glands than is afforded by the ordinary text-book of physiology. The thyroids and parathyroids, adrenal capsules, and the pituitary body are dealt with in some detail, while the thymus, the pineal gland, the mucous membrane of the duodenum, the pancreas, the testicle, the ovary, the corpus luteum, the uterus, the mammary gland, and the placenta receive more summary treatment. The illustrations are mainly tracings showing the influence of extracts on muscular action and drawings of histological preparations.

The placenta regarded as a gland of internal secretion, R. T. FRANK (Surg., Gynecol., and Obstet., 25 (1917), No. 3, pp. 329–331).—A review of the literature is given and a statement made of experimental results secured by the author.

Injection of placental extract caused great increase in functional activity of the mammary gland and the uterus of rabbits. The extract was found to have chemical characters and physiological effects closely resembling those of corpus luteum extract. It is suggested that the placenta does not secrete a hormone of its own but merely acts as a storehouse for corpus luteum secretion, especially during the latter part of pregnancy.

Histological study of ovaries engrafted on castrated male guinea pigs and removed at the onset of lactation, M. ATHIAS (*Compt. Rend. Soc. Biol.* [*Paris*], 79 (1916), No. 12, pp. 553–556).—The author has examined histologically 8 guinea pig ovaries that had been grafted under the skin of young castrated males of the same species. After an interval of time the mammary gland of the male became functional. The four grafts removed during the first three days of lactation are reported on here. Interstitial gland tissue and numerous mature and atretic follicles were found, but no true corpora lutea.

On the causes responsible for the developmental progress of the mammary glands in the rabbit during the latter part of pregnancy, J. HAMMOND (*Proc. Roy. Soc.* [London], Ser. B, 89 (1917), No. B 622, pp. 534-546, pl. 1).—As a result largely of the work of Ancel and Bouin (E. S. R., 21, p. 669), the author regards it as established that the corpus luteum provides the stimulus for the growth of the mammary gland during the early stages of pregnancy. His object in the present paper is to report investigations dealing with the development of the mammary gland during the glandular phase, which in rabbits begins about the sixteenth day of pregnancy.

Contrary to accepted belief the corpus luteum of pregnant rabbits was found not to become atrophied during the latter part of gestation, but to maintain its size even into the period of lactation. In a series of "pseudo-pregnant" rabbits, i. e., females made to ovulate by coitus with vasectomized males, the corpora lutea and mammary glands developed as in pregnant individuals until the sixteenth day after coitus and then decreased in size. By operative mutilations of the uterus of certain pseudo-pregnant does, the author caused the development of masses of decidual cells identical in appearance with the maternal placenta. In such animals the corpora lutea and the mammary gland followed the same course as in ordinary pseudo-pregnant individuals. Pregnant females, from which the fetuses but not the maternal placentæ were removed by operation on the thirteenth to fifteenth days of gestation, also showed atrophy of corpora lutea and mammary glands. It is held that the presence of embryos is necessary for continued existence of corpora lutea, and that the presence of the latter stimulates the mammary gland to complete development.

The cyclic changes in the mammary gland under normal and pathological conditions, L. LOEB and C. HASSELBERG (*Jour. Expt. Med.*, 25 (1917), No. 2, pp. 285-321).—Two studies are presented based upon the histological examination of the mammary gland in normal guinea pigs and those that had been subjected to various operations.

I. The changes in the nonpregnant guinea pig (pp. 285-304).—A definite 15 to 19 day cycle was found in the activity of the mammary gland of the non-

pregnant guinea pig, corresponding to the cycle in the ovary and uterus. Cell division and other proliferative phenomena are at their maximum during the period of heat and ovulation, and at their minimum from the sixth to about the fifteenth day after ovulation. The presence of a functioning corpus luteum seems to inhibit proliferation.

II. The changes in the pregnant guinea pig, the effect of the lutein injections, and the correlation between the cycle of the uterus and ovaries and the cycle of the mammary gland (pp. 305–321).—In 26 normal guinea pigs the mammary gland was examined during different periods of pregnancy. Proliferation becomes regular only after the twenty-fourth day, when gestation is about two-fifths over, and continues apparently until lactation becomes well established. When abortion took place not more than 15 days before term, the gland changed from a proliferating to a secreting organ. In cases where it was possible to remove the ovaries in the early stages without causing abortion, no proliferative changes occurred. Extirpation of the corpora lutea during pregnancy induced a new ovulation and with it the primary proliferation in the mammary gland. Intraperitoneal injections of lutein (from the cow) did not affect proliferation.

The relation of the ovary to the uterus and mammary gland from the experimental aspect, L. LOEB (Surg., Gynecol., and Obstet., 25 (1917), No. 3, pp. 300-315, fig. 1).—In this paper the author presents a general review of the literature and an interpretation of the observations of others in the light of his own publications, some of which have been previously noted (E. S. R., 27, p. 174).

Ovulation in some species of mammals is accompanied by marked degeneration of the larger follicles of the ovary. In forms where the production of corpora lutea is not periodic but initiated by the act of copulation, the cells surrounding the degenerating follicles enlarge and assume a glandular appearance. It is suggested that the use of the term interstitial gland be restricted to glandular tissue of this type. The presence of a uterine placenta hinders rupture of the corpus luteum of pregnancy. The existence of a corpus luteum prevents ovulation in most mammals. Corpora lutea have been produced experimentally without ovulation in rabbits and guinia pigs by cutting a mature follicle. Heat is probably brought about by absence of a corpus luteum and presence of mature follicles in the ovary. The corpus luteum does not interfere with the maturation of follicles.

The relation between the ovary and the mammary gland has not been completely analyzed. During heat and subsequent to ovulation, the gland grows by proliferation of cells. After the corpus luteum develops, these changes cease and the gland secretes milk. The response of the gland to corpus luteum extracts varies in different animals.

On the behavior of the mammalian ovary and especially of the atretic follicle towards vital stains of the acid azo group, H. M. EVANS (*Proc. Soc. Expt. Biol. and Med.*, 13 (1916), No. 4, pp. 80, 81).—By administering dyes of the acid azo group to the female mammal—dogs being apparently the chief subject of experiment—the author finds that he can identify those ovarian follicles that are about to undergo atresia, but which have not yet shown any morphological changes. The granular cells of follicles in the preliminary stage of retrogression take up the dye and store it as cytoplasmic granules. "The conditions which bring about this reaction are typically seen in the atresia which always overtakes the next succeeding crop of Graafian follicles after fertilization of the preceding crop, but this behavior is not repeated further in the pregnancy, where now other forms of atresia may come in. Enough warrant consequently exists for the recognition of types of atresia the occurrence of which is related with certainty to what one may broadly term the cycles undergone by the ovary in general."

The macrophages which invade the zona pellucida of the atretic ovum also react to these dyes but in a different manner.

The noneffect of corpus luteum preparations on the ovulation cycle of the rat, G. W. CORNER and F. H. HURNI (*Amer. Jour. Physiol.*, 46 (1918), No. 4, pp. 483-486).—It is stated that unpublished work of J. A. Long and H. M. Evans shows that the ovulation cycle of rats varies from 4 to 11 days but is fairly constant for a particular female. The corpora lutea persist several weeks, during which time the cycles continue and new corpora are produced.

During the first 4 days following parturition rats were injected daily by the authors with one of Evans's intravitam stains known to color the existing corpora lutea an intense blue. On alternate days thereafter 10 of the rats received doses of commercial extract of corpus luteum from the cow and on the twenty-fifth day were killed. Their ovaries showed from 13 to 30 unstained corpora, about the same number as that found in control animals receiving only the injection of dye. The results are contrasted with those of Pearl and Surface (E. S. R., 32, p. 671) who found corpus luteum extract to reduce ovulation in laying hens.

Corpus luteum and the periodicity in the sexual cycle, L. LOEB (Science, n. ser., 48 (1918), No. 1237, pp. 273-277).—In this discussion the author points out that the presence of the living corpus luteum of pregnancy does inhibit ovulation, and that this fact can not be disposed of by experiments like those of Corner and Hurni and some of his own in which injections of dried lipoidfree lutein derived from a different species failed to modify ovulation.

Continuous and discontinuous variations and their inheritance in Peromyscus, F. B. SUMNER (Amer. Nat., 52 (1918), Nos. 616-617, pp. 177-208; 618-619, pp. 290-300; 620-621, pp. 439-454, figs. 13).—This paper treats of differences in structure (weight, body length, tail length, foot length, ear length, and number of caudal vertebrae) and in pigmentation (intensity, distribution) of four geographical races of deer mice of the genus Peromyscus occurring in Cali-That the differences are hereditary is shown by their persistence fornia. under changed environment and by the magnitude of the coefficients of correlation between parents and offspring. Hybrids between the races are found to be intermediate in character and just as variable in the  $F_1$  as in the  $F_2$  generation. These subspecific characters, it is held, exhibit continuous variation and blended inheritance, and the author puts them in a class distinct from certain "mutations" that have occurred in his cultures, notably a pale, spotted, redeyed form and a yellow form that have proved to be simple Mendelian recessives to the wild type. The author insists that it rests with the "pan-Mendelians" to show that these two types of variation belong to a single category, that of discontinuity.

The factors for yellow in mice and notch in Drosophila, W. A. LIPPINCOTT (*Amer. Nat.*, 52 (1918), No. 618–619, pp. 364, 365).—This note calls attention to the possibility that a factor might be dominant to its allelomorph in one of its manifestations and recessive in another. The yellow mouse case could be interpreted in this way without postulating two separate but completely linked factors, yellow and lethal, as is done by Ibsen and Steigleder (E. S. R., 38, p. 573). A similar explanation offered by T. H. Morgan for some Drosophila results is cited.

Report on commercial feeding stuffs, 1918, E. M. BAILEY (Connecticut State Sta. Bul. 212 (1919), pp. 353-395).—Report is made on samples of feeding stuffs collected by the station's agent during December, 1918, and January, 1919, and those submitted by the dairy commissioner and private individuals during the year. Proximate analyses are published of cottonseed meal, cottonseed feed, linseed meal, wheat bran, wheat mixed feed, wheat middlings, rye feed, rye middlings, barley feed, barley mixed feed, ground barley, corn gluten feed, hominy feed, yellow hominy feed, corn feed meal, brewers' dried grains, distillers' dried grains, dried beet pulp, velvet bean feed, peanut-oil meal, copra cake meal, and various proprietary stock feeds, calf meals, and poultry feeds. Reports on condimental foods and remedies are also included.

The international trade in feeding stuffs (Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 4, pp. 467-510; 8 (1917), No. 4, pp. 489-551).—Statistics are given following the plan previously noted (E. S. R., 33, p. 664). They show the production, foreign trade of the various countries, and prices of residues of the milling, oil, sugar, and brewing and allied industries, also of residues of animal origin. Extensive bibliographies are included.

International trade in concentrated cattle foods, G. DE BRANCION and E. VAN DE WEYER (Internat. Inst. Agr. [Rome], Internat. Trade Concent. Cattle Foods, No. 4 (1918), pp. 72).—The information noted above is published in another form and according to a slightly different plan.

Steer nutrition (*Georgia Sta. Rpts. 1917–18, p. 13*).—In the course of digestion trials, it was found that the time required for feed residues to pass through the alimenary tract of a steer varied from 2.9 to 5.2 days, finely divided material being excreted in the shortest time. Rapidity of passage was associated with lowered digestibility in the case of crude fiber.

Range cow maintenance project on Russian thistle silage (*New Mexico Sta. Rpt. 1918, pp. 62, 63*).—Silage made exclusively of Russian thistle was found to have a disagreeable odor when fresh and to deteriorate rapidly upon exposure to the air, but silage made from a mixture of Russian thistle and corn meal (100:1) proved satisfactory and maintained the body weights of 5 range cows fed no other feed for 20 days. At the end of the test each cow was eating about 40 lbs. per day. It is suggested that a few stalks of corn or sorghum might be substituted for the corn meal.

Milk ration for dairy calves (North Dakota Sta. Rpt. 1917, pp. 18, 19).— It was found that a group of 4 calves, each fed 16 lbs. of skim milk and 1 lb. of boiled flaxseed per day, was essentially equal in thrift and general development at the age of 6 months to another group fed 8 lbs. of whole milk and 8 lbs. of skim milk per head daily. Both lots were fed whole milk exclusively until 3 weeks old, and began to have grain added to the milk ration when 5 weeks old.

Quantity and composition of ewes' milk: Its relation to the growth of lambs, R. E. NEIDIG and E. J. IDDINGS (Jour. Agr. Research [U. S.], 17 (1919), No. 1, pp. 19-32).—This paper from the Idaho Experiment Station furnishes individual data for 18 ewes (3 typical specimens each from 6 breeds) as to amounts of milk produced and its specific gravity and chemical composition on the tenth, twentieth, thirtieth, fortieth, and fiftieth days after parturition and the weights of the ewes and their lambs on these days. The amounts of milk were determined by weighing the lambs before and after suckling. The milk samples for analysis were secured by milking one side of the udder by hand while a lamb suckled the other side. The breed averages for milk yield and chemical composition are summarized in the following table:

176

Breed.	Average daily milk yield.	Specific gravity.	Composition of milk.					
			Casein.	Albumin.	Non- protein nitrogen.	Fat.	Lactose.	Ash.
Hampshire Cotswold, Shropshire Rambouillet Lincoln Southdown	Gm. 2, 170 1, 558 1, 532 1, 495 1, 258 1, 238	$1.032 \\ 1.033 \\ 1.033 \\ 1.036 \\ 1.027 \\ 1.033$	Per cent. 3.06 3.10 3.47 3.60 3.08 3.45	Per cent. 0.74 .74 .77 .81 .77 .79	Per cent. 0.070 .065 .070 .078 .065 .066	Per cent. 7.1 7.7 8.1 7.8 8.1 7.5	Per cent. 4.73 4.78 4.50 4.77 4.76 4.70	Per cent. 0.78 .82 .88 .85 .76 .91

Average quantity and composition of ewe's milk by breeds.

Some of the ewes raised two lambs and some only one, but in spite of this disturbing element, which makes exact comparisons difficult, it appears that the most important factor in securing growth of lambs is amount and not quality of milk.

Green forage crops for lambs, J. W. HAMMOND (Mo. Bul. Ohio Sta., 4 (1919), No. 4, pp. 112-116, figs. 3) .- Three experiments at the Southeastern Test Farm at Carpenter, Ohio, to compare blue grass pasture with annual forage crops for fattening lambs are reported. It is stated that the blue grass was inferior to that found in the best blue grass areas owing to the nature of the soil in the experimental plats. In experiment 1, in which rape was the annual crop used, the lambs weighed about 48 lbs. per head at the start and were kept on pasture 131 days. The daily gain per lamb was 0.11 lb. for the blue grass lot and 0.113 lb. for the rape lot, but the gains per acre were, respectively, 48 and 242 lbs. In each of the other experiments, one of the two lots grazed rye, red clover, and rape in succession, the rape period being the longest. The lambs in these experiments had an initial weight of about 33 lbs. In experiment 2, the average daily gain per head for the blue grass lot was 0.192 lb. during 153 days, and for the lot on annual crops 0.23 lb. during 132 days. In experiment 3, both lots grazed 160 days; the average daily gain with blue grass being 0.121 lb. per head and with the annual crops 0.161 lb. A test with rape at Wooster is also cited in which lambs made a gain of 576 lbs. per acre during 83 days' grazing.

"The gains produced by these annual forage crops indicate that their more extensive use in lamb production would be found advantageous, either to replace or supplement permanent pastures. More labor is required than where permanent pastures are used, but in sections of the State where land is relatively high in price the greater production per unit of land may be more than sufficient to offset the greater labor cost.

"By providing good pasture for lambs after weaning and by using an annual pasture crop, a setback in growth can frequently be avoided and the lambs can be made ready for market at an earlier age. This latter consideration is important, as it is advantageous to the corn-belt farmer, in most instances, to get his lambs on the market in good flesh early in the autumn so they will not have to compete with the heavy runs of range lambs."

[Experiments with swine], F. A. HAYS (*Delaware Sta. Bul. 122* (1918), pp. 21-25).—Some results of feeding tomato waste and garbage to swine are reported. A lot of 5 pigs weighing about 136 lbs. per head were fed hominy feed and tankage in a self-feeder for 40 days and made an average daily gain of 1.25 lbs. per head at an expenditure of 5 lbs. of hominy feed and 0.1 lb. of tankage per pound of gain. A comparable lot fed similarly but with access to tomato waste gained 1.56 lbs. per head per day and consumed about 4 lbs.

of hominy feed, 0.2 lb. of tankage, and 1.9 lbs. of waste per pound of gain. With tankage at \$80 and hominy feed at \$54 per ton, it is estimated that the tomato waste had a value for feeding purposes of \$20.74 per ton. Two lots of 6 pigs, each weighing about 80 lbs., were fed shelled corn, tankage, and linseed meal free choice for 80 days. One lot gained at the rate of 0.68 lb. per head per day; the other, which was given 12.5 lbs. of garbage daily in addition, made a daily gain of 1.24 lbs. per head. Ten lbs. of garbage effected a saving of about 2.7 lbs. of corn, 0.1 lb. tankage, and 0.1 lb. linseed meal.

Records are also published of the feeding of another lot of pigs on garbage (but without a check lot), and of a lot of 6 gilts fed middlings, bran, tankage, corn, corn-and-cob meal, hominy feed, and milk for 140 days. A financial statement is given of the cost of feeding and caring for pregnant brood sows for 6 months during the winter of 1917–18.

Alfalfa hay for brood sows (North Dakota Sta. Rpt. 1917, pp. 17, 18).— Ten 310-lb. brood sows fed crushed barley and bran (2:1) for 65 days were compared with 40 fed as much alfalfa as they would eat and a limited amount of the grain mixture. The former group consumed a 1.8 per cent and the latter a 1.2 per cent grain ration. It is computed that 1.4 lbs. of alfalfa replaced a pound of the grain. The litters from the alfalfa-fed sows were as large and as uniform as those from sows carried on full grain ration. -

Rape pasture for swine, W. L. ROBINSON (Mo. Bul. Ohio Sta., 4 (1919), No. 4, pp. 109–111, fig. 1).—Some pasture tests with hogs are briefly reported. Pigs weighing about 95 lbs. per head were kept on pasture for 76 days, with shelled corn as supplemental concentrate. Compared with dry lot feeding of corn an acre of blue grass effected a saving of 10.4 bu. of corn, an acre of secondgrowth clover 19.8 bu., and an acre of rape 30.3 bu. In a test of rape pasture in comparison with dry lot feeding of corn and tankage, pigs weighing about 44 lbs. were grazed for 119 days. With both corn and tankage as supplements to the pasture, the saving per acre is estimated as 42.8 bu. of corn and 266 lbs. of tankage, assuming a carrying capacity of 20 pigs per acre. With corn alone as supplement and an assumed carrying capacity of 18 pigs, the saving is computed as 23.4 bu. corn and 789 lbs. of tankage.

General directions are given for the use of rape pasture for swine. "An acre of rape pasture may be estimated to carry 18 to 24 full-fed spring pigs from June until the close of the grazing season. If the concentrate ration is limited to three-fourths of a full feed an acre will carry from 12 to 15 pigs." It is suggested that rape be seeded in corn that is to be hogged down so as to provide a more economical ration.

Feeding mineral supplements to pigs, J. O. HALVERSON (Mo. Bul. Ohio Sta., 4 (1919), No. 4, pp. 121–123, fig. 1).—Several mixtures containing precipitated bone flour were tested in various ways as mineral supplements to a hog ration consisting of ground corn, linseed meal, and wheat middlings (7:1:1) and a small amount of common salt. All the 20 pigs used made consistent gains.

"In general precipitated bone flour alone or with 3 per cent salt is a palatable combination to self-feed to growing pigs. To older or more mature hogs (200 lbs.) a mixture of 50 per cent each of steamed and precipitated bone flour or precipitated bone flour with 37.5 per cent 'humus' may be self-fed. An alternative to feed to young pigs of 50 to 100 lbs. in weight is precipitated bone flour with 10 per cent each of 'humus' and molasses."

Stallion enrollment.—VIII, Report of stallion enrollment work for the year 1918 with lists of stallions and jacks enrolled, H. E. MCCARTNEY (*Indiana Sta. Circ. 86 (1919), pp. 104).*—This report of the Stallion Enrollment Board consists mainly of a directory of enrollments and renewals for the

calendar year of 1918, classified by counties. As in previous reports (E. S. R., 39, p. 73) a statistical summary is included. During the year there were enrolled 2,231 pure-bred stallions, a decrease of 325 from the 1917 totals; 1,182 grade and scrub stallions, a decrease of 496; 775 pure-bred jacks, an increase of 34; and 409 grade and scrub jacks, a decrease of 70.

Internal factors influencing egg production in the Rhode Island Red breed of domestic fowl, H. D. GOODALE (*Amer. Nat., 52* (1918), Nos. 614–615, pp. 65–94; 616-617, pp. 209–232; 618–619, pp. 301–321, figs. 40).—This paper from the Massachusetts Experiment Station is described as a survey of the problem of egg production and a preliminary analysis of an egg record into its constituent elements. It is pointed out that the number of eggs laid in unit time is not an adequate measure of a hen's production, is an unsafe basis for breeding operations, and can not be used satisfactorily to study the effect of selection, because it is a complex character dependent upon the interplay of such internal factors as age at which the laying starts, rhythm and persistence of production, tendency to broodiness, occurrence of seasonal egg cycles, etc., each of which must be studied separately with respect to its influence on the numerical record and as to its mode of inheritance. The illustrative data are selected from the records of the Rhode Island Red pullets hatched at the station in 1913 and 1915.

Comparing his Rhode Island Red flock with the Maine Station Barred Plymouth Rock pullets studied by Pearl (E. S. R., 28, p. 576), the author finds that in the former individual pullets show great variations in the age at which they begin laying but that when once started they lay at a fairly uniform rate throughout the winter, whereas in the Plymouth Rocks laying begins at about the same age but continues at widely varying rates. For Rhode Island Red pullets hatched in March and April, 1913, the average age at first egg was 261.2 days, with a standard deviation of 24.3 days. For pullets hatched in March, April, and May, 1915, the mean age was 263.2 days and the standard deviation 37.7 days.

The measure of an individual's rate of production is taken as the percentage of days on which an egg was secured between the date laying began and March 1. The rate of the 1913 flock averaged 62.5, with a standard deviation of 15.8 per cent. For the 1915 flock, the average rate was 54.6 and the standard deviation 18.5 per cent. For the 1915 flock, the average rate was 54.6 and the standard deviation 18.5. The precise figures for the Maine flock with respect to age at first egg and rate of production are not available, but the author has confirmed his interpretation of published statements by personal conference with Pearl. The differences between the two flocks make it impossible to classify the Rhode Island Red genetically into mediocre and high producers by the size of the winter egg record as was done satisfactorily in the case of the Plymouth Rocks.

Suggestions as to the influence of growth, maturity, stamina, and molt on the egg record are given. Seasonal cycles seem to be of no practical importance in Rhode Island Reds for, as the author has indicated (E. S. R., 38, p. 876), the distinction between winter and spring production in this breed is arbitrary. The number of broody periods and the age incidence of broodiness are found to be highly important, but a complete discussion of these is reserved for a future publication of which a preliminary note has been issued (E. S. R., 37, p. 869).

Commercial preservation of eggs by cold storage, M. K. JENKINS (U. S. Dept. Agr. Bul. 775 (1919), pp. 35, pls. 6, figs. 8).—This contribution from the Bureau of Chemistry is based upon the systematic examination of S41 30-doz. cases of eggs of varying grades (April, May, June, and July firsts, June and

[Vol. 41

July seconds, and dirty eggs of April to July) shipped from the Middle West to New York and Philadelphia, and held for various periods at 30 to 33° F. in rooms used commercially for the cold storage of eggs in the shell. The purpose was to investigate the conditions influencing the efficiency of the coldstorage method of preserving eggs.

The commercial selection by inspection and clicking of clean eggs with sound shells from current receipts was found to be inefficient. Commercial packages of spring firsts when ready to be taken to the storage rooms showed an average of 17.5 cracked eggs and one leaking egg to the case. Candling was much more accurate since the eggs could be graded according to quality, and cracked and bad eggs could generally be detected. Cases of spring firsts graded by candling did not average more than 3 cracked eggs per case when ready for storage. Spring eggs prepared for storage by commercial sorting showed, after 7 to 11 months' storage, an average total loss of 18.5 bad eggs per case, **9** of which were due to direct spoilage of damaged eggs or to their contamination of neighboring eggs by molding. Corresponding cases of eggs graded for storage by candling showed, after a similar period of storage, 7 bad eggs per case.

The rate of evaporation of moisture from eggs was very uniform during the storage period, and averaged from 3 to 4 oz. per case per month in the different storage rooms under observation. The moisture is condensed on the brine pipes, and absorbed by the air, case, and fillers, most of the absorption of moisture by the egg package occurring during the first few months in storage. The gain in weight of individual cases with the accompanying cushions, fillers, and flats varied from 11.5 to 14 oz. during an average storage period of 10.8 months.

Eggs that were fresh when stored showed after storing an increased air space and often a tinge of yellow in the white. The yolk membrane was slightly weakened, but commercial separation into white and yolk was readily accomplished even after 11 months' storage. The percentage of ammoniacal nitrogen in eggs increased during storage, the rise being more rapid during the early part of the storage period. The amount of ammoniacal nitrogen in eggs is considered a good index of chemical deterioration.

Evidence is produced to show that the "cold-storage taste," which usually develops after 7 or more months' storage, is due mainly to absorption of odor of the strawboard fillers in which the eggs are packed.

"Imperfections in commercial handling, grading, and marketing previous to storage are mainly responsible for the bad eggs developing in commercial eggs during storage. The preservation in the shell of undergrade eggs, such as dirty, cracked, leaking, heated, and stale eggs, should not be attempted. If not marketed for prompt consumption, the contents should be removed under proper conditions and frozen. The frozen product will keep for a year or more, whereas there would be a marked deterioration in quality if the eggs were stored in the shell."

How to caponize, R. H. WAITE (*Maryland Sta. Bul. 226* (1919), pp. 185–192, figs. 22).—Complete directions are given for caponizing, carefully illustrated with photographs.

# DAIRY FARMING-DAIRYING.

Feed consumed in milk production, H. A. HOPPER, H. M. BOWEN, and F. S. BARLOW (*New York Cornell Sta. Bul. 398 (1918)*, *pp. 3-15*).—The 847 cows enrolled in three New York cow test associations (Otsego and Wyoming Counties) in 1914 and 1915 for which complete records were secured are classified as to

#### DAIRY FARMING-DAIRYING.

milk yield and the average feed records (excluding pasturage) of each production group in each association published. The "total" digestible nutrients (sum of digestible protein, digestible carbohydrate, and 2.25 times the digestible fats) in a feed is used as the chief basis of comparison. The average data of Henry and Morrison are employed for the standard feeding stuffs, while for proprietary feeds whose formulas were not known the published analyses of the New York State Experiment Station were utilized, coefficients of digestibility being selected "to correspond to the ingredient found to be present in largest proportion." The combined results for all three associations are tabulated below:

Digestible nutrients Feed consumed per cow. consumed. Milk Ratio, Cows Butter pro-Range in milk profat per cow. duction grain in Succu-Per duction of group. group per Dry to milk. Annual feed consumption of cows grouped according to milk production.

Attention is called to the uniform amounts of dry roughage consumed and to the increases in grain and silage consumption with increased yield. The uniformity in the ratio of grain fed to milk produced is held to show a tendency to apportion grain without regard to the relative efficiency of individual cows.

A comparison is instituted between the records of these cows and those of a herd at the University of Wisconsin (E. S. R., 20, p. 674). A separate summary is also given of the feeding records of 93 of the cows that were listed as being two years old. Four cows selected at random are compared to show individual differences in economy of production.

Soiling crops for milk production, L. S. GILLETTE, A. C. MCCANDLISH, and H. H. KILDEE (*Iowa Sta. Bul. 187 (1919)*, pp. 29–59).—This is a general discussion of soiling crops based upon the experience of the Iowa Station. The topics treated include advantages and disadvantages of the soiling system, silage v. soiling, production and feeding of soiling crops, crops suitable for soiling purposes, and outlines of suitable systems. "The average of seven years' work at this station indicates that 42 cows may be kept during the summer months on 20 acres of pasture and 12 acres of soiling." A bibliography of 35 titles is included.

The possibility of increasing milk and butter-fat production by the administration of drugs, A. C. McCANDLISH (*Jour. Dairy Sci.*, 1 (1918), No. 6, pp. 475–486).—A preliminary test with a single cow showed an average decrease in milk flow of 3.5 lbs. per day following the administration of a bolus containing aloes, calomel, and nux vomica, a decrease of 2.1 lbs. following injections with pituitrin, a lesser decrease following alcohol feeding, and practically no change accompanying combined injections of pilocarpin and physostigmin (eserin).

A more extensive series of experiments using the same cow and two others was then carried out. Each experimental period lasted two days and was preceded and followed by check periods of four or five days. The following is a list of substances whose galactopoietic porperties were tested, together with the daily dosage: (1) Ethyl alcohol, 4 oz. in water twice daily, (2) castor oil, 16 oz. in the evening and 8 oz. in the morning, (3) pituitary extract injected subcutaneously, 1 dram in the evening, 1 in the morning, and 2 at noon, (4) pilocarpin hydrochlorid 2 grains and physostigmin benzoate 0.5 grain hypodermically thrice daily, (5) aloes, 1 oz. in water in the evening for two cows, 6 drams in the evening in the case of the third cow, and (6) magnesium sulphate 8 ozs. and nux vomica 1.5 drams in the evening. Treatments were apparently begun after the evening milking, with the milk records of the experimental periods starting the next morning. The average records of the three cows show no increased milk yields following any of the treatments, and except for treatment (6) no decrease greater than 0.2 lb. per day. Some modifications of the fat percentages were noted, but none resulted in significant changes in amount of the fat except perhaps the reduction following pituitrin extract of 0.21, 0.16, and 0.1 lb., respectively, in the daily butter-fat yields of the three animals.

These experiments were made at the Iowa Experiment Station.

Influence of environment and breeding in increasing dairy production, II, A. C. MCCANDLISH, L. S. GILLETTE, and H. H. KILDEE (Iowa Sta. Bul. 188 (1919), pp. 61-88, figs. 27).—This is a second edition of Bulletin 165 (E. S. R., 35, p. 570), revised to cover all lactation records completed by August 3, 1918, including some records of second generation grades. It thus summarizes the first 11 years of an experiment in the systematic grading up of unimproved dairy stock under conditions where precise records could be kept. Essentially all the data in the earlier publication are given except the results of digestion trials. In the tabular material in the body of the bulletin the milk and the fat records are now corrected for age so as to permit a more precise comparison of daughters The corrections are based on the conclusion, drawn from a study of and dams. the records of 10,000 cows, that on an average a heifer as a yearling is capable of producing 70 per cent, as a 2-year-old 80 per cent, as a 3-year-old 85 per cent, and as a 4-year-old 95 per cent of her mature yield of milk and butter fat. In an appendix the uncorrected figures for each lactation are published.

The 7 cows brought from Arkansas as mature animals have completed 30 lactations, the 7 of Arkansas stock developed in Iowa 28 lactations, 4 half-blood Holsteins 17 lactations, 3 half-blood Jerseys 7 lactations, 6 half-blood Guernseys 16 lactations, and 5 second generation heifers 6 lactations.

The change in methods of treating the data necessitated no modifications in the conclusions to be drawn from them. The second generation grades averaged better than their dams and grand-dams in yield, persistency, and economy of production. It is noted that the daughters of one of the pure-bred Guernsey bulls showed no substantial increase over their dams' records, while heifers sired by another Guernsey bull showed a 35 per cent increase. Among the first generation grades were two full sisters; one averaged 37 per cent more and the other 23 per cent less butter fat than the dam.

Dairying in northwestern Arkansas, N. RADDER (Hoard's Dairyman, 57 (1919), No. 23, pp. 1139, 1160, figs. 3).—This is an account of improvement in dairying in the Ozark region since the northwestern counties of Arkansas became tick-free in September, 1917. A large number of dairy cows have been purchased in Wisconsin and other northern states. In one county where the banks could not extend the necessary credit to the farmers under the Federal Reserve Act owing to the short-time provision, the county agent arranged with Wisconsin farmers to furnish 250 cattle on three years' credit. It is stated that a large number of silos are being constructed.

Marketing problems of the milk producer, L. M. DAVIS (*Milk Dealer*, 7 (1918), No. 11, pp. 10–15).—This is a general discussion which includes a statement concerning the daily news service on dairy products inaugurated by the Bureau of Markets of the U. S. Department of Agriculture and an outline of the different types of producers' organizations.

Field surveys and dairy marketing investigations, L. M. DAVIS (Jour. Dairy Sci., 1 (1918), No. 6, pp. 517-526).—This paper was presented at the Dairy Marketing Conference at Columbus, Ohio, on October 23, 1917, and gives an outline of the plans of the Bureau of Markets of the U. S. Department of Agriculture in the field of dairy marketing studies. The terminological distinction, adopted for convenience, between a "survey" of production and an "investigation" of distribution is noted.

Dairy marketing survey in Colorado, J. A. RAITT (Colo. Agr. Col. Ext. Serv. Bul., 1. ser., No. 151–A (1919), pp. 54, figs. 17).—This survey is the result of cooperation between the office of the State Dairy Commissioner of Colorado and the Bureau of Markets of the U. S. Department of Agriculture, and presents a considerable amount of statistical material, much of it in graphical form, drawn from census reports, Department of Agriculture estimates, reports of the State Dairy Commissioner, etc. The natural conditions limiting dairy farming in Colorado are pointed out. The number of dairy cows has not increased as rapidly as the population.

Creamery butter is the most important dairy product, with farm butter next. Over 300 cream-receiving stations are operated, mostly in the dry farming areas. There are frequently two or more in the same town, each with too small a volume of business to give the best price to producers. In 1917 the direct shipper received a net return of about 2.5 cts. more per pound for butter fat than the producer selling at a cream station. Some advantageously situated local creameries were able to pay 4.8 cts. above the average price received at cream stations.

Comparatively few sections of the State are able to supply sufficient whole milk to make cheese factories or milk condenseries profitable. In 1917 there were 13 of the former and 4 of the latter in operation.

Report is also made on the supply and distribution of market milk in Denver, Pueblo, and other cities.

A survey of the dairy marketing conditions and methods in New Hampshire, L. M. DAVIS (*N. H. Col. Ext. Bul. 8 (1917), pp. 45, figs. 8*).—This survey of the production of market milk and butter in New Hampshire was conducted by the Bureau of Markets of the U. S. Department of Agriculture in collaboration with the extension service of the New Hampshire College, and deals mostly with the steady decline which has characterized the State's dairy industry for a long period of time. The number of dairy cows decreased 20.6 per cent between 1900 and 1916, while census reports indicate a still greater decrease in production. The creamery business has also been set back, the active creameries in 1917 totaling about half the number in operation in 1888.

Aside from the usual conditions making dairying unprofitable, high feed cost, scarcity of labor, and low milk prices, certain conditions of more local application were noted, including (1) extent of the summer boarder trade, which encouraged summer rather than winter dairying and resulted in little attention to herd improvement, and, coincidentally, (2) the widespread use of bulls of the beef breeds so as to secure the most profit from veal; (3) the more recent development of city markets for whole milk, which has made rearing of dairy stock less easy and decreased the volume of business of the creameries; (4) the transportation monopoly afforded by the leased-car system, which made almost

prohibitive the direct shipment of milk and sweet cream to city consumers by organizations of producers operating their own plants; and (5) the lack of uniform schedules of milk prices. The leased-car system was abolished October 1, 1916, by order of the Interstate Commerce Commission.

Among the measures advocated for improving the industry are greater cooperation among the farmers and the making of definite contracts with distributors for milk in amounts needed for city trade, the surplus being kept on the farm and made into dairy butter and cheese, both of which are readily marketable.

Country milk stations, functions, organization, operation, construction, and equipment, W. A. STOCKING, W. E. AYRES, R. C. POTTS, and H. F. MEYER (N. Y. State/Col. Agr., Cornell Ext. Bul. 30 (1918), pp. 32, pls. 9, fig. 1).—This publication, prepared in collaboration with the Bureau of Markets of the U. S. Department of Agriculture, gives suggestions as to the organization of cooperative milk stations, with a form of preliminary agreement among the organizers, sample by-laws and lease; general directions for construction and equipment; and floor plans and equipment tables for the following types of plants: (1) Cooling and canning station, (2) cream shipping station with equipment for making cottage cheese, (3) milk station with pasteurizer and churn, (4) gravity system plant for cream shipping or butter making (2 plans), (5) milk pasteurizing and bottling plant with equipment for butter and cheese making on the upper floor, (6) whole milk Cheddar cheese factory, and (7) butter and cheese factory.

[Reports of the] committee on the production and distribution of milk, W. ASTOR ET AL. ([Bd. Agr. and Fisheries, London], Interim Rpt. Committee Prod. and Distrib. Milk, 1 (1917), pp. 6, pl. 1; 2 (1917), pp. 8; 3 (1918), pp. 30).-These three reports constitute a synopsis of the war-time problems of the dairy industry in Great Britain and the emergency measures deemed necessary. Among the topics discussed are the distribution of labor and feeding stuffs to dairy herds, reduction of waste in transportation and storage, disposal of surplus summer milk, encouragement of winter dairying, milk reserves for infant feeding, pasteurization, the proper relation between prices of retail milk and prices of other products, new feeding methods, calf rearing, and establishment of country milk depots. At the end of the first report are charts showing the changes in the retail price of dairy products and of feeding stuffs from January, 1915, to April, 1917. There is a series of appendixes to the third report giving subcommittee reports on (1) milch goats, recommending their use, (2) producers' prices for milk during the winter 1918–19, (3) the commercíal practice of pasteurization in England with the results of special bacteriological studies, and (4) soiling crops for dairy cows.

#### VETERINARY MEDICINE.

Practical bacteriology, blood work, and animal parasitology, E. R. STITT (*Philadelphia: P. Blakiston's Son & Co., 1918, 5. ed., rev. and enl., pp.* 3+XV+559+3, *pl.* 1, *figs.* 144).—The fifth edition of this manual previously noted (E. S. R., 36, p. 574), contains new material in the sections on immunity and disinfectants and insecticides, a new chapter dealing with the medical importance of poisonous arthropods and fishes, and a table giving data as to the most important communicable diseases based upon the report of a committee of the American Public Health Association. A number of the illustrations have been replaced by new ones.

Anaphylaxis in veterinary practice, H. P. HOSKINS (Vet. Alumni Quart. [Ohio State Univ.], 7 (1919), No. 1, pp. 258-264).—This paper gives a general discussion of the phenomenon of anaphylaxis, particularly as it concerns the veterinarian in the use of serums for the control and treatment of various infectious diseases of animals. A description is given of anaphylactic symptoms in bovines, horses, dogs, sheep, hogs, rabbits, guinea pigs, and man.

Anaphylaxis, Rössle (Ztschr. Immunitätsf. u. Expt. Ther., I, Orig., 26 (1917), No. 6, pp. 589-601).—The phenomenon of anaphylaxis is explained as follows: The parenteral digestion of protein brings about a physico-chemical alteration of the blood with increased viscosity. This causes an irritation to the vaso-motor centers, which in turn results in an increase in the carbon dioxid in the blood resulting in carbon dioxid poisoning or anaphylactic shock.

Isoanaphylactic poisoning caused by certain immunizing sera, M. CARPANO (Clin. Vet. [Milan], Rass. Pol. Sanit. e Ig., 41 (1918), No. 10, pp. 261-274; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 9 (1918), No. 11, pp. 1337, 1338).—The author describes phenomena of special hypersensitiveness to specic immunizing sera in the following cases:

(1) A horse inoculated with a culture of streptococci and five days later with polyvalent antistreptococcic serum showed symptoms similar to anaphylaxis. The condition could not be considered a state of true anaphylaxis on account of the predisposing causes and the absence of the subsequent phenomenon of antianaphylaxis.

(2) In many cattle injected in the jugular vein with from 80 to 100 cc. of homologous antirinderpest serum, severe poisoning often followed by sudden death occurred. This could not be attributed to the phenol contained in the serum, the action of suspended albumin, or air bubbles. This phenomenon was not observed in subcutaneous inoculations.

(3) In horses suffering from African horse sickness the injection of a homologous serum into the jugular vein has often produced powerful hemolysis.

The author discusses various hypotheses which have been advanced to explain the origin of this phenomenon, to which he gives the name anaphylactoid poisoning. He states in conclusion that, since in some infections a certain number of predisposed subjects show a particular hypersensitiveness to intravenous injections of immunizing sera, such serotherapy in spite of its efficacy is not free from disadvantages and dangers.

Studies in ananaphylaxis (antianaphylaxis), O. THOMSEN (Ztschr. Immunitätsf. u. Expt. Ther., I, Orig., 26 (1917), No. 3, pp. 213-257, figs. 3),—An extensive study is reported of the phenomenon of anti- or ananaphylaxis as observed in guinea pigs sensitized with horse serum injected subcutaneously and subsequently reinjected with the serum intravenously.

It was found that animals sensitized on the same day and with the same dose behaved similarly in respect to sensitization. Through calculation of the minimal lethal dose of such groups of animals the degree of anaphylaxis could be determined quantitatively. Sensitizing doses of 0.004 cc. acted more quickly than doses of 0.1 cc. The degree of sensitization was not influenced by the size of the dose, but rose quickly to a maximum and then decreased very gradually. Very young animals produced stronger antibodies than animals a few months old.

Ananaphylaxis is considered by the author to be due to three causes of the following relative importance: (1) Consumption or destruction of the anaphylactic antibody following the desensitizing antigen injection. This destruction manifests itself clinically quite differently, depending upon the strength of the existing sensitization as well as the strength of the desensitizing dose. (2) Prevention of the reaction between antigen and antibody. This is illustrated by the action of peptones, narcotics, etc., which act through lowering the reaction velocity between antigen and antibody.

#### 1919]

to be greater in weakly sensitized than in strongly sensitized animals. (3) A lowered sensitiveness to the anaphylactic poison. This is considered the least important factor.

Selection hypothesis.—Attempt at a uniform explanation of immunity, tissue immunity, and immunity phenomena, L. VON LIEBERMANN (Biochem. Ztschr., 91 (1918), No. 1-2, pp. 46-85; abs. in Internat. Centbl. Gesam. Tuber-kulose Forsch., 12 (1918), No. 7, pp. 186, 187).—The author discusses the various phenomena of immunity according to the following hypothesis:

In the struggle between virus and cells, the weaker cells perish and the stronger maintain themselves and by means of increased resistance establish a relative immunity. As proof, the increase in virulence of pathogenic organisms in repeated animal passage is cited. The degree of immunity will, therefore, depend upon the proportion of slightly resistant and very resistant tissue cells, and must be higher after severe illnesses, such as typhus, cholera, and smallpox, in which more nonresistant cells are destroyed than after protective inoculation in which only a few such cells are destroyed. The destroyed tissue cells, which include cell protoplasm and the products of reaction between it and the virus, are absorbed by the blood. In this colloidal solution the antibodies can exert a similar influence on the virus as during the struggle in the tissues. The antibodies must be specific for each antigen.

Anaphylaxis is a continuation of the immunization process. The antibodies are decomposed with the formation of poisonous substances which are set free on the reinjection of antigens of strong affinity. Allergy is produced when a rather weak virus attacks the cells only superficially without destroying them, but results in an irritation which manifests itself principally on a reinjection. In cutaneous reactions, local hyperemia originates through the liberation of poisonous decomposition products of the antigen injected first.

In conclusion several references to the literature on the subject are given, with explanatory remarks as to the theories involved in the citations.

Anti-infectious immunity: Presence of specific substances in the leucocytes of immunized animals, A. BACHMANN (*Rev. Zootéc.*, 6 (1919), *No.* 66, *pp.* 404–417).—The author discusses various theories which have been advanced in explanation of immunity, and describes a series of experiments which tend to show the presence of a special substance in the leucocytes of immunized animals which renders these leucocytes better fitted than others to contend with infections and consequently to produce a state of immunity.

**Destructive hyperimmunity**, A. VERNES (*Compt. Rend. Soc. Biol.* [*Paris*], 82 (1919), No. 3, pp. 118, 119).—Attention is called to a phenomenon sometimes observed in rabbits vaccinated progressively against sheep corpuscles. If too large a quantity of erythrocytes is injected into a rabbit whose blood has become strongly hemolytic, paralysis, often fatal, occurs in a few minutes. This is thought to be due to the animal's having acquired the power of destroying too rapidly the foreign blood corpuscles. The name "destructive hyperimmunity" has been given to this phenomenon, the degree of which is apparently governed by the weight of the rabbit and the dose of injected corpuscles.

Quantitative investigation of the influence of complement upon precipitates, H. LAMPL and K. LANDSTEINER (*Ztschr. Immunitätsf. u. Expt. Ther., I, Orig., 26 (1917), No. 3, pp. 193–198).*—To determine whether complement is able to digest specific precipitates, such precipitates were weighed before and after treatment with active and with inactive serum. No change in weight sufficient to indicate a digestive action of the complement was observed.

Preservation of complement, A. D. RONCHÈSE (Compt. Rend. Soc. Biol. [Paris], 82 (1919), No. 5, pp. 193-195).—For preservation of complement the author recommends the addition of an excess of pure neutral sodium fluorid to the serum. When the complement is to be used, one volume of the serum saturated with fluorid is added to five volumes of distilled water. The titration of the complement is recommended, as after five days, during which the initial complementary power remains fixed, there is said to be a gradual diminution of complementary power.

Guinea pig serum, J. FREUND (*Biochem. Ztschr.*, 86 (1918), No. 5-6, pp. 421-425).—The physical constants and chemical composition of guinea pig serum are reported. It is pointed out that the serum differs from other sera only in a somewhat higher water and lower protein content.

The course of bacteriolysis produced by serum and by extract of leucocytes, A. PETTERSSON (*Ztschr. Immunitätsf. u. Expt. Ther., I, Orig., 26 (1917), No. 4, pp. 305–324, figs. 2).*—Observations are reported of the velocity of bacteriolysis as influenced by the organism involved and by the bacteriolytic agent (serum or leucocytic extract).

The velocity of bacteriolysis was found to be proportional to the number of the bacteria present, whether the bacteriolytic agent be serum or leucocytes. Toward the end of the bacteriolysis the velocity decreases, since then only the more resistant bacteria are present. Bacteriolysis varies with the nature of the bacteria, and, in the case of the same organism, with the nature of the bactericidal agent, as shown by the fact that the lysis of *Bacillus anthracis* takes place rapidly in dog or horse serum and very slowly in leucocytic extracts, while pneumococci are digested rapidly by a saline solution of leucocytes and slowly by ascitic bouillon.

On the acceleration of phagocytosis in the citrated blood and citrated blood plasma, M. OTANI (*Kitasato Arch. Expt. Med.* [*Tokyo*], 2 (1918), No. 2, pp. 147–218).—An extensive investigation of the influence of citrates on the phagocytosis of the blood, both in normal and in specially immunized animals, is reported from which the following results were obtained:

Phagocytosis was greater in tuberculous than in normal blood containing sodium citrate. In some cases blood of apparently normal persons showed remarkable phagocytosis and was later found to be infected with tubercle bacilli. The opsonic index in the same cases showed no difference between normal and tuberculous blood. Invigoration of phagocytosis was also observed in citrated rabbit's blood immunized with tubercle bacilli and in human dysentery blood with dysentery bacilli, but no activation of phagocytosis was observed in mixtures of normal blood with other organisms.

The author considers that the phagocytic substance found in citrated blood plasma must be investigated further before its identity can be established, but that doubtless phagocytosis in citrated plasma is also aided by the known immune substances, opsonin and tropin. The citrated blood test is thought to be a specific reaction which has an important diagnostic value.

A lecture on the lessons of the war and on some new prospects in the field of therapeutic immunization, A. E. WRIGHT (Lancet [London], 1919, I, No. 13, pp. 489-501, figs. 11).—In this lecture, delivered before the Royal Society of Medicine (England), the natural defenses of the body against infections, particularly the antitryptic power of blood and the leucocytes, are discussed and experiments described which confirm the views expressed. A method of "immuno-transfusion" for the treatment of septic wounds is described. This consists in allowing the blood from a donor to digest a given amount of the infecting microorganisms, after which the treated blood is injected into the patient.

130002°-19-7

[Vol. 41

Specific serotherapy of wounds and pyogenic infections, A. GUILLAUME and G. BITTNER (*Rev. Gén. Méd. Vét., 28 (1919), No. 327, pp. 113–136*).—The authors have supplemented their earlier report of the use of polyvalent serum for the treatment of wounds (E. S. R., 37, p. 477) by a new series of observations of the success of this treatment with wounds of all kinds and cases of general pyogenic infections in horses, dogs, etc. The results obtained confirm the earlier conclusions as to the value of the treatment.

Some observations on the use of boric acid as a disinfectant, F. W. TANNER and R. S. FUNK (*Amer. Jour. Pharm.*, 91 (1919, No. 4, pp. 206-210).—The efficiency of boric acid as a disinfectant was tested by inoculating media containing different amounts of the boric acid with various organisms, incubating, and comparing the growth obtained with controls containing no boric acid. The silk-thread method was also used.

The results indicate that boric acid possesses very little if any germicidal action, and that any inhibitory power possessed by it is not constant. The authors conclude that the use of this reagent in those cases where disinfection is absolutely essential should be discontinued.

Flavin and brilliant green, powerful antiseptics with low toxicity to the tissues: Their use in the treatment of infected wounds, C. H. BROWNING, R. GULBBANSEN, E. L. KENNAWAY, and L. H. D. THORNTON (*Brit. Med. Jour., No. 2925 (1917), pp. 73–78).*—As the result of a study of the bactericidal power of various antiseptics in the presence of serum, flavin, a substance belonging to the acridin group, is recommended as possessing extremely powerful bactericidal and antiseptic properties which, unlike those of the other antiseptics used, are enhanced rather than diminished by admixture with serum. It is said to be less detrimental to the process of phagocytosis and less harmful to the tissues than the other antiseptics tested, and consequently can be employed in higher concentrations without damaging the tissues or interfering with the natural defensive mechanisms. Brilliant green was found to possess similar properties to a less degree.

The antiseptic properties of acriflavin and proflavin, and brilliant green; with special reference to suitability for wound therapy, C. H. BROWNING, R. GULBRANSEN, and L. H. D. THORNTON (*Brit. Med. Jour., No. 2950 (1917), pp.* 70-75, figs. 4).—Certain features of these antiseptics are discussed in greater detail than in the above article, and the essential differences between the action of the flavins and brilliant green are pointed out.

Both flavin and brilliant green are antiseptics which exert a slowly progressive bactericidal action. The flavin compounds (acriflavin and proflavin) are enhanced in their bactericidal action by the presence of serum, while brilliant green, in common with most other antiseptics, is reduced in its activity by serum. For this reason brilliant green should be applied by repeated irrigation and flavin by means of gauze packing.

The testing of antiseptics in relation to their use in wound treatment, C. H. BROWNING and R. GULBRANSEN (*Jour. Hyg.* [Cambridge], 18 (1919), No. 1, pp. 33-45).—This article deals with a number of points which have been raised relative to the action of the flavins and brilliant green on bacteria as noted above. The choice of a medium for testing antiseptics and the methods of testing antiseptic potency are discussed, and further experiments are reported on the variations in resistance of different organisms to flavins in a serum medium.

Serum is considered the most rational medium for testing antiseptic action, as serous exudate constitutes practically the diluent to which an antiseptic is exposed in wounds. Bacteriostatic action (or inhibition of bacterial activity) is considered of greater value in an antiseptic than toxic action or rapid destruction of the bacteria.

"It is not essential that the chemical agent should by itself actually kill the organisms. Highly successful results can be obtained by a cooperation of the antiseptic and the tissues, so that the pathogenic action of the organisms is restrained. The flavins, in virtue of their low toxicity to mammalian tissues and their high bacteriostatic power, are therefore specially suited to act as local therapeutic agents. In addition, the fact that they are not neutralized by admixture with serum enables them to be applied clinically by a relatively simple method which does not necessitate frequent renewal."

The bactericidal value of the new disinfectant "Victoria", F. DE GASPERI (Arch. Sci. Med. Vet. [Turin], 16 (1918), No. 7-12, pp. 51-102).—An investigation is reported of the antiseptic action of a new disinfectant "Victoria" on anthrax spores, Staphylococcus pyogenes aureus, Bacillus paratyphosus B, and B. pyocyaneus. "Victoria" is essentially a soap solution containing 9 per cent of formalin, corresponding to 3.6 per cent of formaldehyde. Three forms are on the market in Italy for personal, domestic, and veterinary use. The first two, which differ only in quality of the castor oil used for saponification, contain a small amount of alcohol and odorous essences, while the third contains in addition some phenol.

As a result of the reported tests the conclusion is drawn that these preparations, while not destroying spores completely, can be used to advantage in the prophylaxis of the majority of the common infective and contagious diseases of animals. It is recommended that the disinfectant be applied in as concentrated a solution as possible and in amounts in excess of the material to be disinfected.

The local use of antianthrax serum in treatment of anthrax, J. C. REGAN (Jour. Amer. Med. Assoc., 72 (1919), No. 24, pp. 1724, 1725).—A report is given of the successful treatment of anthrax (human) by the injection of antianthrax serum locally around the lesion. The injection of from 10 to 15 cc. of the serum was made very slowly with an antitoxin needle and syringe, the needle being introduced in three places in the tissue just outside the margin of the lesion. The serum was administered once daily till the local process was controlled. It is considered that two or three injections will usually suffice, but that the local measures must be accompanied by suitable general treatment such as intramuscular or intravenous injections of the serum. The local treatment to be successful must anticipate the onset of anthrax septicemia.

The special advantages of this method of local treatment over the customary measures of excision, cauterization, etc., are said to be the absence of excessive scar formation and of toxic and poisonous symptoms.

Studies on the nature of the antibodies in glanders, W. BUROW (Arch. Wiss. u. Prakt. Tierheilk., 44 (1918), Sup., pp. 464-472).—A brief report is given of studies with active glanders serum, from which the conclusion is drawn that the antibody or "interfering substance" in the serum is of the nature of a soluble euglobulin, insoluble in ether and alcohol and completely destroyed by heating for 20 minutes at 70° C.

Glanders; reinfection and etiology, SCHÜTZ (Arch. Wiss. u. Prakt. Tierheilk., 44 (1918), No. 3-4, pp. 115-126).—This is a theoretical discussion of the subject on the basis of observations of the differences between Russian and German horses in the susceptibility to glanders and the course taken by the disease. Special attention is given to the so-called latent form of the disease, the course of which is compared with malaria in man. The question is raised as to the possibility of immunizing horses during this latent period in a similar manner to methods now in use for acquiring immunity to malaria. The diffusibility of rabic virus, P. REMLINGER (Ann. Inst. Pasteur., 33 (1919), No. 1, pp. 28-52).—Experiments are reported showing that rabic virus is capable of diffusing from the head of a dog or rabbit into physiological salt solution or glycerin, and subsequently into a new head, kidney, or liver immersed in the liquid. The author discusses the bearing of this phenomenon on the nature of rabic virus, and proposes the theory that filterable viruses occupy an intermediate position between the visible microorganisms and the colloids, diastases, or toxins. The lessened virulence of rabic virus on passage through a filter of very fine pores is due, acording to the theory proposed, to a change into the finer colloidal form.

A new immunity reaction in experimental trypanosome infection; the blood platelet test, H. RIECKENBERG (*Ztschr. Immunitätsf. u. Expt. Ther., I, Orig., 26 (1917), No. 1, pp. 53–64).*—If blood from a rat infected with experimental trypanosomiasis is mixed with citrate bouillon before coagulation, and this mixture is inoculated with trypanosomes from the original cultures, the trypanosomes in a few minutes become covered with a thick conglomeration of blood platelets so that their movement is almost entirely impeded. The reaction is said to be specific, and to be given in all cases in which an immunity to trypanosomes has been established.

Further experiments on the influence of protein intoxication on tuberculous infection in guinea pigs, A. K. KRAUSE and H. S. WILLIS (*Amer. Rev. Tuberculosis*, 3 (1919), No. 3, pp. 153-165).—In continuation of work previously noted (E. S. R., 35, p. 883), further studies are reported in a controlled investigation of the influence of protein hypersensitiveness and intoxication upon tuberculous infection.

The results obtained indicate that frequent injections of protein over a long period of time render an animal abnormally susceptible to tuberculous infection, but that repeated injections of protein or repeated anaphylactic shock after tuberculous infection is established do not appreciably influence the course of the infection. Intensive and frequently repeated applications of tuberculo-protein fail to produce a state of cutaneous hypersensitiveness in animals in which no tubercles are present, and have no effect on the cutaneous hypersensitiveness in animals in which tuberculous infection has been established.

The complement fixation reaction as applied to tuberculosis, P. A. LEWIS (Amer. Rev. Tuberculosis, 3 (1919), No. 3, pp. 129-152; abs. in Jour. Amer. Med. Assoc., 72 (1919), No. 23, p. 1700).—This paper reports an application of quantitative methods to the study of the reaction of complement deviation in tuberculosis.

The results confirm the observations of others that certain tuberculous individuals give strong deviation reactions while others do not, and that certain apparently normal individuals also give strong reactions. The author concludes that, while continuous applications of the reaction throughout the course of the disease may in the future develop importance, at present "the numerical relations are such as to make it unsafe to apply the complement deviation reaction to the diagnosis of tuberculosis except as a matter of the most limited confirmatory interest."

Certain inherent defects in the method of performing the test for complement deviation are said to have been remedied to a considerable extent by increasing the time of the primary incubation to four hours and by employing several quantities of either complement or antigen simultaneously. It has been found that the extractive antigens of the tubercle bacillus so far examined contain as a prominent feature of their make-up, alcohol-soluble, thermostable substances. The detection of tuberculous meat by means of the precipitin reaction, L. GRANUCCI (Clin. Vet. [Milan], Rass. Pol. Sanit. e Ig., 41 (1919), No. 15, pp. 377-383).—The precipitin reaction was found to be of no value in testing beef for the presence of tubercular infection.

Passive anaphylaxis for the detection of tuberculous meat, L. GRANUCCI (*Clin. Vet.* [*Milan*], *Rass. Pol. Sanit. e Ig.*, 42 (1919), *No.* 4, *pp.* 115–126).—Evidence is given indicating that muscular plasma of tuberculous cattle when injected into rabbits produces a state of hypersensitiveness by means of which passive anaphylaxis is caused on the subsequent injection of tuberculin. The reaction may be considered to be specific in that control rabbits inoculated with the plasma from the flesh of healthy animals do not show true anaphylaxis. The anaphylactic state may be conferred upon other normal rabbits but in an attenuated form.

The author is of the opinion that the anaphylaxis test will be of considerable value to meat inspectors.

Oak-leaf poisoning of domestic animals, C. D. MARSH, A. B. CLAWSON, and H. MARSH (U. S. Dept. Agr. Bul. 767 (1919), pp. 36, figs. 19).—This is a report of investigations conducted with cattle at Salina, Utah, during the summers of 1915–1918 in which the scrub oak of Utah (Quercus gambellii) was fed, and at Monahans, Tex., from March 20 to May 20, 1917, in which "shinnery" oak (Q. havardi) was fed. A preliminary account has previously been noted (E. S. R., 39, p. 386).

It was found that continuous feeding on oak leaves may produce sickness which sometimes will have a fatal termination. "The specially marked symptoms are constipation, feees containing mucus and blood, emaciation, and edema. A diet composed exclusively of oak leaves does not form a sufficiently nutritious diet to permit normal gains in weight. Oak leaves with a small quantity of other feed may provide a maintenance ration. It has been found experimentally that as small a quantity of alfalfa hay as 3 lbs. will supplement the oak for this purpose. Oak leaves may produce injurious effects at any season. Most of the cases, however, occur in the spring, because on the range at that time there is a scarcity of other forage and the young oak leaves are attractive. While cattle later in the season may eat largely of oak, more or less other forage is available and no harmful results are experienced. The 'summersickness' of the Utah ranges is identical with so-called oak-brush poisoning."

The investigations have shown that during the summer and fall the oakbrush ranges of Utah can be used for grazing, not only with no harm to cattle but with positive benefit. The admission of cattle to oak-brush ranges before the grass has been started, however, practically compels the cattle to eat oak, as that is the only forage available. On the shinnery ranges, as on the oak ranges in Utah, the danger to cattle is from an exclusive diet of oak. These ranges can be used without loss, provided a comparatively small quantity of other feed is available.

Studies in abortion disease, H. R. SEDDON (Jour. Compar. Path. and Ther., 32 (1919), No. 1, pp. 1-34, figs. 11).—A detailed study is reported of the reliability of the agglutination test for contagious abortion, as determined by the results of its application to a large herd of cattle in which a number of abortions had occurred previously and during the time of the investigation. As far as possible the agglutination titre of each sample of serum was determined, milk testings (by inoculation of guinea pigs) were made, and aborted fetuses, membranes, and vaginal discharges were examined. In interpreting the results of the agglutination test, the reaction was considered positive when agglutination was obtained with any quantity of serum not exceeding 0.01 cc. The reliability of the test as based on this standard was as follows:

All but two of the animals which had shown clinical signs of the disease gave a positive reaction. The organism was found only in animals giving a positive test. With one exception, all animals experimentally infected with cultures of *Bacillus abortus* subsequently gave positive tests. In all agglutination tests made of guinea pigs which had become infected by inoculation with cow's milk and from which *B. abortus* had been cultured, a positive reaction was obtained. Conversely, guinea pigs which failed to become infected did not give a positive agglutination test.

A detailed history illustrated by charts is given of the course of abortion disease in the herd under investigation, with interpretation of results. In conclusion, the author states that in the light of recent knowledge the problem of abortion disease may be summarized as follows:

When a nonpregnant animal becomes infected, the organism gains a lodgment in the mammary gland. In an infected pregnant animal, the organism is present in both mammary gland and uterus. After abortion the uterus quickly becomes free from abortion bacilli, but infection persists in the mammary gland and provides the source of the abortion bacilli present in the uterus at a future pregnancy.

A certain percentage (10 per cent of the cases reported) become infected only in the uterus and may recover from that infection. Bulls may act as mechanical carriers of infection, or may become infected in the testes or epididymis and eliminate organisms along with the seminal fluid. Animals may give a negative agglutination test till a few weeks before abortion. These conclusions are in agreement with those of Schroeder and Cotton previously noted (E. S. R., 36, p. 881).

Contagious abortion of cattle: A bibliography (Vet Rev., 3 (1919), No. 2, pp. 137-152).—This bibliography of 225 titles covers the literature on contagious abortion of cattle since 1895, with a few references to earlier literature.

Treatment of contagious lymphangitis in horses by pyotherapy, BELIN (*Bul. Soc. Cent. Méd. Vét.*, 95 (1919), No. 4, pp. 73–93).—This is a report of observations of 114 cases of cryptococcic (epizootic) and 247 cases of bacillary (ulcerous) lymphangitis treated by pyotherapy, which strengthens the author's opinion that pyotherapy is the only rational method for the treatment of contagious lymphangitis. A new method of sterilizing the pus for the preparation of the pyovaccine is recommended, in which a solution of 1 part idoin and 4 parts potassium iodid in 1,000 cc. of distilled water is employed in place of the ether previously recommended (E. S. R., 38, p. 587).

The poultryman's parasite problem, W. C. THOMPSON (New Jersey Stas., Hints to Poultrymen, 7 (1919), No. 8, pp. 4).—A brief account is given of the common ectoparasites of poultry and means for their control.

### RURAL ECONOMICS.

How these farmers succeeded, edited by J. R. McMAHON (New York: Henry Holt & Co., 1919, pp. VIII+261, pls. 30).—This book is a collection of articles published in a "Best Farmer" series in the Country Gentleman, describing 16 successful farms in the United States.

Farm products and cost accounting, H. J. DAVENPORT (*Jour. Polit. Econ.*, 27 (1919), No. 5, pp. 354-361).—The argument prompting this analysis is that the high price fixed for wheat becomes a contribution to the cost of the alternative products of farming and limits the supply of them. This analysis,

192

when applied to the price of milk in the city, is said to show the inconsistency of efforts to arbitrate the supply, price, and consumption of it. It is argued that the farmer must be remunerated for the economic costs of this alternative product, and also that a system of regulating the monopoly or of high license of the sale of milk in the city might afford relief from the point of view of the consumer.

Farm credit in Wisconsin, H. C. TAYLOR (Hoard's Dairyman, 57 (1919), No. 18, pp. 906-908).—This address before the American Farm Management Association on January 10, 1919, deals with mortgage and personal credit in Wisconsin, and compares upper Wisconsin and the southern section of the State in this respect. The former is characterized as a deficit credit area where bank credit is unsatisfactory and chattel mortgages are much in use, while it is shown that in the southern section personal and store credit and farm mortgages are general. Several types of farm credit systems and of mortgage and loan associations are described.

Land settlement in the mother country (London: Bd. Agr. and Fisheries, 1918 [vols. 1], pp. 8; [2], pp. 10; rev. in Jour. Bd. Agr. [London], 25 (1919), No. 10, pp. 1152-1160).—These booklets have been issued by the English and Scottish Boards of Agriculture with the approval of the Admiralty and War Office to explain to ex-service men and officers, respectively, the steps that have been taken to settle them on the land and to direct them in making applications for training and for holdings.

Report of the committee appointed by the Agricultural Wages Board to inquire into the financial results of the occupation of agricultural land and the cost of living of rural workers (London: Agr. Wages Bd., 1919, pp. 73; rev. in Agr. Gaz. [London], 89 (1919), No. 2361, p. 305) .- This committee, appointed March 14, 1918, by the Agricultural Wages Board of Great Britain, circulated schedules among farmers asking for particulars of receipts and expenditures during five years, and of acreage and live stock in each year, but omitting a statement of valuation at the beginning and end of the year, interest on capital, remuneration to the farmer for management, or of produce consumed by the farm household The main object was to determine the actual turnover of business and the cash profit or loss. This report is based upon 119 such schedules returned, and on data supplied by farm accounts of various farmers' organizations, the Rothamsted Experiment Station, and others. It includes a summary of the regulation of prices of the farm products of 1917 and subsequently, and gives prices of farm requisites and other farming costs under various systems of management, also retail prices of commodities in 1914 and 1918 and at earlier dates.

It is indicated that farming has been substantially more remunerative during the war than in the period immediately preceding it, and that "the cost of the standard budget would have doubled if the same food had been bought in the same quantities, that owing to modifications and slight reduction in standard, actual expenditure rose 84 per cent, and that if the modifications had been maintained, but the standard of nutrition restored, the increase would have been 90 per cent." It is shown that the cost of clothing has all but doubled, the increase in the cost in the standard budget being 90 per cent.

Detailed tabulation of the data collected is included in the appendixes.

Wages and conditions of employment in agriculture (Bd. Agr. and Fisheries [London], Wages and Conditions Employment Agr., 1919, vols. 1, pp. IV+202; 2, pp. IV+504).—Volume 1 consists of a general report by G. Drage, director of investigations, of the inquiry into the economic position of agricultural labor made by a committee appointed by the Board of Agriculture and Fisheries. It is divided into two main parts, the first dealing with a survey of farming, supply of labor and its quality, conditions of labor, wages and earnings, cottage accommodations and rents, relations of employers and employed, gardens, allotments, small holdings, etc., with reference to England, and the second part following practically the same plan with reference to Wales. Volume 2 embodies the 51 reports of investigators drawn up by counties of England and Wales in accordance with a syllabus prepared by the Board of Agriculture. Some of the data secured by this investigation were incorporated in the report noted above.

Report on the wages and conditions of employment in agriculture (*Jour. Bd. Agr.* [London], 26 (1919), No. 1, pp. 4-15).—This is an abstract of volume 1 of the work noted above.

Profit sharing in agriculture (*Edinb. Rev.*, 229 (1919), No. 467, pp. 1–18; abs. in Scot. Jour. Agr., 2 (1919), No. 2, pp. 229–232).—The author describes in detail a system of partnership in farming, taking into consideration the three interests entitled to a share in the dividends of the enterprises, capital, management, and labor. He urges that this plan is one which can be put into operation at once and without disturbance in systems of management prevailing, or to the habits of mind of the men whom it would concern, that it offers a working alternative to the struggle between labor and capital and the limit imposed on wages by the capacity for productivity of the land, and further that it offers opportunity for managerial ability and facilitates direction of the work of ex-service men, who may desire to settle on the land yet who run an uncertain chance of success on small holdings.

Prevailing plans and practices among farmers' mutual fire insurance companies, V. N. VALGREN (U. S. Dept. Agr. Bul. 786 (1919), pp. 15, fig. 1).—Data secured from questionnaires filled out and returned by 1,161 companies are summarized here. Studies based on the same data have been previously noted (E. S. R., 37, p. 594).

Tropical agriculture: The climate, soils, cultural methods, crops, live stock, commercial importance, and opportunities of the Tropics, E. V. WILcox (*New York and London: D. Appleton & Co., 1916, pp. XVIII+373, pls. 24*).— Several chapters in this volume are devoted to a discussion of the subjects of tropical climate, soils, agricultural methods, importance of tropical products in commerce, economic and social conditions and opportunities in the tropics. In subsequent ones, the author describes briefly the nature, source and commercial importance of about 350 economic plants, and gives an account of the live stock and animal products industry of the tropics.

Rural Denmark and its lessons, H. R. HAGGARD (London and New York: Longmans, Green & Co., 1917, pp. XIV+335, pl. 1).—This is a new impression of a book previously noted (E. S. R., 25, p. 692).

Monthly Crop Reporter (U. S. Dept. Agr., Mo. Crop Rptr., 5 (1919), No. 5, pp. 45-52, fig. 1).—This number reports, as usual, the estimated farm value of important products April 15 and May 1, 1919, average prices received by producers in the United States, range of prices of agricultural products at important markets, the United States crop summary for May, and crop conditions May 1, 1919, with comparisons. It also includes data showing the condition of farm animals May 1 and estimated losses during the year ended April 30, with comparisons, crop conditions in California and Florida, and final returns showing Louisiana sugar and sirup production, 1918, also similar information regarding maple sugar and sirup. It gives a honeybee report May 1, 1919, by States, with comparisons, and special articles on farm live stock changes, varieties of spring wheat, and other topics.
# AGRICULTURAL EDUCATION.

[Canadian studies in rural life for boys and girls] (Agr. Gaz. Canada, 5 (1918), No. 7, pp. 712–721, fig. 1).—In the public schools of Prince Edward Island home projects are being given preference to the garden at the school. In 1915 there were 156 school gardens and 2,688 home projects; in 1916, 113 school gardens and 1,604 home projects; and in 1917, 93 school gardens and 2,250 home projects. Home projects included in 1917 grain raising, vegetable growing, beans, potatoes, flowers, poultry, live stock, and chores.

The recommendations and summary of findings made in the report of the commission on vocational training for boys and girls, appointed by the New Brunswick Government in September, 1918, are given. In accordance with these the legislature of New Brunswick, at its last session, passed the Vocational Education Act, 1918, in which prevocational education is defined as meaning the education to enable the child to select its course of study and training, and vocational education as an education, the controlling purpose of which is to fit for profitable employment, and which includes industrial, agricultural, commercial, and home economics education. The Province is to aid in the maintenance of vocational and prevocational schools established under the act, on a joint basis with the local communities, the total to be expended in any one year being limited to \$50,000.

Every high and consolidated school in Manitoba is now taking part in some form of boys' and girls' club work. The juniors are engaged largely in raising chickens and in gardening, while the older pupils find the most interest in the pig and calf raising contests, and in growing registered seed. The departments of agriculture and education cooperate very closely in an effort to correlate the educational and economic phases of club work.

From November to April, 1917–18, 22 short-course schools in agriculture, gas engines, and home economics, extending over two weeks each, were held in Manitoba. It was found most convenient to organize the schools in three circuits, for each of which there was obtained a carload of equipment consisting of three tractors, four stationary engines, a lighting plant, a grain cleaning oufit, about fifty 16 by 20 inch bromids of champion live stock, and a full supply of the various grains grown in Manitoba, as well as all the troublesome weeds. A staff of expert lecturers was engaged for each circuit. The forenoons were usually given over to lectures for the whole school, while the practical work was done in the afternoons when the school was split into sections. The regular women's classes in home economics were well attended, and probably 8 per cent of those taking gas engine work were women.

The department of education for Alberta has reorganized and extended the instruction work for public school inspectors at the summer school. The most important additions are the lectures on the generalized aspects of agriculture, which include farm management, rural economics, and rural sociology.

A discussion of the duplication of agricultural teaching in general secondary schools and special schools of agriculture, such as there are in Alberta, is included. It is stated that there does not appear to be any real overlapping or duplication of work from the teaching of agriculture in these two types of schools, which differ from each other in the characteristic purpose of the agricultural teaching. Since little instruction in agriculture is given in the normal schools and the agricultural courses in the summer schools are purely optional, the course in agriculture in the high schools is more explicitly designed as a course for teachers in the public schools. The best results of the special school **are the making of good farmers and home makers, while the best results** of the high school are that pupils get some well presented information about agriculture, with some inside laboratory and a little plat work.

Course in agriculture for a four-year high school, F. T. ULLBICH (School Sci. and Math., 19 (1919), No. 3, pp. 214-227).—In this study of a course in agriculture for a four-year high school, the results reported are essentially a collation of judgments of 50 leading educators of the country.

Of these, 42 favor a combination of practical instruction with the general training idea and 21 would require larger emphasis on the practical subjects than is given at present. "Evidently, the agreement is practically unanimous on the use of industrial materials for educational purposes in the high school. The difference of opinion seems to lie in the question as to the degree that this subject matter is to be used for general educational purposes, or for the development of knowledge and skill for direct participation in the industrial life of the nation."

The median of recommendations of 28 of the 50 educators for required work in English is 5.2 units (interpreting a unit to mean a subject pursued for one semester or one-half year, with one recitation daily) in a four-year agricultural course of 32 units, with mathematics 2.68 units, biological science 3.2 units, social science 3.9 units, and physical science 3 units. In addition, one correspondent suggests that 2 units of rural economics and  $1\frac{1}{2}$  units each of manual training, drawing, and music be required; another would require 1 unit each of drawing and music.

With reference to the apportionment of time between the general and the agricultural subjects, the median for 33 correspondents is 34.9 of the time for agricultural instruction, with a range of from 25 to 60 per cent.

"It was a surprise to discover in some of the replies a lack of appreciation of the difference between art and science of a subject." Twenty-four of the educators give a numerical valuation with a median of 52 per cent of the time for the art of agriculture and 54.8 per cent for the science. The range for the art is from 10 to  $66_3^2$  per cent, and for the science from  $33_3^4$  to 90 per cent.

Twenty-one of the replies showed convictions that the fundamentals of science are best learned in the standard sciences, the special features of each science that are applicable being again stressed in the agricultural courses. Five would abandon the science courses and teach the principles of science as the comprehension of the agricultural subject demands. Two subscribe to both of the options, and four maintain that the principles of science should be developed in connection with the agricultural subjects, but that in the last year of the course the principles of each science should be unified and organized, so that at the time of graduation the student may have a body of scientific generalizations.

With reference to the best laboratory for training students in the skill of agriculture, the present tendency, especially in Massachusetts, New York, Minnesota, and Wisconsin, is to push the project idea. Out of 33 of the educators, 31 are favorable to projects, and of these 27 would require them. A classification of 37 answers shows that 19 of the educators are of the opinion that students should devote a portion of school time on a farm to gain proficiency in the practical affairs in agriculture, while 5 favor this idea unless the students are farm born and trained. Three say that some time outside of school should be spent on the farm, and 2 think that project work is better.

The sequence of the agricultural courses with reference to each other, and the semester and year of the academic course, particularly the standard science courses, as well as the content of the agricultural subjects, are also discussed. It is found that "the usual order of agricultural subjects in the course is plant studies the first year, animal studies the second year, soils and fertilizers the third year, and farm mechanics and management the fourth year. A satisfactory arrangement of the general subjects, particularly the science courses, is one of the unsolved problems if the principles of science should be taught in courses more or less separate from the agricultural courses. The content of

the agricultural courses is under vigorous consideration at the present time, under the stimulation of the Smith-Hughes legislation, which is interpreted by some to mean a protest against the present materials in the agricultural subjects." The author finds that a definite formulation of a course in agriculture in harmony with the recommendations of the 50 educators and the discussions does not seem advisable.

Lessons on potatoes for elementary rural schools, A. DILLE (U. S. Dept. Agr. Bul. 784 (1919), pp. 23).—This bulletin contains outlines of twelve lessons dealing with the selection, planting, cultivation, harvesting and grading, marketing, winter storage, judging, and uses of potatoes, the structure of the potato tuber, the place of potatoes in the rotation, soils, seed treatment, and pests. Suggestions are given with reference to sources of information, illustrative material, the survey, the home project, and correlations.

Lessons on dairying for rural schools, A. DILLE (U. S. Dept. Agr. Bul. 763 (1919), pp. 30, figs. 14).—The author outlines twelve lessons in dairying, which deal, respectively, with the production, care, weighing, and testing of milk, records and marketing, profit and loss, judging and purchasing, care and handling of the dairy cow and barn, butter making, the food value of milk, cottage cheese, and the use of milk and its products in cookery. An outline for a district dairy cow survey, score cards for sanitary inspection of dairy farms and for dairy cows and butter, and suggestions with reference to sources of information, illustrative material, and the home project, are included.

List of workers in subjects pertaining to agriculture, home economics, and marketing, 1913–19 (U S. Dept. Agr., List of Workers in U. S. Agr., 1918–19, pp. 73+89).—This is the usual organization list of workers along these lines (E. S. R., 39, p. 497). Part 1 deals with the U. S. Department of Agriculture, and part 2 with the agricultural colleges and experiment stations.

# MISCELLANEOUS.

**Report on experiment stations and extension work in the United States,** 1917 (U. S. Dept. Agr., Rpt. Expt. Stas. and Ext. Work, U. S. 1917, pts. 1, pp. 335:2, pp. 416, pl. 1).—This report, prepared by the States Relations Service for the fiscal year ended June 30, 1917, consists of two parts.

Part I. Work and expenditures of the agricultural experiment stations, 1917.— This part includes the usual report on the work and expenditures of the agricultural experiment stations in the United States, including Alaska, Hawaii, Porto Rico, and Guam, together with detailed statistics compiled from official sources as to the organization, revenues, additions to equipment, and expenditures of the stations.

During the fiscal year ended June 30, 1917, the total income of the stations, including those in Alaska, Hawaii, Porto Rico, and Guam, was \$5,642,149.16. Of this amount \$718,744 was derived under the Hatch Act, \$718,358.04 under the Adams Act, \$143,000 from the Federal appropriations for the insular stations, \$2,322,335.65 from State appropriations, \$30,764.78 from individuals and communities, \$365,552.53 from fees, \$696,108.33 from the sale of products, and \$644,387.87 from miscellaneous sources. The value of additions to the equipment of the stations during the year is estimated as \$751,198.33, of which \$318,500.59 was for buildings.

The stations employed 1,955 persons in the work of administration and inquiry. Of this number 950 were also members of the teaching staff of the colleges, and 691 assisted in the various lines of extension work. During the year the stations published 1,624 annual reports, bulletins, and circulars, aggregating 28,109 pages, and these were distributed to 1,130,219 addresses on the regular mailing list.

Part II. Cooperative extension work in agricultural and home economics, 1917.—This is the third annual report on the receipts, expenditures, and results of cooperative agricultural and home economics extension work in this country. Pages 19–162 are devoted to Extension Work in the South, pages 163–375 to Extension Work in the North and West, pages 377 and 378 to Farmers' Institutes in the United States in 1917, by J. M. Stedman, and pages 379–410 to statistics of farmers' institute and extension work.

Annual report of the director for the fiscal year ending June 30, 1918 (*Delaware Sta. Bul. 122* (1918), pp. 31).—This contains the organization list and the report of the director on the work and publications of the station, including a financial statement for the fiscal year ended June 30, 1918. The experimental work recorded is for the most part abstracted elsewhere in this issue.

Thirtieth and Thirty-first Annual Reports of Georgia Station, 1917 and 1918 (*Georgia Sta. Rpts. 1917–18, pp. 24*).—This contains the organization list, reports by the president of the board of directors and the director of the station on its work during the two years, and a financial statement for the fiscal years ended June 30, 1917, and 1918. The experimental work reported is for the most part abstracted elsewhere in this issue.

Report of Hawaii Station, 1918 (*Hawaii Sta. Rpt. 1918*, *pp. 55*, *pls. 11*).— This contains the organization list, a summary by the agronomist in charge as to the work of the year, and reports of the divisions of horticulture, chemistry, plant pathology, agronomy, and extension, and of the Glenwood substation. The experimental work recorded is for the most part abstracted elsewhere in this issue.

Thirty-first Annual Report of Illinois Station, 1918 (*Illinois Stat. Rpt.* 1918, pp. 20).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1918, brief notes as to the principal lines of work, and a list of publications of the year. Brief notes of progress in horticultural studies are abstracted on page 146 of this issue.

Twenty-ninth Annual Report of New Mexico Station, 1918 (New Mexico Sta. Rpt. 1918, pp. 73, figs. 9).—This contains the organization list, a report of the director on the work and publications of the station, including reports of heads of departments, and a financial statement for the year ended June 30, 1918. The experimental features not previously reported are for the most part abstracted elsewhere in this issue.

The work of the experiment station.—Report of director, 1917, T. P. COOPER (North Dakota Sta. Rpt. 1917, pp. 27, figs. 7).—This. the twenty-eighth report of the station, contains the organization list, a report of the director, and a financial statement for the fiscal year ended June 30, 1917. The experimental work reported is for the most part abstracted elsewhere in this issue.

Monthly Bulletin of the Ohio Experiment Station (Mo. Bul. Ohio Sta., 4 (1919), No. 4, pp. 97-135, figs. 19).—This contains several articles abstracted elsewhere in this issue, together with one entitled Growing Rape for Summer Forage, by F. A. Welton, and notes.

Program of work of the United States Department of Agriculture for the fiscal year 1919, E. H. BRADLEY (*Washington: U. S. Dept. Agr., 1919, pp. IX+6.17*).—The activities of this Department are set forth in project form.

# NOTES.

**Connecticut State Station.**—Major John P. Street, chief of the department of chemistry, resigned August 1 to engage in commercial work and has been succeeded by Dr. E. M. Bailey.

**Georgia Station.**—The legislature has appropriated \$8,000 to supplement the Federal funds in the repair and upkeep of the station.

Hawaii College.—The territorial legislature has recently enacted legislation whereby in 1920 the college will be expanded into the University of Hawaii. Two colleges will be organized, a college of applied science, which will continue most of the present curriculum, including agriculture and mechanical arts, and a college of arts and sciences, to offer courses in cultural lines and leading to the B. A. degree.

Idaho University and Station.—Dr. Wilber R. Kidwell has been appointed assistant professor of veterinary science in the college of agriculture, beginning September 1. R. S. Snyder, assistant in soil chemistry in the Iowa Station, has been appointed assistant chemist in the station.

Maryland Station.—E. V. Miller has been appointed assistant plant physiologist, George F. Stuntz, assistant agronomist, and F. S. Holmes, seed inspector, succeeding S. V. Eaton, W. J. Aitcheson, and C. P. Smith, respectively. E. H. Brinkley has resigned as farm superintendent.

**Massachusetts College.**—The innovation was tried this year of holding farmers' week in midsummer instead of in the spring. The plan is reported as very successful, the maximum attendance aggregating over 1,500 and being of a very representative nature.

**Ohio Station.**—*Science* announces that Don C. Mote, assistant animal husbandman in parasitology investigations, has been appointed State entomologist of Arizona, beginning July 1.

**Oregon College and Station.**—C. I. Lewis, head of the department of horticulture and vice-director of the station, has resigned to engage in commercial work. Dr. E. J. Kraus, dean of service departments and research horticulturist, has been appointed professor of applied botany at the University of Wisconsin. F. S. Wilkins, instructor in farm crops at the Iowa College, has been appointed assistant professor of farm crops.

**Rhode Island Station.**—Chester Bridge and William Mather, 1919 graduates of Wesleyan University and the Massachusetts Agricultural College, respectively, have been appointed assistants in chemistry and have entered upon their duties.

**Vermont University.**—At the last session of the legislature an appropriation of \$25,200 per annum was made for cooperative extension work. This is to be expended through the county farm bureaus, at the rate of \$600 per year for each of the three main divisions, namely, county agents, home demonstrations, and boys' and girls' clubs.

Wyoming University and Station.—Work has been begun on a double house at the university stock farm.

Dr. J. W. Scott, professor of zoology and research parasitologist, is to spend the coming year in research work in the East, partly in Washington, D. C. Dr. J. I. Hardy, associate wool specialist of the station, has accepted a position in connection with the sheep and wool investigations of the Bureau of Animal Industry of the U. S. Department of Agriculture.

**Ontario Agricultural College.**—A memorial hall is projected in commemoration of the former students of the college, numbering over one hundred, who lost their lives in the war. This building will contain an assembly hall seating at least 800 and will cost about \$100,000. The government has appropriated \$40,000 for the purpose, and it is planned to raise the remaining sum by subscription from the alumni and others interested.

Soldier Training at Canadian Experimental Stations.—Arrangements have been made for giving agricultural instruction to returned soldiers at the Dominion Experimental Farms at Fredericton, New Brunswick, and Lennoxville, Quebec. The object will be to qualify returned soldiers as farmers under the Soldiers' Land Settlement Act. An instruction staff and such additional equipment as is found necessary will be furnished by the Soldiers' Settlement Board. The work will be under the direction of the superintendent of the station, and will be so arranged as to interfere as little as possible with the regular experimental work under way.

Agricultural Education for Ex-service Men in Great Britain.—The Department of Demobilization and Resettlement of the Ministry of Labor announces that the British Government has decided to provide assistance to ex-service men, irrespective of their military rank, who desire to continue their education and training but are financially unable to do so. The types of training for which assistance may be granted include courses in both higher education in agriculture and practical training on farms, either in institutions approved by the Board of Agriculture and Fisheries of Great Britain or the corresponding boards in Scotland and Ireland.

Sugar Beet Growing Work of British Board of Agriculture.—An estate of 5,600 acres has been purchased by the British Sugar Beet Growers' Society with the financial assistance of the government at Kelham near Newark. It is planned to develop this estate as a test of commercial beet growing on a large scale.

Agricultural Encouragement in France.—An annual appropriation of \$250,000 has been made to stimulate improved methods in agriculture following the war. This sum will be expended through committees representing the various departments and serving without pay. It is planned to purchase high grade cattle of from 7 to 8 years of age, which now are frequently marketed, and to resell them to farmers in order to demonstrate their value for breeding purposes. It is also planned to purchase American farm machinery for resale to demonstrate its ultimate economy in terms of service. Agricultural fairs are to be further developed and seed grain stocks purchased and distributed at nominal sums for demonstration purposes.

Miscellaneous.—An animal husbandry class in Aberdeen University, Scotland, was opened last April for soldier students of the Canadian, Australian, and South African expeditionary forces with an enrollment of about 100. Visits to leading herds in the vicinity were a noteworthy feature of the course.

The American Association of Agricultural College Editors held its seventh annual meeting at Columbus, Ohio, June 25 to 27. The officers elected for the ensuing year include F. H. Jeter of North Carolina, president; F. C. Dean of Ohio State University, vice-president; and M. V. Atwood of Cornell University, secretary-treasurer. The next meeting will be held at the Massachusetts Agricultural College,

Recent work in agricultural science	201
Notes	300

## SUBJECT LIST OF ABSTRACTS.

#### AGRICULTURAL CHEMISTRY-AGROTECHNY.

Annual reports on chemistry for 1918, edited by Cain and Greenaway Studies relating to milk Preparation of rhamnose, Clark	$201 \\ 201 \\ 201 \\ 202 \\ 202$
Studies relating to milk Preparation of rhamnose, Clark	201 201 202
Preparation of rhamnose, Clark	201 202
reparation of fillenges of the second s	202
The composition of starch.—I-II. Mellanby	200
Nature of the cellulose of cereal straw. Heuser and Haug	-202
Studies on enzym action —XVII Vegetables Falk et al	202
Oxidizing enzyms —I. The nature of "peroxid" Onslow	203
Accuracy of different methods of measuring small volumes Andrewes	203
Replacement of platinum by an allow in analysis. Nicolardot and Boudot	203
Table of $\mathbf{n}\mathbf{H}$ $\mathbf{H}\mathbf{H}$ and $\mathbf{O}\mathbf{H}$ values schmidt and Hogen	204
Table of pli, 11 , and off values, schindt and Hoagiand	204
Determination of nitrites and nitrates in presence of each other, Oeisner	204
Observations on the albuminoid ammonia test, Cooper and Heward	204
Determination of sulphate as BaSO <sub>4</sub> , Kolthoff and Vogelenzang	205
Determination of sulphate as SrSO <sub>4</sub> , Kolthoff and Vogelenzang	205
Acidity and alkalinity, with special reference to soils. Wherry	205
A simplified wet combustion method for carbon in soils. Waynick	206
Analysis of calcium evanamid Hana and van Haaran	207
The vod indetention to at Machalence and Dalmar	201
The red fodotanine test, Tsakalotos and Dalmas	207
Adulteration of fresh with "santen" and condensed milk, Weehuizen	208

I

The loss of moisture from sugar samples, Browne and Hardin       208         Color of sugar cane products and decolorization, Zerban and Freeland       208         Pumpkin seeds as a source of oil, Albrecht       209         Soy bean products and their uses, Williams       209         Modification of composition of vegetable oils, White       209
Color of sugar cane products and decolorization, Zerban and Freeland208Pumpkin seeds as a source of oil, Albrecht209Soy bean products and their uses, Williams209Modification of composition of vegetable oils, White209
Pumpkin seeds as a source of oil, Albrecht       209         Soy bean products and their uses, Williams       209         Modification of composition of vegetable oils, White       209
Soy bean products and their uses, Williams       209         Modification of composition of vegetable oils, White       209
Modification of composition of vegetable oils, White 209
Temperature-time relations in canned foods, Thompson 209
Action of alcoholic KoH on resins, Nicolardot and Coffignier 210
The alkali industry, Partington 210

# METEOROLOGY.

A soil temperature survey of the United States and Canada, Shreve	210
Report of the department of meteorology, Church, jr	211
Climate and meteorology [of Canada], Stupart et al	211
Climate of Sao Paulo, Belfort Mattos	211
The lunar tide in the atmosphere, Chapman	211
The lunar tide in the earth's atmosphere, Chapman	211
Atmospheric pollution, Redway	211

#### SOILS-FERTILIZERS.

Reconnoissance survey of San Joaquin Valley, Cal., Holmes et al	211
Soil survey of the Santa Maria area, Cal., Watson and Smith	211
Soil survey of Saratoga County, N. Y., Maxon and Bromley	212
Land classification in south half of Minnesota, Leverett and Sardeson	212
Peat and muck soils, Ames	212
Nitrification in moor soils, Arnd	212
Nitrogen contents of cacao soils with and without shade, de Verteuil	213
The organic phosphorus of soil, Potter and Snyder	213
The movement of plant food within the soil, Van Alstine	214
Aluminum and acid soil on barley and rye, Hartwell and Pember	214
Influence of heated soils on seed germination and growth, Johnson	215
The Actinomyces of the soil, Waksman and Curtis	217
The occurrence of Actinomyces in the soil, Waksman and Curtis	217
Illinois crop yields from soil experiment fields, Hopkins et al	218
Commercial fertilizers for Indiana: What to use, Wiancko	218
The agricultural value of organic manures, Russell	218
How the nitrogen problem has been solved, Creighton	218
Production of ammonia from lime nitrogen and the yield, Grahmann	219
America's advance in potash production, Ebaugh	219
Trade and fraud in commercial fertilizers, Pompeu do Amaral	219
Report of analyses of commercial fertilizers collected during 1918	219

# AGRICULTURAL BOTANY.

The flora of the American Virgin Islands, Britton	219
Geobotany of the Santa Lucia Mountains Shreve	220
The vegetation of an imperfectly drained desert valley Shreve	220
Isolation and specific change Sinnatt	220
Constitution and specific triange, bindetermining distribution Hawig	- <u>22</u> 0
Osmotic concentration in relation to geographical distribution, Harris	220
Osmotic concentration of tissue fluids of epiphytes, Harris	220
Endurance of extreme conditions and relation to adaptation, Osterhout	220
Investigation on the imbibition of water by gelatin, Shreve	221
Effect of organic acids and amido compounds, MacDougal and Spoehr	221
The absorption of calcium salts by squash seedlings. True and Harvey	221
The nucleus as a center of oxidation, Osterhout	221
Studies on the production of matter in light and shadow plants, Jensen	222
The luminescence of <i>Pseudomonas luminescens</i> , de Coulon	222
Transpiration [in plants], Knight	222
Weather conditions and plant development, Burns	222
Contact stimulation, Stone	222
Apparatus for determining the temperature of leaves, Shreve	222
Evolution by hybridization, Jeffrey	223
Inheritance studies on castor beans, White	223
The inheritance of doubleness in <i>Chelidonium maius</i> . Sax	223
Duplication and cohesion in the main axis in <i>Cichorium intubus</i> , Stout	223
CALLY CAPTION AND THAT A DEFINITION THAT THAT THAT THAT THE THAT THE THAT THAT	

	Page.
Intercrosses between self-sterile plants, East	223
Analysis of changes in progressive mutation, La Rue and Bartlett	224
Variations in somatic chromosomes in <i>Enothera scintillans</i> ; Hance	224
Interrelationships of characters in seedlings of Phaseolus, Harris	224
Tubers within tubers of Solanum tuberosum, Stewart	224

# FIELD CROPS.

[Report of field crops work in Idaho, 1918], Bonnett et al	225
[Report of field crops work on the Aberdeen substation, 1918], Aicher	226
[Beport of field crops work in Iowa 1918]	226
Variety testing and cron improvement Knight	227
Report of agricultural association of Zoaland in 10181 Techson	200
Weper in 1917 of Laterague and Sud Örtenheiten I. Malm	220
[work in 1917 at Leteensuo and Syd-Osterbotten], Main	230
[Irrigation experiment with alfalfa and wheat], Knight	231
Clover and grass seeding in conversion of waste land to meadow, Grisch	231
Brown hay, Linklater	232
Cassava experiments, 1916–1918, de Verteuil	232
How to increase Indiana corn yields, Wiancko	232
Yield of corn from seed grown under different conditions. Stookey	232
Present position and future prospects of natural indigo industry, Davis	233
Experiments with potatoes	233
An analysis of the costs of growing potatoes, Fox	233
Sudan grass as an Ohio crop, Williams	234
A study of sugar cane experiments, Cross	234
Experiments on the time of sowing turnips and rutabagas	234
The heredity of quantitative characters in wheat, Freeman	235
Seed Reporter	235
Pure seed law and the weed control act, Wenger	236

# HORTICULTURE.

The book of the home garden, Fullerton	236
Vegetables and their cultivation, Sanders	236
A handbook of vegetable culture, Molegode	-236
Bud variation as a practical asset in horticulture, Dorsey	236
The effect of the frosts of the winter of 1916–17 on vegetation, Bowles	236
California crop distribution and estimates 1918	237
Analyses of insecticides and fungicides	237
[Beets and peas at Wisley]	237
Cabbage culture, Rigney	237
General arboriculture, Priego	-237
[Report on horticultural investigations]	-237
[Report on horticultural investigations], Hansen	238
Fruit growing in the semiarid Northwest, Pfaender	238
The Australian fruit industryIts development and importance, Allen	238
The Lorette system of pruning, Durham	238
The healing of pruning wounds, Brierley	238
Decade records of Ohio apple orchards, No. 1, Gossard	239
Pruning experiments with peaches, Blake and Connors	239
Pollination of the Bartlett pear, Tufts	240
"Reversion" and resistance to "big bud" in black currants, Lees	241
The pruning of young vines, Daumas	241
Notes on some hybrid bearers, Pée-Laby	241
The hybrid bearers in 1918 at the Toulouse Testing Garden, Pée-Laby	241
The reconstitution in Champagne, Philipponnat	241
Varieties of the Satsuma orange, Scott	241
Pruning v. no pruning of full bearing Washington navel trees, Shamel	241
Improving the soil in a young orchard, Prizer	241
[Cacao, coffee, tea, and rubber in Uganda], Simpson and Maitland	242
Cultivation of the Robusta types of coffee, Deutrom	242
Pruning experiments with young tea, Andrews	242
Report of chief gardener, Moore	242
[Delphiniums, myosotis, and annual poppies at Wisley, 1917]	242
The history of Ananas and Agave, Killermann	242
The dahlia	242

III

	Page.
The American rose annual, edited by McFarland	242
New pillar rose, Van Fleet	242
Mildew-resistant roses, Easlea	242
Hardy trees, shrubs, and flowers for Wisconsin homes, Aust	242
Evergreens for the Northern Plains, Wedge	243

#### FORESTRY.

Modern forestry, Kubelka	243
Report of State Forestry Board of Minnesota for 1918, Andrews et al	243
Reports of the forest branch for 1917 and 1918, Grainger	243
A forest policy for Louisiana, Forbes	243
How can private lands be brought under forest management? Sparhawk	243
Public control of private forests in Norway, Dana	243
Afforestation, Boyd	244
The realizable resources of German forests, Huffel	244
Present status of forest taxation in the United States, McKay	244
Aerial photography and National Forest mapping, Thelen	244
A forest reconnaissance of the Delaware peninsula, Harper	244
A sketch of the forest geography of New Jersey, Harper	244
Micrography of the woods of Javanese trees, IV-V, Moll and Janssonius	244
Analyses of some morphological characters of Bombay species, Sedgwick	244
Coniferous trees, Webster	244
Lignum-vitæ, the vital wood, Record	244
On a new species or form of Eucalyptus, Hall	244
The effect of lightning on Hevea, Rutgers	245

#### DISEASES OF PLANTS.

Ecological conditions of development of parasitic fungi, Dufrénoy	245
Some plant diseases that were especially serious this season	245
Plant disease survey and information service, Whetzel	245
Prevention of insect pests and plant diseases	245
Quick method of eliminating seed-borne organisms, Melhus and Rhodes	245
Presoaking in preventing seed injury due to disinfectants, Braun	246
The black chaff of wheat, Smith, Jones, and Reddy	246
Formaldehyde v. corrosive sublimate in treating cabbage seed	246
Black spot of onion sets, Stevens and True	246
Potato insect and disease control, Rankin	247
Leaf roll and mosaic of potatoes, Vogel	247
A new method of treating seed potatoes for scab	247
Potato spraying profitable	247
A fungus disease of prickly pear, Darnell-Smith and Ross	248
Influence of soil environment on root rot, Johnson and Hartman	248
Fruit insect and disease control, Hesler	248
Apple blotch, a serious fruit disease, Selby	249
The control of crown gall of apples	249
Powdery mildew of the apple, Allen and le G. Brereton	249
Control of black raspberry anthracnose and tip blight	249
Development and treatment of grape downy mildew, Ravaz	249
A consideration of [carnation] yellows, Lamkey	250

#### ECONOMIC ZOOLOGY-ENTOMOLOGY.

Mutanda ornithologica, VII, Oberholser       250         The status of the genus Centronyx Baird, Oberholser       250         The proper name for Limicola platyrhyncha, Oberholser       250         The taxonomic position of the genus Ramphalcyon, Oberholser       250         The generic name of the rook, Oberholser       250         The status of the subgenus Sieberocitta, Oberholser       250         The status of the subgenus Sieberocitta, Oberholser       250         Spizella arborea the proper name for the tree sparrow, Oberholser       250         Methods in entomological field experimentation, Flint et al       250         Value of crude arsenious oxid for cutworms and grasshoppers, Davis       251         Sulphate of ammonia as an insecticide, Colón       251         IReport of thel department of entomology, Severin       251		
The status of the genus Centronyx Baird, Oberholser       250         The proper name for Limicola platyrhyncha, Oberholser       250         The taxonomic position of the genus Ramphalcyon, Oberholser       250         The generic name of the rook, Oberholser       250         The status of the subgenus Sieberocitta, Oberholser       250         Spizella arborea the proper name for the tree sparrow, Oberholser       250         Methods in entomological field experimentation, Flint et al       250         Organization for insect suppression, Burgess       250         Value of crude arsenious oxid for cutworms and grasshoppers, Davis       251         Sulphate of ammonia as an insecticide, Colón       251         Zarpert of thel department of entomology, Severin       251	Mutanda ornithologica, VII, Oberholser	250
The proper name for Limicola platyrhyncha, Oberholser       250         The taxonomic position of the genus Ramphalcyon, Oberholser       250         The generic name of the rook, Oberholser       250         The status of the subgenus Sieberocitta, Oberholser       250         Spizella arborea the proper name for the tree sparrow, Oberholser       250         Organization for insect suppression, Burgess       250         Value of crude arsenious oxid for cutworms and grasshoppers, Davis       250         Sulphate of ammonia as an insecticide, Colón       251         IReport of the I department of entomology, Severin       251	The status of the genus Centronyx Baird, Oberholser	250
The taxonomic position of the genus Ramphalcyon, Oberholser250       250         The generic name of the rook, Oberholser250       250         The status of the subgenus Sieberocitta, Oberholser250       250         Spizella arborea the proper name for the tree sparrow, Oberholser250       250         Methods in entomological field experimentation, Flint et al250       250         Value of crude arsenious oxid for cutworms and grasshoppers, Davis251       250         Sulphate of ammonia as an insecticide, Colón251       251         IReport of the] department of entomology, Severin251       251	The proper name for <i>Limicola platyrhyncha</i> , Oberholser	250
The generic name of the rook, Oberholser       250         The status of the subgenus Sieberocitta, Oberholser       250         Spizella arborea the proper name for the tree sparrow, Oberholser       250         Methods in entomological field experimentation, Flint et al       250         Organization for insect suppression, Burgess       250         Value of crude arsenious oxid for cutworms and grasshoppers, Davis       251         Sulphate of ammonia as an insecticide, Colón       251         IReport of the] department of entomology, Severin       251	The taxonomic position of the genus Ramphalcyon, Oberholser	250
The status of the subgenus Sieberocitta, Oberholser       250         Spizella arborea the proper name for the tree sparrow, Oberholser       250         Methods in entomological field experimentation, Flint et al       250         Organization for insect suppression, Burgess       250         Value of crude arsenious oxid for cutworms and grasshoppers, Davis       251         Sulphate of ammonia as an insecticide, Colón       251         IReport of thel department of entomology, Severin       251	The generic name of the rook, Oberholser	250
Spizella arborea the proper name for the tree sparrow, Oberholser       250         Methods in entomological field experimentation, Flint et al       250         Organization for insect suppression, Burgess       250         Value of crude arsenious oxid for cutworms and grasshoppers, Davis       251         Sulphate of ammonia as an insecticide, Colón       251         IReport of the department of entomology, Severin       251	The status of the subgenus Sieberocitta, Oberholser	250
Methods in entomological field experimentation, Flint et al       250         Organization for insect suppression, Burgess       250         Value of crude arsenious oxid for cutworms and grasshoppers, Davis       251         Sulphate of ammonia as an insecticide, Colón       251         IReport of thel department of entomology, Severin       251	Spizella arborea the proper name for the tree sparrow, Oberholser	250
Organization for insect suppression, Burgess       250         Value of crude arsenious oxid for cutworms and grasshoppers, Davis       251         Sulphate of ammonia as an insecticide, Colón       251         [Report of the] department of entomology, Severin       251	Methods in entomological field experimentation, Flint et al	250
Value of crude arsenious oxid for cutworms and grasshoppers, Davis       251         Sulphate of ammonia as an insecticide, Colón       251         [Report of the] department of entomology, Severin       251	Organization for insect suppression, Burgess	250
Sulphate of ammonia as an insecticide, Colón 251 [Report of the] department of entomology, Severin 251	Value of crude arsenious oxid for cutworms and grasshoppers, Davis	251
[Report of the] department of entomology, Severin 251	Sulphate of ammonia as an insecticide, Colón	251
	[Report of the] department of entomology, Severin	251

	Page.
Notes on some little known pests of red clover, Herric and Detwiler	251
Internal disease of cotton bolls in the West Indies, II, Nowell	251
Important pests collected on imported nursery stock in 1918, Sasscer	251
Experiments with poison baits against grasshoppers, Ricker	252
Grasshopper control in Kansas, Dean, Kelly, and Ford	252
Palmodes præstans and its prev. Caudell	252
Leaf hoppers injurious to apple trees, Lathrop2	52,253
A new genus for <i>Tettigonia trifasciata</i> , McAtee	253
Preliminary key to the Nearctic species of Eupteryx, McAtee	253
Some studies on the eggs of important apple plant lice. Peterson	253
Vegetable plant lice. Headlee	255
Control of plant lice or aphis, Chittenden	255
A Melaphis from moss. Baker	255
The identity of Smunthurodes betwee Westwood, Baker	255
An undescribed species of Dryopea injurious to Phyllostachys, Baker	255
Report on a collection of Coccide from Argentina, Morrison	255
Dry cleaning as a means of destroying holy lice. Hutchison and Pierce	255
Notes on Diacrisia niranica. Mitchell	256
The work in the United States against the pink hollworm. Hunter	256
The European corn herer and its control. Vinal and Caffrey	256
The European corn herer problem Caffrey	257
The European corn horer A menace to the country's corn crop Caffrey	257
A new species of Bucculatrix injurious to bollyhock Busck	257
Two Microlenidontera iniurious to strawberry Busck	257
On some generic synonomy in the family Gelechida, Busck	258
Descriptions of new species of Coleonhora, Braum	258
Notes on the California oak worm. <i>Phruganidia californica</i> . Burke	258
Nicotin sulphate as a control for chrysanthemum gall midge. Guyton	258
Observations with <i>Cuterebra tenebrosa</i> . Parker and Wells	258
Notes on Phlebotomus species attacking man. Parman	259
A new genus in Scatonhagidæ, Greene	259
The dispersion of flies by flight, Bishopp and Laake	259
A new root maggot treatment. Stookey	259
Some notes on <i>Phorbia fuscicens</i> as a bean pest. Hawley	259
Two new genera of Anthonyida, Aldrich	259
A new genus and species of Cerambycidæ from Colorado, Fisher	259
A new genus and species of Buprestidæ from Arizona, Fisher	259
Note on Macrobasis murina, Fisher	259
The striped cucumber beetle and its control. Chittenden	259
Injury from white grubs in Iowa, Ball and Walter	259
Notes on a cocoon making colvdiid. Burke	259
Eleodes opaça, an important enemy of wheat in Great Plains, McColloch	260
Avocado seed weevils, Barber	260
The weevils of the superfamily Curculionoidea, Pierce	261
[Apicultural work]	261
The clover seed chalcid (Bruchophagus funebris), Williamson	261
New genera and species of ichneumon flies, Cushman	261
A new genus of chalcid wasp belonging to the family Eulophidæ, Gahan	261
Parasite introduction as a means of saving sugar, Holloway	261
A new species of the serphidoid genus Dendrocerus, Gahan	261
Description of a new synipoid from Trinidad. Rohwer	261

# FOODS-HUMAN NUTRITION.

Nutritive value of wheat kernel and its products, Osborne, Mendel, et al	261
Nutritive value of coconut globulin and coconut press cake, Johns et al	262

# EXPERIMENT STATION RECORD.

Vol. 41.

Abstract Number.

No. 3.

# **RECENT WORK IN AGRICULTURAL SCIENCE.**

# AGRICULTURAL CHEMISTRY-AGROTECHNY.

Annual reports on the progress of chemistry for 1918, edited by J. C. CAIN and A. J. GREENAWAY (Ann. Rpts. Prog. Chem. [London], 15 (1918), pp. IX +240).—This is the usual annual report (E. S. R., 40, p. 109). Of special interest to the agricultural chemist are notes on the progress in agricultural analysis in the report on Analytical Chemistry by C. A. Mitchell, and the report on Agricultural Chemistry and Vegetable Physiology by E. T. Russell. This report includes advances in the chemistry of soil, fertilizers, plant growth, feeding stuffs, milk, and fermentation.

Studies relating to milk (*New York Sta. Tech. Bul.* 65 (1918), pp. 3-54, figs. 4).—This bulletin consists of three papers which have been previously noted from other sources as follows: (1) The Preparation of Pure Casein, by L. L. Van Slyke and J. C. Baker (E. S. R., 39, p. 801); (2) a Method for Making Electrometric Titrations of Milk and Other Solutions Containing Proteins, by J. C. Baker and L. L. Van Slyke (E. S. R., 39, p. 611); and (3) Free Lactic Acid in Sour Milk, by L. L. Van Slyke and J. C. Baker (E. S. R., 39, p. 611); and (3) Free Lactic

**Preparation of rhamnose, E. P. CLARK** (*Jour. Biol. Chem.*, 38 (1919), No. 2, pp. 255, 256).—Satisfactory yields of rhamnose from quercitron extract are said to be obtained by the following process:

Two kg. of liquid quercitron extract is dissolved in enough hot water to make 5.5 liters. To the boiling solution is gradually added 180 cc. of concentrated sulphuric acid dissolved in 320 cc. of water. After boiling gently for 30 minutes, the mixture is poured into an enameled kettle and cooled quickly. The insoluble matter is filtered off and the remaining liquid neutralized with barium hydroxid and filtered. The filtrate is evaporated to a thin sirup, 8 volumes of 95 per cent alcohol are added slowly with constant stirring, and the precipitate formed is filtered off on a Büchner funnel. The resulting filtrate is evaporated under diminished pressure to a thick sirup, dissolved in 1 liter of 95 per cent alcohol, and treated with 2.5 liters of ether.

The gummy substance precipitated is separated from the supernatant liquid by decantation, dissolved in 50 cc. of water and enough alcohol to make 1 liter, and again precipitated with 2.5 liters of ether. The liquid is decanted and the two ethereal extracts are mixed and allowed to stand over night. The clear solution is poured from the gummy substance, the ether is recovered by distilling on a steam bath, and the remaining alcoholic solution evaporated under diminished pressure to a thick sirup. An equal volume of alcohol and some ether are added and, upon scratching the flask or seeding, the rhamnose separates out and is removed by filtering on a Büchner funnel and washing first with a mixture of 1 part ether and 2 parts alcohol, then with a 1:1 alcohol and ether mixture, and finally with ether. The yield is said to be from 50 to 55 gm. of white sugar, which may be recrystallized from water or alcohol in the usual way.

The composition of starch.—I, Precipitation by colloidal iron. II, Precipitation by iodin and electrolytes, J. MELLANBY (*Biochem. Jour.*, 13 (1919), No. 1, pp. 28-36).—The composition of starch has been studied by means of the effects produced by colloidal iron and by iodin on a solution of potato starch in water.

Precipitation of starch by colloidal iron showed that starch granulose can be separated into three fractions forming 80 per cent, 9 per cent, and 11 per cent, respectively, of the starch granulose. The first fraction is precipitated by colloidal iron only, the second by colloidal iron and electrolytes, and the third is not precipitated by colloidal iron under any conditions.

Precipitation of starch by iodin and electrolytes showed that starch contains an insoluble constituent which does not react with iodin (amylocellulose), that all the soluble constituents of starch are precipitated by iodin in the presence of electrolytes, and that the final fraction precipitated by iodin gives a brown color with iodin.

These results are thought to indicate that "starch contains a variety of polymers varying in complexity from amylodextrin to amylocellulose, the relative quantities of dextrin and cellulose being small while the bulk of the granule is composed of amylogranulose."

Iodin was found to unite with starch quantitatively, forming starch iodid. Approximately 1,600 gm. of starch are equivalent to 127 gm. of iodin. Starch iodid, however, absorbs iodin from solution so that after the equivalent point is reached the amount of iodin contained in the precipitated starch iodid is a function of the amount of iodin contained in the original solution.

Nature of the cellulose of cereal straw, E. HEUSER and A. HAUG (Ztschr. Angew. Chem., 31 (1918), No. 39, Aufsatzteil, pp. 99, 100; No. 41, Aufsatzteil, pp. 103, 104; No. 71, Aufsatzteil, pp. 166–168; No. 73, Aufsatzteil, pp. 172–176; abs. in Chem. Abs., 12 (1918), No. 22, p. 2439; 13 (1919), No. 10, p. 1148).—This paper reports a detailed study of the determination and properties of cellulose in cereal straw, as a result of which the conclusion is drawn that the constitution of straw cellulose apparently corresponds to that of cotton cellulose. It is strongly contaminated with a pentosan, and so modified by the usual bleaching processes that the pulp contains considerable oxycellulose.

Studies on enzym action.—XVII, The oxidase, peroxidase, catalase, and amylase of fresh and dehydrated vegetables, K. G. FALK, G. MCGURE, and E. BLOUNT (*Jour. Biol. Chem.*, 38 (1919), No. 2, pp. 229–244).—In continuation of the series of studies on enzym action previously noted (E. S. R., 38, p. 803), an investigation is reported of the enzyms oxidase, peroxidase, catalase, and amylase in extracts of fresh, air-dehydrated, and vacuum-dehydrated potatoes, tomatoes, carrots, white and yellow turnips, and cabbage at different H-ion concentrations.

The extracts of the fresh vegetables were prepared by straining through muslin the finely ground product. The dehydrated vegetables were soaked for 20 minutes in the average amount of water lost on dehydration and were then ground in the meat chopper and strained. The H-ion concentration of the juice was determined colorimetrically. The technique used in testing the enzyms is described in detail. The results obtained may be summarized as follows: The H-ion concentrations of all the vegetable juices were in the neighborhood of pH 6 with the exception of tomato juice, which was about pH 4. However, in bringing the H-ion concentration of the juices to various values between pH 2 and 12 less acid and more alkali were required for the dehydrated products than for the fresh vegetables for the same concentration. This difference was more marked with air-dehydrated than with vacuum-dehydrated products. This is thought to indicate definite changes brought about in dehydration, probably in the character of the protein material.

The enzym reactions of all the vegetable juices studied were destroyed by boiling for several minutes. The oxidase reaction with carrot, yellow and white turnip, and potato juices was greatly increased on dilution. No well defined H-ion concentration for maximum action with oxidase, peroxidase, and catalase was observed although the actions were better in the more alkaline solutions between pH 7 and 10. They were inhibited in acid solution, pH 2 and 3 for oxidase and peroxidase and pH 4 for catalase, except in the case of the tomato. With the exception of cabbage and carrot, the enzym action was less in the juice from the dehydrated than from the fresh vegetables, and less in the air-dehydrated than in the vacuum-dehydrated products.

The optimum amylase action in cabbage, carrot, and white turnip juices was at about pH 6, and in yellow turnip juices at from pH 4 to 7. The optimum H-ion concentration for the vegetable juice amylases coincided with the natural H-ion concentrations of these juices.

In considering the enzym results, the authors point out that the state of ripeness and the age of the vegetable undoubtedly influence the activities. In regard to dehydration, the shorter the period of time in which heat is applied the smaller will be the changes in enzym action, which probably accounts partly at least for the smaller changes in the vacuum dehydration products. It is suggested that the dark color of unboiled air-dehydrated potatoes may be avoided by increasing the H-ion concentration of  $10^{-6}$  or  $10^{-7}$  N to  $10^{-5}$  N before dehydration, thus equalizing the H-ion concentration of the potatoes with dilute acid solution before dehydration.

Oxidizing enzyms.—I, The nature of the "peroxid" naturally associated with certain direct oxidizing systems in plants, M. W. ONSLOW (*Biochem. Jour.*, 13 (1919), No. 1, pp. 1-9).—Evidence is presented to show that in plants in general which brown on injury the peroxidase is associated with an aromatic substance giving the reaction characteristic of the catechol grouping. In such plants the peroxidase on injury activates the oxidation of the aromatic substances, giving rise to peroxids, and the system peroxid-peroxidase will then blue guaiacum. Plants which do not brown on injury do not contain a substance with the catechol grouping, and their enzyms do not catalyse the oxidation of substances with such a grouping.

Observations on the accuracy of different methods of measuring small volumes of fluid, F. W. ANDREWES (*Biochem. Jour.*, 13 (1919), No. 1, pp. 37-44).—The author reports a comparison of the accuracy of the pipette and drop methods of measuring sera, particularly in the preparation of a series of doubling dilutions.

The chief conclusions from the observations made are (1) that volumes of 1 cc. and 0.5 cc, can be measured by pipette with reasonable accuracy, but that the error resulting from the attempt to deliver 0.1 cc. may amount to 5 per cent even when a 0.1 cc. pipette is employed; (2) that the only way in which accurate results can be obtained with a pipette in preparing an ascending series of dilutions is to use it as a delivery pipette and wash and dry it between successive measurements; and (3) that the drop method, if properly carried out with calibrated pipettes, is greatly to be preferred for serological work.

Contribution to the study of the replacement of platinum by an alloy in apparatus for electrolytic analysis, P. NICOLARDOT and J. BOUDET (*Bul. Soc. Chim. France, 4. ser., 25 (1919), No. 2, pp. 84–86*).—As a result of further investigation of the practicability of using an alloy in place of platinum for electroytic apparatus (E. S. R., 40, p. 109), the authors state that an alloy of gold and copper 9:1, treated for two hours with hot nitric acid and washed and dried, has proved entirely satisfactory for the cathode in long continued practical application. The anode of the same alloy is made in cylindrical form and protected by a thin layer of electrolytically deposited platinum.

Table of pH, H+ and OH- values corresponding to electromotive forces determined in hydrogen electrode measurements, with a bibliography, C. L. A. SCHMIDT and D. R. HOAGLAND (Univ. Cal. Pubs. Physiol., 5 (1919), No, 4, pp. 23-69).—The authors have prepared tables for the conversion of voltage into hydrogen and hydroxyl-ion concentrations for both the normal and N/10 KCl calomel electrode. The pH values according to the Sörenson notation have also been included. The measurements and equations upon which the calculations are based are described in detail.

The publication also contains a bibliography of 467 references to the literature on hydrogen-ion concentration classified under the headings of general and theoretical, biological (including blood, urine, milk, miscellaneous body fluids and tissues, proteins, enzyms, and sea water), bacteriological, soil and plant, miscellaneous, and indicators.

A compilation of methods for the quantitative determination of nitrites and nitrates in the presence of each other, A. OELSNER (*Ztschr. Angew. Chem.*, 31 (1918), No. 73, Aufsatzteil, pp. 170–172; No. 75, Aufsatzteil, pp. 178, 179; abs. in Chem. Abs., 13 (1919), No. 4, pp. 295, 296).—The author points out the importance in the investigation of nitrification and denitrification processes of determining the content of nitrites and nitrates in the culture solution, and discusses the following methods for such a determination: Colorimetric methods, gasvolumetric methods, a modified volumetric method devised by the author, the precipitation method, and the ester method.

The author's method, which is described in detail, consists essentially in estimating the nitrite by titration with potassium permanganate in acid solution and the nitrate by reduction with zinc and iron in alkaline solution. Because of the volatility of the nitrous acid, the titration is made by running the solution of nitrite from a burette into a measured quantity of the acid permanganate solution diluted with water and heated at 40°. The last drops are added slowly, and after decolorization the solution is titrated back with the permanganate solution. For the nitrate determination it is necessary to use an amount of the sample furnishing from 10 to 30 mg. of nitrate nitrogen.

The method is considered to be well adapted for following quantitatively the nitrification processes, provided ferrous sulphate is absent from the sample. If citric acid is present, the nitrite should be added very slowly and the back titration omitted.

**Observations on the albuminoid ammonia test, E. A.** COOPER and J. A. HEW-ARD (*Biochem. Jour.*, 13 (1919), No. 1, pp. 25-27).—Abnormal results in albuminoid ammonia determinations led to the discovery that potassium permanganate may contain a stable nitrogenous impurity, which can not as a rule be removed by prolonged boiling with alkali but which gradually decomposes when the solution is considerably diluted. The authors emphasize the necessity in routine work of testing fresh supplies of chemicals for the impurity, and in very accurate work of conducting a control experiment during each determination of albuminoid ammonia.

The gravimetric determination of sulphate as barium sulphate, I. M. KOL-THOFF and E. H. VOGELENZANG (*Pharm. Weekbl., 56* (1919), No. 5, pp. 122-142; *abs. in Chem. Abs., 13* (1919), No. 9, p. 944).—The various sources of error in the determination of sulphate as barium sulphate are discussed from the literature on the subject and from experiments conducted by the authors. The following conclusions are drawn:

The solubility of barium sulphate (2.3 mg. per liter at room temperature) is greatly increased by higher temperature. The presence of nitric or hydrochloric acid also increases the solubility of barium sulphate. This is more marked with nitric than with hydrochloric acid. Dry ignition in porcelain or moist ignition in platinum causes little or no reduction, dry ignition in platinum considerable reduction. The precipitate should be moistened with sulphuric acid and ignited to constant weight. Occluded salts can not be washed out after ignition as the occlusion is chemical in nature. The error due to phosphates is caused by the formation of barium phosphate from the barium sulphate. It is impossible to prescribe a general method of procedure for the accurate determination of sulphates in any particular solution.

The determination of sulphate as strontium sulphate, I. M. KOLTHOFF and E. H. VOGELENZANG (*Pharm. Weekbl.*, 56 (1919), No. 6, pp. 159–161; abs. in Chem. Abs., 13 (1919), No. 9, pp. 944, 945).—The determination of sulphate as strontium sulphate is shown to be subject to the same errors as in the case of barium sulphate noted above. While alcohol decreases the solubility of strontium sulphate alone, free acids and certain salts act as disturbing factors. A table is given showing this influence.

The statement of acidity and alkalinity with special reference to soils, E. T. WHERRY (*Jour. Wash. Acad. Sci.*, 9 (1919), *No.* 11, pp. 305–309).—The author proposes a method of stating acid and alkaline reactions in terms of so-called "specific acidity" and "specific alkalinity" the unit of which, instead of being 1 gram-equivalent per liter as in the usual method, is the number of gram-equivalents per liter of each ion present in pure water at ordinary temperature. The table given below, an abbreviation of the one given in the original article, shows the actual numbers corresponding to the powers of 10 representing some of the reactions likely to be met with in soil. The new values are called chemical potentials, and at the suggestion of E. Q. Adams are given the letter X, the Greek initial of chemical.

Comparison of different methods of stating reactions.

1919]

In the study of soils associated with various plants, the author has found that certain more or less well-defined types of reaction can be recognized as follows:

Superacid, bog peat supporting a characteristic flora of oxylophytes or acidsoil plants; mediacid, some bog peats, many upland peats, and other soils supporting oxylophytes; subacid, ordinary wood and field soils of low acidity; subalkaline, soils derived from limestone rocks; medialkaline and superalkaline, soils in alkaline regions where free sodium carbonate occurs.

Certain general advantages possessed by the proposed methods of stating reactions are discussed, the most desirable feature being the ease with which the relative magnitudes of reactions under comparison can be appreciated. The method is considered to be applicable to all determinations hitherto expressed in terms of pH.

A simplified wet combustion method for the determination of carbon in soils, D. D. WAYNICK (*Jour. Indus. and Engin. Chem.*, 11 (1919), No. 7, pp. 634-637, fg. 1).—The author, at the California Experiment Station, has modified the apparatus usually used in the wet combustion method in such a way that the carbon dioxide evolved is absorbed in soda line and can be determined gravimetrically. The reagents used are essentially those employed by Ames and Gaither (E. S. R., 32, p. 805), except that the chromic acid solution contains 3.3 gm. in 5 cc. of water. This amount of chromic acid and 50 cc. of sulphuric acid are used for each combustion.

The essential details of the apparatus are given in the accompanying figure. The air enters the apparatus through A, a tube filled with calcium chlorid.

FIG. 1 .- Modified apparatus for the wet combustion method.

It then passes through a column of 30-mesh soda lime in B and a small volume of concentrated potassium hydroxid in C, the latter serving as a means of keeping check on the rate of flow of air through the apparatus which is regulated by the stock-cock of D. The dropping funnel D holds the sulphuric acid before its introduction into the 300 cc. combustion flask E. The first of a series of three scrubbers F is filled with glass beads wet with sulphuric acid. This takes the place of the usual condenser and removes most of the sulphur trioxid fumes coming from the combustion flask. The dilute sulphuric acid condensed in F is caught in a 100 cc. Erlenmeyer flask G connected with a second flask H, to prevent any acid from getting into the scrubber I, filled with 30mesh zinc amalgamated with mercury. The trap H may be partially filled with a concentrated solution of silver sulphate to remove chlorine which might escape absorption in I. The upper half of J is filled with calcium chlorid and the lower half with phosphoric anhydrid, the two being separated by a layer of glass wool which is also used at the lower openings of all three scrubbers. The air current after leaving J passes through the U tube K filled with calcium chlorid and into the Nesbitt carbon combustion bulb L, filled with 20- to 30-mesh soda lime except for a small space at the top in which is a thin layer of phosphoric anhydrid. The U tube M, filled with calcium chlorid and soda lime, prevents contamination of the combustion bulb by stoppage of the pump. The whole system is connected with a suction pump.

From 5 to 15 gm. of soil and 5 cc. of the chromic acid solution are introduced into the combustion flask. Fifty cc. of sulphuric acid is run into the flask rapidly and sufficient heat applied under the flask to bring the mixture to the boiling point in five minutes. The heating is continued for 20 minutes, during which the aspiration should be so regulated that about 5 liters of air are drawn through the apparatus in the entire time. The aspiration is continued for five minutes after the heat is removed. When cool the absorption bulb L is closed and weighed.

Tables are given showing the accuracy of the method as determined by duplicate analyses and by comparison with other methods. The average error in weighing the combustion tube was about 0.02 per cent in terms of carbon, and the determination itself was subject to about the same error. The total time for the determination is about 25 minutes.

Analysis of calcium cyanamid with large percentage of dicyandiamid or urea, I: E. HENE and A. VAN HAAREN (*Ztschr. Angew. Chem.*, 31 (1918), No. 53, *Aufsatzteil, pp. 129–131*).—The method described is said to avoid the error of Caro's method (E. S. R., 25, p. 24) in abnormal samples of calcium cyanamid containing large proportions of dicyandiamid and urea. The technique of the proposed method is as follows:

The sample, the nitrogen content of which should be about 0.2 gm., is dissolved in water, diluted to about 200 cc., and precipitated with 20 cc. of 10 per cent silver nitrate and 30 cc. of 10 per cent potassium hydroxid. The precipitate, which contains all the cyanamid and dicyandiamid and some of the urea, is washed, the filter transferred to 150 cc. of water, and the silver salt dissolved in the smallest possible amount of nitric acid and diluted to 200 cc. Half of this solution is precipitated with 2 cc. of 10 per cent silver nitrate with the addition of 15 cc. of 10 per cent potassium hydroxid. The nitrogen in the precipitate, representing the cyanamid and dicyandiamid, is determined by the Kjeldahl process. The urea nitrogen is estimated in the combined filtrates or, more simply, by difference after determining the total nitrogen. In the other half of the original solution of the silver salt the cyanamid is precipitated by silver nitrate and ammonia. The dicyandiamid is calculated by difference.

The red iodotannic test, D. E. TSAKALOTOS and D. DALMAS (*Bul. Soc. Chim. France, 4. ser., 25 (1919), No. 2, pp. 80–84*).—A further study of the iodotannic test previously noted (E. S. R., 40, p. 610) is reported. With an N/100 solution of iodin the test was found to be more delicate with the tannic reagent than with starch except in the presence of potassium iodid, which in amounts larger than 1 per cent completely inhibits the tannic reaction.

The amounts of iodin and tannin were found to have a marked effect upon the reaction. The maximum intensity is produced when the quantities of iodin and of tannin are in the proportion of 1 cc. of N/10 iodin to from 0.4 to 1.2 of a 1 per cent tannin solution.

The adulteration of fresh milk with "santen" and condensed milk, F. WEEHUIZEN (Meded. Geneesk. Lab. Weltevreden [Dutch East Indies], 3. Ser. A, No. 1-2 (1918), pp. 161-163).—Attention is called to the sources of error in the Seliwannoff resorcin reaction as applied to sucrose, namely, the decomposition of oxymethylfurfurol when mixed with water and acids and of the aldohexoses on boiling. It is stated that both errors may be avoided by the use of a solution of hydrochloric acid gas in absolute alcohol. This can be prepared conveniently by allowing strong hydrochloric acid to drop on strong sulphuric acid and collecting the gas that is formed in absolute alcohol cooled on ice. The alcohol must be completely saturated and the reagent must not be kept for any length of time.

If to a mixture containing ketohexoses as such or in the form of disaccharids, as cane sugar, 0.05 to 0.1 gm. of resorcin and a few cubic centimeters of the alcoholized hydrochloric acid be added, a dark red color is produced rapidly at ordinary temperatures, while if lactose only is present there is no color change. In applying the test to milk suspected of being adulterated with condensed milk, the following technique is employed:

A mixture of 10 cc. of the milk and 30 cc. of absolute alcohol is shaken thoroughly and filtered. Ten cc. of the filtrate is evaporated nearly to dryness on the water bath, and to the residue are added about 0.05 gm. of resorcin and 3 to 4 cc. of the alcoholized hydrochloric acid. If from 1 to 2 per cent of milk sweetened with sucrose is present, the mixture is colored a light or dark cherryred within three minutes.

Adulteration with 10 per cent santen (the juice of coconut meat mixed with water) can be detected in the same way by using 20 cc. instead of 10 cc. of the filtrate.

The loss of moisture from sugar samples under different methods of preservation, C. A. BROWNE and G. H. HARDIN (Internat. Sugar Jour., 21 (1919), No. 246, pp. 274–277).—Various methods of preserving sugar samples were investigated by the New York Sugar Trade Laboratory. The best method, as regards prevention of loss of moisture, was found to be to store the sample in a wide mouth bottle provided with a ground glass stopper sealed with paraffin. It is said that samples prepared in this way can be kept indefinitely without the slightest loss in weight. Another fairly good method makes use of a 6 oz. glass bottle with a 1 in. opening closed with a deep cork and sealed by dipping twice in paraffin.

The color of sugar cane products and decolorization in factory practice, F. W. ZERBAN and E. C. FREELAND (Louisiana Stas. Bul. 165 (1919), pp. 32, figs. 3).—The literature on decolorizing carbons for 1918 is reviewed, the nature and relative importance of the well-known coloring matters occurring in sugarcane and formed during the manufacturing process are summarized, and a study is reported of the color and of the iron and polyphenol content of sugarhouse products as made by the usual methods of clarification, and by the same processes with the additional use of a decolorizing carbon. These sugarhouse tests were conducted during the grinding season of 1918–19 on a larger scale than those reported in Bulletin 161, previously noted (E. S. R., 39, p. 113).

Five full runs were made and a small sixth run. In the first three the generally accepted sulfitation process for making white sugar in Louisiana was adopted, carbon being used in one run and omitted in the other two. In the fourth and fifth runs, the juice, after being sulphured and limed back to neutrality, was acidified to decided litmus acidity. Carbon was used in one run and omitted in the other. The quantitative determination of coloring matters was made by the use of the Hess-Ives tint-photometer standardized for the purpose of translating the readings into concentrations.

The results obtained show that the combination of ferric iron and polyphenols plays a very important part in the color of sugarhouse products and that both must be kept at a minimum in order to make a light-colored sugar. To reduce the amount of iron, it is suggested that copper machinery be used to replace iron, or that the iron machinery be painted wherever possible with an iron-free paint resistant to acids, alkalis, and heat. Decolorizing carbons are effective in removing polyphenols and if a sufficient quantity of an active carbon be used the polyphenols, the iron combined with them, and substances giving rise to new polyphenol compounds, may be removed practically completely. The tests showed further that the yield of sucrose in the form of first sugar is slightly better and that the first molasses is of much lighter color where carbon is used than where it is not.

**Pumpkin** seeds as a source of oil, E. W. ALBRECHT (*Ztschr. Angew. Chem., 31* (1918), *No. 53*, *Aufsatzteil, p. 132*).—The author states that a satisfactory edible oil has been made in Roumania from the seeds of a variety of pumpkin having little flesh and many seeds. These seeds yielded on extraction with benzin and purification from 40 to 42 per cent of their dry weight in oil of a greenish color and pleasing taste. Similar treatment of sunflower seeds yielded from 32 to 36 per cent of a yellow oil suitable for technical, and on purification for edible, purposes.

Soy bean products and their uses, C. B. WILLIAMS (*Pure Products*, 15 (1919), No. 7, pp. 339-345).—This is a general article from the North Carolina Experiment Station in the interests of growing soy beans in that State. The possibilities of utilizing cottonseed oil mills for the extraction of soy-bean oil are pointed out, and the properties, uses, and value of the soy beans and of the oil and meal derived from them are discussed. The soy bean industry in England, Manchuria, and Japan is described.

The modification of the composition of vegetable oils, with special reference to increasing unsaturation, H. L. WHITE (*Jour. Indus. and Engin. Chem.*, 11 (1919), No. 7, pp. 648-651).—The author reports an investigation of the possibilities of increasing the unsaturation of vegetable oils, particularly soy-bean oil, by altering conditions of growth in the plant and by the action of bacteria, enzyms, light, heat, etc., on the oil itself.

It was found that the processes of germination and growth of soy beans under different conditions did not alter the amount of unsaturated acids in the ether extracts from such plants. Bacteria isolated from the "foots" of raw linseed oil and enzym extracts from flaxseed and from fresh pigs' liver did not increase the unsaturation of soy-bean oil. Heat, light, and certain catalyzers were also without effect upon unsaturation. Hydrolysis occurred in most cases, the extent depending upon the presence of moisture in the sample of oil.

Temperature-time relations in canned foods during sterilization, G. E. THOMPSON (Jour. Indus. and Engin. Chem., 11 (1919), No. 7, pp. 657-664, figs. 9).—This is a preliminary communication outlining methods of procedure for the preparation of reference tables and curves expressing temperature-time relations for various food materials in the cans during the sterilization process.

The procedure used in the experimental work consisted in determining by means of thermocouples embedded in the center of cans of food the temperature-time curves when the cans were subjected to various temperatures in hot water, steam, cool air, and cool water. The effect of the size and shape of the container on the heat penetration has been calculated, and the values conductivity, have been found for a number

of the diffusivity, specific heat × density

of canned foods. Formulas have been derived for calculating the temperature at any time and at any point in the can under the following conditions: (1) When contents of the can are of uniform temperature throughout before immersion in the sterilizing bath, which is maintained at uniform temperature after the immersion; (2) when the bath temperature, after the can has been put in, increases uniformly to the boiling point and remains constant thereafter; and (3) when the cans are exhausted at one temperature before processing at another.

The results of the experimental work indicate that substances which contain a great deal of free liquid heat almost as fast as water. The change of viscosity with temperature is effective in increasing the heat flow in the steam processing. The effect of the glass can in retarding the heat flow is very marked when the diffusivity is large, but disappears at values less than 0.375.

In addition to tables and curves showing the results of the experimental work, a chart has been devised which may be used for determining approximately the temperature at the center of a can at any time after immersion in the sterilizing bath maintained at constant temperature.

The action of alcoholic potassium hydroxid on the resins, P. NICOLARDOT and C. COFFIGNIER (Bul. Soc. Chim. France, 4. ser., 25 (1919), No. 4, pp. 200– 206).—The action of alcoholic potassium hydroxid upon different resins has been examined by heating 1 gm. of the resin for an hour under a reflux condenser with 25 cc. of N/2 alcoholic potassium hydroxid and adding gradually 50 cc. of distilled water. The insoluble residue was then filtered and weighed.

Of 27 types of resins examined, one only dissolved completely in the N/2 potassium hydroxid. All the others proved to be more or less insoluble in water. In some the amounts of insoluble matter increased and in others decreased on adding water. It is thought that the alcoholic potassium hydroxid forms resinous soaps, some of which are more soluble in the base than in water and others more soluble in water than in the base. It is suggested that this difference in solubility might serve as a new characteristic for the identification of certain resins.

The alkali industry, J. R. PARTINGTON (London: Baillière, Tindall, & Cox, 1919, pp. XVI+304, figs. 63).—This is one of a series of volumes on industrial chemistry edited by S. Rideal. The book is divided into sections, each of which deals with separate branches of the subject in the manner of a special article or monograph. Following an introductory chapter on the alkali industry in Great Britain, the sections include the salt industry, sulphuric acid, natural soda and the Leblanc process, the ammonia-soda process, electrolytic processes, chlorin and derived products, nitric acid, ammonia and ammonium salts, the oxidation of ammonia, utilization and economy of sulphuric acid, and potassium salts, iodin, and magnesium.

Special attention has been given throughout to the resources and needs of the British Empire and possible future independence of German supplies.

# METEOROLOGY.

A soil temperature survey of the United States and Canada, F. SHREVE (Carnegie Inst. Washington Year Book, 17 (1918), pp. 79, 80).—The survey previously referred to (E. S. R., 41, p. 16) is briefly described. The committee consists of F. Shreve and A. E. Cameron. During 1917 more than 30 stations were maintained in portions of Canada and practically all parts of the United States, and at most of these nearly complete records for the year were secured.

Report of the department of meteorology, J. E. CHURCH, JR. (Nevada Sta. Rpt. 1918, pp. 50-52, fig. 1).—This is mainly a brief account of progress in the snow surveying and forecasting work which has been carried on by the department for several years. Attention is called especially to the accuracy of forecasts of stream flow based on snow surveys.

Climate and meteorology [of Canada], F. STUPART ET AL. (Canada Yearbook, 1918, pp. 154–165).—This article summarizes the principal climatic events and conditions of Canada since confederation, and the weather of each month of 1917.

Climate of Sao Paulo, J. N. BELFORT MATTOS (Bol. Agr. [Sao Paulo], 19. ser., No. 5-7 (1918), pp. 507-562).—The climatic characteristics as related to health and plant growth of different districts of the State are discussed on the basis of observations extending over various periods up to 28 years.

The lunar tide in the atmosphere, S. CHAPMAN (*Nature* [London], 103 (1919), No. 2584, pp. 185-187, fig. 1).—This article briefly discusses the lunar semidiurnal tide in the atmosphere at Greenwich, as determined from the Greenwich records of barometric pressure, 1854-1917.

The lunar tide in the earth's atmosphere, S. CHAPMAN (Quart. Jour. Roy. Met. Soc. [London], 45 (1919), No. 190, pp. 113-139, fig. 1).—This article reviews present knowledge on the subject and discusses "certain new determinations of the lunar diurnal variation of barometric pressure for Batavia and Hongkong." The variation is attributed to tidal action of the moon on the earth's atmosphere, certain unexpected features of which, of theoretical interest, are dealt with in some detail.

Atmospheric pollution, J. W. REDWAY (Quart. Jour. Roy. Met. Soc. [London], 45 (1919), No. 190, pp. 167-169).—Studies made at Mount Vernon, N. Y., showing the menace to health of the wind-blown dust of city streets are briefly discussed.

#### SOILS-FERTILIZERS.

**Reconnoissance soils survey of the Middle San Joaquin Valley. Cal., L.** C. Holmes, E. C. ECKMANN, J. W. NELSON, and J. E. GUERNSEY (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1916, pp. 115, pls 3, fig. 1, map 1).—This survey, made in cooperation with the California Experiment Station, deals with the soils of an area of 2,846,720 acres lying near the geographical center of the State and comprising parts of Fresno, Tulare, and Kings Counties. The area includes approximately the central third of the San Joaquin Valley. Previous surveys dealing with the Sacramento Valley (E. S. R., 34, p. 120) and the Lower San Joaquin Valley (E. S. R., 40, p. 118), together with the present survey, constitute a reconnoissance of the Great Interior Valley.

The topography of the region is somewhat mountainous. Natural drainage is said to be well established on the upper valley slopes but inadequate over extensive lower areas. The soils of the area comprise residual material from the underlying consolidated rocks, old valley-filling and coastal plain material, recent alluvial material, and wind-laid material. In addition to rough stony land 38 soil types representing 19 series are mapped. Panoche loams, occupying 12.6 per cent of the total area, are the prevailing types.

Soil survey of the Santa Maria area, Cal., F. B. WATSON and A. SMITH (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1916, pp. 48, pls. 4, fig. 1,

map 1).—This survey, made in cooperation with the California Experiment Station, deals with the soils of an area of 189,440 acres situated in the southwestern part of the State and including the northwestern part of Santa Barbara County and the southwestern part of San Luis Obispo County. The region comprises the Santa Maria Valley, the Nipomo Mesa lying from 100 to 200 ft. above the valley floor, and the Arroyo Grande Valley, together with the intervening hills and parts of the adjacent mountains.

With respect to their origin the soils of the area are said to be residual from underlying consolidated rocks, derived from coastal plain and old valleyfilling material, eolian, recent-alluvial, and miscellaneous. In addition to coastal beach and dunesand, riverwash, rough, broken, and stony land, and peat, 32 soil types of 12 series have been mapped. Oakley sand, occupying 16.2 per cent of the total area, is the prevailing type.

Soil survey of Saratoga County, N. Y., E. T. MAXON and J. H. BROMLEY (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1917, pp. 42, fig. 1, map 1).—This survey, made in cooperation with the New York State College of Agriculture, deals with the soils of an area of 526,720 acres situated in the east-central part of the State. The topography of the region varies from smooth plains in the eastern part to rolling uplands in the southern and southwestern part. The elevations range from about 200 to 2,600 ft. above sea level. Natural drainage is well established.

The soils of the county are of glacial origin, the upland soils consisting of glacial till or sediments laid down in lakes or as outwash plains. Exclusive of rough stony land and muck, 27 soil types of 13 series are mapped. Gloucester stony fine sandy loam, Merrimac fine sand, rough stony land, and Dutchess loam, occupying 20.8, 19.4, 11.8, and 10.5 per cent of the total area, respectively, prevail.

Agricultural conditions and land classification in the south half of Minnesota, F. LEVERETT and F. W. SARDESON (Univ. Minn., Geol. Survey Bul. 14 (1919), pp. 45–62, pls. 2, fig. 1).—This is a brief outline, particularly as related to their geological origin, of certain of the characteristics and agricultural possibilities of different classes of lands of the southern half of Minnesota, "beginning with the driftless area and taking up the several drifts and associated deposits in order of their age and the alluvial deposits of the present streams." A table is given showing percentages of improved land in each county of the area by decades, 1870–1910, with notes on the dominant soils and vegetation.

Peat and muck soils, J. W. AMES (Mo. Bul. Ohio Sta., 4 (1919), No. 5, pp. 161-165).—The formation and composition of peat and muck soils in Ohio are briefly described and their fertilization, drainage, claying, and adaptation to crop production discussed. A tabular statement is presented showing the chemical composition of 18 representative samples of such soils occurring in the State.

Nitrification in moor soils, T. ARND (*Centbl. Bakt.* [etc.], 2. Abt., 49 (1919), No. 1-4, pp. 1-51).—The author discusses at some length the work of other investigators relative to the subject, together with the results of his own observations on the influence of lime upon nitrification in both high and low moorland soils and on the occurrence of nitrite- and nitrate-forming organisms in these soils.

He concludes that in raw, unlimed, high, and low moor soils of acid reaction no nitrification takes place. Small applications of lime, insufficient to correct acidity, failed to stimulate nitrification, whereas sufficient lime to insure neutralization is said to have so improved the physical conditions of the soil as to produce a favorable environment for the activities of the nitrifying bacteria. Increasing the amount of lime beyond the point necessary for neutralization did not retard nitrification, although the final total nitrate, content of the soil in many cases was found to be less than where smaller applications of lime were made. This was thought to be due to increased ammonia and nitrate assimilation and nitrate reduction through stimulated microbial activities. Low moor soils of neutral reaction required no liming to stimulate nitrification.

With respect to the presence of nitrifying organisms in high moor soils, it is stated that where the soil acidity was reduced through the chemical reaction of the basic elements of a phosphate fertilizer, nitrate formers were completely lacking. Applications of lime made at the rate of 1,000 kg, of calcium oxid per hectare (about 890 lbs. per acre) failed to stimulate the development of nitrifying organisms except in the immediate vicinity of the lime particles. An application of 2,000 kg, resulted in a further increase in nitrifiers, attributed to an increase in the number of spots rich in lime. The nitrifying activities of a moor soil thus treated are said to have been considerably less than in a normal mineral soil.

Nitrogen contents of cacao soils planted with and without bois immortel shade, J. DE VERTEUIL (Bul. Dept. Agr. Trinidad and Tobago, 18 (1919), No. 1, pp. 6-8).—Determinations of the total nitrogen and of nitrate nitrogen in cacao soils shaded with Erythrina and in similar soils without shade were made at quarterly intervals during 1918 to ascertain whether the immortel was beneficial to the cacao in producing a larger supply of nitrogen in the soil.

The shaded soils showed a range in total nitrogen of from 0.078 per cent in June to 0.129 per cent in December, and in nitrates from 0.00062 per cent in September to 0.00093 per cent in March. In the unshaded soil the total nitrogen ranged from 0.091 per cent in September to 0.115 per cent in December, and the nitrates from 0.00042 per cent in September to 0.00077 per cent in December.

The organic phosphorus of soil, R. S. POTTER and R. S. SNYDER (Soil Sci., 6 (1918), No. 4, pp. 321-332, figs. 2).—This paper, a contribution from the Iowa Experiment Station, describes further investigational work planned to determine whether the method proposed by Potter and Benton (E. S. R., 36, p. 212) actually differentiates between the organic and inorganic phosphorus in the soil, this point having been questioned by Gortner and Shaw (E. S. R., 37, p. 121), together with observations on the nature of certain organic phosphorus compounds.

An examination of a subsoil taken 3 ft. below the surface and containing no organic matter but a considerable amount of colloidal clay failed to show any so-called organic phosphorus, which is held to indicate that the latter was not confused with colloidal clay in applying the method under observation. The addition of phytin to the soil did not result in its extraction to any appreciable extent with a 1 per cent hydrochloric acid solution.

Hydrolysis curves for phytin and nucleic acid were determined, hydrolysis being effected with 5 per cent sulphuric acid at 100° C. The curve for phytin was found to be a straight line and after two hours that for nucleic acid approximated a straight line, showing both reactions to be of the first order. Curves for the hydrolysis of the organic phosphorus of Carrington silt loam and two samples of Miami silt loam soil were also ascertained. The results are deemed to be rather inconclusive, except that nucleic acid was evidently absent except in the Carrington silt loam and then was present only to a slight extent. The directions of the curves are said to have been such that the organic phosphorus may have been due to phytin or to a pyrmidin nucleotid.

PRD. [Vol. 41

The movement of plant food within the soil, E. VAN ALSTINE (Soil Sci., 6 (1918), No. 4, pp. 281-308).—This paper, a thesis presented to the Graduate School of the University of Illinois, describes investigations in which a study was made of the total amount of the various plant food elements present in samples of soil from long-time fertilizer plats, including the "park" plats at Rothamsted and the plats of the Pennsylvania and Ohio experiment stations, in order to determine the ultimate fate of the fertility elements added to the soil as fertilizers when not completely removed by the crop. The total amount of organic carbon, ntirogen, phosphorus, potassium, magnesium, and calcium was determined in the Rothamsted soil for samples representing strata of from 0 to 3 in., 3 to 6 in., and 6 to 9 in., respectively. In the case of the Pennsylvania and Ohio soils the observations were confined to a study of the phosphorus content of strata from 0 to  $6\frac{2}{3}$  in.,  $6\frac{2}{3}$  to  $13\frac{1}{3}$  in., and  $13\frac{1}{3}$  to 20 in.

Summarizing the results secured, the author concludes that "when phosphorus is used as a fertilizer, it remains almost where it is placed in the soil until removed in crops or removed by some such process as erosion by water or wind action. The addition of alkali salts (sulphates of potash, soda, and magnesia) seems to encourage the utilization of phosphorus from the surface stratum, especially by legume plants, which probably also secure nitrogen chiefly from the soil air in the surface stratum. There may be some loss of nitrogen through drainage, but when other fertility conditions are right and crops are kept on the ground all through the growing season, this loss is very small and there is a tendency for nitrogen, added in the form of ammonia, to accumulate in the surface soil, probably in plant roots and residues. Potassium, though easily and quickly fixed in soil, is more subject to movement within the soil as a result of fertilizing with other salts and in this way may be leached beyond the reach of plant roots. Carbonates are rather easily washed from the soil even when no other treatment is given, but much more readily washed out when ammonium salts are used. The loss of magnesium is brought about by the use of ammonium salts as fertilizers. Calcium decreases with the loss of carbonates. Also, when alkali fertilizer salts are applied, it decreases more rapidly than acidity develops. Ammonium salts cause as marked a loss of calcium as of carbonates, and its loss occurs relatively as rapidly as the acidity develops."

A list of the references cited, comprising 45 titles, is appended.

The presence of aluminum as a reason for the difference in the effect of so-called acid soil on barley and rye, B. L. HARTWELL and F. R. PEMBER (Soil Sci., 6 (1918), No. 4, pp. 259–279, figs. 2).—This paper, a contribution from the Rhode Island Experiment Station, describes investigations made in an effort to ascertain the cause of the unlike effect of acid soils on different kinds of plants. Rye was selected as a plant which grows well on acid soils and barley as one which is materially injured by the same conditions.

Seedlings of both rye and barley were found to be affected about the same by a given amount of acidity in connection with a nutrient culture in either water or sand, while sterilization of the soil either with heat or toluol failed to produce any change which with certainty influenced differently the two kinds of seedlings. Hydrogen peroxid, dihydroxystearic acid, manure extract, ammonium sulphate, potassium permanganate, chromium, and silicon affected the two plants about alike, while an aqueous extract of an acid soil affected them the same as the acid soil itself. The toxic principle of the extract was concentrated in the residue upon distilling, the distillate being nontoxic. Both the dialyzate and diffusate resulting from dialysis of the extract had the same effect upon rye and barley, while the ash of the soil extract, when brought into solution, had the same effect as the acid soil.
A search for the active factor then being made among the inorganic constituents, aluminum was found to be responsible for the different influence upon the plants. When equivalent amounts of aluminum sulphate and sulphuric acid were added to an optimum nutrient solution, both produced the same depression on the growth of barley. Sulphuric acid caused a similar depression of rye, but aluminum sulphate had very little effect. Since the nutrient solution containing the acid possessed about four time the H-ion concentration of that containing aluminum sulphate, the toxic effect of the latter on barley was attributed largely to the aluminum.

Finally, it is stated that "treatment of an acid soil with either phosphoric oxid or acid phosphate reduced the amount of active aluminum in the soil. Unusually large additions of acid phosphate caused remarkable growths of plants so sensitive to an untreated acid soil that previously no growth was possible, and this was in spite of the fact that the acidity of the soil was very much increased by the acid phosphate. The active aluminum, however, was much decreased by the treatment. The results indicate that the practical advantage of phosphating and liming may often prove to be due to the precipitation of active aluminum quite as much as to supplying phosphorus as a nutrient and lime as a reducer of acidity."

The influence of heated soils on seed germination and plant growth, J. JOHNSON (Soil Sci., 7 (1919), No. 1, pp. 1-103, figs. 16).—Supplementing work previously noted (E. S. R., 35, p. 722), the author describes a series of investigations conducted at the Wisconsin Experiment Station to ascertain primarily the nature of the action of sterilized soils upon plant growth.

The evidence is held to demonstrate the importance of microorganisms in the loss of toxicity in the soil and that reduced toxicity is due to biological action upon ammonium carbonate, resulting in the liberation of gaseous ammonia or its fixation in the soil. The soils employed in the study included Waukesha silt loam, Miami silt loam, Norfolk sand, virgin sandy loam, fine sandy loam, red clay, muck, and peat, and were subjected to widely varying treatments and conditions, and their action on numerous seeds and plants determined. The data are presented in tabular form and fully discussed, together with confirmatory evidence found in the literature bearing on some of the conclusions presented in this paper. The results secured may be summarized as follows:

Heating soil to different temperatures usually resulted in a gradual increase in toxicity to seed germination and to early plant growth which reached its maximum at approximately  $250^{\circ}$  C, but gradually decreased to practically no toxicity on soils heated to  $350^{\circ}$  or above. The time required for recovery from this toxic action was usually directly proportional to the intensity of toxicity produced, but the final beneficial action was often greatest on soils exhibiting the greatest injurious action on early plant growth. Different soils varied markedly in their behavior upon heating to the same temperature both in toxicity and in beneficial action to seeds and plants, this apparently not being correlated with any single distinguishing character in the soil but rather with the balance of all the factors concerned.

Seeds varied greatly in their sensitiveness to the toxic action, the degree of sensitiveness being roughly characteristic of their genetic relationship. The **Graminæ** and the Cucurbitaceæ were usually resistant, and the Leguminoseæ and Solanaceæ were, so far as determined, more susceptible.

With seeds resistant to the toxic action, marked acceleration of the rate of germination may occur on even highly heated soils, this being regarded as another expression of the same substances that cause retardation in more susceptible seeds. Seeds classed as susceptible may, on the other hand, show accelerated germination on soils not productive of high toxicity on heating or upon heating soils to low temperatures only.

Growing plants differed markedly in their sensitiveness to the action of heated soils. The similarity of their behavior and of germinating seeds in this respect suggested that the injurious and beneficial substance in both cases may be the same, although toxicity to seed germination did not appear to be always correlated with toxicity to plant growth and vice versa. Sensitiveness of seeds to the toxic agent in germination was also not indicative of the behavior of the same species in its growth on the same soil. The growth of fungi on heated soil was correlated with toxicity to seed germination and plant growth on any one soil, the development of Pyronema having been studied in particular. This and other fungi and apparently bacteria also grew best in soil heated to 250°, diminishing in rate and profuseness of growth at lower or higher temperatures of heating.

The ammonia content of soil heated to different temperatures was highest on heating to about 250°, and diminished gradually at higher and lower temperatures, this also being true for the concentration of the soil solution. Ammonia content and cencentration of the soil solution were, therefore, roughly correlated with the degree of toxicity to seed germination and early plant growth and the extent of the beneficial action to late growth of green plants and to growth of lower microorganisms in any one soil, although there was apparently no correlation between these factors when different soils were compared with each other.

The absorptive capacity of different soils varied greatly, this in turn markedly influencing the action of toxic compounds produced in the soil. In water extracts of heated soils, the toxicity to seed germination was more directly proportional to the ammonia content, indicating that the toxicity of the soil was not only determined by the amount of the toxic agent produced by heating but also by the absorptive capacity of the soil for the toxic agent, as well as by a number of other factors the additive and subtractive value of which gave balance of toxicity very difficult to analyze properly.

The addition of ammonia as such to soil in varying amounts is said to be capable of producing a condition similar in many respects to that produced by heated soils on seed germination and plant growth. It was found that similar "qualitative" reactions can be produced with certain seeds on highly toxic heated soils or their extracts and with certain strengths of ammonia, these reactions not appearing to be reproducible with chemicals other than ammonia or ammonium salts.

It is believed that much of the toxic action in heated soils is due to the ammonia produced and that it exists in heated dry soils largely as ammonium carbonate, which is, however, gradually decomposed under normal growing conditions. All toxic properties in heated soils are not, however, believed to be the same, certain changes termed "chemical" injuries seemingly being due to quite different causes than ordinary retardation. The toxic property was found to be volatile, and to be destroyed or changed to nontoxic compounds in soils kept under normal-growing conditions due to the activity of ordinary soil flora, which, however, may apparently at the same time increase the amount of ammonia present. Pyronema confluens has also been shown to be efficient in both these respects. Reduced toxicity in the presence of increased ammonia content in the soil is believed to be explained by the existence of the ammonia in various delicate transition stages rather than as true ammonia due to the activity of soil organisms, these transition products being broken down when the ammonia determinations are made. The

reduction of the toxic property to seed germination and plant growth by the activity of soil flora has been demonstrated, and is held to be contrary to Pickering's conclusion that loss of toxicity in storage of heated soils is an oxidation process which may go on under aseptic conditions (E. S. R., 24, pp. 420, 421).

The beneficial action of highly heated soils is believed to be due largely to the ammonia liberated on heating, since increased growth may result in almost total absence of nitrates or in heated soil under aseptic conditions in spite of a considerable toxic action upon the roots. That certain green plants are capable of utilizing nitrogen in the form of ammonia is believed partially to explain the variation of sensitiveness of plants to heated soils. The temperature of the soil was shown to be an important factor in determining the extent of the toxic and beneficial action to plant growth, the toxic action disappearing more slowly and being more destructive at low soil temperatures (below about  $25^{\circ}$ ) than at higher temperatures.

Observations on the growth of Pyronema are held to indicate that the favorableness of heated soils to its growth is not entirely one of concentration of soil solution, as argued by Seaver and Clark (E. S. R., 23, p. 629; 27, p. 620), since Pyronema grew on heated soils very low in concentration as compared with other unheated soils on which growth never occurred. All microorganisms appeared to grow better on soils having a high concentration of soil solution due to increased food supply, but the type of organism and the extent of its growth varied with the competition at hand and the kind of food materials present. Fungi differed in their food requirements in much the same way as green plants, and heating the soil is thought to produce chemical substances specially favorable to the growth of Pyronema.

The conclusions reached are deemed applicable particularly to highly heated soils, although it is not believed that any fundamental difference exists between ordinary steam-sterilized soils and highly heated soils reinoculated with normalsoil flora. "Although the injurious action of heated soils on plant growth has been brought into the foreground in this paper, it is not desired to leave the impression that heat-sterilized soils are of questionable value in research and practice. The opposite is rather true, and little hesitancy need be felt in recommending steam sterilization of soil for practical purposes or for use in research problems where it is necessary to eliminate certain organisms from the soil. But one must be prepared to expect a short period of retardation of growth, followed by a beneficial action, and in special cases, with certain soils or plants or under certain environmental conditions, a very marked interference with the normal development of plants."

A list of references comprising 79 titles is appended.

The actinomyces of the soil, S. A. WAKSMAN and R. E. CURTIS (Soil Sci., 1 (1916), No. 2, pp. 99–134, pls. 3, fig. 1).—In this paper, a contribution from the New Jersey Experiment Stations, the authors demonstrate the presence of Actinomycetes in different types of soil and attempt a classification of the organisms according to their morphological and physiological characters. More than 100 organisms were isolated, representing 30 species which are described and a key prepared for their identification. A list of references comprising 23 titles is appended.

The occurrence of Actinomycetes in the soil, S. A. WAKSMAN and R. E. CURTIS (Soil Sci., 6 (1918), No. 4, pp. 309-319).—Supplementing the work noted above, information is given concerning the number of Actinomycetes and bacteria occurring in 25 soils from different sections of North America and from the Hawaiian Islands previously described (E. S. R., 36, p. 214), together with

#### 1919]

notes on the isolation of various species of Actinomycetes from certain of these soils.

The number of Actinomycetes developing on albumin agar ranged from 7,500 in Jamesburg cranberry soil from New Jersey to 2,400,000 in a cultivated Oregon adobe-like soil. As compared with the total number of bacteria and Actinomycetes developing on the same media, the percentage of Actinomycetes ranged from 3.5 for the Jamesburg cranberry soil to 46 for Alberta (Canada) garden soil. The average number of Actinomycetes for all the soils examined amounted to 870,500, or 17 per cent of the total flora. It is stated that heavy soils and those rich in undecomposed organic matter generally contain a relatively larger number of Actinomycetes than corresponding lighter soils or soils poor in undecomposed organic material. The isolation of 28 distinct species of Actinomycetes from 20 different soils is held to demonstrate their general distribution in North America and the Hawaiian Islands.

A list of references comprising 25 titles is appended.

Illinois crop yields from soil experiment fields, C. G. HOPKINS, F. W. GAR-RETT, J. E. WHITCHURCH, and H. F. T. FAHENKOPF (*Illinois Sta. Bul. 219* (1919), *pp. 401–503*).—Tabulated data are presented giving the detailed results from **38** Illinois soil experiment fields through the season of 1917. The methods of cropping and soil treatment are briefly indicated, more detailed information being given in a previous publication (E. S. R., 36, p. 618).

Commercial fertilizers for Indiana: What to use, A. T. WIANCKO (*Indiana Sta. Circ. 92* (1919), pp. 7, figs. 2).—A tabular statement is presented showing the fertilizer formulas deemed best for different crops and for various soil conditions in the State, as indicated by extensive soil fertility investigations conducted by the station. The composition of the soil, the requirements of the crop, and the practice regarding the use of manure and legumes in the rotation form the basis for classification. Brief notes are included on the interpretation of fertilizer formulas, the estimation and comparison of fertilizer values, the home mixing of fertilizers, and the amount of fertilizer to use.

The agricultural value of organic manures, E. J. RUSSELL (*Jour. Bd. Agr.* [*London*], 26 (1919), No. 3, pp. 228-247, fig. 1).—Experiments at Rothamsted with Peruvian guano, rape cake, and shoddy, as compared with other nitrogenous fertilizers, are briefly reviewed.

The relative effectiveness of the three fertilizers was Peruvian guano 100, rape cake 91, and shoddy S8. Shoddy showed a residual effect which would improve its relative standing. There was no evidence that the nitrogen in rape cake is superior in crop producing power to that of sulphate of ammonia, and it was less effective than that of nitrate of soda. There was little evidence that rape cake and Peruvian guano permanently benefit the soil. As far as fertilizing value is concerned, there appears to be "no reason why rape cake and guano should ever sell at prices above those obtaining for sulphate of ammonia and nitrate of soda."

How the nitrogen problem has been solved, H. J. M. CREIGHTON (Jour. Franklin Inst., 187 (1919), Nos. 4, pp. 377-408; 5, pp. 599-610; 6, pp. 705-735, figs. 20).—This article describes and discusses the advantages and disadvantages of five different methods which have been proposed for fixation of atmospheric nitrogen as follows: "(1) The direct oxidation of nitrogen to its oxids with subsequent formation of nitric acid or nitrates, as exemplified in the arc processes, (2) the direct combination of nitrogen with hydrogen to form ammonia, as typified by the Haber process, (3) the absorption of nitrogen by carbids, as developed in the cyanamid process, (4) the absorption of nitrogen by metals in the form of nitrids, as represented by the Serpek process, and (5) the conversion of nitrogen into cyanids, as set forth in the Bucher process." Processes for oxidation of ammonia to nitric acid are also discussed. It is stated that at the present time the first three of the methods named "are successfully operated on a commercial basis," but that the Bucher process has scarcely passed beyond the experimental stage.

"During the past five years rapid progress has been made in the fixation of atmospheric nitrogen, especially by the cyanamid process and by the direct synthesis of ammonia. As a result of this advance, greatly stimulated by the war, nearly one-third of the nitrogen used by the Allies for military explosives in the autumn of 1918 was obtained from the atmosphere."

The annual production capacity of the world for synthetic nitrogen compounds is given as 75,000 tons in 1914 and 389,000 tons in 1918. It is estimated at 467,000 tons for 1919. The production in the United States is given as nothing in 1914, 55,000 tons in 1918, and estimated at 100,000 tons in 1919, mainly in form of cyanamid (46,000 tons in 1918 and 91,000 tons in 1919).

A very full classified bibliography of the subject is given.

Production of ammonia from lime nitrogen, and the time yield under various conditions, W. GRAHMANN (Ztschr. Elektrochem., 24 (1918), No. 23-24, pp. 385-391, figs. 2; abs. in Jour. Chem. Soc. [London], 116 (1919), No. 677, II, pp. 105, 106).—The rate of production of ammonia from boiling mixtures of lime nitrogen and water, lime nitrogen and sodium hydroxid or carbonate of various strengths, and lime nitrogen and potassium hydroxid or carbonate of varying strengths was determined.

The rate of decomposition of calcium cyanamid in water was very slow in all concentrations at the boiling point and atmospheric pressure. Alkali hydroxids or carbonates accelerated the reaction. Under a pressure of 30 atmospheres and a temperature of  $150^{\circ}$  C. the decomposition was rapid even without the addition of alkali until 75 per cent of the cyanamid was decomposed, after which the rate of decomposition greatly declined.

America's advance in potash production, W. C. EBAUGH (*Bul. Sci. Labs. Denison Univ.*, 19 (1919), Art. 2, pp. 33–64, figs. 2).—It is stated that the production of potash in the United States increased from practically nothing in 1914 to 52,135 tons of actual potash in 1918. The estimated production capacity of American potash plants is given as 100,000 tons annually, or 40 per cent of the normal consumption. The various domestic sources of potash are briefly described.

**Trade and fraud in commercial fertilizers**, A. POMPEU DO AMARAL (*Bol. Agr.* [*Sao Paulo*], *19. ser.*, *No. 5–7* (*1918*), *pp. 492–506*).—This article discusses briefly the various sources and kinds of commercial fertilizing materials, the valuation of fertilizers, and the falsifications to which they are subject. It recommends especially to coffee planters the cooperative buying of fertilizers on guaranty of quality, appealing to the Agronomic Institute of Sao Paulo in case of dispute.

Report of analyses of samples of commercial fertilizers collected by the commissioner of agriculture during 1918 (*New York State Sta. Bul.* 452 (1918) pp. 203-253).—This reports the results of the actual and guarantied analysis of official samples of fertilizers and fertilizing materials collected during 1918.

### AGRICULTURAL BOTANY.

The flora of the American Virgin Islands, N. L. BRITTON (Brooklyn Bot. Gard. Mem., 1 (1918), pp. 19–118, fig. 1).—Lists comprising 890 Spermatophyta and 41 Pteridophyta are thought to be practically complete. Lists including 46 Bryophyta and 75 lichens are thought to be less complete. Endemic plants comprise only about 2.6 per cent of the native flora. Geobotany of the Santa Lucia Mountains, F. SHREVE (Carnegie Inst. Washington Year Book, 17 (1918), pp. 78, 79).—An examination has been made of the Santa Lucia Mountain region in California, which embraces chiefly or entirely the distributional areas of Pinus radiata, Abies venusta, Cupressus macrocarpa, and C. goveniana, as well as the southernmost localities of Sequoia sempervirens and a number of its associates. While geomorphic movements undoubtedly lie at the basis of the present distributional features, a good opportunity is offered for investigation of the factors controlling reproduction and life history of all these endemic forms.

The vegetation of an imperfectly drained desert valley, F. SHREVE (*Carnegie Inst. Washington Year Book, 17 (1918), pp. 76–78).*—Field and laboratory work has been inaugurated with the view of investigating the rôle played by the soil in determining the differences of vegetation which characterize the Avra Valley of Arizona. The fact that this valley is not undergoing the normal course of physiographic development, being subject to frequent checks and reversals of such development, makes it a particularly suitable area for investigation of such a problem.

**Isolation and specific change**, E. W. SINNOTT (*Brooklyn Bot. Gard. Mem.*, 1 (1918), pp. 444-447).—Data are presented and discussed to show that isolated regions are characterized by the presence of large numbers of local, or endemic, genera and species.

Endemism was not equally distributed among the plant groups in the insular floras investigated. The local species and genera were rare among vascular cryptogams and glumaceous monocotyledons but very common among petaloideous monocotyledons and dicotyledons, this fact supposedly indicating that the environment, whether acting directly or through natural selection, has not been the determining factor in the development of endemic forms. Those groups which are poor in endemics are predominantly self-fertilized, those which are rich in endemics predominantly cross-fertilized, these facts suggesting that hybridization has been the predominant factor in the development of these new forms. Isolation is, therefore, regarded not as a factor which, by providing a simple, limited, and peculiar environment, produces local species and genera, but merely as a factor which, by prohibiting dispersal, maintains the endemic character of local types which have originated through other causes.

Osmotic concentration of tissue fluids in relation to geographical distribution, J. A. HARRIS (*Carnegie Inst. Washington Year Book, 17 (1918), pp. 86,* 87).—This work, continued along lines previously indicated (E. S. R., 40, p. 130), has shown that the osmotic concentration of the tissue fluids of epiphytic Bromeliaceæ, Orchidaceæ, Piperaceæ, and Gesneraceæ is lower than that of the terrestrial vegetation. The problem of the osmotic concentration of the tissue-fluids of cryptogamic epiphytes is to be made a subject of further study.

On the osmotic concentration of the tissue fluids of phanerogamic epiphytes, J. A. HARRIS (*Amer. Jour. Bot.*, 5 (1918), No. 9, pp. 490-560).—This is a more extended account than that above noted.

Endurance of extreme conditions and its relation to the theory of adaptation, W. J. V. OSTERHOUT (*Amer. Jour. Bot.*, 5 (1918), No. 10, pp. 507-510, fig. 1).—The author reports that a species of Tradescantia lived for nearly two years without soil or water, growing vigorously afterwards in a saturated atmosphere, and was finally placed under water for a month, being alive at the end of the experiment. It is thought that the explanation of such cases must be sought in physical or chemical conditions of the protoplasm which arise without reference to direct adaptation, and it is suggested that the same kind of explanation may apply to many cases which are now regarded as adaptations. Investigations on the imbibition of water by gelatin, E. B. SHREVE (*Carnegie Inst. Washington Year Book, 17 (1918), pp. 74–76*).—This is a continuation of work previously noted (E. S. R., 40, p. 27). It is said to have shown that it is not safe to draw conclusions regarding the effect which substances within a jelly exert upon its imbibitional capacity when evidence for such a conclusion lies in the known effect of an external solution of the same substance on that jelly. This applies to the theories involving the physicochemical effect of the substance upon the gelatin itself, as well as those concerning physiological phenomena.

The effect of organic acids and their amido compounds on the hydration of agar and on a biocolloid, D. T. MACDOUGAL and H. A. SPOEHR (*Proc. Soc. Expt. Biol. and Med.*, 16 (1918), No. 3, pp. 33-35).—A series of test measurements was carried out in the equable temperature chambers of the Coastal Laboratory from August to November, 1918, on three groups of substances, (1) succinic acid and its amido compound,  $\alpha$  amino succinic or aspartic acid, which are dibasic, and its amid, asparagin, which is monobasic; (2) acetic acid and amino acetic acid or glycocoll, which are monabasic; and (3) propionic acid and  $\alpha$  amino propionic acid or alanin, also monobasic; data were obtained which are here partly tabulated with brief discussion.

It is stated that equimolecular concentrations of the three organic acids present a small divergence of effect on agar and a more positive difference in agar protein. Agar swells more in succinic acid than in its amido compound, but this relation is reversed in the acetic-glycocoll couple and in the propionic-alanin pair. Equimolecular concentrations of amino acids produce notably greater swellings of the biocolloids in comparison with related organic acids, implying the positive action of factors other than the H-ion concentration. Glycocoll facilitates hydration in all concentrations above 0.01 M. in both agar and agar proteins, and also in agar gelatin. Asparagin induces a maximum hydration.

The absorption of calcium salts by squash seedlings, R. H. TRUE and R. B. HARVEY (*Brooklyn Bot. Gard. Mem.*, 1 (1918), pp. 502-512, figs. 3).—During work participated in by True (E. S. R., 36, p. 128), it was found that the rate of absorption of electrolytes by seedlings from solutions of the usual mineral nutrients was influenced largely by the chemical character of the substances offered. It appears that the usual salts of potassium were not absorbed, producing rather an outgoing current of ions from the seedlings into the solution. In case of more dilute magnesium solutions a slight absorption took place, while in calcium solutions absorption was more considerable and occurred in the most dilute solutions.

In preliminary experiments by the present authors some exceptional behavior was observed. Results of a series of experiments as here recorded are considered to show that for both squash and white lupine in the seedling stage the calcium ion favors the absorption of ions. The differences in behavior of the two plants are detailed. The strong influence exerted by the specific characteristerics of the different species of plants is shown by the contrasting behavior of the lupine and the squash in the presence of calcium accompanied by the NO<sub>3</sub> ion. It is considered as clear from the evidence shown that any theory of cell permeability framed to account for the income and outgo of the living plant with respect to electrolytes must take into account the striking differences that exist in the behavior of plants toward even such fundamental factors as the required mineral nutrient ions.

The nucleus as a center of oxidation, W. J. V. OSTERHOUT (Brooklyn Bot. Gard. Mem., 1 (1918), pp. 342-347).—A study is detailed as made by the author on leaf cells of Indian pipe (Monotropa uniflora), which after being injured

132688°-19-3

turn dark. This change, which is interpreted as an oxidation effect, is much more rapid in the nucleus than in the cytoplasm. The facts are held to indicate that this is also the case with oxidation of the uninjured cell.

Studies on the production of matter in light and shadow plants, P. B. JENSEN (Bot. Tidskr., 36 (1919), No. 4, pp. 219-259, figs. 7).—A study of a light plant (Sinapis alba) and of a shadow plant (Oxalis acctosella) is said to have shown that carbon dioxid assimilation and daily production of dry matter are very much more rapid in the former than in the latter. The equilibrium point between assimilation and respiration is reached at a light intensity of 1.0 (Bunsen units×100) for the former and at 0.2 for the latter.

The luminescence of Pseudomonas luminescens, A. DE COULON (Étude de la Luminescence du Pseudomonas luminescens. Thesis, Univ. Neuchatel, 1916, pp. 95, figs. 18).—Results of a study of P. luminescens as here detailed are claimed to show that bioluminescence is independent of respiration, but ceases with the death of the cell. The phenomenon is intracellular, depending upon oxygen which becomes available, though it is not known whether the oxygen is furnished by the atmosphere or by intracellular chemical processes. Ethyl alcohol at 6. 2 per cent or methyl alcohol at 10 per cent concentration, lowering surface tension and semipermeability and permitting the diffusion inward of oxygen, increases the duration of luminosity. Potassium cyanid augments semipermeability but hinders respiration, resulting in the retention of oxygen by the cell. Hydrogen and hydroxyl also affect permeability and increase the duration of luminescence. The shorter light waves augment the intensity of luminosity, the longer having the opposite effect.

**Transpiration** [in plants], R. C. KNIGHT (*Sci. Prog.* [London], 13 (1919), No. 52, pp. 561-566).—A review of findings and views resulting from recent study by various authors named is largely epitomized in the statement that external conditions, as represented by soil and atmosphere, as well as the internal conditions peculiar to the plant, exercise an important regulating influence on transpiration. It is recognized that the problem of water movement through the plant is extremely complex.

Weather conditions and plant development, G. P. BURNS (*Brooklyn Bot.* Gard. Mem., 1 (1918), pp. 119–122).—Numerous examples are claimed to show that averages extending over long periods for humidity, sunshine, wind, air temperature, etc.. may conceal rather than explain the essential facts. It is held that in all study of the relation of weather conditions to plant development the importance of critical periods in the environment must be taken into consideration.

Contact stimulation, G. E. STONE (Brooklyn Bot. Gard. Mem., 1 (1918), pp. 454-479, figs. 4).—Presenting results of experimentation carried on since 1904 with several common plants, the author holds that contacts of plants or parts thereof with one another, with wires, and with other bodies result in a reaction or response which may be connected with electrical phenomena but which appears to be quite primitive and universal among plants, if not common to the lower forms of life in general. Leaves appear to be particularly sensitive. The nature of the reactions appears to be fundamentally similar to that of touch, from which it is thought such highly differentiated reactions as those of tendril and wound responses may have originated.

Apparatus for determining the temperature of leaves, E. B. SHREVE (*Carnegie Inst. Washington Year Book, 17 (1918), pp. 80, 81*).—A description is given of an apparatus which may be used to find the surface temperature of leaves without injuring them, and which has been used with a large number of plants of different ecological types growing under very dissimilar conditions.

222

The results have not yet been sufficiently assembled to warrant definite conclusions. The most outstanding fact is the rapidity with which the surface temperature of a leaf growing in the open may fluctuate within a time of 20 to 60 seconds, often amounting to from 1 to  $3^{\circ}$  C., and in moderately strong winds changing as much as  $5^{\circ}$  in 30 seconds.

Evolution by hybridization, E. C. JEFFREY (Brooklyn Bot. Gard. Mem., 1 (1918), pp. 298-305, pl. 1).—This is a critical review of recent publications.

Inheritance studies on castor beans, O. E. WHITE (*Brooklyn Bot. Gard. Mem.*, 1 (1918), pp. 513-521, pls. 6).—Hybridization studies involving several thousand plants have been pursued through the  $F_1$ ,  $F_2$ , and in some cases, the  $F_3$  generations derived from 50 or more types grown from seeds representing different growers. Very little cross-fertilization occurred. Details are given, with some interpretation of the data obtained, from the study on stem color, bloom, dehiscent and indehiscent pods, and seed coat color.

The inheritance of doubleness in Chelidonium majus, K. SAX (*Genetics*, 3 (1918), No. 3, pp. 300-307).—Presenting results of statistical studies of the relation of petals and stamens and of the inheritance of doubleness in C. majus, the author states that this quality appears to be a simple recessive character. There is apparently a continuous series in degree of doubling from singles to full doubles in the  $F_2$ . Much greater variation is noted in the doubles, which are recessive, than in the singles of which two-thirds are heterozygous. The  $F_2$  doubles are no more variable than individual double plants of that generation. A high degree of negative correlation exists between petal number and stamen number in the  $F_2$ , due to petalody.

Duplication and cohesion in the main axis in Cichorium intybus, A. B. STOTT (*Brooklyn Bot. Gard. Mem.*, 1 (1918), pp. 480-485, pl. 1, fig. 1).—The terms duplication and cohesion are here used to designate a very special type of fasciation, observed by the author to occur in a cultivated variety of chicory and made the subject of a study, the results of which are reported herein. In addition to a very decided duplication with cohesion of the main axis, other irregularities occur in the development of cotyledons and plumule, Involving in some cases fusion or suppression.

The character of duplication and cohesion of the main axis is strongly but not completely heritable. In an  $F_1$  hybrid generation of crosses between plants showing duplication and plants of wild stock free from these abnormalities, the duplication is incompletely dominant both as to degree of expression and number of plants affected. An intermediate type is noted in which the only indication of duplication is seen in a mixed and irregular phyllotaxy.

Intercrosses between self-sterile plants, E. M. EAST (Brooklyn Bot. Gard. Mcm., 1 (1918), pp. 141-153).—Work done with Nicotiana forgetiana and N. alata and their intercrosses, part of the data from which have been published elsewhere (E. S. R., 38, p. 823), is considered to show unmistakably that the behavior of self-sterile plants in intercrosses is governed by a relatively small number of factors, which act through the pollen; also that the gametes of plants having like constitutions as regards effective factors are incompatible in the sense that they do not make a normal pollen tube growth and hence do not reach the ovary in time for fusion to occur.

This interpretation is considered to show why plants are both self-sterile and cross-sterile. It accords completely with the fact that a population of plants may be divided into groups on the basis of their mating proclivities, and that each member of any group is cross-sterile with every other individual of that group although fertile with every individual of every other group. It is considered possible by continuous self-fertilization, utilizing end-season pseudofertility, to obtain ultimately a population in which every individual possesses the same effective self-sterility factors, all the plants in such a population being cross-sterile as well as self-sterile. It is claimed that such a population has in fact been obtained.

An analysis of the changes involved in a case of progressive mutation, C. D. LA RUE and H. H. BARTLETT (*Genetics*, 3 (1918), No. 3, pp. 207-224, fig. 1).—In continuation of a study (E. S. R., 37, p. 724) of mutations derived from *Enothera reynoldsii*, the authors summarize by stating that in a series of mutations showing both reduction and increase in the size of the entire plant and its organs the size characters appear to involve only the number and arrangement of cells, and not at all the size of the cells, which remains the same throughout the whole series.

Variations in the number of somatic chromosomes in Œnothera scintillans, R. T. HANCE (Genetics, 3 (1918), No. 3, pp. 225-275, figs. 12).—Having found that Œ. scintillans does not give constant chromosome counts in the somatic cells, the author carried out comprehensive studies with material collected from three generations, finding that the number varied from 15, the type or fundamental number, to 21, the additional numbers believed for reasons given to be produced by fragmentation of the type chromosomes. Fragmentation appeared to be confined to the longer chromosomes and was not observed to occur in the cells of the germinal line. Two classes of gametes were found, one possessing 7 chromosomes and the other 8. The data obtained are used as a basis for suggestions.

It is believed that the methods of procedure adopted in this study will be found applicable to a number of cytological problems.

Further studies on the interrelationship of morphological and physiological characters in seedlings of Phaseolus, J. A. HARRIS (*Brooklyn Bot. Gard. Mem.*, 1 (1918), pp. 167–174).—The purpose of this paper is to supplement and extend the results of an earlier study (E. S. R., 36, p. 221), in which it was shown that in bean seedlings characterized by certain morphological variations from type the development of primordial leaf tissue is less than in normal controls grown under conditions as nearly as possible identical. The data then available indicated that a reduction of the volume of primordial leaf tissue is associated with abnormalities of all the types studied, but that the type of variation influences, in some degree, the amount of reduction.

While the first experiments gave results based upon primordial leaves only, this paper presents the results of the determination based upon the first trifoliate leaf, the material used being a mixture of slightly different strains of navy beans. Consideration of the data is held to justify the statement that a correlation exists between morphological and physiological variations in plants, seedlings of Phaseolus which show one of the smallest definite structural variations, that is, the slight vertical separation of the two cotyledons in their insertion on the axis, being differentiated from the structurally apparently normal individuals in their physiological and also in their morphological characteristics, producing in this case a smaller weight of dry substance in the leaf tissue and a smaller relative weight of dry substance in both primordial leaves and the first trifoliate leaf.

Tubers within tubers of Solanum tuberosum, F. C. STEWART (*Brooklyn Bot. Gard. Mem.*, 1 (1918), pp. 423-426, figs. 3).—A case is described in which, in addition to the large numbers of new tubers formed on seed potatoes stored over summer in slatted crates in a cement cellar, a number of such new tubers formed within the old tubers, in some cases weighing from 25 to 60 gm. and in one case 67 gm. The dissection of one seed potato showed that the sprout bearing the new tuber had started from an eye where two external sessile new tubers were attached. Apparently the direction of growth had been inward from the beginning. The ingrowing sprouts showed the lenticel-like openings described by Gager (E. S. R., 26, p. 828) in an account of a case which the present case resembles in some respects.

# FIELD CROPS.

[Report of field crops work in Idaho, 1918], R. K. BONNETT, H. W. HULBERT, R. J. LETH, P. A. WENGER, P. P. PETERSON, E. B. HITCHCOCK, and F. H. LAFRENZ (*Idaho Sta. Bul. 113 (1918), pp. 22–24, 28–31, 43, 44*).—This describes the continuation of work previously noted (E. S. R., 39, p. 333). The moisture supply during the season of 1917–18 is said to have been insufficient for normal crop production. Observations on variety tests with cereals may be summarized as follows:

Turkey Red again gave the best results in tests of winter wheat varieties, while Kharkov and Red Russian also gave satisfactory results. Fall-sown Marquis wintered well and produced a good yield of excellent quality. Jenkins Club, Palouse Bluestem, Early Baart, and Marquis appeared to be the most promising spring wheats for this region. White Winter barley, with an average yield of 65.4 bu. per acre since 1911, has surpassed all other winter varieties and has also given good results as a spring variety. As a rule six-row types of barley have outyielded the two-row types, while the bearded varieties have outyielded the beardless sorts. Swedish Select, Banner, Danish Giant, Abundance, Colorado No. 37, and White Russian oats are deemed to be specially adapted to this section. Petkuser winter rye was first with a yield of more than 35 bu. per acre. The crop is also said to show much promise as an early spring pasture crop. Spring rye can not be recommended.

Cultural and variety tests with forage crops seeded alone and in mixtures are briefly noted. Alfalfa gave the best results when seeded in rows, as did also Sudan grass. Other legumes and grasses which gave promising results included red, alsike, and sweet clover, brome grass, orchard grass, tall meadow oat grass, perennial rye grass, Italian rye grass, and slender wheat grass. A few plants of an annual white sweet clover grown from seed secured from the Iowa Experiment Station (see p. 227) made an excellent growth and ripened some seed. It is stated, however, that this plant can not replace biennial white sweet clover in hay or pasture mixtures. A number of varieties of millet made fair yields, but were not so satisfactory as Sudan grass. None of the sorghum varieties tested produced seed, and only a few developed sufficiently to make a good quality of coarse hay. Ogemaw soy beans, an early sort, appeared to be best for northern Idaho. White Canada or White Colorado field peas are deemed best for seeding with oats for hay. Ear-to-row plantings of Rustler White Dent corn, said to be best for both grain and silage in the northern part of the State, yielded as high as 123 bu. per acre, while a number of rows produced at the rate of more than 90 bu.

A report of the seed analyst for the year ended December 1, 1918, prepared by P. A. Wenger, comprises a brief statement of the number of samples of different field crop seeds examined for purity and germination. A total of 1,291 samples were tested for purity and 198 for germination.

Wheat grown in rotation with and without manure on Palouse silt loam produced on the average 16.8 bu. per acre without manure and 19.2 bu, with manure.

Work on the Sandpoint substation showed that wheat grown on clover and timothy sod produced 12.6 bu. as compared with 8.5 bu. from plats otherwise similarly treated. These results are held to indicate that newly broken forest land should first be seeded to clover or clover and timothy. Crop yields on the substation were as follows: Clover hay 2.5 tons (2 cuttings), Japanese and Silver-hull buckwheat 24.8 and 13.2 bu., respectively, Russett, Early Ohio, and Rural New Yorker potatoes 181, 160, and 148 stacks, respectively, Half Sugar and Danish Sludstrup mangels 57,080 and 52,200 lbs., Danish Baldhead cabbage 36,300 lbs., White Belgian stock carrot 24,500 lbs., and Danvers Half Long carrot 30,200 lbs. per acre.

[Report of field crops work on the Aberdeen substation, 1918], L. C. AICHER (*Idaho Sta. Bul. 113* (1918), pp. 34–37).—The continuation of work along the same general lines as previously indicated (E. S. R., 39, p. 334) is described. It is stated that this was the driest season since the substation was established, the precipitation during the growing season being 3.37 in. as compared with an average of 4.16 in. Work on the dry land farm may be summarized as follows:

Alberta Red, Ghirka, and Theiss winter wheats produced average yields of 18.8, 18.6, and 18.1 bu. per acre, respectively, for the 6 years 1913 to 1918, while the yield of spring wheat varieties tested ranged from 6.6 bu. for Kubanka to 12 bu. for both Early Baart and Bluestem. Sixty-day oats produced 20.4 bu., and Smyrna and Beldi spring barleys 14.1 and 12.9 bu., respectively. The highest yield of flax, 7.8 bu. per acre was secured from C. I. No. 30.

Field peas grown in a variety test for the period of 1913 to 1918, inclusive, ranged in yield from 6.7 bu. per acre for Cossack and Bangalia to 8.1 bu. for both Grey Winter and McAdoo (formerly Kaiser).

The average yield of potatoes for 3 consecutive seasons ranged from 160.8 bu, per acre for Early Six Weeks to 224.5 bu, for Idaho Rural. Potatoes grown from seed produced on irrigated land yielded 8.9 bu, more per acre than those grown from seed produced on dry land. With yields ranging over 200 bu, per acre, however, this increase is deemed negligible and is held to indicate that the supposed superiority of irrigated seed potatoes does not exist.

Cultivating winter wheat or plowing under green manure did not prove profitable. Wheat grown on summer fallow produced 6.2 bu. per acre as compared with a general average of 4.4 bu, for the winter wheat plats. A rotation of wheat and field peas has given the best results of any rotation, but if continued without fallow is said to lead to reduced yields of both crops.

Results secured on the irrigated farm may be summarized as follows: Spring wheat yields ranged from 39.1 bu. per acre for Early Baart to 51.2 bu. for Dicklow for the period of 1913 to 1918. The yield of oats ranged from 106.1 bu. for Swedish Select to 115.1 for Golden Rain, and of barley from 73.1 bu. for Smyrna to 87.4 bu. for Trebi for the same period. Smyrna flax produced a 3-year average yield of 26.6 bu.

World Prize and Wellwood field peas are said to have given the highest yields in a 5-year test. The average yield for 19 varieties of field peas was 55 bu. per acre. Grimm alfalfa produced at the rate of 5 bu. of seed per acre, red clover 3 bu., and alsike clover 2.5 bu.

Idaho Rural, Green Mountain, and Irish Cobbler potatoes, with 5-year average yields of 400, 397.4, and 352.3 bu. per acre, respectively, were the leading varieties tested. No increase in yield has been secured in transposition tests.

[Report of field crops work in Iowa, 1918] (*Iowa Sta. Rpt. 1918*, *pp. 10-12*, 24, 25, 26).—This describes the progress of work along the same general lines as previously noted (E. S. R., 40, p. 328).

1919]

Forcing air, heated to a temperature of from 160 to  $180^{\circ}$  F. through cribbed corn reduced the moisture content from more than 30 to less than 10 per cent at an estimated cost of 3 cts. per bushel for fuel and power.

Iowa 103 and Iowa 105 oats continue to show a marked superiority over common varieties in cooperative tests throughout the State. An annual white sweet clover, said to have been isolated for the first time at Ames during the winter of 1915–16, when seeded in the field made a growth of 4.5 ft. within 3.5 months, as compared with a growth of only 4 in. for red clover, 9 in. for annual yellow sweet clover, and 14 in. for biennial white sweet clover all seeded at the same time and subjected to identical conditions.

Winter wheat seeded as late as November 21 survived with practically no winterkilling, this being attributed to the fact that the seed sprouted very little or not at all before winter conditions checked growth.

In germination tests of weed seeds buried in the soil in the fall of 1911, ten species germinated readily in April, 1918. Among these 30 per cent were jimson weed, 25 per cent burdock, 20 per cent Indian mallow or butterprint, and 18 per cent horse nettle. Weeds were found to transpire a large amount of water which should go to cultivated crops. Rape, wheat, and oats when properly planted crowded out quack grass.

Observations on a number of varieties and strains of oats grown in the nursery in an effort to secure sorts resistant to crown and black stem rust led to the discovery of Green Russian and White Russian, both resistant to stem rust, while the latter is also said to be quite resistant to crown rust.

Variety testing and crop improvement, C. S. KNIGHT (Nevada Sta. Rpt. 1918, pp. 23-30, figs. 2).—Variety tests with wheat, oats, barley, and forage and root crops are described in continuation of similar work previously noted (E. S. R., 39, p. 128).

The average yield of wheat varieties grown in 100-ft. rows for four years ranged from 2,720 lbs. of grain per acre for White Australian to 3,157 lbs. for Colorada No. 50. The superiority in quality of Marquis and Blue Stem, yielding 2,970 and 2,979 lbs. per acre, respectively, is said to more than offset the difference in yield between these varieties and the highest producing sorts. Of the oat varieties tested for three years Early Mountain No. 2 was first with an average yield of 2.843 lbs. per acre, and was affected less by the shattering of the seed, due to blasting of the panicles before ripening, than any of the other varieties tested. Barley yields ranged from 2,708 lbs, for White Moravian to 2,926 lbs. for California Feed for varieties grown four years, while Swedish Gold grown for two years produced on the average 4,821 lbs. The leading varieties of cereals tested in plats during 1916 and 1917, together with their respective yields per acre, were as follows: White Club wheat 2,641 lbs., Great Dakota oats 1,037 lbs., and Chevalier barley 2,135 lbs. In tests conducted in cooperation with the Truckee-Carson reclamation project experiment farm, Little Club, Marquis, and Sonora were found to be the highest yielding wheat varieties when compared with the local sorts, while Beldi barley outyielded the local variety.

The total yield of alfalfa for two cuttings ranged from 4.57 tons per acre for Grimm to 6.04 tons for Australia 23,753. The proportion of leaves to stems varied from about 34 to 40 per cent.

Improved Learning corn produced 28,422 lbs, of silage as compared with 46,240 lbs, for Russian sunflower. The latter is said to have made silage superior in quality to that from corn. Sudan grass surpassed the millets and field peas both in forage and seed production. A yield of 8 tons per acre of excellent silage was secured in 1917. The average yield of seed for the past 3 years amounted to 1,218 lbs, per acre.

Great Divide, Burbank, and Peerless potatoes have produced maximum average yields for a 5-year period of 13,546, 12,991 and 11,782 lbs. per acre, respectively. Our Ideal mangel produced the highest average yield, 30,469 lbs. per acre, for a 4-year period in a comparative test of different varieties of beets, but is deemed inferior in feeding value to sugar beets which produced at the rate of 25,907 lbs. for a 3-year period. In date-of-planting tests with sugar beets the best results were secured from plantings made before the first of May.

[Report on the activities of the agricultural association of Zealand, Denmark, in 1918], A. P. JACOBSEN (*Ber. Landbofor. Virks. Plantcavl. Själland*, 1918, pp. 551, pls. 3, figs. 2).—The activities reported on included cooperative experiments with fertilizers and lime, rotations and fallows, variety tests of different field crops, examination and testing of seeds, studies of methods of weed destruction, and determination of the nitrogen content of fertilizers. The report presents also the proceedings of the meetings of the association, together with a discussion of the association's work in general. The conditions affecting agriculture during the year are briefly noted.

In fertilizer experiments conducted with cereal crops from 100 to 200 kg, of nitrate of soda per hectare (about 89 to 178 lbs. per acre) were used, alone or in combination with 150 to 300 kg, of superphosphate or with this amount together with 100 to 150 kg, of 37 per cent potash salt. It is calculated that to defray the cost of the fertilizers 100 kg, of nitrate of soda had to produce an increase in yield of 160 kg, of grain and 1,600 kg, each of roots and grass; 100 kg, of 18 per cent superphosphate, 100 kg, of grain and 1,000 kg, each of roots and grass; and 100 kg, of 37 per cent potash salt, 72 kg, of grain and 720 kg, each of roots and grass.

A series of experiments was conducted with rye, barley, oats, and root crops on clay soils. The average results of five experiments with barley after another grain crop indicated an increase of 207 kg. of grain and 282 kg. of straw from the use of 100 kg. of nitrate of soda, and the unprofitable use of an addition of 100 kg. of superphosphate or of 100 kg. each of superphosphate and potash salt. The average results of 12 similar experiments with barley following root crops showed an increase of only 142 kg. of grain and 308 kg. of straw from the use of 100 kg. of nitrate of soda per hectare, and also an unprofitable use of either superphosphate or superphosphate and potash salt in addition. The plants receiving no fertilizers and on which barley was grown after another grain crop produced in 1918 an average of 2,088 kg. of grain and 2,884 kg. of straw, where the barley followed root crops.

The use of 100 kg, of nitrate of soda in growing oats gave a profitable increase only where the oats followed grass.

The average results of 21 experiments with mangels following different crops showed an increase of 3,200 kg, where 100 kg, of nitrate of soda had been applied. The addition of 100 kg, of superphosphate was profitable in only nine of the experiments, and the average results were also unsatisfactory. The application of 100 kg, of potash salt together with superphosphate gave, on the average, profitable returns. The results from the use of superphosphate and potash salt varied to a marked extent.

In a limited number of fertilizer experiments with grass grown for seed, it was found that nitrate of soda and potash salt applied to land in Italian rye grass gave satisfactory average increases in yield.

For three years nitrate of soda at the rate of 100 kg, per hectare was used alone and in combination with a complete application, including a like amount in growing barley and oats. In 1918 a large increase in yield was secured from the nitrate used with the complete application, but in the two preceding years a single application appeared the more profitable. A similar experiment with corresponding results was conducted with mangels, but in this case 150 kg. of the nitrate were used.

A comparison of Norwegian nitrate, ammonium nitrate, ammonium sulphate, and lime nitrogen of German, Swedish, and Norwegian manufacture was begun in 1914 and completed in 1918. Swedish turnips and orchard grass responded in general quite favorably to the use of the different substances, while sugar beets and mangels responded very unfavorably, and oats, barley, and potatoes gave intermediate results. In discussing these data the belief is expressed that the sodium of the nitrate of soda may have acted injuriously upon the Swedish turnips and the orchard grass and favorably upon the sugar beets and mangels, while it remained neutral with reference to oats, barley, and potatoes.

Experiments conducted for one year with superphosphate and Bornholm raw phosphate used on different crops indicated that the raw phosphate had produced from 50 to 80 per cent of the effect of the superphosphate on the basis of the phosphoric acid content of the two substances. The raw phosphate was most effective on lime-poor soils.

In variety tests with different crops the following were the leading sorts: Tystofte Small wheat II, Tystofte Prentice 2-rowed barley, Svalof Victory oats, and Up-to-date and Richter Imperator potatoes.

Of different methods tried for control of thistles deep plowing late in the fall and subsoiling gave the best results.

In connection with a rotation experiment in 1916, certain plats were in fallow while others were devoted to 6-rowed barley, soiling crops, potatoes, or turnips. In the fall of that year the entire series was sown to wheat and rye, the wheat receiving barnyard manure and the rye superphosphate. In the spring of 1917 one-half of each plat was given 100 kg, and the other 250 kg. of nitrate of soda per hectare. Cropping as compared with fallowing apparently reduced the yields of wheat and rye to a marked extent, the greatest reduction being after 6-rowed barley and the smallest after potatoes or turnips. A comparison of the total production for the two years with the plats in fallow showed the following average increase in the production of feed units per hectare where the smallest quantity of nitrate of soda was applied; 6-rowed barley plats 2,480, soiling crop plats 2,510, and potato plats 4,331. On the plats receiving 250 kg, of nitrate of soda the corresponding increases were 2,671, 2,669, and 4,407 feed units, respectively. In another similar experiment, the largest increase in production of feed units per hectare was also in favor of the plats which had produced the root crops.

Culture experiments conducted with wheat crops showed that plantings made April 10 gave better yields than plantings made April 23. Mangels thinned at the proper time gave a yield 3,800 kg. greater than that secured from a plat 11 days later, and plants thinned to 24 cm. apart in the row gave a yield greater by 800 kg. per hectare than the yield from plants thinned to 30 cm. apart as compared with greater distances between plants and later planting. Chicory produced the best yield when set about 4 in. apart in the row on April 28. Turnips grown for seed and not thinned did not produce as large a yield as when derived from those thinned to 6 in. apart in the row. Cutting back Swedish turnips to two-thirds their actual size about June 1 caused a marked reduction in yield. Covering the rows on February 12 with seaweed at the rate of 20 loads per töndeland (1.36 acres) increased the yield by about one-third.

Tests with different grass and clover mixtures resulted in the best yields, even the first year, from a seed mixture of 6 kg, of red clover and 16 kg, of

[Vol. 41

alfalfa per hectare sown on good soil. On lime-poor soil, mixtures containing a large proportion of bird's foot clover (*Lotus corniculatus*) succeeded best. The results from drilling and broadcasting the seed mixtures differed but little.

Cultural experiments were conducted also with oil and fiber plants. Yellow mustard produced the best yield where sown at the rate of 4 kg. per hectare. In another test drilling in rows 16 cm. apart gave the best results. Russian sunflowers compared with two other varieties led in yield with about 2,500 kg. of seed per hectare. Planting the sunflower seed April 17 proved best. The yield was only slightly larger than that from a planting made May 1, but planting May 18 was found too late for good results. Brief directions for harvesting sunflower seed are given. The highest yield and quality of flax seed and fiber were obtained from sowing April 25. Hemp sown April 30 gave a higher yield than that sown May 14.

[Work in 1917 at the experiment stations at Leteensuo and in Syd-Osterbotten], E. A. MALM (*Finska Mosskulturför. Årsbok, 22* (1918), No. 1, pp. 12– 19).—At Leteensuo, the yields of hay on meadows drained by ditches of different depths were in favor of the depth of 0.5 meter (19.18 in.) as compared with 0.75 meter and 1 meter depths. The ditches were dug 10, 20, and 30 meters apart and where the distances were 10 and 20 meters the yields were about equal. The smallest yields were secured where the ditches were 30 meters apart.

The effect of sand and clay applied to bog soils was studied. Applications of clay and sand were made at the rates of 100, 200, 300, and 400 cubic meters per hectare. The increase in yields was greater where the clay had been used than where the sand was applied. However, an application of 100 kg. of phosphoric acid or of this amount with 100 kg. of potash per hectare produced increases in yield very much greater than those secured from the use of either sand or clay alone. The highest yield of hay, 6,240 kg. per hectare on the soil treated with sand, was obtained where 300 cubic meters of sand and phosphoric acid and potash had been given, while on the soil treated with clay the best return, 7,096 kg. of hay per hectare, was obtained where only 100 cubic meters of clay were applied with the phosphoric acid and potash.

It is pointed out in this connection that some years ago Swedish turnips were grown on a series of plats treated with clay in the manner described and receiving also 200 kg. of bone meal and 300 kg. of kainit per hectare. The best yield, 28,900 kg. per hectare was secured from the treatment of 300 cubic meters of clay and the least, 15,100 kg. per hectare, where no clay had been given. The plat treated with 400 cubic meters produced 26,800 kg. of turnips per hectare, standing next to the highest yield.

The results of experiments in applying lime at different rates on bog lands treated with sand and clay were not conclusive. Only in one instance, where 3,000 kg, of lime per hectare were applied in 1907 and again in 1913, and where during the particular crop season 200 kg, of bone meal and 300 kg, of kainit or 230 kg, of ammonium sulphate in addition to this application were used per hectare, did lime appear to increase the yield of hay, the increase being 932 and 2,225 kg, per hectare for the two applications, respectively.

In a comparison of Thomas slag and so-called Bernard phosphate as fertilizers for oats, the best yields of grain and straw were obtained with the Thomas slag. The two fertilizers were applied with 500 kg. of kainit at the rate of 40 and 80 kg. per hectare. In a test of superphosphate and the socalled diphosphate on land not treated with either sand or clay, it was found that the results were slightly in favor of the diphosphate. In a third experiment on land treated with clay, 150 or 200 kg. of nitrate of soda and 115 kg. or 230 kg. of sulphate of ammonia per hectare, given in addition to 200 kg. each of bone meal and kainit, increased the yields, the better results being from the larger quantities applied. It was found in this experiment also that on limed soil the increases in yield due to these fertilizers were much greater than those on unlimed soil.

Fertilizer experiments conducted at the experiment station in Syd-Österbotten showed that on bog soil treated with clay and given 150 kg. of bone meal per hectare the use of 2,000 kg, of lime per hectare resulted in a marked increase in the yield of hay. The best yield was 4,776 kg, per hectare, as compared with 1,160 kg, where the soil had been treated with 300 cubic meters of clay per hectare.

A study was made also at this station of the effect of either oats or leguminous crops or different mixtures of the same on a succeeding crop of turnips. The crop mixtures varied by 20 per cent of each other as to the proportion of oats and legumes. Yields of turnips were increased from 15,100 kg. per hectare where the crop followed oats to 33,127 kg. where it followed a leguminous crop. The turnip crop following the mixtures increased in about the proportion the leguminous crops increased and the oats decreased in the crop mixture.

[Irrigation experiment with alfalfa and wheat], C. S. KNIGHT (Nevada Sta. Rpt. 1918, pp. 19-23).—This describes further progress of work previously noted (E. S. R., 39, p. 132).

From results secured during the period of 1915–1917, inclusive, it was concluded that the most economical method of irrigating alfalfa in Nevada is to make 12-in. applications of water when the leaves turn dark-green in color and begin to droop. Under these conditions an average yield of 5.18 tons per acre was secured with 36 in. of water. The maximum yield, 6.63 tons, was secured with a total of 80 in. of water made in 12 in. applications before the plants showed need of water.

In the wheat experiments, the highest yield per acre and per acre-foot of water for the period of 1914-1917, inclusive, was obtained with four 7-in. applications, the irrigation at the five-leaf stage being omitted. The lowest yield per acre-foot of water applied followed five 7-in. applications. The lowest yields with both 3- and 7-in. applications followed the omission of irrigations at the boot and bloom stages, respectively. Omitting irrigation at two stages of growth, the maximum yield, 32.4 bu. per acre, was obtained with 21 in. of water made in three 7-in. applications, omitting the five-leaf and dough stages. With both 3- and 7-in. applications the most critical period in the irrigation of wheat was found to be between the boot and milk stages. Where only two irrigations were made the largest yield, 31 bu., was secured from 9-in. applications, one before and one after heading. An application of only 12 in. made in two irrigations produced the highest yield per acre-foot of water, 27.4 bu., as compared with 14.1 bu. for 24 in. of water, and 20.7 bu. for 18 in. The average annual precipitation for the four years of the experiment was 7.52 in. See also previous notes (E. S. R., 39, pp. 338, 343).

Clover and grass seeding in the conversion of waste land into meadow, A. GRISCH (*Landw. Jahrb. Schweiz*, 32 (1918), No. 4, pp. 505–524, figs. 3).— Field tests conducted during 1912–1915, inclusive, are described in which observations were made upon the effect of seeding poorly drained waste lands with a mixture of 14 different sorts of clovers and grasses, and of applications of superphosphate, Thomas meal, and potash in various combinations. It is concluded that by harrowing, seeding with a suitable clover and grass mixture, and applying appropriate fertilizers poorly drained land may be converted into profitable hay land within a comparatively short time and with a small outlay of money and labor, either as a permanent improvement or as a step toward the further development of the area for growing cultivated crops.

Brown hay, W. A. LINKLATER (*Washington Sta.*, *West Wash. Sta. Mo. Bul.*, 7 (1919), *No. 3*, *pp. 38*, 39).—The preparation of so-called brown hay, in western Washington, under weather conditions adverse to the proper curing of ordinary hay, is briefly described. The material is cut about the time of heading out in June and cured until in prime condition for cocking, when it is placed in a stack, either in the barn or outside and firmly packed. The stack is said to heat considerably, the curing process continuing from 30 to 60 days. The hay is described as dark brown or black in color, nutritious, and palatable.

Cassava experiments, 1916–1918, J. DE VERTEUIL (Bul. Dept. Agr. Trinidad and Tobago, 17 (1918), No. 4, pp. 193–198).—Variety, cultural, and fertilizer tests with cassava are described in continuation of work previously noted (E. S. R., 38, p. 530).

Yields of roots ranging from 5.53 to 8.59 tons per acre for Maman l'Enfant and Sellier, respectively, were secured in the variety tests. Level cultivation with the plants spaced 3 by 3 ft. continued to give the best results. Sellier planted the latter part of April and harvested 17 months later produced 10.77 tons of roots containing 15.26 per cent starch, as compared with 1.42 tons of roots and 12.35 per cent of starch from a planting made the latter part of March and harvested 6 months later. Plantings of the same variety made about the middle of April and harvested from 6 to 17 months later showed a range in yield of from 2.02 to 8.88 tons of roots per acre, respectively. The percentage of starch in the roots appeared to be little affected by the age of the plant eight months after planting, increasing from 7.86 per cent for roots harvested at 6 months of age to 22.03 per cent for those harvested when 8 months old. The maximum percentage of starch, 27.62, was attained in roots harvested 11 months after planting, but the yield of roots was only 6.4 tons. The maximum yield of starch, 4,708 lbs. per acre, was secured from roots 14 months of age.

Applications of pen manure at the rate of 20 tons per acre and of a complete fertilizer at the rate of 300 lbs. per acre resulted in average yields of 13.45 and 10.96 tons of roots per acre, respectively, as compared with 4.85 tons from the checks. The low yields of the latter are thought to be due to shading by the fertilized plats.

An attempt to develop improved strains of cassava from seed in 1916 resulted in six seedlings which gave sufficient promise to justify their further propagation by cuttings. The yields secured from single plants at about 19 months of age ranged from 4.75 to 25 lbs., representing yields of from 10.26 to 54 tons per acre from plants spaced 3 by 3 ft.

How to increase Indiana corn yields, A. T. WIANCKO (*Indiana Sta. Circ.* 91 (1919), pp. 20, figs. 10).—Stating that the area devoted to corn in Indiana should be reduced and that the average yield could be materially increased, the author maintains that more attention to seed selection, crop rotation, and soil fertility will produce the desired results. The selection, storage, and testing of seed corn, the place of the crop in the rotation and the maintenance of soil fertility, field practices and cultural methods employed in growing the crop, and insect pests and diseases affecting corn in Indiana are discussed in a general manner.

Comparison of yield of Minnesota No. 13 corn from seed grown under different conditions, E. B. STOOKEY (*Washington Sta., West. Wash. Sta. Mo. Bul.,* 7 (1919), No. 1, pp. 5, 6).—Cooperative tests with Minnesota No. 13 corn, said to have given the best results in variety tests at the Puyallup substation for the past six years, are described in which seed grown at Prosser, Wash., under irrigation, and at Dufur, Oreg., a mid-mountain district, was compared with that grown at Puyallup for five years. It is concluded that seed corn produced just north of the forty-fifth parallel in South Dakota, Minnesota, or Wisconsin merits extensive trial, while that from regions having a long, hot growing season is not deemed suitable for western Washington conditions.

Present position and future prospects of the natural indigo industry, W. A. DAVIS (Agr. Jour. India, 13 (1918), Nos. 1, pp. 32-46, pl. 1; 2, pp. 206-221, pls. 3; 3, pp. 441-459; 14 (1919), No. 1, pp. 21-41; Agr. Research Inst. Pusa Indigo Pub., 1918, Nos. 2, pp. 18; 4, pp. 19; abs. in Nature [London], 101 (1918), No. 2528, p. 116; 102 (1918), No. 2550, pp. 27, 28).—This comprises a comprehensive account of the natural indigo industry; the possibilities of cheapening the production and improving the quality of natural indigo; the position of synthetic indigo production before the war and the effect of the war upon the production of natural indigo, especially in India; the present methods of manufacture in Bihar; and the future of natural indigo in India, with particular reference to maintaining the yield and quality of the crop through the use of superphosphates.

Experiments with potatoes (*Tidsskr. Norske Landbr.*, 25 (1918), No. 9, pp. 354-366).—Potatoes were grown for five years, 1913–1917, in rows 55, 63, and 73 cm. (21.5, 24.6, and 28.5 in.) apart. The average starch content for the five crops was 16.1, 16.2, and 16.3 per cent for the close, medium, and wide planting, respectively. The difference in yield of tubers was insufficient to offset the greater value of the seed tubers required for the close planting, so that planting at the medium distance was slightly more profitable.

For the same period broadcasting the fertilizer was compared with applying it in the furrow. The larger yield of potatoes, together with a slightly higher percentage of large tubers, was secured from the applications made in the furrow, but the method of applying the fertilizer apparently had no influence on the starch content.

Other results indicated that the starch content and the total yield of starch may increase very perceptibly during the period beginning about August 20. The yield of tubers in these experiments continued to increase up to the close of September, even if the stems died down somewhat earlier, but later a decline in yield was notable, especially on dry soil. The starch content of the tubers increased up to the death of stems and foliage, after which it declined somewhat, and the absolute starch production behaved in a similar manner.

An analysis of the costs of growing potatoes, D. S. Fox (New York Cornell Sta. Mem. 22 (1919), pp. 525-627, figs. 27).--Extensive studies planned to secure more definite and accurate knowledge of the cost of growing potatoes and of the factors influencing their profitable production in New York are described and the results fully discussed. The information was secured by both the survey and cost-accounting methods. Surveys were made on 355 farms in Steuben County during 1912, 300 farms in Clinton and Franklin Counties during 1913 (data furnished by W. M. Peacock), 161 farms in Suffolk County during 1912, and 41 farms in Nassau County during 1912. Cost-accounting records made in cooperation with the Office of Farm Management, U.S. Department of Agriculture, during 1913, 1914, and 1915, included 26 crops on 20 farms located in the central and western parts of the State. The relation of numerous factors to production, cost of production, and profit in Steuben County and in Suffolk and Nassau Counties is also discussed in some detail. A suggested form of survey blank for cost of production work with potatoes is included.

The average cost per acre of growing and marketing potatoes for the different areas was found to be as follows: In Steuben County \$51.13 or 42 cts. per bushel, in Clinton and Franklin Counties \$67.43 or 38 cts. per bushel, on 20 cost-account farms \$52.78 (exclusive of marketing charges), in Suffolk County \$85.52 or 54 cts. per bushel, and in Nassau County \$113.51 or 61 cts. per bushel. The amount of seed employed ranged from 10.2 bu. per acre in Steuben County to 14.7 bu. on the cost-account farms. The up-State farms used more manure than the Long Island farms, this being attributed to the fact that more was produced on the former and because its use tended to produce scab in Suffolk and Nassau Counties. Much more commercial fertilizer, insecticides, and Bordeaux were used on the Long Island farms, however, than in the up-State areas. The principal difference in the cost of producing potatoes on Long Island and up-State farms is said to be due to the use of better seed, more fertilizer, and higher land rentals on Long Island.

Sudan grass as an Ohio crop, C. G. WILLIAMS (Mo. Bul. Ohio Sta., 4 (1919), No. 5, pp. 139-142).—The production and utilization of the crop in the State is briefly described and the principal competing crops indicated.

In rate-of-seeding tests covering a 3-year period the yields of hay ranged from 2.74 tons per acre for a seeding rate of 7.5 lbs. drilled in rows 32 in. apart to 3.12 tons for a seeding rate of 30 lbs. drilled in rows 8 in. apart, while the most profitable rate was found to be 15 lbs. per acre drilled in rows 8 in. apart, resulting in an average yield of 2.96 tons. When grown for seed it is suggested that from 4 to 6 lbs. of seed be used in rows from 30 to 36 in. apart. The yields of seed are said to range from 10 to 30 bu. per acre.

A comparison of Sudan grass with its principal competitors, German millet and Early Amber sorghum, for a 7-year period resulted in average yields of air-dry forage amounting to 3.7, 3.7, and 8.3 tons per acre, respectively. The cost of seeding these crops at the most profitable rate based on present seed prices is estimated to be \$0.875 per acre for Early Amber sorghum, \$2.80 for German millet, and \$3.80 for Sudan grass.

A study of sugar cane experiments, W. E. CROSS (*Estudios Relacionados con la Experimentación de la caña de azúcar. Buenos Aires: Tucumán, Dept. Invest. Indus., 1918, pp. 109, figs. 33*).—This publication comprises a series of six conferences held with the agricultural alumni at the University of Tucumán, Argentina, for the purpose of discussing problems relating to sugar cane production and describing the experimental methods employed in their solution. The points considered included varieties, methods of planting, cultivation, fertilization, rotation and soil improvement, and moisture conservation, drainage, and irrigation.

Experiments on the time of sowing turnips and rutabagas (*Tidsskr. Norske* Landbr., 25 (1918), No. 9, pp. 367–374).—Thèse experiments were conducted with Dale Hybrid turnip and Bangholm rutabagas for five seasons from 1912 to 1917, exclusive of 1915, when insects destroyed the crop. Comparative tests were made of crops sown on the 10th, 20th, and 30th of May each year, and the yields of roots, leaves, and dry matter by years are given in tables.

In general the yields decreased with the lateness of sowing, the only exception being the results of 1914, when on account of a dry season the largest yield of turnips was secured from the latest sowing. The dry matter content seemed to be influenced but little by the time of planting, but was determined by the yield of roots. There was a difference in the yield of dry matter of over 1,200 kg. per hectare (1,068 lbs. per acre) between the first and second dates of sowing rutabagas, and of nearly 1,400 kg. per hectare between the second and third dates. It is pointed out that a unit of dry matter in root crops has the feeding value of a unit of barley, and that on this basis a difference of 10 days in sowing caused a reduction in the yield of dry matter corresponding to the value of nearly half of a medium yield of barley. The average yield of roots was also in favor of the earlier plantings.

The production of stems, and foliage as compared with the yield of roots was much less affected by the time of planting. Both crops produced the largest quantity of stems and leaves from the plantings made May 30.

The heredity of quantitative characters in wheat, G. F. FREEMAN (*Genetics*, 4 (1919), No. 1, pp. 1–93).—This paper is the first of a series of contributions to the knowledge of the inheritance of quantitative characters in wheat crosses made at the Arizona Experiment Station. The work was begun in 1913 by making a number of reciprocal crosses between an Algerian white macaroni wheat, Algerian red bread wheat, Early Baart, and Sonora. The present paper deals with the date of appearance of the first head on each plant, the total height of the plants measured in centimeters from the ground to the top of the tallest head, not including beards, and the Width of the broadest leaf. The data secured for the parental strains and the  $F_1$ ,  $F_2$ , and  $F_3$  generations are presented in tabular form, together with their statistical analysis, fully discussed and summarized in detail for each character.

In a general summing up the author states that "the  $F_1$  of the macaronibread wheat crosses developed normally and were in every case equal or superior to the mean of the parents in vegetative vigor, and they were no more variable in size characters or time of maturity than were the pure races. We may, therefore, conclude that a single complete set of macaroni wheat characters with a complete single set of bread wheat characters (the maximum of heterozygosis between the two varieties) will produce a perfectly normal plant. In the second generation, on the other hand, many of the seeds would not germinate and those germinating produced plants differing in vegetative growth from those which were more vigorous than either parent to such as never got beyond the rosette stage. Moreover, those which made a normal vegetative development exhibited every degree of sterility from completely sterile plants to those entirely normal in seed production. It would appear, therefore, that these facts alone refute any idea of blending inheritance, for if blending had taken place in the  $F_1$ , sterile or vegetatively deficient plants would be no more likely to occur in the  $F_2$  than in the  $F_1$ . Hence we are compelled to predicate segregation and recombination in these quantitative characters. There is nothing to indicate even partial blending in any of the factors concerned.

"In the use of the coefficient of variation as an indication of heterozygosity in hybrids involving quantitative characters, care should be exercised to make due allowance for the fact that races with high means resulting from increased vegetative growth have their variability limited or reduced by the apparent law that size factors are more effective in producing variability in combinations tending to produce a result below the mean of the hybrid population than in combinations which tend to exceed this mean. The suppression of variability in cultures with high means applies to pure as well as hybrid cultures. It appears to be a telescoping of variability as the mean approaches the upper physiological limit of growth rate for the species concerned."

Seed Reporter (U. S. Dept. Agr., Sced Rptr., 2 (1919), No. 12, pp. 8, figs. 6).— Information is presented concerning vegetable seed crop conditions in California and the North Pacific division, the Kentucky blue grass and orchard grass seed outlook, seed dealers' receipts of leading forage crop seeds, wholesale and retail selling prices of 21 kinds of field seeds on May 28, 1919, and on market conditions in different sections of the country, together with statistics relating to the number of growers of various classes of field seeds who follow certain practices in testing, cleaning, and marketing their seed. Tentative seed production and consumption maps are presented showing the counties in the United States reported as normally producing either a surplus, a sufficient, or an insufficient quantity compared with their planting requirements of seed of redtop, Kentucky blue grass, orchard grass, Canada field peas, cowpeas, and soy beans.

The establishment in England of the National Institute of Agricultural Botany for the increase and dissemination of improved strains of field and garden crops is briefly noted.

The usual statistics regarding imports of forage plant seeds permitted entry into the United States are included.

Pure seed law and the weed control act, P. WENGER (*Idaho Sta. Circ.* 8 (1919), pp. 12).—The text of both the pure seed law and the weed control act is presented and briefly discussed, together with rulings pertaining to seed inspection and analysis.

# HORTICULTURE.

The book of the home garden, E. L. FULLERTON (New York and London: D. Appleton & Co., 1919, pp. XX+260, figs. 77).—A popular treatise on the culture of vegetables, fruits, and flowers in the home garden.

Vegetables and their cultivation, T. W. SANDERS (London: W. H. & L. Collingridge, 1917, 4. ed., pp. XV+496, pls. 13, figs. 150).—A guide to the history, cultivation, and forcing of culinary vegetables, salad crops, and herbs for home use and exhibition; also the formation of the vegetable garden; the management of soils; manures and their uses; the eradication of injurious insect and fungoid pests; etc.

A handbook of vegetable culture, W. MOLEGODE (Colombo, Ceylon: Times of Ceylon Co., Ltd., 1918, 2. ed., rev. and enl., pp. IX+124).—Specific directions are given for the culture of various vegetables adapted to Ceylon, including general instructions on vegetable growing.

Bud variation as a practical asset in horticulture, M. J. DORSEY (*Minn.* Hort., 46 (1918), No. 8, pp. 304-311, figs. 2).—A contribution from the Minnesota Experiment Station, discussing the types of variations which occur in horticultural plants, the extent to which these types occur, the use that has been made of them in horticultural practice, and the influence of selection in horticultural varieties.

A review of the literature shows that bud variation may affect such important commercial fruit characters as color, season, size, growth, habit, and yield. These variations, however, have not been much of a factor in the origin of new varieties in the apple, cherry, plum, or grape, but have been in ornamentals and flowers. The work of bud selection by Shamel and others with citrus (E. S. R., 38, p. 541) has been more successful than with other fruits. The author concludes that the question of selection in the navel orange resolves itself down to a basis of working with differences that are constantly arising within the variety. When such differences arise within the varieties of any other fruit bud, selection has an importance other than that of developing new varieties for, "if by selecting automatically from the better types we are not selecting from the poorer types, then the procedure acts to hold the type stable."

The effect of the frosts of the winter of 1916–17 on vegetation, E. A. BowLES (*Jour. Roy. Hort. Soc.*, 43 (1919), No. 2-3, pp. 388-461).—A report on this subject to the Royal Horticultural Society, based on evidence received from important gardens in different parts of Great Britain. The general conditions during the winter of 1916–17 are reviewed, minimum temperatures where available are recorded, and an alphabetical list is given of trees, shrubs, and other plants, showing the extent of damage, or escape from injury, as well as the number of years the plant has been grown in its present position.

California crop distribution and estimates 1918 (Mo. Bul. Cal. Com. Hort., 8 (1919), No. 4, pp. 127-225, figs. 38).—This number of the bulletin deals with the acreage, distribution, tonnage, and valuation of commercial fruit and vegetable crops in California.

Analyses of insecticides and fungicides (*New York State Sta. Bul.* 454 (1918), pp. 15).—This comprises analyses of materials sold as insecticides and fungicides in the State of New York.

[Beets and peas at Wisley] (Jour. Roy. Hort. Soc., 43 (1919), No. 2-3, pp. 488-520).—Descriptions are given of varieties of beets and peas tested at Wisley, 1916-1918, including selected lists of meritorious varieties.

Cabbage culture, J. W. RIGNEY (New Mexico Sta. Bul. 118 (1919), pp. 25, figs. 8).—A practical treatise on the culture, harvesting, and marketing of cabbage, including some data on cultural and varietal experiments conducted at the station.

General arboriculture, J. M. PRIECO (Arboriculture General. Madrid: M. G. Hernández Sons, 1917, pp. VI+393, figs. 131).—A treatise on arboriculture, with special reference to Spanish conditions. Part 1 discusses the general principles of arboriculture, including methods of propagation and nursery practices. Part 2 comprises a treatise on fruit growing, harvesting, and marketing.

[Report on horticultural investigations] (*Iowa Sta. Rpt. 1918, pp. 32–36*).— A progress report on various projects for the year.

As a result of spraying experiments with fruit trees conducted for several years the following definite recommendations as to schedule of spraying best adapted to meet Iowa conditions are offered: Use lime-sulphur or Bordeaux mixture combined with arsenicals before the blooming season; use lime-sulphur with arsenicals between the blooming season and late June; use Bordeaux mixture with arsenical mixture after June. In orchards where there has been a high percentage of wormy fruit and in seasons when the worms are unusually abundant, it is advisable to spray twice for the second brood of codling moth, once during the last third of July and again after two or three weeks. In 1918 the brown rot of plums was kept under control at the State Fruit Breeding Farm by the use of Bordeaux mixture, 4:4:50, applied the middle of July, and repeating the applications two weeks before ripening season.

The long-continued experiments in the use of hardy and disease-resistant varieties as stocks on which to top graft some of the less hardy commercial apples thus far indicates the value of Wealthy and Virginia Crab as stocks for Jonathan, and of Virginia Crab and Delicious as stocks for Grimes. It has also been found that Delicious, when top-worked on Virginia Crab, comes into bearing earlier and gives a more satisfactory yield than on its own stock.

In the soil management experiments started in 1910 in an unproductive orchard of bearing age at Council Bluffs, various systems of tillage, cover crops, and management have been followed. Thus far the indications are against the practice of continuous clean cultivation, although it appears that certain methods of cultivation have their place in the management of a bearing orchard, as opposed to a continuous sod-bound condition. Under continuous clean cultivation, the loss of trees from winter injury is noticeably greater than where the land is kept in blue grass sod or legume crops. This injury has been greatest with Ben Davis and least with Grimes, Jonathan, and Roman Stem, in the order named. Northwest Greenings, Wealthy, and Oldenburg have escaped injury thus far.

132688°-19-4

[Vol. 41

Experiments covering several years have demonstrated that the canker on limbs and trunks of apple trees of bearing age, which is known as Illinois blister canker and is prevalent in orchards in western and southwestern Iowa, may be checked by chiseling out the infected wood and painting the entire wound with an antiseptic paint. Experiments dealing with the prevention of crown gall of nursery stock are yielding promising results although no definite methods of treatment are recommended at this time.

[Report on horticultural investigations], N. E. HANSEN (South Dakota Sta. Rpt. 1918, pp. 22–24).—Work in the breeding and selection of hardy fruits was continued (E. S. R., 39, p. 346). The Tecumseh, a fine extra large plum of Shiro×Surprise pedigree was sent out for the first time. Eight seedling apples on Siberian Crab stock were sent out for trial because they appear promising after three years of very severe invasion from blight. The quality of the fruit is unknown.

In the work of breeding blight-resistant pears Japan pear seedlings have not been successful as stocks, since they winterkill. After extensive test two species of Siberian pear (*Pyrus ussuriensis* and *P. ovoidea*) appear to be resistant both to the blight and the rigorous climate of the Northwest. Seedlings of these species are to be used as stocks. A number of hybrids of *P. oroidea* with the standard cultivated pear (*P. communis*) of western Europe have already been bred and distributed.

Fruit growing in the semiarid Northwest, M. PFAENDER (*Minn. Hort.*, 47 (1919), No. 5, pp. 194–202, figs. 3).—A paper with discussion following, in which the author briefly notes the results secured with various orchard and small fruits at the Northern Great Plains Field Station, Mandan, N. Dak., and elsewhere in the Northern Great Plains area, and describes experimental methods of growing fruit trees being tested at the station.

The Australian fruit industry.—Its development and importance, W. J. ALLEN (*Fruit World Austral., 20 (1919), No. 4, pp. 80–83*).—A report on the extent and value of the fruit industry in Australia, including suggestions relative to organization, standardization, and cooperation.

The Lorette system of pruning, H. E. DURHAM (Jour. Roy. Hort. Soc., 43 (1919), No. 2-3, pp. 261-277, pls. 4, fig. 1).—The author describes a "springsummer-autumn" method of pruning and training fruit trees employed by L. Lorette, chief of practical horticulture at the Wagnonville school near Douai, France, which has for its set purpose stimulation of growth in certain dormant eyes, whose productions are apt to possess fruit-bearing proclivities. A note on the nomenclature of fruit-tree parts, together with a bibliography of related literature, is appended.

The healing of pruning wounds, W. G. BRIERLEY (*Minn. Hort.*, 47 (1919), No. 4, pp. 145–152, figs. 7).—An extensive study was made of pruning wounds on apple trees in the Minnesota Experiment Station orchards and in several other orchards, including young and old trees as well as neglected and well-kept trees. Data are given showing the relation of size and treatment of wounds to healing and the causes of failure to heal in well-made wounds.

The results of the study show that there is very little variation in the percentage of wounds healing on a basis of size of wounds, although larger wounds heal more slowly. The rate of wound healing was directly proportionate to the vigor of the tree. For all wounds examined, a general average of 93.7 per cent were healing. Of the wounds not healing, poor pruning accounted for the failure of nearly 9 out of every 10. Out of 2,256 well-made wounds, only 17 failed to start healing. These failed chiefly from fire blight infection. Previous decay in wood and drying back of the bark caused a few failures. A comparative study of protected and unprotected wounds indicated that protection with wax or paint is of little value unless the wound is well made and both wound and tools sterilized against disease. Paints and waxes often fail to prevent disease or decay, because infection may have reached the wound before the covering was applied.

The author calls attention to the beneficial results found in other investigations in protecting the heartwood of large wounds with gas tar or liquid asphaltum to prevent decay while the relatively slow healing process is going on. These materials, however, should not be applied to the sapwood and cambium, as injury may result.

Decade records of Ohio apple orchards, No. 1, H. A. GOSSARD (Mo. Bul. Ohio Sta., 4 (1919), No. 5, pp. 152–160, figs. 6).—Long-continued spraying experiments were brought to a conclusion in 1918 in three fairly representative Ohio orchards. This paper records cultural and marketing practices, as well as yield and financial returns, for one of these orchards during a 10-year period. A record is also given of worminess in the orchard for each year under different spraying treatments.

The constant high record of clean fruit maintaining throughout the decade indicates that maximum effectiveness in applying the sprays was reached by the third season with an average of 98 per cent of clean fruit. The average yield per acre for the 10-year period was approximately 234 bu. The average annual cost of production per acre, figured at a cost of 40 cts. per bushel, was \$93.60, and the annual net income per acre \$100. Assuming that it costs 50 cts. per bushel to produce apples, as generally claimed among orchardists in Ohio, the net income per acre was about \$80, indicating that even a good producing orchard does not offer the financial inducement sometimes put forth in orchard schemes.

Pruning experiments with peaches, M. A. BLAKE and C. H. CONNORS (New Jersey Stas. Bul. 326 (1917), pp. 5-88, pls. 16).-Experimental orchards were established both at Vineland and New Brunswick in 1912, with the view of comparing different systems of pruning as applied to varieties showing varying habits of growth such as the spreading, open habit; the compact spreading habit; and the upright habit of growth. The following five general forms of pruning were studied: Pruning out only such twigs as may have died or branches that may have been broken by accident; winter pruning to remove dead twigs, interfering and crossed branches and twigs, with a little top-thinning to prevent the formation of weak crotches and to admit sufficient light for the coloring of the fruit; winter pruning similar to the above, accompanied by cutting back the leading branches and twigs from one-third to one-half of the previous season's growth; summer pruning in which any suckers or undesirable shoots are removed during the growing season, and all leading shoots are pinched back during June or July to encourage a compact growth of the tree; and combined winter pruning and cutting back with summer pruning. All of the trees were cut back to a height of 18 in. when set, and the experiments in both orchards also included a comparative test of planting in dug holes as compared with holes made with dynamite. Measurements were made of the total linear twig growth and the circumference growth of the trees during the first season prior to the assignment of various pruning treatments. These measurements, together with growth data secured by different systems of pruning during the first two seasons after planting, are here presented in tabular form and discussed. No definite conclusions as to the actual effect of the various pruning treatments are drawn at this time.

Generally speaking, during the first season the trees at Vineland, where the soil is a sandy loam, averaged from about 200 to 350 in. more growth according

to the variety than at New Brunswick, where the soil is gravelly red shale loam. Considerable variation in total twig growth was found to occur between individual trees at the close of the first season. This apparently had no influence upon the growth of the trees in the second season, for whereas between some groups an average difference of 50 in. the first season was appreciable in the second season, between other groups an average difference of 100 in the first season was not noticeable the second season. In both the Vineland and New Brunswick experiments the smaller the circumference in 1912 the greater the percentage increase in circumference in 1913.

The data already secured indicate that permitting the development of branches, shoots, or suckers on the lower part of the trunk during the growing season tends to increase the girth of the trunk more rapidly than where such growth is removed and where the trunk is longer and the branches higher above the ground. In the summer pruned treatments the shoots are removed from the trunk, giving in almost every case a greater twig growth to each inch increase in trunk circumference. In the no pruning and winter pruning treatments the twigs were allowed to remain on the trunks, resulting in a narrow ratio of increase in trunk circumference to increase in twig growth. Where most of the growth is made at the very top of the tree it will have proportionally less influence upon the circumference of the trunk near the ground.

Summer pruning reduces the amount of the necessary thinning of twig growth in winter, but increases the amount of clipping back due to the increase in vigor of the secondary twigs on the leaders. The summer pruning of the combined winter and summer treatment reduced the pruning required in winter to about one-half at Vineland and from one-third to one-half at New Brunswick as compared with the winter and cut back treatment. Pinching back the main twigs increases the number of secondary or side twigs.

The summer pruning only treatment at Vineland made the greatest average total growth and the winter cut back treatment was second. At New Brunswick the no pruning treatment made the best total growth and the summer pruning only treatment was second. Summer pruning apparently did not affect or reduce the amount of twig growth made by the trees during the second season. Of the various treatments the winter pruning without cutting back was the cheapest and the combined winter and summer pruning the most expensive. The data thus far secured indicate that varieties having an upright habit with numerous twigs and branches are more expensive to prune than varieties with spreading, open habit growth.

Pollination of the Bartlett pear, W. P. TUFTS (*California Sta. Bul. 307* (1919), pp. 369–390, figs. 8).—The results are given of pollination studies conducted during the three seasons 1916–1918, to determine the relative sterility or fertility of the Bartlett pear under both foothill and valley conditions in California. Tests were made of suitable pollinizers for the Bartlett pear and the pollen viability of pears in general was also studied. The results of early investigators are briefly noted.

The Bartlett was found to be self-sterile under foothill conditions and selfsterile to a limited degree under valley conditions. Since no cases of intersterility were found to exist between pear varieties it is concluded that any variety overlapping in blooming period with the Bartlett may be expected to be an efficient pollinator. Pears resulting from cross-pollination did not appear to exhibit the same tendency to fall at the June drop as those resulting from self-pollinations. It is recommended that all Bartlett orchards should be provided with facilities for cross-pollination, and pollinating agencies such as the honeybee should also be provided. A list of varieties pollinating the Bartlett successfully is given. "Reversion" and resistance to "big bud" in black currants, A. H. LEES (Ann. Appl. Biol., 5 (1918), No. 1, pp. 11-27, pls. 4, figs. 2).—A further contribution to the so-called reversion of black currants (E. S. R.; 39, p. 646) leads the author to conclude that reversion is associated with and apparently caused by a check to the terminal growth through change of the terminal wood bud into either a big bud, a killed bud or blind bud, or a fruit bud. It may also be associated with aphis attack. It is characterized by four symptoms, "running off" or dropping of the fruit, unusual amount of lateral wood growth, sharp pointed leaves, and long, thin internodes. The mite resistance shown by varieties such as Seabrook Black is said to be due to the fact that in normal climates and seasons the mite kills the attacked growing point and thus starves itself. The form of reversion which occurs in young bushes before mite or aphis is present has not yet been accounted for.

The pruning of young vines, H. DAUMAS (*Prog. Agr. et Vit.* (*Ed. VEst-Centre*), 40 (1919), No. 20, pp. 462–464, figs. 2).—In the author's experience short pruning or pruning back to basilary buds during the early years of the life of a vine promotes a much better distribution of shoots, a better developed stock, and earlier bearing than the usual method of pruning back to short arms. The two methods of pruning are illustrated, and yield data are given for two vineyards of French vines growing on their own roots which came into satisfactory bearing at two years of age.

Notes on some hybrid bearers, E. PÉE-LABY (Vie Agr. et Rurale, 8 (1918), No. 34, pp. 132, 133).—This comprises a brief review relative to the fertility and production of various hybrid grapes tested at the Toulouse Experimental Garden in 1918.

The hybrid bearers in 1918 at the Toulouse Testing Garden, E. PÉE-LABY (*Vie Agr. et Rurale*, 8 (1918), Nos. 35, pp. 144, 145; 39, pp. 215, 216; 42, pp. 280, 281; 46, pp. 357-359; 50, pp. 423-425).—Notes are given on the resistance of various hybrid grapes to disease, as well as on their general cultural value.

The reconstitution in Champagne, G. PHILIPPONNAT (*Rev. Vit.*, 50 (1919), *Nos. 1285, pp. 97–103; 1286, pp. 113–120*).—The results of experiments and observations dealing with the reconstitution of phylloxera-infested vineyards in the Champagne district are here recorded, including data on the adaptability and affinity of various graft stocks employed in the work of reconstitution.

Varieties of the Satsuma orange, L. B. SCOTT (*Cal. Citrogr.*, 4 (1919), No. 7, pp. 176, 199, figs. 4).—A further contribution on varieties of the Satsuma orange occurring in the United States (E. S. R., 40, p. 342), in which the author furnishes information relative to various nurserymen growing distinct varieties of the Satsuma orange.

Some results from an experiment with pruning as compared with no pruning of full bearing Washington navel trees, A. D. SHAMEL (Cal. Citrogr., 4 (1919), No. 7, pp. 174, 175, figs. 4).—The author presents yield data based on pruning operations conducted in a commercial orchard during the 5-year period 1914–1919. The data, which indicated that the pruning operations resulted in a total loss of about \$2 per tree for the entire period, are given chiefly with the idea of showing the undesirability of pruning in healthy and normal navel orange trees unless it is definitely known that such pruning will be beneficial instead of detrimental. It is not intended to discourage judicious pruning by experienced and careful pruners.

Improving the soil in a young orchard, J. A. PRIZER (*Cal. Citrogr.*, 4 (1919), *No.* 8, *pp.* 202, 203, 226, *figs.* 6).—A contribution from the California Citrus Substation, discussing methods of soil improvement in citrus orchards with special reference to practices at the station,

[Vol. 41

[Cacao, coffee, tea, and rubber in Uganda], S. SIMPSON and T. D. MAITLAND (Ann. Rpt. Dept. Agr. Uganda, 1918, pp. 10–12, 17–23, 26, 29, 30, 33–36, 56–60).— Notes are given on cultural and variety tests, including also tapping experiments with rubber, conducted in the Botanic Gardens at Entebbe and on various government plantations and estates.

Cultivation of the Robusta types of coffee, H. A. DEUTROM (Dept. Agr. Ceylon, Leaflet 10 (1918), pp. 6, pls. 2).—Practical suggestions are given on the culture of a number of varieties of coffee of the Robusta type that have been tested by the direction of the Ceylon Department of Agriculture.

Pruning experiments with young tea, E. A. ANDREWS (Indian Tea Assoc., Sci. Dept. Quart. Jour., No. 4 (1918), pp. 129–132, pl. 1).—Data are given for the season 1917–18 of pruning experiments conducted at the Tocklai Experiment Station, Assam, with three varieties of tea.

**Report of chief gardener**, H. J. MOORE (Ann. Rpt. Comrs. Queen Victoria Niagara Falls Park, 32 (1917), pp. 24–29, pl. 1).—A general report on ornamental planting operations in the Queen Victoria Niagara Falls Park System, including descriptive notes on varieties of hardy and semihardy primulas, all of which have been tested in the park for at least two seasons.

[Delphiniums, myosotis, and annual poppies at Wisley, 1917] (*Jour. Roy. Hort. Soc.*, 43 (1919), No. 2-3, pp. 462-487).—Descriptions are given of varieties tested at Wisley during 1917, including selected lists of meritorious varieties.

The history of Ananas and Agave, S. KILLERMANN (*Naturw. Wchnschr.*, 33 (1918), No. 35, pp. 497-503, figs. 3).—A historical review of these genera, including references to cited literature.

The dahlia (*Missouri Bot. Gard. Bul.*, 7 (1919), No. 4, pp. 41-46, pls. 2).—Cultural notes on the dahlia, including a list of some of the best varieties for decoration and cutting which were grown at the Missouri Botanical Garden in 1918.

The American rose annual, edited by J. H. McFARLAND (*Harrisburg*, *Pa.: Amer. Rose Soc.*, 1919, pp. 184, pls. 11, figs. 5).—As in previous editions (E. S. R., 39, p. 244) the annual for 1919 contains a report of the activities of the American Rose Society for 1918, notes progress on breeding and variety testing and other phases of rose growing, and contains numerous miscellaneous articles on roses and rose growing in various countries. The partial list of roses introduced in America is revised to March 10, 1919.

New pillar rose, W. VAN FLEET (Jour. Heredity, 10 (1919), No. 3, pp. 136– 138, figs. 2).—The author describes and illustrates a rose seedling developed at the Bell Experiment Plat, Glendale, Md., which gives great promise as a new hardy pillar or low-climbing rose. The seedling, which bears pure white blossoms with prominent yellow stamens, is a result of applying pollen of a vigorous hybrid between the new Chinese Rosa soulieana and R. setigera, the wild Michigan or Prairie rose, to the stigmas of an unusually hardy seedling of R. wichuraiana that had the Tea rose Devoniensis as its pollen parent.

Mildew-resistant roses; with some suggestions as to increasing their number, W. EASLEA (Jour. Roy. Hort. Soc., 43 (1919), No. 2-3, pp. 253-260).—The author points out what various hybridists have already done toward breeding mildew-resistant roses, suggests lines of attack which might result in increasing the number of resistant varieties, and appends a list of roses which have proved to be more or less mildew-resisting.

Hardy trees, shrubs, and flowers for Wisconsin homes, F. A. AUST (Univ. Wis. Agr. Ext. Serv. Circ. 112 (1919), pp. 15, figs. 6).—Suggestions and plans for laying out and planting the home grounds, including lists of trees, shrubs, and flowers.

#### FORESTRY.

Evergreens for the Northern Plains, C. WEDGE (*Minn. Hort.*, 47 (1919), No. 5, pp. 203–209, fig. 1).—Summing up his experiments in growing evergreens in northern Minnesota, the author concludes that the trees best adapted to the plains are the evergreens that are found in the eastern foothills of the Rockies, especially the strains that grow on the detached groups and buttes, where they have become inured to the hardships of the plains throughout generations of natural selection.

### FORESTRY.

Modern forestry, A. KUBELKA (Moderne Forstwirtschaft. Vienna and Leipzig: Franz Deuticke, 1918, pp. X+190, pl. 1).—A, treatise on the selection system of forest management, based primarily on the author's successful experience on various private forests in carrying out the principles advocated by Wagner (E. S. R., 20, p. 645). A modification of Wagner's method of regeneration is advocated, in that the author recommends felling-strips 30 to 50 meters broad in coulisse-form arrangement, with a limited number of regeneration cuttings, whereas Wagner advocates the use of narrow border strips with many regeneration cuttings.

The subject matter is discussed under the following general headings: Principles of modern forest management; preparations for the installation of a natural working system with special reference to the selection-strip system; growing the most important timber species in the holes and gaps of the selection strips; and the application of the selection-strip system in modern forestry.

Annual report of the State Forestry Board of the State of Minnesota for the year ending July 31, 1918, C. C. ANDREWS ET AL. (Ann. Rpt. State Forestry Bd. Minn., 1918, pp. 19).—A review of the work of the board during the fiscal year 1917–18, with its recommendations for the subsequent biennium. A report on The Recent Forest Fires, by W. T. Cox, is included.

Reports of the forest branch of the Department of Lands for the years ending December 31, 1917, and 1918, M. A. GRAINGER (*Rpt. Forest Branch Dept. Lands, B. C., 1917, pp. 11–26, figs. 3; 1918, pp. 27, figs. 2).*—Statistical reports of the work on land classification, yields in major and minor forest products, export trade, forest fires, revenues, expenditures, etc., in British Columbia are given for the calendar years 1917 and 1918, respectively.

A forest policy for Louisiana, R. D. FORBES (Jour. Forestry, 17 (1919), No. 5, pp. 503-514).—As a result of 14 months' study of Louisiana conditions, the author briefly classifies the lands of Louisiana from the standpoint of their value for agriculture, live-stock production, and forest growth, and presents the broader phases of what he considers the proper state forest policy to be carried out by the State forester, working under the Commissioner of Conservation.

How can the private forest lands be brought under forest management? W. N. SPARHAWK (*Jour. Forestry*, 17 (1919), No. 5, pp. 490-496).—The author critically reviews plans already advocated for bringing about the practice of forestry on private lands, and presents a plan by which it is believed that the practice of forestry on lands now in private ownership may be made entirely practicable. This plan is essentially a leasing system, which provides for the retention of private ownership with public operation.

Public control of private forests in Norway, S. T. DANA (*Jour. Forestry*, 17 (1919), No. 5, pp. 497-502).—A review of the Government policy with respect to private forests in Norway, with special reference to its bearing on the private forestry question in the United States.

Afforestation, J. BOYD (London: W. & R. Chambers, Ltd., 1918, pp. 40).—A discussion of afforestation problems in Scotland, with special reference to national afforestation on land purchased or rented for the purpose from the present owners.

The realizable resources of German forests, G. HUFFEL (Les Ressources Réalisables des Forêts Allemandes. Paris: Berger-Levrault & Co. [1918], pp. 15).—A brief statistical study of German forest resources.

**Present** status of forest taxation in the United States, M. K. McKAY (*Jour. Forestry*, 17 (1919), No. 5, pp. 472–489).—A discussion of recent Federal and State legislation dealing with forest taxation, including a summary of the laws concerning taxation of wooded lands in various States.

Aerial photography and National Forest mapping, R. THELEN (*Jour. For*estry, 17 (1919), No. 5, pp. 515–522, fig. 1).—The author briefly outlines the manner of making aerial photographs and maps; sketches the requirements of National Forest surveys and reconnaissance, and present methods of meeting, the principal of these requirements; and discusses the possible value of aerial photography as an adjunct or supplement to these methods.

A forest reconnaissance of the Delaware peninsula, R. M. HARPER (Jour. Forestry, 17 (1919), No. 5, pp. 546-555, fig. 1).—The results of a study of the vegetation of the Delaware peninsula, especially the trees, are here brought together as a preliminary forest census of the area, both as a contribution to our knowledge of the forest resources of the United States and also to depict some significant relations between soil and vegetation in an area where differences of topography and climate are practically eliminated. A method of tabulating forest resources where the fieldwork has not been sufficiently thorough to warrant one in assigning percentages to each species is also illustrated.

A sketch of the forestry geography of New Jersey, R. M. HARPER (Bul. Geogr. Soc. Phila., 16 (1918), No. 4, pp. 1-19, pls. 3, fig. 1).—A study of the original distribution of forest species in New Jersey.

Micrography of the woods of Javanese trees, IV-V, J. W. MOLL and H. H. JANSSONIUS (*Mikrographie des Holzes der auf Java vorkommenden Baumarten. Leyden: E. J. Brill, vol. 3, 1914, pt. 4, pp. 336, figs. 39; vol. 3, 1918, pt. 5, pp. 337-764, figs. 40*).—The present volume comprises the fourth and fifth parts of a report on the study of the wood anatomy of Javanese trees which the authors have conducted since 1903. Some 208 species are described along the lines previously noted (E. S. R., 25, p. 543).

Analyses of some morphological characters of Bombay woody species from an ecological standpoint, L. J. SEDEWICK (*Indian Forester*, 45 (1919), No. 4, pp. 193–199).—An analysis is given of the leaf apex, armature, and methods of seed dispersal of a number of evergreen, deciduous, xerophytic, and maritime species.

Coniferous trees, A. D. WEBSTER (London: Constable & Co., Ltd., 1918, pp. XX+298, pls. 28).—This work contains concise descriptions of the species and varieties of conifers, with the most recently approved nomenclature, a list of synonyms, and cultural notes. Chapters are also included which deal with the commercial aspect of conifers, quality and value of British-grown coniferous timbers, conifers for various soils and situations, conifers of different characteristics, propagating conifers, enemies of conifers, etc.

Lignum-vitæ, the vital wood, S. J. RECORD (*Sci. Amer. Sup.*, 88 (1919), No. 2270, pp. 4, 5, 15, 16, figs. 6).—An account of the uses of lignum-vitæ, with special reference to its importance to the American Navy and merchant marine, and its present and future sources of supply.

On a new species or form of Eucalyptus, C. HALL (*Proc. Linn. Soc. N. S. Wales, 43 (1918), pt. 4, pp. 747-749, pl. 1).*—This comprises a botanical descrip-

244

tion of a form of Eucalyptus, which has been designated *Eucalyptus marsdeni* n. sp., occurring in New South Wales. The appearance and structure of the wood as well as the character of oil obtained from this species are also described.

The effect of lightning on Hevea, A. A. L. RUTGERS (Arch. Rubbercult. Nederland. Indië, 3 (1919), No. 4, pp. 163–171, pls. 11).—A discussion, with illustrations, of various types of injury to Hevea rubber trees caused by lightning.

# DISEASES OF PLANTS.

Ecological conditions of development of parasitic fungi, J. DUFRÉNOY (*Bul. Trimest. Soc. Mycol. France, 34 (1918), No. 1–2, pp. 8–26).*—Of the three sections comprising this article, the first deals with altitude as related to the distribution of parasitic fungi, including such significant factors as heat, light, and moisture; the second with the virulence of rusts; and the third with such biotic factors as the presence of other fungi and of insects.

The Pyrenees offer no obstacle to the spread of fungus diseases, although the study of disease fungi shows the existence of species adapted to mountain regions, to plains, or to both. The principal factor determining specialization appears to be insolation rather than temperature or humidity. Mountain species may be protected by strong coloration of the hosts or by that of their own spores, the less strongly pigmented species of lower levels not being able to bear the more intense insolation at the greater altitudes.

Some of the plant diseases that were especially serious this season, with suggestions (*Iowa Sta. Rpt. 1918, pp. 28, 29*).—Notes are given on a number of plant diseases and suggestions are made for their control. It is stated that seed treatment with formaldehyde did not prove fully adequate for the control of wheat scab, but it is thought that coupling this treatment with the avoidance of the use of highly infected seed will prove practicable. Black chaff, another wheat disease, is reported as quite prevalent, but it is thought from the record of disease surveys that not much damage need be anticipated from this source.

Cedar apple rust is said to have been abundant, seriously damaging Wealthy apples, and the removal of red cedars near apple orchards is recommended.

The late blight of potatoes was troublesome in the northeastern part of the State, and for the control of this disease thorough spraying with Bordeaux mixture is recommended.

Plant disease survey and information service, H. H. WHETZEL (*Rpt. N. Y. State Food Sup. Com., 1917, pp. 44, 45*).—The leader of this service reports that in addition to other work done, over 500 specimens of diseased plants have been examined.

**Prevention of insect pests and plant diseases** (*Rpt. N. Y. State Food Com.,* 1918, pp. 108-110).—This is a brief statement of the work, chiefly informational and advisory, of the three experts on insect pests and plant diseases employed to assist farmers and fruit growers, their work being confined mainly to Wayne, Orange, and Cortland Counties.

A quick method of eliminating seed-borne organisms of grain, I. E. MEL-HUS and L. L. RHODES (*Science, n. ser., 50 (1919), No. 1279, p. 21*).—From studies made on account of the injury to seed treated with hot formaldehyde, the authors have found that suspending the grain above the formaldehyde solution for about 20 seconds destroyed all the fungi in or on the seed, as well as the majority of the bacteria present. The formaldehyde solution used was 1:240, and it was raised to a temperature of from 98 to 99° C. (208.4 to  $210.2^{\circ}$  F.). The short treatment did not injure the germinating capacity of the seed, while the fungus flora was destroyed. It is believed that this method can be made practical for the control of scab and other seed-borne diseases of grain.

Presoaking as a means of preventing seed injury due to disinfectants and of increasing germicidal efficiency, H. BRAUN (*Science, n. ser.*, 49 (1919), No. 1275, pp. 544, 545).—In the course of investigations of the bacterial black chaff disease of wheat, the author discovered a means of disinfecting without injuring the seed. This is accomplished by allowing the seed to absorb water for a definite period in advance of treatment. The wheat, after screening and removal of shriveled grains, is soaked for 10 minutes in water, drained, and kept moist for 6 hours, after which it is soaked for 10 minutes in formalin (1:400), drained, covered for 6 hours, dried overnight, and planted. If copper sulphate is used, the presoaked seed are thoroughly wetted in the 1:80 solution for 10 minutes, drained, and kept moist for 20 minutes, after which they are plunged for a moment in milk of lime, dried overnight, and planted. The effect of this method of seed treatment is said to be twofold—first, seed injury is prevented by dilution of the disinfectant as it enters the presoaked tissues of the seed, and, second, the efficiency of the disinfectant on the pathogene is increased.

The black chaff of wheat, E. F. SMITH, L. R. JONES, and C. S. REDDY (*Science*, *n. ser.*, 50 (1919), No. 1280, p. 48).—As a result of a study of black chaff of wheat, the authors were struck with the resemblance of the organism causing this disease to that which is responsible for the bacterial blight of barley which has been named *Bacterium translucens* (E. S. R., 38, p 548). Cross inoculations of the barley organism on wheat either proved it noninfectious or resulted in the production of small, nontypical lesions. On the other hand, inoculation experiments with the wheat organism showed that it was practically as pathogenic on barley as it is on wheat. Some minor cultural differences were observed, and it is believed that the wheat organism should be distinguished from that on barley. For the present the name *B. translucens undulosum* is given it.

This organism, which causes the black chaff disease of wheat, is said to produce yellow or translucent stripes on the leaves, water-soaked or black stripes on the culms, and longitudinal, more or less sunken, dark stripes or spots on the glumes. The organism also attacks the kernels, especially at the base, causing them to be shrunken or honeycombed. Where the kernels are not directly attacked, their surface is liable to be affected from the diseased glumes. When the disease appears early and is severe, dwarfed heads are said to result. Infections have been obtained repeatedly on wheat leaves and glumes, and the disease is considered to be transmitted to the young seedlings through the wheat kernels.

The black chaff of wheat is known to occur in all the wheat States of the Middle West.

Formaldehyde v. corrosive sublimate in treating cabbage seed (*Iowa Sta. Rpt. 1918, p. 27*).—On account of unsatisfactory results in treating cabbage seed with formaldehyde, a test has been made comparing formaldehyde and corrosive sublimate. It is reported that a solution consisting of 1 gm. corrosive sublimate in 1 qt. water has been found to do little injury to the seed and at the same time to kill the disease-producing organisms on the seed.

Black spot of onion sets, F. L. STEVENS and E. Y. TRUE (*Illinois Sta. Bul.* 220 (1919), pp. 507-532, figs. 19).—Serious losses in storage are reported to have occurred in onions, particularly in onion sets and especially in the white varieties. Examinations were made of onions and onion sets, and it was found that the white varieties were affected to the extent of 60 to 80 per cent by the disease formerly described under the name *Vermicularia circinans*. Three types

of disease are recognized, the most common one being that usually described and figured as due to Vermicularia. This is characterized by the occurrence on the dry outer scales of the bulbs of circular black spots 15 to 25 mm. in diameter. The second type of the disease is said to occur on the dry outer scales, but it is usually limited to the upper part of the bulb. It is distinguished from the first type by the invasion of the fungus starting at the top of the bulb and usually stopping with the drying of the scales before the equatorial region is reached. It is thought that this type probably results from infection through wounds caused in removing the tops. The third type of the disease is manifest in the bulb scales while still succulent and juicy. The chief manifestation is said to be the formation of tubercles or warty growths. This form of the disease often remains progressive until the scales dry and inhibit further progress.

A study was made of the various phases of the fungus, and it has been determined that the conidial form belongs to the genus Volutella. The name *V. circinans* is given it. The perithecial stage has been determined, and is described as *Cleistothecopsis circinans* n. g. and sp.

It has been ascertained from observations that moisture favors the development of the fungus, and it is suggested that onion sets be dried as rapidly and thoroughly as possible after they have been harvested. Artificial drying in rooms properly equipped for the purpose is considered the most promising method for checking the progress of this disease and reducing losses from rot.

Potato insect and disease control, W. H. RANKIN (*Rpt. N. Y. State Food* Sup. Com., 1917, pp. 30-36).—An account is given of preliminary work and community, individual, and demonstration spraying, with results therefrom.

Leaf roll and mosaic of potatoes, I. H. VOGEL (*Proc. N. Y. State Potato* Assoc., 1918, pp. 21-24).—Leaf roll was somewhat generally distributed during the previous season, the number of infected plants found in hills inspected ranging from 0 to 80 per cent, with an average of about 25 per cent. It seems to occur in all varieties, some developing the disease apparently as a response to the influence of unfavorable environment. Certain climatic conditions are important predisposing causes, among which warmth and dryness are prominent.

Mosaic was quite generally distributed in 1918, the degree of infection also ranging between 0 and 80 per cent with a corresponding reduction in yield. Data which are mentioned are said to indicate that the percentage of mosaic infection from the same strain is about the same in Northern as in Southern States. Experiments are in progress bearing upon the possible agency of insects in the spread of the disease.

The most rapid progress in the elimination of either disease is said to be attained by employing a seed plat as a source of seed for field planting. The proper management of the seed plat is indicated.

A new method of treating seed potatoes for scab (*Iowa Sta. Rpt. 1918, p.* 27).—A method of treating seed potatoes with formaldehyde is described in which the potatoes are soaked from 3 to 5 minutes in a solution composed of 2 pints formaldehyde in 30 gal. water, the solution being held at  $122^{\circ}$  F.

In order to facilitate handling in large quantities, a machine has been devised by which the potatoes are drawn through the hot solution on an endless chain. This machine has proved efficient for treating 100 bu. an hour.

Potato spraying profitable (*Iowa Sta. Rpt. 1918, p. 36*).—As a result of spraying experiments covering a period of five years, spraying with Bordeaux mixture is recommended. Five applications are said to have given an increase in yield of 17 per cent, three applications proved not to be sufficient, and seven represented a diminishing net return.

A fungus disease of prickly pear, G. P. DARNELL-SMITH and H. Ross (Agr. Gaz. N. S. Wales, 29 (1918), No. 6, pp. 440, 441, fig. 1).—At Harrington Inlet on the Manning River, a disease affecting the pest prickly pear (Opuntia inermis) was studied by the authors, who found many of the young segments dead and older ones rotten and filled with slimy pulp. Others showed a sickly yellow color in areas where diseased segments had been thrown into clumps of healthy plants. The infection usually starts at or near the base of the segments, being marked by concentric dark lines in the latter case. The disease may, it is thought, afford means of control for prickly pear.

Influence of soil environment on the root rot of tobacco, J. JOHNSON and R. E. HARTMAN (Jour. Agr. Research [U. S.], 17 (1919), No. 2, pp. 41-86, pls. 8, figs. 2).—A report is given of a study undertaken cooperatively by the Wisconsin Experiment Station and the Bureau of Plant Industry, U. S. Department of Agriculture, with a view of determining the environmental conditions which might influence the tobacco root rot caused by *Thielavia basicola*.

There seems to be no variation in the pathogenicity of the fungus secured from different sources, the amount of disease being determined by the susceptibility of the host, the amount of infection, and the soil environmental factors surrounding the roots of the host. Moisture, temperature, reaction, physical structure, and fertility of the soil were investigated, and under normal conditions the amount of injury due to root rot is said to be determined by the sum total of the favorable and unfavorable action of these factors on the disease. Root rot is apparently capable of developing in relatively dry soils, but increasing the moisture content up to three-fourths of the water-holding capacity was not found to materially increase the amount of disease. Saturated soils, however, are considered more favorable to the disease than unsaturated ones.

Studies of soil temperature carried on for four seasons have indicated that the occurrence of root rot is determined primarily by soil temperature, the most favorable temperature for the disease ranging from 17 to 23° C. Below 15° the disease is less marked, and above 26° the severity is gradually reduced until, at about 29 or 30°, the disease has little or no influence. At 32° practically no infection occurs, even in the most heavily infested soils.

Root rot is said to be checked by high soil acidity, but tests of tobacco soils in Wisconsin indicate that the use of acid fertilizers will not reduce infection by *T. basicola*. Organic matter present or introduced into the soil was not found to play an important part in the amount of infection, although a high organic content of the soil is believed to favor infestation and also to aid the fungus in persisting in the soil. Clay soils were found no more favorable to infection than sand and under some conditions possibly less so. Clay may, however, favor the persistence of the parasite in the soil. Fertilizers applied to heavily infested soils under practical conditions are considered to be largely wasted except in seasons in which such high temperatures result that the disease is held in check. Field observations, as well as limited laboratory experiments, are thought to show that infested soils when compacted are more favorable to the disease than loose, open soils. Transplanting infected seedlings to an uninfested field is considered a bad practice, although recovery from the disease may occur.

Fruit insect and disease control, L. R. HESLER (*Rpt. N. Y. State Food Com. Sup.*, 1917, pp. 36-38).—Brief notes are given of the working of a plan employing, besides ordinary means, an extensive telephone relay system organized in some counties of New York, over which the field agent in Wayne County was able to send out two days before a rain period was due the recommendation

248

that a spraying of lime-sulphur and lead arsenate be applied. This was sent to committeemen who by prearrangement passed it on until every grower was reached. It is stated that great savings have been effected by following this plan of organization, which is to be extended.

Apple blotch, a serious fruit disease, A. D. SELEY (*Ohio Sta. Bul. 333* (1919), pp. 491-505, figs. 5).—According to the author, the apple blotch due to *Phyllos*ticta solitaria has become a serious menace to apple production in southern Ohio. The characteristics of the disease are described, and it is stated that fruit affected by the blotch is rendered unsightly and is at times distorted and malformed. The juiciness of the fruit is considerably reduced. On the twigs cankers are formed, and the fungus is said to live over winter in the cankers on the twigs. The leaves and leaf stalks are also attacked in a characteristic manner.

A review is given of experimental work that has been reported for the control of this disease, and, based very largely on work done outside of Ohio, the author suggests methods of control. These include proper pruning, spraying, and working over orchards that are planted to specially susceptible varieties of apples.

The control of crown gall of apples (*Iowa Sta. Rpt. 1918, p. 26*).—A brief report is given on two years' experiments in which a number of fungicides were tested to determine their value in preventing crown gall of apples.

In most instances the materials used proved of little value. However, a thick paste composed of copper sulphate and lime into which the grafts were dipped just before planting has given rather promising results. The mixture sticks to the union, does not interfere with the healing process, and seems to kill the organisms that come in contact with the young tree. This method of treatment has been tried for two seasons with such satisfactory results that a nursery company treated this year about 500,000 apple trees preparatory to setting them out.

**Powdery mildew of the apple,** W. J. ALLEN and W. LE G. BRERETON (*Agr. Gaz. N. S. Wales, 29 (1918), No. 6, pp. 408–412).*—Noting results of experiments with various fungicides carried out since 1915, the author states that from this work, which is still in progress, it can be concluded that all mildewed terminal buds or affected wood should be removed and burned at the time of winter pruning. Iron sulphid should be applied as a spray first in the pink stage before the petals begin to open, second in connection with the calyx spray (arsenic) for codling moth, third three weeks later with a second arsenic spray, and fourth with a third arsenic spray.

Apparently this treatment is more effective for the second season, due to the weakening effect of the first year's spraying on the fungus.

Control of black raspberry anthracnose and tip blight (*Iowa Sta. Rpt. 1918, pp. 26, 27*).—These two diseases are said to be quite prevalent in the State, and experiments for their control were conducted at Council Bluffs. Lime-sulphur and Bordeaux mixture were tested, three applications being given. No tip blight developed during the season, so that the report of the experiments applies only to the anthracnose. Both fungicides checked the disease, but lime-sulphur seemed more efficient than Bordeaux mixture in this respect.

Development and treatment of grape downy mildew, L. RAVAZ (*Prog. Agr.* et Vit. (Ed. VEst-Centre), 38 (1917), Nos. 48, pp. 529-531; 50, pp. 577-581; 39 (1918), Nos. 2, pp. 25-29; 4, pp. 73-76; 6, pp. 121-125, fig. 1).—The author gives results of studies on grape downy mildew as carried on since 1914 in the School of Agriculture at Montpellier.

It is stated that the chemical composition and the physical state of copper fungicides depend largely upon the proportions employed and the mode of preparation, Burgundy mixture, for example, prepared by pouring copper sulphate into soda having very different composition and properties from that involving the reverse process. The qualities of several liquids tested are discussed, as are various periods more or less favorable to the success of fungicidal applications; the relative efficacy of acid, alkaline, and neutral sprays and of the constituents lime, soda, and carbon dioxid; the significance of a difference in the physical, associated with an apparent similarity in the chemical, composition of the precipitate; the production and significance of adherence by different devices; and the effect of concentration.

It is concluded that Burgundy prepared by slow or rapid pouring of either main component into the other, with or without rapid stirring, gives practically the same results whether the reaction be acid, alkaline, or neutral, but that when the precipitate has changed from blue to greenish-yellow and has passed into the globular state it is almost without effect on downy mildew. This change is more or less rapid according to the temperature and reaction of the mixture and other complicating circumstances, such as the presence of carbon dioxid and the adherence of fine crystals to the leaves.

Bordeaux is fully as efficacious as Burgundy mixture against downy mildew. It is claimed that the occasional burning of leaves by the use of neutral or alkaline Bordeaux mixture is due to the fact that the lime reacts with the copper compound to form copper carbonate.

A consideration of [carnation] yellows, E. M. R. LAMKEY (*Proc. Amer. Carnation Soc.*, 26 (1917), pp. 25–35).—In a discussion of carnation yellows it was stated that diseased plants show closure of the stomata, reduction in quantity or quality of diastase resulting in starch accumulation, and excessive production of oxidase which interferes with certain physiological functions. Other internal changes are mentioned as being under investigation. Suggestions on the improvement of the general situation in regard to yellows include control and improvement of strictly healthy plants to furnish cuttings. It is noted that a few plants of the cuttings of 1915 seedlings have become badly yellowed. The suggestion is made that these plants may have acted in a way analogous to the behavior of human carriers of disease.

### ECONOMIC ZOOLOGY-ENTOMOLOGY.

Mutanda ornithologica, VII, H. C. OBERHOLSER (Proc. Biol. Soc. Wash., 32 (1919), pp. 127, 128).

The status of the genus Centronyx Baird, H. C. OBERHOLSER (Proc. Biol. Soc. Wash., 32 (1919), p. 141).

The proper name for Limicola platyrhyncha, H. C. OBERHOLSER (*Proc. Biol. Soc. Wash.*, 32 (1919), p. 140).

The taxonomic position of the genus Ramphalcyon, H. C. OBERHOLSER (Proc. Biol. Soc. Wash., 32 (1919), p. 140).

The generic name of the rook, H. C. OBERHOLSER (*Proc. Biol. Soc. Wash., 32* (1919), p. 141).

The status of the subgenus Sieberocitta, H. C. OBERHOLSER (Proc. Biol. Soc. Wash., 32 (1919), pp. 135-137).

Spizella arborea the proper name for the tree sparrow, H. C. OBERHOLSER (*Proc. Biol. Soc. Wash., 32 (1919), p. 139*).

Methods in entomological field experimentation, W. P. FLINT, C. F. TURNER, and J. J. DAVIS (*Jour. Econ. Ent.*, 12 (1919), No. 2, pp. 178–183, pl. 1).

Organization for insect suppression, A. F. BURGESS (Jour. Econ. Ent., 12 (1919), No. 2, pp. 136-141).
The value of crude arsenious oxid in poison bait for cutworms and grasshoppers, J. J. DAVIS (*Jour. Econ. Ent., 12 (1919)*, No. 2, pp. 200-203).—This is a brief summary of tests made by entomologists in various parts of the country of finely powdered crude arsenious oxid obtained from a Montana copper smelter, a test of which on the army worm has been previously noted (E. S. R., 39, p. 361). Good results were obtained in its use against grasshoppers and cutworms. The author considers it a satisfactory and reliable substitute for Paris green at about one-seventh the cost. Only the powdered grade is recommended.

Sulphate of ammonia as an insecticide, E. D. COLÓN (Porto Rico Dept. Agr. Sta. Circ. 15 (1919), Spanish Ed., pp. 3-6; Sugar [New York], 21 (1919), No. 7, pp. 396, 117).—Attention is called to the insecticidal properties of sulphate of ammonia when it is applied to soil infested with the white grubs which attack sugar cane. The author quotes from a report by Illingworth<sup>1</sup> of observations of its use in Australia.

[Report of the] department of entomology, H. C. SEVERIN (South Dakota Sta. Rpt. 1918, pp. 18-21. This report deals with investigations that have been conducted with the web spinning sawfly (Neurotoma inconspicua) and the common field cricket (Gryllus abbreviatus).

*N. inconspicua* was found to be highly parasitized by a tachinid, said to represent a new genus and species, which destroyed from 40 to 60 per cent of the larvæ at times. Liquid sprays consisting of lead arsenate 2 lbs. to 25 gal. of water or a 5 per cent kerosene emulsion are said to be the most satisfactory control measures.

In the experimental destruction of G. *abbreviatus* in alfalfa fields at Capa, poison baits, consisting of (1) bran 25 lbs., blackstrap molasses 2 qts., 6 oranges, and water 4 gal., and (2) fresh horse manure 25 lbs., blackstrap molasses 2 qts., 6 oranges, and water 4 gal., gave very satisfactory results.

Notes on some little-known pests of red clover, G. W. HERRICK and J. D. DETWILER (Jour. Econ. Ent., 12 (1919), No. 2, pp. 206-209, figs. 3).—The notes here presented relate to the lesser clover leaf weevil (*Phytonomus nigrirostris*), the clover head weevil (*P. meles*), and the clover Tychius (*Tychius picirostris*).

Internal disease of cotton bolls in the West Indies, II, W. NowELL (West Indian Bul., 17 (1918), No. 1, pp. 1-26, fig. 1).—The author reports a continuation of studies previously noted (E. S. R., 39 p. 754), referring chiefly to conditions in St. Vincent late in 1917 and to the activities of bugs other than Dysdercus spp., more particularly to those of the green bug (Nezara viridula). He states that the control measures employed against the cotton stainer have reduced the trouble to negligible proportions over large areas of that island, although in some localities severe infestations by the green bug and pea chink (Edessa meditabunda) were found worthy of study.

Punctures of the bolls by bugs, in particular the green bug, cotton stainers, and the leaf-footed bug, and resulting injury to the seeds, check growth of the lint, and cause drying or shedding of young bolls. Experiments on the effect of confining bugs from known food plants on previously protected bolls give evidence that the punctures by the green bug readily cause infection with the fungi of internal boll disease, but only when the bugs are transferred from infected plants. The same observation was made in the case of the pea chink.

Important foreign insect pests collected on imported nursery stock in 1918, E. R. SASSCER (*Jour. Econ. Ent.*, 12 (1919), No. 2, pp. 133–136).—A brief account is given of the more important species intercepted.

[Vol. 41

Experiments with poison baits against grasshoppers, D. A. RICKER (Jour. Econ. Ent., 12 (1919), No. 2, pp. 194–200).—This is a report of experiments conducted in the vicinity of Janesville, Wis., where the red-legged locust, Melanoplus atlanis, and M. bivitattus occurred in greatest numbers and nearly all were almost mature at the time of the experiments.

In the tests of the attractiveness of different baits based upon the standard formula, apples and bananas when used alone or with molasses were as attractive as, or slightly more so than, lemon fruit or lemon extract. Apples and molasses gave practically the same results as lemon fruit and molasses, while lemon fruit and salt gave practically the same results as molasses and salt, but both were slightly less effective than the first two combinations. Salt alone seemed to give slightly better results than molasses alone. In all cases bananas showed as good results as lemon fruit and seemed to give a heavier early mortality.

In determining the period of attractiveness of different fruits, it was found that citrus fruits become flat within a day or two after application, whereas the noncitrus fruits increased in odor and attractiveness as fermentation progressed. It was found that the young hoppers responded better toward the more odorous bait.

In tests of the comparative value of different arsenicals it was found that wherever crude arsenious oxid was used in a direct comparison with Paris green, as was the case in 6 experiments in which applications covered approximately 65 acres, very little choice could be found, both working with nearly the same rapidity and being equally effective. Calcium arsenate used in 4 experiments in direct competition with both Paris green and crude arsenious oxid gave equally as good results. The addition of lemon extract to the standard formula made a much more odorous bait and proved effective at the usual rate of application, while the standard bait used at the rate of from 6 to 8 lbs. per acre gave efficient results. It is pointed out that the rate of application appears to depend upon the infestation and attractiveness of the bait.

Grasshopper control in Kansas, G. A. DEAN, E. G. KELLY, and A. L. FORD (*Jour. Econ. Ent.*, 12 (1919), No. 2, pp. 213–217, pl. 1).—A brief report of work carried on during one of the worst grasshopper outbreaks in the history of Kansas, which took place in the summer and fall of 1918.

Palmodes præstans and its prey, A. N. CAUDELL (*Proc. Ent. Soc. Wash., 21* (1919), No. 2, p. 40).—*Capnobotes fuliginosus*, an orthopteran, is said to have been captured by *P. præstans*, a wasp which is scarcely one-third the length of its prey.

Leaf hoppers injurious to apple trees, F. H. LATHROP (New York State Sta. Bul. 451 (1918), pp. 185-200, pls. 4, figs. 2).—Among the serious insect enemies of the apple in New York State are the three species of small leaf hoppers here reported upon by the author, namely, the apple leaf hopper, Empoasca unicolor, and Empoa rosæ.

Contrary to certain recorded observations the apple leaf hopper, of which two generations were observed, hibernates largely, if not exclusively, in the adult stage. On the other hand, *E. unicolor* spends the winter in the egg stage and is single brooded; *E. rosæ* overwinters in the egg stage, largely on roses, although a few eggs are placed on apples, and has two generations. These species differ considerably in feeding habits, the apple leaf hopper obtaining its food almost exclusively on tender terminal growth and causing a characteristic curling of the foliage, while *E. rosæ* and *E. unicolor* feed largely on older leaves and may be found on young and older apple trees, *E. rosæ* being more abundant on older trees and *E. unicolor* on the younger trees. The leaves attacked by these two species display white stippling on the upper surfaces. In experiments with leaf hoppers as carriers of fire blight (*Bacillus amylovorous*), positive results were obtained with the apple leaf hopper but no infections were noted in similar efforts with the other species.

A number of natural enemies were observed, including *Anagrus armatus* which parasitizes the egg. Control measures consist chiefly in protection through spraying with soap and nicotin mixtures to combat the younger nymphs. The destruction of weeds which harbor the insects serves as a supplementary measure.

"In a series of spraying tests in which soap, nicotin, and kerosene emulsion were also compared, a high degree of effectiveness was indicated for a spraying mixture of nicotin sulphate 1 pint, lump lime 60 lbs., copper sulphate 4 lbs., and water 100 gal."

The life histories as observed at the station are illustrated in the following diagram (fig. 2):

FIG. 2.—Diagram of life histories of leaf hoppers injurious to apple trees as observed at Geneva, N. Y.

Leaf hoppers injurious to apple trees, F. H. LATHROP (New York State Sta. Bul. 451, popular ed. (1918), pp. 3-6, fig. 1).—A popular edition of the above.

A new genus for Tettigonia trifasciata (Homoptera; Euptergidæ), W. L. MCATEE (Proc. Biol. Soc. Wash., 32 (1919), pp. 121-123, figs. 2).

Preliminary key to the Nearctic species of Eupteryx (Homoptera; Eupterygidæ), W. L. MCATEE (*Ent. News*, 30 (1919), No. 7, pp. 182-186).

Some studies on the eggs of important apple plant lice, A. PETERSON (*New Jersey Stas. Bul. 332, pp. 5–63, figs. 17*).—This detailed report of investigations on the structure, behavior, and susceptibility of the eggs of three important aphidids found on apple trees (*Aphis avenæ*, the apple aphis, and *A. sorbi*) is summarized in part as follows:

A morphological study of the eggs of these three apple plant lice "shows two distinct layers in the eggshell, an outer semitransparent layer which is soft and glutinous when the egg is deposited, but hardens and becomes somewhat tough (maybe brittle) and impervious upon long exposure to weather, and an inner, soft, elastic, membranous, black layer. A third layer, thin and membranous, may be seen about the nymph when it starts to emerge. This skin is probably the first exuvium, since it is shed by the nymph as it emerges.

"Under out-of-door conditions the outer layer of the egg usually splits along the dorsomesal line a number of days (2 to 30 or more for A. avenx) before the nymph emerges. So far as observed under greenhouse conditions the eggs of all three species split their outer covering at least a few hours before the pigmented layer is severed. In 1918 the first eggs of A. avenx with split outer

132688°-19-5

coverings were seen on February 15, and when the first nymphs emerged, on March 21, approximately 95 per cent of the normal live eggs (45–50 per cent of the eggs were dead) had split their outer semitransparent covering.

"These observations on the morphology and behavior of the egg coverings show conclusively that the egg is not a hard resistant body, and that it goes through a critical change previous to the emergence of the nymph. It is in the midst of this critical period that the egg is most susceptible to evaporating factors and certain contact insecticides.

"The outer semitransparent layer of the egg is somewhat impervious to water; consequently, the water content of the embryo does not undergo very much evaporation in moist weather, or in other words, when low evaporating factors exist, such as high humidity, low temperature, and probably small wind velocity. The outer layer, however, is not entirely impervious, for extreme drought will cause the vast majority of the eggs to shrivel and never hatch. In other words, low humidity, high temperature, and probably air velocity undoubtedly bring about a greater evaporation of the water content of the embryo, and thus destroy the living form. The inner pigmented (black) layer of the egg is not an efficient protector against evaporation. Numerous and varied experiments at the laboratory and observations made on the percentage of hatched eggs, of A. avena during the past two totally different seasons, 1917 and 1918, show conclusively the pervious nature of this layer. The eggs are most susceptible to evaporating factors and contact insecticides the latter part of March, or in other words, when the greatest number shows a split outer layer, and this occurs when the first nymphs start to emerge.

"Experiments conducted in the laboratory under controlled percentages of moisture and also experiments where similar eggs of *A. avenæ* were kept out-of-doors during the critical period (February 15 to March 31, and especially important March 15 to March 31) in 1917 which was wet, while in 1918 this period was dry, show quite conclusively that the percentage of hatched eggs is much higher in a low evaporating environment than in a high evaporating medium.

"Contact insecticides probably prevent the egg from hatching in several ways. From a physical viewpoint some substances tend to harden the outer semitransparent shell (lime-sulphur) and this makes it impossible for the nymphs to split the hardened layer. This hardening effect may be due to desiccation. Desiccating substances may also remove the water content of the embryo within, especially if applied after the outer layer has split. Other substances soften and disintegrate the outer impervious layer (crude carbolic acid and cresols) and thus expose the inner pigmented layer to evaporating factors. The above physical reaction of contact insecticides on eggs of aphids may be important, but it is probable that the toxic effect upon the embryo of various contact insecticides is more important. So far, no technique has been found which will determine the penetrative ability of the various chemicals used. . . .

"We can safely recommend as a control measure for aphids a delayed dormant spray of lime-sulphur (1:8 or 1:9) combined with nicotin (blackleaf 40) 1:500. The combined spray kills 98 to 100 per cent of all the eggs that are coated and will also kill all the newly hatched nymphs, provided they are hit with the spray. Dormant lime-sulphur (1:9) by itself will kill a large percentage (90 per cent or better) of the eggs, but not enough to rely upon it alone. Furthermore, lime-sulphur alone will kill only a small percentage of the newly hatched nymphs if they have made their appearance. Therefore, a combined spray is better, for it will kill a greater percentage of eggs and all the nymphs. The time of application is important."

The best results can be obtained "by delaying the dormant spray until the fruit buds start to swell and when they first show green. At this stage the eggs of the oat aphis (A. *avenæ*) will be hatching, while the eggs of the rosy aphis (A. *sorbi*) and the green apple aphis (A. *pomi*) will not hatch for 7 to 14 days later. The dormant spray will not injure swollen fruit buds or those showing short projecting tips of leaves, while a dormant spray applied when the leaves are distinct and separated will burn the foliage of most varieties. Also, the recently emerged nymphs of the aphids will conceal themselves to a large extent between the separated leaves, and it will be impossible to hit all of them with a contact spray."

Vegetable plant lice, T. J. HEADLEE, (New Jersey Stas. Circ. 107 (1919), pp. 3-21, figs. 16).—This is a popular summary of information on the more important aphid enemies of vegetables in New Jersey. Of the 94 species recognized as affecting various plants within the limits of the State 12 are known as enemies of vegetable crops of which 7, known to be seriously and at times severely injurious, are here considered, namely, the pink and green aphis of the potato (Macrosiphum solanifolii), the green peach aphis, the green pea louse (M. pisi), the bean louse (Aphis rumicis), the cabbage aphis, the false cabbage aphis (A. psudobrassicw), and the melon aphis.

**Control of plant lice or aphis,** F. H. CHITTENDEN (*Potato Mag.*, 1 (1919), No. 11, pp. 10, figs. 3).—A brief discussion of the plant lice that attack the potato, in which it is pointed out that the spinach aphis is commoner and more important than the pink and green aphid. The author recommends the use of nicotin sulphate (40 per cent)  $\frac{2}{3}$  pint, laundry or fish-oil scap 2 lbs., and water 50 gal.

A Melaphis from moss, A. C. BAKER (*Ent. News, 30* (1919), No. 7, pp. 194– 196, fig. 1).—A species reared from moss found infested with an aphid at Springfield, W. Va., is described as *Melaphis minutus* n. sp.

The identity of Smynthurodes betæ Westwood, A. C. BAKER (*Proc. Ent. Soc. Wash., 21 (1919), No. 2, pp. 36-38, fig. 1*).—The author concludes that *S. betw,* described by Westwood in 1849, is distinct from our American beet aphid and that it should be known as *Forda betw.* 

An undescribed species of Dryopea injurious to Phyllostachys, A. C. BAKER (*Proc. Ent. Soc. Wash., 21 (1919), No. 5, pp. 104–106, fig. 1*).—A plant louse found to attack the roots of Phyllostachys at Yarrow, Md., is described as *Dryopea morrisoni* n. sp.

A report on a collection of Coccidæ from Argentina, with descriptions of apparently new species, H. MORRISON (*Proc. Ent. Soc. Wash., 21 (1919), No. 4, pp. 63-91, pls. 4*).—Twenty-one species of Coccidæ are here recorded from Argentina, of which 7 are described as new.

Studies on the dry cleaning process as a means of destroying body lice, R. H. HUTCHISON and W. D. PIERCE (*Proc. Ent. Soc. Wash.*, 21 (1919), No. 1, pp. 8–20).—" The open rotary washer system of dry cleaning, when done according to the specifications quoted, is entirely effective in destroying both the active stages and the eggs of body lice and has additional advantages in the cleansing of the garments and absence of shrinkage. The high temperature required in the drying tumbler was found to be essential for the destruction of the eggs. The wash and rinse in gasoline are effective in destroying active stages but a large percentage of the eggs will survive this part of the process. Gasoline itself is of no value as an ovicide; 18.7 per cent of the eggs in one test hatched after 54 hours' immersion in gasoline.

[Vol. 41

"An attempt to find a washing formula which of itself would be effective without depending on the high temperature of the drying tumbler was not successful, although results of one experiment with benzol,  $30.5^{\circ}$  B. indicated that the oil could be used for this purpose, if infested garments were soaked 2 to 4 hours before washing. A preliminary soaking in kerosene or in a 52° kerosenegasoline mixture followed by washing in gasoline was found in laboratory tests to be ineffective.

"Laboratory tests with a series of oils showed that benzol  $(30.5^{\circ})$  killed after 2 to 4 hours' immersion; kerosene  $(44^{\circ})$  killed within 10 minutes; gasoline-kerosene mixtures (48 and 52°) killed after 15 minutes; a 56° mixture did not kill within 17 hours. Gasoline did not kill all eggs after 54 hours' immersion. When immersion in any of the heavier oils was followed by a rinse in gasoline hatching occurred. Gasoline-soap emulsion was found to have little killing effect on eggs even after 30 minutes' immersion."

Notes on Diacrisia virginica, J. D. MITCHELL (*Ent. News, 30 (1919), No. 7, pp. 191–194*).—The author reports observations made of the yellow bear caterpillar in Calhoun and Victoria Counties, Tex. In the summer of 1917, it was found feeding over all of Victoria County on various species of plants and shrubs, of which 36 are listed, and on cultivated plants, including cotton, corn, cantaloup, alfalfa, peanuts, and all garden crops.

The damage which it caused to cotton in the two counties in 1918 through stripping of the leaves is claimed by farmers to be from 25 per cent to total destruction, and in one field of 65 acres in Calhoun County visited by the author the destruction was complete.

In rearings by the author a large percentage of the caterpillars were destroyed by a fungus caused by *Entomophthora anticæ*. *Eremotylus arctiæ* was the only parasite reared. When very young the caterpillars can be killed by the application of 3 lbs. of Paris green and 5 lbs. of lime made into 50 gal. of spray, but when the caterpillars have reached a large size no poison or repellents seem to have any effect on them.

The work in the United States against the pink bollworm, W. D. HUNTER (*Jour. Econ. Ent., 12 (1919), No. 2, pp. 166–175*).—A detailed account of the work by the U. S. Department of Agriculture, a bulletin relating to which by the author has previously been noted (E. S. R., 39, p. 764).

The European corn borer and its control, S. C. VINAL and D. J. CAFFREY (*Massachusetts Sta. Bul. 189 (1919)*, pp. 71, figs. 14).—This is a detailed report based upon investigations conducted by the authors and a review of the literature, including data presented in the preliminary account by Vinal previously noted (E. S. R., 39, p. 62). The investigations reported in the present bulletin were conducted by the station in cooperation with the Bureau of Entomology of the U. S. Department of Agriculture.

Up to November, 1918, the European corn borer had become established in an area of about 320 square miles, comprising 34 towns, immediately west, north, and northwest of the city of Boston. A colony had also been found near Schenectady, N. Y., as noted by Felt (E. S. R., 41, p. 60). A list is given of 33 plants attacked of which corn is its favorite host, all parts except the fibrous roots being attacked.

"The economic injury to corn consists of the following: (1) Injury to tassel which results in poor fertilization, (2) injury to stalk which reduces vitality of plant, (3) injury to stalk which causes breaking over of plant, (4) injury to stalk which indirectly affects the ear by cutting off its supply of nutriment, (5) injury to ear which directly affects the yield, (6) injury to the silk of the ear which results in poor fertilization. "A maximum of 117 full-grown European corn borer larvæ have been taken from one corn plant and 311 full-grown larvæ were dissected from a single hill of corn containing four plants. The average number of larvæ dissected from 75 corn plants, taken at random in the same field, was 46. This is at the rate of 1,050,640 larvæ per acre of corn. As many as 15 were found attacking a single ear of sweet corn. Field counts made in infested cornfields showed that frequently as high as 100 per cent of the ears were infested.

"The other economic plants mentioned as hosts of the European corn borer are attacked by the insect only in the absence of corn, or as a result of their nearness to corn in badly infested fields. The wild plants mentioned as hosts of the insect, are attacked only in the absence of corn, and are not economically important except that they serve as intermediate hosts for the multiplication of the pest.

"There are two generations of the insect each year. The nearly full-grown second generation larvæ pass the winter in a dormant condition within their tunnels, and resume feeding with the approach of warm weather in the spring. They pupate about the middle of May. The pupal period lasts about 17 days, and moths emerge the first week of June to deposit eggs for the first generation. A maximum number of 727 eggs was deposited by a single second generation female in life history cages, and the average number deposited by a single female was 337 eggs. These eggs are deposited in masses from 5 to about 50 eggs, on the undersides of the leaves of the host plant. The first generation larvæ hatch in about 7 days and reach their full growth in about 44 days. They pupate within their larval tunnels, and the pupal period lasts about 9 days. The moths emerge about the middle of July and deposit eggs for the second generation. A maximum number of 903 eggs was deposited by a single first generation female in life history cages, with an average number per female of 545 eggs. The second generation larvæ hatch in about 6 days and are nearly full grown by winter."

The natural enemies mentioned include four tachinid parasites, namely, Masicera myoidea, Exorista pyste, E. nigripalpis, and Phorocera erecta, reared from the larvæ, and two hymenopterous parasites, namely, (Pimpla) Epiurus pterophori and (Ichneumon) Amblyteles brevienctor, from the pupæ. The percentage of parasitism by any of these species is very small.

"Burning the plants containing the overwintering larvæ, any time during the period from the middle of October to the middle of the next May, is the most effective control method now known. Other methods, applicable under certain conditions, for destroying infested plants are placing in manure or compost, in a silo, burying deeply in the soil, or feeding directly to live stock, preferably shredded or chopped fine."

The European corn borer problem, D. J. CAFFREY (Jour. Econ. Ent., 12 (1919), No. 1, pp. 92-105).—This account is based upon data presented in the bulletin above noted.

The European corn borer: A menace to the country's corn crop, D. J. CAFFREY (U. S. Dept. Agr., Farmers' Bul. 1046 (1919), pp. 28, figs. 17).—This is a popular summary of information based on the investigations reported in the bulletin noted above.

A new species of Bucculatrix injurious to hollyhock, A. BUSCK (*Proc. Ent. Soc. Wash., 21 (1919), No. 5, pp. 109, 110).—Bucculatrix althææ*, which appears to do considerable damage to hollyhock in California by skeletonizing the leaves, is described as new.

Two Microlepidoptera injurious to strawberry, A. BUSCK (Proc. Ent. Soc. Wash., 21 (1919), No. 3, pp. 52, 53).—Tortricodes fragariana, which breeds commonly in the buds at the head of the crowns of strawberry, and Aristotelia fragariæ, the so-called strawberry crown borer, both taken at Victoria, B. C., are described as new.

On some generic synonymy in the family Gelechiidæ, A. BUSCK (*Proc. Ent. Soc. Wash., 21 (1919), No. 4, pp. 94–96*).—Attention is called to the fact that Pectinophora Busck may prove to be a synonym of Platyedra Meyrick erected in 1895.

Descriptions of new species of Coleophora, A. F. BRAUN (*Ent. News, 30* (1919), Nos. 4, pp. 108-112; 5, pp. 127-131).—Among the species of Coleophora reared by the author at Cincinnati, Ohio, and here described are *C. apicella* n. sp., the larval cases of which are found on the lower side of the rosette leaves of the fire pink (*Silene virginica*); *C. polemoniella* n. sp., the larvæ of which feed on the lower side of leaves of Greek valerian (*Polemonium reptans*); *C. cricoides* n. sp., the larvæ of which mine the seeds and receptacle of a wild white aster (*Aster ericoides*); *C. amaranthella* n. sp., reared from larvæ eating out of the seeds of pigweed (*Amaranthus hybridus*; and *C. granifera* n. sp., the cases of which are found on the underside of leaves of *Aster shortii*.

Notes on the California oak worm, Phryganidia californica, H. E. BURKE (*Proc. Ent. Soc. Wash.*, 21 (1919), No. 6, pp. 124, 125).

Nicotin sulphate solution as a control for the chrysanthemum gall midge, Diarthronomyia hypogæa, T. L. GUYTON (*Jour. Econ. Ent.*, 12 (1919), No. 2, pp. 162-165, pl. 1).—The author concludes that D. hypogæ can be successfully controlled at the time of the emergence of the adult by spraying with a solution of one volume of nicotin sulphate containing 40 per cent nicotin to 500 volumes of water, to which fish-oil soap has been added at the rate of 1 oz. to each gallon of solution. The plants must be completely covered with the spray solution, and since all adults do not emerge at the same time the treatment must be repeated every four or five days as long as any living forms of the midge remain in the galls.

**Observations on and experiments with Cuterebra tenebrosa**, R. R. PARKER and R. W. WELLS (*Jour. Parasitology*, 5 (1919), No. 3, pp. 100-104, pl. 1).— This is a report of observations and experiments conducted in Powder River Valley, Mont., in 1916 on the rodent botfly (*C. tenebrosa*) during the course of investigations of the Rocky Mountain spotted fever tick.

Under natural conditions the larvæ of this oestrid parasite were found infesting pack rats and grasshopper mice. Prairie dogs were infested under laboratory conditions, but negative results were secured with Belgian hares and 13striped ground squirrels.

"A female deposited 186 eggs within a period of several days. These eggs contained active larvæ which were still alive after six months in the laboratory. By mechanically transferring larvæ from eggs to the mouths of prairie dogs infestation was secured. In three experiments with these animals (experiment 2 excluded because the host was killed) 20 larvæ were used, of which 11 reached the subcutaneous tissue, 5 died in this situation, and 6 emerged as fully matured larvæ. (One of these was dissected out just as it was completing the last molt.) Evidence that the larvæ had reached the subcutaneous tissue was found on the twelfth day in two instances, and within maximum limits of 9 and 10 days in two other experiments.

"The length of time elapsing after the first apparent evidence of larvæ under the skin and before the skin was punctured was about 2 days. The period spent in the subcutaneous tissue was 17, 25, 26, and 27 days in the several cases observed. The total period from infestation to the emergence of the fully developed larva was, respectively, 37, 38, and 47 days in three instances. After emergence from the host the mature larva entered the ground and soon pupated a few inches below the surface. The period between the emergence of the mature larvæ from the host and that of the fly was 47 days (June to August) in one instance and 173 days in another (July to January 8). Winter apparently may be passed in the pupal stage."

Notes on Phlebotomus species attacking man, D. C. PARMAN (Jour. Econ. Ent., 12 (1919), No. 2, pp. 211-213).—These notes relate to attacks by P. vcxator at Uvalde, Tex.

A new genus in Scatophagidæ, C. T. GREENE (Proc. Ent. Soc. Wash., 21 (1919), No. 6, pp. 126-129, fig. 1).—Ambopogon hyperboreus n. g. and n. sp. is described.

The dispersion of flies by flight, F. C. BISHOPP and E. W. LAAKE (*Jour. Econ. Ent.*, 12 (1919), No. 2, pp. 210, 211).—In extensive tests made by the authors in 1918 of the dispersion tendency of various species of flies, 60,000 colored flies were liberated at one point and 80,000 at another. The greatest distance from the point of liberation at which marked flies were recovered was for house flies 13 miles, screw worm flies 15 miles, *Phormia regina* 11 miles, and *Ophyra leucostoma* 7 miles.

A new root maggot treatment, E. B. STOOKEY (*Jour. Econ. Ent.*, 12 (1919), No. 2, pp. 219, 220).—In experiments at the Western Washington substation at Puyallup anthracene oil treated soil, scattered about the base of the plant to form a protecting collar, and 1 gal. of the mixture used to about 200 plants, gave quite satisfactory results.

Some notes on Phorbia fusciceps as a bean pest, I. M. HAWLEY (*Jour. Econ. Ent.*, 12 (1919), No. 2, pp. 203-205, pl. 1).—A brief account of the seedcorn maggot, which was the source of serious injury to the bean crop in New York State in the spring of 1917.

Two new genera of Anthomyidæ, J. M. ALDRICH (*Proc. Ent. Soc. Wash., 21* (1919), No. 5, pp. 106-109, fig. 1).—Two new genera, Pergandea and Sphenomyia, are erected.

A new genus and species of Cerambycidæ from Colorado, W. S. FISHER (*Proc Ent. Soc. Wash., 21 (1919), No. 2, pp. 38-40*).—*Elatotrypes hoferi* n. g. and n. sp. was collected from under bark of a dead limb of a partially dead limber pine (*Pinus flexilis*) at Ute Pass, El Paso County, Colo.

Descriptions of a new genus and species of Buprestidæ from Arizona, W. S. FISHER (*Proc. Ent. Soc. Wash., 21 (1919), No. 4, pp. 91–93*).—The genus Paratyndaris is erected for *P. coursctiæ*, a new species reared from pupæ collected in dead stems of a legume (*Coursetia microphylla*) in Tucker Canyon, Santa Catalina Mountains, Ariz.

Note on Macrobasis murina, W. S. FISHER (*Proc. Ent. Soc. Wash., 21 (1919), No. 1, pp. 1, 2*).—This meloid is said to have proved to be a serious menace to the pea tree (*Caragana* sp.) at Mandan, N. Dak., where the tree has been introduced for ornamental purposes.

The striped cucumber beetle and its control, F H. CHITTENDEN (U. S. Dept. Agr., Farmers' Bul. 1038 (1919), pp. 20. figs. 15).—A popular summary of information on this pest with directions for its control.

Injury from white grubs in Iowa, E. D. BALL and E. V. WALTER (*Iowa Sta. Circ. 60, pp. 4, figs. 2*).—A popular summary of information on white grubs, serious outbreaks of which have occurred in northeastern Iowa during the past ten years.

Notes on a cocoon making colydiid, II. E. BURKE (Proc. Ent. Soc. Wash., 21 (1919), No. 6, pp. 123, 124).—These notes relate to Deretaphrus oregonensis.

[Vol. 41

Eleodes opaca, an important enemy of wheat in the Great Plains area, J. W. McColloch (*Jour. Econ. Ent.*, 12 (1919), No. 2, pp. 183–194, pl. 1).—'The life history of the false wireworm (*E. opaca*), an insect which is becoming of increasing importance, having caused considerable injury in western Kansas and southwestern Nebraska, has been worked out by the author and is here reported upon.

This species has a wide distribution throughout the Great Plains area, occurring from Texas to South Dakota. Its principal injury is caused by the larvæ during the fall, at which time they attack the wheat seed immediately after planting and destroy it before germination. After the seed germinates the injury becomes less noticeable and often ceases altogether. In some cases, however, considerable damage may occur after the wheat is several inches high. Occasionally some damage occurs in the spring due to the larvæ burrowing through the stalks or even cutting them off. In addition to wheat the worms have been reared on sprouting corn, foxtail seeds, and crabgrass roots.

The eggs deposited during midsummer hatch in from 6 to 10 days, while later in the fall the period is prolonged to 19 days. The first oviposition recorded occurred on July 5 and the last on October 4. The larvæ which molt 11 times between hatching and pupation require for each stadium 4, 3, 4, 6, 8, 13, 15, 12, 18, 199, and 20 days, respectively, or an average total of 317.7 days for larval development, based on 50 larvæ, extending over a period of 3 years. Most of the larvæ become full-grown by October, in which stage they pass the winter, become active in early spring, and usually molt once in April. Pupation occurs during the last of April and throughout the month of May, 14.1 days being the average length of the pupal stage, based upon observations of 149 pupæ observed during a period of 4 years. The adults commence to emerge about the middle of May and continue through June, the adults being found in the field until the middle of October, the greatest number being present in July and early August. Most of the adults under observation lived from 60 to 90 days and 1 male lived 130 days.

Three generations have been reared by the author from adults collected in the field in 1915, 341.5 days being the average period required for each brood, based upon the average length of the various stages.

The hymenopterous parasite *Perilitus eleodis* has been reared each year from a few beetles, and a gregarine (*Stylocephalus giganteus*) has frequently been found in the alimentary tract of the adults. Two species of fungi have been found attacking the larvæ, namely, *Sporotrichum globuliferum* and *Metarrhizium* sp.

While no extensive control experiments in the field have been carried out, the author's studies suggest several promising methods of procedure which have proved beneficial in controlling E. opaca or reducing the amount of injury. The investigations show that in nearly all cases the greatest injury occurred on land continuously cropped to wheat, while fields that have been in a row crop or fallowed previous to wheat have suffered little damage. The rotation suggested for western Kansas is wheat 2 years, Kafir or other sorghums 1 year, and summer fallow 1 year.

A list is given of 11 references to the literature cited.

Avocado seed weevils, H. S. BARBER (Proc. Ent. Soc. Wash., 21 (1919), No. 3, pp. 53-60, pl. 1).—An avocado weevil, distinct in habitus from Heilipus lauri and described as H. pittieri n. sp., was taken at Washington, D. C., from seeds of Persea pittieri from San Jose, Costa Rica. Conotrachelus persea, reared from avocado seed from Coban and Guatemala City, Guatemala, is also described as new. Several other insects reared from seeds of the avocado are also considered.

Contributions to our knowledge of the weevils of the superfamily Curculionoidea, W. D. PIERCE (Proc. Ent. Soc. Wash., 21 (1919), No. 2, pp. 21-36).

[Apicultural work] (*Iowa Sta. Rpt. 1918, pp. 31, 32*).—In tests of the comparative yield of honey from 1-, 2-, and 3-lb. packages of bees shipped from the South, the 1-lb packages gained 12 lbs. during the season, the 2-lb. packages, 39 lbs., and the 3-lb packages, 45 lbs., while the average gain from overwintered swarms was 59 lbs. In a study of the cost of wintering bees, it was found that each colony consumed about 17 lbs. of stores from October to April, inclusive. Careful measurements of a large number of bees from the best and from the poorest colonies showed the average length of the tongues of the highest producing colony to be 4 per cent greater than that of the lowest producing one, and this variation was found to be quite consistent.

The clover seed chalcid (Bruchophagus funebris), W. WILLIAMSON (*Rpt. State Ent. Minn.*, 17 (1918), pp. 95–110, figs. 10).—A report of this pest, based upon investigations in Minnesota, where it appears to be present wherever clover is grown. The greatest amount of damage to clover seed recorded in Minnesota is 39 per cent.

New genera and species of ichneumon flies, R. A. CUSHMAN (*Proc. Ent.* Soc. Wash., 21 (1919), No. 5, pp. 112–120, fig. 1).—This paper contains descriptions of three new genera, namely, Derocentrus, Cyrtobasis, and Atopognathus, three new species, and a new variety of the Ichneumonidæ and one new braconid species. Among the new forms are *Hyposoter fugitivus pacificus* from *Malacosoma pluvialis* and *M. ambisimillis* from Tacoma, Wash., and several localities in California, and *Apanteles iselyi* from *Canarsia hammondi* at Bentonville, Ark.

A new genus of chalcid wasp belonging to the family Eulophidæ, A. B. GAHAN (*Proc. Ent. Soc. Wash., 21 (1919), No. 1, pp. 2-8, fig. 1*).—The genus Apterolophus is erected for *A. pulchricornis* n. sp., thought to be parasitic on the larva of *Epargycus tityrus*.

**Parasite** introduction as a means of saving sugar, T. E. HOLLOWAY (*Jour. Econ. Ent.*, 12 (1919), No. 2, pp. 175–178).—A brief account of the introduction of parasites (*Euzenilliopsis diatrax*, *Bassus stigmaterus*, and *Apanteles* sp.) for the control of *Diatrax saccharalis*, based upon data presented in the bulletin previously noted (E. S. R., 41, p. 60).

A new species of the serphidoid genus Dendrocerus, A. B. GAHAN (Proc. Ent. Soc. Wash., 21 (1919), No. 6, pp. 121-123).—Dendrocerus conventziæ reared from Conventzia hageni at Amherst, Mass., and D. conventziæ rufus from cocoons of Conventzia sp., at Felida, Wash., are described as new.

Description of a new cynipoid from Trinidad, S. A. ROHWER (Proc. Ent. Soc. Wash., 21 (1919), No. 6, p. 156).—Diglyphosema anastrephæ reared from Anastrephæ sp., Trinidad, British West Indies, is described as new.

## FOODS-HUMAN NUTRITION.

The nutritive value of the wheat kernel and its milling products, T. B. OSBORNE, L. B. MENDEL ET AL. (Jour. Biol. Chem., 37 (1919), No. 4, pp. 557-601, pls. 11, figs. 3).—A detailed study is presented of the composition and nutritive value of the wheat kernel and its milling products, with special reference to the problems raised by modern milling methods and the degree to which it is desirable to mill flour for general use. The literature on the composition of the embryo, seed coats or bran, endosperms, and whole wheat kernel is reviewed, and data compiled from the literature and from original studies are presented.

The principal experimental work reported is an extensive series of investigations on rats for the purpose of comparing quantitatively the entire wheat kernel and its milling products with respect to the nutritive value of their proteins and their content of water-soluble vitamin, both for the maintenance of adult rats and the growth of young ones. The results of these studies may be summarized as follows:

The proteins of the wheat kernel are not greatly inferior for maintenance to casein, or even the total proteins of milk, and are superior to gliadin. They suffice to promote growth of rats to normal adult size, but the quantity of protein required for growth is relatively large. The crude protein of commercial embryo meal is apparently more efficient than that of the entire wheat kernel for maintenance and much more efficient for growth. The crude protein of wheat bran has a higher value for growing animals than that of the embryo, and is quite as efficient as that of a combination of wheat flour with eggs, milk, or meat. This would indicate that the farmer is justified in his high estimate of the value of wheat bran as a protein concentrate.

The proteins of the endosperm are adequate for maintenance of adults, but inadequate for growth even when liberal quantities are eaten. A diet containing only 10.3 per cent of protein furnished by flour supplemented with eggs, milk, or meat produced more rapid growth than when it contained even 50 per cent more protein derived entirely from wheat flour. This shows that under the ordinary human dietary conditions the proteins of wheat are advantageously employed.

Commercial wheat embryo is much richer in the water-soluble vitamin than commercial bran and flour. The pure embryo, carefully separated from all the other parts of the seed and used as the sole source of vitamin, suffices to maintain young rats but fails to promote their growth. Wheat kernels from which the embryo has been carefully removed are still rich in watersoluble vitamin. From these observations the question is raised as to whether the water-soluble vitamin is a single substance or a mixture of two or more. If it is a single substance it is considered that it must be a constituent of the endosperm.

Rats fed for one year from the time of weaning on diets containing 92 per cent of wheat or 50 per cent of commercial wheat embryo reached full maturity without giving any evidence that wheat contains a toxic substance.

In applying these results to the question of the extent to which wheat should be milled, the authors conclude that, except in special cases, little can be gained by including bran and embryo in the flour when it is used for human consumption under the conditions prevailing in this country. On the contrary, since the rations of farm animals require protein supplements and wheat bran is a valuable source of such proteins, the by-products of milling will be better utilized on the farm than on the table. Moreover, since "about 80 per cent of the wheat kernel can be so improved in nutritive value by adding animal products to the diet that a much smaller amount of flour will satisfy the protein needs of nutrition, it may well be that the use of the byproducts of milling for the production of meat, milk, or eggs will result in a greater economy in the use of flour than if these were used directly for human food."

Studies in nutrition.—I, The nutritive value of coconut globulin and coconut press cake, C. O. JOHNS, A. J. FINKS, and M. S. PAUL (*Jour. Biol. Chem.*, 37 (1919), No. 4, pp. 497-502, figs. 4).—Feeding experiments with rats to determine the nutritive value of coconut globulin and coconut press cake, the composition of which has been previously noted (E. S. R., 40, p. 502), are reported which indicate that coconut globulin produces normal growth when used as the sole source of protein in an otherwise complete diet, and that commercial coconut press cake furnishes the necessary protein for growth at almost **a**  normal rate. The press cake was found to contain sufficient water-soluble vitamin and some fat-soluble vitamin, but the rate of growth was increased by adding butter fat to the diet. Preliminary experiments indicated that 'the press cake is deficient in inorganic constituents, probably calcium, phosphorus, and chlorin.

Baker's yeast as food for man, P. B. HAWK, C. A. SMITH, and R. C. HOLDER (*Amer. Jour. Physiol.*, 48 (1919), No. 2, pp. 199–210).—Metabolism experiments upon man are reported in which the value of baker's yeast was studied, first when added to a high protein diet defective in lacking the water-soluble vitamin, second, when added to a low protein defective diet, and third, when used to replace varying amounts of protein in a normal diet. The yeast (Fleischmann) was in most cases dried at  $105^{\circ}$  C. in a current of air, milled to produce a yeast flour of the approximate fineness of ordinary wheat flour, and then made into biscuits with wheat flour. As much as 20 per cent of the wheat flour could be substituted by the yeast flour without destroying the palatability of the product. A palatable mixture could also be made from the undried yeast with chopped meat.

Of the six men who served as subjects, four found the diet more satisfactory when yeast was included as shown by an improved nitrogen balance. The average daily gain of nitrogen in all the experimental periods when no yeast was present in the diet was 0.48 gm., while this gain was increased to 0.82 gm, when yeast was eaten along with other foods. It was found that from 10 to 30 per cent of the nitrogen of the ordinary mixed diet may be replaced by yeast nitrogen without detriment to the best nutritive interests of the individual. The average individual may ingest yeast sufficient to yield from 1 to 2 gm, of nitrogen per day without securing any laxative effect, but if as much as 4 gm, of yeast nitrogen are eaten a laxative effect is generally observed.

The favorable results obtained in these experiments are compared with the opposite conclusions of Funk et al. (E. S. R., 36, p. 158), and factors to account for the difference are suggested.

Note on an indigenous process for the conservation of meat at Fez, CAR-PENTIER (*Rec. Méd. Vét.*, 95 (1919), No. 5, pp. 149–156).—An indigenous method of preserving meat, particularly beef, in Morocco is described. The sterilization of the meat is obtained by the triple action of salt, desiccation, and heat, and external contamination is avoided by a covering of fat. Attention is called to the fact that the method combines almost all of the known processes for the conservation of meat.

Military soups and porridges, BALLAND (Compt. Rend. Acad. Sci. [Paris], 168 (1919), No. 8, pp. 383–386).—Analyses are reported of several varieties of dried, or so-called instantaneous, soup preparations and soup extracts used by the French and German armies.

French table mustards, P. CARLES (Ann. Falsif., 11 (1918), No. 119–120, pp. 310–316).—Analyses are reported of 11 samples of prepared French mustards, some of the results of which are given in the following table:

Analysis.	Moisture.	Residue.	Total ash.	Sodium chlorid.	Mustard oil.	Total acidity as acetic acid.
Minimum. Maximum Average.	Per cent. 62,50 75,00 67,00	Per cent. 21.20 41.00 31.40	Per cent. 2.50 11.30 5.39	Per cent. 0.66 7.30 3.31	Per cent. 0.056 .257 .13	Per cent. 1.84 4.80 3.74

Analyses of mustards.

The author is of the opinion that a prepared mustard should contain at least 5 per cent of sodium chlorid and 0.1 per cent of mustard oil.

Nutritive value of food, H. ARON (*Biochem. Ztschr.*, 92 (1918), No. 3-4, pp. 211-233, figs. 12).—This is a general discussion of the various factors other than calorific value which must be taken into consideration in determining the real value of food materials. The importance of butter fat and of vegetable extracts is emphasized particularly.

Studies on bacterial nutrition.—The utilization of nitrogenous compounds of definite chemical composition, S. A. KOSER and L. F. RETTGER (*Jour. Infect. Discases, 24* (1919), No. 4, pp. 301–321).—An extensive review of the literature on bacterial nutrition is given, and results are reported of an investigation of the ability of various species of bacteria to utilize the simpler nitrogenous substances of known chemical structure, such as amino acids, purins, and extractives, and combinations of these substances.

All of the amino acids employed, with the possible exception of tryptophan, showed similar ability to furnish nitrogen to certain organisms. Tryptophan appeared to possess a slight advantage over the other amino acids but, contrary to expectation, lysin showed no greater power than the monamino acids. The organisms which were able to develop on an amino acid medium appeared to require only small amounts of the amino acid. When only a few hundred cells were introduced into the amino acid culture medium multiplication took place as usual, and eventually the growth attained was as luxuriant as that resulting from a much larger inoculation. This is thought to indicate that some organisms are able to assimilate the amino acid nitrogen without the aid of enzym action. When glycerol was withdrawn from the medium, the bacterial development was not so luxuriant but dextrose could be substituted for glycerol.

With the exception of the cholera vibrio, the organisms which utilize an amino acid developed with equal readiness on diammonium acid phosphate and on allantoin. Urea, taurin, creatin, hypoxanthin, and uric acid were inferior to the amino acids as available sources of nitrogen. Combinations of amino acids or of amino acids and other nitrogen-containing compounds appeared to possess little value over any one of the single amino acids.

Bacillus anthracis, Proteus zenkeri, B. abortus, B. diphtheriæ, B. hoffmanni, B. dysenteriæ, and all of the cocci studied, with the exception of Sarcina lutea in a few cases, consistently failed to develop in all of the media employed. Bacterium pullorum developed slightly in one instance only, while B. typhosus exhibited a slight growth in a few mediums.

Suggestions offered as to the probable nature of the nitrogenous bodies required by these species for initial development are dipeptids or polypeptids, vitamins, and simple and unstable bodies which defy all known methods of isolation.

The pathogenesis of deficiency disease, R. MCCARRISON (Indian Jour. Med. Research, 6 (1919), No. 3, pp. 275–355, figs. 22).—This article consists of the report of an extensive study of clinical, anatomical, and histological findings in pigeons subjected to dietetic deficiency. The paper is divided into three parts, (1) the effects of inanition alone, (2) the effects of a milled and autoclaved rice dietary alone, and (3) the effects of this dietary in association with septicemic states.

Six pigeons deprived of all food with the exception of water died in an average period of 12 days, with an average loss of 23 per cent of their original body weight. The thymus, testicles, spleen, ovary, and pancreas were found

to have undergone atrophy in the order mentioned. The adrenals underwent hypertrophy with increase of their adrenalin content.

The effects of a sole diet of milled and autoclaved rice were studied in 34 pigeons whose heart's blood and organs were demonstrated to have been sterile at the time of death. Of these, three types of morbid state were recognized clinically: Seventeen cases in which cerebellar symptoms predominated, 9 cases of polyneuritis without cerebellar symptoms, and 8 cases of pronounced asthenia. The average loss in weight was about 33 per cent of the original weight. The pituitary glands were found unchanged, the adrenals had undergone marked hypertrophy, while the thymus, testicles, spleen, ovary, pancreas, heart, liver, thyroid, kidney, and brain had atrophied. The central nervous system underwent little atrophy, the paralytic symptoms being due mainly to impaired functional activity of the nerve cells rather than to their degeneration.

The most remarkable finding is considered to be the hypertrophy of the adrenals, which is thought to be due to a want of vitaminic substance. The similarity is pointed out between this phenomenon and the hypertrophy of the thyroid for want of iodin. An intimate and causal connection is thought to exist between the hypertrophy of the adrenals and the origin of edema, in both inanition and beriberi, wet beriberi and dry beriberi being essentially the same disease but differing in the degree of derangement of the adrenal glands.

Another significant finding is the constant and pronounced atrophy of the testicles in males and the similar but less pronounced atrophy of the ovary in females. In the human subject such degrees of atrophy would result in sterility in males and amenorrhea and sterility in females. The finding is thought to account in great measure for the occurrence of "war amenorrhea."

The study of the relation between infection and deficiency disease was conducted on pigeons naturally and artificially infected with *Bacillus suipestifer*. Preliminary accounts of these studies have been previously noted (E. S. R., 32, p. 563). The general results obtained were as follows:

Infected birds when fed on polished rice developed symptoms of polyneuritis more rapidly than noninfected birds. Asthenic and fulminatory forms of polyneuritis were much more frequent in infected birds, which rarely survived long enough to develop cerebellar symptoms. This type, however, developed in birds in which infection had been prevented by isolation and immunization. Control birds fed on a liberal diet of mixed grains were in general immune, although exposed to infection. These results are thought to illustrate the influence which infectious agencies probably exert in man under like conditions of dietetic deficiency. It is pointed out that in nature beriberi arises in communities subjected to the attack of innumerable bacterial and other parasitic agencies, to which they are rendered highly susceptible in consequence of the dietetic deficiency. A tabular comparison of the anatomical findings in avian and human beriberi illustrates further the resemblance between the two diseases.

In conclusion the author points out that as the absence from the dietary of the so-called antineuritic food factors has been shown to lead not only to functional and degenerative changes in the central nervous system but to similar changes in every organ and tissue of the body, the condition produced is not a neuritis. "The symptom-complex is due (a) to chronic inanition, (b) to derangement of function of the organs of digestion and assimilation, (c) to disordered endocrine function especially of the adrenal glands, and (d) to malnutrition of the nervous system." The term "antineuritic vitamins" as applied to the food factors, the lack of which is the essential cause of beriberi, is therefore considered inaccurate, and the name "nucleopast" (that which feeds the nucleus) is suggested as more appropriate.

Factors affecting the antiscorbutic value of foods, A. F. HESS and L. J. UNGER (*Amer. Jour. Diseases Children, 17 (1919), No. 4, pp. 221-240, figs. 2).*—In continuation of the series of papers on human scurvy (E. S. R., 40, p. 70), the authors have reviewed the available reports on the occurrence of scurvy in the troops and in civilian populations during the war, and have summarized recent data in regard to the antiscorbutic value of fresh, pasteurized, and dried milk, and fruits and vegetables.

The significance is noted of the measures instituted by the British Government for the prevention of scurvy, including the maintenance of vegetable gardens in Mesopotamia and a change in the dietary scale.involving an increase in the amount of vegetables ordered for the British troops in India.

In discussing the possible deficiency in antiscorbutic vitamin of pasteurized and dried milk, it is pointed out that much of the antiscorbutic factor is lost subsequent to heating in the course of the handling and aging of the milk, and that "in connection with the effect of aging, of alkalinization, of heating, and probably of other agencies deleterious to this 'vitamin,' the length of time to which it is subjected to the injurious environment is in general more important than the intensity of the process." This is thought to apply also to the dehydration of vegetables. In dehydration "too much attention has been paid to the degree of the heating process, and too little to the more important factors—the age of the vegetables, their freshness previous to dehydration, their manner of preservation, etc."

Clinical reports are given indicating that diuresis and catharsis do not play an important rôle in the cure of scurvy, and that consequently the disorder can not be essentially toxic in nature. It was found also that giving an antiseptic (sodium benzoate) was without effect.

The strained juice of canned tomatoes has been found to be a very effective antiscorbutic and to be well tolerated by babies a few weeks of age, and is therefore recommended as an inexpensive and practical addition to the dietary of the bottle-fed infant.

The effect of heat, age, and reaction on the antiscorbutic potency of vegetables, A. F. HESS and L. J. UNGER (*Proc. Soc. Expt. Biol. and Med.*, 16 (1919), *No. 4, pp. 52, 53*).—In continuation of experiments on antiscorbutics previously noted (E. S. R., 39, p. 771), the authors report a slight difference in the antiscorbutic properties of old and fresh carrots. It was found that while 35 gm. of old carrots were sufficient to protect a guinea pig from scurvy when used raw, after cooking for three-quarters of an hour their addition to the dietary proved insufficient for protection. In a parallel test with freshlyplucked carrots, 35 gm. proved a sufficient protection even after cooking. It is pointed out that, in a consideration of vegetables as foodstuffs, account must be taken of the factor of freshness, particularly as older vegetables are tougher and therefore require more prolonged cooking, thus lessening their antiscorbutic value still further.

Attention is called to the fact that the antiscorbutic value of canned tomatoes is slightly diminished by boiling, so that they should not be subjected to cooking when employed as an antiscorbutic for infants. Their efficacy is not diminished immediately by rendering them slightly alkaline to phenolphthalein, but neither tomato nor orange juice will retain antiscorbutic properties long after having been rendered alkaline. Is vitamin identical with secretin? B. C. P. JANSEN (Meded. Geneesk. Lab. Weltevreden [Dutch East Indies], 3. Ser. A, No. 1-2 (1918), pp. 99-104).—To determine whether the water-soluble vitamin is of the nature of secretin, its stimulating effect upon the secretion of pancreatic juice of dogs was tested by the temporary fistula method. While repeated secretin injections caused repeated secretion of the juice the vitamin, in the form of a water solution of an alcoholic extract of rice bran, had no perceptible effect. The conclusion is therefore drawn that the water-soluble vitamin is not identical with secretin.

The presence of calcium in the red blood corpuscles of ox and man, D. M. COWIE and H. A. CALHOUN (*Jour. Biol. Chem.*, 37 (1919), No. 4, pp. 505-509).— By the use, with slight modifications, of the Lyman method for the determination of calcium in blood (E. S. R., 37, p. 207), the red blood corpuscles of men and of oxen were found to contain calcium, but in somewhat smaller concentration than the serum.

## ANIMAL PRODUCTION.

Scientific principles applied to breeding, S. WEIGHT (Breeder's Gaz., 75 (1919), No. 8, pp. 401, 402).—The importance of the more modern concepts of heredity in clearing away mystical beliefs and their service in interpreting the complicated facts of animal improvement are briefly set forth in this paper, and a modest claim made for genetics as a useful guide in modifying current practices. A short statement is presented of some results of the inbreeding experiments of the Bureau of Animal Industry of the U. S. Department of Agriculture which are now being conducted by the author. In these experiments, which involve over 26,000 guinea pigs, a number of families have been maintained for 19 generations without any very obvious degeneration.

"There has been, however, some decline in constitutional vigor, size, and especially fertility. On crossing together inbred families there is marked improvement in all respects, suggesting that the different families have usually deteriorated for different reasons, [thus] enabling each parent in a cross to supply most of what the other lacks. The detailed study of the separate families bears out this view. Marked hereditary differences in average vitality, size, fertility, and the like are in fact characteristic of the different families. It is also found that vigor in one respect is as likely as not to be associated with weakness in another. Again, certain families remained practically constant in average vigor throughout the experiment, while others degenerated so rapidly in one or more respects that they became extinct in spite of all efforts to keep them going."

Applications of mathematics to breeding problems, II, R. B. ROBBINS (*Genetics*, 3 (1918), No. 1, pp. 73-92).—Continuing his studies (E. S. R., 38, p. 367) of the theoretical distribution of Mendelian characters in successive generations of an ideal population, the author in the first section of the present paper investigates a single sex-linked character under (1) random mating, (2) assortative mating, (3) brother and sister mating, both at random and assortative, and (4) parent and offspring mating. In the second section he deals with a single typical factor when offspring are systematically bred back to their parents. A large number of algebraic formulas are developed to express the theoretical conditions in any generation. The results are mainly generalizations of special cases discussed by Jennings (E. S. R., 34, p. 764).

Some applications of mathematics to breeding problems, III, R. B. ROB-BINS (Genetics, 3 (1918), No. 4, pp. 375-389).—Extending the investigations noted above by the inclusion of a second Mendelian character, the author studies by algebraic methods the behavior of two allelomorphic pairs, linked in any degree, under (1) random mating, (2) a type of selection in which the only zygotes allowed to breed are dominants with respect to one of the pairs, and (3) self-fertilization. The topics are among those discussed by Jennings (E. S. R., 38, p. 268), but with the use of neater methods much greater generality is secured.

In all three systems of breeding, the relative proportion of each kind of gamete approaches a definite limit as the number of generations increases, and under random mating these limits are independent of the degree of linkage. The formulas indicate clearly the conditions necessary for stability when mating is at random. As is the case with only a single factor, the heterozygous types tend to disappear under self-fertilization.

Random mating with the exception of sister by brother mating, R. B. ROBBINS (Genetics, 3 (1918), No. 4, pp. 390-396).—Theoretical study of the fate of a single Mendelian character in a population in which mating is at random, except that brother and sister mating does not occur, shows that as the number of generations increases the proportions of the three possible types of individuals approach a fixed limit. Constant number of offspring to a pair is assumed, and if this number be 3 or more the limits approached are found to be the same as those of standard random mating. If the number of offspring is 2, the proportion of heterozygotes in the limiting population is higher. In complete brother and sister mating, as the author has previously shown (E. S. R., 38, p. 367), the limit for heterozygotes is zero.

Numerical effects of natural selection acting upon Mendelian characters, H. C. WARREN (*Genetics*, 2 (1917), No. 3, pp. 305–312).—When only one pair of allelomorphs is considered, it is well established that the proportion of dominants to recessives in a population remains fixed after the first generation, provided mating is at random and there is neither differential fertility nor selective eliminations of one or the other class of individuals. This paper discusses the changes that occur when a type of selective elimination is admitted such that there is a constant relative difference in the juvenal death rates of the two classes. With the aid of H. S. Jennings, a general formula is derived.

For a given difference in death rates, it is found that if the higher rate is characteristic of the dominants their elimination takes place more rapidly than would the elimination of the recessives if the latter class were the less viable.

The influence of the male on litter sizes, E. N. WENTWORTH (*Proc. Iowa Acad. Sci.*, 24 (1917), pp. 305–308).—Statistics are presented showing the average size of litters got by sires classified according to the size of litter in which they were born. Probable errors of the averages considered, no significant differences in the breeding performance of the different classes of sires of the same type of animal were apparent. The records include 9,026 Southdown rams, 415 Chester White boars, and 23 collie dogs. The rams in pedigrees started from single and from twin births are recorded separately.

The material was assembled mainly because Harris (E. S. R., 40, p. 662), in examining the litter frequencies reported by Wentworth and Aubel (E. S. R., 35, p. 68) for swine and by Rietz and Roberts (E. S. R., 34, p. 73) for sheep, found slight indications of an influence of sire on litter size.

Inheritance of fertility in sheep, E. N. WENTWORTH (*Trans. Kans. Acad. Sci.*, 28 (1916-17), pp. 243, 244).—Data from the Southdown births mentioned above are tabulated, as in a paper previously noted (E. S. R., 38, p. 574), to show the relative influence of sire and dam on litter size. It is concluded that

the production of triplets requires an hereditary equipment on the part of the dam different from that sufficient to produce only one or two lambs at a birth.

Unpublished results of J. M. Evvard are cited to show that the rate at which ewes are growing at the time of mating influences the number of offspring produced.

The Maoilin of Ireland, S. L. MITCHELL (Hoard's Dairyman, 57 (1919), No. 11, p. 551).—The Maoilin are dun-colored polled cattle constituting a very old breed, of which, however, only eight or nine herds are still in existence. A number of their skulls have been found in the crannogs of pre-Christian Ireland, and the author suggests that the polled character of some present-day Scotch and English breeds might have been derived from cattle taken to Scotland and East Anglia by early Irish colonists.

Feminized male birds, H. D. GOODALE (*Genetics*, 3 (1918), No. 3, pp. 276–299, figs. 10).—This paper reports the successful retention of homoiotransplants of ovarian tissue by 10 Brown Leghorn capons and 3 castrated Gray Call drakes at the Massachusetts Experiment Station.

The operated cockerels resembled normal males in weight and body proportions and in spur development, and were surprisingly like males in their sexual behavior. However, the combs and wattles remained infantile, the combs when single developed a typical female droop, crowing was rare, and, with three partial exceptions, the plumage was entirely female in color and form, even to the details of barbule development. In the exceptions the feather length, in regions where the male has long feathers, somewhat exceeded that of typical females, and there were also color variations due, it is thought, to the fact that the stock was not pure bred but extracted from experimental crosses with White Plymouth Rocks. The first feminized cockerel described (E. S. R., 34, p. 870) was one of these exceptions.

The castrated drakes serving as hosts for duck ovaries developed duck-colored heads and had no white ring on the neck and no curl in the tail feathers. The other plumage characters resembled those of males, but the color was toned down. In two cases the quack was imperfect. It is stated that ordinary castrated drakes and spayed ducks always retain the typical voice of their own sex.

In one case an ovary was successfully engrafted in a cock from which one testicle only had been removed. The secondary sexual characters were unmodified. At autopsy the remaining testicle was found to be undersized, but motile spermatozoa were present.

These facts are discussed at some length with respect to theories of gonad secretion.

The laws of bone architecture, J. C. KOCH (Amer. Jour. Anat., 21 (1917), No. 2, pp. 177-293, pls. 5, figs. 23).—This is an elaborate investigation of bone structure from the standpoint of analytical mechanics.

It is shown that the human femur, which was selected for study as a typical bone, obeys the mechanical laws that govern elastic beams under stress. The relation between the computed internal stresses due to load on the femur head and the internal structure of the different parts was found to be in very close agreement with the theoretical relations that should exist for the greatest economy and efficiency. The inner architecture is a mechanical model designed to produce the maximum strength with the least possible material.

An experimental study of the effect of stress and strain on bone development, J. A. HOWELL (Anat. Rec., 13 (1917), No. 5, pp. 233-252, figs. 7).—In a four weeks old fox-terrier dog the main nerves supplying the brachial plexus on

132688°-19-6

the right side were severed. This operation prevented voluntary movement of the right front leg but did not interfere with the blood supply. Contraction of the muscles controlling the upper arm served to hold the leg close to the body in a fixed position. The leg thus bore no weight and was subject only to slight muscular pull. Growth of the bone in the living animal was studied by means of radiographs. The subject was killed at the age of 23 weeks and a detailed comparison made of the bones of the two front limbs.

The long bones of the unused leg attained nearly the same length as those of the other side but the diameters were only about half as great, due to decrease both in the amount of bone tissue and in the size of the marrow cavity. The weight required to crush the bones of the operated limb was 14,845 lbs. per square inch of bone cross section, only 19 per cent less than that required for the normal bones. The unused shoulder blade was very thin and in places entirely membraneous.

The author concludes that bone development is not entirely controlled by the mechanical stresses to which it is subjected.

Effects of inanition and refeeding upon the growth and structure of the hypophysis in the albino rat, C. M. JACKSON (*Amer. Jour. Anat., 21 (1917)*, No. 2, pp. 321–358, figs. 5).—The experiments reported here were undertaken because of the intimate relations that seem to exist between the pituitary body (hypophysis cerebri) and the general growth process. A total of 91 rats, young and adult, were used. The diet consisted of graham bread soaked in whole milk and was varied only as to amounts fed. After an experimental feeding period, the rats were killed and the body length, body weight, and weight of hypophysis determined. These data are tabulated for each individual. The volumes of the different parts of the hypophysis were estimated from serial sections.

During restricted feeding the relative proportions of parts were altered but, except after long periods of maintenance, there was a gradual return to normal upon refeeding. Cell division in the hypophysis generally ceased during underfeeding, but there was no evidence as far as this organ is concerned in favor of the suggestion of Osborne, Mendel, et al. (E. S. R., 34, p. 862) that accelerated growth following periods of suppression is due to specific histological changes in the ductless glands.

Cytological studies of the reproductive cells of cattle (*Idaho Sta. Rpt.* 1918, p. 34).—On the basis of an examination of the testes of a bull by J. E. Wodsedalek, it is stated that there are 37 chromosomes in the spermatogonia and that the unpaired one passes undivided to one pole at the first spermatocyte (reduction) division.

Composition and nutritive value of feeding stuffs, T. B. Wood and E. T. HALNAN (*Cambridge, Eng.: Univ. Press* [1918], pp. 24, figs. 6).—This is a compilation in tabular form of proximate analyses of materials used by British farmers as feeding stuffs and of the available data as to digestible nutrients in each, together with a computation of the nutritive ratio, the maintenance and production starch equivalents, and the food units per ton. A series of charts gives curves showing the relation of food requirements to body weights in the different classes of live stock.

The composition and food value of bracken rhizomes, J. HENDRICK (Scot. Jour. Agr., 1 (1918), No. 4, pp. 423-430).—Proximate analyses of nine samples of fresh washed bracken rhizomes and one sample dried and ground to meal are presented, together with notes on the amounts to be secured from bracken-infested pastures, the cost of digging, and the preliminary results of the feeding trials noted below. It is stated that, in some cases at least, unringed pigs learn to root up the rhizomes and eat them.

Report on experiments on the feeding value of bracken rhizomes for pigs and poultry (*West of Scot, Agr. Col. Bul. 89 (1919)*, *pp. 101–107*).—In a 20weeks' trial reported by J. Wyllie, a lot of 6 pigs fed bracken rhizomes mostly dried and ground and "ordinary meals" gained at a rate of 0.77 lb. per head per day, while a comparable lot receiving only the "ordinary meals" gained 0.71 lb. About 1.5 lbs. of the dried rhizome was consumed per pound of gain. No records were kept of consumption of the other feeds.

A feeding trial during October and November with 29 White Leghorn pullets, four of which did not lay, is reported by A. Kinross. A lot of 10 birds, all layers, that received bracken rhizome in the form of meal as part of the wet mash averaged 10.3 eggs per bird during the period. Two other lots not fed bracken produced 23.8 and 34.1 eggs per layer, respectively. The wet mash fed the latter group contained corn meal.

[Emergency concentrates for range sheep], C. E. FLEMING (Nevada Sta. Rpt. 1918, pp. 47-49).—From a study of the situation resulting from the gradual extermination of the white sage (Eurobia lunata), the most important winter forage plant on the Nevada desert ranges, and the loss of sheep during periods of deep snow and very cold weather, the following emergency measures are advised: (1) Transportation of cottonseed cake to the range during November, (2) feeding of cake morning and evening during extreme weather, allowing the sheep to rustle in the middle of the day, and (3) division of the band for feeding purposes into units of about 500 head so that weak animals will have a better chance to secure feed. It is estimated that with wool at 40 to 50 cts. a pound a sheepman can afford to pay \$45 a ton for cake delivered at a railroad station within hauling distance of his range.

Effect of age or weight of pigs on rate and economy of gains, W. L. RoBIson (Mo. Bul. Ohio Sta., 4 (1919), No. 5, pp. 148-151).-The growth and feeding records from birth of 3 groups of pigs selected for uniformity are here reported, the object being to compare the economy of each 100 lbs. increase in live weight until 500 lbs, was reached. The pigs were selected shortly after weaning and were fed individually, only barrows being used. Feed records before weaning are based on litter averages. One group was composed of pigs farrowed in the spring; the other two of fall pigs. The spring pigs were fed corn, middlings, and tankage (10:4:1) until slaughtered. When started on individual feeding the fall pigs (both lots) were given corn and tankage, 8:1; the proportion of corn was gradually increased during the next 24 weeks to 14:1, and remained constant thereafter. As each 100 lb. increment in live weight was attained a certain number of pigs in each group were slaughtered to secure information as to the weights and quality of the carcasses. The following tabulation is a summary of the combined results of the two groups of fall pigs:

	Num-	im- er of gs.	Initial weight per head.	Daily gain per head during period.	Average daily ration.		Feed per pound of gain.		Dressed
Growth period.	of pigs.				Per head.	Per 100 pounds weight.	Corn.	Tank- age.	at end of period.
Birth to 50 pounds 50 to 100 pounds 100 to 200 pounds 200 to 300 los 300 to 400 pounds 400 to 500 pounds	27 27 22 17 12 5	Days. 144 200 254 312 363	$\begin{array}{c} Pounds, \\ 2.6 \\ 50.4 \\ 99.9 \\ 201.9 \\ 301.0 \\ 402.5 \end{array}$	Pounds. 0.54 .89 1.72 1.78 1.70 1.59	Pounds. 1.57 3.01 5.91 7.15 7.74 7.86	Pounds. 5.92 4.01 3.92 2.85 2.21 1.74	Pounds. 3.05 3.15 3.73 4.25 4.60	Pounds. 0.33 .29 .29 .30 .33	Per cent, 77, 7 83, 4 87, 6 88, 2 88, 2

Influence of weight of pigs on rate and economy of gains.

272

The spring pigs showed the same general results. The time from birth required to reach the successive 100 lb. weights were 125, 182, 231, 286, and 362 days, respectively. The amounts of feed required per pound of gain averaged, respectively, 2.9, 3.9, 4.5, 5, and 5.3 lbs. in the successive growth periods.

Some financial computations are given which suggest that "smaller returns over the total feed cost may be expected from pigs carried beyond the point at which the maximum rate of gain is reached than from those marketed before the rate of gain begins to decrease."

Effect of age of pigs on the rate and economy of gains, W. L. ROBISON (*Ohio Sta. Bul. 335 (1919), pp. 545–575, figs. 11*).—A final detailed report is made of the three experiments noted above. The pigs used were Duroc-Jerseys. The tabulations include the individual weights and feed records of each of the 37 animals from birth to slaughtering. Proximate analyses are presented of the feeds given the spring pigs and the first group of fall pigs, including linseed meal and skim milk fed to some of the pigs in the interval between weaning and individual feeding.

Considerable attention is given to the economic conditions which determine the most profitable time to stop a feeding operation in view of the data secured in the experiments. "The weight at which it is most profitable to market pigs full fed from birth is influenced by the method of proportioning the supplemental feed, by the amounts of supplement used and its relative price with that of corn or other carbonaceous feed, and by the relative price of feed and the market value of hogs." The most profitable market weight was heavier in the case of the groups in which the proportions of supplement was gradually reduced than in the case of the spring pigs where this proportion remained constant.

Three other experiments are briefly reported. (1) Two lots of 35-lb. pigs on rape pasture were compared, one receiving a full grain feed throughout the three 7-week periods of the test, the other a limited (2 to 3 per cent) grain ration for 2 periods and a full feed for the last period. At the end of 14 weeks the limited feed lot were not as heavy nor in as high condition as the full-fed pigs, but during the last third of the experiment they made more rapid gains. Their concentrate requirement per unit of gain was 13 per cent lower than the full-fed lot. (2) A duplication of this experiment with 40-lb. pigs during three 5-week periods yielded similar results. (3) A comparison was made of narrow, medium, and wide rations of corn and tankage during 18 weeks of dry-lot feeding divided into 6-week periods. "The medium ration contained approximately one-half as much tankage as the narrow one, and the wide ration one-half as much as the medium one. In all three rations the proportion of tankage to corn was decreased each week. For the first and second periods the pigs fed the most tankage made the most rapid gains and required the least feed per unit of increase in live weight. For the third period, however, they gained more slowly and required more feed per unit of gain than those of either of the other two lots."

[Swine feeding studies], (*Iowa Sta. Rpt. 1918, pp. 19–22, 29*).—Short preliminary reports are presented of several swine-feeding experiments.

Variously prepared meat meals and tankages (all made up on the 60 per cent protein basis) were tested as supplements to corn in the dry-lot fattening of hogs under the free choice system. A bone and blood meal mixture produced a pound of gain at an outlay of 3.8 lbs. of corn and 0.28 lb. of supplement. With blood meal as sole supplement, 4.2 lbs. of corn and 0.5 lb. of supplement were required for a pound of gain.

A lot of 52-lb. fall pigs fed shelled corn and a mixture of corn gluten feed and tankage (1:1) free choice required 150 days to attain a weight of 250 lbs., and consumed 3.5 lbs. of corn and 0.8 lb. of the mixed supplement per pound of gain. A similar lot fed corn and unmixed tankage reached the same weight in 136 days and used 3.6 lbs. of corn and 0.36 lb. of tankage for a pound of gain. When corn, tankage, and gluten feed were self-fed in separate feeders, it took 157 days, and the consumption per pound of gain was 3.46 lbs. of corn, 0.41 lb. gluten feed, and 0.3 lb. tankage.

In a study of buttermilk powder v, tankage, self-fed with corn, the requirements per pound of gain were in the former case 2.5 lbs. of corn and 0.9 lb, of buttermilk powder, and in the latter 3.1 lbs. of corn and 0.8 lb, tankage. The buttermilk fed lot made 30 per cent better gains. When corn was given in one feeder and a mixture of tankage and buttermilk powder (9:1) in another, the gains were increased 10 per cent over the straight corn and tankage fed lot.

In the course of investigations on forage crops it was found that young alfalfa and blue grass plants have a protein content as high as 40 per cent of the dry weight, but that as the season advances the percentage is reduced below 10. On the other hand, Dwarf Essex rape maintains a fairly constant protein percentage throughout the growing period.

"It has been determined that the lactic and acetic acids found in silage are easily digested and utilized when fed to swine. This means that the acids of rape silage would do no harm to growing pigs. It has also been found that the sulphuric and phosphoric acids which are formed when a grain or other high protein ration is digested are easily neutralized and are harmless to growing pigs. It is not necessary, therefore, to neutralize the acidity of a ration if it is otherwise satisfactory." It was found that an ounce per day of concentrated sulphuric acid properly diluted could be incorporated in a pig's ration without injurious effects. The ingestion of a "fairly large amount of alkali" was also harmless.

"We have some interesting preliminary developments indicating that the more rugged type of swine, as exemplified in the Tamworth or Yorkshire conformation, are of greater practical utility than the smaller, heavier types. Nevertheless, our tests indicate quite strongly to date that the deeply covered, large type of lard hog is highly efficient. The outstanding lesson to date is that the small, short, low-down, refined, heavily jowled, bulging 'hammed' pigs that develop early and stay fat continuously will have a high production cost after the 200-lb. mark is reached, and, furthermore, may experience considerable difficulty in reaching the heavier weights, because this type is more prone to pulmonary difficulties."

Alfalfa meal for fattening pigs, J. M. EVVARD (Breeder's Gaz., 75 (1919), No. 16, p. 918).—At the Iowa Experiment Station two groups of weanling pigs averaging 52 lbs. in weight at the start were fattened on grain and tankage fed separately in self-feeders. The first lot, whose grain ration was shelled corn only, reached an average weight of 225 lbs. per head in 115 days. The second lot, which received a mixture of ground corn and ground alfalfa, did not attain this weight until 138 days, a 20 per cent longer period. The second lot consumed less tankage than the first, but the data on feed cost of gain indicate that about 1.8 lbs. of alfalfa and 3.2 lbs. of corn were required to replace a pound of tankage. Without counting the additional 23 days labor, the alfalfa-fed lot was thus not profitable.

Swine management in Idaho, O. E. McCONNELL (*Idaho Sta. Bul. 116* (1919), pp. 3-35, figs. 14).—A brief treatise on swine management under Idaho conditions, including swine types, housing, feeding, and management, and prevention of disease.

The nutrition of the horse, J. B. LINDSEY (*Massachusetts Sta. Bul. 188* (1918), pp. 243-263).—Some of the classic work on the nutrition of horses is reviewed, and report made of several feeding experiments with two horses during three years under practical working conditions.

A daily ration of 8.5 lbs. of alfalfa hay and 8.5 lbs. of oats and corn (1:4) per 1,000 lbs. live weight, found satisfactory for artillery horses by the Kansas Station (E. S. R., 29, p. 873), did not prove sufficient for the two horses doing "reasonably hard" farm work, as they lost in weight and were restless. Increasing the ration by 10 per cent checked the loss in weight but not the restlessness. Partial replacement of the alfalfa by timothy hay served to reduce the restless action considerably.

"While recognizing the large number of horses in the Kansas experiment and the satisfactory results secured, on the basis of our own observations and the accepted feeding standards, it seems to the writer that the amounts of the several feeds are not likely to be sufficient, nor the combination particularly satisfactory, for most work horses. It is believed that for each 100 pounds of live weight a pound of roughage is a reasonable allowance, and that one-half of this roughage may consist to good advantage of alfalfa, and the balance of a timothy mixture."

Various successful modifications of a grain ration of oats, corn, and bran by the partial or complete substitution of brewers' dried grains, velvet bean-andhull meal, or linseed meal for one of the ingredients are reported on the basis of extended tests. Mixed timothy hay was used in these experiments. It was found that 50 per cent or more of the oats could be replaced by an equal weight of brewers' grains. Mixtures of oats, corn, velvet-bean feed, and bran (5:8:2:2 and 5:7:3:2) were given continuously for over 3 months and "the results were in every way satisfactory." Linseed meal was fed as a grain supplement for 10 weeks and proved practicable. The mixture mostly used was oats, whole corn, and linseed meal (5:8:1). A higher proportion of linseed meal was not so well relished, as the meal did not mix well with the unground corn.

Egg-weight as a criterion of numerical production in the domestic fowl, P. [B.] HADLEY (Science, n. ser., 49 (1919), No. 1270, pp. 427-429).—A year's egg records of 31 hens (breed not specified) at the Rhode Island Experiment Station are summarized to show that the relative difference between the average weight of the 10 or fewer eggs laid by a hen at the period of highest production of the flock in September and the average weight of the first 10 eggs she lays at the beginning of the laying year is a good index of her yearly production. Similar but less striking results are claimed when egg weights during the April peak in production are used in the same comparison. It is held that higher producing hens can be identified more readily by the greater increase in the weight of their eggs than by any other means. A tentative announcement of a "fundamental law" of egg production is made embodying these facts.

## DAIRY FARMING-DAIRYING.

Dairy production in Ohio, R. I. GRADY and M. O. BUGBY (*Ohio Sta. Bul. 334* (1919), pp. 509-541, figs. 3).—This bulletin is a report on the cost of producing milk as revealed by 84 yearly records of 33 Ohio dairy herds during the period 1910-1915. Two preliminary reports have been noted (E. S. R., 37, p. 575; 40, p. 375). The methods of collecting the data are explained in detail, and the blank forms supplied to collaborators are reproduced. A noteworthy feature of the report is the fact that the individual herd averages of all the items

274

entering into the computations (except inventory values of cows) are tabulated as well as the area of the farm, the size of the herd, the predominating breed, and the highest and lowest milk and butter fat production in each herd.

The average amounts of feed and labor in all herds consumed annually per cow were as follows: Grain 1,534 lbs., silage 4,971 lbs., hay 1,462 lbs., stover 1,065 lbs., green feed 484 lbs., pasture 187.2 days, man labor 162.8 hours, and horse labor 26.8 hours. About 62 per cent of the grain was purchased. Feed constituted 54 per cent, labor 28 per cent, and other charges 18 per cent of the total cost. The average expenditures for items other than feed and labor are also computed as percentages of the average inventory value of a cow (\$69.70), viz: Land and building charge 8.1, equipment 3, interest, insurance, and taxes 6.3, service fees 2.5, depreciation 3.5, and miscellaneous 4.3, making a total of 27.7 per cent. As evidence that this method of dealing with such items leads to uniform results, the data furnished by Bulletin 501 of the U. S. Department of Agriculture (E. S. R., 36, p. 873) are treated in a similar manner and the items total 27.9 per cent of the inventory value of a cow.

The fertilizing constituents recovered in the manure of a cow are computed for each herd. The average estimates are nitrogen 103.9, phosphoric acid 42.9, and potash 78.4 lbs. The average annual milk production was 5,884 lbs., and the average butter fat 255.4 lbs. The total returns from milk, calves, and manure averaged \$124.62 per cow, while the expenses average \$98.55, leaving \$25.47 net returns. In five of the farms the expenses exceeded the gross returns. The net cost of producing milk, including loss on young stock, was \$76.66 per cow, or \$1.30 per 100 pounds of milk. In July, 1918, it is estimated, the net costs would have been \$1.78 and \$2.61, respectively. No charge for managerial ability was added to these costs.

"In fixing a price for milk, it would be unjust to use the average cost of production, as this would cause about one-half of the dairymen to operate at a loss, and no line of business could long endure such conditions. If 20 per cent of the dairymen who furnished the foregoing data had been eliminated because of inefficiency, a price could not justly have been set at a lower figure than \$1.58 or, under July, 1918, prices, approximately \$3.58. If seasonal variations were computed according to Warren's suggestion, such a price would range from about \$2.50 to \$4.30 per 100 lbs."

The composition, digestibility, and feeding value of alfalfa, J. B. LINDSEY and C. L. BEALS (*Massachusetts Sta. Bul. 186 (1918)*, *pp. 105–141*).—This paper considers alfalfa as a feeding stuff with special reference to its value in milk production, and is intended partly as a complement to a study of alfalfa culture in Massachusetts previously noted (E. S. R., 31, p. 735). Seven feeding *f* experiments with dairy cows are reported, each conducted by the reversal method during two periods. From 4 to 8 cows were used in each. In experiment 6 the periods were 4 weeks long; in the others, 5 weeks.

Experiments 1 to 3 compare alfalfa hay, beet pulp, and corn meal with firstcut mixed hay, beet pulp, and corn gluten feed or meal. The hay in each ration furnished about 71 per cent of the dry matter. The 5 weeks' milk yield of the 22 animals on the alfalfa ration totaled 15,866 lbs. and on the mixed hay ration 15,733 lbs. Since there was a small difference in favor of the alfalfa ration in each experiment, this result is held to indicate a slight stimulating effect of alfalfa on milk flow. The animals showed a total increase in weight of 13 lbs. on the alfalfa and 481 lbs. on the mixed hay ration, a difference attributed to the lower energy value of alfalfa. The total protein in the milk (N×6.25) produced by the alfalfa ration was 545.3 lbs. and by the mixed hay ration 558.8 lbs. The total milk solids were, respectively, 2,125 and 2,149 lbs. These results show that the protein of the alfalfa rations, 78.2 per cent of which was from alfalfa hay, was as satisfactory a source of protein for milk formation as the mixed hay rations where 58.1 per cent of the protein came from the beet pulp and corn gluten. No marked influence of the diuretic effect of alfalfa was discovered on either milk yield or the milk ingredients.

Experiments 4 and 5 compare alfalfa hay and rowen (hay from second cutting of mixed grasses). The grain in both rations was the same, corn meal and wheat bran (7:3). In experiment 4, alfalfa apparently increased the milk yield 5.2 per cent, but in the fifth experiment there was only a 0.5 lb. difference in the totals of the two rations.

The milk produced per 100 lbs. of dry matter consumed was in the case of the alfalfa ration 97.76 lbs., and in the case of the rowen 93.77 lbs., while the amounts of fat produced per unit of dry matter were identical. In digestion trials conducted in connection with these experiments, the digestibility of the rowen protein was only 60 per cent whereas the average of previous trials is 70. The alfalfa protein was 72 per cent digestible.

In experiment 6 a mixture in equal parts of alfalfa and English hay was compared with unmixed English hay. Gluten feed was used as a protein supplement to the latter. Corn-and-cob meal and bran formed part of each ration. The milk yields totaled, respectively, 5,540 and 5,602 lbs., with only triffing differences in the milk solids.

Experiment 7 was a repetition of the sixth except that corn stover was substituted for English hay in the alfalfa ration. The latter ration produced 8.2 per cent less milk and 8.6 per cent less milk solids than the English hay ration. "The writer is convinced that the milk shrinkage on the alfalfa ration was due largely to the corn stover. While of good quality it was stooked out-of-doors and brought to the barn every few days and cut fine before being fed. It varied considerably in moisture content, depending upon the weather. If the stover had been brought from the field in November and stored under cover, in all probability more satisfactory results would have been secured."

Proximate analyses are given of the samples used of mixed hay, alfalfa hay, English hay, rowen, corn stover, corn-and-cob meal, corn meal, corn gluten meal, corn gluten feed, wheat bran, beet pulp, and molasses beet pulp. Available analytical data for green alfalfa and red clover at various stages of growth are also summarized. The results of new digestion trials with alfalfa hay (2 series), red clover, and rowen are reported.

The tabulations include the milk, the milk solids, and the fat produced by individual cows in each experiment. For experiments 1 to 5, the nitrogen in the milk is also tabulated individually.

In summing up their work, the authors state that "in the light of our present knowledge it is preferable, particularly in the Eastern States, not to use alfalfa as the entire source of roughage for milk production, but to feed one-half alfalfa and one-half hay, or two-thirds alfalfa and one-third corn stover, or 10 to 15 lbs. of alfalfa and 1 bu. of silage daily. Such combinations, together with a grain ration of 10 to 80 per cent corn-and-cob meal and 20 to 30 per cent wheat bran or oats or barley, ought to give quite satisfactory results."

The value of corn bran for milk production, J. B. LINDSEY and C. L. BEALS (*Massachusetts Sta. Bul. 186* (1918), pp. 142–153).—To compare corn bran and wheat bran for milk production two experiments are reported with 6 and 8 cows, respectively, each ration being tested by the reversal method during two 5-week periods in each experiment. The basal ration consisted of mixed hay, corn gluten feed, ground oats, and cottonseed meal. Four pounds of the appro-

priate bran was daily given to each animal. During wheat bran feeding 1.2 per cent more milk and 1.3 per cent more butter fat on the average were produced.

Proximate analyses of the feeding stuffs used are reported. The corn bran was noticeably lower than the wheat bran in ash, protein, and fat. It is stated that digestion trials made at the station with sheep show that the coefficient of digestibility of dry matter of corn bran is 80 and of wheat bran 66.

Milking machines: III, As a source of bacteria in milk. IV, Methods of maintaining in a bacteria-free condition, G. L. A. RUEHLE, R. S. BREED, and G. A. SMITH (*New York State Sta. Bul. 450 (1918)*, pp. 113–181, figs. 11).— These studies, of which a preliminary report has been noted (E. S. R., 38, p. 377), are grouped in a series with two previous bulletins (E. S. R., 28, p. 472) and include observations of the use of milking machines on the station herd and at 10 commercial dairy farms.

To study the milking apparatus as a source of bacteria, an artificial udder was constructed from which sterile water was "milked" by the machine. To determine at what stage bacteria gets into the water, means were devised for collecting samples at two points in its passage into the pail. The chief source of bacteria was found to be the teat-cups and rubber tubes, although the pail in some cases was an important medium of infection. The suction trap placed upon the recent types of one of the makes of milking machines used was found to be efficient in preventing the return of contaminated condensation water from the vacuum piping to the pails.

The stable air which enters the machine during milking was analyzed and found not to be responsible for increasing the bacterial content more than 34 per cubic centimeter under the worst conditions tested. The cotton filters for which provision is made on one machine were found to remove more than twothirds of the bacteria from the air and also a small amount of dust. Since the total amount of contamination from the air was insignificant, the improvement due to the filters was too slight to be detected in ordinary analyses of machinedrawn milk.

Dropping the teat-cups to the floor in dirty bedding was found to cause relatively large amounts of dirt to appear in the pails of the machines; but the bacteriological analyses of the sterile water, milked through the machine at the same time, did not reveal excessively high counts. These conditions failed to give counts in excess of 25,000 per cubic centimeter. Here, as in other studies of the amount of bacterial contamination derived from dust, the germ count was found to be an unsatisfactory index of the amount of dirt and filth present.

Although it was found possible to sterilize milking machines completely by means of steam applied to the metal parts and by harmless antiseptics on the rubber parts, the precautions necessary are considered impracticable where certified milk is produced and quite impossible on the average farm. Satisfactory bacterial results were secured where practicable methods were used for keeping the machines cleaned, provided the teat cups and tubes were immersed in any of the following antiseptic solutions: (1) Brines containing at least 10 per cent of salt; (2) solutions of chlorid of lime; (3) a combination of brine and chlorid of lime; (4) lime water; (5) cold running water; and (6) a commercial germicide, which, however, is not recommended for general use, because a trace of it gives milk a disagreeable taste. Chlorid of lime and running water were ineffective if the temperature of the solution was as great as  $60^{\circ}$  F. The solution recommended for general use is chlorid of lime dissolved in a saturated brine. Antiseptic solutions were not found to be successful unless the teat cups and tubes were maintained in a cleanly condition. Control of bacteria in milking machines, F. H. HALL (New York State Sta. Bul. 450, popular ed. (1918), pp. 3-15, fig. 1).—This is a popular edition of the above.

Clarification of milk, I, C. E. MARSHALL, E. G. HOOD ET AL. (*Massachusetts Sta. Bul. 187 (1918)*, pp. 151–242, figs. 10).—The amount and nature of clarifier slime and the immediate effect of clarification upon milk are the topics considered.

A section on the clarification of certified milk by the late E. L. Davies, an officer in the Canadian Army, is included. It records the percentage of slime secured in 440 tests of the milk of 74 cows, together with the breed and age of the cow and the stage of lactation. The average slime percentage was 0.067. In 16.8 per cent of the tests the slime percentage was 0.1 or over. In 14.7 per cent of the cases the slime was bloody.

The authors add to these data a number of other determinations, showing particularly that increased temperature and increased time of holding (resulting in greater acidity) tend to increase the amount of slime (dry weight) from a unit amount of milk, and comment as follows: "The amount of slime differs widely when secured from the milk of the same cow, from milk of different individual cows, and from mixed milks, whether the mixed milks have the same origin or not. It is also manifest from the work of this laboratory that samples from the same milk when clarified under the same conditions yield practically the same amount of slime. It follows, therefore, that the causes for these variations must be found in the condition of the animal, the conditions which surround the manipulation of the milk, and the conditions which are involved in the clarification. From Lieut. Davies's investigations it seems clear that with the beginning of the period of lactation there is a great This may be attributable to the colostral milk, in which increase of slime. colostral cells are numerous. Evidence also seems to point directly to inflammatory conditions of the udder as a cause of increase; garget and other products of inflammation and germ action within the udder are common, probably much more so than is usually recognized."

The slime was found to be composed of insoluble dirt, bacteria, leucocytes ("so-called"), fibrin ("so-called"), and any garget discharge present in the milk. A number of quantitative determinations of the bacteria and leucocytes are recorded. The clarifier was found more efficacious in the removal of insoluble dirt than the cotton filters used in the Wisconsin sediment test. Some observations are included as to the solubility of manure and stable dirt in water and milk. It is held that the reduction, if any, in the nutritive value of milk as the result of clarification may be disregarded.

The leucocyte counts before and after clarification are tabulated for 25 samples of certified milk and 6 samples of commercial milk, and bacterial counts for 37 certified and 15 commercial milk samples, while several similar series of counts are assembled from the literature. In about 70 per cent of the tests of fresh certified milk clarification effected a reduction in bacterial content as shown by plating methods. Milk held before clarification seemed to increase its bacterial count by clarification to an extent more or less proportional to the length of holding. These results are thought to indicate that fresh certified milk is relatively free from clumps of bacteria, whereas clumping takes place in held milk. The disruption of clumps through clarification is considered the cause of the increased counts. Only 10 or 15 per cent of the market milk samples showed decrease in bacterial counts after clarification, an indication of extensive clumping.

Ten graphs are given comparing cultures of clarified milk, unclarified milk, and clarified milk plus slime with respect to the number of colonies visible at two-hour intervals for 72 hours after plating. Tables are also given showing the effects of clarification upon pure cultures of several species of bacteria.

Study of Babcock test for butter fat in milk (*Iowa Sta. Rpt. 1918, p. 30*).— "The Babcock test for milk, when read from the top on the upper meniscus to the bottom of the lower meniscus, gave results which are higher than those obtained by the gravimetric (Roese-Gottlieb) method. On the average of 190 comparisons, as carried out in the work reported, the difference amounted to 0.06 per cent... The Babcock test would read about 0.11 per cent low, depending somewhat on the per cent of fat in the sample, if the meniscuses were not included in the reading."

"The amount of fat left in the liquid below the fat column is quite variable and on the average equaled 0.13 per cent expressed as reading on the neck of the test bottles. There were impurities in the fat column that on the average amount to 0.78 per cent of the reading."

A bacteriological study of the method of pasteurizing and homogenizing the ice cream mix, B. W. HAMMER and L. R. SANDERS (*Iowa Sta. Bul. 186* (1919), pp. 17-26).—As part of a series of bacteriological studies of ice cream (E. S. R., 38, p. 868), the authors have made bacterial counts of nine pasteurized and homogenized mixes and of the ice cream made therefrom.

The heating of the mix to about 145° F. but without holding resulted in a decrease in bacteria of from 91.5 to 99.5 per cent, the average being 96.4. Part of each pasteurized mix was run through the homogenizer without pressure to see whether the machine might be an important source of contamination. In all cases the count was higher after such a run and was generally more than doubled. "The homogenizer was given what was considered to be satisfactory care, since it was thoroughly washed after use, and then in most runs flushed with boiling water just before use." In 6 cases the rest of the mix, which was run through under the usual pressure, had a lower content than the nonpressure portion, sometimes approximating that of the mix immediately after pasteurization. The operation of the machine under pressure is thought to have a tendency to break up clumps of bacteria. In 4 runs the homogenized mix was passed over a cooler and the bacterial count was thereby increased slightly.

## VETERINARY MEDICINE.

Regional anatomy of domestic animals, L. MONTANÉ and E. BOURDELLE (Anatomic Régionale des Animaux Domestiques. Paris: J. B. Baillière & Sons, 1913, vol. 1, pts. 1, pp. VII+512; [2], pp. 513-1069, figs. 564; 1917, vol. 2, pp. [VI]+384, figs. 259).--Volume 1 of this work deals with the horse and volume 2 with ruminants.

Farm hygiene, P. REGNARD and P. PORTIER (*Hygiène de la Ferme. Paris:* J. B. Baillière & Son, 1917, 2. ed., pp. 441, figs. 167).—This volume, which is one of the Encyclopédie Agricole published under the direction of G. Wery, deals particularly with infectious diseases and parasites attacking farm animals, their control, and remedial measures.

The municipal abattoir at Alexandria, Egypt, F. PIOT BEY (Notice sur l'Abattoir Municipal d'Alexandrie (Egypte). Alexandria: Whitehead, Morris & Co. (Egypt), Ltd., 1917, pp. 47, pls. 22, fig. 1).—A detailed account of this municipal slaughterhouse.

Seventh annual report of the commissioner of animal industry for the year ending November 30, 1918, L. H. HOWARD (Ann. Rpt. Comr. Anim. Indus. [Mass.], 7 (1918), pp. 46, figs. 3).—Included in this report on the occurence of and work with infectious diseases are charts showing the reported num-

ber of cases of bovine tuberculosis, glanders, and rabies in Massachusetts for the 10-year period ended 1918.

Report of proceedings under the diseases of animal acts, with returns of the exports and imports of animals for the year 1917, D. S. PRENTICE (*Dept. Agr. and Tech. Instr. Ireland, Rpt. Diseases Anim., 1917, pp. 30*).—The usual annual report (E. S. R., 38, p. 180).

Veterinary service and meat inspection in Norway in 1917 (Norges Off. Statis., 6. ser., 1917, No. 148, pp. VII+213).—The usual annual report (E. S. R., 39, p. 787).

Veterinary research, annual report of director, 1916–17, A. THEILER (Union So. Africa Dept. Agr. Rpt. 1916–17, pp. 45–50).—A brief statement of investigations carried on during the year.

Report of the government bacteriologist, C. J. POUND (Ann. Rpt. Dept. Agr. and Stock [Queensland], 1915–16, pp. 88–91, pl. 1).—Included in this report of work of the year are accounts of further observations with reference to alleged tick-resisting cattle, the fertility of ticks matured on so-called resistant cattle, and further observations on the life history of the warble fly (Hypoderma bovis).

Studies in forage poisoning.—The relation of B. botulinus to forage poisoning or cerebrospinal meningitis in horses, R. GRAHAM and A. L. BRUECKNER (Jour. Bact., 4 (1919), No. 1, pp. 1-21, figs. 4).—This is a report of investigations, a reference to which has been previously noted (E. S. R., 39, p. 387).

"A goat injected with sublethal doses of broth culture of the bacillus (ss) isolated from the silage developed an antitoxic serum which, injected intraperitoneally, apparently protected guinea pigs against a fatal amount of the homologous toxin per os. The protective nature of the goat serum was also observed in guinea pigs receiving fatal amount of *B. botulinus* per os.

"*B. fbotulinus* antitoxic serum prepared from a mule and injected intraperitoneally into guinea pigs apparently provided a protection against 10 times the lethal amount of the culture filtrate of the bacillus (ss) isolated from the silage and against 5 times the lethal dose of the unfiltered broth culture.

"Two horses ingested in wholesome feed 2 cc. broth culture of the bacillus (ss) isolated from the silage and were apparently protected by an intravenous injection of *botulinus* antitoxic serum. A control horse receiving a similar amount of the unfiltered broth culture manifested clinical symptoms of forage poisoning and died. Post-mortem examination revealed gross anatomic lesions analogous to some of the gross lesions observed in animals naturally afflicted with forage poisoning.

"Serum immune to *B. botulinus* possessed a positive agglutinating potency toward the homologous strain, as well as toward the bacillus (ss) isolated from the silage. The agglutinins present in serum immune to the bacillus (ss) isolated from the silage were active against *B. botulinus* as well as against the homologous strain.

"The cultural, morphological, pathological, and serological relation observed between *B. botulinus* and the bacillus isolated from the silage in preliminary experiments are suggestive of the possible etiologic significance of *B. botulinus* or closely allied anaerobes in some outbreaks of forage poisoning or cerebrospinal meningitis in horses."

**Report of the department of chemistry**, C. A. JACOBSON (Nevada Sta. Rpt. 1918, pp. 39-44, figs. 3).—This report relates to investigations made with a view to isolating and characterizing the toxic constituent of a species of death camas which occurs in Nevada and is quite different from Zygadenus intermedius studied at the Wyoming Station (E. S. R., 30, p. 412), being most nearly

1919]

like Z. paniculatus. This form grows at an elevation of from 5,500 to 7,000 ft. and covers a wide area over the Sierra foothills to considerable distances up the mountains.

Considerable losses to sheepmen due to this death camas have been recorded, but nearly always when the pasturage was scanty or following a long and exhausting drive of the herd, there being scarcely any danger from it when the sheep are kept grazing under normal conditions.

The name Z-alkaloid is given to the poison liberated, for the sake of convenience in referring to it. It was found to be soluble in ethyl and methyl alcohol, chloroform, and acetone, but much less in benzene and carbon tetrachlorid. With one exception all attempts to obtain a crystalline product from all these solvents by varying the conditions, such as time, temperature, and pressure, failed. The yield of the purified Z-alkaloid was found to be only about 0.3 per cent of the weight of the dried death camas plant. The crude alkaloid was tested and found poisonous to rabbits. The toxicity of the plant has been determined at different periods of growth and found to be poisonous at all periods except when the plant has dried up in late summer. While the physiological action of the poison has not been carefully studied, it produced at first twitchings of the head and limbs, then a comatose condition with rapid and shallow respiration, after which the animal died in a convulsion. The Z-alkaloid has no relation to zygadenin isolated at the Wyoming Station,

Curative treatment of bush sickness by iron salts, C. J. REAKES and B. C. ASTON (Jour. Agr. [New Zeal.], 18 (1919), No. 4, pp. 193–197, figs. 2).—" Summarizing the results of the medicinal experiments to date, it would appear that of the inorganic preparations, while either the administration of (a) phosphates or (b) iron compounds to cattle on phosphate-dressed pasture may enable them to be kept healthy for a much longer period than otherwise would be possible, it is only by drenching with a sirup-of-iron phosphate that animals may be kept healthy indefinitely or cured of bush sickness. Of organic compounds, it is certain that the double citrate of iron and ammonium is a quicker cure for bush sickness than the sirup-of-iron phosphate. It is probable that other organic salts of iron would be similarly successful."

Castor bean meal as a poultry food, H. T. ATKINSON (Utility Poultry Jour. [Harper Adams Agr. Col.], 4 (1918–19), No. 2, p. 21).—Feed consisting of 1 part castor bean meal and 5 parts mixed meal comprised of sharps, ground oats, etc., was fed to cockerels in quantities of 4.5 to 5 oz. per bird each day, a little grain food being given in addition and grit and water also being available. The feed was eaten eagerly, but the birds steadily lost weight, and by the end of 3 weeks the total loss in weight was 4 lbs. 10 oz. The loss in weight continued steadily and at the end of the thirty-sixth day one bird died, followed 4 days later by another. On the fortieth day the castor meal feed was discontinued and the 4 remaining birds fed on ordinary meal. After the change of food the birds commenced to recover slowly, but at the end of 3 weeks had put on but very little flesh.

The principles of acidosis and clinical methods for its study, A. W. SEL-LARDS (*Cambridge: Harvard Univ. Press, 1917, pp. VI+117, pl. 1*).—The several chapters of this work deal with the equilibrium between acids and bases, methods of diagnosing acidosis, behavior of the body in health, and in acidosis toward sodium bicarbonate, relative value of the various tests for acidosis, definition of acidosis, occurrence of acidosis, therapy, differential diagnosis, and etiology of acidosis. A résumé follows and technique of methods is dealt with in an appendix. A bibliography of 71 titles is included. Anaphylaxis, allergy; antianaphylaxis, antiallergic therapy, R. KRAUS (*Rev. Inst. Bact. [Argentina]*, 2 (1919), No. 1, pp. 1–18).—This is a summary of modern investigations and theories regarding experimental anaphylaxis and its chemical relationship to allergy.

Anaphylatoxin and anaphylaxis.—XI, Ultra-filtration and fractionation of anaphylatoxin, P. H. DEKRUIF and A. K. EGGERTH (*Jour. Infect. Diseases*, 24 (1919), No. 6, pp. 505–532).—In continuation of the study of anaphylatoxin and anaphylaxis previously noted (E. S. R., 37, p. 578), an attempt has been made to locate the toxic principle of anaphylatoxin by applying various methods of fractionation of serum proteins and by ultrafiltration.

It was found that the toxic principle of rat and guinea pig anaphylatoxin could be recovered on the globulin fractions of the serum. Various methods of isolating these fractions were studied. The best results were obtained by removal and purification of the serum proteins by precipitation of the serum in the cold with absolute alcohol or acetone and extraction of the precipitate with ether. In this process the toxic principle was recovered quantitatively on the serum proteins, and by fractionation was concentrated on the euglobulin fraction.

By means of ultra-filtration, using a membrane prepared from a solution of celloidin in alcohol-ether with castor oil and glycerin as modifying agents, 79 per cent of the total serum protein could be filtered off with a total retention of the toxic principle in the sac. The results obtained are considered "important in that they furnish an excellent and simple means of concentrating the toxic principle, furnish material for a tentative hypothesis of the nature of the toxin, and effectively exclude the notion that protein degradation products are concerned in this toxicity."

A preliminary report of the fractionation of primarily toxic normal and immune sera is also given. Such toxins are not recovered on the euglobulin fraction as in the case of anaphylatoxin but on the water-soluble globulin.

On the separation of antitoxin and its associated proteins from heatdenatured sera, A. HOMER (*Biochem. Jour.*, 13 (1919), No. 1, pp. 45-55).—The investigations on antitoxic sera previously noted (E. S. R., 40, p. 288) have been extended to determine (1) "to what extent the limits for the precipitation with ammonium sulphate can be narrowed so as to include, in the second fraction precipitates from heated sera, only those proteins with which the antitoxin is definitely associated, and (2) whether or no the antitoxin is evenly distributed throughout the protein fractions precipitated at successive stages between the limits indicated in (1)."

The results indicate that, for the complete recovery of antitoxin during the concentration of sera showing a heat-denaturation of 35 per cent or less by fractional methods employing the use of ammonium sulphate, it is advisable to precipitate the second fraction between 30 and 45 per cent of saturation with the sulphate, as reduction of the upper limit results in incomplete precipitation of pseudoglobulin and antitoxin and raising of the lower limit results in the precipitation of antitoxin in a form not readily soluble in brine.

In heated sera showing a denaturation of 35 per cent or less, the bulk of the antitoxin is associated with the proteins precipitated between 36 and 45 per cent of saturation with ammonium sulphate. The further fractionation of the protein isolated between these limits "showed that the percentage of the total antitoxin precipitated between progressively increasing percentages of saturation with the sulphate is directly proportional to the percentage precipitation of protein at the respective stages. From these observations it is clear that, in order to isolate antitoxin, means other than the fractional precipitation of the serum proteins must be employed." On the increased precipitability of pseudoglobulin and its associated antitoxin from heat-denatured solutions, A. HOMER (*Biochem. Jour.*, 13 (1919), No. 1, pp. 56-64, figs. 3).—The conclusion drawn in the above paper that in order to isolate antitoxin as a separate entity means other than the fractional precipitation of pseudoglobulin solutions by salts must be employed is further substantiated by the results of this study, which are summarized as follows:

"(1) The increased precipitability of pseudoglobulin from its heat-denatured solutions at concentrations of ammonium sulphate ranging from 26 to 47 per cent of saturation is a function of the heat-denaturation. (2) The increased precipitation of pseudoglobulin thus induced in (1) at 30 per cent of saturation with ammonium sulphate is accompanied by an increased precipitation of antitoxin. With the least extensive denaturation, the percentage of the total proteins precipitated at this stage is greater than that of the antitoxin; as the denaturation increases the further increased precipitability of the protein becomes a linear measure of the increased precipitation of the antitoxin. (3) In the concentration of antitoxin sera by the fractional precipitation of the serum with ammonium sulphate, there is no need for a preliminary prolonged heating of the serum. The results that are now obtained by the isolation from the heated serum of the protein fraction precipitated between 30 and 44 per cent of saturation with ammonium sulphate could be obtained from the unheated serum between 36 and 50 per cent of saturation with the sulphate."

Vaccines and sera, their clinical value in military and civilian practice, A. G. SHERA (London: Henry Frowde and Hodder & Stoughton, 1918, pp. XXI+ 226).—This book deals with the clinical value of vaccines and sera in military and civilian practice, illustrated largely by cases from the author's own experience. In addition to the subject matter proper the book contains an introduction by C. Allbutt, a classification of vaccines and sera according to their therapeutic value from the prophylactic and curative standpoint, a glossary of terms, and a list of literature references.

Sodium oxy-mercury-ortho-nitro phenolate (mercurophen) with special reference to its practical value as a disinfectant, J. F. SCHAMBERG, J. A. KOLMER, G. W. RAIZISS, and M. E. TRIST (*Jour. Infect. Diseases, 24 (1919), No. 6, pp. 547-582, figs. 5*).—This is a more extended report of the properties and disinfecting value of mercurophen previously noted (E. S. R., 38, p. 481). Throughout the study other mercurial preparations, particularly mercuric chlorid, were employed for comparative tests which are reported in detail.

Mercurophen or sodium oxy-mercury-ortho-nitro phenolate was found to possess certain superior properties over other mercurial compounds, as follows:

In germicidal activity, mercurophen is equal or superior to mercuric chlorid and other mercurial compounds containing more mercury. It is generally more rapid in its germicidal action and less toxic than other mercurial compounds. It appears to possess a special destructive affinity for cocci and spore-forming bacilli, is capable of temporarily raising the bactericidal action of the blood after intravenous administration, is somewhat more trypanocidal than mercuric chlorid, and maintains a higher degree of germicidal activity in blood serum.

Mercurophen does not precipitate protein in as high concentrations as 1:100, nor does it irritate the skin or tarnish surgical instruments. It has proved superior to mercuric chlorid in the disinfection of urine, feces, sputum, pus, catheters, instruments, rubber gloves, and the skin.

The subcutaneous injection of Tallianine in cases of respiratory disease, J. F. D. TUTT (*Vet. Jour.*, 75 (1919), No. 527, pp. 180-184).—From the experiments conducted and here reported upon it is concluded that "Tallianine, if used early and repeated at intervals, has a marked effect in cases of respira-

[Vol. 41

tory disease, and is the best remedy so far discovered for subcutaneous medication. Its action is rapid, an alteration in respiration has been observed within 10 minutes of inoculation, and usually within 30 minutes in every case.

"It can be used when the administration of medicines per os is impracticable. It should 'bubble' on exposure to the air. In some supplies this was not observed, and in these cases there was little or no benefit from its use. It can be used for smaller animals, such as the dog, in doses of 3 to 5 cc. in cases of the respiratory form of distemper, and has given good results."

Studies on anthrax vaccine.—III, Accidents following vaccination, R. KRAUS and P. BELTRAMI (*Rev. Inst. Bact.* [Argentina], 2 (1919), No. 1, pp. 98–113, figs. 5).—This is a continuation of work previously noted (E. S. R., 40, p. 582).

Reports are given of accidents following vaccination which emphasize the necessity of an official control of the preparation of the vaccine. It is thought that certain intercurrent diseases and other factors such as pregnancy lower the natural resistance of the animal and decrease the artificial immunity conferred by the vaccine. The virulence of vaccine II does not increase in the organism provided it is not virulent for rabbits, but vaccines which are virulent for rabbits are liable to increase in virulence and are thus dangerous to use.

The treatment of human anthrax with normal bovine serum, IV, J. PENNA, J. BONORINO CUENCA, and R. KRAUS (*Rev. Inst. Bact.* [Argentina], 2 (1919), *No. 1, pp.* 89–97).—Further success is reported in the treatment of human anthrax with normal bovine serum (E. S. R., 40, p. 582). In 372 cases thus treated the mortality was only 6.2 per cent.

Malignant epizootic aphtha (foot-and-mouth disease), SACCO (Vet. Jour., 75 (1919), No. 526, pp. 139–141).—A grave form of foot-and-mouth disease has been spreading through Italy since the beginning of December, having already extended over upper and middle Italy. In certain byres in Lombardy 50 of 100 animals are said to have been lost within a few days.

The trypanosomes found in domestic mammals in south-central Africa, H. V. HORNBY (Vet. Jour., 75 (1919), No. 526, pp. 128–138).—"The common trypanosomes found in domestic mammals in south-central Africa are three in number, viz., Trypanosoma brucei, T. congolense, and T. vivax.

"They are readily distinguishable by their morphological characters. *T. brucei* is very fatal to equines, smaller ruminants, and dogs, but is almost nonpathogenic for cattle. *T. congolense* is the commonest cause of trypanosomiasis of cattle, but it is also pathogenic for the other domestic mammals. *T. vivax* resembles *T. congolense* in the forms of disease it causes in stock. Dogs are generally immune to its ill effects.

"The distribution of these parasites is coincident with that of tsetse flies. Different strains of the same species of trypanosome vary greatly in their range of virulence. Individuals and races of the same species of domestic animal vary greatly in the resistance they offer to infection. The presence in the blood of one species of parasite appears to inhibit the development of another.

"A fourth species, *T. simiw*, causes disease in pigs. It is conceivable it may be only a variety of *T. congolense* modified by passages through the warthog."

The tuberculin test at Jackson, Mich., T. H. BROUGHTON (*Purdue Agr.*, 13 (1919), No. 8, pp. 367-369, 398, 400).—The tuberculin test was started in June, 1915, and all cattle supplying milk for the city of Jackson were tested. Four and two-tenths per cent reacted and were slaughtered. The second year only 2 per cent reacted to the test, and a considerable number of the reactors were from herds that were not tested the previous year, due to the fact that they were not producing milk for the city.

**Recent** discoveries concerning the life history of Ascaris lumbricoides, B. H. RANSOM and W. D. FOSTER (*Jour. Parasitology*, 5 (1919), No. 3, pp. 93-99).—The authors here review the results of recent investigations of A. *lumbricoides*, and report upon studies carried on in continuation of those previously noted (E. S. R., 38, p. 385).

The authors have found that in guinea pigs and rabbits the larvæ behave in respect to their development, migration, and elimination as they do in rats and mice, and in respect to the fact that they are liable to cause a more or less serious pneumonia. They have come to the conclusion that the real explanation of the behavior of Ascaris larvæ in rats and mice is that the worms are merely going through the same course as they do in their usual hosts, man and pig. The only essential difference is that in unsuitable hosts, such as rats and mice, the parasites are unable to complete their development to maturity, whereas, in human being and pigs, after their migration through the lungs and return to the alimentary tract they can continue their growth to the adult stage.

The fact that immature worms that had developed beyond any stage yet obtained from rats, mice, guinea pigs, or rabbits were recovered from a young goat and a lamb after having fed them eggs of the pig Ascaris and other experiments lend support to the common belief that *A. ovis* occasionally found in sheep is merely the pig Ascaris in a strange host. "In a scale of host adaptations we may, therefore, recognize three grades—rats, mice, guinea pigs, and rabbits in the lowest, sheep and goats in the intermediate grade, and pigs in the highest, with which we may also include human beings, if it be true that the Ascaris of man and of the pig are identical. . . .

"The symptoms shown by experimentally infected pigs at the time of the invasion of the lungs by the larvæ are frequently exactly similar to those exhibited by pigs suffering from so-called 'thumps,' a popular name for a serious condition of very common occurrence among pigs, and it is accordingly not improbable that Ascaris is an important factor in the production of 'thumps,' especially when it is considered how very commonly Ascaris occurs as a parasite of pigs."

The factors which bring about the hatching of the eggs have not yet been determined, the authors having been unable to cause more than a very small percentage of the eggs to hatch outside the body in vitro.

A list of 17 references to the literature is appended.

Recent experiments on the life history of Ascaris lumbricoides, F. H. STEWART (*Brit. Med. Jour., No. 3030 (1919), p. 102*).—The author first refers to the report of Ransom and Foster, previously noted (E. S. R., 38, p. 385), after which he reports several experiments with young pigs in continuation of the work previously noted (E. S. R., 39, p. 587).

Doses of 22,000 ripe eggs of A. suilla each administered to two 4-day-old pigs (A and B) and a dose of about 50,000 eggs to a pig (C), 2 months and 10 days old, resulted in the two former suffering from Ascaris pneumonia on the eighth day after infection, while the latter, or older pig, showed no sign of pulmonary trouble.

"Pig A was killed on the fourteenth day, and young forms of Ascaris measuring between 2.5 and 3.8 mm. [0.1 to 0.15 in.] were found in great numbers in the small intestine and cecum. Their heads had lost the appearance of the larval head and had taken on the adult head character. Pig B was killed on the nineteenth day, and although there can be no doubt that on the eighth day the lungs contained thousands of active larvæ, not a single worm was found in the stomach, small intestine, cecum, or colon. The nature of the feces found in the colon proved that the pig was not suffering from diarrhea  $132688^\circ-19-7$ 

due to excessive infection, which might have accounted for the disappearance of the worms. Pig C was killed **31** days after infection, and again no worms were found in the intestine."

On the development of Ascaris lumbricoides, S. YOSHIDA (*Jour. Parasitology*, 5 (1919), No. 3, pp. 106–115, pl. 1).—This is a report of investigations conducted by the author at Osaka, Japan. Experiments are reported and discussed under the headings of development of uninjured fertilized eggs, non-infectiveness of unripe eggs, hatching place of eggs, migration of larvæ in the body of host, the fate of the larvæ in the body of the feeding animal, experiments on other mammals, experiments on immunity, the migrating power of the larvæ, human experiments with Ascaris larvæ, and morphological changes in the larvæ during development.

**Parasitic** mange (*Vet. Rev., 3* (1919), No. 2, pp. 185–194).—This is a review of the more recent literature relating to the subject, in which 17 titles are dealt with.

Practical methods of prophylaxis against worm infestations, B. H. RAN-SOM (Jour. Amer. Vct. Med. Assoc., 55 (1919), No. 1, pp. 46-62).

Practical methods of treatment for worm infestation, M. C. HALL (Jour. Amer. Vct. Med. Assoc., 55 (1919), No. 1, pp. 24–45, fig. 1).—This paper deals briefly with a dozen of the more important parasites affecting cattle, horses, sheep, swine, dogs, cats, and poultry.

Tick eradication plans for 1919, J. R. MoHLER (Jour. Amer. Vet. Med. Assoc., 54 (1919), No. 7, pp. 745-748).

Dips and dipping, I, H. H. GREEN (So. African Jour. Indus., 2 (1919), No. 5, pp. 410-418).—A discussion of the work in South Africa of dipping against tick-transmitted diseases, life history of the tick, interval between dippings, efficacy of dips, and arsenite of soda.

Bovine piroplasmosis in Switzerland, B. GALLI-VALERIO and H. STALDER (Schweiz. Arch. Tierheilk., 60 (1918), No. 10, pp. 471-477, fig. 1; abs. in Vet. Rev., 3 (1919), No. 1, pp. 50, 51).—This is an account of piroplasmosis observed in cattle in the canton of Vaud. This is the first record of its actual occurrence in Switzerland, where it has long been suspected of occurring. Piroplasma divergens is thought to be the species present and Ixodes ricinus the transmitter.

Atlas of the viscera, in situ, of the dairy cow, G. S. HOPKINS (*New York: The Macmillan Co., 1919, pp. 23, pls. 10*).—This atlas has been prepared to meet the needs of the veterinarian for a concise and graphic exposition of the relations of the viscera of the cow.

Investigations to determine the cause of certain sheep diseases in Colorado, G. H. GLOVER, I. E. NEWSOM, and E. W. ALKIRE (Jour. Amer. Vet. Med. Assoc., 55 (1919), Nos. 1, pp. 3-22; 2, pp. 128-146).—A general discussion of losses of sheep in Colorado from disease.

Feed given the pregnant ewe may affect the immunity of the newborn lamb to hemorrhagic septicemia (*Iowa Sta. Rpt. 1918, pp. 18, 19*).—During the course of experiments in which potassium iodid was fed to pregnant ewes to determine whether it would prevent goitre in lambs, hemorrhage septicemia broke out in the paddock in which the lambs were confined and all were subjected to its ravages. It was found that in the lots where a very heavy iodin allowance and a medium allowance were given the death rate was extraordinarily high, whereas in the lot where no iodin was fed it was particularly low. Thus it appears that the addition of iodin to the mother's ration decreased the immunity of the lambs to hemorrhagic septicemia.

Studies on the hyperimmunization of hogs against hog cholera, M. DORSET, C. N. McBRYDE, W. B. NILES, and J. H. RIETZ (Jour. Amer. Vet. Med. Assoc.,
55 (1919), No. 3, pp. 259–280).—These studies reported from the Bureau of Animal Industry, U. S. Department of Agriculture, were conducted for the purpose of determining whether improvements in the production of antihogcholera serum could be made along the lines suggested by Holmes<sup>1</sup> for the preparation of antirinderpest serum, namely, hyperimmunization at the negative phase and hyperimmunization with diluted and laked blood.

The results obtained indicate that there is no evidence of a negative phase or state of hypersusceptibility to log cholera following simultaneous inoculation and that hogs which are hyperimmunized within a short time after simultaneous immunization do not produce serum of satisfactory potency. As the ability of hyperimmunized hogs to yield a potent serum increases within certain limits with the interval between immunization and hyperimmunization, it is recommended that an interval of not less than seven weeks and preferably three months should be allowed to elapse between immunization and hyperimmunization. The ability of immune hogs to respond to hyperimmunization to the desired degree, when once acquired, is said to remain unimpaired for at least a year.

Hyperimmunization with virus blood diluted with 0.5 per cent citrate solution and with distilled water did not materially increase the antigenic properties of the virus blood.

Salicylic acid as a remedy for chronic hog cholera, D. J. HEALY (*Jour. Amer. Vet. Med. Assoc.*, 54 (1919), No. 6, pp. 633-638).—In work at the Kentucky Experiment Station, the author has found salicylic acid a distinctly effective remedy in chronic hog cholera, although of no value whatever in the acute form of the disease.

The blood pressure of the horse, S. J. SCHILLING (Vet. Alumni Quart. [Ohio State Univ.], 7 (1919), No. 1, pp. 245–256, figs. 3).—" The ordinary type of sphygmomanometer as used in human practice is applicable in taking the blood pressure of the horse, mule, and ox. The normal diastolic pressure for the horse is from 40 to 50 mm. of mercury. The normal systolic pressure is from 90 to 100. The systolic pressure is subject to the widest variation; the diastolic pressure is more constant. The systolic pressure is higher in the colt than in mature animals. An increase in blood pressure is common in old age. Females have a slightly higher systolic pressure than males. Weight and condition as to flesh seem not to have any noticeable influence upon the blood pressure."

Studies on the bacterial flora of the mouth and nose of the normal horse, É. E. H. BOYER (*Jour. Bact.*, 4 (1919), No. 1, pp. 61-63).—" The nose and mouth of the normal horse harbor a large flora of microorganisms. The great majority of these organisms are harmless saprophytes. Occasionally present are a few bacteria which may become pathogenic under certain conditions."

A note in regard to the seasonal appearance of Anoplocephala mammilana, H. P. HOSKINS (*Cornell Vet.*, 9 (1919), No. 2, pp. 110, 111).—The author records the occurrence of this rare horse tapeworm (A. mammilana) in two horses in addition to the cases previously reported (E. S. R., 40, p. 186).

Note on the occurrence of Filaria papillosa, W. H. DALRYMPLE (*Jour. Amer.* Vet. Med. Assoc., 54 (1919), No. 6, pp. 643-645).—A note on the occurrence of *F. papillosa* in the aqueous humor of a horse's eye.

The diagnosis of fowl cholera and fowl typhoid infections in domestic birds, P. [B.] HADLEY (Jour. Amer. Vet. Med. Assoc., 55 (1919), No. 2, pp. 186– 192).—This paper is based upon Bulletin 174 of the Rhode Island Experiment Station, previously noted (E. S. R., 40, p. 685).

<sup>1</sup> Indian Civ. Vet. Dept. Mem. [1912] No. 3, pp. 98-205.

Contagious epithelioma in chickens, E. RECORDS (Nevada Sta. Rpt. 1918, pp. 37, 38) —A study of various affected birds received has shown three distinct conditions to be encountered which presented a clinical picture hard to distinguish: (1) The true contagious epithelioma due to the "scab-virus" infection, (2) a nonspecific type due to an infection with various microorganisms, and (3) a type in which in the conjunctival sacs and suborbital sinuses, and to some extent the throat, occur deposits of material distinguished from the psuedomembranes found in the other two types by their chalk-white color and being extremely loose or having no attachment. A number of birds showing types 1 and 2 were vaccinated during the year with quite satisfactory results. The indications are that type 3 is of rheumatic origin.

#### RURAL ENGINEERING.

Machine-made cement pipe for irrigation systems and other purposes, G. E. P. SMITH (Arizona Sta. Bul. 86 (1918), pp. 71–171, pl. 1, figs. 37).—This bulletin is a general treatise on cement pipe, its manufacture, characteristics, and applications. Descriptions are given of various machines used in pipe making, the details of making and laying, the dangers inherent in cement pipe making and in pipe lines, the testing of pipe and the results obtained, the design of pipe lines and structures, and the utility of cement pipe for various purposes.

With reference to pipe it is stated that the two general classes of pipe machines are those employing the tamping principle and the centrifugal or packerhead machines. The latter machines have greater speed and capacity per day and are especially adapted to small sizes of pipe. The purchase of a machine and equipment requires an investment of from \$4,000 to \$10,000. It is stated that handmade pipe is extremely variable in quality. Tamping alone does not produce a smooth interior, and the pipe should be washed inside with neat cement. Greater strength can be secured by increasing the thickness of the pipe wall and by using a wet consistency of the mortar. It is stated that machine-made pipe is safe when subjected to hydrostatic heads up to 25 ft., and that the strength of handmade pipe of good quality is about one-half as great. Wet-cast pipe can be designed to carry water under heads of somewhat over 100 ft. Machine-made cement pipe up to 20 in. in diameter is safe in trenches under 10 ft. of back fill and the smaller sizes are safe for much greater depth. Handmade pipe 16 in. in diameter, of good quality, can be used under 10 ft. of earth. Machine-made pipe is practically impervious. Good handmade pipe washed inside with neat cement is nearly impervious and becomes entirely so in time. It is stated that in design the value of n in Kutter's formula should be taken as 0.013.

Cement pipe of good quality is considered in all respects the equal of vitrified clay pipe for use in sewer lines. "In Arizona, where the cost of cement pipe is much less than that of clay pipe, the cement pipe should be employed. Cement pipe likewise should have the preference for farm and road culverts. When properly made and placed, it is more durable, has a greater carrying capacity, and is much cheaper than corrugated iron pipe. Cement pipe, if used for draintile in alkaline areas, should be of great density and impervious."

Composition of the waters of the inter-mountain region, J. E. GREAVES and C. T. HIRST (Jour. Indus. and Engin Chem., 10 (1918), No. 12, pp. 1001-1004, figs. 4).—Analyses made at the Utah Experiment Station of the waters of 58 Utah streams, most of which are used for irrigation, are reported and discussed with special reference to their suitability for this purpose. In most cases samples were taken monthly during the irrigation season.

288

The waters show considerable variation in the amount and character of the soluble salts. Some are free from excess of objectionable constituents; others, good at their source, dissolve large quantities of alkali in their course. Viewed in the light of Hilgard's interpretation, 13 of the streams contain amounts of alkali which make them dangerous for irrigation, "or, if interpreted in the light of Forbes' experience, only two, but according to the work of the Bureau of Soils [of the U. S. Department of Agriculture] none should be condemned." Caution in the use of the waters is, however, advised.

Surface water supply of Pacific slope basins in California, 1916 (U. S. Geol. Survey, Water-Supply Paper 441 (1918), pp. 330+XXXVI, pls. 2).—This report, prepared in cooperation with the State of California, presents the results of measurements of flow made on streams in Pacific coast drainage basins during the year ended September 30, 1916.

Laying out fields for tractor plowing, H. R. Tolley (U. S. Dept. Agr., Farmers' Bul. 1045 (1919), pp. 40, figs. 33).-This embodies descriptions of methods found best suited to their conditions and recommended by a majority of several hundred tractor owners who have reported their methods and experiences. The methods in general use are divided into two general classes: (1) Those in which the plows are lifted and no plowing is done across the ends, and (2) those in which the plows are lifted in the ground while going across the ends. The advantage of plowing by the methods of the first class are that the short, awkward turns are eliminated, except in some cases at the beginning and the ending of the lands, and usually less space will be left at the corners to be plowed out with horses. It is considered generally possible also to do a little higher quality of plowing if the plows are lifted at the ends. The advantages of the methods of the second class are that little or no time is lost in traveling with the plows out of the ground and that ordinarily the number of dead furrows and back furrows will be considerably less. Taking the country as a whole, it is the opinion that the methods by which the plows are idle across the ends are the more popular, but a large number of farmers have a decided preference for those by which the plows are kept in the ground continuously.

New labor-saving machinery for harvesting grain, W. R. PORTER (North Dakota Sta. Bul. 128 (1919), pp. 3–13, figs. 18).—This bulletin describes four distinct types of new machinery for saving labor and harvesting and thrashing grain in use in North Dakota at the present time, as follows: The Stewart bundle loader, the Paulson shock bucker, the Fisher motor bundle truck, and the Graham-Roach stacker.

The bundle loader is designed to load the shocks directly on the wagon. It is drawn by four horses and requires one man as operator. It is stated that one machine will load on wagons all the bundles that an ordinary separator can thrash, that it gathers the grain cleaner than hand pitchers and shells but very little grain in its operation, and that a saving of two teams and 11 men can be effected by its use. An improvement of the machine loads and carries the bundles direct to the separator.

The shock bucker is intended to pick up a load of shocks in much the same manner as the sweep rake and is drawn by four horses. When loaded the sweeps are lifted off the ground, the machine runs on two wheels, and the load of bundles is dumped on the ground beside the separator. It does not shell any grain, and gathers up the loose stuff. "It is claimed that two men with two machines and eight horses can bring in all the grain that an ordinary separator can handle, so that five men with two of these machines and 20 men when the grain is all forked by hand and hauled in on wagons. Two of these ma-

[Vol. 41

chines are claimed to save the labor of 15 men and 6 teams in ordinary thrashing. This machine is a decided advance over the Stewart bundle loader, as it supplies the thrashing separator with the shocked grain much more economically."

The object of the motor bundle truck is to gather up shock grain and deliver it at the thrashing machine. "It is claimed that seven men with two of these machines can do exactly the same work as a crew of 20 men and 10 teams would accomplish in ordinery thrashing practice, thus saving the labor of 13 men and 10 teams daily. No horses whatever are required with this machine, as it is a large motor truck which will hold about two tons of hay or bundles. The bundles are loaded on the machine by a device on the front of the truck. This loading mechanism is run by the motor of the truck but can be started and stopped independent of it."

When the stacker is used, the binding device is removed from the ordinary<sup>•</sup> harvester, and the grain elevator is extended and raised to a much greater height to deliver the grain directly into the stacker. The stacker and harvester are each drawn by two horses. The capacity is about 2,500 lbs. of mature wheat or other grain as it comes direct from the elevator of the harvester. It is stated that the grain in these stacks seems to cure much better than when in shocks. "When this machine is used in place of the binder it eliminates 90 per cent of the cost for twine, as but a small amount is used to tie the stacks. It requires the same amount of labor to stack and tie the stacks as to shock the grain behind the binder. This machine has the further advantage that it removes the weed seed from the land, such as wild oats." It is also claimed that the stacker saves practically all the grain lost by use of the ordinary self-binder.

A study of the factors governing the efficiency of distribution and rate of discharge of spray nozzles, H. L. CRANE (West Virginia Sta. Bul. 169 (1919), pp. 3-65, figs. 24).—A rather extensive review of work by others bearing on the subject is given, and the results of a study of the capacity of different types of nozzles and of their efficiency in distribution is reported. An attempt was also made to determine, if possible, some of the principles of nozzle construction which influence their rate of discharge and distribution.

With reference to factors influencing the distribution of the spray, it was found that increasing the size of the outlet orifice increased the angle of discharge and widened the ring of spray, but so far as could be told by observation did not increase the size of the spray particles. High pressures gave the better distribution, more perfect cones, and smallest particles. Up to a certain point the angle of the discharge was increased and the width of the ring decreased with the pressure, but the size of the spray particles became smaller as the pressure was increased. The results indicate that for each nozzle there is an optimum pressure at which it works best, and any additional pressure results in partial loss of energy. As the depth of the eddy chamber is increased the angle of discharge and the width of the ring is decreased and the size of the spray particles is increased. The results seem to indicate that increasing the width of the eddy chamber increased the angle of discharge and the width of the ring and also breaks up the spray particles. The angle at which the supply holes in the directing disk were drilled exerted a great influence on the angle of discharge, width of ring, and size of drops. The smaller the angle of the supply holes the wider was the angle of discharge and the width of the ring and the smaller the drops of spray. A central supply hole in the directing disk changed the spray discharged from a hollow cone to a solid cone, narrowed the angle of discharge, and in some cases increased

considerably the size of the drops. The greater the number of supply holes at the edge of the directing disk, the greater was the decrease in the angle of discharge, the narrower the width of the ring, and the larger the drops. One supply hole was not sufficient as a one-sided cone. was produced. Two supply holes if located properly and of the right dimensions produced a spray that was perfectly distributed. The presence of a post on the directing disk decreased the angle of discharge, narrowed the width of the ring, and produced a more evenly distributed spray. A thick disk was found to reduce greatly the angle of discharge, narrow the width of the ring, and increase the size of the spray particles. Burrs in the outlet orifice, orifices that were oblong in shape or not properly centered, disks that fitted loosely in the caps, or cracks near the holes in the directing disk were responsible for a great deal of the imperfections found in this study since they produced an unevenly distributed spray.

With reference to factors influencing the rate of discharge, it was found that an increase in the area of the outlet orifice gave a greater rate of discharge. The increase per unit of area was found to vary inversely with the area of the orifice. An increase in pressure resulted in a greater rate of discharge. No general rule can be given for the increase for all nozzles except that as the pressure is doubled the discharge is greater by 1.4 times. In most cases a deeper eddy chamber increased the rate of discharge, which varied with the size of the outlet orifice. Exceptions were found where a deeper eddy chamber reduced the rate of discharge to a certain point, and then an increase began to show. Widening the eddy chamber was found to increase only slightly the rate of discharge, the rate of increase varying inversely with the size of the outlet orifice. Within certain limits, the greater the area of the supply holes in the directing disc the greater was the rate of discharge. A supply hole placed in the center of the directing disc was found to have much more influence on the rate of discharge than did a corresponding area located at the outer edge. An increase in the angle of the supply holes in the directing disc gave a greater rate of discharge, the increase varying with the size of the outlet orifice. Placing a post on the center of the directing disc just under the outlet orifice increased the rate of discharge. A thick discharge disc diminished the capacity of the nozzle. An angle on the nozzle, or a strainer just behind the directing disc, was found to reduce the rate of discharge by increasing friction, Burrs in the outlet orifices, or orifices that were not perfectly smooth and round, greatly influenced the rate of discharge, the amount depending on the imperfection.

Influence of silo-wall construction on freezing of silage (*Iowa Sta. Rpt.* 1918, p. 9).—Temperature readings have been taken for five winter seasons in three silos on the college campus constructed of wood stave, monolithic concrete, and hollow tile. In each silo thermometers were placed at the inside of the north wall and also in the central part of the silo. The purpose of the work was to find out which type of silo wall afforded the greatest protection from freezing.

The results show that during cold weather the temperature at the inside of the north wall of the silo is only a little warmer than the outside temperature with any of the silo walls tested. The difference between mean temperatures at the north wall in different silos was seldom as much as  $2^{\circ}$  F. and was not always in favor of the same type of silo. It is concluded that there is no practical difference between the insulating properties of these three types of silo wall, and that under the same conditions the same amount of freezing may be expected in them.

[Vol. 41

The Puyallup laying house, G. R. SHOUP (Washington Sta., West. Wash. Sta. Mo. Bul., 7 (1919), No. 1, pp. 6–16, figs. 7).—This article describes, illustrates, and gives plans for a laying house considered ideal for western Washington conditions. It has been attempted to construct a building which will provide, besides roosting and nesting quarters, all necessary equipment to make conditions inside the building during the fall and winter a duplicate of those prevailing during the spring when production is normally highest.

**Poultry house equipment,** G. R. SHOUP (*Washington Sta., West Wash. Sta. Mo. Bul.*, 7 (1919), No. 2, pp. 26-32, figs. 4).—This article describes and illustrates the construction of furnishings and equipment for the efficient handling of laying pullets.

Trap nests, open nests, and trolley carriers, G. R. SHOUP (*Washington Sta*. *West. Wash. Sta. Mo. Bul.*, 7 (1919), No. 3, pp. 42-49, figs. 3).—This article gives plans and descriptions of trap nests, open nests, and trolley egg carriers, considered adapted to western Washington conditions.

## RURAL ECONOMICS.

Report of committee appointed by the Secretary of Agriculture to consider the subject of land economics as one of the divisions of research work of the proposed Bureau of Farm Management and Farm Economics (U. S. Dept. Agr., Off. Sec. Circ. 138 (1919), pp. 8).—This outline for investigations by the proposed Bureau of Farm Management and Farm Economics includes land resources, land values, land ownership and tenancy, land settlement and colonization, and land policies. The report contains recommendations for cooperation between the Office of Farm Management and other bureaus and departments of the Government in the classification of lands from the standpoint of their economic utilization. It also points out, for special emphasis, questions of the economic causes which prevent areas of land suitable for agriculture from being used, the good and evil of tenancy as a method of holding land, the settlement of undeveloped regions by colonization under governmental direction, and the most economical methods of using these areas while in public ownership.

Report of committee appointed by the Secretary of Agriculture to consider the subject of farm-life studies as one of the divisions of research work of the proposed Bureau of Farm Management and Farm Economics (U. S. Dept. Agr., Off. Sec. Circ. 139 (1919), pp. 8).—The list of topics for study submitted by the committee includes rural home life, opportunities for social contact in typical rural communities, the relation of educational and religious institutions to farm-life problems, problems relating to geographical population groups, rural organizations (without definite geographical boundaries), social aspects of tenancy and landlordism, social aspects of various types of farm labor, the relation of various forms of disability to farm-life problems, the social consequences of local disasters due to natural causes, and the social consequences of thrift and agencies for promoting thrift.

**R**ural and forest surveys, P. CAZIOT (*Expertises Rurales et Forestières. Paris: J. B. Baillière & Sons, 1917, pp. 396, flgs. 22*).—This is one of the volumes of the Encyclopèdie Agricole, published under the direction of G. Wery. It is a technical guide for the valuation of various types of rural property and improvements, forests, and vineyards.

Tenancy in an ideal system of landownership, R. T. ELY and C. J. GALPIN (Amer. Econ. Rev., 9 (1919), No. 1, Sup., pp. 180-212).—Part A is a considera-

tion of some of the good aspects of tenancy and of the prerequisites for an ideal system of tenancy. Part B is the report of investigations recently noted (E. S. R., 40, p. 892).

The Irish land acts: A short sketch of their history and development, W. F. BAILEY (*Dublin: Govt., 1917, pp. 48, pls. 8*).—The various Irish land acts of the period 1860–1909 are discussed in chronological order, showing the advantages and evils and the progress under each. The author describes the establishment of the Congested Districts Board and statutes dealing with congestion, the provision of allotments of land and dwellings for agricultural laborers, and miscellaneous details.

Method of colonization, O. SCHULZ (Ausiedlungs-Wegweiser. Berlin: Deutsche Landbuchhandlung, 1918, pp. 64).—This booklet sets forth various means of acquiring capital and applying it to the purchase of agricultural small holdings in various sections of the German Empire.

[Women's work on the land in England and Wales] (Jour. Bd. Agr. [London], 25 (1918), No. 7, pp. 785-839, pls. 7).—This number contains a series of eight articles descriptive of the official organization of women farm labor, the origin and work of the Women's Land Army, the training of women on the land, and women's institutes in the United Kingdom.

Cooperation in the new world, L. SMITH-GORDON (*Better Business*, 4 (1919), No. 3, pp. 168–185).—This article deals with the status of mortgage credit in the United States, particularly with the inception and progress of the Federal farm loan system. The information has been largely derived from the report of the United States Commission to Europe in 1913 (E. S. R., 30, p. 492), the text of the Federal Farm Loan Act (E. S. R., 35, p. 104), a summary of the first official report of the American Bankers' Association<sup>1</sup>, and the report of the Secretary of the Treasury for 1918.

Cooperative buying and selling, J. L. TENNANT (Agr. Gaz. Canada, 6 (1919), No. 5, pp. 449-455).—Under this title are included notes on the status of farmers' cooperative activities in Prince Edward Island, New Brunswick, Quebec, Ontario, and British Columbia.

[Agricultural cooperative societies of the Union of South Africa], J. RETIEF (Union So. Africa Dept. Agr. Rpt. 1917–18, pp. 131–144).—These pages report the progress of the cooperative movement and the position of individual societies in the Union of South Africa in 1917–18 continuing previous information (E. S. R., 40, p. 93).

[Agricultural associations in liberated regions], E. DE WARREN (Mission Assoc. Agr. [Paris] Brochure No. 2 (1919), pp. 104).—The Mission of Agricultural Associations of the Office of Agricultural Reconstruction of the Ministry of Liberated Regions outlines cooperative societies adaptable to various needs and conditions of agriculturists in the liberated regions of France, with several constitutional models, and suggests means for acquiring capital and loans and collecting upon war damages.

Effects of the great war upon agriculture in the United States and Great Britain, B. H. HIBBARD (Carnegie Endowment Internat. Peace, Div. Econ. and Hist., Prelim. Econ. Studies War No. 11 (1919), pp. IX+232, figs. 8).—A compilation of data largely from official sources, showing live-stock and crop production and prices and exports of the United States in the period 1914–1918, and summarizing the policies and results of the work of the Council of National Defense, the U. S. Food Administration, and the U. S. Department of Agriculture in aiding the production and distribution of food. The domestic production and trade in agricultural products in the United Kingdom after the outbreak of the war, and the activities of the government, particularly of the Ministry of Food, and the Board of Agriculture and Fisheries in the control of consumption and price of food, are also reviewed. Numerous charts and statistical tables are included.

Agricultural France and the war, C. CHAUVEAU (La France Agricole et la Guerre. Paris: Baillière, vol. 1, 1916, pp. 302; vol. 2, 1918, pp. VII+322).— In Volume 1 the author has included articles that were published in French periodicals at intervals during 1916, relating principally to the assembling of small and scattered holdings, but dealing also with syndical associations, long-term agricultural credit, registry of the survey of lands, mechanical cultivation, and forests and meadowlands of France and the French colonies. Volume 2 contains a digest of legislation relating to, and various legal phases of, the same topics.

Agricultural Serbia and her democracy, M. ZÉBITCH (La Serbie Agricole et Sa Démocratie. Paris: Berger-Levrault, 1917, pp. 84).—A brief historical sketch of land-holding systems and an account of educational, economic, and social phases of Serbian agriculture. The author includes also discussions of the effects of Turkish and Austrian occupation of the country, the form of government in Serbia, and the outlook for future development.

Agriculture in early Latium, T. FRANK (*Amer. Econ. Rev.*, 9 (1919), No. 2, pp. 267–276).—The author discusses the evolution of the Roman Compagna and tradition and history connected with it to show that in the sixth century it supported a dense population, enjoying a remarkable agricultural prosperity, before the thin soil was worn out and eroded away and the region became an arid waste.

Monthly Crop Reporter (U. S. Dept. Agr., Mo. Crop Rptr., 5 (1919), No. 6, pp. 53-60).—This number shows the estimated farm value of important products for May 15 and June 1, the average prices received by producers of the United States, range of prices of agricultural products at important markets, the United States crop summary for June, and estimated crop conditions June 1, 1919, with comparisons. It contains also a cotton report for May 25 and various data regarding conditions of crops. It reports corn movement by grades, wheat movement both by varieties and grades from November 1, 1917, to July 14, 1918, and the proportion of each important feed stuffs as consumed in each month.

Montana, 1918 (*Helena: Dept. Agr. and Publicity, 1918, pp. 245, figs. 130*).— This continues information previously noted (E. S. R., 39, p. 796).

Census of agricultural resources of New York, 1917-18 (Albany: N. Y. State Food Com., 1919, pp. 69).—The results of the census of 1917, taken by order of the New York State Food Supply Commission, and that of 1918, taken by order of the New York State Food Commission, are published here. The data were secured from blanks placed in the hands of teachers, county agents, and others to be filled out. Enumerations of farm population, farm labor, conveniences, machinery, and amount of fertilizer used, and information relating to land in New York and uses made of it, acreage and yields of crops, and numbers of live stock are given.

Annual statistical report of the New York Produce Exchange for the year 1918 (Ann. Statis. Rpt. N. Y. Produce Ex., 1918, pp. 137).—This continues information previously noted (E. S. R., 39, p. 690).

Farmers' Market Bulletin (North Carolina Sta., Farmers' Market Bul., 6 (1919), No. 28, pp. 24, fig. 1).—This number contains the usual list of products which North Carolina farmers have for sale, also a brief note on cooperative live-stock marketing, by C. S. Jones.

Ohio agricultural statistics, 1916–17 and 1917–18 (Ohio Agr. Statis., 1916–17, pp. 78; 1917–18, pp. 86).—These volumes continue information previously noted (E. S. R., 37, p. 191).

[Agricultural statistics of Uruguay], R. B. WILSON (An. Estadís. Agr. [Uruguay], 1917–18, pp. XLV+609).—Statistics for 1917–18 are given, continuing the information previously noted (E. S. R., 38, p. 896). The index is inserted in this number in Spanish, French, and English. In the appendix are included data for 1916 relating to number and extension of farms, stock of cattle and other live stock, machinery and implements, and bee and silk culture.

Imports, exports, and supplies of agricultural produce of the United Kingdom during the war (*Jour. Bd. Agr.* [London], 25 (1919), No. 12, pp. 1462–1474).—A summary is given of the returns for the year 1918 relating to prices and supplies of agricultural produce in the United Kingdom, with special reference to imports and with comparisons through the period 1914–1918.

[Agricultural statistics] (Statis. Abs. Brit. Self-Gov. Dominions [etc.], 52 (1900–1914), pp. 318–379; 53 (1901–1915), pp. 328–389).—These pages of these volumes continue to date the information on agricultural production, imports, and exports for the British self-governing dominions, crown colonies, possessions, and protectorates previously noted (E. S. R., 33, p. 295).

[Agricultural statistics of Canada] (Canada Yearbook, 1917–18 pp. 166– 230).—Among the data included in these pages are those relating to area and yield of field crops, number and value of live stock, land values, wages, manufacturing of agricultural products, prices, and miscellaneous agricultural statistics.

Report of the Canada Food Board (*Rpt. Canada Food Bd., 1918, pp.* [5]+ 87, *figs.* 5).—This report of February 11 to December 31, 1918, sets forth the Canadian policy of food control and the work of the Food Board as affecting supplies of important food commodities.

[Agricultural statistics of the Union of South Africa, 1914–15 and 1915–16] (Statis. Year Book Union So. Africa, Nos. 3 (1914–15), pp. 4–17, 46– 55, 134–137; 4 (1915–16), pp. 8–22, 40–49, 116–132).—The first of these numbers of the yearbook, No. 1 of which was previously noted (E. S. R., 33, p. 789), gives statistics of urban and rural population of the Cape of Good Hope for the years 1910 to 1914, inclusive, and statements, for the Union as a whole, of numbers of animals, exports of agricultural and pastoral products, and the transactions of agricultural cooperative societies. In the second, population enumerations for all districts of the Union, according to the 1911 census, and information in regard to agriculture more detailed than in the preceding report are given.

## AGRICULTURAL EDUCATION.

Agricultural education, 1916–1918, C. H. LANE (U. S. Bur. Ed. Bul. 44 (1918), pp. 40).—This is the usual review of progress in agricultural instruction, in 1916–1918, in secondary and elementary schools, in agricultural colleges, agricultural extension and short courses, and the Graduate School of Agriculture; of agricultural education at meetings; the educational work of the U. S. Department of Agriculture; and of the principal developments in agricultural education in foreign countries. The bulletin represents advance sheets from the Biennial Survey of Education in the United States, 1916–1918 (E. S. R., 39, p. 392).

Statistics of agricultural and mechanical colleges, 1916-17, B. F. ANDREWS (U. S. Bur. Ed. Bul. 41 (1918), pp. 43).—This is a compilation, from official sources, of statistics of the land-grant colleges with reference to faculties, students, courses of study, value of funds and equipment, revenues, additions to equipment, disbursements of Federal funds, etc., for 1916-17.

[Agricultural education and research in the Province of Quebec, 1917– 18], J. E. CARON (*Rpt. Min. Agr. Prov. Quebec, 1918, pp. VIII+182, pls. 26*).— This report of the department of agriculture of the Province of Quebec includes detailed information concerning the activities of the agricultural and domestic science education institutions, experimental stations (demonstration fields), school gardens and extension work, etc., under its control.

Agricultural education and agricultural development in America, A. E. V. RICHARDSON (*Melbourne, Australia: Govt.* [1918], pp. 135, pls. 19, fig. 1).— This report has been discussed editorially (E. S. R., 40, p. 107).

[American agriculture], A. E. V. RICHARDSON (Jour. Dept. Agr. Victoria, 16 (1918), Nos. 5, pp. 257-275, figs. 13; 6, pp. 339-354, figs. 6; 7, pp. 385-396; 8, pp. 463-468; 9, pp. 555-568, figs. 11; 10, pp. 577-591, figs. 10; 11, pp. 658-668, figs. 6).-This series of articles, based on the six months' visit of investigation in the United States and Canada, noted above, consists of (1) a report on agricultural education methods and agricultural research work in the State of California; and (2) notes on the organization and work of the agricultural colleges and experiment stations in Utah, Colorado, Kansas, Iowa, Illinois, and Ohio; the Ohio State department of agriculture; the U.S. Department of Agriculture; the essential features in the organization of agricultural education of college grade in the United States; the organization of agricultural instruction of secondary grade, including the home project principle and the cooperation of Federal and State Governments for the promotion of vocational training in agriculture in the United States; agricultural production in Canada; agricultural education in Quebec and Ontario; the Dominion department of agriculture and experiment farms; the Ontario department of agriculture; and extension work in the United States.

[Opportunities in agriculture for disabled soldiers, sailors, and marines], W. J. QUICK (*Fed. Bd. Vocat. Ed., Rehabil. Ser., 1919, Nos. 21, pp. 14, figs. 3;* 26, pp. 22, figs. 5).—These publications outline the opportunities in farm management and general farming, respectively, as vocations for disabled soldiers, sailors, and marines.

Outline of plans for vocational education in Colorado under the Smith-Hughes Act (*State Bd. Vocat. Ed.* [Colo.], *Vocat. Bul.* 1 (1918), pp. 31).—This is an outline of the plans for the promotion of vocational education in Colorado for 1918–19. The text of the State act accepting the provisions of the Smith-Hughes Act is included.

The State Board of Agriculture is designated as the State Board for Vocational Education. Since during the year 1918–19 the State director of vocational education spends only one-half of his total time in the supervision of vocational agriculture, an arrangement has been made whereby special supervisors from the departments of agronomy and animal husbandry of the Colorado College will be loaned to inspect all schools and classes in agriculture twice during the year and a specialist in home economics from the extension service of the college to supervise vocational schools and classes of home economics approved for Federal aid.

It is provided that all classes in teacher training in agriculture and home economics will be conducted in the agricultural college. Four-year type courses in vocational agriculture and home economics and 4-year teacher-training courses in agriculture and home economics are outlined. Outline of plans for the cooperation of the State Board of Education with the Federal Board for Vocational Education for vocational education in Idaho, year 1918–19, also an act accepting the provisions of the Smith-Hughes Act (*Idaho Bul.* [State Bd.] Ed., 5 (1919), No. 5, pp. 30).—The plans for the administration and supervision of vocational education in Idaho for 1918–19, including the training of vocational teachers, are outlined. The University of Idaho has been designated as the institution to conduct all classes in teacher training in agriculture and home economics. Outlines are included of the 4-year teacher-training courses in vocational agriculture and home economics, of a 4-year course in vocational agriculture for high schools as a type of the course that will be required, and of a suggested 4-year course in vocational home economics.

Administrative boards and officers, approved plans of the State for vocational education, Federal and State law, 1918-19 ([*Iowa State Bd. Vocat. Ed.*], *Vocat. Ed. Bul. 2* [1918], *pp.* 46).—This bulletin contains a detailed outline of the approved plans for vocational education in Iowa for 1918-19, and the text of the Federal and Iowa State laws for vocational education.

Plan for the cooperation of the Kansas State Board of Education with the Federal Board for Vocational Education, 1918–19 (Kans. Dept. Ed., Vocat. Ed. Bul. 2 (1918), pp. 38).—This plan supplants the one previously noted for 1917–18 (E. S. R., 40, p. 395). The texts of the Federal and Kansas State acts relating to vocational education are included.

Massachusetts Board for Vocational Education: Plans of Massachusetts for year 1918–19 (*Bul. Bd. Ed. Mass., No. 10* (1918), pp. 98, figs. 2).—A comparative statement is given, by years, of the distinctively agricultural and nonagricultural instruction in the county agricultural school and the highschool department, respectively. In the former, 80 per cent including 50 per cent in project study and work and 30 per cent in related study), and in the latter, 50 per cent of the students' time is devoted to strictly agricultural subjects, and 20 per cent and 50 per cent, respectively, to nonagricultural or cultural and good-citizenship training. The differences in the method of instruction followed in the school and the department are also comparatively stated.

Suggested types of short unit courses in vocational home economics on progressive and nonprogressive plans of organization are briefly indicated.

The proposed percentage use of funds as to training teachers is 20 per cent each for agricultural teachers, supervisors, and directors, industrial and trade teachers, and household arts teachers. The tentative plan for training vocational teachers of agriculture, just put into practice, is briefly outlined and includes the training of teachers in service. A tentative scheme for training teachers of vocational home making is given in tabular form, together with an explanation.

Plans for the administration of the Smith-Hughes Act for vocational education in the State of South Dakota: Agriculture (*Pierre*, S. Dak.: State Bd. Vocat. Ed. [1919], pp. 12).—This pamphlet outlines the plans for vocational agricultural education in South Dakota under the Smith-Hughes Act for 1918–19. It is provided that 75 per cent of a 1-year vocational agricultural course in a high school shall be devoted to instruction in agriculture, 60 per cent of a 2-year course, and at least 50 per cent of a 3 or 4-year course. The related work and practical work shall in no case be given for less than 90 minutes each per day. Suggested outlines of a 4-year and a 1-year vocational agricultural course are included.

Plans for the administration of the Smith-Hughes Act for vocational education in the State of South Dakota: Home economics (*Pierre, S. Dak.: State Bd. Vocat. Ed.* [1919], pp. 8).—This is an outline of the plan for voca-

. [Vol. 41

tional home economics education in South Dakota under the Smith-Hughes Act for 1918--19. It is planned that in the vocational home economics course in the high school at least half the time shall be devoted to practice work and related subjects. Outlines are given of the 4-year and 2-year home economics courses for the vocational schools.

The training of teachers of vocational agriculture, W. G. HUMMEL (Fed. Bd. Vocat. Ed. Bul. 27 (1919), pp. 47).—The author discusses the qualifications and training desirable for teachers of vocational agriculture, the necessity for such qualifications, the special facilities and conditions needed in order to carry on such training successfully, the training of special teachers of agriculture, the certification of teachers, the training of teachers in service by means of itinerant teaching, agricultural teachers' meetings and conferences, professional improvement projects, and the foundation for the training of teachers in service, viz, cooperation between the agricultural teachertraining institution and the supervisor of agricultural education in a State.

Vocational education: Bibliography of Government publications suitable for use of agriculture classes in elementary and secondary schools, W. T. SKILLING (*Cal. State Bd. Ed. Bul. 23B (1919), pp. 26*).—This is a bibliography of Farmers' Bulletins of the U. S. Department of Agriculture, with brief descriptions, topically arranged.

Agriculture in Ohio elementary schools.—A manual for teachers of grades 7 and 8, F. E. HEALD and A. DILLE ([Columbus, Ohio]: State Dept. Pub. Instr., 1919, pp. 178).—The material outlined in this manual, which is arranged in seasonal sequence, includes in each year one main crop and one principal animal study, while poultry and gardening lessons recur throughout the entire two years. The subject matter for one year is not planned to be more elementary than, or prerequisite for, the other. It is recommended that in the smaller schools the two grades should be combined for agriculture, and the two years' work done in alternate years. Each lesson suggests problems, sources of information, illustrative material, class exercises, practical exercises or projects, and correlations.

Laboratory manual in field crops, C. C. FARR (*New York: The Macmillan* Co., 1918, pp. X+63, pl. 1, figs. 5).—A series of practicums in field crops, intended to equip the high-school student as a "practitioner agriculturist."

Garden crops: Production and preservation, L. S. IVINS (*Chicago: Rand* McNally & Co., 1919, pp. 335, figs. 112).—This book is intended primarily as a textbook for schools below the tenth grade, but may be found useful also by senior high schools or special vocational departments desiring a less advanced course in gardening, as well as by individuals interested in the subject. Section 1 of the text discusses the production of the most important garden crops grown in this country and presents problems and projects for classroom and outdoor work. Section 2 tells how such crops may be preserved and stored. Outlines for study and for home and community work are also included in most of the chapters of the first two sections. Section 3 consists of suggestions to teachers on lesson assignments, projects and problems, types of gardens, school exhibits of garden crops, score cards, suggestive record and report forms, etc.

Suggestions for the study of weeds in agriculture in the elementary schools, F. T. ULLRICH (Bul. State Norm. School, Platteville, Wis., 15 [1919], No. 4, pp. 22, figs. 12).—Suggestions are offered to teachers for the selection and organization of information on weeds.

Forest study in the primary grades, E. R. MOSHER ([Lansing, Mich.]: Pub. Domain Com. Mich. [1918]. pp. 76, figs. 42).—According to the author this publication is primarily intended to stimulate and assist the teacher by giving

a broader viewpoint of the subject and showing something of the educative value of forest materials for use in the schoolroom; also to furnish suggestions and subject matter adapted to the child mind. In order to illustrate methods of teaching, the material is arranged successively in topical subjects in rhyme and story, in question form, making a direct appeal to observation and experience, and in cultural selections offered as helps for the teacher.

#### MISCELLANEOUS.

Annual Report of Idaho Station, 1918 (*Idaho Sta. Bul. 113* (1918), pp. 46).—This contains the organization list, reports of the director and heads of departments, the experimental features of which are for the most part abstracted elsewhere in this issue, and financial statements for the Federal funds for the fiscal year ended June 30, 1918, and for the remaining funds for the fiscal year ended December 31, 1918.

Annual Report of Iowa Station, 1918 (*Iowa Sta. Rpt. 1918*, *pp. 62*, *figs.* 3).—This contains the organization list and a report by the director on the work of the station, including a financial statement for the fiscal year ended June 30, 1918. The experimental work recorded is for the most part abstracted elsewhere in this issue.

Annual Report of Nevada Station, 1918 (Nevada Sta. Rpt. 1918, pp. 53, figs. 8).—This contains the organization list, a report of the director on the work of the station, departmental reports, the experimental work in which is for the most part abstracted elsewhere in this issue, a list of the publications of the year, and a financial statement for the fiscal year ended June 30, 1918.

Annual Report of South Dakota Station, 1918 (South Dakota Sta. Rpt. 1918, pp. 27).—This contains a report by the director on the organization, work, and publications of the station, a financial statement for the fiscal year ended June 30, 1918, and departmental reports, of which that of the entomologist and portions of that of the horticulturist are abstracted elsewhere in this issue.

Thirtieth and Thirty-first Annual Reports of Texas Station, 1917 and 1918 (*Texas Sta. Rpts. 1917–18, pp. 40, pl. 1*).—This contains the organization list, a financial statement for the Federal funds for the fiscal years ended June 30, 1917, and June 30, 1918, and for various State funds for the fiscal years ended August 31, 1917, and August 31, 1918, a report of the director on the work of the station and the various substations, and a list of the station publications available for distribution.

Monthly Bulletin of the Ohio Experiment Station (Mo. Bul. Ohio Sta., 4 (1919), No. 5, pp. 139-167, figs. 14).—This contains several articles abstracted elsewhere in this issue, together with the following: Methods of Feeding and Feeds for Chicks, by W. J. Buss; Apple Blotch.—A Serious Fruit Disease in Ohio, by A. D. Selby; and Notes.

Monthly bulletin of the Western Washington Substation (*Washington* Sta., West. Wash. Sta. Mo. Bul., 7 (1919), Nos. 1, pp. 20, figs. 11; 2, pp. 21-36, figs. 4; 3, pp. 37-52, figs. 3).—These numbers contain several articles abstracted elsewhere in this issue, and brief articles as follows:

No. 1.—Proposed Plan for Buying and Distributing Breeding Sheep tor Western Washington Farm Flocks, by W. A. Linklater; Apple and Pear Scab, by A. Frank; and Potato Planting, by J. L. Stahl.

No. 2.—Establishing a Farm Flock, by W. A. Linklater; Late-Sown Crops, by E. B. Stookey; Rose Diseases and Insect Pests and Their Control, by A. Frank; and Grow More Squash, by J. L. Stahl.

No. 3.—What Makes Prime Berries? by J. L. Stahl; Testing Cereal Varieties, by E. B. Stookey; and Insect Pests of the Garden and Their Control, by A. Frank.

Florida Station.—A tract of land at Lake Aldred has been selected as a site for the new citrus substation. Funds for the erection of a building and the maintenance of the substation for the present biennium have been subscribed by citrus growers of Polk County, and a sum of \$10,000 has been placed in the hands of the board of control.

Cooperative work with pineapple growers of St. Lucie County is being begun with a view to studying the best means of growing pineapples and controlling certain pineapple diseases.

**Purdue University.**—School and Society announces that a general increase in salary of 15 per cent to all members of the instructional corps was authorized by the board of trustees at its June meeting.

Iowa College.—Plans are being made to acquire a tract of 200 acres adjoining the present property, using an appropriation of \$70,000 for an animal husbandry farm made two years ago.

Two new buildings are to be erected. One of these is a poultry house to be used for class laboratory work pending the erection of a permanent poultry husbandry building, and then as an incubator and brooder house. A concrete manure shed is to be built for the station. This will enable it to carry on more fertilizer experiments, especially with commercial fertilizers, the use of which is reported to be increasing in the State.

Kansas College.—A new course has been added known as agricultural relationships, and is required of agricultural students in the second semester of the senior year. This course deals with the relationships of the individual to agricultural enterprises and is designed to direct attention to the duties, opportunities, and responsibilities of agricultural college graduates as citizens of the agricultural community and as specialists in various phases of agricultural activities.

New York State Station.—Joseph W. Wellington, assistant horticulturist, has accepted a position with the U. S. Department of Agriculture in connection with its potato work. George H. Howe, assistant horticulturist, has been promoted to associate horticulturist. Recent appointments of assistants include Rossiter D. Olmstead and Clarence R. Phipps in entomology, Theodore E. Gatey in horticulture, Harold L. Weinstein in chemistry, and George J. Hucker in bacteriology.

South Dakota College.—The agricultural hall and administration building, containing a museum and auditorium seating 1,200 persons, 20 class and lecture rooms, and 19 laboratories, is ready for occupancy at a cost of \$210,000.

Vermont University.—The honorary degree of doctor of literature was conferred on Dr. L. H. Bailey at the recent Commencement.

Washington Station.—J. L. St. John has been appointed assistant chemist, beginning September 15.

West Virginia University.—E. A. Livesay, assistant county agent leader in Missouri, has been appointed professor of animal husbandry, beginning September 1.

**Prospective Scientific Meetings.**—The thirty-third annual convention of the Association of American Agricultural Colleges and Experiment Stations will be held at Chicago, Ill., November 12 to 14.

The Association of Official Agricultural Chemists will hold its thirty-sixth annual convention at the New Willard Hotel, Washington, D. C., November 17 to 19.

Legumes, Sudan grass, and cereal crops for silage, Eckles	334
Frost injury to grain and legumes, Fischer	335
Soil inoculation for legumes, Albrecht	335
The improvement of the barley crop, Hunter	335
Late planted variety tests of corn, Cauthen	335
Fertilizer experiments with cotton in Alabama, Williamson and Duggar	335
Transmission of characters in potatoes, von Seelhorst	336
Missing hills in potato fields: Their effect upon the yield, Stewart	336
Handling and loading southern new potatoes, Grimes	337
Rhodes grass, Tracy	337
Culture and multiplication of Ilocano and Tagalog lowland rices, Romero_	337
Saving man labor in sugar beet fields, Moorhouse and Summers	337
Bud variations in sugar cane, Pomeroy	337
Spacing experiments with sugar cane, Mirasol y Jison	338
Sweet potato storage, Johnson	338
The synthetic production of wild wheat forms, Love and Craig	338
Third biennial report State seed commissioner, 1917–18, Leth	339

#### HORTICULTURE.

Fruits, vegetables, and flowers, Gardner et al	339
Report of nursery and market garden, 1918, Lister	339
Evolution of the commercial greenhouse in relation to horticulture, Cobb_	339
[Report of experiments on lettuce growing], Johnson	339
Growing tomatoes for the canning factory, Rosa	340
The relation of phenology to fruit growing, Barnett	340
Roeding's fruit growers' guide, Roeding	340
[Varieties of fruit for British Columbia], Middleton	340
Our best varieties of fruit, Böttner	340
The improvement of fruit culture in Baluchistan, A. and G. L. C. Howard	340
Report of the Fruit Experiment Station, Shillong, 1918, Holder	340
Maintaining proper vigor in our fruit trees, Lewis	340
Protecting the orchard by dusting, Reddick	340
Orchard spraying experiments, Turney	340
Fertilizing of apple orchards, Kraus	341
Fertilization of apple orchards, Stewart	341
Cultural methods and fertilization of the apple orchard, Oskamp	341
Cost of producing apples in Illinois orchards, Stanford	341

	Page.
A test of commercial fertilizers for grapes, Gladwin	341
Some recent marketing developments in the Pacific Northwest, Lewis	341
Tropical and semitropical fruits (exclusive of citrus fruits), Fenzi	341
Some profitable and unprofitable coffee lands, McClelland	342
Effect of different methods of transplanting coffee, McClelland	342
[Report on date investigations], Forbes	342
[Report of date breeding experiments], Freeman and Bryan	342
Weather conditions as affecting plant growth, Thornber	343
Annual and other flowers which can not be classed as hardy perennials	343
The preservation of pollen for hybridizing, Saunders	343
Horticultural libraries in the United States, Warner	343

#### 4 FORESTRY.

National afforestation, Webster	343
Commercial forestry	343
Forestry, Honda and Takenob	343
A forestry policy of New Zealand, Bell	343
Reclamation of sand dunes, Turner	343
Vacation days in Colorado's National Forests	344
Vacation trips in the Cochetopa National Forest	344
The Ouray Mountains of the Uncompany National Forest	344
A vacation land of lakes and woodsThe Superior National Forest	344
Historical review of Bergius arboretum for the period 1885–1914, Fries	344
Storied or tier-like structure of certain dicotyledonous woods, Record	344
Studies of regeneration conditions in Norrland pine forests, II, Hesselman_	344
The arborescent indigenous legumes of Hawaii, Rock	344
The production of aspen, Schotte	345
The larch and its importance in Swedish forest economy, Schotte	345
The cultivation of osiers and willows, Elmore, edited by Okey	345
Rubber plants, Hall and Long	345
Thitsi, with special reference to the oleo-resin obtained from it, Wright	345

#### DISEASES OF PLANTS.

Plant disease inquiries Thornhor	245
Name disease inquiries, findinger IV House	346
On coll response tion in Rotratis cinered Briorloy	246
Blasson infaction by south Longon	246
Diossofi milection by sinus, Jensen	246
Ine black of stem fust of wheat	240
Lesf opt discasses of alfalfa and red alayar Japan	240
West in plant generation. Deat generation and the clover, Jones	947
[ work in plant genesis], blakesiee	011
Charles of Annualt and of Alternatic on poteto Sonding	341
The initiance of drought and of Afternaria on potato, Sordina	311
The eradication of years stripe of sugar cane	341
Blister canker of apple trees, a physiological and chemical study, Rose	341
The effect of crown gan upon a young appeor chard, Greene and Menus.	040
[Spraying at the Neoga Station, filmols, 1913–10], Brock	348
Brown Fot, its importance and control, Benson	348
Control of cherry lear spot, Roberts and Pierce	348
Notes on vine black spot or anthrachose, de Castella and Brittlebank	349
Black spot and leaf curl, Laidiaw and Brittlebank	349
Disease of the vine [New South Wales]: Downy mildew, Laner	349
Downy mildew [grape] Plasmopara viticola, de Castella and Brittlebank_	349
Copper fungicides for vine diseases, de Castella	349
Comparative effect of basic and acid copper sprays, Capus	349
Citrus spots and blemishes, Matz	350
Coconut bud rot, Nowell	350
Coffee leaf disease ( <i>Hemileia vastatrix</i> ) in Uganda, Simpson	350
Sprays for coffee affected with <i>H. vastatrix</i> and other diseases, Dawson	350
Report on white pine blister rust control, 1918	350
Status of white pine blister rust control in 1918, Detwiler	351
Scientific research and field investigations in 1918, Spaulding	351
Investigation [of white pine blister rust], McCubbin	352
Infection of Ribes and white pines with <i>Cronartium ribicola</i> , Clinton	352

.

	rage.
Summary of the white pine blister rust situation, Metcalf	352
Progress of experiments for destroying Ribes with chemicals, Regan	352
Report of conference re disease attacking plane trees	353
Cultures with Melampsoræ on Populus, Weir and Hubert	353
,	

#### ECONOMIC ZOOLOGY-ENTOMOLOGY.

California ground squirrels	353
Destruction of live stock by predatory animals, Musgrave	353
Principal species of birds protected by law in Egypt, Flower and Nicoll	353
Description of a new Conurus from the Andaman Islands, Oberholser	353
An unrecognized shrew from Warren Island, Alaska, Jackson	353
Mutanda Ornithologica, VI, Oberholser	354
Proceedings of the Entomological Society of Nova Scotia for 1918	354
Report of the imperial entomologist, Fletcher	354
[Economic insects in Sumatra], den Doop	354
Monthly notes on grubs and other cane pests, Illingworth	354
Insect pests of the avocado, Condit	354
Insects injurious to the black wattle (Acacia mollissima), Hardenberg	354
Linseed oil-Bordeaux, Berger	355
"White ants" in United States and preventing damage, Snyder	355
Entomology, Morrill	355
The black fly, Newell	355
The green soldier bug or pumpkin bug in citrus groves, Watson	355
The grain bug, Caffrey and Barber	355
New species of Jassoidea from Honduras, Gibson	356
Combining dormant and first summer spray in apple orchards, Talbert	356
The fruit worms of the apple in Nova Scotia, Sanders and Dustan	357
The tea tortrix (Homona coffearia), Jardine	357
Pseudograsserie, a new disease of caterpillars of the gipsy moth, Paillot	357
Reports and papers on malaria contracted in England in 1917	358
The cabbage fly (Chortophila brassica)	358
Eumerus strigatus again, Metcalf	358
Protection from the locust borer, Craighead	358
The confused flour beetle ( <i>Tribolium confusum</i> ), Chapman	358
Shot-hole borer (Xyleborus fornicatus), Speyer	359
Report of the State apiarist for the year 1917, Millen	359
Nosema disease, White	359
The ants of France and Belgium, Bondroit	360
Notes on chalcid flies belonging to Aphelininæ with a new species, Gahan	360
A list of families and subfamilies of ichneumon flies, Viereck	360
A preliminary report of the Trombidiidæ of Minnesota, Howard	360

#### FOODS-HUMAN NUTRITION.

Bacteriology and mycology of foods, Tanner	360
The relative digestibility of our food materials, Rubner	361
Digestibility of our food, Rubner	361
Fats and fatty acids as food	361
Availability of fatty acids as a source of fat in the diet of man	362
The nutritive value of hardened fats, Pekelharing and Schut	362
Report on a dried meat powder, Cole	362
The [Jerusalem] artichoke as a source of carbohydrate, Hopkins	-362
Influence of percentage extraction and admixture on yeast, Lloyd	362
Food Surveys	362
The food requirements of man and their variations	362
The quantity of fat-soluble vitamins in coconut oil, Jansen	363
A study of the physiology of endogenous uric acid, Höst	363
Formation of sugar from proteins and degradation products, de Corral	363
Observation on hyperglycemia and glycosuria, Hamburger	-364
The splitting of neutral salts in contact with colloids, Scala	364
The diagnosis of acidosis, Macleod	364
Accessory food factors in the etiology of rickets, Mellanby	364
An experimental investigation on rickets, Mellanby	365
The cause and prevention of scurvy	365
Trench feet a deficiency disease, Bruntz and Spillman	365
Note on the influence of the rate of cooling on metabolism, Hill	365

## ANIMAL PRODUCTION.

	Page.
The American Society of Animal Production	366
The average correlation within subgroups of a population, Wright	366
Further illustrations of a coefficient measuring correlation, Harris	366
The modified Wolff-Lehmann feeding standards, Morrison	367
Nitrogenous constituents of feeding stuffs, Grindley	-367
Corn as a source of protein and ash for growing animals, Hogan	367
Utilization of apple pomace for animal feeding, Warcollier and Hédiard	367
[Analyses of] unusual feeding stuffs, Vinson and Catlin	367
Weights of typical Shorthorns, Tormey	367
Investigations with growing steers, Haecker	367
More grass to make more beef, Farrell	367
The utilization of grain sorghums in meat production, Cochel	367
[Velvet beans for] beef cattle, Templeton	368
Silage as a factor in beef production, Tomhave	368
Silage for range cattle, Williams and Cunningham	368
Tests of work oxen of Morocco at Casablanca (October, 1918), Leroy	368
Forage crops for lambs, Horlacher	368
Vegetable diets, growth, and reproduction, Hart and McCollum	369
Alfalfa pasture for hogs, Williams and Cunningham	369
Dry lot finishing of hogs following peanut pasture], Templeton	369
Cottonseed meal as a feed for hogs, Burns	369
Southern pork production, Ewing	-369
Horse management, Clark	370
Poultry feeds and feeding, Robertson	370
Object and plan of the Nebraska national egg-laying contest	370
Final report on the fourth poultry egg-laying trials, 1915–16	370
[Report of the fifth poultry egg-laying trials 1916–17]	370
Sixth egg-laying competition extending over twelve months, 1917–18	370
Egg-laying tests at Hawkesbury, 1917–18, Whitbread and Hadlington	370
[Victorian egg-laying competitions 1915–16 to 1917–18], Hart	371
Cause of death of chicks in shell in artificial incubation, Arbuckle	371

#### DAIRY FARMING-DAIRYING.

Alfalfa as a sole feed for dairy cattle, Woll	371
Alfalfa hay v. alfalfa hay and silage, Williams and Cunningham	371
The mineral metabolism of the milch cow [I–III], Forbes	372
Report of International Association of Dairy and Milk Inspectors, Weld	372
Report of International Association of Dairy and Milk Inspectors, Weld	372
Report of International Association of Dairy and Milk Inspectors, Weld	372
Machine v. hand milking, Riddell	373
Safe milk for the small town, Miller	373
Questions concerning the control of a city milk supply answered, Breed	373
Observations on the washing of milk cans, Webster	373
Refrigeration on southern dairy farms, Bowen	374
The alkali-forming bacteria found in milk, Ayres, Rupp, and Johnson	374
Bacteria in whole and skim milk, separator and centrifuge cream, Lamson_	374
Influence of separator on distribution of bacteria, Bushnell and Hunter	375
The microbial flora of graded cream, Hunter and Bushnell	375
Sweet cream butter, Bendixen	375

#### VETERINARY MEDICINE.

Pyotherapy, Velu	375
Behavior of bacteria toward arsenic, Green and Kestell	376
The Wright and Carrel methods of treating wounds, Van Wallendael	376
Researches on antistreptococci immunity, Vinaver and Frasey	376
Complement inactivation by bacteria, Ritz and Sachs	376
Preparation of lipovaccines, Rosenow and Osterberg	377
Experiments on the effect of agglutinins, Fujimoto	377
Production of a homogeneous suspension of <i>Bacillus anthracis</i> , Noble	377
Vaccination against Anthrax in Brazil, Moses	378
Inoculation as a prophylactic against foot-and-mouth disease, Lutrario	378
Researches on ulcerous lymphangitis, Van Saceghem	379
Treatment of ulcerous lymphangitis, Van Saceghem	379
Progress report on Sarcocystis tenella.—II, Seasonal infection, Scott	379

#### RURAL ENGINEERING.

	Page.
Irrigation investigations, Smith and Enger	379
The Tempe drainage ditch, Vinson and Catlin	379
Pubilc Roads	380
Determining sizes of culverts, Grover	381
Thickness of concrete slabs, Goldbeck	381
The commercial sizes of crushed stone aggregates, Jackson and Mitman	382
Bonding new cement-mortar and concrete to old in tests, Rosengarten	382
[A total of 6,146,617 motor vehicles in the United States], Anderson	383
Motor transportation for rural districts, Collins	- 383
The farm tractor in the Dakotas, Yerkes and Church	-384
Poultry buildings: Laving and breeding houses, Lewis and Thompson	-385

#### RURAL ECONOMICS.

Farm organization as division of proposed Bureau of Farm Management	386
Farm types in Nebraska, Spafford	386
Dairying and general farming for the timbered section, McGuire	386
Select list of references on economic reconstruction, Meyer	387
The country church in the new world order, Brunner	387
The problem of land ownership: A proposal for its solution, Balinsky	387
Farm tenantry in Nebraska compared with farm ownership, Kano	387
The foundations of society and the land, Jeudwine	387
The minmum wage on light land	388
Agricultural wages in Ireland	388
French farm loans	388
Report of proceedings of first American Cooperative Convention, 1918	388
Address of [U. S. wheat director] to grain trade conference, Barnes	388
Resources, trade, and legislation of the dominions, D'Abernon et al	388
Prices and supplies of agricultural produce in England and Wales	388
[Exports and imports of French products], de Lagorssee et al	388
Agricultural and live stock statistics of Finland	388
Statistics of industrial crops, Peglion	388
Economic and financial resources of Russia	389
The agricultural resources of Morocco, Hitier	389
Prices and wages in India	389

#### AGRICULTURAL EDUCATION.

American amigultural collegest Organization and requirements. Tanvis	900
American agricultural coneges: Organization and requirements, Jarvis_	- 389
Report of the education branch for the year 1916-17	390
Report of the Director of Agriculture for 1917	390
Report of the Department of Agriculture of Norway for 1917	391
Report of the Department of Agriculture, Sweden, 1916	391
Report of the eleven district agricultural schools of Georgia, Stewart	391
The Gary public schools: Household arts, White	391
Domestic science in rural school	391
Report Wellesley College training camp and experiment station, Diehl	391
[Opportunities for disabled soldiers, sailors, and marines]	392
Vocational legislation passed at 1919 session of Arizona Legislature	392
[Vocational home economics education in California], Murchie	392
First report of the Colorado State Board for Vocational Education	392
Administration of Smith-Hughes Act in Georgia for 1918	392
First report of the Massachusetts Board for Vocational Education	393
Annual report of the State Board for Vocational Education, 1918	393
Report on vocational education for Montana for the year 1917-18, Abbey	394
Plans for vocational education in Nevada under the Smith-Hughes Act	394
Vocational education laws in Nevada relating to Smith-Hughes Act	394
Federal aid for vocational education in North Carolina	394
Vocational education : Plan of the State Board for Vocational Education	395
Courses of study in vocational agriculture and home economics. Elliff	395
Unit and short courses in vocational agriculture for high schools. Eaton	395
Making lessons in agriculture count, Shambaugh	395
Vocational agricultural education by home projects. Stimson	395
Agriculture and home economics bulletin with a moral code. Wilson et al	396
[Elementary agriculture and home economics in New Mexicol, Miller	396
	200

.

Plant production, Moore and Halligan	396
Vocational agriculture: Animal husbandry series No. 2, Eaton and Lee	396
Malaria: Lessons on its cause and prevention, Carter	396
Distribution of eggs to school children	396
Domestic science : Principles and application, Bailey	396

#### MISCELLANEOUS.

Annual reports of the Department of Agriculture, 1918	397
Annual report of the director of the experiment station, 1918, Duggar	397
Twenty-eighth Annual Report of Arizona Station, 1917	397
Director's report for 1918, Jordan	397
Twenty-eighth Annual Report of Wyoming Station, 1918	397
Quarterly bulletin of the Michigan Experiment Station	397

# EXPERIMENT STATION RECORD.

Vol. 41.

SEPTEMBER, 1919.

No. 4.

At this time, when the experiment stations are feeling keenly the pressure of unusual conditions, the necessity for rigid economy is impressed upon every administrative officer. The question is not now primarily one of growth and development, but of how to carry forward the work of the station on its present basis, and how to get done the things that need to be done and which the station has set itself to do. It has become a very real problem with most of the stations, often involving adjustment and even retrenchment.

The exercise of economy in the conduct of such an enterprise calls for clear thinking and discrimination. There is a false as well as a true economy, and the decision between the two requires a clear interpretation of the function of an experiment station and sound judgment in the policy of management. Economy does not relate primarily to the withholding of expenditure, although this is often compelled by present necessity, but it applies quite as much to the method and purpose which underlie the station work, and especially to the best utilization of research ability in the presence of a depleted supply. In its broad aspects judicious economy is the attempt to make the utmost of all the available resources of the station, human, physical, and financial, and direct these into the most effective channels.

With practically no increase in regular appropriations in the past five years, reaching back to the time of prewar prices and conditions, it goes without saying that every possible leak needs to be guarded; and this relates not only to expenditures but to lost motion and efforts which are unproductive from the standpoint of the station. Economy at such a time will dictate that the funds of the station and the facilities at its disposal be devoted to activities properly within its scope and which promise the most profitable returns. This means a discriminating judgment guided by a policy and a plan well within the scope and function of the station, designed to fit the exigency without a lowering of quality or standards.

The determination of such a policy and adaptation to present conditions requires rigorous self-examination. There are some drains upon the stations which may be corrected, and there are some hin-

301

drances and obstacles which it ought to be possible to remove. There are also some economies which might be effected by a redirection of certain features that have grown up in times of less stringency or persisted from the early days.

Since sound economy is a matter of good administrative judgment, adequate provision for administration is one of the prime essentials. During the period of the war there were unusual calls upon administrative officers, and to some extent their attention was diverted from the affairs of the station. In not a few cases the stations have begun to show the effects of this, and with the shortage of funds and of persons suited to do their work larger attention to their administrative details will be necessary to prevent their drifting or going backward.

The station work is not of less special character or less entitled to administrative oversight than the extension work; and research as the most advanced and intensive phase of agricultural education needs a type of administrative supervision which, with a keen understanding of its function and methods, will studiously organize and stimulate its activities so as to best utilize the resources at its command. Such an administration is fundamental to the proper recognition of values and to adjustment to the straitened circumstances.

In a general way the function of the experiment station has become clearer and more sharply differentiated year by year. There are certain features, however, which have been adhered to and which at the present time may afford a means of more definitely conserving funds and effort.

We no longer think of the management of large farms with incidental experimental features as being properly within the scope of the experiment station. There has been much improvement in this respect since the time when the college farm was turned over to the station to operate, and experimental work is now generally conducted on a more restricted and intensive scale. There are still numerous cases, however, where the station as such is responsible for the management of the entire farm, or of special features such as the poultry department, dairy, orchard, greenhouses, etc., and supplies the facilities for instruction as well as for experimentation. If in such cases the college contributes to their support there is no clear division and the responsibility rests with the station organization. Funds appropriated by the State for station purposes are employed in the support of these features, and men of the station staff give considerable of their time to their management. These workers are frequently judged in no small measure by the success of their management of these joint features in which the commercial element is prominent, and naturally they soon realize it and are guided by it. It tends to make the station work a secondary consideration.

#### EDITORIAL.

There has been a tendency also to enlarge the station plant in various directions, to acquire considerable areas for the station in order to secure tracts suited to extensive field experiments and plantations, the remainder being carried by the station in general crops; and donations of farms or lands to the college have been turned over to the station to administer and to develop for such use as might be made of them in experimentation. The responsibilities and overhead expense are thus added to the station, and may result in a considerable diversion of funds and attention. Conditions may even prevent for the time being much real station work being done in connection with them. Indeed, there are instances in which persons on the station staff are doing no real experimental work, but are managing and developing tracts or herds or other features which may ultimately be used in part for experimental purposes. The staff is therefore enlarged by this amount without corresponding return, and the station budget is enlarged to carry on these non-experimental features. The station seems to have more staff and more funds than are available for its real work.

It is easy to underestimate the effect of such added responsibilities and the influence they may have on the station. It will be charged by the public with these funds as well as with the success of the enterprise, and it may not always be clear that it is making adequate return in actual experimental work. A large enterprise conducted in the name of the station without a substantial amount of experimental work is likely not to make a very favorable impression or to strengthen the station in appeals for funds.

The extent to which these large operations are engaged in is indicated in a way by the sales of station farm products. These now amount to considerably over a million dollars a year. They are thus no longer incidental features but one of the main elements in the total revenues of the stations. To a large extent, however, they represent a turnover rather than an addition to revenue, sometimes a net financial loss. Even where they seem to be commercially profitable a false impression is created if they exceed the actual needs of the station for experimentation.

There is opportunity for economy of both effort and funds in a revision of the project list so as to direct the work to live topics and confine the expense to substantial undertakings involving real inquiry. Agricultural investigation is an effort to determine and relate phenomena in such a way as to make the art intelligible and practice more effective. Experiments which only half answer a question do not meet the needs. Superficial work which must be gone over again multiplies the effort. Much has been said about duplication in station work, a type of repetition which is not regarded as wholly profitable because it is a going-over of similar ground in a similar way, without adding anything new that is material in a broad sense, or contributing to the final solution. In some cases it may be largely a redemonstration. It is not constructive in the best sense, because it does not recognize what has been done and build upon it. It is opposed to careful analysis of the questions and originality in attacking them. There is still considerable of such work in the aggregate, and it accounts for quite an item of expenditure.

Satisfaction with the mere practical result applying to the immediate present, without attempt to analyze or weigh the factors which go to comprise it or may modify it, represents an attitude which is inadequate at the present time. The same attitude of inquiry needs to be encouraged in the simpler forms of experiment as in more fundamental investigation, although it may not lead as far. This attitude of inquiry, of searching for reasons as well as for facts, of guarding against inaccuracy, and of critical attention to the provision of conditions for sound conclusions, leads to a larger element of permanency in results and hence a more adequate return on the investment. It is important that the method and the procedure are adequate to the problem, and to insure this requires critical examination at the outset or at definite stages. Field and feeding experiments not infrequently exhibit evidences of haste and insufficient consideration in planting. The adequacy of the plan to give a clear and definite answer has not been critically scrutinized in advance. Too many things have been assumed, with the result that there are too many variables which rise up later to cause confusion and uncertainty.

Several stations have recently undertaken a critical examination of their projects to determine their importance and adequacy, and to ascertain where they are leading. It is an attempt to strengthen the program of investigation and experiment and at the same time to adapt ends to means. It provides for a certain measure of realignment with concentration upon the more important and promising lines, allowing the retrenchment to apply to the less significant ones.

The human element is recognized as the largest controlling factor in agricultural research, far overshadowing all others, and yet in practice it seems not always to be given the weight it is entitled to. The staff is usually provided with physical equipment without stint, but in a multiplicity of duties and calls its energies are dissipated to an extent which is serious for the station work, and it is itself sometimes made the subject of economy. Economy which begins with the staff begins at the wrong end, and is dwarfing to the institution. The soundest economy requires a frank acknowledgment of the high requirements and the high standards which ought to prevail in agricultural research, and of the attractions necessary to draw into and hold in it persons of marked ability and training. The efficiency of a station is the sum of the efficiency of its staff, and one or two inadequate members may materially lower the average.

There are indications in some cases that the quality of agricultural investigation is being lowered by the employment of persons not properly adapted or prepared for it, and by the advancement to positions near the top of those inadequately trained or experienced. The effects of such a course may not be wholly immediate or temporary but may extend over a period of years. They are likely to do so unless the mistake is corrected. Unfortunately in some instances, due to scarcity no doubt, the standards formerly striven for are not being fully maintained, and these standards are not advancing with the development of the problems.

The stations need strong, well-equipped men now more than ever. Competition in securing and holding them has never been so keen as at present, and it now includes in larger extent than formerly various commercial and industrial concerns, which having become convinced of the need for scientific men seek the best. It is rarely that the stations can meet the offers from these agencies in terms of salary, but in some cases real economy will make larger attempt than has been made and will hold out attractions which have much weight with the man of research tendencies. And as between institutions of similar grade, the disadvantage of change and the present scale of salaries needs to be fully recognized. The flat salary scale of some institutions in which the station is included, with the difficulty in securing advance out of order or in proportion to real merit, is a decided handicap. The fact that research calls for a preparation and special ability beyond that of most other branches of activity is not yet recognized in all institutions or reflected in the salary roll. Ability to assess the value of men in the work of a station is one of the attributes of a successful director. He realizes that it is better to dig deep than to spread thin, more real economy to retain an investigator of demonstrated ability at a somewhat unusual salary than to risk a change with the present scarcity and with the inevitable lost motion which will result.

The shifting of men from one station to another is an element of weakness in our research at present. It is an uneconomical procedure resulting in loss to the progress of investigation through interruption and often abandonment of lines under way. One such move frequently results in a chain of changes affecting a considerable group of institutions.

138958°-19-2

In a specific instance, the calling of a head of department at one institution to a new position in another created a vacancy which was filled by drawing a worker from still another State, who had hitherto been wholly engaged in the station upon a fundamental inquiry for which special facilities had been developed. The project was in its eighth season, just beginning to give results, and probably represented an investment to the station in salary and material of approximately twenty-five thousand dollars. Being largely a field enterprise dealing with growing trees, it could not be moved and hence another expert must be looked for to continue it. Even with excellent records left behind, the human factor in such an investigation, the interest attaching to a personal effort, and the interpretation of the results so as to realize their full meaning count for very much.

There seems no sure remedy for this under present circumstances and no feasible means of avoiding the chain of lost motion which is usually set up. It is a result of the present competition and system of recruiting men. A certain amount of change, especially among the younger men, is to be expected and is desirable. It provides a stimulus and a means of growth. But greater consideration for the work would avoid some of the changes most serious in their effect, even at the expense of a departure from established procedure. A firm determination to withstand the taking away of key men would tend somewhat to discourage it.

The decreased efficiency through interruption and the doing of a variety of things is another source of economic loss. It is quite as important that the energies of the station workers should be economized and directed to productive channels as it is that the funds be spent in an economical and judicious way. It affords quite as large opportunity, although there may be even more difficulties involved in it. It may be far more fundamental in determining the product of a station.

Station workers are rarely in complete control of their time. They have other duties than their investigations—regulatory, teaching, correspondence, advisory, etc. These other duties serve as interruptions and as such may involve more than the actual time concerned. Many men need to be protected against themselves as well as against demands from without, to be stimulated to concentrate and to persist in their efforts, and to put the best that is in them into their work. The personal equation figures largely in this connection and hence requires sympathetic attention on the part of the director. Notable progress has been made in the proper division of time and effort where other duties are involved, and in grouping together the teaching periods or restricting this function to a particular season. Where this has not been accomplished it offers considerable opportunity for the economy of time and the proper direction of effort. Larger freedom for uninterrupted time in the station is still much to be desired. Economy of the supply of workers, and especially those of outstanding ability in research, suggests utilization of their talents to the utmost. Research is not alone for the few if proper guidance can be supplied. Leadership is of great importance to make most highly effective the work of the rank and file. The history of science shows to how large an extent discoveries and important deductions have rested upon long series of accurate observations requiring care and patience, but not necessarily great genius. "The method of science is not a mysterious gift of genius but a practical tool in the discovery of facts and their application to the problems of everyday life." Much credit, therefore, belongs to the patient workers whose efforts help to make discovery possible provided their work is so done that it can be knit together.

In the drift toward specialization, scientific men have more and more segregated themselves into groups each of which confines itself to the study of a special and often narrow field. Specialization represents a great advance. It recognizes the deeper insight, the necessity of intensive study, and a differentiation of field and of skill. But specialization is opposed to generalization and may unfit men for it.

While specialization has served to advance scientific knowledge there is a danger in its isolation of retarding the solution of complex problems like those in agriculture. These problems have often been worked upon from the standpoint of the individual specialist, without particular reference to what investigators in another branch are doing. From the standpoint of the individual a special phase and not the broad problem may become the unit. It does not necessarily require a specialist to see a problem, and he may not see it in its entirety. The analysis of a question is an important step toward its study, and such analysis often needs the combined insight of specialists in different fields. Hence the advantage of organization of research around problems in such a way as to unite this viewpoint and means of attack.

Without administrative attention to the matter, however, correlation and joining of effort in accordance with a broad plan is usually not a prominent feature, and the necessary steps for rounding out the information and enabling the final solution must wait upon the different groups to voluntarily supply their parts. This tends to make results fragmentary and incomplete as relates to broad general questions, and may also lead to faulty conclusions because the factors are not all taken into account. The determination of how one set of facts and phenomena are related to another, the grouping of observations and experiments so as to derive from them broad general facts or principles, is a more delicate task than the development of isolated

[Vol. 41

facts. It is like one division of agricultural science attempting to develop an agricultural program for the country in war time. A combination of experts is more likely to view the matter with proper perspective and arrive at trustworthy conclusions. This promises more for the speedy solution of complex questions than the attempt to carry the methods of one science over into another, or the adoption of the findings of other branches of science while working in seclusion.

The combined action of investigators at different institutions who are engaged on common topics also offers opportunity for profitable joint effort. Competition and rivalry are less pronounced than formerly, and there is more disposition to meet upon a common ground if given encouragement. There is less reserve among those engaged in the more advanced lines of research in disclosing what they are doing, and regret if often expressed for the limited time at their disposal and the lack of help in following out suggestions which come to them.

But the largest opportunity for cooperation is perhaps in the less exacting and intensive class of experimental work, much of it local in character and dealing with conditions as they exist. This comprises a vast amount of the station work. A simple form is illustrated by variety testing, done quite independently by different stations and with little attempt to determine the range of varieties or the factors which modify their local adaptation. There is a lack of attempt to fix certain basic facts relating to classes of varieties which will relieve each State from going over much the same ground sooner or later, and often repeating this in different localities within its borders. It should not be difficult to determine the factors which underlie the success of a variety, and this would be made easier if a range of environmental conditions were involved in the plan, as in the case of a cooperative undertaking.

Field work is one of the most expensive types of experimental work and accounts for the necessity for large tracts and overhead in maintenance. It is being carried on by stations in the same region to test similar or like points, and involves a great amount of repetition and duplication of expense. But its results are largely local in character and contain relatively little that is basic because unrelated; and it usually does not go deep enough into the conditions represented to disclose the reasons for the results and the factors which modify them locally. A proper organization of such activity would offer opportunity for real economy and for more rapid advancement.

The need for more adequate funds for agricultural research is very generally recognized and relief is confidently expected sooner
or later. In the meantime the situation may be remedied somewhat by judicious management and a scrupulous conserving of all the stations' resources.

Economy in its sanest form will take the course of greater concentration, a focusing of the stations' revenues and energies on its specific work, a narrowing of its field to that of actual experiment and inquiry. It will not mean a lowering of standards or a weakening of forces, though it may mean a reduction in numbers. It will not mean dividing time with other branches in order to maintain a larger staff. Dilution and dissipation are opposed to strength.

Economy at the present time means retention of the key workers as far as possible, and the devotion of station forces more fully to disclosing and proving the facts of both science and practice, in an even more thorough and final way. This will mean a strengthening of the force that is employed and protection from scattering their energies in ways that do not make for actual progress.

If the situation is met in this manner it may prove a profitable experience, and better prepare for larger resources.

# **RECENT WORK IN AGRICULTURAL SCIENCE.**

# AGRICULTURAL CHEMISTRY-AGROTECHNY.

Colloid chemistry, J. ALEXANDEB (New York: D. Van Nostrand Co., 1919, pp. V+90, pls. 3, fig. 1).—Brief chapters on the most important general properties of colloids are followed by a discussion of the practical applications of colloid chemical principles in many different fields. Among the topics included are agriculture, soap, milk, ice cream, confectionery, brewing, tanning, rubber, chemical analysis, pharmacy, foods and their preparation, and physiology and pathology.

Catalytic hydrogenation and reduction, E. B. MAXTED (London: J. & A. Churchill, 1919, pp. VIII+104, figs. 12).—The subject matter in this volume is presented under the following heads: Introductory, the preparation of catalysts, the methods of catalytic hydrogenation, the hydrogenation of unsaturated chains, the hydrogenation of unsaturated rings, miscellaneous reductions, dehydrogenation, and the technical hydrogenation of unsaturated oils.

Changes in oils upon storage, H. A. GARDNER (Jour. Indus. and Engin. Chem., 11 (1919), No. 8, pp. 759-761).—Tables are given showing the analytical constants of commercial samples of vegetable and fish oils after different periods of storage of from two to eight years in indirect light and at ordinary room temperature.

The aging of nearly every oil caused a drop in the iodin number and a rise in the specific gravity, saponification number, and acid number. Changes in acid number were particularly marked in fish oils. Samples of American tung oil showed only moderate changes in the acid number but decided changes in the saponification number. Only slight changes took place in samples of corn, cottonseed, lumbang, sunflower, and hempseed oils which were perfectly clear and free from moisture at the time of storage. Sterilized oils were found to undergo less change than unsterilized samples. Oil stored in tin was found to undergo more change in storage than corresponding oil stored in glass.

The author concludes that "the changes that take place in oil upon standing are due very largely to autohydrolysis caused by the presence of either moisture or, in some instances, fat-splitting enzyms. Whenever oil is heated to a temperature of 105° C. for a sufficient period of time to remove the moisture, and then filtered, a moisture-free, clear, and sterile oil will result. Such oil will apparently keep for a long period of time without showing any marked changes."

The rotatory powers of the amids of active  $\alpha$ -hydroxy acids, C. S. HUDSON (Jour. Amer. Chem. Soc., 40 (1918), No. 5, pp. 813-817).

The rotatory powers of the amids of several a-hydroxy acids of the sugar group, C. S. HUDSON and S. KOMATSU (Jour. Amer. Chem. Soc., 41 (1919), No. 7, pp. 1141-1147).

The amid of  $a-\delta$ -mannoheptonic acid, C S. HUDSON and K. P. MONROE (Jour. Amer. Chem. Soc., 41 (1919), No. 7, pp. 1140, 1141).

The constitution of capsaicin, the pungent principle of Capsicum, E. K. NELSON (Jour. Amer. Chem. Soc., 41 (1919), No. 7, pp. 1115-1121).

[Urease], M. JACOBY (Biochem. Ztschr., 74 (1916), No. 1-2, pp. 93-122; abs. in Chem. Abs., 10 (1916), No. 13, pp. 1754, 1755).—This is a series of articles dealing with urease as follows: Adsorption of Urease and Its Activity (pp. 93-96); Enzym Immunity (pp. 97-104); The Auxoaction of Amino Acids upon Urease (pp. 105, 106); The Action of Antiseptic Substances upon Urease (pp. 107, 108); Urea Decomposition by Bacteria (pp. 109-115); Action of Serum upon the Bacterial Urea Decomposition; and The Problem of Increase of Virulence of Bacteria in the Animal Body (pp. 116-122).

The substitution of methyl alcohol and denatured alcohol for ethyl alcohol, J. PRESCHER (Ztschr. Untersuch. Nahr. u. Genussmtl., 36 (1918), No. 11-12, pp. 286, 287).

I. Attempts to substitute methyl for ethyl alcohol in the Gottlieb-Roese method for determining fat (pp. 286, 287),-Methyl alcohol proved unreliable in the Gottlieb-Roese test on account of the lack of a clear line of separation between the ether and water layers of the mixture.

II. The use of denatured alcohol in judging the freshness of milk (p. 287).-Alcohol denatured by the addition of pyridine bases is considered reliable for this test on account of the very small amount of bases required for denaturation. Alcohol denatured by acid is, however, considered unsuitable unless it is distilled over potassium hydroxid and the first part of the distillate discarded.

A simple weighing burette, D. W. MACARDLE (Jour. Indus. and Engin. Chem., 11 (1919), No. 7, p. 670, fig. 1) .- The burette consists of an ordinary 100 cc. Erlenmeyer flask fitted with a two-hole stopper. In one of the openings is placed a glass stopcock taken from a broken burette and in the other a bent glass tube drawn at the outer end to a capillary. Both stopcock and tube end just below the cork and above the level of the standard solution in the flask. To use the burette the cock is closed, the flask turned so that the capillary is over the titrating vessel, and the solution forced into the capillary by the warmth of the hand. On opening the cock the liquid will then flow freely. When near the end-point the cock may be closed and the solution forced out in drops by the heat of the hand.

The accuracy of the burette is said to be-limited only by the sensitiveness of the end-point.

A laboratory drying apparatus, S. FRÄNKEL (Biochem. Ztschr., 74 (1916), No. 3-4, pp. 170-175, figs. 3).—The apparatus, which is constructed on the principles of the commercial apparatus, consists of a kettle heated with gas, a condenser, and a drying cupboard which can be heated with hot water or steam through a series of pipes supporting the drying tray. The vacuum is obtained by means of an electric pump.

A new condenser, S. FRÄNKEL (Biochem. Ztschr., 74 (1916), No. 3-4, pp. 165, 166, fig. 1).—The condenser described is a modified Liebig type having seven small inner tubes in place of the single one of the usual condenser.

A new form of distilling bulb, J. S. MCHARGUE (Jour. Indus. and Engin. Chem., 11 (1919), No. 7, pp. 670, 671, figs. 2).-The principal feature of the new form of distilling bulb devised by the author at the Kentucky Experiment Station is that the part within the bulb of the tube connected with the distilling flask is T-shaped. The arms of the T tend to diminish the possibility of any of the alkaline contents of the distilling flask being forced into the condensing tube. Steam flowing out of the two arms keeps the bulb at a more uniform temperature and hastens distillation. The arms of the T slope downward, and the openings at the end are large enough to prevent water from being held in them by back pressure. Two small holes blown in the stem of the T within the bulb allow condensed water to return to the flask as soon as formed.

The bulb is illustrated by a diagram.

1919]

An instrument for the determination of small quantities of carbon monoxid in hydrogen, E. K. RIDEAL and H. S. TAYLOR (*Analyst*, 44 (1919), No. 516, pp. 89-94, figs. 2).—An instrument is described and illustrated which has been adapted for the continuous analysis of hydrogen supplies and for automatic registration of the carbon monoxid content. The principle employed is that of preferential catalytic combustion of the carbon monoxid with a small amount of added oxygen, the carbon dioxid formed being suitably absorbed and estimated. The preferential combustion of the carbon monoxid was found to occur in the presence of metallic oxids and to be increased by using a mixture of several oxids. A mixture of iron and chromium oxids with small quantities of cerium and thorium oxids proved very satisfactory.

By means of this instrument it has been found possible to determine and record very quickly minute traces of carbon monoxid in hydrogen and also to differentiate rapidly between various catalytic agents.

Analytical method for determining efficiency of ammonia oxidation, D. P. GAILLARD (Jour. Indus. and Engin. Chem., 11 (1919), No. 8, pp. 745–747, fig. 1).— The efficiency of ammonia oxidation is determined by a comparison of the percentages by weight of combined nitrogen in the entrance and exit gases of the converter. In the "bulb" method of analysis here described a sample of the gases to be analyzed is drawn into a previously weighed evacuated bulb, and a second weighing is made to obtain the weight of the sample. In the case of the entrance gases, the combined nitrogen in the form of ammonia is determined by absorption in water and subsequent titration with N/10 sulphuric acid. In the case of the exit sample, after the introduction of water, oxygen is drawn in and the bulb shaken for several minutes, after which the liquid and washings are transferred to a beaker and titrated with N/10 sodium hydroxid.

The detailed procedure is described in full and suggestions are given for variations in procedure. The average precision of a single efficiency determination in duplicate is thought to be within  $\pm 0.75$  per cent. The chief merit of the method is its simplicity; both in the analytical work and in the calculations.

Adaptation of the Mohr volumetric method to general determinations of chlorin, L. YODER (*Jour. Indus. and Engin. Chem.*, 11 (1919), No. 8, p. 755).—The author at the Iowa Experiment Station has developed a modification of the Mohr method of determining chlorids which has proved applicable to rapid determinations of chlorin in various materials, particularly in organic products containing small amounts of the element. The procedure adopted is as follows:

"To the sample is added 5 cc. of a 30 per cent solution of calcium acetate with sufficient distilled water to thoroughly saturate the material. The mixture is evaporated to dryness at  $120^{\circ}$  C. and ignited at a temperature not over 450°. The cooled residue is thoroughly moistened with a few cubic centimeters of a 10 per cent solution of ferric acetate, and again evaporated to dryness and ignited below 450°. The residue is triturated with hot water, filtered, and washed until free from chlorids. The filtrate is evaporated to dryness or nearly to dryness and taken up with just sufficient hot water to insure complete solution of the chlorids when cooled. After the addition of 2 or 3 drops of potassium chromate, the solution is titrated with 0.05 N silver nitrate."

Tables are given of the results obtained in the determination of chlorin by this method and by the gravimetric method in different samples of cow feces, mixed grains, and alfalfa hay. The results were in all cases well within the limits of experimental error. The choice of indicators for the acidimetric determination of boric acid, J. PRESCHER (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 36 (1918), No. 11-12, pp. 283-286).—Sources of error in the use of various indicators in the acidimetric determination of boric acid are discussed, and phenolphthalein is recommended as giving the most accurate results.

The alkalimetric determination of small amounts of magnesium, P. L. HIB-BARD (Jour. Indus. and Engin. Chem., 11 (1919), No. 8, pp. 753, 754).—Certain modifications in the Bruckmiller process for determining magnesium by titration of ammonium magnesium phosphate (E. S. R., 37, p. 412) have been introduced by the author in an application of the method to the determination of magnesium in soil extracts. The principal changes consist in the use of the Gooch crucible for filtration, of neutralized alcohol followed by a water solution of ammonium magnesium phosphate for washing, and of methyl red instead of methyl orange as an indicator. The method as modified is said to be exact for the estimation of quantities of magnesium of 5 mg. or less down to 0.1 mg.

Standards of purity for food products (U. S. Dept. Agr., Off. Sec. Circ. 136 (1919), pp. 22).—This circular contains the definitions and standards for food products published in the form of Food Inspection Decisions since Circular 19 (E. S. R., 18, p. 459), which it supersedes, and those originally published in that circular which have not been superseded by such decisions.

Analyses of flours for the determination of the percentage extraction, O. PRANDI and F. PERRACINI (*Staz. Sper. Agr. Ital., 50 (1917), No. 6–8, pp. 391–393; abs. in Chem. Abs., 13 (1919), No. 12, p. 1349).*—To determine the percentage of extraction of a flour the authors state that, in addition to the microscopic and organoleptic examination, the test should include determinations of nitrogen, ether extract, cellulose, and ash. The formation of furfural from flour by heating with hydrochloric acid and its subsequent determination as phloroglucid are recommended as furnishing additional evidence in doubtful cases. The results obtained by the authors with this determination, using the Tollens-Krüger method on 400 cc. of the distillate and calculating to the dry basis, are as follows: Flour of 80 per cent extraction, minimum 3.81, maximum 4.61, average 4.09; and 90 per cent extraction, minimum 6.7, maximum 7.18, average 6.95 per cent.

The milling grade of rye flour, J. GERUM (Ztschr. Untersuch. Nahr. u. Genussmtl., 31 (1916), No. 6, pp. 176–180).—The author considers the determination of total nonstarches to be the best method for judging the milling grade of rye flour. Starches are determined by the method of Lehmann and Schowalter (E. S. R., 28, p. 807), 30 minutes heating with alcoholic potassium hydroxid being sufficient. The nonstarches are estimated by difference. The results are reported of the application of this method to the examination of several samples of rye flour.

The marc content of sugar beets and its determination, H. CLAASSEN (Ztschr. Ver. Deut. Zuckerindus., 1916, No. 723, II, pp. 359-370; abs. in Chem. Abs., 11 (1917), No. 9, p. 1330).—A method of determining the marc content of sugar beets which is said to give very concordant results is described as follows:

Twenty-five gm, of the shredded beet pulp is placed in a beaker having a mark at 400 cc. The beaker is filled to the mark with boiling water and the mixture digested for 2 minutes. The solution is poured off as completely as possible and the process repeated three times. The marc is then transferred to a weighed filter or Gooch crucible, washed with a little alcohol, dried for from 6 to 8 hours at 105 to  $110^{\circ}$  C., and weighed. To determine the solubility of the

1919]

marc on long-continued extraction, the dried and weighed residue should be subjected to further extraction with six different portions of boiling water.

The critical temperature of solution applied to the analysis of fats, F. OLIVARI (Staz. Sper. Agr. Ital., 50 (1917), No. 6-8, pp. 365-381, figs. 2; abs. in Chem. Abs., 13 (1919), No. 12, pp. 1347, 1348, figs. 2).—The author states that the concentration of the fat in any solution may be considered as if the fat were a single substance and the system studied as if it consisted of two components, fat and solvent. The conditions of equilibrium in two simple cases, an anilin-tallow system and an acetic acid-tallow system, are illustrated by curves from which the percentage of tallow in the mixture can be determined. The measurements involved can be carried out by fixing either the temperature or the concentration of the fat. The last method has had a partial application in the measurement of the solubility of oil.

Tentative standard methods for the sampling and analysis of commercial soaps and soap products, A. CAMPBELL (Jour. Indus. and Engin. Chem., 11 (1919), No. 8, pp. 785-788).—These tentative methods are presented by the committee of the American Chemical Society on the methods of analysis and specifications of commercial soaps and soap products. For some determinations alternative methods are reported for suggestions and criticism preparatory to adopting standard methods.

Some notes on paint analysis, G. J. HOUGH (Jour. Indus. and Engin. Chem., 11 (1919), No. 8, pp. 767, 768).—Methods devised by the author at the Bureau of Soils, U. S. Department of Agriculture, to meet particular cases in testing paint supplies are outlined. These include the determination of cuprous copper in copper paints, a rapid method for lime in white lead, the detection of chromium in mixed pigments, and an improved method for chromium in chrome yellow. A convenient method for the preparation of a starch indicator which will keep indefinitely is also described, in which a dilute solution of salicylic acid is employed as a solvent.

Acid test on enamel ware, W. D. COLLINS (Jour. Indus. and Engin. Chem., 11 (1919), No. 8, pp. 757-759).—Acid tests were made at the Bureau of Chemistry, U. S. Department of Agriculture, on 51 samples of white, gray, and blue enamel ware from 26 different American manufacturers.

The test most used was made by boiling 500 cc. of 4 per cent acetic acid in the vessel for 30 minutes. About half of the samples of white and gray ware suffered no loss of glaze on such treatment, while nearly all the blue ware was badly affected by 2 per cent acid. From 34 of the samples antimony was dissolved in amounts of from 0.5 to 2 mg. Lead was found in ware from only one manufacturer.

The desaccharification of beet molasses with lime by extraction of the sugar juice, DAUDE (*Ztschr. Ver. Deut. Zuckerindus.*, 1916, No. 723, II, pp. 370-397, figs. 6; abs. in Chem. Abs., 11 (1917), No. 9, p. 1330).—A review of patent literature.

Date pasteurizing and ripening apparatus, A. E. VINSON and C. N. CATLIN (Arizona Sta. Rpt. 1917, pp. 479, 480).—For several years the entire output of the Tempe Date Orchard has been pasteurized with a small pasteurizer heated by a gasoline brooder heater. A new pasteurizer of wood, recently constructed, is described in detail, together with an improved carbon dioxid ripener of greater capacity than formerly used.

Reaction products of alkali-sawdust fusion; acetic, formic, and oxalic acids and methyl alcohol, S. A. MAHOOD and D. E. CABLE (Jour. Indus. and Engin. Chem., 11 (1919), No. 7, pp. 651-655).—An investigation is reported from the Forest Products Laboratory, U. S. Department of Agriculture, of the amount of acetic, oxalic, and formic acids and methyl alcohol obtainable from the sawdust of various species of wood by fusion with alkali. The data obtained are summarized as follows:

"From 17 to 20 per cent of acetic acid can be obtained from hardwood sawdust by fusion with sodium hydroxid. A simultaneous production of oxalic acid amounting to approximately 50 per cent of the dry weight of the wood is obtained. If the reaction is carried out in a closed vessel, a simultaneous production of methyl alcohol results amounting to 2.4 per cent; but as the temperature is increased beyond 200° the yield of oxalic acid is considerably reduced. At lower temperatures both formic and acetic acids are produced, amounting to approximately 15 per cent each. It has been found possible to recover as much as 91 per cent of the alkali used."

## METEOROLOGY.

The importance of climatology to tropical agriculture, F. T. McLEAN (*Philippine Agr.*, 7 (1919), No. 7, pp. 191–194).—The subject is discussed particularly from the standpoint of conditions prevailing in the Philippine Islands. It is stated that "the great variety of climatic conditions to be found in the mountains and lowlands of the Philippines makes a study of climatology especially profitable for Philippine students of agriculture."

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. OSTRANDER, A. L. CHANDLER, and G. A. SMITH (*Massachusetts Sta. Met. Buls. 365–366* (1919), pp. 4 each).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during May and June, 1919, are presented. The data are briefly discussed in general notes on the weather of each month.

Meteorology report for 1917, F. E. HEPNER (Wyoming Sta. Rpt. 1918, pp. 90-94).—Monthly summaries are given of observations at Laramie, Wyo., during 1917 on temperature, pressure, precipitation, humidity, sunshine, and wind movement. The highest temperature was 88° F., July 22; the lowest,  $-24^{\circ}$ , January 22. The total precipitation was 9.71 in. The highest relative humidity was 100 per cent; the lowest, 16 per cent, June 23. The greatest velocity of wind was 740 miles per day, May 8. The first killing frost was September 15.

Measurements of precipitation under trees, F. LINKE (*Met. Ztschr.* [*Brunswick*], 33 (1916), No. 3, pp. 140, 141).—It is stated that observations at the Taunus Observatory, near Frankfort, at an elevation of about 800 meters (2,624 ft.) above sea level and with a mean annual precipitation of about 1,000 mm. (39.4 in.), show 66 per cent more precipitation annually under trees than in the open. The excess occurred during dewy and foggy days. Without fog and dew the precipitation was less under trees than in the open.

Fourth report of the Committee for the Investigation of Atmospheric Pollution, 1917-18 (Lancet [London], 1919, I, No. 24, Sup., pp. XXIII, figs. 6; No. 24, p. 1035).—In continuation of previous reports, data obtained at 24 stations in England and Scotland are summarized and discussed.

The data indicate some improvement in the state of the atmosphere during the winter months, but that pollution during the summer months is on the increase as compared with previous years. The deposit of sulphates was greatest during the winter months. The deposit of ammonia was practically the same in summer as in winter. "Sulphates, chlorin, and ammonia vary more or less together, and this is to be expected, as they all form part of the soluble deposit, which is to a great extent governed by the rainfall. None of the other deposits appear to show any special relation to each other." Are soils mapped under a given type name by the Bureau of Soils method closely similar to one another? R. L. PENDLETON (Univ. Cal. Pubs. Agr. Sci., 3 (1919), No. 12, pp. 369-498, pls. 32, figs. 37).—This study conducted at the University of California is an attempt to see whether certain soil types, mapped as the same from different areas of California and judged to be the same by the criteria used by the Bureau of Soils of the U. S. Department of Agriculture, are the same or similar when examined from the laboratory standpoint. Twentyfour presumably typical samples of four soil types from widely distributed localities in the State were submitted to physical, chemical, and bacteriological analyses and to pot culture tests to determine their ability to produce different crops.

With reference to physical relations between the soils, it was found that the mechanical analysis by the Hilgard elutriator showed that the soils of a given type were in some cases quite divergent from each other in their content of certain of the sizes of particles. The mechanical analysis by the Bureau of Soils method showed that 6 of the 24 soils were not true to their type names, and that of those soils within the type there was considerable variation. The moisture equivalents for the several types showed distinct enough values to substantiate the field separation. The hygroscopic coefficients varied widely within each type, and the types were not shown to be distinctly different by this criterion.

With reference to chemical relations it was found that the total nitrogen averages varied markedly from type to type, with the Altamont clay loam containing three times that in the San Joaquin sandy loam. The average humus content of the San Joaquin samples was about half that of the other types. The variations in humus content between the types were small, considering the diverse nature of the types and the large range in the amount of humus within the type. The loss on ignition showed considerable variation within the type and no significant distinction between the four types. The average total calcium content of the types was distinct, though the wide range within each type minimized the significance of the variation in the averages. With regard to magnesium, the types were neither distinct nor were the soils within the type closely similar. The average phosphorus content of the types was distinct, though the ranges within the several types frequently overlapped. The total potassium results did not show the types to be distinct nor the soils within a type closely similar.

With reference to bacteriological relations, it was found that the ammonifying power showed rather larger variations from type to type than between the samples of a type. The nitrogen fixation data did not show characteristic differences for the several types.

"Regarding nitrification as a whole there may be a greater divergence between the samples of a type than between types. The relative nitrification of the soil's own nitrogen varies with the type, as does the relative nitrification of the several nitrogenous materials added."

Pot cultures in the greenhouse showed that "different representatives of a given type are not the same in their ability to produce crops. The arrangement of the samples of a given type according to their fertility may or may not vary with the special crops used as the indicators. The types are distinct with respect to their fertility, considering their average production. Therefore it is concluded that with regard to the 24 soils of four types examined, all soils mapped under a given name by the Bureau of Soils method may or may not be closely similar, depending upon the criteria used. The greater number of

the criteria show the soils of a type to be not closely similar, and the types to be but little differentiated from each other."

In addition, there are given an historical sketch of the development of soil classification and mapping and a discussion of certain of the methods employed by the Bureau of Soils. It is pointed out that despite its defects the work of the Bureau of Soils is of value, and is practically the only type of soil classification and mapping possible under the conditions imposed.

Field operations of the Bureau of Soils, 1914 (sixteenth report), M. WHIT-NEY ET AL. (U. S. Dept. Agr., Field Oper. Bur. Soils, 1914, pp. 2850, pls. 89, figs. 73, maps 67).—Supplementing similar work previously noted (E. S. R., 36, p. 210), this comprises a general review of the field work conducted by the Bureau of Soils during 1914, together with detailed reports on 78 surveys which have already been noted from time to time.

During the year 37,618 square miles or 24,075,520 acres were surveyed and mapped in detail, making the total area surveyed and mapped up to January 1, 1915, 353,412 square miles or 226,183,680 acres. Reconnoissance surveys covering an area of 40,120 square miles or 25,676,800 acres were also made.

Soil survey of Howard County, Ark., M. W. BECK, M. Y. LONGACRE, F. A. HAYES, and W. T. CARTER, JR. (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1917, pp. 48, pls. 3, fig. 1, map 1).—This survey deals with the soils of an area of 385,280 acres situated in the southwestern part of the State and lying in the southern part of the Appalachian Mountain and Plateau Province and in the northern part of the Gulf Coastal Plain Province. The topography of the northern section of the region is hilly to mountainous and of the southern part level to gently rolling. Natural drainage is generally well established.

The soils of the county include residual upland soils derived from sandstone and shale, sedimentary upland soils, terrace or old alluvial soils, and first-bottom or recent alluvial soils. In addition to rough stony land and chalk, 33 soil types of 21 series have been mapped. Hanceville stony fine sandy loam and Hanceville fine sandy loam, occuping 21.8 and 11.5 per cent of the total area, respectively, comprise the prevailing types.

Analyses of soils of DeKalb County, W. A. WORSHAM, JR., D. D. LONG, L. M. CARTER, M. W. LOWRY, and W. O. COLLINS (*Ga. State Col. Agr. Bul. 163 (1919)*, *pp. 29, pl. 1. figs. 3*).—This bulletin reports and discusses chemical analyses of samples of each of the 11 soil types found in an area of 174,080 acres in north central Georgia.

The discussion of analyses indicates that the upland soils of the county are fairly well supplied with potash, with the exception of the Iredell types. The bottom soils and at least two of the upland types are considered to be abundantly supplied with potash. The nitrogen and phosphoric acid contents are low in all the upland types. Nitrogen and organic matter are considered to be the limiting fertility factors of the soils of the county, followed by phosphoric acid, and liming and deep tillage of the soils are considered advisable.

A considerable variation in the composition of the different soil types of the county is shown.

Analyses of soils of Dougherty County, W. A. WORSHAM, JR., D. D. LONG, L. M. CARTER, and M. W. LOWRY (*Ga. State Col. Agr. Bul. 126 (1917)*, pp. 47, pl. 1, figs. 4).—This bulletin reports and discusses chemical analyses of samples of soil from each of the 24 soil types of an area of 219,520 acres in southwestern Georgia.

The analyses indicate that phosphoric acid is the limiting factor in the fertility of these soils, and that the nitrogen and potash contents are generally low. It is also concluded that these soils are in need of lime and deep tillage. Analyses of soils of Jackson County, W. A. WORSHAM, JR., D. D. LONG, L. M. CARTER, M. W. LOWRY, and W. O. COLLINS (*Ga. State Col. Agr. Bul. 144 (1918)*, *pp. 24, pl. 1, figs. 2*).—This bulletin reports and discusses analyses of soil samples from each of the 9 soil types from an area of 221,440 acres in north-eastern Georgia.

The discussion of analyses indicates that nitrogen is the limiting fertility factor in these soils and that they are relatively deficient in phosphoric acid. They are well supplied with potash but are in need of lime and deep tillage.

Analyses of soils of Polk County, W. A. WORSHAM, JR., D. D. LONG, L. M. CARTER, M. W. LOWRY, and W. O. COLLINS (*Ga. State Col. Agr. Bul. 127 (1917)*, *pp. 54, pl. 1, figs. 6*).—This bulletin deals with the chemical composition of both the soil and subsoil of the various soil types of an area of 200,320 acres in northwestern Georgia. Thirty-one soil types and three phases are discussed, of which the Clarkville gravelly loam covers 33 per cent, the Decatur clay loam 14 per cent, and the Talladega slate loam 10.1 per cent of the county.

It is concluded that nitrogen and phosphoric acid are the limiting factors in the fertility of Polk County soils. The potash content is relatively high. Practically all of the soils are acid and in need of lime.

The soils of Anne Arundel County, J. C. BRITTON and C. R. ZAPPONE, JR. (In *Md. Geol. Survey—Anne Arundel County. Baltimore: Johns Hopkins Press,* 1917, pp. 133–174, pl. 1).—This report deals with the soils of an area of about 275,840 acres lying wholly within the Coastal Plain region of Maryland.

In general there is a fairly definite relationship between the soils and topography. Eighteen soil types of five series are recognized, of which the Sassafras series cover about 55 per cent of the area. The Sassafras fine sandy loam, sand, and silt loam cover, respectively, 15.5, 14.6, and 11.2 per cent of the area. It is stated that the soils of the Sassafras series are the most productive of the area. Practically all the soils are said to be deficient in organic matter.

Soil survey of Barbour and Upshur Counties, W. J. LATIMER (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1917, pp. 51, fig. 1, map 1).—This survey deals with the soils of an area of 447,360 acres situated in the north central part of the State and lying within the greatly dissected portion of the Appalachian Plateau. The topography in general is steep and broken although modified somewhat over the northwestern part of the region. Elevations range from 1,000 to 3,250 ft. above sea level. Natural drainage is generally well established.

The upland soils of the area have been derived from the weathering in place of alternate strata of sandstone, gray and red shale, and thin beds of limestone of the Carboniferous era, while alluvial soils also occur along the streams. In addition to rough stony land, 15 soil types of 9 series are mapped. Dekalb stony loam and Dekalb silty clay loam, occupying 37.2 and 29.4 per cent of the total area, respectively, predominate.

Arable lands (*Rpt. Min. Agr. Prov. Quebec, 1917, pp. 90–100*).—Analyses of 14 samples of soils from the island of Orleans, Province of Quebec, are presented and discussed. Twelve of the soils were acid. The two soils not acid were black mucks containing a large proportion of organic matter and a good proportion of lime. All the soils were deficient in potash, which is apparently their chief defect. They were all relatively well provided with nitrogen.

Analyses of all samples of clay soils from Abitibi, Province of Quebec, are also reported. All of these except one showed pronounced acidity.

Fertility survey of the Egyptian Delta, B. F. E. KEELING (*Trans. 3. Internat. Cong. Trop. Agr. 1914, vol. 2, pp. 366-369*).—The results of a soil survey of the central and western Delta showed that the fertility survey is a close approx-

imation of the salt survey by eye estimation. The mean salt content of what is considered good land was about 0.3 per cent, of medium land 0.5 per cent, and of poor land about 0.8 per cent. Barren land contained any amount of salt up to 25 per cent. Considerable quantities of both sodium carbonate and bicarbonate were found in the soils of the more northerly part of the Delta. The close dependence of soil fertility upon altitude above sea level is also noted.

Malayan rubber and coconut soils, M. BARROWCLIFF (*Trans. 3. Internat. Cong. Trop. Agr. 1914, vol. 2, pp. 410-421*).—The Malayan rubber soils are classed as undulating land, flat land, and flat peaty coast land, the first and last being the most productive. Mechanical and chemical analyses of 10 representative samples of rubber soils showed the undulating soils to be of a light sandy nature with perfect natural drainage, the flat soils to be of close and impermeable texture, and the flat peaty soils light and porous owing to their content of organic matter.

The nitrogen and lime contents of these soils, while relatively low, seemed sufficient for the growing of rubber. No relation was established between potash content and fertility. With the exception of the peaty soils, the soils were markedly deficient in phosphates, this being apparently the limiting factor.

The coconut soils are mostly peaty soils containing much clay and organic matter. "They are well supplied with nitrogen and with potash and phosphate, both in the total and 'available' forms. Observations go to show that if badly drained they are infertile; but that for coconuts the drainage need be less deep and thorough than for rubber."

The effect of organic matter on soil reaction, R. E. STEPHENSON (Soil Sci., 6 (1918), No. 6, pp. 413-439).—Studies conducted at the Iowa Experiment Station on the effect of albumin, casein, blood, starch, dextrose, alfalfa, and ammonium sulphate on the reaction of a silt loam soil fairly rich in organic matter and a sandy loam soil low in organic matter are reported. The treatments with organic matter were made at the rate of 10 tons per acre. Alfalfa was applied to the silt loam soil at the rate of 20 tons per acre, and ammonium sulphate was applied in all cases at the rate of 1 ton per acre.

It was found that none of the organic treatments increased the lime requirement of the soils. The highly nitrogenous materials rather had the effect of decreasing the acidity. This effect was very marked at the first sampling. Ammonium sulphate, on the other hand, consistently caused a marked increase in the lime requirement of both soils. The carbohydrate materials had a small and inconsistent effect upon the soil reaction. The highly nitrogenous organic materials which diminshed the acidity tended to protect the carbonates of the soil at the first sampling. Later, the same materials used up the limestone quite completely in some cases and to a much greater extent in all cases than did the soil alone. Ammonium sulphate, likewise, very consistently exhausted the lime of the treated soils. The carbohydrates and the alfalfa had no more marked effects in exhausting the carbonates than in increasing the acidity.

Ammonification was greater in the absence of lime on both acid soils. A difference in the soil flora is considered a possible explanation. Both casein and albumin ammonified more rapidly than blood, which is of higher nitrogen content. Ammonia did not accumulate in the presence of either carbohydrates or alfalfa.

Nitrification occurred most rapidly in the presence of lime. Nitrification was slow in starting in the presence of the nitrogenous materials, except blood, probably due to a slight toxicity of accumulated ammonia and exhaustion of nitrates caused by the multiplied flora. No nitrates were found in the presence of the carbohydrates until the end, probably because they were consumed by the organisms of the soil. Taking the sum of nitrates and ammonia, there was the greatest action in the presence of lime on the untreated soil, but the reverse was true in most cases for the treated pots.

The two soils showed as marked differences in their behavior as did the different treatments. The more acid soil was much more active, probably because of greater content of organic matter and a more abundant flora.

The relation of the lime requirements of soils to their retention of ammonia, L. P. HOWARD (Soil Sci., 6 (1918), No. 6, pp. 405-411).—Experiments conducted at the Rhode Island Experiment Station on the determination of the lime requirement of soils are reported in which soils were treated with ammonium hydroxid, the excess ammonia evaporated off at the temperature of boiling water, and the retained ammonia estimated.

Within reasonable limits the requirement based upon this retention was independent of (1) concentration of ammonia added, (2) time of contact, and (3) temperature during evaporation. The requirement was about 25 per cent lower than that indicated by the Veitch method. Aeration in the presence of sodium carbonate for 18 hours (300 liters of air per hour) was sufficient to remove completely from 50 to 75 mg. of ammonia from the soil. Sodium, ammonium, and potassium from solutions of their hydroxids and carbonates were retained in practically equivalent amounts. It is believed that the ammonia retained is held chemically by a neutralization of either free acids, acid organic compounds, or acid salts, while physical absorption is largely prevented. The lime requirement based upon the ammonia retention agreed in general with field observations, to the extent that soils needing the most lime showed the greatest lime requirement.

Toxicity of "alkali" salts, T. M. SINGH (Soil Sci., 6 (1918), No. 6, pp. 463– 477).—Studies conducted at the Oregon Experiment Station are reported to determine (1) the toxic points of sodium chlorid, nitrate, carbonate, and sulphate on wheat and peas, (2) the toxic point of a combination of alkali salts in field soils on wheat and peas, and (3) the effect of sodium chlorid, nitrate, carbonate, and sulphate upon ammonification, nitrification, and nitrogen fixation. The soil used was a productive heavy silt loam.

It was found that in order of toxicity the salts ranked as follows: Sodium chlorid, nitrate, carbonate, and sulphate. The percentage of the anion and not the cation was the determining factor. Small amounts of each of the different salts used stimulated both crop growth and bacterial activities. This amount varied with the crop grown, and the concentrations at which stimulation took place bore the same relationship to each other as did their toxicity points.

Sodium chlorid became toxic to both ammonification and nitrogen fixation at a concentration of 0.01 per cent. The toxic point for wheat was 0.4 and for field peas 0.2 per cent.

Sodium nitrate became toxic to ammonification at a concentration of 0.01 per cent and to nitrogen fixation above 0.4 per cent. Small concentrations of sodium nitrate proved toxic to nitrification, but at a concentration of 0.4 per cent a marked stimulation took place. The toxic points for wheat and for peas were 0.8 and 0.6 per cent, respectively.

Sodium carbonate was toxic to ammonification at a concentration of 0.02 per cent, to nitrification at 0.8 per cent, and to nitrogen fixation at 0.01 per cent. For wheat the toxic point was 1 per cent and for peas 0.6 per cent.

Sodium sulphate proved to be the least toxic of all the salts. Neither ammonification nor nitrogen fixation was inhibited to any extent at concentrations up to 2 per cent and peas up to between 1 and 2 per cent.

The toxicity point as found when salts were used in combination, as under field conditions, checked very closely with the points found when the individual

320

1919]

salts were present. The toxic point of the combined salts depended upon the percentages of the chlorids, nitrates, carbonates, and sulphates present and the combination in which they existed. Calcium sulphate, when present, lowered the toxic point of the chlorid, carbonate and nitrate of sodium.

Notes on recent work concerning acid soils, L. T. SHARP and D. R. HOAGLAND (Soil Sci., 7 (1919), No. 3, pp. 197–200).—The authors refer to previous reports by Gillespie and Hurst (E. S. R., 38, p. 620) and Rice and Osugi (E. S. R., 40, p. 123) bearing on the subject, and since they disagree with the latter report a number of experiments were conducted at the California Experiment Station on the inverting power of soils and their extracts. The soil or soil extract was heated with a 10 per cent sugar solution at 85° C. for one hour and the amount of copper reduced determined.

It was found that soils of the highest hydrogen-ion concentration caused the greatest inversion, and the very slightly acid soils and alkaline soils gave only a slight inversion. A marked inversion was also produced by the extracts of the soils of high hydrogen-ion concentration. A larger inversion resulted when the sugar solution was heated in the presence of the solid soil particles.

It is concluded that "large inversion occurs only in soils of distinctly acid reaction, with the greatest inversion occurring coincidently with the highest H-ion concentration of the soil suspension as well as of the water and the sugar extracts."

Direct evidence was also obtained that acid soils do give acid filtrates, giving acid reactions generally of a magnitude very similar to those obtained with the suspensions. Boiling the extract for several minutes produced no large changes in hydrogen-ion concentration.

Determination of the rate of solution of atmospheric nitrogen and oxygen by water, W. E. ADENEY and H. G. BECKER (Sci. Proc. Roy. Dublin Soc., n. ser., 15 (1918), pp. 385-404; abs. in Jour. Chem. Soc. [London], 116 (1919), No. 677, II, pp. 104, 105).—Experiments are reported, the results of which confirm previous conclusions by the authors to the effect that the gases are absorbed by the surface layer of the water but do not remain concentrated there, diffusing gravitationally through the lower layers of the water with comparative rapidity.

Can we predict probable fertility from soil biological data? P. S. BURGESS (Soil Sci., 6 (1918), No. 6, pp. 449-462).—Experiments at the Hawaiian Sugar Planters' Station are reported, the purpose of which was to determine the relation between microbiological data and the crop-producing powers of the soil. Tests of ammonification, nitrification, total organic nitrogen supplied rendered water soluble, and nitrogen fixation were conducted in 9 Hawaiian sugar-cane surface soils, using dried blood, fine alfalfa meal, and fish scrap. Three of the soils were exceptionally fertile, 3 were capable of producing good average crops, while 3 produced poor crops of cane after fair fertilizer applications.

It is concluded that "ammonification tests are not suitable to differentiate between the fertilities of average Hawaiian soils, although they will often show differences between very poor and very good soils. The abilities of soils to render organic nitrogen (of blood or alfalfa) water-soluble are of no value as measures of their crop-producing powers." Nitrification is considered by far the most accurate biological soil test for predicting the probable fertility of Hawaiian soils. There was a remarkable correlation between the amounts of nitrogen fixed in mannite solution cultures and the known fertilities of the soils studied. There was little difference in the comparative rating of the soils, depending upon whether nitrification or nitrogen fixation tests were used as the criteria of fertility.

 $138958^{\circ} - 19 - 3$ 

Some notes on the cause of the unproductivity of "raw" subsoils in humid regions, P. R. McMILLER (Soil Sci., 7 (1919), No. 3, pp. 233–236).—Vegetation experiments conducted at the Minnesota Experiment Station with certain Minnesota prairie subsoils, previously found "raw" toward inoculated legumes, showed that an application of soluble potash and phosphoric-acid fertilizers removed this infertility, rendering the subsoils as productive as the corresponding surface soils. This is considered evidence that rawness in these soils is due to a lack of readily available mineral nutrients.

The inhibition by stable manure of the injurious effects of alkali salts in soils, C. B. LIPMAN and W. F. GERICKE (Soil Sci., 7 (1919), No. 2, pp. 105–120).— Pot experiments conducted at the California Experiment Station are reported to determine the effect of stable manure on soil containing alkali salts as a medium for the growth of barley. The soil was a clay adobe, and the salts were tested singly at rates of 0.3 per cent each for sodium chlorid and sodium carbonate and 0.6 per cent for sodium sulphate. Stable manure was added at rates of 20, 40, 60, and 80 tons per acre, and four successive crops were grown in the same pots.

While no final conclusions are drawn, the data indicate that the tolerance of the barley plant to the toxic effect of salts is very much enhanced by the addition of organic matter in the form of barnyard manure. Culture pots containing sodium chlorid and sodium sulphate gave more definite results than those containing sodium carbonate. It is concluded that the data point to a practical application of this method of reducing the toxicity of alkali salts.

Farm manure: Its production, conservation, and use, E. O. FIPPIN (Cornell Reading Course for the Farm, No. 127 (1917), pp. 37-72, figs. 16).—This is a brief popular bulletin on the subject, prepared with special reference to New York conditions.

Botanical composition of a permanent pasture as influenced by fertilizers of different compositions, J. J. SKINNER and C. F. NOLL (Soil Sci., 7 (1919), No. 2, pp. 161-175, figs. 7).—The results of fertilizer experiments begun in 1910 (E. S. R., 35, p. 517) on grass on loam soil at the Pennsylvania Experiment Station are reported.

The fertilizers acid phosphate, sodium nitrate, and potassium chlorid were used alone and in combinations of twos and threes, the ingredients varying in 10 per cent stages. The total amount applied on each plat annually was 50 lbs. per acre of phosphate, nitrate, or potash. The plats were located in a pasture where the vegetation was originally Canada and Kentucky blue grasses, timothy, and white and red clover.

It was found that at the end of seven years the differently fertilized plats contained the various species in distinctly different proportions. Kentucky blue glass had become the predominant variety, while in the beginning Canada blue grass prevailed in larger proportion. Complete fertilizer mixtures high in nitrogen seemed specially favorable for the dominance of Kentucky blue grass over its competitors, while timothy was somewhat more favored by the fertilizers high in potash.

Grass generally had predominated over clover in the plats receiving fertilizers with high ratios of nitrogen, while clover and especially red clover had been crowded out of such fertilized plats. Clover had existed most easily in the plats fertilized with mixtures of phosphate and potash with no, or only a small amount of, nitrogen. The largest amount of clover occurred in the no-nitrogen series of plats, and decreased in the plats as the nitrogen content of the fertilizer increased. This was very marked in the case of red clover.

The soil of the plats receiving well-balanced mixtures of acid phosphate, sodium nitrate, and potassium chlorid, or mixtures containing principally sodium nitrate, tended to remain neutral or become alkaline, but where no sodium nitrate or only a small proportion was in the mixture the soil became acid. The lime requirement increased as the proportion of sodium nitrate in the fertilizer mixture used decreased.

Nitrate in Amargosa Valley, southeastern California (Amer. Fert., 49 (1918), No. 4, p. 32).—Investigations by the U. S. Geological Survey on the nitrate deposits in the Amargosa Valley in southeastern California have led to the following conclusions:

"The nitrate in the Amargosa district occurs in a blanket of so-called 'caliche' about 5 in. in average thickness, which lies about 9 in. below the surface of the ground. The nitrate is accompanied by other salts, chifley sodium chlorid. The soil above and the bedrock below the deposits contain insignificant amounts of nitrate. The high dip and the great thickness of the strata covered by the prospecting make it improbable that deeper beds of nitrate occur in this region. The caliche in general contains an average of less than 2.5 per cent of sodium nitrate, the areal distribution of which is uneven.

"The Zabriskie field, in which the newly found deposit was reported to lie, contains no commercially valuable nitrate. The Upper Canyon and Lower Canyon fields, the most promising in the Amargosa district, together contain, according to careful estimates, about 168 acres of niter-bearing deposits, which, if worked regardless of cost, might produce about 1,980 short tons of refined nitrate.

"The quantity of nitrate available in the Amargosa district is so small and the cost of production would be so great that the district as a whole can not be regarded as a source of commercial nitrate. No further work on the areas already examined is justified, except, perhaps, as purely scientific research. The occurrence of caliche nitrate deposits in the Amargosa district, rather than the usual cave or disseminated deposits, makes it seem possible, though improbable, that really valuable deposits of nitrate may occur elsewhere in the same general region. Prospecting should be continued until all similar deposits in other districts have been tested sufficiently to determine their value."

Nitrogenous fertilizers: Their use in India, C. M. HUTCHINSON (*Agr. Jour. India, 14 (1919), No. 2, pp. 203–214*).—From this discussion, it is concluded that nitrogen is required in Indian agriculture, but that other plant-food constituents are also needed, without which, in most cases, nitrogen would do more harm than good. It is stated, further, that India can not afford to import nitrogenous fertilizers at the same rate as other countries having greater mineral wealth and local consumption, but must depend rather upon a better utilization of indigenous supplies of nitrogen and upon more intensive methods of farming designed to maintain the fertility of the soil.

Some information and suggestions concerning the use of phosphorus, M. M. MCCOOL, G. M. GRANTHAM, and C. E. MILLAR (*Michigan Sta. Bul.* 284 (1919), pp. 30, figs. 22).—This comprises a general discussion of the terms used in connection with phosphate fertilizers; commercial phosphorus carriers; the effect of phosphate fertilization on crop growth and on the soil; the time, manner, and amount of the phosphorus application; the removal of phosphorus from different types of Michigan farms and the amount of commercial phosphate required to make good the loss; the amount of phosphorus in the surface layer of some typical Michigan soils; and results secured from the use of phosphate fertilizers on Michigan farms.

Florida's soft rock phosphate (Com. Fert., 18 (1919), No. 5, pp. 36, 38).—Experiments of one year's duration, conducted at the North Carolina Experiment Station, in which soft rock phosphate was compared with 16 per cent acid

phosphate on a soil poor in phosphates showed that soft rock phosphate was not so available to corn as acid phosphate, and in fact showed practially no availability except in one instance.

Effect of sulfofication and nitrification on rock phosphate, J. W. AMES and T. E. RICHMOND (Soil Sci., 6 (1918), No. 5, pp. 351-364).—Experiments at the Ohio Experiment Station, in which the effect of sulfofication and nitrification on the availability of rock phosphate were studied by incorporating sulphur, dried blood, and ammonium sulphate in silt loam and black clay soil, peat, and quartz sand, are reported.

In an acid soil the oxidation of sulphur proceeded vigorously, approximately 50 per cent being changed to the form of sulphate. While sulfofication was somewhat depressed in an acid soil by the addition of calcium carbonate, in sand mixtures the presence of calcium carbonate was essential. In the absence of other bases the calcium of rock phosphate did not serve as a base for the sulfofying process to any appreciable extent. The proportion of rock phosphate to soil was such that phosphorus was added at the rate of 1,900 parts per million. The oxidation of sulphur, incorporated with rock phosphate in the absence of calcium carbonate or nitrogen carriers, changed 630 parts of phosphorus into a form soluble in neutral ammonium citrate solution.

When calcium carbonate was added to the mixture prepared with an acid soil, the oxidation of sulphur had practically no effect on rock phosphate. In a basic soil the acidity resulting from sulfofication was partially neutralized by calcium naturally present as carbonate and in other combinations, so that the solvent action on rock phosphate was much less than occurred in the acid soil.

Ammonium sulphate affected the solubility of rock phosphate very little. Whatever action ammonium sulphate had is attributed to the sulphate ion rather than to biochemical action, since nitrification of ammonia did not occur in a soil deficient in bases unless calcium carbonate was added. Active nitrification of dried blood and ammonium sulphate occurred in the mixtures when conditions were favorable.

Nitrification was stimulated by rock phosphate to a very limited extent. This fact, independent of the results for either phosphorus or calcium solubility, is considered to be sufficient indication that the process has had no appreciable action on rock phosphate in soil.

Nitrification of dried blood, so far as the citrate soluble figures furnish evidence of availability, was not an active agent for increasing the solubility of rock phosphate mixed with soil. In the absence of rock phosphate or calcium carbonate, the nitrification of dried blood as well as the action of ammonium sulphate, independent of the oxidation of its nitrogen, increased the concentration of water soluble calcium.

More calcium was taken into solution from the soil than from added rock phosphate. This is considered to be evidence that the calcium of the soil, existing chiefly as silicates and partly in other combinations, is almost, if not altogether, as readily attacked as rock phosphate.

Effect of sulfofication and nitrification on potassium and other soil constituents, J. W. AMES and G. E. BOLTZ (Soil Sci., 7 (1919), No. 3, pp. 183-195).— A continuation of experiments at the Ohio Experiment Station on the effect of sulphur on soils and crops is reported (E. S. R., 39, p. 823), the results of which indicated that "nitrification of dried blood and oxidation of sulphur in soil mixtures increased the water-soluble potassium. The liberation of potassium was brought about by salts formed, rather than by the direct action of acidity on insoluble potassium compounds. "Calcium nitrate was present where nitrification was stimulated by calcium carbonate. Ammonium sulphate was formed, by the reaction between sulphuric acid and ammonia from dried blood, where a deficiency of basic calcium compounds restricted the nitrification of ammonia. Considerable amounts of calcium, aluminum, and manganese sulphate were also present in certain mixtures.

"Ammonium sulphate, independent of the ammonia being nitrified, affected the solubility of potassium. Calcium naturally present in the soil as silicate and in other combinations was readily attacked by the acidity resulting from nitrification and sulfofication. Ammonium sulphate was also an active solvent of calcium.

"Magnesium compounds were much more resistant to the action of these solvent agencies.

"Large quantities of aluminum and manganese were converted into soluble forms where sulphur was oxidized in an acid silt loam soil. Small amounts of these elements were made soluble by this action in a basic clay. Nitrification had no effect on aluminum."

Summary of the potash situation submitted by the Bureau of Mines and the Geological Survey of the Department of the Interior, June 1, 1919 (*Amer. Fert.*, 51 (1919), No. 2, pp. 39-42).—This report states that the domestic potash industry has practically been the outgrowth of the war situation. The several domestic sources actually produced 54,562 tons of K<sub>2</sub>O in 1918, and the estimated capacity at the close of 1918 was 100,000 tons.

"Although the greatest output is shown for the western sources, they will be handicapped in competition with foreign potash by their remoteness from the market, the eastern potato and truck regions and southern cotton districts. The by-product sources, located mainly in the East, may be expected, when properly developed, to supply a large part of total requirements at competitive prices."

Data on cost and consumption are also presented.

Some details about the Alsatian potash fields (*Amer. Fert.*, 50 (1919), No. 3, p. 45).—It is stated that there are at present approximately 100 fields in Alsace for which concessions for potash working have been granted, of which about 80 are considered workable.

"The thickness of the deposits in Alsace ranges from 2 to 10 meters [6.56 to 32.8 ft.]; the quantity is estimated at 1,472,058,000 tons of potash salts, which represents about 300,000,000 tons of pure potash. The advantages are that the deposits are uniform; the potash content with 15 to 20 per cent and more, on the average, is higher than in central Germany, and concessions are practically unnecessary for the disposal of the discharged water. On the other hand, the disadvantages are that it is difficult to produce sulphate."

Potash content of blast furnace charges, N. H. GELLERT (*Com. Fert.*, 18 (1919), No. 3, pp. 74, 76).—Analytical data are given which show that the iron ores ordinarily used in blast furnaces in the United States have contained from 0.29 to 2.07 per cent potash. Experience indicates that ores from the Lake district run low in potash (about 0.3 per cent), while foreign ores run high, particularly the manganese ores of Brazil, which usually contain 1 per cent and above. Indian ores rank next to the Brazilian ores in potash content, and Alabama ores are said to be quite high.

It is believed "that between 40 and 50 per cent of the potash charged into a blast furnace can be readily secured by the proper treatment of the charge and by proper collecting devices. The device that can most successfully collect this potash with the greatest saving for blast-furnace operation is the Cottrell electrical precipitator. Experiments conducted on a semicommercial scale indicate that such a collection is possible."

Electro-potash, a Swedish potash fertilizer, and its effect upon mineral soils, P. EHRENBERG ET AL. (*Jour. Landw.*, 66 (1918), No. 4, pp. 209-240).—Pot experiments with wheat and buckwheat are described in which a comparison was made of a potash fertilizer designated as electro-potash with sulphate of potash and a 30 per cent potash salt in both limed and unlimed sandy and loam soils. The electro-potash, said to contain about 11 per cent HCl-soluble potash, is secured as slag after fusing either a granulitic rock or potash gneiss or feldspar with charcoal and iron ore in the electric furnace. The results are held to indicate that the new material is inferior to the two potash salts, both in its effect upon the yield of dry matter and its availability to the plant.

The limestones of Canterbury considered as a possible source of phosphate, L. J. WILD and R. SPEIGHT (*New Zeal. Jour. Sci. and Technol.*, 2 (1919), No. 3, pp. 180–192).—The character, extent, and possible fertilizing value of these limestones are discussed. They are shown to contain variable amounts of impurities, mostly sand, but many of them contain sufficient phosphate to be of considerable importance for fertilizing purposes. Analyses of a number of samples of the limestones showed from 0.16 to 3.14 per cent of phosphoric acid, while certain of the nodules associated with the limestones contained from 10.6 to 51.8 per cent of tricalcium phosphate.

The action of some common soil amendments, J. E. GREAVES and E. G. CAR-TER (Soil Sci., 7 (1919), No. 2, pp. 121–160, figs. 2).—An extensive review of the work of the authors and others bearing on the subject is given, and experiments conducted at the Utah Experiment Station are reported on the effect of 17 different salts, including the sulphates of magnesium, calcium, manganese, and iron, the chlorids of sodium, iron potassium, magnesium, manganese, and the carbonates of manganese, iron, and magnesium, or the available nitrogen and phosphorus of soil.

It was found that the increased available nitrogen and phosphorus is sufficient to account for the noted increase in crop yields resulting from the use of these soil amendments. The increase in nitric nitrogen varied from 1 to 96.7 per cent. The water-soluble phosphorus was increased by all but 5 of the 17 salts, the increase varying from 0.2 to 15.5 per cent. Three of the salts which failed to increase the water-soluble phosphorus increased the organic phosphorus, hence the available phosphorus was increased by all but 2 of the 17 salts listed. The increase in organic phosphorus varied from 3.3 per cent with calcium sulphate to 62.6 per cent with manganese carbonate. The strong stimulant sodium chlorid acted to a great extent by rendering phosphorus soluble, whereas the equally strong stimulant calcium sulphate acted by rendering available more nitrogen.

Use of sludge as a fertilizer, F. T. HAMBLETON (*Engin. and Contract.*, 51 (1919), No. 18, p. 446).—It was found that the expense of disposal of the sludge from a sewage plant yielding 500,000 gal. of sludge per year was met by the proceeds from the crops obtained from 6 acres of land to which the sludge was applied in liquid form. Mixing the sludge with phosphatic and potassic fertilizers gave even more profitable results.

Fertilizers, F. A. LÓPEZ DOMÍNGUEZ (*Porto Rico Dept. Agr. Sta. Bul. 18* (1919), *Spanish Ed.*, *pp. 79*).—This publication comprises a rather detailed but general discussion of the relations between plants, soils, and fertilizers, together with information relative to the regulation of the sale of fertilizers, particu-

larly in Porto Rico. Legislation pertaining to commercial fertilizers in Porto Rico is reviewed and various commercial fertilizer materials described.

The results of the actual and guarantied analysis of commercial fertilizers and fertilizing materials examined during the period from July 1, 1917, to August 31, 1918, are presented in tabular form.

The international movement in fertilizers and chemical products useful to agriculture, 1918 (Internat. Inst. Agr. [Rome], Bur. Statis. Doc. Leaflet, 3 (1919), No. 5, pp. 44).—Tables are given which include fairly complete data on production, trade, and prices for the years 1913 to 1918, inclusive.

#### AGRICULTURAL BOTANY.

[Plant studies], J. A. HARRIS (Carnegie Inst. Washington Year Book, 17 (1918), pp. 116, 117).—This is a brief report of investigations along various lines, including osmotic concentration of vegetable saps, variation and correlation in plants, and variation, correlation, and selective death rate in garden beans.

[Plant ecology], F. E. CLEMENTS (Carnegie Inst. Washington Year Book, 17 (1918), pp. 287, 288).—The principles of synthetic ecology have served as a guide in the experimental work centered at the Alpine Laboratory on Pike's Peak and around Colorado Springs and Tucson. It has been recognized that animals contribute a factor of profound importance in all plant associations, and steps have been taken to begin a quantitative study of this influence. During the year emphasis has been laid upon plant indicators, climatic cycles, and grazing research. A notable feature is the employment of standard plants as indicators in the study of transpiration and rate of growth.

The phytometer method, F. E. CLEMENTS, J. E. WEAVER, and F. C. JEAN (Carnegie Inst. Washington Year Book, 17 (1918), pp. 288, 289).—Batteries of standard plants, termed phytometers, have been installed and three series have been measured. The plants employed have been wheat, oats, sunflower, and raspberry (Rubus strigosus), all of these growing readily at different altitudes. The method promises to be of great value in interpreting climates and soils in terms of plant behavior and perhaps to exceed in value analysis by physical instruments. It should, it is thought, have wide application in dry land agriculture, grazing, and forestry in determining the possibilities of climates and soils and in definitizing the use of plant indicators.

**Permanent quadrats**, F. E. and E. CLEMENTS and G. V. LOFTFIELD (*Carnegie Inst. Washington Year Book*, 17 (1918), pp. 295, 296).—Progress is reported in the work of extending the number of quadrats for the exact quantitative study of climax formations and their succession. In the attempt to secure a record of the plant parts below ground a quadrat-bisect method has been devised by which depth, spread, and competition relations may be charted for wet and dry phases of the cycle.

Ecology of root systems, J. E. WEAVER (Carnegie Inst. Washington Year Book, 17 (1918), pp. 291, 292).—Examination of the root systems of a large number of dominant and subdominant species of important plant communities, with reference to their relation to the nature of the soil, the amount and penetration of the water content, and competition with each other, is said to have shown that the character and location of the root system were correlated with the water content in nearly all cases. Plains and prairies are much alike in regard to root behavior, except that roots of plains species tend to spread laterally while those of the prairie species go more directly downward. The great majority of the roots are highly plastic, those of ecads especially so, but some species, as Kæleria cristata and Allionia linearis, possess very stable root systems. A detailed study of roots begun in Washington and Idaho in 1914 is to be reported in a monograph on root systems.

The influence of snow on the proportion of different vegetation at the same altitude in the Pyrenees, J. BOUGET (*Rev. Gén. Bot., 30 (1918)*, *No. 358, pp. 305-320*).—It is stated that the distribution of vegetation among the high mountains is strongly influenced by the relief of the surface and by the duration of snow. At a given altitude, vegetation may be xerophilous on exposed portions and hygrophilous on the flat or depressed areas, with all intermediate gradations according to exposure. The upper limits of forests are determined directly by these influences. This fact is thought to preclude the possibility of restoring pine forests above the level of 1,800 meters (1.1 miles) on the north slope of the Pyrenees.

**Reciprocal transplants,** F. E. CLEMENTS and H. M. HALL (*Carnegie Inst. Washington Year Book, 17 (1918), pp. 292, 293).*—A new method has been devised for transplanting related species and ecads to determine the effect of a change of habitat in causing adaptation and variation and in producing new forms. The essential feature is the reciprocal planting as illustrated, insuring an exact reversal of conditions and permitting a clear-cut demonstration of the extent to which the varieties are reversible as well as plastic. For the sake of detailed correlation, determinations of water content, light intensity, and air and soil temperatures are made at occasional intervals after the plants are fully established. Type specimens have also been preserved for comparison, and histological material has been obtained for studies of leaf and stem adaptation.

Synchronism in plant structures, J. M. MACFARLANE (Brooklyn Bot. Gard. Mem., 1 (1918), pp. 313-326).—A detailed account of phenological and related events observed during several years (a considerable period being considered essential) states that for any one locality under like environmental conditions the average annual period of seed germination, leaf formation, blooming, dissemination of pollen, and other responses by flowering plants seem to be synchronous often to the day and even to certain hours of the day. In monœcious and diœcious flowering plants, maturation of complemental floral organs seems to be affected in exactly synchronous relation, abundant pollination usually ensuing. A like principle apparently applies to the maturation and dispersal of spores and organs of conjugation. The behavior of plant hybrids suggests that each is a blended combination of parental characters as to period of living and defoliation, blooming and pollination, capacity for climatic resistance, and other phenomena, showing synchronous behavior, that is, a mean (all environmental factors being considered) between those of its parents.

A study in the anatomy of hazel wood with reference to conductivity of water, M. G. HOLMES (Ann. Bot. [London], 32 (1918), No. 128, pp. 553-567, figs. 10).—The anthor describes a statistical method of investigating the constitution of wood from the standpoint of its efficiency for conducting water. This is an attempt to record definitely the number, size, and distribution of the elements in wood which are concerned in this process and to present the results in a graphical form. The method is designed to serve as a basis for correlating with anatomy the facts of specific conductivity as obtained by experiments.

In stool shoots of the hazel a very considerable variation has been observed in the constitution of the wood formed during the first season. On the whole, there is a general decline in total conductivity and a general rise in specific conductivity from the base of the shoot to its apex. The explanation offered is that these facts are related to the provision for other functions carried out by the wood and in particular to the greater proportion of mechanical elements in the lower part of the shoot supplying the necessary support in this region. The influence of immersion in certain electrolytic solutions upon permeability of plant cells, M. WILLIAMS (Ann. Bot. [London], 32 (1918), No. 128, pp. 591-599, figs. 2).—In an attempt to discover what factors besides surface tension may be involved in alterations of permeability in plant cells and how far the time of immersion in a particular solution may be significant, the author has experimented with surface strips taken from leafstalks of Saxifraga umbrosa in solutions of electrolytes. He has found that immersion in these solutions rendered these cells permeable to 0.2 per cent ferric chlorid as indicated by reaction of the ferric chlorid with the tannin contained in the cells, the time required for the production of the abnormal permeability depending upon the concentration. Abnormal permeability to iron chlorid did not involve permeability to the rose-colored material which was observed frequently in the cell sap.

Absorption of gold from colloidal solutions by fungi, M. WILLIAMS (Ann. Bot. [London], 32 (1918), No. 128, pp. 531–534).—A study of Penicillium glaucum, Oïdium lactis, and Aspergillus niger in a series of gold solutions, gum arabic being added as a nutrient, showed that conidia of P. glaucum and O. lactis can develop in a colloidal gold solution containing tannin or gum arabic, the growing fungus taking up the metal and retaining it in noncuticularized cell walls. The process goes on more irregularly when masses of dead fungus are introduced. Coloration of the fungus is more intense in solutions having a higher rate of diffusion. In all cases a blue coloration finally results from the accumulation of gold.

Behavior of stomata, G. V. LOFTFIELD (*Carnegie Inst. Washington Year Book*, 17 (1918), pp. 289, 290).—The work here reported is said to be a continuation of that done in the Selby smelter investigation, some accounts of which have been previously noted (E. S. R., 37, p. 634). Forty species of crop plants have been studied to determine the relation of stomata to the injurious action of smelter fumes upon plant tissues. Similar studies were made at the Desert Laboratory on several species of xerophytes and winter annuals. In addition, particular attention was paid to the relation of the stomatal opening to transpiration and to wilting.

Results of the investigation seem to harmonize the diverging views as to the regulatory action of stomata, since they not only show that species exhibit extreme differences in the daily activity of their stomata but also that the upper and lower epidermis of the same species may vary considerably. Probably the most important result noted is that all the species studied with reference to wilting indicated that the stomata exercised a decisive regulatory action at this time, even in the case of those most passive under less extreme variations in the water relations.

A contribution to the study of variations in respiration of plants as related to age, G. NICOLAS (*Rev. Gén. Bot.*, 30 (1918), No. 355, pp. 209-225).— The author has followed up work previously noted (E. S. R., 22, p. 327; 26, p. 628) with studies on different plants. He concludes that in the young organs, principally the leaves, intracellular oxygenation is more complete than in older organs. The younger tissues absorb much more oxygen than the more developed ones, while fixing relatively less, and thus set free larger quantities of energy which are utilized in growth.

Transpiration of trees, J. E. WEAVER and A. MOGENSON (Carnegie Inst. Washington Year Book, 17 (1918), pp. 290, 291).—A comparative study of the transpiration in coniferous and deciduous trees was carried on at the University of Nebraska from September to May and at the Alpine Laboratory during June and July. These studies, employing Pinus ponderosa, P. banksiana, Pseudotsuga mucronata, Picea engelmannii, Abies grandis, Acer saccharinum, A. glabrum, Ulmus americana, and Quercus macrocarpa, showed the daily transpiration loss from the conifers during autumn to be nearly twice as great as that from the deciduous species with the exception of Q. macrocarpa. The results indicated that the conifers studied were more xerophytic than the broadleaved species during the summer, and that the needle habit was practically as efficient as the deciduous habit in preventing serious loss of water during winter.

Light measurements, F. E. CLEMENTS (*Carnegie Inst. Washington Year Book*, 17 (1917), p. 291).—A study of light intensity and quality on account of its relation to plant requirements and behavior is said to indicate that the intensity on heights such as Pike's Peak and Mount Garfield is scarcely or not at all higher than at points 6,000 to 8,000 ft. lower. This is supposed to be due to low humidity and the absence of dust and other impurities. Earlier observations have been confirmed that forest light is white light, containing the various rays in essentially a normal proportion, although sufficient tests have not been applied in such dense forests as those of cedar and hemlock on the Pacific Coast and of beech in the East.

**Photosynthetic efficiency**, F. E. CLEMENTS and F. LONG (*Carnegie Inst. Washington Year Book, 17 (1918), p. 289).*—Standard plants used as phytometers have served to show the photosynthetic behavior of different species in several habitats as well as the efficiency of each species in different habitats. Studies have also been made of the photosynthetic activity of ecads growing naturally in sun and shade and of paired species found in opposite light conditions. An attempt has been made to determine the rate of carbohydrate production during the day and its relation to the curve of daily light intensity. Factor readings have been secured, special attention having been paid to light intensity and quality. The method is expected to be valuable for use in forestry, where reproduction and growth are largely determined by the light intensity, also in permitting comparisons of the food-making efficiency of varieties of crop plants, as well as of native species.

Experimental pollination, F. E. CLEMENTS and F. LONG (*Carnegie Inst. Washington Year Book, 17 (1918), pp. 293, 294).*—A method of experimentation designed to test the mutual responses of plants and insects is indicated, the results of which up to the present time are said to have thrown much light upon actual functions of flower parts, also to have furnished a large amount of interesting material on the habits and individuality of insects.

Field and garden study of genera and species, F. E. CLEMENTS and H. M. HALL (*Carnegie Inst. Washington Year Book*, 17 (1918), p. 294).—A general investigation of taxonomic criteria and study on the Madieæ in field and garden have been carried on for a number of years. The genera Chrysothamnus, Artemisia, Atriplex, and Haplopappus have recently been special subjects of inquiry into criteria and their application to the problem of distinguishing species from minor units. Field study of certain variants indicated has rendered it possible to make a working outline for the species and to relate the various segregates provisionally to them. This constitutes the basis for the application of statistical and experimental methods by which it is hoped to outline a synthetic system based upon relationship. It should not only permit the grouping of segregates of all sorts about the proper parent species, but should likewise determine the nature of the minor unit, whether variant, ecad, or mutant. At the same time it is proposed to furnish a convenient and accurate way of designating species and their minor units.

Variation and mutation in Epilobium, E. CLEMENTS (Carnegie Inst. Washington Year Book, 17 (1918), p. 293).—Studies continued for some years in connection with E. spicatum produced in earlier work an unusual number of ap-

parent flower and rosette mutants, which have been since grown under control, in order to ascertain the range of possible variation for accumulating and fixing characters. The present study is devoted to the isolation of pure lines and to the experimental production of mutants. Production of flower mutation by manipulating the flow of food to different parts through such means as pruning, mutilation, change of position, and correlation has proved unusually successful, and these plants are to be grown to determine the extent to which such artificial mutants are capable of being placed.

The inheritance of leafing time in the descendants from beeches differing in this respect, C. RAUNKLÆR (*Bot. Tidsskr., 36* (1918), *No. 3, pp. 197–203*).— A study of beech trees in regard to their time of leafing shows that subspecies exist within the species *Fagus sylvatica* which differ markedly as to their time of leaf production, a correspondence existing between parents and descendants in this respect. It is thought, however, that the case is by no means simple as regards the inheritance of the genotypic factors involved.

#### FIELD CROPS.

Farm crops, their cultivation and management, F. D. GARDNER ET AL. (*Philadelphia: The John C. Winston Co., 1918, pp. 288, pls. 2, figs. 122*).—This book, described as "a nontechnical manual for the cultivation, management, and improvement of farm crops," and based on practical experience and the results of agricultural research, is designed as a reference work for all engaged in farming. The work is divided into three parts, dealing with (1) the relation and cultivation of the various farm crops, (2) diseases and insect pests affecting the different crops, together with measures for their remedy and control, and (3) statistical information relative to cost of production, the fertilizing value and percentage composition of agricultural products, etc.

**Productive farm crops,** E. G. MONTGOMERY (*Philadelphia and London: J. B. Lippincott Co., 1918, 2. ed., rev., pp. XIX+501, pl. 1, figs. 208).*—This is a second and revised edition of a work previously noted (E. S. R., 35, p. 593).

[Report of field crops work in Arizona], W. C. HEARD (Arizona Sta. Rpt. 1917, pp. 415-417, 418-426, figs. 5).—This describes the continuation of work along the same general lines as previously noted (E. S. R., 39, p. 735) for the year ended June 30, 1917.

Variety tests with small grains on the Phoenix farm were limited to Early Baart wheat, Texas Red, and San Saba oats, and Wisconsin No. 6 and common 6-rowed barley, with yields ranging from 41 to 50 bu. per acre for wheat, from 93 to more than 100 bu. for oats, and from 40 to 65 bu. for barley which had been lightly pastured.

Hairy. Peruvian alfalfa is said to have given better results than common alfalfa. Tests of 10 varieties of cowpeas and 14 of soy beans are held to indicate that these crops may become of considerable importance in the State. The more promising varieties of cowpeas included Red Ripper, Two Crop Clay, Iron, and Clay. Black Eyebrow and Ito San soy beans are deemed to be desirable early sorts, while Mammoth Yellow and Tarheel Black are especially promising among the larger, later kinds. White Canadian and Colorado Stock field peas seeded late in November and harvested for hay the following April produced 3,300 and 4,400 lbs. per acre, respectively. Garbanzos yielded at the rate of 2.5 tons of cured hay per acre.

Rhodes grass, Natal grass, and perilla, the last said to be native to Japan and of interest as a possible source of a linseed oil substitute, failed to give satisfactory results on the Salt River Valley farm. In tests with fall-sown cereals on the Prescott dry farm, early planting of wheat and rye proved to be quite satisfactory, while later plantings were less so. Barley winterkilled completely, and emmer yields were small. Rye seeded early in rows 7 in. apart produced 3,200 lbs. of hay per acres and in 21-in. rows slightly less than 2,000 lbs. Similar plats allowed to mature grain yielded from 9 to 14 bu. per acre, while later plantings produced as low as 5.5 bu. per acre. The wheat yields amounted to about 2 bu. per acre more than the rye, but in no case was the grain of the best quality.

Sudan grass seeded in May produced approximately 2 tons of hay per acre in addition to a slight amount of pasturage. A portion harvested for seed yielded about 550 lbs. of recleaned seed per acre.

Plantings of different varieties of corn grown for forage produced from 2,960 lbs. of green fodder per acre for Reid Yellow Dent to 49,783 lbs. for Papago Sweet.

Field peas and beans were considerably damaged by rabbits and prairie dogs, and later by a bacterial blight said to be due to *Pseudomonas phaseoli*, which entirely destroyed the peas and greatly reduced the yield of the beans. It is deemed probable that the disease is identical with a similar infection appearing on the same field about three seasons before. The maximum yield of beans, 539 lbs. per acre, was secured from a planting of tepary. White sweet clover produced a fair stand but made meager growth the fist season.

Variety tests with sorghums resulted in yields of green forage ranging from 1,259 lbs. per acre for feterita to 11,061 lbs. for Amber and 11,159 lbs. for Club-Top. Darso, a drought-resistant strain, developed by the Oklahoma Experiment Station, is said to have given encouraging results at Prescott.

Potato yields ranged from 920 lbs. per acre for a planting of Rural New Yorker to 4,011 and 4,122 lbs. for White Rose and Early Rose, respectively.

Seasonal conditions on the Sulphur Springs Valley dry farm are said to have been so unfavorable as to render the results of little value. Mexican June corn produced on the average 2,100 lbs. of green forage per acre; tepary beans sown as a catch crop after Sudan grass which had failed, 133 lbs. of seed, and after an indifferent wheat crop, 121 lbs.; and Dwarf Kafir and Club-Top sorghum 7,350 and 2,600 lbs. of green forage per acre, respectively.

Average crop yields on the university farm amounted to 4 tons per acre for alfalfa, 1 ton of hay per acre for barley,  $5\frac{1}{7}$  tons of green forage for corn, 70 bu. of mature corn, 6 tons of green fodder for feterita, and 5 tons for milo maize. Peanuts are thought to be well adapted to the soil and climatic conditions of the region.

[Report of plant breeding work in Arizona], G. F. FREEMAN and W. E. BRYAN (*Arizona Sta. Rpt. 1917, pp. 452-454, 456-461, figs. 3*).—Observations on selections of pedigree strains of alfalfa and hybridization and selection studies with tepary beans and wheat are briefly reviewed in continuation of similar work previously noted (E. S. R., 39, p. 736).

Individual selections from a strain of alfalfa originating from a single plant selection made in 1909 showed variations in the average yield per plant for three cuttings ranging from 0.3 to 0.53 lb. Different varieties of alfalfa seeded on 4-acre plats in 1916 produced at the rate of from 7,723 lbs. per acre for Turkestan to 16,223 lbs. for European. Due to its productivity and hardiness, hairy-leaved Peruvian is said to be growing in popularity in the Southwest.

Results secured during the past three years in a comparative study of Arizona wheats are held to indicate that grain of excellent milling and baking quality can be produced on irrigated land in the State, and that there are marked differences in the bread-making qualities of different varieties grown under identical conditions. Data obtained from milling and baking tests for 1915 and 1916 at the Kansas Station are summarized.

Wyoming forage plants and their chemical composition, V, F. E. HEPNER (Wyoming Sta. Rpt. 1918, pp. 117-128).—Supplementing work previously noted (E. S. R., 25, p. 130), the author presents a tabulated statement showing the nitrogen content of 63 samples of grasses, rushes, and sedges collected at different altitudes ranging from about 6,900 to 10,000 ft., together with the nitrogen content of the soils upon which they grew. The average nitrogen content of all crop samples collected below 8,000 ft. elevation was 1.268 per cent, and that for all samples collected above 8,000 ft. was 1.385 per cent. Data relative to the total nitrogen content of soils from different altitudes were inconclusive, while nitrate determinations in several soils having approximately the same amount of total nitrogen but differing greatly in the amount of nitrogen in the plants grown thereon also failed to lead to any definite conclusion, the nitrate content being quite small in all cases. A complete analysis of some twenty-five of the soils by the strong acid digestion method failed to reveal any correlation between the nitrogen content of the plants and any of the soil constituents. It is concluded, therefore, that "the abundance of nitrogen found in high altitude grasses is not due entirely, if at all, to the greater amount of nitrogen, either total or nitrate, in the soils, nor is it due to excessive quantities of any other soil constituent." Other factors are believed to play a much more important rôle than does the soil in causing an increased storage of nitrogen by high altitude plants, although the author does not advance any theories as to what these factors may be.

Tabulated data are also presented showing the complete proximate analysis of the following plants: Western wheat grass (Agropyron occidentale), western couch grass (A. pseudorepens), slender wheat grass (A. tencrum), redtop (Agrostis alba), slough grass (Beckmannia crucæformis), grama grass (Bouteloua oligostachya), smooth brome grass (Bromus incrmis), Porter brome grass (B. porteri), giant sedge (Carex aristata), mountain sedge (C. festiva ebenea), Nebraska sedge (C. nebraskcnsis), Alpine or cliff sedge (C. scopulorum), hillside sedge (C. siccata), bottle sedge (C. utriculata), variable sedge (C. variabilis), tufted hair grass (Deschampsia cæspitosa), spike rush (Eleocharis palustris), Macoun rye grass (Elymus macounii), reed meadow grass or manna (Glyceria grandis), squirrel-tail grass (Hordeum jubatum), wire grass or Baltic rush (Juncus balticus), long-styled rush (J. longistylis), knotted rush (J. nodosus), Merten rush (J. mertensianus), Richardson rush (J. richardsonianus), mountain timothy (Phleum alpinum), timothy (P. pratense), nodding blue grass (Poa reflexa), alkali meadow grass (Puccinellia airoides), American rush (Scirpus americanus), fine top salt grass (Sporobolus airoides), drop seed (S. brevifolius), downy oat grass (Trisetum subspicatum), Nevada blue grass (Poa nevadensis), and spike rush (Eleocharis palustris).

Brief descriptions of Macoun rye grass, Richardson rush, and American rush are included.

Farm crops, C. A. ZAVITZ (Ontario Dept. Agr. Bul. 268 (1919), pp. 80, figs. 18).—Variety, cultural, rotation, fertilizer, seed selection, and date of seeding tests with numerous field crops, including cereals, potatoes, root crops, field peas and beans, vetches, soy beans, cowpeas, corn, sorghum, millet, and sunflowers for seed and forage, and flax for seed and fiber, together with miscellaneous tests of mixtures of grains, grasses, and legumes for pasture, etc., are reviewed in connection with work in progress at the Ontario Agricultural College for several years. Much of this has been referred to from time to time in previous reports and bulletins.

Hay and pasture crops, grasses, clovers, etc., C. A. ZAVITZ and W. J. SQUIR-RELL (*Ontario Dept. Agr. Bul. 269* (1919), pp. 72, figs. 35).—Twenty-six varieties of grasses and legumes suitable for hay and pasture are described and illustrated, and tests conducted at the Ontario Agricultural College with different pasture and hay crops, both singly and in combination, are briefly noted. Mixtures are recommended for annual, temporary, and permanent pastures.

Field experiments [in Ireland], 1918 (Dept. Agr. and Tech. Instr. Ireland Jour., 19 (1919), No. 2, pp. 180-208).—Continuing work previously noted (E. S. R., 40, p. 434) this report describes fertilizer, variety, and cultural tests with potatoes, mangels, oats, turnips, and wheat.

[Report of field crops work in Assam], J. W. McKAY and A. A. MEGGITT (Ann. Rpt. Agr. Expts. Assam, 1918, pp. 1-46+76-146).—This comprises a detailed account of work previously mentioned (E. S. R., 40, p. 523).

Legumes, Sudan grass, and cereal crops for silage, C. H. ECKLES (*Missouri* Sta. Bul. 162 (1919), pp. 3–25, fig. 1).—Experimental work conducted during the period of 1913 to 1917, inclusive, is described in which observations were made on the relative value for silage of field peas and oats, soy beans, cowpeas, alfalfa, red clover, sweet clover, Sudan grass, wheat, and rye. The different materials were analyzed for total moisture, total dry matter, protein, ether extract, ash, crude fiber, and nitrogen-free extract when placed in the silo and again when the silage was removed from the silo. Small experimental silos previously described (E. S. R., 35, p. 270) were employed. The results secured are fully discussed, and may be summarized as follows:

Under proper conditions legume crops may be successfully preserved in the silo, although as a rule it is thought best to preserve them as hay on account of the much greater weight to be handled if put into the silo and the lack of suitable machinery for handling the green crop in the field. When legumes are put in the silo, in addition to ordinary precautions concerning the exclusion of the air, it is deemed essential that the proper amount of dry matter be present in the material. A dry-matter content of approximately 40 per cent was found to give the best results. It is stated that while legumes cut for hay may contain as low as 20 to 25 per cent dry matter, if put into the silo under these conditions the silage will have an extremely disagreeable odor when removed and be almost worthless for feeding purposes. The wide variation in results from using legumes for silage as reported in agricultural literature is believed to be largely explained by the dry-matter content of the materials Sufficient dry matter to insure proper preservation in the silo may be used. assured by allowing the crop to reach a suitable stage of maturity before cutting, or in case the crop has not attained the necessary maturity, by allowing the forage to lie in the field from five to six hours after cutting before putting into the silo.

It was found that ordinarily alfalfa could not be allowed to stand in the field until the proper stage of maturity was reached, and except in dry seasons when the dry-matter content of the plant is abnormally high it is recommended that it be allowed to lie in the field from four to six hours before placing in the silo. Canada peas and oats were in condition to go into the silo when the pea pods were becoming yellow and the oat heads were showing the first indications of ripening. Clover contained the proper amount of dry matter when allowed to stand until somewhat more than one-half of the blossoms were brown. Soy beans and cowpeas were ready for silage when the beans were well developed and the pods beginning to turn yellow. Due to wide variations in condition and time of planting, it is said to be necessary frequently to put cowpeas in the silo before the proper stage of maturity is reached, and that under such conditions partial drying in the field is essential to good results. Silage from legumes, while superior in protein content, is somewhat inferior to corn silage in total digestible nutrients. With a proper amount of dry matter present, the loss of feeding value while in the silo was found to be no greater with legume silage than with corn silage.

Sudan grass was preserved readily in the silo with no special attention necessary to the amount of dry matter, its feeding value ranging from twothirds to three-fourths that of good corn silage, depending upon the maturity of the crop when put into the silo. Wheat supplied a silage of reasonably good quality, having a feeding value approximately that of corn silage. It is stated that wheat should be put into the silo when the grain is in the dough stage, no special precautions being deemed necessary to insure proper preservation. Rye was preserved readily in the silo, but the resulting silage was not palatable. For best results rye should be put into the silo in the blossoming stage or earlier.

Frost injury to grain and legumes, H. FISCHER (Zentbl. Agr. Chem., 47 (1918), No. 7, pp. 212, 213).—Observations on the effect of low temperatures on rye, oats, peas, and beans are noted, the author concluding that the death of the plant cell due to cold may be attributed to an irreversible mixture of the colloidal substance of the cell. The dark green color of the leaves accompanying frost injury was observed to occur with temperatures ranging from -4 to  $-6^{\circ}$  C. (24.8 and 21.2° F. and to be complete at from -8 to  $-10^{\circ}$ . The stems of the cereals showed some injury upon exposure to temperatures of from -4 to  $-6^{\circ}$  and were frequently split with temperatures of from -8 to  $-12^{\circ}$ , resulting in their subsequent collapse.

With temperatures of  $-8^{\circ}$  or less, frosted spikes which were about to blossom showed marked injury, while spikes still remaining in the sheath were only slightly injured with temperatures of from -10 to  $-12^{\circ}$ . Rye pollen from spikes cooled 12 hours at  $-8^{\circ}$  still exhibited a few grains capable of germination, while exposure for 4 hours at  $-10^{\circ}$  resulted in complete loss of vitality. Free pollen exposed to a temperature of  $-4^{\circ}$  for 5 hours was entirely killed. The extruded stigmas of the rye blossoms were rendered unfruitful at  $-2^{\circ}$ .

Ligowo oats showed the least injury from freezing of the four varieties studied. Although varying widely with different sorts, it is stated that in general the greater the frost injury the more vigorous was the development of new shoots.

Soil inoculation for legumes, W. A. ALBRECHT (*Missouri Sta. Circ.* 86 (1919), pp. 15, figs. 6).—This comprises a popular discussion of the nature, purpose, and value of legume inoculation, together with brief descriptions of the soil and pure culture methods.

The improvement of the barley crop, H. HUNTER (Dept. Agr. and Tech. Instr. Ireland Jour., 19 (1919), No. 2, pp. 139–159, pls. 10, figs. 2).—The improvement of the crop in Ireland through pure-line selection and hybridization is described and some of the results secured indicated.

Late planted variety tests of corn, E. F. CAUTHEN (Alabama Col. Sta. Circ. 41 (1919), pp. 4).—Limited variety tests with corn, following a winter grain crop on sandy upland soil are held to indicate that certain varieties are better for early planting than for late planting. Station Yellow, Dwarf Mexican June, and Goliad are said to give good results with late planting, while large one-ear types, such as Henry Grady and Calhoun Red Cob, are regarded as unpromising. It is stated that the planting may be deferred until the latter part of June, although earlier planting is deemed advisable.

Local fertilizer experiments with cotton in south Alabama, 1914-1918, inclusive, J. T. WILLIAMSON and J. F. DUGGAR (*Alabama Col. Sta. Bul.* 207 (1918), pp. 153-240).—This bulletin reports the results of 44 conclusive fertilizer experiments with cotton on Coastal Plain soils, conducted in cooperation with farmers for the period indicated in continuation of similar work previously noted (E. S. R., 30, p. 636). The results secured may be summarized as follows:

The average increase, following the use of cottonseed meal, was greater than that from acid phosphate in 68 per cent of the experiments, equal to it in 16 per cent, and less in 16 per cent. Cottonseed meal resulted in an average increase greater than that secured from kainit in 73 per cent of the tests, equal to it in 7 per cent, and less in 20 per cent. Acid phosphate surpassed kainit in 52 per cent of the tests, equaled it in 14 per cent, and was less in 34 per cent. With cottonseed meal as a basis, the relative increases in crop yields, due to the use of 200 lbs. cottonseed meal, 240 lbs. acid phosphate, or 200 lbs. kainit, were as 100:45:34. As an average of a much greater number of experiments, however, it is stated that potash is of much more relative importance, and acid phosphate slightly more so, than indicated above.

A 100-lb. application of kainit was found to be nearly as effective and, on the average, more profitable than a 200-lb. application. Nitrate of soda, applied at the rate of 100 lbs. per acre where the plants were from 6 to 8 in. in height to make a complete fertilizer, was found to be slightly more effective than a 200-lb. application of cottonseed meal applied in a complete fertilizer before planting. The maximum average increase in yield and the highest average profit were obtained from an application of 240 lbs. acid phosphate and 100 lbs. of kainit per acre before planting, and 100 lbs. of nitrate of soda when the plants were from 6 to 8 in. high.

Transmission of characters in potatoes, C. VON SEELHORST (Jour. Landw., 66 (1918), No. 3, pp. 141-162).—In continuation of work previously noted (E. S. R., 16, p. 360), the author presents further evidence regarding the transmission of yielding qualities in potatoes by the selection of seed from high-yielding strains. It is stated that almost always the use of small seed tubers from large mother plants resulted in higher yields than the use of large tubers from small plants. Furthermore, the yield expressed as a multiple of the seed employed increased markedly with a decrease in the size of the seed tubers.

Missing hills in potato fields: Their effect upon the yield, F. C. STEWART (New York State Sta. Bul. 459 (1919), pp. 45-69, figs. 3).-Experimental work conducted during 1918 is described in which an effort was made to determine how much of the loss in yield of potatoes, due to missing hills, is compensated by increased yields of the adjoining plants. Each of 360 tubers was divided lengthwise into two equal parts, and the resulting seed pieces planted in ten rows, 36 in. apart and 15 in. apart in the row in groups of four, with blank spaces of 30 in. between the groups. Each group contained the pairs of seed pieces from two tubers, so that one member of each pair adjoined a missing The difference in yield between the exterior plant and its mate, the hill. interior plant, was taken as a measure of the effect of the missing hill. Data were secured from 351 pairs of plants. As a check on the experiment, an attempt was also made to ascertain the extent of the variation in yield occurring between the plants from two seed pieces from the same tuber when grown under parallel conditions. For this purpose the pairs of seed pieces were planted 15 in. apart in two continuous rows without blank spaces, and data secured from 85 pairs of plants. The weight and number of tubers per plant are recorded in tabular form and the results summarized as follows:

Based on the weight of the total yield, the exterior plants outyielded the interior ones on the average 23.2 per cent, indicating that in the case of a skip containing a single missing hill, the two adjoining plants together make up 46.4 per cent of the loss in total yield, and a little more in the yield of market-

able tubers. Skips of more than one hill are deemed to be a total loss except for 46.4 per cent of the yield of one plant.

The number of tubers per plant was 20.7 per cent greater for the exterior than for the interior plants, and the tubers were larger on the average. The exterior plants produced on the average 5.6 marketable tubers, and the interior plants 4.7.

In all, 30 pairs of plants entering into the experiment were severely affected with leaf roll, and the influence of this factor on the results is discussed. It is stated that although the leaf roll plants were small, they did not have the effect of missing hills.

In the check rows, the differences in total yield between the different pairs of seed pieces ranged from 0 to 66.7 per cent of the mean yield of the two plants, the average difference being 20.7 per cent. Such wide differences are held to indicate that certain factors exist which have an important bearing on the yield of potatoes that are either unknown or underestimated.

Recognizing that the loss from missing hills probably varies considerably with the variety, the distance between hills, the character and fertility of the soil and cultural and meteorological conditions, a modification of the formula frequently used to obtain the so-called corrected yield to plat experiments with potatoes is deemed justified by the results of this experiment, whereby the estimated stand will be replaced by "stand value," the correct formula being  $CY = \frac{actual \ yield}{stand \ value}$ . The stand value is to be calculated by means of the formula  $SV = 1 - \frac{m-0.464s}{stand \ value}$  in which *m* is the number of the missing hills per

acre, s the number of skips or series of consecutive missing hills per acre, and n the number of hills per acre in a full stand.

Handling and loading southern new potatoes, A. M. GRIMES (U. S. Dept. Agr., Farmers' Bul. 1050 (1919), pp. 18, figs. 18).—Factors contributing to loss in transit and in the market of southern new potatoes are outlined and methods of handling, packing, and loading the crop to minimize such losses described. Field cuts and bruises and exposure to the sun after digging are said to occasion considerable loss, together with improper methods of loading which permit shifting and breakage in transit. Double-headed barrels are said to be the most satisfactory container, while it is suggested that in loading provision be made for a maximum amount of ventilation throughout the load and for the prevention of shifting.

**Rhodes grass, S. M. TRACY** (U. S. Dept. Agr., Farmers' Bul. 1048 (1919), pp. 14, figs. 3).—The history and adaptation of Rhodes grass (Chloris gayana) are discussed, and field practices employed in growing and handling the crop both for hay and pasture are described. Proximate analyses are included.

Élite culture and multiplication of some standard Ilocano and Tagalog lowland rices, L. M. ROMERO (*Philippine Agr.*, 7 (1918), No. 5, pp. 149–153).— In a continuation of work previously noted (E. S. R., 40, p. 336), the author describes the further propagation and multiplication of the best strains of Ilocano and Tagalog lowland rice secured through selection at Los Baños, P. I.

Saving man labor in sugar beet fields, L. A. MOORHOUSE and T. H. SUM-MERS (U. S. Dept. Agr., Farmers' Bul. 1042 (1919), pp. 18, figs. 26).—Laborsaving devices employed in the preparation of the soil, the cultivation and harvesting of the crop, and hauling the crop to the factory are described and illustrated for several important sugar beet areas in the United States.

Bud variations in sugar cane, C. S. POMEROY (*Jour. Heredity, 10 (1919), No. 3, pp. 129-135, figs. 2).*—The author discusses briefly the bud origin of several 138958°—19—4

sugar-cane varieties on the basis of recorded observations made in Louisiana, the West Indies, Mauritius, Hawaii, and Australia.

Differences between mother plants and sports are said to be frequently as marked as between recognized varieties. Bud varieties have been recorded as differently colored side shoots from a single cane, differently colored canes in one stool springing from a single piece of plant cane, a stalk with some joints striped and some unstriped, strains showing differences in hardiness, and strains showing differences in sugar content. It is stated that plants grown from cuttings of bud sports tend to reproduce true to the character of the sport.

Spacing experiments with sugar cane, J. MIRASOL Y JISON (*Philippine Agr.*, 7 (1918), No. 5, pp. 127-136, figs. 2).—Spacing experiments with sugar cane conducted at Los Baños, P. I., during the season of 1916-17 led to the following conclusions:

The percentage of germination increased as the planting rate decreased, with a corresponding decrease in the mortality of canes from two months of age to time of harvest. Close spacing resulted in tall canes of small diameter and small stools, while wide spacing resulted in larger stools and thick canes. The closest spacing with the cane laid end to end in rows 50 cm. apart (about 19.7 in.) resulted in the highest yield of cane, 82,000 kg. per hectare (36.49 tons per acre), while the maximum yield of sugar was secured from cane planted in rows 150 cm. apart with the seed pieces 50 cm. apart in the row.

Sweet potato storage, S. B. JOHNSON (Arizona Sta. Rpt. 1917, p. 441).—A comparison was made of sweet potatoes handled in the usual rough way and carried from the field in sacks with potatoes carefully placed in crates and cured in a room kept at a temperature of from S5 to 90° F. for one week, the two lots being subsequently stored in piles between layers of straw with a thick cover of straw.

It is stated that at the end of the storage period the first lot contained 38 per cent and the second lot 48 per cent of marketable potatoes. These results are held to indicate that in storing sweet potatoes out of doors the dry air is sufficient to cure them, and that to prevent excessive drying a layer of dry soil should be thrown over the pile after curing has been completed.

The synthetic production of wild wheat forms, H. H. LOVE and W. T. CRAIG (Jour. Heredity, 10 (1919), No. 2, pp. 51-64, pl. 1, figs. 9).—The authors describe a cross between the *Triticum vulgare* variety Early Red Chief and the *T. durum* variety Marouani, made at Cornell University, in which two plants similar in all respects to the typical wild wheat of Palestine appeared in a population of 113 individuals in the  $F_2$  generation.

"These two plants ... possessed the brittle rachis and long basal hairs or bristles. One form was beardless, while the other was partially bearded. The kernels were longer than in the other segregates and resembled the wild type. The heads were flat, similar to the true wild form.... The one main difference between the true wild wheat and these segregates was that the spikelets of the segregates were somewhat broader than those of the wild type. Each spikelet, however, carried away the joint of the rachis attached to it just as does the true wild wheat." The behavior of the progeny of these two plants in the  $F_s$ , together with a limited number of individuals in the  $F_4$ and  $F_5$  of one family, is described and their possible relation to the wild prototype discussed.

While the appearance of this wild form may be regarded as evidence in favor of the prototype theory in relation to the wild wheat of Palestine, the authors maintain that "the occurrence of wild segregates in the cross described does not prove that the wild wheat is the prototype of wheat, but rather raises the question whether it really is a prototype or a contemporary form. More data

#### HORTICULTURE.

from other crosses will be needed before any definite statement can be made. May it not be possible that there is a certain type (or types) in Palestine that, when crossed with others, may frequently produce the wild type?"

Third biennial report State seed commissioner, 1917-18, R. J. LETH (*Idaho Sta.* [*Pub.*], 1918, pp. 12, fig. 1).—This report, prepared by P. A. Wenger and C. B. Hobson, shows that 1,979,290 lbs. of agricultural seed was actually inspected during the biennium, that 3,037 samples were examined for purity, and that 310 samples were tested for germination.

# HORTICULTURE.

Fruits, vegetables, and flowers, F. D. GARDNER ET AL. (*Philadelphia: The John C. Winston Co., 1918, pp. 279, figs. 135*).—A popular reference work on the culture of vegetables, fruits, nuts, and flowers prepared by a corps of specialists in the subjects presented.

In part 1, under the general heading horticulture, forestry, and floriculture, the successive chapters deal with the principles of vegetable gardening, the culture of specific vegetables, the farm vegetable garden, vegetable forcing, mushroom culture, medicinal and aromatic plants, growing fruit on the home plantation, the culture of small fruits, grapes, pome fruits, stone fruits, citrus fruits, nuts, miscellaneous tropical fruits, the farm woodlot, beautifying the home grounds, and window gardening. Part 2 comprises a treatise on plant diseases and insect enemies and their control. Part 3 contains tables of weights, measures, and agricultural statistics.

[Fourth annual report of nursery and market garden experimental and research station in Hertfordshire in 1918], A. B. LISTER (*Expt. and Research Sta., Waltham Cross. Ann. Rpt., 4 (1918), pp. 36, figs. 4).*—A progress report on cultural and manurial experiments with cucumbers and tomatoes (E. S. R., 40, p. 147). Some data are given on a study of sources of error and uncertainty in determining experimental results in the greenhouse with special reference to the position of the plants in the house. The study of the effect of sterilization on crop yield was continued. Of 6 methods of treatment applied in two houses, 5 of them yielded opposite crop results in the one house to what they did in the other, thus indicating that sterilization is of no benefit in producing greater crop yield other than in destroying disease organisms.

A progress report is made on a study by Mrs. D. J. Matthews of the use of sterilizing agents in the control of tomato soil pests. A preliminary note is also given on a study of methods of controlling the noctuid moth (*Hadena oleracea*).

The evolution of the commercial greenhouse in relation to horticulture past and present, W. R. COBB (Ann. Rpt. Hort. Socs. Ontario, 13 (1918), pp. 128-131, fig. 1).—A brief review of some of the more important changes in greenhouse construction.

[Report on experiments in lettuce growing], S. B. JOHNSON (Arizona Sta. Rpt. 1917, pp. 434-441).—Tests of the New York and Iceberg varieties of lettuce secured from several different seed firms and of 47 other varieties are reported in tabular form. The essential difference between seed of the same variety from different sources was the difference in germination percentage.

Experiments conducted with organic and inorganic fertilizers, though for the most part inconclusive, did show that the plat receiving stable manure at the rate of 20 tons per acre was the first to come to maturity and produced the best lettuce.

Under irrigation conditions planting the lettuce on ridges gave better results than planting on the level. Planting in single rows appears to be more

#### 1919]

satisfactory than planting in double rows, under conditions where the price of land does not warrant hand cultivation.

Growing tomatoes for the canning factory, J. T. ROSA, JR. (*Missouri Sta. Circ.* 87 (1919), pp. 16, figs. 4).—Detailed cultural directions are given for growing tomatoes, including the control of pests.

The relation of phenology to fruit growing, R. J. BARNETT (*Rpt. Proc.* Mont. Hort. Soc., 21 (1918), pp. 102-113).—A discussion of the influences of various climatic factors on fruit growing.

Roeding's fruit growers' guide, G. C. ROEDING (*Fresno, Cal.: Author, 1919, pp. 101, figs. 123*).—A practical guide to fruit growing in California, including a discussion of the general principles of fruit growing, detailed directions for growing, harvesting, and handling the more important fruits, and briefer notes on those now grown to a limited extent. The text is well illustrated.

[Varieties of fruit for British Columbia], M. S. MIDDLETON (Ann. Rpt. B. C. Fruit-Growers' Assoc., 28 (1917), pp. 46-50).—A discussion of the factors influencing the selection of varieties, including a suggested list of varieties for the different districts in British Columbia.

Our best varieties of fruit, J. BÖTTNER (Unsere Besten Obstsorten. Frankfort on the Oder: Trowitzsch & Son, 1918, pp. 80, figs. 42).—Descriptions of the more important varieties of orchard and small fruits grown in Germany.

The improvement of fruit culture in Baluchistan, A. and G. L. C. HOWARD (*Fruit Expt. Sta. Quetta [India] Bul. 9 (1918), pp. 21*).—This paper presents the results of investigations carried out on the production of a supply of budded trees of good varieties for Baluchistan. The subject matter is presented under the following general headings: Stocks, the management of nurseries and methods of budding, and the selection of varieties. A list of imported varieties of fruit trees is included.

Annual report of the Fruit Experiment Station, Shillong, for the year ending June 30, 1918, C. H. HOLDER (Ann. Rpt. Agr. Expts. Assam, 1918, pp. 47-75).—A record is given of the varieties of orchard and small fruits planted under test at the station, including brief notes on their present condition.

Maintaining proper vigor in our fruit trees, C. I. LEWIS (*Trans. Ind. Hort. Soc. 1917, pp. 93–113, figs. 2*).—A review of some of the more practical results secured by the Oregon Experiment Station relative to the interrelation of pruning, tillage, fertilizing, intercropping, moisture, etc., and proper vigor in fruit trees.

Summarized data are given on the results of orchard management experiments conducted at the Oregon Station during the four years 1914–1917 and the principal results secured, including also a summary of results secured by Kraus and Kraybill in their study with tomatoes (E. S. R., 40, p. 40).

**Protecting the orchard by dusting, D. REDDICK (***Trans. Ind. Hort. Soc. 1917, pp. 126–139***).**—A summarized account of experiments conducted at the New York Cornell Experiment Station (E. S. R., 34, p. 738) and at other stations.

Orchard spraying experiments, A. G. TURNEY (Ann. Rpt. Dept. Agr. New Brunswick, 1918, pp. 98-101).—Data are given on cooperative experiments conducted in apple orchards in New Brunswick under the direction of E. G. Sanders.

The results, in general, indicate that it is practically impossible to control apple scab in ordinary years with repeated lime-sulphur sprays. A 3:10:40 Bordeaux mixture has proved a safe and efficient fungicide for the preblossom spray and a spray two weeks after blossom. The use of lime-sulphur at this period results in more or less injury to the fruit. Arsenate of lead as a spray after the blossom fall was an efficient but costly spray. Both lime-sulphur and Bordeaux used at this period result in more or less injury to the fruit. Thus far no satisfactory sprays have been developed for the apple maggot, green apple bug, and plum curculio.

Fertilizing of apple orchards, E. J. KRAUS (*Trans. Ill. Hort. Soc., n. ser., 52* (1918), pp. 188-207, fig. 1).—A consideration of various orchard practices, including fertilization, as factors in maintaining a proper balance between the nitrogenous and carbohydrate compounds within the tree. See also a previous note (E. S. R., 40, p. 147). In the discussion following is included a plan prepared by A. D. Shamel of arrangement of furrow-manure applications as recommended for citrus growers (E. S. R., 40, p. 246).

Fertilization of apple orchards, J. P. STEWART (*Trans. Ind. Hort. Soc. 1917*, *pp. 55-73*).—In this paper the author reviews the more practical results of orchard fertilizer experiments conducted under the direction of the Pennsylvania Experiment Station (E. S. R., 39, p. 445).

Cultural methods and fertilization of the apple orchard, J. OSKAMP (*Trans. Ind. Hort. Soc. 1917, pp. 73-84, figs. 3*).—A popular review of some of the more important results in orchard management at Purdue and other State experiment stations.

Cost of producing apples in Illinois orchards, H. R. STANFORD (*Trans. 111. Hort. Soc.*, *n. ser.*, 52 (1918), *pp.* 63-80).—The cost data here presented are based on questionnaires sent out to a number of the representative orchard men of the State.

A test of commercial fertilizers for grapes, F. E. GLADWIN (New York State Sta. Bul. 458 (1919), pp. 27-43).—This comprises the results for the second 5-year period of an experiment started in 1909 (E. S. R., 31, p. 339), including also a summary of results from the work to date.

Nitrogenous fertilizers have continued to give the best results. Phosphorus and potassium have also had a marked beneficial effect upon wood growth, yield, and quality of the fruit, but have not influenced the quality to the same extent as the nitrogen. Nitrogen has not only affected the growth of the wood favorably, but it has increased the fruit and given larger berries and clusters. Potassium caused earlier ripening of the foliage than the other elements, but after the first few years the foliage has been of better color and size in the plats to which nitrogen was applied. The foliage on the check plat was inferior to the foliage on any of the fertilized plats.

All of the fertilized plats have produced a decided gain of fruit over the unfertilized plats, and with prices paid for fertilizers in 1914 as a basis the fertilizers have paid a good return on the investment. A comparison of the financial returns from the different plats indicates that the nitrogen applied in conjunction with either phosphorus or potassium, or with both, is worth something more than \$100 per acre for the 10-year period. The author concludes that where all other fundamentals favorable to grape growing have been taken care of and the condition and production of the vines are still unsatisfactory, fertilizers should be applied. The evidence at hand suggests that a fertilizer containing a rather large percentage of nitrogen be used.

Some recent marketing developments in the Pacific Northwest, C. I. LEWIS (*Trans. Ind. Hort. Soc. 1917, pp. 193–206*).—The author describes the organization and status of the Fruit Agency, Incorporated, which was organized with the assistance of the Office of Markets of the U. S. Department of Agriculture in 1915 to promote cooperation between large individual operators, cooperative bodies, and other groups making a business of selling fruit.

**Tropical and semitropical fruits (exclusive of citrus fruits)**, E. O. FENZI (*Frutti Tropicali e Semitropicali (Esclusi gli Agrum*). Florence: Ist. Agr. Colon. Ital., 1915, pp. 261, figs. 60).—This manual has been previously noted in serial form (E. S. R., 34, p. 438).

#### 1919]

[Vol. 41

Some profitable and unprofitable coffee lands, T. B. McCLELLAND (Porto Rico Sta. Bul. 21 (1919), Spanish Ed., pp. 15, pls. 2, figs. 5).—A Spanish edition of the bulletin previously noted (E. S. R., 37, p. 43).

Effect of different methods of transplanting coffee, T. B. McCLELLAND (*Porto Rico Sta. Bul. 22 (1919)*, *Spanish Ed.*, *pp. 12*, *pl. 1*).—A Spanish edition of the bulletin previously noted (E. S. R., 37, p. 649).

[Report on date investigations], R. H. FORBES (Arizona Sta. Rpt. 1917, pp. 442-451).—A review of crop conditions in the date orchards in 1915 and 1916, including information on present methods of ripening, packing, and marketing the crop. A statement of sales for the graded crop of a few leading varieties is given, together with a summary, by varieties, prepared by F. H. Simmons, of date crops borne at the Tempe orchard in 1915 and 1916. The summary is accompanied by brief notes on the quality and behavior of the different varieties for the two seasons.

Acting on the observations of San Francisco dealers, who found that the dates kept well in dry, cold storage, crates of different varieties of dates were packed for shipment and then placed in dry, cold storage in Phoenix at a temperature of 36 to 38° F. The date of storage was September 20, 1916, and the samples were examined at various times during a period of 14 months. The results as here tabulated show that all of the 10 varieties tested except 1, Hayany, kept well until February, and 1 variety, Iteem Joher, rich in sugar, kept perfectly for 14 months. The Rhars variety kept fairly well for this time also. These observations indicated that many varieties of dates may be harvested and held in storage for sale as fresh fruit, thereby avoiding overstocked markets.

A further experiment with the Hayany crop in 1917 was conducted by evaporating several samples of fresh fruit to 90, 80, 70, and 60 per cent of the fresh weight, and then putting them in dry, cold storage at about 34 to 36°. The results of examinations indicate that the fruit of this variety would have kept well at about 85 per cent of its fresh weight; while at 70 to 80 per cent it kept perfectly and was of superior quality after three months of storage.

In view of the very high percentage of mortality among date palm suckers distributed to individuals, distribution of suckers has been discontinued for the present, and suckers are now being rooted by the new method developed by the U. S. Department of Agriculture in the Coachella Valley (E. S. R., 36, p. 142.)

[Report of date breeding experiments], G. F. FREEMAN and W. E. BRYAN (Arizona Sta. Rpt. 1917, p. 455).—Breeding work was started several years ago by the senior author, with special reference to securing Deglet Noor seedlings true to type. The orchard of seedling Deglet Noor dates planted at the Tempe Date Garden in 1912, bloomed and bore fruit for the first time in 1917. Forty-nine out of 235 trees bloomed, 22 of which were females and 27 males. Twenty-one females bore fruit; of these 10 bore fruit as light in color as the female parent, whereas the other 11 had fruits which were deep red when matured and black when ripe.

This indicates that the Deglet Noor variety is homozygous for the light colored fruit, whereas the Deglet Noor male seedlings used as a parent in this cross had for a male parent some dark colored date. It would also appear that the dark color of certain dates is a unit character.

As to quality of fruit, date of ripening, and response to the stimulus of heat in artificial ripening these seedlings varied widely. The quality was for the most part poor, although there were one or two rather promising trees, indicating that an amply sufficient number may be found among the 235 trees well worthy of selection as stocks for further breeding studies. Weather conditions as affecting plant growth, J. J. THORNBER (Arizona Sta. Rpt. 1917, pp. 428-430).—Lists are given of ornamental trees and shrubs on the university grounds and at Tucson that were killed or more or less injured during the cold winter of 1916-17 when the temperature fell below  $32^{\circ}$  F., on an average of one out of every three nights, with minimum temperature of  $9^{\circ}$  F. A list is also given of ornamental trees and shrubs, mostly exotic, which were not injured in the least.

A complete list of annual and other flowers, including greenhouse, tender and half-hardy perennials which, in Canada, can not be classed as hardy perennials (*Ann. Rpt. Hort. Socs. Ontario, 13 (1918), pp. 74-78*).—The list here presented was prepared by the Committee on Names and Varieties of the Ontario Horticultural Association.

The preservation of pollen for hybridizing, A. P. SAUNDERS (*Bul. Peony* News No. 6 (1918), pp. 2–9).—A partial review of the literature on the preservation and viability of pollen of various plants which have been prepared for special use in hybridizing peonies. The author concludes that peony pollen under favorable conditions is very long-lived, and that there should be no difficulty in carrying it through the entire season from the earliest to the latest blooming species.

Horticultural libraries in the United States, M. F. WARNER (*Gard. Chron.*, 3. ser., 65 (1919), No. 1691, p. 247).—This is largely a résumé of the scope of the horticultural literature in the library of the U. S. Department of Agriculture.

# FORESTRY.

National afforestation, A. D. WEBSTER (London: T. Fisher Unwin, Ltd., 1919, pp. 160).—In this work the author sketches the history of British woodlands, presents evidence to show the approaching dearth of timber, and makes an appeal for national afforestation in the United Kingdom as opposed to private and communal activities. Data are given on the cost of establishing plantations, with actual figures from English, Scottish, Welsh, and Irish estates, together with the details of afforestation practice, a list of the best trees for economic planting, and examples of financial returns. Recommendations relative to a national forest policy, the establishment of schools of forestry, and the use of unemployed labor in forestry are also included.

Commercial forestry (*Min. Reconstr.* [*Gt. Brit.*], *Reconstr. Prob. No.* 11 (1919), pp. 14).—This pamphlet is prepared with special reference to forestry problems in the United Kingdom. It discusses the position before the war, the position in 1918, the scope of commercial forestry, the renovation and extension of forest areas, and other important factors in a forest scheme. A concrete example of an afforestation scheme deemed suitable to the conditions of Great Britain-is briefly outlined.

Forestry, S. HONDA and Y. TAKENOB (*Japan Year Book*, 1918, pp. 562-569).— A statistical account of the forests and forest industry in Japan.

A forestry policy for New Zealand, F. BELL (*Jour. Agr.* [*New Zeal.*], 18 (1919), No. 5, pp. 313-318).—An address given at the Conference of Crown Lands Commissioners, in which the author briefly discusses present conditions of forest management in New Zealand and presents suggestions relative to the foundation of a policy for the future.

Reclamation of sand dunes, E. P. TURNER (Jour. Agr. [New Zeal.], 18 (1919), No. 3, pp. 148-154, figs. 3).—Instructions are given for fixing and afforesting sand dunes under New Zeland conditions, together with a translation of an article by E. D. Van Dissel on the treatment of sand dunes in Holland.

Vacation days in Colorado's National Forests (U. S. Dept. Agr., Forest Serv., 1919, pp. 60, figs. 24).—A popular document describing the recreational features of the National Forests of Colorado, and giving information to campers relative to fire prevention and camp sanitation, camping outfits, rations, etc.

Vacation trips in the Cochetopa National Forest (U. S. Dept. Agr., Forest Serv., 1919, pp. 14, pl. 1, figs. 6).—A popular document dealing specifically with the recreational features of the Cochetopa National Forest of Colorado.

The Ouray Mountains of the Uncompany National Forest (U. S. Dept. Agr., Forest Serv., 1919, pp. 14, pl. 1, figs. 6).—A document similar to the above, dealing with the Ouray Mountains of the Uncompany National Forest in Colorado.

A vacation land of lakes and woods.—The Superior National Forest (U. S. Dept. Agr., Forest Serv., 1919, pp. 12, pl. 1, figs. 6).—A document similar to the above, dealing with the Superior National Forest in northern Minnesota.

A historical review of the Bergius arboretum for the period 1885-1914, R. E. FRIES (*Acta Horti Bergiani* [Stockholm], 6 (1918), No. 1, pp. 5-24, pls. 108).—A progress report on activities at the arboretum of the Royal Swedish Scientific Academy at Stockholm. The report is accompanied by maps and numerous illustrations of the arboretum.

Storied or tier-like structure of certain dicotyledonous woods, S. J. RECORD (*Bul. Torrey Bot. Club, 46 (1919), No. 7, pp. 253-273*).—A contribution from the Yale School of Forestry.

The author's studies show that storied or tier-like arrangement of part or all of the elements is characteristic of many dicotyledonous woods representing a wide range of natural orders and families. The storied structure is found also in the secondary phloëm. It is exhibited on longitudinal sections, typically the tangential, as fine transverse striations "ripple marks." "Ripple marks" were constant enough in stems of considerable thickness to serve as a valuable diagnostic feature. In some woods pit areas on the fibers were in seriation and the cells of the wood parenchyma strands are arranged in a secondary seriation, visible under the lens.

A table is appended giving for each wood the various elements storied, the uniformity and distinctness of the markings, and the height of the tiers. A list of cited literature is also included.

Studies of regeneration conditions in Norrland pine forests, II, H. HESSEL-MAN (Meddel. Stat. Skogsförsöksanst., No. 13-14 (1916-17), pt. 2, pp. 1221-1286, CXLIX-CLXVII, figs. 16).—In a previous study<sup>1</sup> of regeneration in the pine forests of Norrland the results of which are here briefly summarized, the author concluded that the real cause of unsatisfactory regeneration in open lands adjoining the forests must be attributed to the unfavorable nature of the humus cover. The studies here reported at length were taken up from that point of view. The work is presented under the general headings of exterior hindrances to plant development, the growth of pine seedlings upon various parts of a forest, chemical analysis of the soils of pine forests, the nature and properties of the humus cover in various parts of a pine forest, cultural experiments, the cause of slow and unsatisfactory germination in the pine forests, and the management of pine forests on the basis of the evidence obtained in the studies.

The arborescent indigenous legumes of Hawaii, J. F. ROCK (*Bd. Agr. and Forestry Hawaii*, *Div. Forestry Bot. Bul.* 5 (1919), pp. 53, figs. 18).—In this paper the author has brought together the botanical information concerning the few endemic arborescent species of the family Leguminosæ found in the

344

<sup>&</sup>lt;sup>1</sup> Meddel. Stat. Skogsförsöksanst. (Mitt. Forstl. Wers. Anst. Schwedens), 1910, No. 7.
Hawaiian Islands. These include some species of Acacia and Sophora and single representatives of Mezoneurum and Erythrina.

The production of aspen, G. SCHOTTE (Meddel. Stat. Skogsförsöksanst., No. 13-14 (1916-17), pt. 2, pp. 1205-1219, CXLVII-CXLVIII, figs. 5; also in Skogsvårdsför. Tidskr., No. 11-12 (1918), pp. 641-655, figs. 5).—A preliminary study of production in several experimental stands of aspen leads the author to conclude that the aspen when grown on good soils in Sweden is a valuable tree that merits being well cared for. The aspen is used primarily in the match industry.

The larch and its importance in Swedish forest economy, G. SCHOTTE (*Mcddel. Stat. Skogsförsöksanst, No. 13–14 (1916–17), pt. 2, pp. 529–840, LIX-LXXXIV, pls. 10, figs. 107).*—An account of the results thus far attained in the cultivation of different kinds of larches in Sweden, as studied in some 66 experimental plats, in mixed or pure larch stands, belonging to the Swedish State Institute of Experimental Forestry. Swedish literature dealing with the forest qualities of the larch is perused and cited almost in its entirety, and the foreign literature, especially German and English works, is also reviewed.

The cultivation of osiers and willows, W. P. ELLMORE, edited by T. OKEY (London and Toronto: J. M. Dent & Sons, Ltd., 1919, pp. X+96, pls. 9).—A practical treatise on willow cultivation and the preparation of osiers for market, based upon articles originally published by the author and editor in the Journat of the Board of Agriculture. The subject matter is discussed under the general headings of the cultivation of basket willows, expenses and returns, varieties of willows, preparation and marketing, insect pests of basket willows, and tree willows.

**Rubber plants**, H. M. HALL and F. LONG (*Carnegie Inst. Washington Year* Book, 17 (1918), p. 297).—An extensive survey of the Great Basin region for rubber-producing plants, begun in 1917 as a war emergency project, has broadened out during 1918 into a comprehensive search throughout the West. It is proposed to continue this work. Rubber has been found in 25 of the species examined, the percentage being sufficiently high in 11 species to justify further investigation, and sufficiently high in 4 to warrant the hope that these species may serve as a basis for rubber production on a commercial scale.

A further note on thitsi (Melanorrhœa usitata), with special reference to the oleo-resin obtained from it in the Lawksawk and Myelat States, Southern Shan States Forest Division, F. A. WRIGHT (Indian Forest Rec., 7 (1919), No. 2, pp. 14, pl. 1).—The present paper is supplementary to one previously issued on the same subject by Benskin and Rodger (E. S. R., 38, p. 247), and contains much information on the subject of tapping this species for oleo-resin.

## DISEASES OF PLANTS.

Plant disease inquiries, J. J. THORNBER (Arizona Sta. Rpt. 1917, pp. 431, 432).—The author reports the occurrence of a root rot of white sweet clover due to Ozonium omniverum, early potato blight, sore shin and angular leaf spot diseases of cotton, tomato wilt, a dry-rot disease of the potato caused by species of Fusarium, and a serious disease of date fruits. The last disease affects both green and ripe fruit at the Yuma date orchard, at least 90 per cent of the crop of the year being damaged. The fruits become mummified and acquire a bitter taste, thus being rendered unfit for use. Three species of fungi have been found associated with this disease, which is in process of further investigation.

New or interesting species of fungi, IV, H. D. HOUSE (N. Y. State Mus. Bul. 197 (1917), pp. 25-51).—Some of the fungi here named as new to the flora of New York, with brief descriptive discussion, are parasitic and a few may be of economic importance.

On cell regeneration in Botrytis cinerea, W. B. BRIERLEY (Ann. Bot. [London], 32 (1918), No. 128, pp. 601-604, figs. 3).—In the course of an investigation of B. cinerea the author noted that regenerative and related changes occurred in cells which had suffered division, severe flexion, or other injury. Recovery was observed. It is stated that the healing process and the rapidity of its occurrence depended largely upon age and condition of the cells involved, being hindered by starvation, for example. The regenerative response appears to be related largely to the condition of vacuolation of the protoplast. Types of injury stimulating a healing reaction are divided into acute cell flexion, punctures, and relatively large superficial lesions. It is thought that this potentiality, if widely distributed among the fungi, may have important bearings.

It is stated that certain hyphæ of *B. cinerca* in tissues of *Æsculus pavia* were found to be in a naked condition, existing as free protoplasmic substance. The author holds, however, that mycoplasm involves far more than the mere existence of fungus protoplasm in a naked state, and that the merging, and subsequent dissociation of host and fungus must be regarded as not yet established.

Blossom infection by smuts, C. N. JENSEN (*Trans. Utah Acad. Sci., 1* (1908– 1917), pp. 106–113).—The author, summing up a review of work on smuts, states that, in addition to seedling infection, other forms exist, as blossom infection and leaf infection. As a rule, attack occurs only in very young embryonic tissues which are exposed at various points during growth. The flowering period offers an opportunity for infection comparable to that of seedling infection, so that these two distinct forms of attack at different periods have to be reckoned with.

The black or stem rust of wheat (*Canada Expt. Farms Bul. 33, 2. ser.* (1917), pp. 15, fig. 1).—An account is given of the nature and cause of the black stem rust of wheat, together with suggestions for its control. These include eradication of the common barberry, early sowing of wheat, and the use of early maturing varieties. Most satisfactory results have been obtained where early maturing varieties were sown on high or sandy lands.

**Destroy the common barberry**, E. C. STAKMAN (U. S. Dept. Agr., Farmers' Bul. 1058 (1919), pp. 12, figs. 7).—The relation of the common barberry as a carrying host to the black stem rust is pointed out, and its destruction is recommended as at least a partial means of reduction of loss in crops.

The leaf-spot diseases of alfalfa and red clover caused by the fungi Pseudopeziza medicaginis and P. trifolii, respectively, F. R. JONES (U. S. Dept. Agr. Bul. 759 (1919), pp. 38, pls. 3, figs. 5).—This bulletin is a contribution on the study of alfalfa and clover diseases being carried on cooperatively between the Bureau of Plant Industry of the U. S. Department of Agriculture and the Wisconsin Experiment Station.

The author describes the alfalfa leaf spot (*P. medicaginis*) said to be the most important foliage disease of alfalfa, and a similar leaf-spot disease of the red clover due to *P. trifolii*. Both fungi have been obtained and studied in pure culture, and efforts to cross these fungi from one host to the other have been unsuccessful. The author claims that morphological as well as physiological differences have been found which justify retaining the fungi as distinct species. No imperfect fungi which have been regarded as a stage in the development of these fungi have been found to be related.

The fungi are said to overwinter on dead leaves which escape decay, and the source of new infection is furnished by ascospores produced in the spring. Efforts to exclude the disease from alfalfa fields by the use of seeds that have been given surface sterilization were without success, and it is believed that the fungus is not carried on the surface of the seed and probably not with the seed at all.

[Work in plant genesis], A. F. BLAKESLEE (*Carnegie Inst. Washington Year Book, 17 (1918), pp. 114–116*).—Besides other more or less related matters, reports are made on the apparent immunity of adzuki beans to anthracnose in connection with their susceptibility to bean mosaic.

Chlorotic corn, W. H. DAVIS (*Proc. Iowa Acad. Sci.*, 24 (1917), pp. 459, 460).— Observations on chlorotic progeny of seeds from an ear of yellow dent corn and on corn leaves pierced with needles which have been used to wound chlorotic leaves appear to show that corn embryos may be chlorotic, that chlorosis in corn is probably not transferable by contact or with the sap by way of wounds, and that corn plants which are entirely chlorotic will not mature.

The influence of drought and of Alternaria on potato, J. SORDINA (*Prog.* Agr. et Vit. (Ed. VEst-Centre), 39 (1918), No. 6, pp. 131–134, figs. 2).—The author notes, in connection with somewhat exceptional weather in exposed situations in the island of Corfu, the appearance of a potato disease apparently connected with A. solani which is discussed in relation with treatment. Two sprayings employing Bordeaux mixture at 1 per cent and 0.5 per cent, respectively, are considered as sufficient.

The eradication of yellow stripe of sugar cane (*Porto Rico Dept. Agr. Sta. Circ. 14* (1918), *Spanish Ed.*, *pp. 8*, *pls. 3*).—This circular includes an account by E. D. Colón of data and deductions regarding the yellow stripe disease of sugar cane noted by Stevenson (E. S. R., 38, pp. 851, 852), which is now causing much injury to the sugar industry in parts of Porto Rico. The disease is not curable by treatment or by improvement of cultural conditions. Varieties differ as regards susceptibility to the disease, which appears to be hereditary. The boundaries of the areas affected are being extended.

The second part of this publication, by F. S. Earle, deals with matters relating to control of the disease, which is said to be incurable as regards individual plants. The employment of strictly sound material for propagation, inspection of growing crops at frequent intervals, and eradication of all but unquestionably sound canes are relied upon to relieve the situation, which is declared to be critical.

Blister canker of apple trees, a physiological and chemical study, D. H. Rose (Bot. Gaz., 67 (1919), No. 2, pp. 105-146, figs. 10).-In a continuation of work previously noted (E. S. R., 34, p. 136), employing in this latter phase also the simplified Bunzel apparatus previously described, with the addition of a study of catalase activity with microchemical and macrochemical analysis of both healthy and diseased apple tree bark, the author claims to have found that apple bark attacked by Nummularia discreta approximately doubles the oxidation of pyrogallol, pyrocatechin, guaiacol, and benzidin, as compared with that occurring in healthy bark. The gradual slowing down of oxidation in the Bunzel apparatus is due, in part at least, to increasing H-ion concentration brought about by the oxidation process itself, the equilibrium reached in the apparatus being supposedly a false one, readily upset by addition of fresh oxidase reagent or plant material. The oxidase may be a catalytic agent. H-ion concentration is less in diseased than in healthy bark. Temperature and duration of drying have an effect on the acidity and the oxidase activity of both healthy and diseased bark. When oxidase is precipitated in two fractions the

first has more oxidizing power than the second, and both combined have more than either separately. A partial disintegration of cellulose is noted in diseased bark, also the disappearance of cyanogenic glucosid and a lower content of starch, calcium oxalate, and tannins. Diseased bark has a higher percentage of dry matter, lipoids, alcohol-water-insoluble residue, and total nitrogen than healthy bark. Other contrasts are detailed.

The greater oxidase activity of diseased bark is thought to be due to the combined activity of the oxidases of fungus and host, to lower acidity, and possibly to a greater degree of dispersion of the oxidizing agent. The lower tannin content of diseased bark is possibly another contributing factor.

The effect of crown gall upon a young apple orchard, L. GREENE and I. E. MELHUS (*Iowa Sta. Research Bul. 50 (1919)*, pp. 147–176, figs. 30).—This bulletin is a record of progress in a study of the effect of crown gall upon an apple orchard from the time it was set out until it became of bearing age. Data have been collected on the relative influence of various types of galls upon the annual growth of the trees and on the amount and position of the galls in relation to the growth and percentage of stand in the orchard. The orchard in question was planted in 1912 with 310 trees infected with crown gall and 246 normal trees. The varieties Wealthy and Jonathan were used in the experiment, and at planting time it was noted that the Wealthy trees were infected with hard gall and very little hairy root, while the Jonathan were infected with both kinds of gall.

At the end of five years it was found that more of the crown gall infected apple trees were alive than normal trees, and the experiment confirmed the general idea that the variety Wealthy is more susceptible to crown gall than the Jonathan. In the experiment, the trees infected with gall did not show nearly so rapid growth as normal trees. Data are presented which show that crown gall greatly retards the growth activities of young apple trees, as manifested by a reduction in the amount of increase in trunk diameter, and in the number, length, thickness, and weight of twigs. It is claimed by the authors that twig measurement is a much more accurate and valuable index of the effect of crown gall than trunk diameter growth. Large galls appeared to be more injurious than smaller ones. Small galls on the underground portion of the tree did not seem to injure the twig growth materially. Fruit spurs developed earlier on badly infected trees than on the normal trees. Galls occurring on stock and union appeared to be equally harmful, while those on secondary roots were less so, and hard galls were less injurious than soft ones.

[Spraying at the Neoga Station, Illinois, 1915-16], W. S. BROCK (*Trans. Ind. Hort. Soc. 1916, pp. 69-81, figs. 3*).—This includes a brief account, with discussion, of dust spraying for apple scab since its first employment about 1905 of a mixture containing fine sulphur 35 per cent, lead arsenate 15 per cent, and hydrated lime 50 per cent. Some details of the 1915 trials near Neoga suggest that the dust spray can compare favorably with the liquid form. A report is also given of the 1916 experiments at the same place, the main substance of which has been noted previously (E. S. R., 38, p. 551). There appears to be need of a better fungicide than powdered sulphur. Clean fruit can be obtained with standard liquid sprays if properly applied.

Brown rot, its importance and control, E. B. BENSON (Ann. Rpt. State Hort. Soc. Mich., 46 (1916), pp. 44, 45).—This is a discussion of brown rot (said to attack practically all varieties of peach, plum, and cherry) and of prevention thereof as regards orchard control and cooperation, particularly in regard to packing, loading, and shipping.

Control of cherry leaf spot, J. W. ROBERTS and L. PIERCE (U. S. Dept. Agr., Farmers' Bul. 1053 (1919), pp. 8, figs. 6).—A description is given of the leaf spot of cherries due to *Coccomyces hiemalis*, formerly known as *Cylindrosporium padi*. For the control of leaf spot the authors recommend spraying sour cherries with lime-sulphur solution or Bordeaux mixture and sweet cherries with dilute lime-sulphur solution.

Notes on vine black spot or anthracnose, F. DE CASTELLA and C. C. BRITTLE-BANK (Jour. Dept. Agr. Victoria, 16 (1918), No. 7, pp. 420-425).—It is stated that the fears expressed in the communication previously noted (E. S. R., 38, p. 853) have been fully realized, vine black spot or anthracnose having appeared with a virulence corresponding to the unusual humidity of the season and hitherto unprecedented in this State, but varying somewhat with different grape varieties. Although this is a slow spreading fungus as compared with Oïdium or downy mildew, it has been steadily disseminated through the agency of such carriers as birds and insects until it now constitutes a menace of extreme gravity. Modes of treatment as recommended are detailed for both winter and summer. Discussion is also given of cultural conditions considered as important in this connection.

Black spot and leaf curl, W. LAIDLAW and C. C. BRITTLEBANK (*Jour. Dept. Agr. Victoria*, *16* (1918), *No. 8*, *pp.* 479–488, *figs.* 11).—This is an account of experimentation covering four seasons, and at least in part reported elsewhere (E. S., R., 40, p. 749).

Disease of the vine [New South Wales]: Downy mildew (Plasmopara viticola), H. E. LAFFER (Agr. Gaz. N. S. Wales, 29 (1918), No. 8, pp. 581-584).— Within the season of 1918 grape downy mildew (P. viticola) was identified throughout New South Wales and Victoria, the area affected being of very considerable extent. This fact tends to show that the disease has existed in that region for several years, having become noticeable as a consequence of unusual weather, the connection of which with the unusual development of fungus being briefly discussed as regards the life history of the organism. It is thought that under Australian conditions a 6:4:30 or even a 6:4:40 Bordeaux mixture might be sufficient for protection. One advantage of the treatment involving one or more applications as discussed herein is that grape downy mildew and black spot occur at the same period.

**Downy** mildew [grape], **Plasmopara** viticola, F. DE CASTELLA and C. C. BRITTLEBANK (Jour. Dept. Agr. Victoria, 16 (1918), No. 9, pp. 568-574, figs. 6).— It is stated that the foothold obtained in northeast Victoria by grape downy mildew (P. viticola) during the summer of 1916-17 permitted an early start for the disease in October, 1917, and resulted in a crop loss during 1918 generally estimated at 90 per cent, while some vines which were adequately sprayed showed a saving of 95 per cent of their crop. Contributory conditions are discussed. The standard spray, 2 lbs. copper sulphate to 10 gal. of water with enough good lime to neutralize the solution, is effective, but is much improved by the addition of casein at the rate of 1 oz. to 10 gal. of spray mixture in order to increase its spreading and wetting capacity. The life history of the fungus is outlined, and plans and results of spraying in other regions are briefly discussed.

Copper fungicides for vine diseases, F. DE CASTELLA (Jour. Dept. Agr. Victoria, 16 (1918), Nos. 10, pp. 592-599; 11, pp. 674-678; 12, pp. 735-737).—This is mainly a discussion of fungicidal mixtures based on copper, as regards their physical and chemical composition, properties, and effects, and of changes therein as produced by the aging of the mixtures.

Comparative effect of basic and acid copper sprays, J. CAPUS (*Prog. Agr. et Vit.* (*Ed. VEst-Centre*), 39 (1918), No. 6, pp. 129–131).—Studies at least in part reported previously (E. S. R., 40, p. 850) showed that the efficacy of the five copper sprays employed (three containing lime and two soda) is much lowered

by abundant precipitation, but that for a long period of rainy weather (20 days) the alkaline are much more durable than are the acid sprays.

Citrus spots and blemishes, J. MATZ (*Porto Rico Dept. Agr. Sta. Circ. 16* (1919), pp. 8, pls. 3).—Descriptions are given of some of the more common diseases to which citrus trees and fruits are subject, with tentative suggestions for control. Directions, based on recent experiments, are given for the identification and treatment of the different rots and blemishes of the trees.

**Coconut bud rot**, W. NowELL (*Agr. News* [*Barbados*], 17 (1918), No. 428, p. 302).—Some particulars are given of the type of bud rot referred to in previous accounts (E. S. R., 40, p. 750). The type of bud rot occurring on the fruit stalks is believed to be of bacterial causation, but the characters of the organism held by different workers to cause this rot are said to differ widely. The symptoms and progress of the disease are briefly discussed. The treatment recommended adds to the usual plan of firing the dry matter in the top of the coconut tree a Bordeaux spray with 2 lbs. lead arsenate to each 50 gal. of spray in order to prevent weevil damage to the scorched tissues.

Coffee leaf disease (Hemileia vastatrix) in Uganda, S. SIMPSON (*Trans. 3.* Internat. Cong. Trop. Agr. 1914, vol. 2, pp. 652-654).—Coffee leaf disease (H. vastatrix) is stated to have been present in Uganda for many years, but no record exists, so far as known, of Coffee robusta in this region being attacked by any other species of Hemileia.

A note by W. Small states that the disease of cultivated coffee is probably the same as that which occurs on the native coffee, though experiments which are in progress to determine this point have given only negative results. The best results as regards protection have been obtained with Bordeaux or Burgundy mixture.

Three sprays for coffee affected with Hemileia vastatrix and other fungus diseases, W. J. Dowson (*Nairobi*, *British East Africa: Govt.*, 1915, pp. 4).— An account of tests carried on for two years in order to ascertain the most effective and economical spray against H. vastatrix and other fungus diseases on coffee states that all fungicides were effective, the dilute not less so than the ordinary sprays. Bordeaux mixture, which at the time of this report was cheapest at 0.25 strength, produced a marked invigorating effect not given by any other spray. The carbid mixture, though easy to prepare, was very expensive and gave the trees an unsightly appearance. Liver of sulphur, though easiest to prepare, was expensive and hard to obtain. Burgundy mixture proved to be expensive with no corresponding advantage.

**Report on white pine blister rust control, 1918** (*Amer. Plant Pest Committee Bul. 2* [1919], pp. 1–16).—This report is published by the American Plant Pest Committee, formerly designated as the Committee on the Suppression of the Pine Blister Rust in North America (E. S. R., 39, p. 758). This committee is composed of four members from each American State and from each of the Canadian Provinces, and its purpose is to secure and disseminate information and to bring to bear measures looking to the eradication or control of dangerous plant pests, in particular to attack effectually any such pest in its initial stages and thus prevent its establishment. The publication gives in brief form the results of the third season's experiments and investigations by the persons responsible for them, as noted in some detail below.

White pine blister rust attacks 5-leaf pines only after a period of growth on Ribes, the total destruction of which is the only successful method of protecting pines. The maximum distance to which Ribes bushes must be removed does not exceed one-third of a mile under the most favorable conditions for infection. Ordinarily a distance of 200 yds. is probably sufficient to allow commercial growth of white pine. Pines of all ages are attacked, but older trees survive longer than younger ones, which should be protected first to insure their reaching a marketable size. Cultivated black currants are specially susceptible to the disease, which is not prevented or cured by spraying on currant, gooseberry, or pine.

The activity of the committee has been extended to cover other new and introduced plant pests.

Status of white pine blister rust control in 1918, S. B. DETWILER (Amer. Plant Pest Committee Bul. 2 [1919], pp. 4-11).—This is a discussion, according to territorial sections or regions in the United States and Canada, of white pine blister rust and of matters relating to its control.

It is thought that thorough scouting and removal of Ribes once in five years in a space one-third of a mile wide around a pine growth will afford adequate protection to areas affected. In Rhode Island pastures where sheep were kept no Ribes were found even when these plants were abundant in areas of the same sort immediately adjoining. Apparently the majority of wild Ribes seeds are scattered by birds and squirrels. Observations made in New York confirm the opinion that wild gooseberries will not sprout if the crown is completely removed, although skunk currants and swamp black currants have underground stems which start new growth if not completely removed.

A summary is given of Ribes eradication on demonstration control areas in different States. It is thought that the hope of saving the western white pine forests from infection lies in the enforcement of the Federal and State quarantines against 5-leaf pines and Ribes.

Results of scouting in Canada are considered to show that the blister rust can not be eradicated at once from large areas where it is already abundant. Small trial areas are being systematically worked to determine whether or not white pine can be grown successfully in selected areas where the disease is present.

Scientific research and field investigations in 1918, P. SPAULDING (Amer. Plant Pest Committee Bul. 2 [1919], pp. 11-13).—This contains a summary of the reports given by members of the Office of Forest Pathology, Bureau of Plant Industry, U. S. Department of Agriculture, regarding scientific studies on the white pine blister rust as carried on in 1918 at several places named.

Air currents are important agents for the dissemination of æciospores, which were found in traps 2,700 ft. above the nearest known source, which was  $5\frac{1}{2}$ miles distant, this and other facts evidencing the extreme lightness of such spores. Apparently spores produced on pine are much more widely distributed than was formerly supposed. A large percentage of these will germinate even after a period of several weeks.

The spores of the early sumer stage on Ribes are much less widely distributed than has been supposed, 100 to 300 yds. being a common distance, and one-third of a mile somewhat unusual. They also retain their germinating power for a shorter period than do the spores produced on pines. A period of several rainy days is quickly followed by a new output of spores on Ribes. Studies from Ribes back to pine have not yet reached a very satisfactory stage.

The width of Ribes free zones necessary to protect the pines will vary from 100 to 600 yds. according to various conditions. Moisture is supposed to be an important factor in the survival of teliospores.

Overwintering of the uredo stage and resulting inoculation are considered as fully established. The incubation period on pine appears to vary from about 18 months to 15 years.

A Cronartium on Ribes in Colorado has been shown to be distinct from C. ribicola, and has been named C. occidentale. It attacks none of the 5-leaf pines and so far as known only the pinon pines (*Pinus monophylla* and P. edulis). A

comparison of these two fungi has been noted from another source (E. S. R., 39, p. 858).

Investigation [of white pine blister rust] in the Canadian Department of Agriculture, W. A. McCUBBIN (Amer. Plant Pest Committee Bul. 2 [1919], pp. 13, 14).—Studies carried out in 1917 and 1918 show that uredospores and accospores of the white pine blister rust fall through the air very slowly, so that their wide dispersal by air currents is possible. The fact that the effect of sunlight in inhibiting artificial inoculation is to be counted on only during the day decreases considerably the importance of this agency.

A survey of pine infection areas, made in order to ascertain the actual damage done by this disease, shows an average of 2.3 per cent infected, though the infection percentage recorded ranged as high as 33.54 per cent in one instance. Supposedly about 1 per cent of the pines have suffered new attack each year on the areas examined.

Apparently the principal factors to be reckoned with as regards pine infection include nearness and number of cultivated Ribes (particularly black currants) and the humidity of the area infested.

Artificial infection of Ribes species and white pine with Cronartium ribicola, G. P. CLINTON (*Amer. Plant Pest Committee Bul. 2* [1919], pp. 14, 15).— A study has been made of the degree of infection produced on different species of Ribes grown in crocks. It was possible to trace the germ tubes of both the æcial and uredinial spores through the stomata into the leaf tissues, showing that the epidermis is probably not pierced in case of ordinary infection. Of 35 species of Ribes tested, 25 species were infected; with æcial spores, 24 plants out of 36 tests; and with uredinial spores, 40 out of 59.

Studies carried out during the fall of 1916 and 1917 on the infection of pines one to three years old by the telial stage gave as the first visible signs of infection the characteristic golden-yellow spots on the leaves, these being noted from 25 days to 6 months after the telia with sporidia were placed on the leaves. Microscopic sections show these golden-yellow spots to be filled with a sclerotial mass of mycelium more or less closely surrounding the fibro-vascular system. Strands of mycelium later run lengthwise near the bundles down the leaf into the stem, but cause no discoloration of the leaf. Inoculations of the young stems and unopened buds have not been successful. Within 6 months after infection the plants have oozed out pycnial spores, but no plants have yet matured the æcial stage. However, the plants thus far employed, being young, have mostly been killed by the fungus within one or two years after infection.

Summary of the white pine blister rust situation, H. METCALF (Amer. Plant Pest Committee Bul. 2 [1919], p. 16).—The results of work done to date are said to have shown that, even under unfavorable conditions, wild Ribes can be eradicated at a cost which is inconsiderable in comparison with the damage caused by the presence of this host of the white pine blister rust. It is, therefore, practical to plant white pine in the East if the areas are kept free from Ribes to a distance of one-third of a mile of the nearest pine. More and more stress must be laid on local control of Ribes, which has been shown to carry this disease through the winter.

**Progress of experiments for destroying Ribes with chemicals**, W. S. REGAN (*Amer. Plant Pest Committee Bul. 2* [1919], pp. 15, 16).—Tests begun in 1917 show that in certain cases the chemical method possesses distinct advantages over hand pulling as a means of destroying Ribes. Undiluted fuel oil applied as a fine spray offers a most satisfactory means of this kind, a single thorough application producing defoliation, and under favorable conditions penetrating the bark and killing the plants. Direct sunlight favors and hastens this result,

which requires about 4 days in direct sunlight and 12 or 14 days in the shade, which is preferred by the skunk currants. Rain, occurring shortly after the treatment is applied, may to a great extent protect the buds and twigs. Individual plants differ considerably as regards resistance. Other and generally less effective sprays tested include sodium arsenite, salt solution, kerosene, and other compounds.

Report of conference re disease attacking plane trees (*Jour. Dept. Agr. Victoria, 15 (1917), No. 7, pp. 443–447, figs. 2).*—This is a report of the discussion at a conference of experts held on February 21, 1917, regarding a new and destructive disease attacking plane trees in many portions of Victoria, in some of which considerable injury was done. The causal fungus is *Glæosporium nervisequum* on leaves, *Myxosporium valsoideum* on branches. Recommendations regarding the control of the disease included early winter pruning, destruction of all prunings and leaves, spraying with Bordeaux mixture all winter and also upon resumption of growth in spring, and careful inspection of all nursery stock.

Cultures with Melampsoræ on Populus, J. R. WEIR and E. E. HUBERT (*Mycologia*, 10 (1918), No. 4, pp. 194–198).—The authors, reporting on further work with some of the fungi formerly studied (E. S. R., 38, p. 253), state that the rusts of Populus, hitherto distinguished as *Melampsora medusæ* and *M. albertensis*, are able to infect both Pseudotsuga and Larix. It is suggested that these two fungi are only different host manifestations of the same species, which should be referred to *M. medusæ*. Two new hosts recorded for this rust are *L. lyalli* and *P. macrocarpa*. New features are reported in regard to production of pycnia in the Melampsoræ.

## ECONOMIC ZOOLOGY-ENTOMOLOGY.

California ground squirrels (Mo. Bul. Cal. Com. Hort., 7 (1918), No. 11-12, pp. 593-807, pls. 6, figs. 67).—A comprehensive account of the life histories, habits, and methods of control of ground squirrels in California is here presented as follows: Natural History of the Ground Squirrels of California, by J. Grinnell and J. Dixon (pp. 597-709); The Columbian Ground Squirrel (*Citellus columbianus columbianus*), by W. T. Shaw (pp. 710-720); A History of Ground Squirrel Control in California, by W. C. Jacobsen (pp. 721-761); A Study of Fumigation Methods for Killing Ground Squirrels, by J. S. Burd and G. R. Stewart (pp. 762-765); The Work of the Rodent Control Division, by S. V. Christierson and C. A. Wilkins (pp. 766-780); and Rodent Eradication Work of the Biological Survey in California, by F. E. Garlough (pp. 781-789). Directions and formulas for destroying noxious rodents and a complete index are included, as are colored plates of ground squirrels, by L. A. Feurtes and others.

Destruction of live stock by predatory animals and their practical means of destruction, M. E. MUSGRAVE (*Proc. Ann. Conv. Ariz. Cattle Growers' Assoc.*, 12 (1919), pp. 111-113).

The principal species of birds protected by law in Egypt, S. S. FLOWER and M. J. NICOLL (*Cairo: Min. Agr., Egypt, 1918, pp. IV*+8, *pls.* 8).—A list of the principal species, giving their English, French, Arabic, and scientific names, their local status, their approximate size, and concise notes on their coloration, for purposes of identification. Illustrations of 26 species in colors are included.

Description of a new Conurus from the Andaman Islands, H. C. OBERHOL-SEE (Proc. Biol. Soc. Wash., 32 (1919), pp. 29-32).

An unrecognized shrew from Warren Island, Alaska, H. H. T. JACKSON (Proc. Biol. Soc. Wash., 32 (1919), pp. 23, 24).

138958°-19-5

Mutanda ornithologica, VI, H. C. OBERHOLSER (Proc. Biol. Soc. Wash., 82 (1919), pp. 21, 22).

**Proceedings of the Entomological Society of Nova Scotia for 1918** (*Proc. Ent. Soc. Nova Scotia, No. 4 (1918), pp. 89, pls. 7*).—The papers here presented are as follows:

A Few Notes on Ant History and Habits, by H. J. Fraser (pp. 6-9); The Meaning of Natural Control, by J. D. Tothill (pp. 10-14); Further Notes on the Apple Magot (1918) (*Rhagoletis pomonella*), by W. H. Brittain (pp. 15-23); The Salt Marsh Caterpillar (*Estigmene acraca*), by H. G. Payne (pp. 24-31); A Copper Dust, by G. E. Sanders and A. Kelsall (pp. 32-37); Notes on the Life History and Immature Stages of Three Common Chrysomelids, by W. E. Whitehead (pp. 38-50); A Modified Bordeaux Mixture for Use in Apple Spraying, by G. E. Sanders and W. H. Brittain (pp. 51-61); Some Notes on Olene vagans in Nova Scotia, by W. H. Brittain and H. G. Payne (pp. 62-68); Some Miscellaneous Observations on the Origin and Present Use of Some Insecticides and Fungicides, by G. E. Sanders and A. Kelsall (pp. 69-75); Notes on Lygus campestris in Nova Scotia, by W. H. Brittain (pp. 76-81); Life History and Immature Stages of Abbotana clemataria, by H. G. Payne (pp. 82-85); Key for Determining the Crambinæ of Nova Scotia, by E. C. Allen (pp. 86-88); and A Tree Hopper New to Our List, by W. H. Brittain (p. 89).

**Report of the imperial entomologist**, T. B. FLETCHER (Sci. Rpts. Agr. Research Inst. Pusa, 1917–18, pp. 84–116, pls. 18).—The author discusses the occurrence of and work with the more important insects of the year, particularly those attacking sugar cane and rice. Drawings illustrating the larval and pupal structure are presented of Chilo simplex, Diatræa auricilia, D. venosta, Diatræa spp., Anerastia ablutella, Anomala biharensis, Adoretus caliginosus, Autoserica sp., Monolepta signata, Tirathaba n. sp., Calandra stigmaticollis, Eugnamptus marginatus, Azygophleps scalaris, Argyroploce paragramma, Nodostoma subcostatum, Balaninus c-album, Belionota prasina, Alcides frenatus, Giaura sceptica, Eublemma hemirhoda, etc. Studies of the life histories and habits of various borers and root feeders of cane and rice are reported upon, as many as five new pests having come to light.

[Economic insects in Sumatra], J. E. A. DEN DOOP (Meded. Deli Proefstat. Medan, 2. ser., No. 3 (1919), pp. 20).—The three papers presented are entitled Combating the Tobacco Aphid (Myzoides persicæ) in Deli (pp. 1–6); Notes on the Control of the Cigarette Beetle (pp. 7–18); and Brief Notes on the "Green Capsid" (Gallobelicus nicotianæ) (pp. 19, 20).

Monthly notes on grubs and other cane pests, J. F. ILLINGWORTH (Bur. Sugar Expt. Stas. Queensland, Div. Ent. Bul. 7 [1919], pp. 29).—This consists of monthly reports made by the author for August, 1917, to June, 1918, inclusive, relative to investigations of Lepidiota frenchi, L. rothei, and other cane pests.

Insect pests of the avocado, I. J. CONDIT (Mo. Bul. Cal. Com. Hort., 8 (1919), No. 1, pp. 27-29, figs. 4).—Brief reference is made to several insect enemies which occur in California and may become important as enemies of the avocado under California conditions, including a wood borer in the axils of the leaves identified as the twig borer (Polycaon confertus); a June beetle (Serica alternata), which injured the foliage at Fillmore; a species of thrips, undoubtedly Heliothrips hamorrhoidalis, which was found infesting the leaves, and the citrus mealy bug.

Some insects injurious to the black wattle (Acacia mollissima), C. B. HARDENBERG (Union So. Africa, Dept. Agr. Bul. 1 (1918), pp. 62, pls. 21).—A report of the work at the field station for the study of wattle insects at New Hanover, Natal. Linseed oil-Bordeaux, E. W. BERGER (*Proc. Fla. State Hort. Soc.*, 30 (1917), pp. 44-47).—In search for a mixture which would serve effectively as a fungicide and insecticide, 3 per cent raw linseed oil was mixed with strong Bordeaux (double strength and stronger) by stirring the oil into the Bordeaux. While the effect of this mixture on San José scale, purple scale, and citrus white fly on which it was tested has not been definitely determined, the linseed oil was found to have great value as a sticker for the Bordeaux, its presence being visible for five or six months. The efficiency did not appear to be diminished by the addition of the oil.

"White ants" as pests in the United States and methods of preventing their damage, T. E. SNYDER (U. S. Dept. Agr., Farmers' Bul. 1037 (1919), pp. 16, figs. 11).—A popular summary of information.

Entomology, A. W. MORRILL (Arizona Sta. Rpt. 1917, pp. 472, 473).—This report relates entirely to control work with the differential grasshopper (Melanoplus differentialis), the most destructive species in Arizona, a more extended account of which by the author has previously been noted (E. S. R., 39, p. 359).

The black fly, W. NEWELL (*Proc. Fla. State Hort. Soc., 31 (1918), pp. 90-96*).—A discussion of the status of *Aleurocanthus woglumi*, particularly as related to Florida. See also a previous note (E. S. R., 39, p. 864).

The green soldier bug or pumpkin bug in citrus groves, J. R. WATSON (*Proc. Fla. State Hort. Soc., 30 (1917), pp. 34–36*).—The author reports upon the results of a test to determine the actual cost of collecting the green soldier bug (*Nezara viridula*), made on a 200-acre grove, and to try out on a large scale several different types of nets. The trees in the orchard were 10-year-old trees, set 20 by 30 ft., and averaged from 30 to 100 bugs per tree, 97 per cent of which were *N. viridula*.

It was found that the nets should be at least 3 ft. in diameter and of equal depth, having a short handle which extends across the diameter of the net to stiffen the rim, which is of telephone wire. One man can manipulate the net, although two work to better advantage, one holding the net under a limb full of fruit and the other giving the limb a vigorous shake, causing the bugs to drop and roll to the bottom of the net. After finishing each tree the tip of the net with the contained bugs is dipped into a bucket of kerosene, which keeps the net constantly wet with the oil.

It is stated that in the experimental grove it cost between 30 and 75 cts. per acre to collect the bugs. Two men working together cover an acre in from one to two and one-half hours, depending on the amount of fruit and the number of bugs present. The author considers this the most satisfactory method of dealing with the green soldier bug thus far devised. Larger nets can be used early in the morning, on moonlight nights, and on cold days.

The grain bug, D. J. CAFFREY and G. W. BARBER (U. S. Dept. Agr. Bul. 779 (1919), pp. 35, figs. 13).—This report is based upon observations by the senior author in 1915 and the junior author in 1916 during a destructive outbreak of Chlorochroa (Pentatoma) sayi in northeastern New Mexico and adjacent territory.

Since 1911 it has become a serious enemy of wheat and other small grains in the intermountain and southwestern States. "The most important damage is caused by the insect piercing the newly-formed heads of various cereals and removing the liquid contents, thus preventing the formation of the grain or greatly reducing its weight. The reduction in yield from grain-bug attack varies from 10 to 50 per cent of the crop. In extreme cases the entire crop may be destroyed. "The cultivation of large areas formerry devoted to grazing eliminated the native food plants of the insect and caused it to attack cultivated plants. This change to more succulent food plants, together with the superior facilities afforded for hibernation in the cultivated areas, resulted in an increase of the pest beyond its former abundance. Wheat, barley, and rye are the preferred food plants among the cultivated crops. The species also feeds upon other cereals, and upon alfalfa, cotton, peas, beans, cabbage, tomato, and lettuce, in addition to many native plants. The first recorded damage occurred in 1903, and since that time destructive outbreaks have been reported from most of the States west of the Great Plains area. Weather influences and the work of the parasites generally restrict destructive outbreaks in each locality to periodic intervals of two or three years.

"Adults emerge from hibernation in the early spring and deposit eggs on the material composing the hibernating quarters. The resulting nymphs feed upon tender plants growing in the vicinity. Upon reaching maturity the adults migrate to grain fields and feed upon the developing heads. There are three distinct generations and sometimes a partial fourth generation annually. About 50 days are required to complete the life cycle of each generation.

"After midsummer the numbers of the insects are greatly reduced by an egg parasite, *Telenomus ashmeadi*, and by two species of tachinid parasites, *Gymnosoma fuliginosa* and *Ocypterodes euchenor*, which parasitize the adults. Several kinds of predacious enemies contribute to the same result.

"Hibernation occurs in the adult stage under weeds or rubbish. No nymphs or eggs survive the winter. Severe winters result in the death of a large percentage of hibernating adults and constitute one of the most important factors in restricting destructive outbreaks of the species. During normal winters at least 95 per cent of the adults survive when hibernating in protected locations.

"The most effective and practical method of control is the destruction of the adults while they are concentrated in their winter quarters. This is best accomplished by plowing under, or burning, all rubbish and weeds, particularly Russian thistle, in and about cultivated fields. These control measures should be included as a part of the regular farm practice, and any special work required may be carried on during the inactive season at a time when the farm labor and equipment ordinarily are idle. Trap crops, hand picking, and hopperdozers might prove practical in the control of the insect under special conditions."

Five new species of Jassoidea from Honduras (Hemiptera: Homoptera), E. H. GIBSON (Proc. Biol. Soc. Wash., 32 (1919), pp. 25-28).

Combining dormant and first summer spray in apple orchards infested by San José scale, T. J. TALBERT (*Missouri Sta. Bul. 161 (1919)*, pp. 3–15, figs. 3).— This is a report of experiments and observations, extending over a period of four years, which have shown that the dormant or San José scale spray consisting of commercial lime-sulphur testing 33° B. may be applied to apple trees at a dilution of 1:7 or 1:8 after growth starts and until the trees begin to bloom without material injury to leaves or flower buds. When applied after the leaves are out and the buds are beginning to show their petals, it takes the place of the so-called cluster-bud or first summer spray, thus eliminating the cost of labor and materials for one summer application.

"Commercial lime-sulphur when used at a dilution of 1:7 produces more burning than when used at a dilution of 1:8, 1:10, or 1:12. As a rule, the weaker the solution the less the burning. The difference in the caustic or burning effect, however, has been very slight, especially between the dilution of 1:7 and 1:8. A spraying pressure of from 250 to 300 lbs. is much more apt to cause injury by burning than a pressure of 200 lbs. or less." 1919]

When the strong spray is applied at the cluster-bud period, it is very effective in killing San José scale. The bark of the infested trees is left covered with a strong spray, and the young scales which are produced later have considerable difficulty in finding suitable places to settle down and begin sucking sap.

The late concentrated spray has also been found to be of great value in controlling aphids or plant lice, oyster-shell scale, scurfy scale, Forbes scale, spring cankerworm, bud moth, and other sap-sucking and leaf-eating insects, which are killed through contact with their bodies. It is said to be effective in controlling apple scab, and is believed to be effective against other fungus diseases, such as Illinois canker, black rot, etc.

The fruit worms of the apple in Nova Scotia, G. E. SANDERS and A. G. DUSTAN (*Canada Dept. Agr., Ent. Branch Bul.* 17 (1919), pp. 28, figs. 9).—This is a report of studies of fruit worms, which are a source of an immense amount of damage in Nova Scotia and throughout eastern Canada. The adults of nine species were found to feed on apple foliage and fruit, and the adults of eight others were taken in apple orchards, though attempts to rear them on apple foliage failed.

Technical descriptions are given of the several stages of the nine species treated in this bulletin, namely, *Graptolitha bethunei*, *G. laticinerea*, *G. antennata*, *G. georgii*, *G. baileyi*, *Conistra walkeri*, *Xylena nupera*, *X. cineritia*, and *X. curvimacula*, together with notes on *G. ferrealis*, *G. disposita*, *G. unimoda*, *G. fagina*, *G. pexata*, *G. petulca*, *G. cinerosa*, and *G. innominata*.

"The fruit worms of the apple are responsible annually for a large amount of damage in the apple orchards of Nova Scotia. The injury is effected by the larvæ eating into the young fruit or the set of the apples, causing about 72 per cent of the injured fruit to drop, and deforming about 78 per cent of the remainder enough to cause it to be degraded to No. 3 and culls.

"The adults of the fruit worms are strong flying moths which are to be found on the wing during September, October, April, and May. They deposit their eggs on the twigs of the apple during the month of May. These eggs hatch about the time the apple buds are beginning to show pink. The young larvæ feed for the first two weeks on apple leaves and blossoms and drop to the ground very readily when disturbed. After the first two weeks the larvæ feed more on the fruit of the apple than on the leaves, causing an immense amount of injury, as previously indicated. In early July the larvæ enter the earth to pupate, and form an almost naked pupa 2 or 3 in. below the surface. In September and October the adult moths emerge and during the winter hibernate under tufts of grass, etc."

The investigations show an arsenical spray applied immediately before the blossoms open to be the most valuable spray in fruit-worm control, while that applied immediately after the blossoms fall is the next in value.

The tea tortrix (Homona coffearia), N. K. JARDINE (*Dept. Agr. Ceylon Bul.* 40 (1918), pp. 38, pls. 2, figs. 2).—This is a preliminary report of investigations during the year 1917–18 of *H. coffearia*, which is distributed over the entire southern half of the Central Province of Ceylon and is a serious enemy of tea. A list is given of the food plants, representing 14 orders, on which it has been found to propagate.

**P**seudograsserie, a new disease of caterpillars of the gipsy moth, A. PAL-LOT (*Compt. Rend. Acad. Sci.* [*Paris*], 168 (1919), No. 4, pp. 258–269).—The author describes a disease of the gipsy moth which presents symptoms resembling grasserie and flacherie, and to which he gives the name pseudograsserie. The gipsy moth was found to be infected by two coccobacilli to which the names *Bacillus lymantricola adiposus* and *B. lymantriæ*  $\beta$  are given, of which the first is the cause of the disease here considered. The disease was reproduced in caterpillars of *Vanessa urticæ*, brown-tail moth, and silkworm by inoculation. The cultural characteristics of the bacillus are described.

Reports and papers on malaria contracted in England in 1917 (*Rpts. Local* Govt. Bd. [Gt. Brit.], Pub. Health and Med. Subjs., n. ser., No. 119, abridged ed. (1918), pp. IX+55, pls. 6).—Included in this report are a paper by A. J. Grove on English Mosquitoes (pp. 44-50), tables showing recorded observations of anophelines in England (pp. 51-53), and General Abstract from a Report to the Army Medical Department on the Mosquito Survey of the Aldershot District, by A. C. Parsons (pp. 54, 55).

The cabbage fly (Chortophila brassicæ) (Meded. Phytopath. Dienst Wageningen, No. 8 (1919), pp. 18, pls. 3).—A report of studies of C. brassicæ, the injury which it causes, and control measures employed.

Eumerus strigatus again, C. L. METCALF (*Ent. News, 30* (1919), No. 6, pp. 170-174).—The author presents records of the occurrence of the lunate onion fly which supplement the paper by Weiss and Nicolay previously noted (E. S. R., 40, p. 654).

**Protection from the locust borer**, F. C. CRAIGHEAD (U. S. Dept. Agr. Bul. 787 (1919), pp. 12, pls. 3).—The author reports at length upon investigations which have shown it to be practically certain that plantations of the black or yellow locust (Robinia pseudacacia) can be protected successfully from the locust borer (Cyllene robiniæ) and grown profitably on a commercial scale if the locusts are planted in thick stands or mixed with other trees so as to produce a densely shaded condition and natural pruning during the first 10 or 15 years of growth. It is said to be very essential that the shade be present after the trees reach 1.5 to 2 in. in diameter, and that it be continued until they attain 5 or 6 in., after which thinning and pruning can be done with little or no subsequent injury by the borers.

"That difference in site or locality is not the influencing factor in the growing of uninjured trees is evident from the fact that in every locality examined it was possible to find examples of borer-free and destroyed trees growing 100 yds. apart. It is also evident that goldenrod is not necessarily associated with greater damage by the borer, for in the same abandoned field, massed with this plant, were found plats of trees absolutely free from injury and near-by isolated trees badly infested. Again, localities where no goldenrod is growing may have borerinfested trees, the adults feeding on other composites."

Among the other recommendations are that locust plantations be gone over and the broken-down and infested trees removed and burned during the winter. If the cutting out of the infested trees can be done early in November, it is not necessary to destroy or burn the wood.

It has been found that the young borers can be killed readily by the use of an arsenical spray, consisting of 0.25 lb. of sodium arsenite or arsenate in 5 gal. of water to which 1 qt. of miscible oil is added and agitated thoroughly, applied to the bark when the new growth begins to open at the tips of the twigs in the spring. Kerosene emulsion may be used in place of the miscible oil to carry the arsenical, 1 gal. of the stock solution being added to 0.25 lb. of the arsenical in 4 gal. of water.

The confused flour beetle (Tribolium confusum), R. N. CHAPMAN (*Rpt. State Ent. Minn.*, 17 (1918), pp. 73–94, figs. 10).—This is a report of work at the Minnesota Experiment Station with the confused flour beetle, which has six larval instars. The relative infestation of wheat flour and wheat flour substitutes and their relative susceptibility are considered at length, together with measures of control, a discussion of which by the author has been previously noted (E. S. R., 40, p. 59).

Shot-hole borer (Xyleborus fornicatus), E. R. SPEYER (*Dept. Agr. Ceylon Bul.* 43 (1919), pp. 16, pls. 2).—A discussion of the treatment of tea prunings on estates infested with the shot-hole borer (X. fornicatus).

Report of the State apiarist for the year 1917, F. E. MILLEN (*Rpt. State Apiarist Iowa, 6 (1917), pp. 89, figs. 12*).—This consists in large part of the proceedings of the sixth annual convention of the Iowa Beekeepers' Association, held at Des Moines, December 4 and 5, 1917. Among the papers presented are the following:

The Present and Future of Beekeeping in the United States, by E. R. Root (pp. 31-33); The Proper Spacing of Frames, by C. P. Dadant (pp. 37-41); A New-Old Method of Wintering, by E. R. Root (pp. 41, 42); Painted v. Non-painted Comb Foundation, by J. W. Tinsley (pp. 42-44); Points of Interest in the Anatomy of the Honeybee, by H. E. Ewing (pp. 44-51); Beekeeping in War Times, by E. F. Phillips (pp. 51-56), previously noted from another source (E. S. R., 39, p. 869); The Mechanism which Determines Sex in the Honeybee, by H. R. Werner (pp. 56-65); The Maintenance of Colonies from the Close of the Honey Flow One Year until Its Beginning the Next, by G. S. Demuth (pp. 65-73; Beekeeping in the South, by F. C. Pellett (pp. 74-79); Rearing of Queens, by E. W. Atkins (pp. 79-82).

Nosema disease, G. F. WHITE (U. S. Dept. Agr. Bul. 780 (1919), pp. 59, pls. 4, figs. 7).—This is a detailed report of investigations conducted by the author extending over a period of several years. The results, which are presented in detail, much of the data being recorded in tabular form, have led to the following summary and conclusions:

"Nosema disease is an infectious disorder of adult bees caused by Nosema apis. The disease is not particularly malignant in character, being in this respect more like sacbrood than the foulbroods. Adult workers, drones, and queens are susceptible to infection but the brood is not. The infecting agent N. apis is a protozoan that attacks the walls of the stomach and occasionally those of the Malpighian tubules. A colony can be inoculated by feeding it sirup containing the crushed stomachs of infected bees. One-tenth of the germs present in a single stomach are sufficient to produce marked infection in a colony. Within a week following the inoculation the parasite can be found within the walls of the stomach. Before the close of the second week infection can be determined by the gross appearance of the organ. The disease can be produced at any season of the year by feeding inoculations. Infected bees may be found at all seasons of the year, the highest percentage of infection occurring in the spring.

"Nosema infection among bees occurs at least in Australia, Switzerland, Germany, Denmark, England, Canada, and the United States. This distribution shows that the occurrence of the disease is not dependent altogether upon climatic conditions. The course of the disease is not affected directly by the character or quantity of food obtained and used by the bees. A sluggish body of water, if near an apiary and used by bees as a water supply, and the robbing of diseased colonies, must be considered for the present as two probable sources of infection. The transmission of the disease through the medium of flowers is not to be feared. The hands and clothing of the apiarist, the tools used about an apiary, and winds need not be feared as means by which the disease is spread. Hives which have housed infected colonies need not be disinfected, and combs from such colonies are not a likely means for the transmission of the disease. Bees dead of the disease about the apiary are not likely to cause infection unless they serve to contaminate the water supply.

"N. apis suspended in water is destroyed by heating for 10 minutes at about 136° F. (58° C.). Suspended in honey, N. apis is destroyed by heating at about

138°. N. apis, drying at room and outdoor temperatures, respectively, remained virulent for about 2 months, at incubator temperature about 3 weeks, and in a refrigerator about 7.5 months. N. apis was destroyed in the presence of fermentative processes in a 20 per cent honey solution in 3 days at incubator temperature and in 9 days at outdoor temperature. In a 10 per cent sugar solution it was destroyed in from 7 to 11 days at room temperature. N. apis resisted putrefactive processes for 5 days at incubator temperature, for 2 weeks at room temperature, and for more than 3 weeks at outdoor temperature. N. apis when dry was destroyed in from 15 to 32 hours by direct exposure to the sun's rays. N. apis suspended in water was destroyed by exposure to the sun's rays in from 37 to 51 hours. N. apis if suspended in honey and exposed to the sun's rays frequently will be destroyed on account of the temperature of the honey which results from the exposure. N. apis remained virulent in honey for from 2 to 4 months at room temperature. N. apis in the bodies of dead bees ceased to be virulent in 1 week at incubator temperature, in 4 weeks at room temperature, in 6 weeks at outdoor temperature, and in 4 months in a refrigerator. N. apis in the bodies of dead bees lying on the soil ceased to be virulent in from 44 to 71 days.

"N. apis is readily destroyed by carbolic acid, a 1 per cent aqueous solution destroying it in less than 10 minutes. The time element which by the experiments is shown to be sufficient for the destruction of N. apis should be increased somewhat to insure their destruction in practical apiculture. The prognosis in Nosema disease varies markedly from excellent, in case of strong colonies with a comparatively small percentage of Nosema-infected bees, to very grave, in case of weak ones with a high percentage of infected bees.

"From a technical point of view the results here given must be considered as being approximately only. They are, however, in most instances sufficient for practical purposes."

The ants of France and Belgium, J. BONDROIT (Ann. Soc. Ent. France, 87 (1918), No. 1-2, pp. 1-174, figs. 83).—A synopsis of the Formicidæ.

Notes on some genera and species of chalcid flies belonging to the Aphelininæ with description of a new species, A. B. GAHAN (*Proc. U. S. Nat. Mus.*, 55 (1919), pp. 403-407, figs. 5).—Attention is called to the fact that the generic name Paraphelinus erected by Perkins is a synonym of Centrodora, Foerster. *Tumidiscapus orthopteræ* reared from the eggs of a locustid deposited in the stems of a grass (*Andropogon glomeratus*) at Titusville, Fla., is described as new.

Additions and corrections to A List of Families and Subfamilies of Ichneumon Flies of the Superfamily Ichneumonoidea (Hymenoptera), H. L. VIERECK (*Proc. Biol. Soc. Wash.*, 32 (1919), p. 48).—Additions and corrections to the paper previously noted (E. S. R., 40, p. 65).

A preliminary report on the Trombidiidæ of Minnesota, C. W. HOWARD (*Rpt. State Ent. Minn., 17 (1918), pp. 111–144, figs. 93*).—This paper includes keys to adults and nymphs of species found in Minnesota and to the larvæ, and descriptions of five species new to science.

## FOODS-HUMAN NUTRITION.

Bacteriology and mycology of foods, F. W. TANNER (*New York: John Wiley* & Sons, 1919, pp. VI+592, pls. 9, figs. 88).—This volume, which is an outgrowth of a course in food microbiology at the University of Illinois, has been developed for those who wish to fit themselves for food control work, for food chemists, and for students in household science possessing a sufficient fundamental training in chemistry. The plan followed has been to present the

methods of analysis along with sufficient discussion on the literature of the subject to show the history and derivation of these methods. Material has been taken freely from the reported investigations and each chapter contains numerous references to the literature on the subject. The subject material is considered under the following heads:

Bacteriological apparatus; media and their preparation; staining technique and microscopic methods; classification and description of bacteria; sterilization and disinfection; proteins, carbohydrates, and fats; yeasts and molds; intestinal bacteria; bacterial examination of air; water hygiene; milk and milk products; bacteriology of eggs; meat and meat products; food preservation; and epidemiology.

The book contains much illustrative material, including eight colored plates on the candled and opened appearance of market eggs.

The relative digestibility of our food materials, M. RUBNER (Berlin. Klin. Wchnschr., 55 (1918), No. 47, pp. 1113–1119).—The author points out certain features in the estimation of the nutritive value of foods which in his opinion need to be taken into consideration, with consequent revision of values. Among the points discussed are the proportion of protein in different nitrogen-containing substances, the amount of indigestible pentoses and celluloses in carbohydrates, the relative value and digestibility of mixtures of foods of vegetable and animal origin, individual idiosyncrasies, the palatability of foods, and satiety.

Digestibility of our food, M. RUBNER (Umschau, 22 (1918), No. 51, pp. 671-676).—A résumé of the article noted above.

Fats and fatty acids as food (*Jour. Physiol.*, 52 (1919), No. 5, pp.  $328-34\mathcal{E}$ ).— Five papers are presented.

**I.** *Introductory*, W. D. Halliburton and D. N. Paton (pp. 328–330).—A brief outline is given of the purpose of the investigation, which was to determine the possibility during the shortage in the supply of fats of utilizing as human food the fatty acids obtained from fats in the preparation of glycerol for the manufacture of explosives.

II. Preparations from oils, J. C. Drummond (pp. 330-333).—An investigation of various sources of fatty acids led to the conclusion that the most suitable for study were those obtained from hardened whale or seal oil, hardened palm or palm-kernel oil, and hardened "soy-cot" oil, the latter a mixture of palmkernel, soy-bean, and cottonseed oil. An addendum by W. D. Halliburton mentions the impurities which may be present in hardened fats, including nickel and arsenic, both of which under ordinary conditions are present in so small amounts as to be harmless.

III. Feeding experiments on man, D. Burns and J. S. Sharpe (pp. 333-339).— Hardened whale oil and the fatty acids obtained from it were used in comparative feeding experiments from which the following conclusions were drawn:

"The fatty acids of hardened whale oil in amounts of 36 gm. per diem, or more than one-third of the usual intake of fat, were as thoroughly digested and absorbed as was the hardened oil from which they were prepared. Their administration for a period of six days caused no disturbance in the absorption of the other constituents of the food as is indicated by the nitrogen and energy balances, nor any other disturbance in health. They may, therefore, be used as a source of fat in the diet of man."

IV. Feeding experiments on animals, J. C. Drummond and W. D. Halliburton (pp. 339–343).—The effect of the three fatty acids on maintenance and growth in rats was studied, and the following conclusions were drawn:

"There is no toxic action excited by an admixture of from 5 to 10 per cent fatty acids of the three fats used. The animals on such a diet take their food readily, grow healthily, and in some cases have produced young while on the diet."

V. The fat-soluble accessory factor, J. C. Drummond (pp. 344-346).—Experiments on rats showed that while ordinary whale oil is rich in fat-soluble A, the hardening process involving exposure to hydrogen gas at  $250^{\circ}$  C. for four hours or more destroys this factor, as does also heating the oil to  $100^{\circ}$  or more for four hours. In this connection, it is pointed out that margarins made from hydrogenated animal fats are of inferior nutritive value through their lack of the fat-soluble accessory factor.

Report upon the availability of fatty acids as a source of fat in the diet of man (London: Food (War) Committee, Roy. Soc., 1918, pp. 11).—This is the official report, the details of which are noted above.

Investigations of the nutritive value of hardened fats, C. A. PEKELHAR-ING and W. SCHUT (*Pharm. Weekbl.*, 53 (1916), No. 26, pp. 769–785, figs. 3).— The nutritive value of certain hardened fats, such as are used in the margarin industries of Holland, was studied by feeding experiments with rats, mice, and dogs.

When all of the fat of the diet consisted of the hardened fat, the rats maintained their body weight but did not grow. The mice grew at the customary rate, and a dog not only increased in weight but assimilated by far the largest part of the fat introduced into the digestive tract.

The results obtained on feeding a mixture of lard and hardened cottonseed oil indicate that the hardened fat can be utilized better if mixed with natural softer fats, as is the case in margarin.

Report on a dried meat powder, S. W. COLE (London: Food (War) Committee, Roy. Soc., 1917, pp. 6, figs. 5).—The chemical analysis digestibility, and possible utilization of a dried meat powder, said to have been obtained by drying and grinding the lean meat from Argentine cattle, are reported. The protein of the meat had been rendered extremely insoluble by the method of treatment, and appeared to be more resistant to artificial digestion than fresh meat but to be digested and absorbed by the human body almost as readily as beefsteak. Feeding experiments with rats showed that the powder contained a good supply of accessory food factors.

It is suggested that such a product, while not particularly appetizing when eaten alone, could be used successfully in soups, croquettes, and sausages.

The [Jerusalem] artichoke as a source of carbohydrate, F. G. HOPKINS (London: Food (War) Committee, Roy. Soc., 1918, pp. 2).—As the result of digestion experiments in which the relative utilization of diets furnishing 3,000 calories and containing, respectively, 1 lb. of potatoes and 1 lb. of Jerusalem artichokes was determined, the conclusion is drawn that while artichokes are probably less well utilized than potatoes they can, when eaten in reasonable quantities, replace potatoes or similar carbohydrate material in a satisfactory manner.

The influence of the percentage extraction and of admixture upon yeast activity, D. J. LLOYD (*London: Food* (*War*) *Committee, Roy. Soc., 1918, pp. 2*).— The admixture of foreign flours with wheat was found not to decrease yeast activity, although the addition of corn or barley to wheat flour slightly decreased the maximum expansion of the dough.

Food Surveys (U. S. Dept. Agr., Food Surveys, 2 (1919), No. 27, pp. 8+4).— This number, which is announced as the final issue, reports data as to commercial stocks of grain, flour, and miscellaneous food products in the United States on June 1, 1919. An index to Volumes I and II is included.

Report on the food requirements of man and their variations according to age, sex, size, and occupation (London: Food (War) Committee, Roy. Soc.,

1919, pp. 19, figs. 3).—This report of the Food (War) Committee of the Royal Society is a summary of modern conceptions of the food requirements of man under different conditions.

The quantity of fat-soluble vitamins in coconut oil, B. C. P. JANSEN (Meded. Geneesk. Lab. Weltevreden [Dutch East Indies], 3. Ser. A, pt. 1-2 (1918), pp. 78-94, pl. 1).—A study of the fat-soluble vitamin content of coconut oil was made by means of growth experiments with wild house rats, fed upon a basal diet of polished rice and the water-soluble extract from rice bran, with the addition of equivalent amounts, respectively, of cold-pressed coconut oil, olive oil, and ether extract of egg yolk. While growth was satisfactory on the diet containing the ether extract of egg yolk, addition of olive or coconut oil had no growth-promoting influence, indicating that coconut oil, like olive oil, is lacking in the fat-soluble vitamin.

The author points out a possible connection between the small stature of the natives of the Dutch Indies and the use during so many generations of a diet poor in vitamins.

A study of the physiology of endogenous uric acid, H. F. Höst (Jour. Biol. Chem., 38 (1919), No. 1, pp. 17-31, figs. 4).—This report deals with the determination of uric acid in the urine and blood in 17 subjects, 2 of whom were normal while the remainder were convalescents and patients who had never had symptoms of gout. The nitrogen output was determined in all cases and the H-ion concentration in four. The experiments are reported in detail for the two normal subjects only, but conclusions are drawn on the basis of the results obtained with all subjects.

In none of the 17 subjects was the uric acid output for 24 hours constant. With a fixed diet and under similar conditions the output was in most cases extremely irregular, showing daily variations up to 80 per cent. Even in individuals whose output of uric acid was most regular the output was found to be dependent on several factors, of which variations in the diet were the most important. Beyond a certain minimum a change in the caloric value of the food produced a change in the same direction in the uric acid output, the change, however, being greater when the amount of calories was varied by means of protein than by nitrogen-free foods. With a constant caloric value, the uric acid output depended to a certain extent on the food protein. The excretion of nitrogen and the H-ion concentration of the urine were without influence, but an increase of body temperature was accompanied by a considerable increase in the uric acid output.

The endogenous uric acid output in 24 hours varied between 0.27 and 0.99 gm. The endogenous uric acid in the blood varied from less than 0.5 to 2.68 gm. per 100 cc. of blood, but was in the case of each individual constant within the limits of error of the method (10 per cent).

The author states that definite conclusions regarding synthetic uric acid formation can not be drawn from these experiments, but that the results indicate that a not inconsiderable part of the endogenous uric acid comes from metabolism in the tissues of the digestive glands.

Respiratory metabolism investigations on the question of the formation of sugar from proteins and their degradation products, J. M. DE CORRAL (Biochem. Ztschr., 86 (1918), No. 3-4, pp. 176-222; abs. in Chem. Abs., 12 (1918), No. 22, p. 2353).—The liver of a dog was rendered free from glycogen by the administration of peptone, after which the capacity for glycogen formation from fats and proteins was determined by measurement of the respiratory quotient with the Jaquet apparatus (E. S. R., 16, p. 287).

The capacity for forming glycogen from carbohydrates after administration of peptone was found to be somewhat diminished but still to exist. On administering fats exclusively after two days' treatment with peptone the respiratory quotient in a following period of starvation was the same as that after peptone, but on administering amino acids or proteins the resulting respiratory quotient indicated combustion of carbohydrates, showing that carbohydrates can be formed from proteins. Such a formation is thought to take place, however, only when carbohydrates are lacking in the organism.

**Observation on hyperglycemia and glycosuria**, H. J. HAMBURGER (*Brit-Med. Jour.*, No. 3036 (1919), pp. 267-271).—From perfusion experiments with isolated frog kidneys, the author concludes that the glomerular membrane of the kidney has the power of retaining free glucose. This power appears to be governed by the influence of the chemical composition of the perfusion liquid upon the glomerular epithelium, a definite relation between Ca and K ions being necessary.

This is thought to render needless the conception of a colloidal sugar compound (the "sucre virtuel" of Lépine). The rentention of glucose is considered to be due rather to the structure or configuration of the molecule. If there is hyperglycemia of a certain degree the glomerular epithelium weakens and allows glucose to pass through, causing a state of glycosuria.

The splitting of neutral salts in contact with colloids with the formation of acids and bases, A. SCALA (Ann. Ig. [Rome], 28 (1918), No. 11, pp. 605–619).— Animal gelatin, agar, siliceous gelatin, and muscular flesh were allowed to stand with distilled water for 12 hours, the water drained off and titrated for acidity, and the process repeated until the wash water was neutral. The same process was repeated after the addition of from 0.5 to 1 gm. of various salts to the neutral colloidal material.

Sodium chlorid and sulphate were found to form with animal and vegetable colloids complexes which on hydrolysis formed acids, while the complexes with disodium phosphate tended to form alkalis. It is pointed out that these states in normal physiological conditions tend to compensate each other, but that in pathological conditions one or the other may predominate. The author attributes diabetes to excess of alkali and pellagra to excess of acid.

The diagnosis of acidosis, J. J. R. MACLEOD (*Jour. Lab. and Clin. Med.*, 4 (1919), No. 6, pp. 315-329).—This is a review and criticism of the methods at present in use for diagnosing acidosis, with many references to the literature on the subject.

A further demonstration of the part played by accessory food factors in the etiology of rickets, E. MELLANBY (*Jour. Physiol.*, 52 (1919), No. 5, pp. *LIII*, *LIV*).—This is a brief report of feeding experiments with puppies to show the part played by diet in producing and preventing rickets. The standard diet, which is said to produce rickets within six weeks, consisted of separated milk (175 to 350 cc.), 70 per cent wheat bread ad libitum, linseed oil (5 to 10 cc.), yeast (5 to 10 gm.), orange or lemon juice 3 cc., and sodium chlorid 2 gm. The effect of various additions to this diet was as follows:

Lean meat (10 gm. a day) delayed but did not prevent rickets, the extent of the delay depending on the initial weight and rate of growth of the animal. An increase in the separated milk to 350 or 400 cc. did not prevent rickets, thus excluding the possibility that the calcium intake was deficient. The addition of 10 gm. of butter or cod liver oil completely prevented rickets, but the substitution of 10 gm. of cottonseed oil, olive oil, or babassu oil for the linseed oil of the basal diet did not prevent the disease.

All vegetable oils were not equally ineffective in preventing rickets. The oils tested in order of increasing merit were linseed, babassu, cottonseed, peanut, and olive. A hydrogenated fat tested was similar to linseed oil. Suet and lard appeared to be effective if a small amount of meat was also eaten.

It is pointed out that the results are for the most part in keeping with the idea that rickets is a disease primarily due to a deficiency of fat-soluble A, and that substances containing and associated with fat-soluble A appear to be particularly concerned in the calcification processes of bones and teeth.

An experimental investigation on rickets, E. MELLANBY (Lancet [London], 1919, I, No. 11, pp. 407-412).—The first of two lectures on rickets delivered at the Royal College of Surgeons of England reports in detail the results of the investigations noted above.

The second lecture consists of a general discussion of rickets as a deficiency disease. Three difficulties in considering the antirachitic factor and fatsoluble A as identical are the relation of rapidity of growth to the development of rickets, the action of meat and meat extracts, and the different effects of vegetable oils. The fact that large and rapidly growing puppies require more of the antirachitic factor is thought not to be out of keeping with the supposition that fat-soluble A and the antirachitic factor are identical if it is considered that the function of fat-soluble A in the diet is not so much to insure growth as to promote correct growth, in which case the greater the amount of growth in any period the greater will be the amount of fat-soluble A necessary to keep it along normal lines. The favorable effect of meat and meat extracts is thought to be due to their specific dynamic or stimulating action. The varying effects of vegetable oils, which have hitherto been considered to be quite lacking in fat-soluble A, may be explained on the supposition that previous work involving the growth of rats has not furnished a sufficiently delicate test for fat-soluble A. The author is of the opinion that the antirachitic factor and fat-soluble A are identical, or at least that the distribution of the two substances is remarkably similar. Some earlier hypotheses as to the etiology of the disease are cited in confirmation of this theory.

In conclusion, the author states that the diet of an infant should include a maximum amount of the antirachitic factor. He points out in this connection that care should be taken not to include too much of foodstuffs such as bread, vegetable oils, proprietary articles, etc., which are lacking in the antirachitic factor, as the more of such foodstuffs is eaten the greater is the necessity for foods containing this factor. While emphasizing the importance of milk as an antirachitic factor, attention is called to the probability that the cow fed in the stall largely on vegetable oil cake will give a milk deficient in accessory food factors and that if a nursing mother's diet is deficient in the antirachitic factor the breast-fed child may develop rickets.

The cause and prevention of scurvy (London: Food (War) Committee, Roy. Soc., 1918, pp. 2).—This is a summary of conclusions, drawn chiefly from investigations at the Lister Institute which have been previously noted from other sources, as to the cause and prevention of scurvy. It is particularly emphasized that in cooking the destruction of antiscorbutic properties depends rather upon the time than the temperature employed.

Trench feet a deficiency disease, L. BRUNTZ and L. SPILLMAN (*Compt. Rend.* Soc. Biol. [Paris], 82 (1919), No. 1, pp. 8–10).—The authors attempt to prove that trench feet, a disease characterized by polyneuritis of the extremities, is caused primarily by a lack of vitamin in the diet, the conditions of trench life serving to accentuate the primary neuritic condition.

Note on the influence of the rate of cooling on metabolism, L. HILL (London: Food (War) Committee, Roy. Soc., 1918, pp. 5, figs. 2).—The author maintains that in most calorimeter experiments sufficient attention has not been given to the cooling power of moving air, and presents data from various sources illustrating the effect of wind upon metabolism. Data are given showing an increase of from 37 to 65 calories per square meter of surface in the resting metabolism of a young woman exposed to inclement cold winds. A calculation of the cooling power on the surface of the check as determined by the Kata-thermometer gave results from six to seven times that of the loss of body heat, showing that under the conditions of cool moving air the resting metabolism is apparently controlled by the surface temperature of the check and can be calculated by taking the record of the dry Kata-thermometer cooling power and check surface temperature.

# ANIMAL PRODUCTION.

The American Society of Animal Production.—Record of proceedings of annual meetings, December, 1915, and December, 1916 (Amer. Soc. Anim. Prod. Procs. 1915–16, pp. 270, figs. 30).—This is a combined report published December, 1917, of the meetings held, respectively, at Manhattan, Kans., and Urbana, Ill. Some 27 papers reporting or discussing research are printed, together with a report on Methods of Experimentation in Animal Nutrition (pp. 101–111) by a committee composed of H. S. Grindley, W. A. Cochel, J. M. Evvard, L. D. Hall, and W. A. Carroll.

The average correlation within subgroups of a population, S. WRIGHT (Jour. Wash. Acad. Sci., 7 (1917), No. 17, pp. 532-537).-The "populations" used in breeding experiments and similar investigations are frequently composed of several fairly well differentiated groups, such as families or even breeds. A measure of correlation of two characters in the entire population, disregarding as far as possible the group differences, is often desired but, as the author points out, the ordinary coefficient of correlation does not meet the requirements because its magnitude is influenced by heterogeneity in the material, which, moreover, can seldom be considered "normal." The average of the coefficients of correlations of the individual groups is suggested as a good approximation to the desired measure. If the separate group correlations are not needed for the purpose of the experiment or their determination would be statistically worthless on account of the small size of the group, the straightforward computation of this average involves some very laborious numerical work not otherwise utilized. Formulas developed in this paper indicate how the average group correlations can be computed from a knowledge of the correlation and standard deviations of the two characters in (1) the total population, and (2) the means of the groups. In many cases all these statistical constants will have a value in connection with an investigation apart from this use.

Further illustrations of the applicability of a coefficient measuring the correlation between a variable and the deviation of a dependent variable from its probable value, J. A. HARRIS (Genetics, 3 (1918), No. 4, pp. 328-352, figs. 6).—In a previous paper<sup>1</sup> the author pointed out that in studying the interrelations of two variables in which one is a fraction of the other (such as the number of fertile eggs laid by a hen and the percentage hatched) the ordinary coefficient of correlation does not provide as much useful information as a coefficient showing whether the value of the fraction becomes relatively larger or smaller with increasing values of the independent variable. The formulas derived in the earlier paper are repeated in a form convenient for computation and supplementary ones added A number of illustrations of the use of the coefficient, both with plant and animal material, are given, including problems of fertility and fecundity, the proportionality of parts, the relationship between chemical data such as total solids and a particular solid constituent, and the measurement of differential viability of zygotic types in a breeding experiment.

The modified Wolff-Lehmann feeding standards, F. B. MORRISON (Amer. Soc. Anim. Prod. Proc. 1915, pp. 64-69).—After a discussion of the limitations of feeding standards and the necessity of modifying the Wolff-Lehmann standards, suggested modifications are presented which have since been embodied in Table V of the appendix to Henry and Morrison's Feeds and Feeding (E. S. R., 34, p. 261).

Nitrogenous constituents of feeding stuffs, H. S. GRINDLEY (Amer. Soc. Anim. Prod. Proc. 1916, pp. 133-141).—The analytical data on the amino-acid content of blood meal, tankage, skim milk, wheat, barley, oats, corn, white soy beans, cottonseed meal, and alfalfa hay published by Grindley and Slater (E. S. R., 34, p. 412) are reprinted, and a general discussion is given as to the value of such determinations in feeding investigations.

Concerning corn as a source of protein and ash for growing animals, A. G. HOGAN (*Amer. Soc. Anim. Prod. Proc. 1916, pp. 227-232*).—This contribution from the Kansas Experiment Station presents without essential modifications the material in a publication by the author previously noted (E. S. R., 37, p. 164), with an added section reporting the observation that a pair of rats kept on a ration of corn and ash consistently ate their young (5 litters) until the diet was changed. Parturition was difficult during the corn-feeding period.

Utilization of apple pomace for animal feeding, G. WARCOLLIER and HÉDIARD (*Vie Agr. et Rurale, 8 (1918), No. 1, pp. 11, 12*).—Suggestions are given for the use in animal feeding of fresh, ensiled, and dried pomace. Proximate analyses of four samples of the latter are published.

[Analyses of] unusual feeding stuffs, A. E. VINSON and C. N. CATLIN (Arizona Sta. Rpt. 1917, pp. 477, 478).—Proximate analyses are given of samples of Yucca elata, sword beans (Canavalia ensiformis), alfalfa hay, alfalfa straw, tepary-bean hay, sorghum refuse, milo maize head chop, and wheat bran. The protein content of other samples of wheat bran, of shallu whole grain, and of cotton-stalk hurds is also noted.

Weights of typical Shorthorns, J. L. TORMEY (*Breeder's Gaz.*, 75 (1919), No. 24, pp. 1408, 1410).—A table is presented showing the average weights and the range in weights by age groups of breeding animals of the Shorthorn breed exhibited at the International Live Stock Expositions of 1908 and 1910.

Investigations with growing steers, T. L. HAECKER (*Amer. Soc. Anim. Prod. Proc. 1916, pp. 169–173*).—In continuation of work at the Minnesota Experiment Station previously mentioned (E. S. R., 32, p. 99) and published elsewhere,<sup>1</sup> the author reports the individual slaughtering data of 5 calves killed at the weight of 100 lbs. and 5 killed at 400 lbs., together with the average for each group of the water, protein, fat, and ash content of the several tissue components of the carcasses.

More grass to make more beef, F. D. FARRELL (*Breeder's Gaz.*, 75 (1919), No. 15, pp. 841, 842).—A consideration of some of the problems of grassland management, with particular reference to the native pastures of Kansas.

The utilization of grain sorghums in meat production, W. A. COCHEL (*Amer.* Soc. Anim. Prod. Proc. 1915, pp. 9–14).—The following feeding trials at the Kansas Experiment Station are summarized: (1) Experiments in wintering beef calves and cows on Kafir corn silage or fodder with a protein supplement, reported in Bulletin 198 (E. S. R., 32, p. 68); (2) a comparison, apparently not elsewhere published, of ground corn, ground Kafir corn and hominy feed for fattening steers, with sweet sorghum silage as roughage; and (3) the hog-feeding tests given in the report of the station for 1915 (E. S. R., 36, p. 167).

The grain sorghums are considered the best feeding stuffs available for the dry-land farmer.

[Velvet beans for] beef cattle, G. S. TEMPLETON (Alabama Col. Sta. Circ. 40 (1919), pp. 24, 25).—A cooperative experiment is reported comparing three methods of preparing velvet beans for steer feeding. Four lots of 15 steers each were fed 117 days beginning December 15, 1917. One lot was given cottonseed meal as a check. Sorghum silage was the only roughage fed.

It is computed that 3.07 lbs. of the beans fed dry in the pod, 2.7 lbs. fed in the pod but soaked in water, and 2.16 lbs. of the beans and pods ground into a meal were each equal in feeding value to a pound of cottonseed meal. The charge for grinding the beans was \$4.50 per ton, but this operation increased the profit per head \$15.65 over the lot fed the dry beans and \$8.60 over the lot fed the soaked beans.

Silage as a factor in beef production, W. H. TOMHAVE (Amer. Soc. Anim. Prod. Proc. 1916, pp. 158-164).—The author summarizes a series of experiments at the Pennsylvania Experiment Station (E. S. R., 24, p. 269; 30, p. 372; 37, p. 365), in which various amounts of silage were fed to steers, and gives a brief account of changes in methods of cattle feeding since 1905 leading to a more widespread use of silage.

Silage for range cattle, R. H. WILLIAMS and W. S. CUNNINGHAM (Arizona Sta. Rpt. 1917, pp. 469, 470).—Practical tests at the Cochise and Prescott Dry Farms are cited to show that corn and grain sorghum silages are suitable feeds to tide cattle over periods of range shortage. "Since there are large areas in dry farming and overflow districts suitable for growing crops for silage, these experiments suggest that stockmen should put forth every possible effort to secure good land and raise crops which may be fed the animals during short range."

Tests of the work oxen of Morocco at the Moroccan agricultural exhibition at Casablanca (October, 1918), A. LEROY (*Compt. Rend. Acad. Agr. France, 4* (1918), No. 35, pp. 965–969).—The author publishes a table showing for each of 14 oxen and 2 zebu crosses the age, the body weight, the height at the withers, the maximum force exerted on a dynamometric spring, the maximum velocity attained without load, and the power available for sustained muscular work. The last-named determination is assumed equal to 8.25 per cent of the product of the two preceding, following the practice of Ringelman (E. S. R., 20, p. 70), whose methods were used throughout.

Forage crops for lambs, L. J. HORLACHER (*Breeder's Gaz.*, 75 (1919), No. 26, pp. 1508, 1510).—An experiment at the Kentucky Experiment Station comparing rape and blue grass as forage crops for lambs is reported. The lambs were allowed to suckle the ewes night and morning, ran on pasture during the day, and received from 0.5 to 0.75 lb. of grain (oats and bran, 2:1) per head daily. The test lasted 42 days commencing June 20, 1918.

The lot of 10 lambs with access to an acre of blue grass (not previously pastured) had an average initial weight of 62.3 lbs., made a daily gain per head of 0.3 lb. and consumed 2.2 lbs. of grain per pound of gain. The lot of 10 lambs with access to an acre of Dwarf Essex rape had an average initial weight of 59.4 lbs., gained at the rate of 0.38 lb. per head per day, required only 1.8 lbs. of grain to make a pound of gain, and were in better market condition at the end than the other lot.

"During the first two weeks the lambs scarcely touched the rape at all, with the result that the lambs on blue grass pasture made practically double the gains of those on rape... By the middle of July the pastures were getting very dry. The blue grass was still good, but it was getting short and brown. The rape was turning brown and yellow. At the end of four weeks the lambs on rape had regained all they lost at the beginning and were forging ahead.... During the fifth week of the test continuous rains fell; the pastures freshened up greatly and the difference in favor of rape was not so marked as it would have been under normal summer conditions."

There were no cases of bloat.

Influence of strictly vegetable diets on growth and reproduction of swine, E. B. HART and E. V. MCCOLLUM (*Amer. Soc. Anim. Prod. Proc. 1915, pp. 49-53, figs. 4*).—This paper gives the details of an investigation previously noted (E. S. R., 35, p. 563). Microphotographs are reproduced of sections of the spinal cord of a normal and of a grain-fed pig. The spinal cord of the latter showed a marked edematous condition with the motor cells noticeably constricted.

Alfalfa pasture for hogs, R. H. WILLIAMS and W. S. CUNNINGHAM (*Arizona Sta. Rpt. 1917, pp. 466, 467*).—Two lots of five Duroc-Jersey pigs were fed a daily ration of from 2 to 3 lbs. of rolled barley and 6 lbs. of skim milk per 100 lbs. live weights, for 12 weeks. One lot had access to a small alfalfa pasture and gained 433 lbs. during the period. The other received no forage and gained 373 lbs. The former lot consumed 80.5 lbs. more barley and 108 lbs. more milk and showed much more finish.

Another test with two pigs on alfalfa pasture without other feed is cited, in which the respective gains were only 6 and 7 lbs. during 8 weeks, while litter mates fed grain and pasture gained 40 lbs. each.

[Dry lot finishing of hogs following peanut pasture], G. S. TEMPLETON (Alabama Col. Sta. Circ. 40 (1919), p. 26).—Seventy hogs were grazed for 8 weeks on peanut pasture. They were then divided into two lots, one of 40 head being continued on peanut pasture for another period of 6 weeks, and a second of 30 head being fed in a dry lot on corn and tankage in a self-feeder. At the close of the 6 weeks' period they were marketed. The lot fed 14 weeks on peanuts were classified by the packer's expert as oily, and sold for 15 cts. per pound. Those finished in the dry lot were classified as medium soft and sold for 15.5 cts.

Cottonseed meal as a feed for hogs, J. C. BURNS (*Amer. Soc. Anim. Prod. Proc. 1915, pp. 15-20*).—A 96-day feeding experiment during the winter of 1914-15 at the Texas Experiment Station is reported, in which cottonseed meal was used as a supplement to milo maize chop in fattening 110-lb. hogs.

It was found that untreated cottonseed meal in amounts sufficient to balance the ration (1 part in 7) gave results equal to fermented cottonseed meal (1 part in 7, and 1 part in 4) previously found satisfactory (E. S. R., 18, p. 667), and to unfermented meal (1 part in 4) treated with ferrous sulphate solution as recommended by the North Carolina Experiment Station (E. S. R., 31, p. 578). The average daily gains per head varied from 1.24 to 1.26 lbs. in the different cottonseed meal lots, while in the check lot which received no supplement it was only 0.65 lb. There were no fatalities, but the lot fed the heavy ration of fermented cottonseed did not eat well toward the end.

It is pointed out that cottonseed meal is ordinarily one of the cheapest sources of protein at the command of the southern hog raiser, and its use should not be abandoned because heavy or prolonged feeding is injurious. "It would not be advisable to feed more than one-half pound of meal per 100 lbs. of live weight per day to any class of hogs for a very long period, and if continuous meal feeding is practiced it would be well not to feed over 0.35 lb., or 10 per cent of the whole ration when hogs are on full feed."

Southern pork production, P. V. EWING (New York: Orange Judd Co., 1918, pp. X+285, figs. 57).—The topics customarily found in manuals of swine hus-138958°—19—6 bandry are discussed in this volume, including breeds, judging and fitting for the show ring, diseases, and the utilization of pork and pork products. In the sections on feeding, management, and marketing, and in the introductory discussion of economic aspects, the problems and practices peculiar to the Southern States are given particular attention and are contrasted with corn belt conditions.

Horse management, R. W. CLARK (Colo. Agr. Col., Ext. Serv. Bul., 1. ser., No. 150-A (1918), pp. 32, figs. 14).—Information is assembled concerning draft horses, particularly with reference to the selection of stallions and the care of colts.

**Poultry feeds and feeding**, G. ROBERTSON (*Canada Expt. Farms, Bul. 91* (1918), pp. 31, figs. 13).—This manual deals with the feeding of domestic fowl, turkeys, ducks, and geese. A paragraph is devoted to each of the common poultry feeds, and a compilation of the chemical composition and digestibility of various feeding stuffs is tabulated. Designs for hoppers and feeding troughs are included.

Outline of object and plan of the Nebraska national egg-laying contest (*Nebraska Sta. Circ.* 7 (1919), pp. 4).—This is an announcement of a 5-year egg-laying and breeding contest beginning November 1, 1919.

Final report on the fourth poultry egg-laying trials, 1915–16 (Poultry Competition Mo. [Harper Adams Agr. Col.], 1 (1915–16), No. 10, pp. 1–32, pl. 1, figs. 3).—In a continuation of reports previously noted (E. S. R., 33, p. 572; 38, p. 72), of the egg-laying contests held at Newport, Shropshire, by the Harper Adams Agricultural College, this article gives a final summary of the fourth 1-year contest and a report of the first year of a 2-year contest. Records of separate pens by 4-week periods, and the total record of each individual entrant are published. The 4-week records of individuals are to be found in the preceding numbers of this periodical, which is almost exclusively devoted to statistical matter connected with the competitions.

A study of the relations of winter production to the year's record based on the data accumulated is included.

[Report of the fifth poultry egg-laying trials 1916–17] (*Poultry Competi*tion Mo. [Harper Adams Agr. Col.], 2 (1916–17), No. 12, pp. 3–23).—This is a less complete report than the preceding, giving the second year's records by pens of the 2-year contest and the year's records of individual pullets. The records by periods of four weeks are published in the other numbers of the volume.

Sixth poultry egg-laying competition extending over twelve months, 1917-18 (Utility Poultry Jour. [Harper Adams Agr. Col.], 3 (1917-18), No. 12, pp. 1-28, pls. 2, fig. 1).—A report similar to the above of the sixth contest at the Harper Adams College. As before, the individual records by 4-weeks periods are published in the earlier numbers of this volume.

The following body measurements are recorded for about 160 birds, classified according to egg record: (1) The base of the neck to the oil gland, (2) the breadth of the back, "taken between the inside of the fingers when spanning between the depressions on the hips," (3) the length of the keel, (4) the distance from the hind end of the keel to the pelvic bones, (5) the distance between the pelvic bones, and (6) the girth of the position of measurement 2, with the legs directed backward. Measurement 4 is held to be most indicative of laying capacity.

Egg-laying tests at Hawkesbury Agricultural College, sixteenth year's results, 1917–18, E. F. WHITBREAD and J. HADLINGTON (Agr. Gaz. N. S. Wales, 29 (1918), No. 5, pp. 348–369, figs. 8; also in Dept. Agr. N. S. Wales Farmer's *Bul. 118* (1918), pp. 24, figs. 8).—This is a discussion of the New South Wales contest concluded March 31, 1918. Monthly individual egg records are tabulated of 420 pullets and 120 second-year hens. The production of the latter as pullets is also given. The report of the previous contest has been noted (E. S. R., 38, p. 72).

[Reports on the fifth, sixth, and seventh Victorian egg-laying competitions, 1915-16 and 1917-18], A. HART (Jour. Dept. Agr. Victoria, 14 (1916), No. 6, pp. 329-340, figs. 8; 15 (1917), No. 6, pp. 321-332, figs. 7; 16 (1918), No. 6, pp. 321-338, figs. 8).—Continuing previous summaries (E. S. R., 33, p. 673) these reports discuss the results of the egg-laying contests held annually at Burnley, Victoria, beginning April 15. The seventh contest was closed after 11 months, while the others continued a full year. Tables give the monthly egg records for each pen of six birds and the breed averages. Individual records of 136 pullets by months are tabulated in the seventh report.

Report of an investigation as to cause of death of chicks in shell in artificial incubation, H. B. ARBUCKLE (Jour. Elisha Mitchell Sci. Soc., 34 (1918), No. 3, pp. 141-145, pl. 1).—The author states that under the standard conditions of artificial incubation generally considered essential for a good hatch most deaths in the shell occur after the eighteenth day. The oxygen content of the incubator air at this stage was found to be reduced. The percentage of fertile eggs hatched was increased by introducing a current of oxygen into the incubator during the last few days of incubation.

## DAIRY FARMING-DAIRYING.

Alfalfa as a sole feed for dairy cattle, F. W. WOLL (*Jour. Dairy Sci.*, 1 (1918), No. 6, pp. 447-461).—Lactation and other records are reported of 6 heifers of the California Experiment Station herd put on an exclusive ration of alfalfa hay (following methods used by dairymen in western irrigated districts) several months before freshening and continued on alfalfa for upward of 3 years. Similar records are presented for comparison of 6 heifers of like age and breeding fed a mixed ration of alfalfa hay, silage, and various concentrates (mainly rolled barley, dried beet pulp, coconut meal, and wheat bran). Records of 6 first lactations and 3 second lactations are available in each group.

During the first lactation the alfalfa-fed heifers averaged 5,743 lbs. of milk and 204.2 lbs. of butter fat, while the group on mixed rations produced 7,359 lbs. of milk and 297.1 lbs. of fat. The milk records of the second lactation averaged 6,372 and 7.420 lbs. and the butter-fat records 285.8 and 351.5 lbs., respectively. Under average California market prices from 1910 to 1916 the mixed ration cost about 50 per cent more than the alfalfa ration.

Six body dimensions of the heifers were measured, and the averages and the average increases of each lot are presented. "While the evidence can not be considered conclusive, the tendency is toward a slightly larger body development of the animals on the mixed rations than of those on alfalfa only."

The relation of alfalfa feeding to abortion is discussed, but the small amount of new data is not thought to require modification of conclusions previously noted from the same station (E. S. R., 34, p. 269).

Alfalfa hay v. alfalfa hay and silage for dairy cows, R. H. WILLIAMS and W. S. CUNNINGHAM (*Arizona Sta. Rpt. 1917*, *pp. 468*, 469).—Two lots comprising 4 and 3 cows, respectively, were fed alternately by the reversal method during two 3-week periods on the following rations: (1) Alfalfa hay 20 lbs., corn silage 35 lbs., and (2) alfalfa hay 30 lbs. The average daily yields during the feeding of the first ration were 24.27 lbs. of milk and 0.881 lb. of butter fat; during the feeding of the second ration 24.72 lbs. of milk and 0.846 lb. of butter fat. The two rations are thus considered of equal feeding value, and it is pointed out that with alfalfa hay at \$20 and corn silage at \$6 per ton each costs about the same.

It is stated that Arizona dairymen are beginning to make more extensive use of silage.

The mineral metabolism of the milch cow [I, II, III], E. B. FORBES (Amer. Soc. Anim. Prod. Proc. 1915, pp. 1-8; 1916, pp. 117-125; Jour. Dairy Sci., 2 (1919), No. 1, pp. 9-18).—These three papers are extensive extracts from the three bulletins of the same title issued by the Ohio Station (E. S. R., 40, p. 373).

Fifth annual report of the International Association of Dairy and Milk Inspectors, I. C. WELD (Ann. Rpt. Internat. Assoc. Dairy and Milk Insp., 5 (1916), pp. 319, pls. 2, figs. 3).—Besides a number of papers read at the annual convention at Springfield, Mass., in October, 1916, this publication contains the following committee reports: On dairy-farm inspection, by C. B. Lane, J. A. Gamble, and H. A. Harding (pp. 45–53); on city milk-plant inspection, by H. E. Bowman, F. H. Bothell, and W. P. Palmer (pp. 54–59); on legislation and legal limits for the control of milk and cream, by J. S. Abbott, J. O. Jordan, and G. B. Taylor, with the assistance of H. S. Bailey (pp. 60–70); and on methods of appointment of dairy and milk inspectors and their compensation, by E. Kelly, W. S. Gimper, and G. S. Hine (pp. 181–188), previously noted from another source (E. S. R., 36, p. 774).

The Report of the Committee on Statistics of Milk and Cream Regulations of the Official Dairy Instructors' Association, by I. C. Weld, E. H. Farrington, J. A. Gamble, H. E. Ross, and R. C. Potts, of which an extract has been noted (E. S. R., 36, p. 874) and which was read by request before the convention, is also printed (pp. 71–125).

The following papers have been noted from other sources or are based upon discussions previously noted: Relation of the Fat in Milk to the Solids-not-fat, by L. P. Brown and C. V. Ekroth (pp. 126–133) (E. S. R., 37, p. 113); Chemical Quality of New York City Milk, by the same authors (pp. 134–140) (E. S. R., 37, p. 175); The Sterilization of Dairy Utensils on the Farm and a Demonstration of a New Steam Sterilizer, by G. B. Taylor (pp. 200–206) (E. S. R., 35, p. 677; 36, p. 663); and The Reliability and Significance of the Bacteriological Analysis of Milk, by H. W. Conn (pp. 207–227) (E. S. R., 36, p. 775).

Sixth annual report of the International Association of Dairy and Milk Inspectors, I. C. WELD (Ann. Rpt. Internat. Assoc. Dairy and Milk Insp., 6 (1917), pp. 232).—The papers read at the annual convention held in Washington, D. C., in October, 1917, are printed, as well as the reports of committees, including the following: On dairy-farm inspection, by J. A. Gamble (pp. 40–47); on methods of bacterial analyses of milk and milk products and the interpretation of results, by G. E. Bolling (pp. 85–88); on rules and regulations necessary for securing a clean and safe milk supply, by E. Kelly (pp. 106–111), also published elsewhere;<sup>1</sup> and on the care of milk in transportation, by J. O. Jordan (pp. 114–121).

Seventh annual report of the International Association of Dairy and Milk Inspectors, I. C. WELD (Ann. Rpt. Internat. Assoc. Dairy and Milk Insp., 7 (1918), pp. 239).—This publication covers the proceedings of the convention at Chicago, in December, 1918. Among the committee reports presented are the following: On cost of dairy and milk inspection, by H. Lloyd (pp. 42–47); on

legislation affecting milk and milk products, by J. O. Jordan (pp. 71–73); on methods of bacterial analyses of milk and milk products and the interpretation of results, by G. B. Taylor (pp. 115–117); and on organization of milk control, by W. H. Price (pp. 214–223).

A number of papers are also printed.

Machine v. hand milking, F. T. RIDDELL (*Michigan Sta. Quart. Bul.*, 1 (1919), No. 4, pp. 163, 164).—The following is a summary of data assembled from 93 farms in the condensery districts of Michigan as to the comparative labor cost of machine and hand milking:

Methods of milking and herd sizes included.	Num- ber of herds.	Cows per herd.	Labor per cow per year.			Labor per 100 lbs. of milk.		
			Milk- ing.	Care of milk and uten- sils.	Total.	Milk- ing.	Care of milk and uten- sils.	Total.
Machine—all herds Machine—15 or fewer cows Machine—more than 15 cows Hand—all herds	51 17 34 42	$   18.2 \\   13.1 \\   20.8 \\   13.6 $	Hours. 57.9 65.2 55.6 89.2	Hours. 13.4 14.7 13.0 11.2	Hours. 71.3 79.9 68.6 100.4	Hours. 0.91 .99 .88 1.26	Hours. 0.21 .22 .21 .16	Hours. 1.12- 1.21 1.09 1.42

Labor used in machine and in hand milking.

"Less difference would probably be found where market milk was being produced, as the higher requirements specified for milk used for such purposes would necessitate greater attention to the care and cleaning of the milk machines."

Safe milk for the small town, K. E. MILLER (*Pub. Health Rpts.* [U. S.], 33 (1918), No. 50, pp. 2213-2217).—The plans of Tarboro, N. C., to maintain a municipal pasteurizer and to distribute all the milk (about 400 qt. a day) sold in the town are outlined. A note added to the paper states that the pasteurizing plant was placed in operation October 1, 1918. The town will refuse to buy milk not produced under satisfactory sanitary conditions.

The text of the ordinance authorizing the town to engage in the milk business is appended.

Questions concerning the control of a city milk supply answered, R. S. BREED (New York State Sta. Bul. 456 (1918), pp. 3-10).—Information concerning the milk supply of Geneva, N. Y., is furnished by the answers to a series of 18 questions. The topics include the measures taken to guard against sophistication and contamination, prices and the basis of payment, pasteurization, and the efficiency of inspection. Through a cooperative arrangement members of the station staff exercise supervision over the milk supply of the city.

Observations on the washing of milk cans, R. O. WEBSTER (Ann. Rpt. Internat. Assoc. Dairy and Milk Insp., 6 (1917), pp. 54-66; also in Jour. Dairy Sci., 2 (1919), No. 1, pp. 50-59).—This paper presents a portion of the data collected by the Bureau of Chemistry of the U. S. Department of Agriculture in the course of an investigation under the Food and Drugs Act of the milk supply of a large middle western city. The methods and equipment used by 32 dealers in washing cans are noted. Eight washed by pouring washing solutions from one can to the next. Only one used hot water, and two clean water for washing. The cans were steamed in 23 dairies, but in no case was the steaming effective. Three had what was considered a complete equipment, a tank with mechanical brush, rinsing tank, steam jet, and air blast. A physical and bacteriological inspection of 184 empty cans as returned to the shippers during June and July is summarized. The odor of 14 was classified as sour and of 83 as foul. Over 42 per cent, if used without further rinsing, would have added from 500,000 to 4,332,000 bacteria to each cubic centimeter of milk. It is pointed out that milk produced under very insanitary conditions seldom has an initial bacterial content in excess of 20,000. Prompt drying of the cans after washing is considered the most urgent reform.

The proper methods of caring for milk cans are outlined.

**Refrigeration on southern dairy farms, J. T.** BOWEN (*Hoard's Dairyman, 57* (1919), No. 10, pp. 489-491, figs. 5).—This is a discussion by the author of Bulletin 98 of the U. S. Department of Agriculture (E. S. R., 31, p. 575), based upon the section on cooling milk on the farm in that publication, but considerably augmented. Data are furnished as to the cost of operating quarter-ton and half-ton refrigerating machines under different precooling temperatures. In the Southern States, where ice is scarce, it is held that refrigeration would eliminate the principal hot-weather difficulties in the care of milk. By precooling the milk with spring or well water and by storing up refrigeration it is possible to make a small machine provide refrigeration for a comparatively large herd.

A study of the alkali-forming bacteria found in milk, S. H. AYERS, P. RUPP, and W. T. JOHNSON, JR. (U. S. Dept. Agr. Bul. 782 (1919), pp. 39, figs. 2).—The authors, working in the laboratories of the Dairy Division, have investigated the occurrence and activities of the group of alkali-forming bacteria, limiting that term to nonpeptonizing types capable of rendering milk alkaline. An intensive study was made of 68 cultures isolated mostly from market milk, a few being obtained from ice cream. Both bacilli and cocci were included. The organisms grew best at temperatures between 20 and 30° C. and had thermal death points ranging from 60 to 65.5° when heated in milk tubes for 30 minutes. No spores were observed.

Record is made of the ability of each culture to ferment ethyl, propyl, and amyl alcohols, dextrose, 22 different organic acid salts, and urea, the results being given in terms of pH values except in the case of the alcohols. Statements are also made with respect to several other substances. Synthetic media were used, nitrogen being supplied by sodium ammonium phosphate with the test substance furnishing the carbon. Dextrose and galactose were fermented readily, lactose and saccharose by a few cultures, and raffinose not at all. The monatomic alcohols were fermented by more cultures than were mannite and glycerin. Study of the organic acid data indicates that the carboxyl radical does not serve as a source of carbon for these organisms. Carbon was most easily obtained from the methyl group. It is held that the characteristic reaction produced by these bacteria in fresh milk is due to the oxidation of the citric acid salts present to alkaline carbonates.

The alkali-forming bacteria (as defined) are considered to be primarily soil organisms. They were present in numerous samples of soil, in water, on the hands of farm laborers, in unsterilized milk utensils, and in small numbers in cow feces. An arbitrary classification based on the substances fermented is proposed.

A comparison of bacteria counts in whole and skim milk, separator and centrifuge cream, R. W. LAMSON (Jour. Dairy Sci., 1 (1918), No. 6, pp. 498-507).—The author claims that many of the published statements as to the bacterial content of cream are based upon laboratory centrifuging of milk in flasks, and records the results of 10 experiments conducted by the Bureau of Chemistry of the U. S. Department of Agriculture in which it was possible to compare the bacterial counts of separator skim milk, separator cream, centrifuge skim milk, and centrifuge cream with the counts of the whole milk sample from which they were derived. Most of the samples were analyzed independently by more than one bacteriologist and each observer's results are tabulated.

Averaging the separate observations on each sample, it was found that in 3 cases the separator skim milk and in 6 cases the separator cream showed a higher count than the whole milk. In only one case was a count of centrifuge skim milk higher than whole milk, but centrifugally separated cream in every case was higher. "These results for separator cream are in quite close agreement with the findings of other investigators who actually worked on separator cream. The results obtained on centrifuge cream are also very similar to those reported by other writers on this class of product."

No close relation was found between the bacterial count of the cream and the percentage of butter fat.

On the basis of these results and of observations made in New England creameries in the summer of 1917, the author advocates the same bacteriological standard for cream as for market whole milk.

The influence of the separator upon distribution of bacteria in milk and cream, L. D. BUSHNELL and O. W. HUNTER (*Trans. Kans. Acad. Sci., 28 (1916-17), pp. 61-69).*—Observations made at the Kansas Experiment Station on a number of milk samples are summarized.

The number of organisms revealed by agar plates in 23 tests of good market milk averaged for whole milk 80,000, skim milk 107,500, cream 101,100, and bowl sediment (per gram) 399,800. The cream in each case was added to skim milk and the mixtures showed an average count of 157,900. The increased counts are attributed to the breaking up of clumps. Fifty-five tests were made on a lower grade milk hauled from distant farms and showed similar results; the bowl sediment was not examined in these cases.

The amount of butter fat seemed to have no effect on the distribution of bacteria between cream and milk. Considerable differences were found between different separators, between different runs of the same separator, and even between different samples of the same milk drawn from the separator spouts during the same run.

The microbial flora of graded cream, O. W. HUNTER and L. D. BUSHNELL (*Trans. Kans. Acad. Sci.*, 28 (1916–17), pp. 69–76).—Observations from the Kansas Experiment Station are reported showing that the grading of cream by flavor and odor was more satisfactory than grading by acidity in discriminating between cream high in lactic acid bacteria and cream whose microbial flora consisted, predominantly, of organisms harmful or not useful in butter making.

Sweet cream butter, H. A. BENDIXEN (*Hoard's Dairyman*, 57 (1919), No. 10, p. 499, fig. 1.—The author recites the success of a cooperative creamery in Iowa in producing sweet cream butter for the U. S. Navy, and predicts that this type of butter will be increasingly in demand because of its keeping qualities.

#### VETERINARY MEDICINE.

**Pyotherapy**, H. VELU (*Rev. Gén. Méd. Vét.*, 28 (1919), *No. 330*, *pp. 297–311*).— This is a general review and discussion of the literature on the subject, including a comparison of the methods employed by different workers in the preparation and use of pyovaccines and the results and mode of action of pyotherapy. A bibliography of 26 titles is appended.

[Vol. 41

Behavior of bacteria toward arsenic, H. H. GREEN and N. H. KESTELL (So. African Jour. Sci., 15 (1919), No. 5, pp. 369-374).—This is a preliminary report of an examination of arsenic-resistant bacteria in soil, air, feces, and cattle dips.

Resistant types were found to be infrequent in soil and air but fairly frequent in feces, about 10 per cent of the bacterial count of fresh stable manure being moderately tolerant and 1 per cent highly tolerant to arsenic. In arsenical dipping tanks an automatic enriching of resistant fecal bacteria and suppression of sensitive forms apparently take place.

Variations in tolerance of different bacteria for arsenic were found to be very marked. Certain groups, notably the "subtilis" group, were very sensitive, while others, notably the "putidum" group, were very resistant. The colon-typhoid group, while sensitive as a family, contained one or two resistant members.

Of the 12 or more arsenic-resistant species examined, only two showed any chemical activity toward arsenic, namely *B. arsenoxydans* which oxidizes arsenite to arsenate and *B. arsenreducens* which reduces arsenate to arsenite. No relationship was discovered between arsenate reduction and nitrate reduction.

The Wright and Carrel methods of treating wounds, VAN WALLENDAEL (Ann. Méd. Vét., 64 (1919), No. 3-4, pp. 86-93).—The Wright and Carrel methods of treating wounds are discussed with particular reference to their applicability in veterinary practice. The Wright method is thought to have no practical application in veterinary medicine, but the Carrel method with certain modifications is considered excellent for the treatment of fistulous withers, boils, synovitis, and other lesions.

It is recommended that the Carrel tubes in contact with the wound be kept in place by a gauze compress soaked in Dakin's solution, and that 10 cc. of the solution be introduced into the tubes every two hours by means of a simple syringe. The wound and its surroundings should be washed every day with a liquid soap (sodium oleate), diluted with a little hot water and then with ether. The progress of the treatment should be controlled every two days by a bacteriological examination of the secretions, and the wound closed when sterile or when it no longer contains *Bacillus streptococcus* or *B. perfringens*. The presence of staphylococci is thought not to contraindicate the closing of the wound.

Experimental researches on antistreptococcic immunity, S. VINAVER and V. FRASEY (Compt. Rend. Soc. Biol. [Paris], 82 (1919), No. 17, pp. 606-608).— The authors report the successful immunization of horses by means of a single relatively large dose of a living 24-hour culture in ascitic bouillon of a human strain of streptococci virulent for mice. The serum from an animal thus immunized is said to be superior to that obtained by fractional immunization over a period of several months, showing after 15 days very active preventive properties not only against the particular strain used for immunization but also against other strains of streptococci.

The intravenous injection of as much as one liter of the living culture is said to provoke no greater thermal reaction, but at the same time no better results, than a much smaller dose.

Complement inactivation by bacteria, H. RITZ and H. SACHS (*Ztschr. Im*munitätsf. u. Expt. Ther., I, Orig., 26 (1917), No. 5, pp. 483-502).—The results are reported of a study of complement inactivation by suspensions of *Bacillus* prodigiosus.

It was found that suspensions of this bacillus exerted an anticomplementary action on guinea pig serum when warm but only to a small degree in the cold  $(0^{\circ}$  C,). The action, which required contact with the serum for some little

time, was within certain limits proportional to the amount of serum. The action was prevented by the action of acids and alkalis.

Attention is called to the resemblance between the anticomplementary action of bacillary suspensions and that of cobra poisoning, and the possible nature of the action is discussed.

A method for the preparation of prophylactic and autogenous lipovaccines, E. C. ROSENOW and A. E. OSTERBERG (Jour. Amer. Med. Assoc., 73 (1919), No. 2, pp. 87-91, figs. 3).—The method, which is described in detail, for the prepararation of large quantities of specific oil vaccines and for smaller amounts of autogenous lipovaccines, is said to eliminate the chief difficulty encountered in the usual preparation of lipovaccines, namely, a successful drying of the bacteria. This is accomplished by removing the water by distillation in vacuo from a water-bacterial-oil emulsion. It is said to prevent clumping of the bacteria and to obviate the necessity of grinding the resulting product.

In the application of this method to the preparation of autogenous lipovaccines the common 6-oz. nursing bottle is used as a culture flask, centrifuge tube, and vacuum flask. The bacteria are grown in 150 cc. of glucose broth for 24 hours, centrifugalized, the supernatant clear broth decanted, and the sediment suspended in 10 cc. of a 1.5 per cent solution of purified cresol in water or salt solution. After standing at a temperature of  $37^{\circ}$  C. for from 2 to 15 hours, or until found to be sterile, the suspension is centrifugalized, the supernatant fluid is decanted, 6 cc. of cottonseed oil containing 2 per cent anhydrous lanolin and a number of sterile glass beads or steel shot are added, and the mixture is emulsified by shaking for a short time. The water is then removed very readily from the mixture by applying the vacuum and immersing the bottom of the bottle in water heated to  $60^{\circ}$  until bubbling ceases and the mixture becomes clear. The clearing usually takes place in from 20 minutes to 1 hour.

The method is said to give perfectly even homogeneous suspensions with various species of bacteria.

Experiments on the effect of agglutinins, B. FUJIMOTO (Jour. Immunol., 4 (1919), No. 3, pp. 67–76).—The agglutinin obtained by immunizing rabbits with *Bacillus coli* was used to determine whether agglutinins have any influence on the glycolytic action of bacteria, on the permeability of bacteria and red blood corpuscles for glucose solution, and on the resistance of red blood corpuscles for salt solution. The results obtained are summarized as follows:

"The glycolytic action of the living *B. coli* may be markedly weakened by agglutinin. The agglutinin is able so to change the cell membrane of the bacteria that their endoenzym can permeate it. Neither agglutinin nor hemagglutinin alters the permeability of bacteria and red blood corpuscles for glucose. The resistance of the red blood corpuscles to hypotonic solutions is slightly decreased by agglutinin or hemolysin."

A method for the production of a homogenous suspension of Bacillus anthracis to be used in agglutination reactions, A. NOBLE (Jour. Immunol., 4 (1919), No. 3, pp. 105-109).—A satisfactory suspension of B. anthracis for agglutination reactions has been prepared as follows:

Four strains of *B. anthracis* were transplanted daily for ten days on plain agar and incubated at  $42.5^{\circ}$  C. until a sporeless and very vigorous growth was obtained. Each strain was then planted on plain agar in quart flasks and incubated for 12 hours at  $42.5^{\circ}$ . The growths were washed off in physiologic salt solution containing 0.5 per cent formalin (about 100 cc. to a flask), and the suspensions shaken in a mechanical shaker for 48 hours. After standing for several days and being tested for sterility, equal parts of each suspension were mixed in a cylinder, shaken for 24 hours, and allowed to stand over night. The upper portion, containing a homogeneous suspension, was filtered several times through four thicknesses of sterile cheese cloth. The suspension was then diluted with physiologic salt solution plus 0.5 per cent formal in to a density corresponding to a suspension of *B. typhosus* containing 2,000,000 bacteria per cubic centimeter.

The suspension thus prepared is said to be perfectly homogeneous and to show no spontaneous agglutination. By means of it antianthrax sera from 13 horses have given agglutination titers of from 1 in 6,400 to 1 in 20,000, as against titers of from 1 in 80 to 1 in 200 in normal horses. In the absence of a satisfactory animal-protection test or method of complement fixation, the agglutination test is considered to be practicable as a method for standardizing antianthrax serum.

Vaccination against anthrax in Brazil, A. Moses (*Rev. Vet. e Zootech., 9* (1919), No. 1, pp. 3-10).—Three vaccines used in Brazil against anthrax are described.

The first consists of a culture in 2 per cent peptone solution of anthrax bacilli attenuated by heating for 12 days at a temperature of  $42^{\circ}$  C. It is used for bovines in a single dose of 2 cc., corresponding to eight times the dose formerly used according to the classic method of Pasteur in two inoculations at 15 days' intervals. The best results for other animals have been obtained by using 1 cc. for horses, donkeys, and hogs, and 0.5 cc. for calves and sheep. The second vaccine is prepared in a similar manner with slight variations, and is used in doses of 2 cc. for adult animals indiscriminately. The third is a spore vaccine prepared by growing on a solid culture medium at 35 to 37° for several days a mixture of different strains of anthrax bacilli of attenuated virulence. An emulsion of this culture rich in spores is prepared in appropriate solution and heated at 60° for several hours. It is used in doses of from 0.5 to 1 cc., the dose being repeated 10 times.

The first vaccine, which is in use officially by the Brazilian Department of Agriculture, is considered the most satisfactory and is said to have better keeping qualities than the Pasteur vaccine.

Inoculation as a prophylactic measure against foot-and-mouth disease, D. LUTRARIO (Off. Internat. Hyg. Pub. [Paris], Bul. Mens., 11 (1919), No. 3, pp. 266-272).—A summary is reported of the results of an extensive investigation conducted during 1914-1917 by a special commission in Italy for the purpose of developing possible means of immunization against foot-and-mouth disease.

The method of immunization proposed by C. Terni consists of reenforcing and prolonging by successive inoculations of specially prepared foot-and-mouth virus the immunity already acquired by a natural or artificial attack of the disease. Under these conditions the inoculation of virus causes a rise in temperature but with no internal manifestations of the disease. In general, after three inoculations an active hyperimmunity against the natural infection is produced which lasts through the entire period of use of the dairy cows.

For intravenous use the committee recommends a first inoculation of from 25 to 50 cc. of hyperimmunized blood of either young or adult animals, followed 4 or 5 days later by a similar inoculation with the addition of 25 cc. of a 1 per cent solution of filtered virus, or 50 cc. of blood of a fixed virulence. This is followed in from 8 to 10 days by a similar inoculation. For subcutaneous use the same inoculation is employed, with the exception that the dose of hyperimmunized blood is doubled.

Investigations conducted by G. Cosco, with the collaboration of Aguzzi, showed that both the red corpuscles and the serum of the blood of animals with foot-and-mouth disease are virulent during the period of the fever, and that the red corpuscles after repeated washings with sterile physiologic solution can reproduce the disease in cows when inoculated subcutaneously, even in as small doses as 1 cc. The intravenous injection of virulent blood obtained from producing animals after a series of passages and a minimum period of incubation of about 70 hours did not result in the development of the disease, provided the dose did not exceed about 30 cc.

The treatment recommended as a result of this study is a series of three intravenous injections of virulent blood in doses of 25, 30, and 45 cc., respectively. The first inoculation is said to be followed an hour or two later by a rise in temperature, which persists for 8 or 10 hours. The fever is less marked after the second and often insignificant after the third inoculation. A period of 10 days should elapse between successive inoculations. A case is reported of the successful immunization of two cows by this method.

**Researches on ulcerous lymphangitis**, R. VAN SACEGHEM (Ann. Méd. Vét., 64 (1919), No. 3-4, pp. 80-83).—The author has used with success for the treatment of ulcerous lymphangitis in its early stages subcutaneous inoculation of a pure culture of the bacilli of Preisz-Nocard. It is emphasized that this treatment should be begun as early as possible in the disease, before sensitization to the bacilli has taken place and extensive lesions have been produced.

Treatment of ulcerous lymphangitis, R. VAN SACEGHEM (Ann. Méd. Vét., 64 (1919), No. 3-4, pp. 83-86).—The method noted above is being employed to immunize against future attacks horses which have been cured of ulcerous lymphangitis.

A progress report on Sarcocystis tenella.—II, Seasonal infection, J. W. Scorr (*Wyoming Sta. Rpt. 1918, pp. 95–116*).—This continuation of earlier work (E. S. R., 34, p. 658) has been noted from another source (E. S. R., 40, p. 585).

## RURAL ENGINEERING.

Irrigation investigations, G. E. P. SMITH and A. L. ENGER (*Arizona Sta. Rpt.* 1917, pp. 481-491, figs. 2).—In continuing the irrigation investigations (E. S. R., 39, p. 792), in the Casa Grande Valley, measurements of seepage losses have not confirmed those of the previous year, but water table fluctuations, including the special observations in the vicinity of active pumping plantts, have confirmed results previously reported.

Deep well drilling in the Lower Gila Valley, in which the depth of drilling was increased, has revealed an extensive aggregate potential water supply, which is considered important from the standpoint of further development but is thought to be confined to the bottom lands. Evaporation studies made in three localities of widely different climatic conditions but under approximately similar soil conditions showed in all three locations a close agreement between temperature and evaporation, which is, however, modified by wind movement. "Reduced to the lowest terms, the evaporation-rate depends upon temperature and the vapor pressure directly at the water surface."

An investigation of machine-made cement pipe for use in irrigation lines leads to the conclusion "that pipe-making by machinery is entirely practical, that the pipe is much superior in quality to handmade cement pipe and that the cost is less... For the larger laterals and main canals cement lining is the best method of improvement. Careful estimates show that by lining the canals of the Salt River Valley enough water will be saved to permit an increase of 25 per cent in the project area."

A tabular summary of the station pumping plants is given.

The Tempe drainage ditch, A. E. VINSON and C. N. CATLIN (Arizona Sta. Rpt. 1917, pp. 474-476).—Analyses of samples of water from the Tempe drainage ditch are reported.

While the ditch was completed early in 1917 and the season was very dry, great fluctuations in the composition of the drainage water are noticeable. "March 9 the water, which had hitherto been hard, was alkaline, containing 3.4 parts per 100,000 of black alkali; but the following month, April 10, it was again found to be as hard as it had been the previous November. The analysis made in February seems to indicate that the permanent hardness of the water was decreasing at that time. During the summer months the hardness remained fairly constant, but increased three or four fold in September, then became neutral in October and again strongly black alkaline in December, which is the last analysis available.

"The total solids dissolved in the water and the chlorids showed similar fluctuations. September 15 both total solids and chlorid reached a maximum, but dropped abruptly to about one-half that amount in October. This period of high solids and chlorids was accompanied by very high permanent hardness. In November and December the temporary hardness ('lime') increased to double the average for the other months of the year, which had been nearly uniform...

"The present fluctuations . . . are probably due to changes in the amount of seepage from various areas according to the amount of irrigation, and also to overflow reaching the ditch which would tend to dilute the usual seepage flow. At no time has the drainage water been entirely satisfactory for irrigating purposes on account of its high salt content."

**Public Roads** (U. S. Dept. Agr., Public Roads, 1 (1919), Nos. 11, pp. 40, figs. 23; 12, pp. 44, figs. 25; 2 (1919), Nos. 13, pp. 36, figs. 20; 14, pp. 40, figs. 29).— These numbers of this periodical contain miscellaneous notes and the following articles:

No. 14.—Secretary Houston Discusses Federal Road Commission Bill; Delaware's Federal-Aid Work, by A. R. Losh; Suggestions for Contractors on Concrete Road Construction, by C. E. Learned; 11,326 Miles of Federal-Aid Roads in Approved Projects; Bonding New Cement-Mortar and Concrete to Old in Tests, by W. E. Rosengarten (see p. 382); Road Making at Front in France, by F. G. Eason; and The Commercial Sizes of Crushed Stone Aggregates, by F. H. Jackson and C. W. Mitman (see p. 382).

Determining sizes of culverts, O. L. GROVER (U. S. Dept. Agr., Public Roads, 1 (1919), No. 12, pp. 39-44).—Tables and formulas showing the practices of some of the State highway commissions and railroads on the determining of drainage areas and waterway areas are compiled in convenient form and accompanied by brief discussions.

Thickness of concrete slabs, A. T. GOLDBECK (U. S. Dept. Agr., Public Roads, 1 (1919), No. 12, pp. 34-38, figs. 7).—This is a report on pressure measurements made under a concrete road to discover how the road slab is stressed directly under the wheels of heavy trucks. The road surfacing was 18 ft. wide, 8 in. thick at the center, and 6 in. thick at the sides, and consisted of  $1:1\frac{1}{2}:3$  gravel concrete having a crushing strength of 3,190 lbs. per square inch. The soil of the subgrade consisted of sticky clay, which, when wet, has very little bearing value. A class B standard army truck loaded with 5 tons of sand was used, and the load on the front axle was 5,000 lbs. and on the rear axle 17,000 lbs.

It is tentatively concluded that a concrete road slab under the action of traffic or under the influence of frost and different percentages of moisture in the subgrade is continually bending, so that the reaction pressures between the subgrade and slab are neither constant nor uniform in intensity. The reaction pressures due to heavy wheel loads were found to be a maximum directly under the loads and vanished to zero in a comparatively small radius, partially depending upon the intensity of the load.

"A heavy wheel load is distributed over a larger radius than a light wheel load. For this particular subgrade a load of 8,500 lbs. has a radius of distribution of pressure of about 6 ft., most of the pressure, however, being exerted over a radius of about 4 ft. As the concrete slab recovers from its deflection after the passage of a load more readily than the soft subgrade, there is a tendency for the continual deflection of the slab to produce areas having very little or no bearing. . .

"As nearly as can be estimated from the results of this test, the tensile stress in an 8-in. concrete slab directly under an 8,500-lb. wheel load at rest on the road is only 34 lbs. per square inch when the slab is well supported on the subgrade. As the modulus of rupture of  $1:1\frac{1}{2}:3$  concrete is about 600 lbs. per square inch, this pavement should be able to withstand considerable impact before cracking. Should the concrete arch over very soft spots, so that there is no support directly under the load, the tensile stress may become very high. Such a condition arises when the sides of the slab are raised by frost action or possibly when the subgrade is worked any from under the slab by continual deflection. It is probable that the tensile stress which results in the slab directly under the heavy wheel loads is never very great as long as the slab rests on the subgrade, and it is unlikely that the slab design would ever be controlled by this stress."

The commercial sizes of crushed stone aggregates, F. H. JACKSON and C. W. MITMAN (U. S. Dept. Agr., Public Roads, 2 (1919), No. 14, pp. 35-40).—A survey of the present practice in the States of Ohio, Kentucky, Tennessee, North Carolina, and Georgia, for the purpose of securing data to be used in the development of a system of standard sizes and uniform nomenclature of crushed stone products, is reported. The results confirm the conclusions of a report previously noted (E. S. R., 39, p. 494), and it is concluded that the necessity for standardizing stone sizes has been demonstrated.

Bonding new cement-mortar and concrete to old in tests, W. E. ROSEN-GARTEN (U. S. Dept. Agr., Public Roads, 2 (1919), No. 14, pp. 26-34, figs. 5).— The results of an extensive series of tests conducted in the Bureau of Public Roads to obtain definite data on the relative value of various methods of increasing the strength of bond between new and old cement mortar and concrete are reported. These tests included "(1) tests on the bond strength in tension of a 1:2 mortar in the form of the standard tension briquette, (2) tests on the bond strength in cross bending of a 1: $\frac{2}{3}$ :  $1\frac{1}{3}$  concrete in 4 by 4 by 14 in. prisms bonded to concrete slabs, (3) tests on the bond strength in shear of a 1: $\frac{2}{3}$ :  $1\frac{1}{3}$  concrete in specimens in the form of 8-in. diameter cylindrical disks, 2 in. high, [and] (4) tests on the permeability or water-tightness of the joints formed by various bonding methods. The same specimens were used in this series as in the shear tests." The following results were reached regarding the tensile strength of bonds:

It was found that the ability of fresh mortar to adhere to older material decreased rapidly as the old set up. Where the older material had set for 24 hours before adding the fresh, the bonding strength was but 44 per cent of that of monolithic construction. Further aging of the old mortar caused a slight decrease in the bonding ability, which at 7 days was 39 per cent of the original and at 28 days was reduced to 35.5 per cent.

It was possible, however, to increase the bond by treating the old surface, either by roughing with a steel tool, or by applying dilute hydrochloric acid of 1:10 strength. Roughing the surface increased the strength of bond 20 per cent and the acid treatment increased it 13 per cent, except where the old concrete had aged seven days, in which case there appeared an unexplainable detriment to the bond, due to the acid treatment. Combining both roughening and acid treatment gave but a slightly greater bonding ability than either by itself.

The application of a thin layer of cement butter as a bonding medium had a decided effect in increasing the adhesive strength. Twenty-five per cent increase in strength was developed by this method, and 28 per cent if the butter layer was allowed to stand one hour prior to adding the fresh mortar. Hard tamping of the new mortar against the old increased the strength of bond about 8 per cent.

The broken surface showed a greater bond strength than either the plain molded or natural surface, but roughing of the two latter placed them on a par with the broken surface. The ability to bond to the molded and natural surface appeared about equal, although surfaces molded against forms showed a decrease in strength as the age of the old concrete increased.

With reference to cross-bending strength, it was found that by careful treatment new concrete can be made to adhere to old with a strength equal to 60 per cent of monolithic concrete. If no special treatment other than cleaning is given the old concrete, a bond strength of but 20 per cent of the monolithic concrete is developed. Roughening of the old concrete or treatment with dilute hydrochloric acid increased the bond strength by 20 per cent, as did also a bonding medium of a thin layer of neat cement butter. Tamping the fresh concrete hard against the old concrete increased the bond strength 5 per cent.

With reference to shearing strength, it was found that the strength of a joint was greatly increased by treatment of the surface of the old concrete. It was further found that there was no danger of leakage at a joint made in concrete of a mixture as rich as  $1:\frac{2}{3}:1\frac{1}{3}$  under pressures up to 40 lbs. per square inch when the surface of the old concrete had been treated.

The results of tests by others, bearing on the subject, are also reviewed.

[A total of 6,146,617 motor vehicles in the United States], A. P. ANDERSON (U. S. Dept. Agr., Public Roads, 1 (1919), No. 11, pp. 8-16, fig. 1).—Data are given covering registrations, licenses, and revenues in the United States during the calendar year 1918.

A total of 6,146,617 motor cars and commercial vehicles and 240.564 motorcycles were registered in 1918 in the 48 States and the District of Columbia. Registrations and license fees, including chauffeurs, operators, and dealers, amounted to a total of \$51,477,416.61. These figures do not include about 107,000 automobiles and motor trucks manufactured for the Government during the year. As compared with 1917 the data for 1918 represent an increase of 19 per cent in the number of cars and 27 per cent in revenues.

Motor transportation for rural districts, J. H. Collins (U. S. Dept. Agr. Bul. 770 (1919), pp. 32, figs. 5).—This bulletin reports in general the results of preliminary studies of rural motor routes established, or in process of establishment, with the purpose to call to the attention of operators and prospective operators those features of the industry which apparently are not understood or appreciated.

It was found that there are five general classes engaged in rural hauling on a schedule basis as follows: (1) The farmer who hauls for his neighbor or for the community as well as for himself, (2) the regular local truck operator with limited capital, whose income is derived largely from the business, (3) local automobile or truck agencies operating as a side-line, (4) city transfer companies, and (5) large corporations operating a fleet of trucks and commanding considerable capital. It was found that the four important factors which must be considered by the beginner in the field of rural motor transportation are (1) the volume of farm products produced along the contemplated route, (2) the volume of miscellaneous hauling which can be secured to supplement regular loads, (3) competition with other carriers, and (4) the character of the highways. "Above all, attention should be concentrated on the problem of arranging for loads so that there is a profitable load on all trucks whenever they are operated." It is stated that in considering competition particular attention should be given to rates, schedules, and delivery arrangements. Good roads are considered a prerequisite to successful motor truck operation.

With reference to certain operating costs, it was found that the gasoline mileage for trucks of different sizes showed a very wide range under varying conditions. Data from about 60 typical motor routes showed from 5 to 9 miles per gallon of gasoline for 2-ton trucks, 4 to 6 miles for 3-ton trucks, and 3 to 5 miles for 5-ton trucks. Drivers' wages varied from \$2.75 to \$7.50 a day. Depreciation was estimated by operators at from 20 to 33½ per cent of the cost of the truck annually. The annual average interest on the investment was calculated by the following formula:  $\frac{A+1}{A} \times \frac{C \times B}{2}$  average yearly interest. In this formula A represents the estimated life of the truck in years under actual operating

[Vol. 41

conditions, B represents the original investment, and C represents the rate of interest. Annual costs for repairs ranged from about \$100 to as high as \$800 or \$900. Where trucks were kept in a constant state of repair the annual repair charge was relatively small. For solid tires it was found that this cost ranged from 1 to 4 cts. per mile. It was found that the solid tire is more commonly used because it is more adaptable and cheaper than the pneumatic, does not suffer from blow-outs or puncture, and stands up well on bad roads and under very heavy loads.

Numerous other suggestions and information are given covering costaccounting, delivery methods, collection and delivery arrangements, etc. A standard bill of lading, a driver's daily report card, and insurance provisions covering shipments are suggested.

It is concluded that the chief factor limiting development in the field of rural motor hauling is the cost of operation as compared with that of railroads, electric lines, and boat lines. The limiting factor second in importance is considered to be the condition of average country highways. Financial responsibility is considered the limitation third in importance. It is generally concluded that under proper conditions, and where a fair knowledge of the limitations and difficulties obtains, motor truck transportation premises to play an important rôle in rural districts.

The farm tractor in the Dakotas, A. P. YERKES and L. M. CHURCH (U. S. Dept. Agr., Farmers' Bul. 1035 (1919), pp. 32).—This reports data obtained from over 300 tractor owners in North and South Dakota, based on operating results during the fall of 1917 and spring and fall of 1918.

It was found that the principal disadvantage of the tractor in the Dakotas lies in its inability to do satisfactory work under moist soil conditions. Difficulty of efficient operation was the next disadvantage.

Of the farmers reporting, 44 per cent were able to increase the farm acreage. Over half of those reporting owned 3-plow machines, the remainder being about evenly distributed among the 2-plow, 4-plow, and larger sizes. After using these tractors nearly the same percentage recommended the 3-plow tractors as owned them, 30 per cent recommended the 4-plow tractor, and only 5 per cent recommended the 2-plow tractor. The minimum number of acres on which the 2, 3, or 4-plow outfits were profitable were 185, 225, and 314 acres, respectively.

The tractors were used an average of 50 days annually, about 40 days on home work and 10 days on custom work. The number of days the tractor was used on home work increased rapidly with the size of farm, and the number of days on custom work decreased gradually.

The average quantity of fuel consumed per acre in plowing was  $2\frac{1}{2}$  gal. The fuel cost per acre for plowing averaged about 38 cts. for kerosene and 69 cts. for gasoline. The average cost per acre for plowing for fuel, oil, and grease was about 78.5 cts. where gasoline was used and 49 cts. where kerosene was used. The cost for repairs for 2, 3, and 4-plow outfits averaged 15, 13, and 11 cts. per acre plowed, respectively, and the corresponding average depreciation, assuming a 9-year life for a tractor, was estimated at 41, 36.5, and  $31\frac{3}{4}$  cts. The cost per acre for man labor at \$4 per day for the 2, 3, and 4-plow outfits averaged 63.5, 47, and  $36\frac{3}{4}$  cts., respectively, and interest at 6 per cent averaged 11, 10, and 8.5 cts., respectively, per acre plowed. The total approximate cost of plowing an acre, using kerosene for fuel, averaged \$1.80, \$1.56, and \$1.38 for the 2, 3, and 4-plow outfits, respectively, and where gasoline was used for fuel, \$2.09, \$1.85, and \$1.67. Horses were displaced on only about 57 per cent of the farms where tractors were used and where no increases was made in the farm acreage, and amounted to an average of slightly less than 4 horses displaced on each farm by the purchase of the tractor.

**Poultry buildings: Laying and breeding houses,** H. R. LEWIS and W. C. THOMPSON (*New Jersey Stas. Bul. 325 (1917), pp. 5–102, figs. 57*).—This bulletin is the first of a series of four which deal with the construction and equipment of buildings in general demand for use in poultry farming. This number deals with laying and breeding houses.

The first part of the bulletin is devoted to a theoretical discussion of the principles governing the design and construction of poultry houses.

The second part reports the results of a two-season study of the cost and winter and summer temperature and humidity of six different types of poultry houses. Type-J house is 20 ft. deep and 40 ft. long and is somewhat similar in design to the type known as the Wood's fresh-air house. The roof construction is of the half-monitor type, with an entire glass front in the peak. The front is entirely open from 2 ft. above the ground upward, the opening being covered with inch wire. Type-K house is of half-monitor construction, somewhat similar to J except that it is elevated about 2 tt. from the ground. The dimensions are 16 by 40 ft. Type-L house, known as the New Jersey multiple unit house, is 20 by 40 ft. in dimension and houses 200 birds. The house has concrete foundation walls and is of the shed-roof type. Type-M house is a shed-roof type, 16 by 40 ft., and built entirely of hollow building tile stuccoed with cement plaster on the outside and heavily whitewashed on the inside. Type-R house is a shed-roof type, built entirely of lumber, cheapness being a primary object. It is 36 ft. long by 14 ft. deep. The cost per bird was 77 cts. Type-P house represents a 48-ft, section of a 144-ft, laying house and is divided into four pens 12 by 16 ft. It is a shed-roof type of frame construction and has a hinged clapboard on the outside of the back wall for ventilation. A concrete floor and foundation was built on deep cinders. With reference to cost, the cheapest house was the R type, 77 cts. per bird (not including labor), followed in order by the L, J, P, K, and M types, with 88 cts., \$1.08, \$1.12, \$1.24, and \$1.44.

The temperature studies led to the conclusion that in order to be efficient the average poultry house should be warmer than the outside normal temperature during the winter and cooler than the outside normal temperature during the summer. "These differences in temperature should be much greater on the plus side during the winter than is shown on the minus side during the summer. The use of solid glass sash in the poultry house with no adequate means of continuous ventilation is conducive to frozen combs and cold. An increase in height of the poultry house not only makes the construction more costly, but is apt to make the house colder in winter by increasing the exposed wall area, thus making possible more radiation. The figures show that a house with some muslin and some glass, of the shed-roof type, with provision for ventilation, is the house which more nearly fulfills the above requirements." During the winter the P type of house was the warmest, followed in order by the L, M, J, R, and K types. The K type was exceptionally cold. During the summer period the R type was the coolest, followed in order by the M and L types.

The moisture studies showed the L type to be the driest house, followed closely by the J type. The type-K house was found to be the dampest.

With reference to sunlight it was found that "a shed-roof house from 16 to 20 ft. deep, with openings in the front wall ranging from 2 ft. above the ground to 7 ft., is a most excellent arrangement. These openings, distributed almost continually along the front, were found to provide the most  $138958^{\circ}-19-7$ 

complete and uniform distribution of sunlight, type house L being exceptionally well planned with reference to the total amount of sunlight secured on the floor at one time, and also with reference to the large area of floor space which was bathed in sunlight sometime during the day."

A consideration of relative total efficiency of the types "shows that the houses stand in the following order, L, R, J, P, M, and K; that is, type house L, considered from the standpoint of low cost, warmth in winter, coolness in summer, and dryness, was the most efficient type. Type houses M and K, the former of hollow-tile construction and the latter elevated, with an entire glass front, are not desirable types."

The third part of the bulletin discusses in considerable detail a number of different standard types of poultry houses which have been tested out at the station. A bibliography is appended.

#### RURAL ECONOMICS.

Report of committee appointed by the Secretary of Agriculture to consider the subject of farm organization as one of the divisions of research work of the proposed Bureau of Farm Management and Farm Economics (U. S. Dept. Agr., Off. Sec. Circ. 135 (1919), pp. 12.—This report represents the conference of April 17–19, 1919, as outlining studies for a proposed division of farm organization in the proposed Bureau of Farm Management to include types of farming covering determination of enterprises; balance or combination of enterprises; size of business, farm plan or layout; effective use of labor and equipment; intensity of production; and business methods. It states briefly the value of survey, cost accounting, observation, geographic, historical, statistical, and experimental methods of studying farm organization. Recommendations as to procedure in bringing about cooperation between the Office of Farm Management and agricultural colleges and experiment stations, and suggestions for a memorandum of agreement that should be drawn up between the U. S. Department of Agriculture and the colleges or stations are made.

Farm types in Nebraska, as determined by climatic, soil, and economic factors, R. R. SPAFFORD (Nebraska Sta. Research Bul. 15 (1919), pp. 5–85, figs. 38).—This bulletin treats of the agricultural areas of Nebraska, as determined by climatic, soil, and economic factors, the emphasis being placed upon the kind of farm crops grown and their yields. The data were principally derived from the Thirteenth Census and cover the crop year 1909. The effect of heat and other factors upon the acreage of crops treated as annuals, the size of the farm in relation to rainfall, and other factors in the Great Plains are discussed in detail. Farm types are grouped and farm-type areas described and located. Acreage, yield, and value of crops, crop indexes, and live-stock and miscellaneous statistics are given.

Dairying and general farming for the timbered section, A. J. MCGUIRE (Minnesota Sta., Spec. Rpt. Grand Rapids Substa. 1904–1914, pp. 37, figs. 19).— This report is a résumé of results of work at the substation at Grand Rapids, Minn., from 1904 to 1914, to find the most practical and profitable system of farming for the timbered section of northern Minnesota, and especially to demonstrate making a living from 20 acres or less under cultivation while clearing and developing more land to a point where the farm can be made most profitable. Some of the conclusions arrived at are as follows:

Dairying, with potatoes as a cash field crop, is believed to be the most profitable system of farming for the average farm of the timbered section of northern Minnesota. A production of 200 lbs. of butter fat a year is necessary for a cow to be profitable from a business standpoint, even on moderately priced land, The crops found most profitable for the average farm of the timbered section of northern Minnesota were oats, clover, fodder corn, potatoes, and rutabagas. A 3-year crop rotation of grain, clover, and cultivated crops was found the best system of cropping for large yields.

Clover seeded among the stumps on cut-over land produced excellent pasture. Dairy cows on the experiment farm produced as much as 40 lbs. of butter fat for the pasture season from an acre of cut-over land pasture that was the result of clover seeding.

Only potatoes should be sold from the farm, other crops being fed and sold in the form of butter fat and other finished products. Practically all kinds of roots and vegetables were grown successfully. Plums, raspberries, currants, and strawberries were grown with continued success, but apples were a failure. Swamp land, known as "muskeg," was tile-drained and thoroughly tilled, but proved unsatisfactory for crop production.

Pig raising was found profitable in connection with dairying. Poultry on a small scale was profitable, but less so on a large scale. Sheep gave fair returns.

Tables are drawn up to show different factors that influence profit or loss in dairying, records of the dairy herd 1904–1914, and a summary of the crop production through the same period.

Select list of references on economic reconstruction, including reports of the British Ministry of Reconstruction, H. H. B. MEYER (*Washington: Libr. Cong.* [U. S.], 1919, pp. 47).—A list of selected books, in English and French, on economic reconstruction, including some relating to agriculture and food supplies.

The country church in the new world order, E. DES. BRUNNER (*New York:* Assoc. Press, 1919, pp. XI+164).—Examples are given of the success of country churches in meeting war problems in their respective communities, and their functions and responsibility in reconstruction are forecasted.

The problem of land ownership: A proposal for its rational solution, P. BALINSKY (*New York: [Author], 1919, pp. 96, pls. 7*).—A project is advanced which includes purchase by the Government of all the land, its resale by lots, and the organization of four departments under a central institution which shall administer and guarantee to farmers all the benefits of modern science and culture.

Farm tenantry in Nebraska compared with farm ownership, H. KANO (*Thesis, Univ. Nebr., 1918, pp. 42, pls. 2, figs. 2*).—Fifty-one individual farm records taken in Thurston County, 52 in Seward County, and 55 in Gage County, Nebr., were used as the basis for this study. Those from Thurston were classified as owned, part owned, share-cash rented, and cash rented; those from the other two counties as owned, part owned, and share-cash rented, giving a total of 10 groups in the three counties. The various items recorded in the records of the group were totaled and then averaged, reducing each of the 10 tenure groups to an average one-record basis.

The foundations of society and the land, J. W. JEUDWINE (London: Williams & Norgate, 1918, pp. XXVIII+514, pl. 1, fig. 1).—The account of the communal society by Tacitus in his Germania, Ancient Laws of England, Ireland, and Wales, Year Books of Edward I, II, and III, Scandinavian sagas, and numerous ancient and recent official and personal records furnished the basis of this study of beginnings of agriculture in Great Britain and Ireland, transition to the feudal system, holding and transfer of land in mediæval society, alienation and inheritance, uses of waste land and forest under both communal and feudal systems, and inclosures. Much purely historical matter is treated from the author's point of view of the social as opposed to the constitutional historian to show the agricultural and economic ruin of Ireland and Scotland.

The minimum wage on light land (*Country Life* [London], 45 (1919), No. 1168, p. 584).—There is summarized here a report by representative farmers and land owners on agricultural problems in connection with the light land of Norfolk, England, and the form of Government aid required there.

Agricultural wages in Ireland (U. S. Dept. Labor, Bur. Labor Statis., Mo. Labor Rev., 8 (1919), No. 6, pp. 180, 181).—Data relating to the fixed minimum weekly rate of wages are given, as tabulated in a report from the United States consul at Dublin.

French farm loans (U. S. Dept. Labor, Bur. Labor Statis., Mo. Labor Rev., 8 (1919), No. 3, pp. 56, 57).—A brief note on the assistance rendered, through various State and private agencies, to French agriculturists returning to abandoned farms.

Report of the proceedings of the first American Cooperative Convention, Springfield, Ill., 1918 (*Rpt. Proc. Amer. Coop. Conv., 1* (1918), *pp. 264*).—Addresses and discussions on cooperation among farmers, heard at the first American Cooperative Convention, at Springfield, Ill., September 25–27, 1918, under the auspices of The Cooperative League of America, are included here.

Introductory address of [United States wheat director] to grain trade conference, held in New York, June 10–11, 1919, J. H. BARNES (*New York: Chamber Com.*, 1919, pp. 21).—The speaker describes the destroyed economic existence of some of the nations of Europe, and the ways in which their needs have been supplied by the U. S. Grain Corporation in cooperation with private and Government agencies. In outlining future policies for the handling of our share of the bread-grain supplies of the world, he urges that the Government pledge to the grower be kept but without profiteering out of the needs of Europe. He favors exportation of grain rather than of the milled product, in order to relieve unemployment in Europe.

Final report of the Royal Commission on the natural resources, trade, and legislation of certain portions of His Majesty's dominions, D'ABERNON ET AL. (Final Rpt. [Dominions] Roy. Com. [London] Nat. Resources, Trade and Leg. [etc.], 1917, pp. IX+199, pl. 1).—Among the topics reported upon here are the agricultural and pastoral resources of the five British self-governing dominions (Canada, Australia, New Zealand, Union of South Africa, and Newfoundland), control of food supplies during the war, organization for scientific research in relation to the development of the natural resources of these regions, and the marketing of products. The commission recommends surveys relative to Empire requirements and Empire production, research and institutions in the dominions, and improvement of imperial communications and commercial practices.

Prices and supplies of corn, live stock, and other agricultural produce in England and Wales (*Bd. Agr. and Fisheries* [London], Agr. Statis., 52 (1917), No. 3, pp. 59-90).—This bulletin continues information previously noted (E. S. R., 38, p. 495), by adding statistics for 1917.

[Exports and imports of French agricultural products], J. M. DE LAGORSSE ET AL. (Cong. Nat. Export. et Import. Prod. Agr., Compt. Rend. Trav., 1913, pp. 230, pl. 1, figs. 5).—This embodies reports made to meetings of the National Congress of Exports and Imports of Agricultural Products held at Paris, February 18–20, 1913, relating to production and movements of cereals, live stock, wines, fruits, and other crops in France, her colonies, and a few foreign countries.

Agricultural and live stock statistics of Finland (*Statis. Årsbok Finland*, *n. ser.*, 15 (1917), pp. 124–196).—This volume continues information previously noted (E. S. R., 40, p. 392).

Statistics of industrial crops, V. PEGLION (Comitato Naz. Tariffe Dog. e Trattati Com., Monograph 6 (1917), pp. 171).—Statistics and notes on the production, trade, and tariff regulations of certain industrial crops, such as hemp, jute, flax, and sugar beets in Italy.

Economic and financial resources of Russia, by regions and by governments (*Bul. Statis. Lég. Compar.*, 42 (1918), *No.* 8, *pp.* 304-325).—Two tables showing the area, population, agriculture, industry, and means of communication, and the finances of Russia, by regions and by governments, are reproduced here from a Statistical Outline of the Economic Geography of Russia, published recently by the Paris Chamber of Russian Commerce.

The agricultural resources of Morocco, M. HITTER (*Bul. Soc. Encour. Indus. Nat.* [*Paris*], 118 (1919), I, No. 2, pp. 348–363).—Brief descriptions of the principal agricultural products of Morocco and a discussion of the possibility of developing new crops there are given.

Prices and wages in India (Dept. Statis. India, Prices and Wages India, 33 (1918), pp. IX+278, pl. 3).—This continues information previously noted (E. S. R., 37, p. 792.

#### AGRICULTURAL EDUCATION.

American agricultural colleges: A study of their organization and their requirements for admission and graduation, C. D. JARVIS (U. S. Bur. Ed. Bul. 29 (1918), pp. 125, figs. 4).—Part 1 of this bulletin comprises general discussions and tabulations concerning the government and organization and the agricultural curricula of each of the agricultural colleges in this country. Parts 2 and 3 deal respectively with the requirements for admission and graduation. Tabulated outlines, showing the scope and credit value of the graduation requirements for the several institutions, are appended.

The following principles are suggested concerning scholastic requirements for admission: The colleges should exert an influence upon improved secondary schools in such a way as to enable them to prepare adequately students for colleges and to maintain their usefulness for the mass of students who may never enter college. Work should be prescribed by the colleges only in such preparatory subjects as are regarded as prerequisite to the freshman work in the college curriculum for which the applicant seeks admission; it being understood that the colleges, in accrediting or passing upon the qualifications of high schools, have an opportunity for prescribing the general qualifications for their prospective students. For the guidance of prospective candidates for the degree of bachelor of science in agriculture, each State should publish a statement showing what are believed to be appropriate sequences of studies and an acceptable amount of coordinated work covering the combined high school and college periods.

Special attention is called to the necessity for a more uniform basis for college credit. The lack of such uniformity renders difficult the comparison of institutions from the standpoint of the amount of work required for graduation, and interferes with the free and just exchange of credit for work done in two or more institutions.

The great variation among institutions in their quantitative requirements for graduation indicates either a great waste of time in some institutions, or a sacrifice of quality of work for quantity in others. The wide difference of practice in regard to the relative proportion of prescribed and elective work offered by the institutions shows that the question of freedom of election is still a matter of contention.

The most conspicuous disagreement in the placement of courses within the 4-year schedule is the tendency on the part of some colleges to defer the offering of strictly agricultural courses until the sophomore or even the junior year, while others require such work from the very beginning of the course.

[Vol. 41

There is a growing belief that more technical work should be given early in the curriculum. That some institutions, in making up their schedules, apparently give more attention to classroom and laboratory facilities and to the convenience of instructors than to a careful balancing of the student's work would appear to be indicated by the uneven distribution in the curriculum of the heavy science courses. A lack of a clear conception of what should be required for the bachelor's degree in agriculture is suggested by the variation in content of the curriculum.

The great variation in the distribution of the required work among the various groups or classes of subjects suggests a divergence of views concerning educational aims. There is a tendency among certain institutions during recent years to emphasize the economic and sociological phases of the training, while others place the emphasis upon technical efficiency. The danger lies in the failure to adapt college curricula to the ever-changing economic conditions.

It is found that in only a few States is any conspicuous attempt being made to consolidate the curricula of the elementary and preparatory schools with the curriculum of the college in such a way as to suggest appropriate sequences embracing the whole period of training for professional agriculture. Such a consolidation contemplates a single and complete program of instruction covering a period of approximately 10 years instead of two or three quite distinct programs of shorter duration.

Many colleges still fail to appreciate the importance of requiring a fair degree of proficiency in practical farm operations.

Report of the education branch for the year 1916–17 (*Jour. Bd. Agr.* [*London*], 25 (1918), No. 8, pp. 934–941).—This is the annual report of the British Board of Agriculture and Fisheries, dealing with the educational, research, and advisory work of the various institutions and local education authorities for 1916–17, as well as with the payment of grants during the fiscal year ended March 31, 1917.

Grants paid to institutions providing higher agricultural education have been reduced or withdrawn in certain cases. The Holmes Chapel College, Cheshire, was closed on account of the war, while the Seale-Hayne College, Newton Abbott, received a grant of \$972 for the equipment of the college farm when the institution was opened for the training of women for work on the land. The college buildings, the completion of which had to be suspended after the outbreak of the war, were taken over by the war office as a military hospital, as were also the new buildings of the Midland Agricultural and Dairy College at Sutton Bonington. The attendance of students for long courses at the higher agricultural education institution (348) showed a further material decrease from prewar standards (1,200). The agricultural activities of the county councils were again directed mainly toward war problems.

The total of the grants made by the board for 1916–17, which was \$370,220, included \$58,125 for universities and colleges, \$33,111 for advisory work, \$87,553 for research institutes and other research centers, \$36,304 for special research and investigations, \$3,198 for research scholarships, \$127,434 for farm schools, technical classes, local lectures, etc., \$7,650 for the establishment of farm schools, \$4,447 for expenses of advisory councils, and \$12,398 for forestry advice, research, and experiments.

**Report of the Direction of Agriculture for 1917** (*Dept. Landb., Nijv. en Handel* [*Netherlands*], *Verslag Dir. Landb., 1917, pp. VII+77*).—This is a report on the status of higher, secondary, and elementary instruction in agriculture, horticulture, and forestry, instruction in home economics, veterinary science and dairying, and extension and experimental work under the Direction of Agriculture in the Netherlands in 1917. Report of the Department of Agriculture of Norway for 1917 (Aarsber. Offentl. Foranst. Landbr. Fremme, 1917, III, Statsforanst., pp. [5]+5+V-XCVIII+711, pls. 3, figs. 58).—This is the annual report for 1917 on the activities of the various government agencies for the promotion of agriculture in Norway, including chemical, seed, and milk control stations, experimental farms, sheep farms, dairy and horticultural schools, the school of home economics for training teachers, itinerant instructors, etc.

Report of the Department of Agriculture of Sweden, 1916 (K. Lantbr. Styr. [Sweden] Underdåniga Ber. 1916, pp. [10]+783+X, fig. 1).—This is the annual report on the activities of the various agencies for the promotion of Swedish agriculture, including the work of agricultural, horticultural, dairy, and house-keeping schools, dairy, chemical, and seed control stations, and the extension service.

Ninth annual report of the eleven district agricultural schools of Georgia, J. S. STEWART (Ga. State Col. Agr., Bul. 155 (1918), pp. 40, fig. 1).—This report contains the organization lists of these schools; statements of improvements in the school plants during 1917–18, of extension work, including home projects cooperation with the Georgia State College of Agriculture, of teacher training at the various schools, special features of the year, and recommendations, war work, and physical training; an outline of the course of study in operation; an outline of the revised course adopted for 1918–19 to meet the provisions of the Smith-Hughes Act, with a schedule of hours and explanatory notes; the text of the legislative act creating the schools; and statistics of attendance, equipment, receipts, and disbursements, etc.

It is shown that for individual schools, the total attendance ranged from 72 to 211 students, the total number of acres cultivated from 75 to 257, the value of live stock from \$1,695 to \$6,600, the value of farm stock from \$500 to \$4,000, the State appropriation from \$14,000 to \$17,000, the total receipts from \$14,496 to \$25,812, and the total disbursements from \$13,347 to \$26,301.

The Gary public schools: Household arts, E. W. WHITE (*New York: Gen. Ed. Bd., 1918, pp. XIX*+49, *pls.* 7, *figs.* 2).—This is a report on the instruction in cooking and sewing in the Gary (Ind.) public schools, including time schedules and enrollment, the cafeteria, equipment, staff and instruction, tests, and a discussion of the merits and defects of the instruction.

In concluding, the author states that this account may mislead because it fails to give a proper realization of the attitude and spirit of the Gary pupils. These pupils are happy, and in the author's judgment "the happiness and spontaneity of the children are due to a variety of causes—to the flexibility of the schedule, to the development of special activities, to the absence of repressive rules, to the general feeling that the school exists for the child, not the child for the school."

**Domestic science in rural school** (*Agr. Gaz. Canada, 6* (1919), No. 1, pp. 51– 60, figs. 3).—This is a series of brief accounts, by education officials, of the present status of instruction in domestic science in the rural schools of the Provinces of Nova Scotia, New Brunswick, Quebec, Saskatchewan, Alberta, and British Columbia. These indicate that domestic science is a comparatively new subject in the rural schools of these Provinces, in three of which it is aided by government grants. In four of the Provinces the hot school lunch has been introduced into the rural schools.

Report Wellesley College training camp and experiment station for the Woman's Land Army of America, E. DIEHL ([Wellesley, Mass.: Wellesley Col.], 1919, 2. ed., pp. 95, figs. 10).—This is a report, by the camp director, on the organization and activities of the training camp and experiment station which was opened August 1, 1918, with 32 women. Outlines of courses for

supervisors; a course in emergency aid, hygiene, and sanitation; and specifications, together with estimates of material and cost of camp buildings for a camp of from 30 to 40 women; lists of equipment with cost, and of camp menus, etc., are included.

[Opportunities in agriculture for disabled soldiers, sailors, and marines] (Fed. Bd. Vocat. Ed., Rehabil. Ser., 1919, Nos. 33, pp. 20, figs. 12; 36, pp. 20, figs. 20; 37, pp. 31, figs. 28).—These bulletins outline the opportunities in Technical Agriculture as a Vocation, by W. J. Quick; Farm Mechanics from Tank or Truck to Tractor, by J. H. Gill and W. J. Quick; and Beekeeping, by W. J. Quick, respectively, to disabled soldiers, sailors, and marines in choosing a vocation.

Vocational legislation passed at the 1919 session of Arizona State Legislature and a statement of requirements and qualifications to secure State and Federal aid (*Bul. State Bd. Control Vocat. Ed.* [*Ariz.*], *No. 3* (1919), *pp.* 15).—Under this legislation the State undertakes to reimburse for 75 per cent of the expenditures for salaries of teachers of vocational subjects, provided the Smith-Hughes requirements which are set forth in this bulletin are met. In a course in vocational agriculture, half of the school day must be devoted to agricultural subjects, of which 90 minutes a day must be given to supervised practical work. The texts of the two State legislative acts of 1919 are included.

[Vocational home economics education in California], M. I. MURCHIE (Cal. State Bd. Ed., Dept. Vocat. Ed., Ext. Serv. Teachers Home Econ., Corresp. Nos. 1 (1919), pp. 4; 2, pp. 3; 3, pp. 2; 5, pp. 3).—These pamphlets deal respectively with home economics education as outlined in Bulletin No. 23 (E. S. R., 40, p. 394); vocational courses of study for Federal and State aided full-time classes in home economics in high or intermediate schools; progress in home economics education in California; and the organization of part-time classes in home economics.

First annual report of the Colorado State Board for Vocational Education (Ann. Rpt. Colo. State Bd. Vocat. Ed., 1 (1918), pp. 23, figs. 8).—This is a report for the first fiscal year under the Smith-Hughes Act.

Of the total Federal funds, amounting to \$15,000, available for this work, \$5,000 was devoted to the teaching of agriculture, \$1,000 to the teaching of home economics, and \$5,000 to the training of teachers, viz, \$1,000 each for the training of agricultural and trade teachers, and \$3,000 for the training of home economics teachers. Practically all of the expenses for the administration of the act were met out of the maintenance funds of the Colorado Agricultural College, local school districts, and other cooperative agencies.

The agricultural project work was engaged in by 125 students and ranged from raising a garden to many acres of farm crops. Potato, poultry, and tractor projects are outlined to indicate how the work was conducted. All home economics funds were used to promote the teaching of home economics classes in consolidated rural schools, of which two were aided, and the plans for 1918–19 provide for a continuance of this practice.

The training of teachers of vocational agriculture and home economics was done at the Colorado Agricultural College, the students receiving actual teaching experience in these subjects in the Colorado School of Agriculture, located on the college campus.

The administration of the Smith-Hughes vocational act in Georgia for the first year, July 1, 1917, to July 1, 1918 (*Ga. State Vocat. Bd.* [*Bul.*], 3 [1918], pp. 37).—This review of vocational education work under the Smith-Hughes Act for 1917–18 in Georgia includes a brief resume of the work in each of the schools receiving aid under this act.

It was necessary to rearrange the schedule of the 11 district agricultural schools to give 50 per cent of the time to agriculture.

Teacher training for vocational agriculture was organized at the university at the beginning of the second term in 1917. A new division of agricultural education was established in the Georgia State College of Agriculture. The courses given in this division were supplemented by training in pedagogy and social sciences given in the Peabody School of Education, while the scientific and humanistic courses were given in connection with the regularly organized courses in the university. A 3-months war emergency course was also introduced by the college of agriculture to meet the shortage of available men for teachers. Teacher training in home economics was offered at the State Normal School at Athens and the State Normal and Industrial College at Milledgeville, and was begun in the South Georgia Normal School at Valdosta.

First annual report of the Massachusetts Board for Vocational Education to the Federal Board for Vocational Education (*Bul. Bd. Ed. Mass., No. 11* (1918), pp. 160, figs. 4).—This report comprises a brief description of the vocational education work carried on in Massachusetts in 1917–18 under the Smith-Hughes Act, a financial summary of receipts and expenditures of vocational education funds, and a statistical report. These are followed by appendixes, including among others detailed reports on the agricultural work by R. W. Stimson, household arts schools by L. I. Pryor, and plans for agricultural teacher training by W. R. Hart and F. E. Heald, and statistical tables showing the distribution and allotments of benefits from the Smith-Hughes Act, forms of application for allotments, administrative regulations, the text of the State laws relating to the extension of State aided vocational education during the period of the war, and the training and instruction of disabled soldiers and sailors by the Commonwealth and the Federal Government, etc.

The State Board for Vocational Education approved four separate schools and 10 high school departments for vocational agricultural instruction, and nine all-day and 19 evening schools for vocational home economics instruction. Notes are included on the work of each of these approved schools and departments, including war emergency work. A plan recommended for the training of teachers of vocational agriculture is set forth, as well as outlines of several other training courses.

Annual report of the State Board for Vocational Education for the year ending June 30, 1918 (*State Bd. Control Vocat. Ed.* [Mich.], Vocat. Ed. Bul. 209 (1918), pp. 10).—This first report of the Michigan State Board for Vocational Education contains a digest of the State law accepting the provisions of the Smith-Hughes Act, the procedure in the organization of the work, and financial and statistical statements.

The total disbursements from local, State, and Federal funds included \$661.13 for a supervisor of agriculture. \$46,441 for salaries of teachers of agriculture, \$7,157.36 for teacher training in agriculture and home economics at the Michigan Agricultural College, and \$5,077.97 for teacher training in home economics at the State Normal College. The disbursements of Federal and State funds for home economics amounted to \$4,706.67.

There were 43 schools teaching agriculture aided by Federal and State funds, with an enrollment of 2,535 students in these subjects. Five all-day home economics schools were attended by 387 students, and four evening home economics schools by 894 students. Eight schools received Federal and State aid for instruction in home economics. Training courses in agriculture and home economics were attended by 45 and 81 teachers, respectively. **Report on vocational education for Montana for the year 1917–18**, M. J. ABBEY (*Rpt. Vocat. Ed. Mont., 1917–18, pp. 14*).—This first report on vocational education in Montana contains digests of the Smith-Hughes Act and the State act accepting its provisions and appropriating \$15,000 for the years 1918 and 1919, respectively, and an account of the organization of the work.

Eight high schools were approved for State and Federal aid for vocational agriculture and three for home economics. The Montana State College of Agriculture and Mechanic Arts was selected to train teachers of vocational subjects. At present 28 men are preparing to teach agriculture and 16 women to teach home economics.

Plans for vocational education in Nevada under the Smith-Hughes Act, year 1919-1920 (*State Dept. Ed. Nev. Bul. 3 (1919*), pp. 15).—This bulletin contains in brief form and in part the State plans for vocational education for the year 1919-20, which supersede those previously noted (E. S. R., 40, p. 597).

Vocational education laws in Nevada appertaining to the Smith-Hughes Act for years 1919–1920 (*State Dept. Ed. Nev. Bul.* 4 (1919), pp. 16).—This bulletin is intended specifically for use in the resident teacher-training classes at the University of Nevada and for itinerant teacher-training throughout the State. It includes an analysis of the Smith-Hughes Act.

Federal aid for vocational education in North Carolina under the Smith-Hughes law (Bul. State Bd. Vocat. Ed. N. C., No. 2 (1918), pp. 40).—Part I of this bulletin contains an outline of the plans for 1918–19 for vocational education in North Carolina under the Smith-Hughes Act.

The North Carolina State College of Agriculture and Engineering has been designated as the institution for training white teachers for vocational agriculture; The Negro Agricultural and Technical College at Greensboro, for training negro teachers of vocational agriculture; The North Carolina State Normal and Industrial College at Greensboro, for training teachers of vocational home economics for the white race; and the Slater Industrial and State Normal School at Winston-Salem, for the training of teachers of vocational home economics for the colored race. It is proposed to use \$3,000 of the funds for teacher training work in training teachers of agriculture for the white race and \$1,000 for the colored race, while for home economics the respective allotments are \$4,000 and \$1,000.

The teacher-training course in agriculture for white students extends over four years. Students are required to complete 190 hours for graduation, of which 18 are in education. Forty per cent of the students' time must be devoted to technical subjects, 30 per cent to science, 10 per cent to professional subjects, including practice teaching, and 20 per cent to general education subjects. It has been arranged to use the Carey farm-life school as a practice and observation school.

The 4-year course for the training of home economics teachers comprises 61 unit hours. Thirty per cent of the time in this course must be devoted to home economics subjects, 30 per cent to related science. 30 per cent to academic subjects, and 10 per cent to professional education, including practice teaching and observation.

Outlines of a suggested 4-year course for vocational schools in agriculture, with at least 50 per cent of the students' time devoted to vocational work, and a 2-year course in home economics, in which a 90-minute period each day is devoted to practical work and a 60-minute period to related subject work in science, are included.

Part II contains financial and statistical reports of the State Board for Vocational Education for the fiscal year 1917–18. Vocational education: Plan of the State Board for Vocational Education (Bul. State Bd. Ed. [Va.], 1 (1918), No. 1, Sup. 2, pp. 29).—Under approved plans, 18 or 20 high schools are operating departments of vocational education in agriculture and home economics. The State Board of Education, which has been designated as the State Board for Vocational Education, has apportioned 45 per cent of the teacher-training fund for 1918–19 for the training of teachers, supervisors, or directors of agriculture and 30 per cent for the training of teachers of home economics.

The 4-year course in vocational agriculture, including suggestions for project work, is outlined. The first year is devoted to plant production, the second to animal production, the third to general horticulture and field crops, and the fourth to rural engineering and farm mechanics in the first term and rural economics and farm management in the second term. Outlines are also given of a suggestive millinery course, a 2-year course in home economics proposed for cities with a population of over 25,000, and a 4-year course for cities, towns, and communities of less than 25,000 inhabitants.

Courses of study in vocational agriculture and vocational home economics, J. D. ELLIFF (*Missouri State Bd. Ed.*, *Vocat. Ed. Bul. 3 (1918–19)*, *pp. 45*).— This bulletin contains outlines of the first-year course in vocational agriculture; a suggested curriculum in vocational home economics showing the distribution of time by years, terms, and weeks; courses in drawing and design; garment making, including textile work; food study and home cooking; housekeeping, planning and serving meals, household accounts, and household management; physiology, hygiene, and home nursing; elementary dressmaking and millinery; references to helpful literature on agriculture and home economics; laboratory exercise in agriculture; a suggested list of agricultural home projects; and suggested projects in home economics.

The Missouri plan for vocational instruction in agriculture for 1918–19 provides for two years' continuous instruction. The first year of the agricultural course requires one-half of the student's time and deals with soils, soil fertility, farm crops, farm animals, farm management, and farm mechanics. The second year's work will consist of two of the intensive courses in soils, horticulture, farm crops, and animal husbandry.

Brief description of a plan for unit and short courses in vocational agriculture: Unit plan for high schools, T. H. EATON (State Bd. Ed. Conn. Bul. 37 (1918–19), pp. 7).—A plan is described opening up to high schools and to students opportunities for one and two or four years of work, and to the community the possibilities of short-course instruction for pupils not in the high school or in any school at all, and for adults.

Making lessons in agriculture count, J. F. SHAMBAUGH (*Bul. Teaching Agr.* [*Off. Supt. Pub. Instr.*, *N. C.*], *No. 1 (1917)*, *pp. 16*).—These lessons suggest methods of teaching agriculture and are based on the text, Agriculture for Beginners (E. S. R., 16, p. 832), adopted for the North Carolina public schools.

Vocational agricultural education by home projects, R. W. STIMSON (*New York: The Macmillan Co., 1919, pp. XXXVIII*+[2]+468, figs. 304).—This is a detailed review of the Massachusetts home-project plan, which meets the minimum requirements of the Smith-Hughes Act of at least six months a year of supervised practice in agriculture. It includes a brief reference to the various forms of organization of secondary vocational agricultural education; discussions of the home project school or department v. the self-contained school; project study v. subject study; vegetable growing project study outlines in Massachusetts; suggestions to supervisors, superintendents, and directors, supported by experience in Massachusetts, regarding certain principles of procedure which the author believes to be of importance for the advancement of vocational agricultural education; and suggestions to agricultural instructors on organizing and conducting project work. A comparison is made of the county schools and high-school departments in the Massachusetts no-dormitory system as to requirements and advantages. A chapter is devoted to a description of the Massachusetts method of listing agricultural project and related study reference materials and their sources.

Agriculture and home economics bulletin with a moral code, R. H. WILSON ET AL. (Oklahoma City: State Bd. Ed., 1917, pp. 48, figs. 11).—A 2-year course in agriculture for the rural schools of Oklahoma is outlined by months, including class work, field or laboratory work, and mechanical work in soils and crops in the first year, and animal husbandry in the second year. Instructions to teachers are included. The home economics work outlined is for the sixth, seventh, and eighth grades of the rural schools. The work of the first year consists entirely of sewing, and that of the second and third years, of foods. The work is planned for one lesson a week for 30 weeks in class periods of not less than 30 minutes.

[Elementary agriculture and home economics instruction in New Mexico schools], R. C. MILLER (Dept. Ed. N. Mex., Ed. Bul., Indus. Ser., 1918, Nos. 3, pp. 14; 4, pp. 6, figs. 2; 5, pp. 8; 1919, Nos. 6, pp. 24; 9, pp. 16; 10, pp. 14; 11, pp. 16).—These bulletins deal, respectively, with thrift clubs for patriotic service in food production, a project for classes in sewing, agriculture in the elementary schools, and elementary home projects in gardens, pig raising, calf raising, and field crops.

Plant production, R. A. MOORE and C. P. HALLIGAN (*New York: American Book Co., 1919, pp. 428, figs. 211*).—This text on the science and art of producing agricultural plants consists of two parts, viz, agronomy, including the more important economic crops, and horticulture. Following each chapter are suggested exercises and home projects.

Vocational agriculture in high schools: Animal husbandry series No. 2, T. H. EATON and C. E. LEE (*State Bd. Ed. Conn. Bul. 20 (1918–19), pp. 23).*— Suggestions are given with reference to the teaching of poultry husbandry in the approved course in agriculture as regards the place of poultry husbandry in the course; a preliminary survey to find the place of poultry keeping as a farm interest in the vicinity; surveys of types of poultry husbandry to find the chief factors in the business; local feeding practices and available feeds, poultry houses and arrangements, and feeding and watering devices; marketing poultry products; and incubating and brooding equipment. A brief list of reference books and other publications is included.

Malaria: Lessons on its cause and prevention, H. R. CARTER (*Pub. Health Rpts.* [U. S.], *Sup. 18* (1918), *rev. ed.*, *pp. 20*, *pls. 4*).—These lessons, which are intended for the use of schools and especially those in the country, deal with malarial fever and its cause and four methods of prevention of malaria. The subject matter is arranged as questions and answers.

Distribution of eggs to school children (Agr. Gaz. Canada, 6 (1919), No. 3, pp. 274–278).—This series of articles describes the methods of distribution of eggs to school children in the Provinces of Nova Scotia, New Brunswick, Quebec, Manitoba, Saskatchewan, Alberta, and British Columbia by agricultural officials.

**Domestic science:** Principles and application, P. L. BAILEY (St. Paul, Minn.: Webb Pub. Co., 1918 [2.] ed., rev., pp. XVI+353+[13], pl. 1, figs. 44).—This is a revised edition of an earlier text, previously noted (E. S. R., 32, p. 394), to which has been added material on the cold-pack method of canning vegetables and fruits, 100 caloric portions of common foods, and tables and lists of foods with their ash constituents, together with many changes in the recipes to conform to the more thorough application of the principles involved and to the unusual economic food conditions prevailing.

#### MISCELLANEOUS.

Annual Reports of the Department of Agriculture, 1918 (U. S. Dept. Agr. Rpts. 1918, pp. VII+520).—This contains the reports of the Secretary and heads of bureaus and other administrative officers. The various reports are also issued as separates.

Annual report of the director of the experiment station on work done under the Local Experiment Law in 1918, J. F. DUGGAR (*Alabama Col. Sta. Circ.* 40 (1919), pp. 54).—This includes a summarized report by the director of work in all departments conducted under this law (E. S. R., 24, p. 400) for 1918, a financial statement for the year, and detailed reports of heads of departments, including reports on boys' and girls' club work and other extension activities. Experimental work in beef cattle and pig feeding is abstracted on pages 368 and 369 of this issue.

Twenty-eighth Annual Report of Arizona Station, 1917 (Arizona Sta. Rpt. 1917, pp. 387-498, figs. 17).—This contains the organization list, an administrative report by the director on the work and publications of the station, a financial statement for the fiscal year ended June 30, 1917, and departmental reports, the experimental features of which are for the most part abstracted elsewhere in this issue. A brief report on the work and expenditures of the college of agriculture is appended.

Director's report for 1918, W. H. JORDAN (New York State Sta. Bul. 457 (1918), pp. 25).—This contains the organization list and a review of the work and publications of the station during the year.

Twenty-eighth Annual Report of Wyoming Station, 1918 (Wyoming Sta. Rpt. 1918, pp. 65–127).—This contains the organization list, a financial statement for the Federal funds for the fiscal year ended June 30, 1918, reports of the director and heads of departments, and meterological observations and two special articles abstracted elsewhere in this issue.

Quarterly bulletin of the Michigan Experiment Station (Michigan Sta. Quart. Bul., 1 (1919), No. 4, pp. 149–196, figs. 18).—In addition to the usual list of available bulletins, this contains the following articles: Diversified Farming after the War; The Pure-bred Sire Campaign; Grading of Milk by Microscopic Examination, by G. L. A. Ruehle; Legume Inoculation, by C. G. Nobles; Botanical Notes, by G. H. Coons; Analyses of Insecticides and Fungicides, by A. J. Patten; Machine v. Hand Milking, by F. T. Riddell (see p. 373); The College Jerseys, by J. E. Burnett; Ox Warbles, by W. L. Chandler; Periodical Cicada, by R. H. Petiti; Sorghum Sirup Production, by C. R. Megee; Meeting the Hay Shortage, by J F. Cox; Robust Beans, by F. A. Spragg; Care of the Tractor and Splicing the Hay Rope, both by H. H. Musselman; Preservative Treatment of Fence Posts, by A. K. Chittenden; Thinning the Wood Lot, by F. H. Sanford; Horticultural Notes, by H. J. Eustace; Cooperative Experimental Soil Projects, by M. M. McCool; Culling the Farm Flock, by C. H. Burgess; and Control and Eradication of Rats, by A. C. Conger.

## NOTES.

**Connecticut State Station.**—Philip Garman, Ph. D., assistant entomologist at the Maryland Station, has been appointed assistant entomologist.

Georgia Station.—An approximately 30 per cent increase in enrollment for all courses over last year is predicted. The total enrollment in agriculture will be approximately 400. The college became co-educational last year, and now has approximately 40 women taking courses in home economics. A threestory dormitory for women is under construction.

A series of land clearing demonstrations has been undertaken in 18 south Georgia counties. In one of these counties 69,428 of the 87,428 acres of land under cultivation are filled with stumps which are estimated to take up an average of approximately 13.6 sq. ft. per stump, so that the question of land clearing is one of great importance. The demonstrations consist of stump pulling and blasting, ditch blasting, and work with tractors. At the first six demonstrations there was a total attendance of 13,500 people, as many as eight counties being represented at some of them. The campaign has attracted unusual notice from the press of the State.

Iowa College and Station.—Dr. R. E. Buchanan, head of the department of bacteriology and for six years dean of the division of industrial science, has been made dean of the graduate school. He has been succeeded by Dr. S. W. Beyer, for nineteen years vice dean and for the war period dean of the engineering division.

Massachusetts College and Station.—A campaign is under way to raise \$150,000 from the alumni and undergraduates with which to build and equip a students' activities building. This building is designed to be a memorial to the 49 graduates and former students who lost their lives in the war.

Dr. J. K. Shaw, research pomologist of the station, has resigned effective November 1, to become head of the department of horticulture at the University of West Virginia. John B. Smith, assistant chemist, has accepted a similar position with the Texas Station.

F. A. Waugh and G. Edward Gage, captains in the Sanitary Corps, have resumed their former duties in the college and station. W. S. Welles, head of the school of educational agriculture at the River Falls (Wis.) Normal School, has been appointed professor of agricultural education.

Montana College and Station.—C. N. Arnett, head of the animal husbandry department, has resigned effective November 1 to become manager of a large stock ranch in the State. Ray S. Jones, assistant chemist of the station, returned from war service September 1.

New Mexico Station.—A number of native goats have been purchased to start the investigations contemplated on the improvement of the native strain for milking purposes by crossing with the Toggenburg breed.

Charles E. Cormany and Gates S. Vickers, assistants, respectively, in agronomy and poultry husbandry, have resigned to engage in graduate work at Cornell University. Donaldson Ryder and R. M. Parks have been appointed to succeed them. Cleave W. Humble, assistant animal husbandman, has resigned to engage in commercial work and has been succeeded by J. L. Lantow. North Dakota College and Station.—Three members of the staff have recently resigned, including J. W. Ince, as chemist in the station to become professor of chemistry in the Rhode Island College; T. A. Hoyerstad, in charge of marketing investigations, to engage in business; and Edwin Mayland, in charge of cost accounting investigations in the station, to accept a position as farm manager.

**Tennessee University.**—A department of agricultural economics has been established in the college of agriculture with C. E. Allred, formerly farm help specialist, as head. All work in agricultural economics, farm management, and rural sociology is to be grouped in this department, and considerable research work is contemplated.

**Texas College and Station.**—The legislature just adjourned appropriated slightly over \$3,000,000 for the college and its branches for the next two years. Of this, \$2,244,985 was for the main institution at College Station, including the extension service and station, and with \$250,000 for an agricultural building. The John Tarleton Agricultural College at Stephenville received \$184,490, the Grubbs Vocational College at Arlington \$235,800, and the Prairie View Normal and Industrial College \$397,070.

Plans have been completed for an office building for the extension service of the college to cost \$100,000.

**Virginia Station.**—T. K. Wolfe, associate agronomist, has been granted leave of absence beginning October 1 to pursue graduate studies at Cornell University. His duties have been assigned to J. C. Hart, superintendent of the county station at Chatham, while D. J. Berger has been appointed acting superintendent of that station. C. F. Warren, assistant horticulturist, resigned September 16.

Wyoming University and Station.—C. V. Singleton has resigned as assistant animal husbandman to engage in farming in Virginia. Dr. F. A. Hays, for the past two years head of the animal husbandry department at the Delaware College and Station, has been appointed associate professor of animal husbandry beginning September 1.

Karl Steik, engineering chemist, has resumed station work after a year's leave of absence.

Research in Entomology and Plant Pathology in Great Britain.—Announcement was recently made in Parliament of a change in policy in 1918 regarding research in entomology and plant pathology through public funds. These subjects were originally allocated to the University of Manchester and the Royal Botanic Garden at Kew, respectively, with grants from the Development Fund for their support. In 1918, however, the Development Board decided that all research in plant diseases, whether due to insects or fungi, should be concentrated at a single phytopathological institute at Rothamsted, where also the board's scientific advisory staff in the subject would be stationed. Accordingly the staff at Manchester and a portion of the mycological staff at Kew were transferred to Rothamsted. A grant of \$5,000, per annum, was however continued to the University of Manchester to maintain certain phases of its entomological work and also to take up work in mycology there.

American Meteorological Society.—According to a note in *Science*, steps are being taken to organize an American Meteorological Society at the American Association for the Advancement of Science meeting in St. Louis next December.

International Research Council.—This organization met at Brussels from July 18–28. A general constitution was agreed upon, and steps taken toward the international organization of several of the sciences represented. Provision was made for triennial meetings at Brussels, which was designated as the legal domicile of the council. A resolution inviting the cooperation of nations which had remained neutral during the war was unanimously adopted.

Union Check List of Agricultural Periodicals.—At the last meeting of the Agricultural Libraries Section of the American Library Association, held at Asbury Park, N. J., June 26, the subject of preparing a union check list of agricultural periodicals in the libraries of the United States received special consideration and indorsement. A committee consisting of C. R. Green of the Massachusetts Agricultural College, H. O. Severance of the University of Missouri, and Miss Lydia K. Wilkins of the U. S. Department of Agriculture was appointed to decide as to the scope of such a list and the methods to be undertaken in its compilation.

**Necrology.**—Dr. Emil Fischer, professor of chemistry at the University of Berlin since 1892 and one of the most eminent organic chemists of his generation, died in July at the age of 67 years. Among his many epoch-making achievements may be cited his discovery of phenylhydrazine in 1875, the synthesis of the most important sugars, his notable work on the enzyms and purin group, and the hydrolysis and synthesis of the proteins. He was the recipient of many honors, including the Nobel prize in chemistry in 1902. His researches were compiled and published in book form in three large volumes: Untersuchungen über Amino-Sauren, Polypeptide, und Proteine (1899–1906), Untersuchungen in der Purin Gruppe (1882–1906), and Untersuchungen über Kohlenhydrate und Fermente (1884–1908). His fame attracted students from all over the globe, including many men well known for their contributions to organic chemistry in this country.

Dr. Aaron Aaronsohn, agricultural expert and director of the Jewish Agricultural Experimental Station at Haifa, Palestine, was killed by a fall from an airplane May 15, near Boulogne, while flying from London to Paris. He had been a technical adviser to the U. S. Department of Agriculture for several years, and will be recalled through his rediscovery in 1906 of a wild emmer (*Triticum dicoccum dicoccoides*) in Palestine and Syria, believed to be a prototype of true wheat (E. S. R., 23, p. 533).

Adrian J. Brown of the University of Birmingham, England, well known for his studies in fermentation and permeability, died July 2.

Dr. W. G. Farlow, professor of cryptogamic botany of Harvard University, died June 3 in his seventy-fifth year.

Miscellaneous.—According to a recent note in *Science*, an association of the employees of the various public and private experiment stations in the Dutch East Indies was organized in connection with the eighth meeting of the technical personnel of these stations and the Department of Agriculture, held at Medan, Deli, Sumatra, April 23–26, 1919.

J. B. Knight, professor of agriculture in the Poona Agricultural College, India, has been appointed principal vice Dr. H. H. Mann, now acting director of agriculture for Bombay.

The Franklin Institute of Philadelphia has awarded its Edward Longstreth Medal of Merit to Dr. J. J. Skinner of the Bureau of Plant Industry, U. S. Department of Agriculture, for a paper entitled Soil Aldehydes.

## CONTENTS OF VOL. 41, No. 5.

Editorial notes:	Page.
The beginnings of agricultural research in California	401
Recent work in agricultural science	407
Notes	496

#### SUBJECT LIST OF ABSTRACTS.

#### AGRICULTURAL CHEMISTRY-AGROTECHNY.

An introduction to the study of biological chemistry, Schryver	407
The chemical examination of three species of larkspurs, Beath	407
Composition of the fruit of Cicer arietinum, Zlataroff	408
Soft corn : Chemical composition and nitrogen distribution, Spitzer et al	408
Ilex vomitoria as a native source of caffein, Power and Chesnut	409
Isolation of the iodin compound which occurs in the thyroid, I, Kendall	409
The catalytic decomposition of hydrogen peroxid, Phragmén	409
Catalase action in yeast cells, von Euler and Blix	409
The catalytic decomposition of hydrogen peroxid, Phragmén	409
Action of enzyms upon starches of different origin, Sherman et al	409
Growth of bacteria in media of different concentrations, Cohen and Clark_	410
Coal as a substitute for talcum to induce rapid boiling, Kendall	410
The use of turpentine resin in turpentine as a foam breaker, Kendall	410
Estimation of perchlorates, with chlorates and chlorids, Williams	411

	Page.
A method for the volumetric estimation of sulphates, Rivett	411
Phosphoric oxid in fertilizers, soil extracts, etc., Marchand	411
Total nitrogen in soils with large amounts of nitrates, Snyder	411
Aids to the analysis of food and drugs, Moor and Partridge	412
Determination of caffein in vegetable material, Power and Chesnut	412
Estimation of butter, coconut, and palm kernel fat, Blichfeldt	412
The iodin value (Wijs) of palm kernel oil, Ellis and Hall	412
The cuprous chlorid-iodin method for reducing sugars simplified, Scales	412
Inorganic constituents of blood and other material, Greenwald	413
Determination of ammonia in the blood, Morgulis and Jahr	413
Lewis-Benedict method of blood sugar determination, Morgulis and Jahr_	413
Determination of lead in urine, feces, and tissues, Denis and Minot	413
Colorimetric method for uric acid in urine, Folin and Wu	414
A simplified macro-Kjeldahl method for urine, Folin and Wright	414
Vinegar making from apples, Anderson	414
Process for production of acetone and ethyl alcohol, Northrop et al	414
Biochemistry of <i>Bacillus acetoethylicum</i> , Northrop et al	415
Acetone and butyl alcohol by bacteriological process, Speakman	415
Bacteriology and technology of preserving meat, Kossowicz and Nassau	415
Vegetable decolorizing carbons for the cane sugar industry, Zerban et al	415
The deterioration of cane sugar by fungi, N. and L. Kopeloff	416
An improvement in casein making, Sammis	417
Agricultural industries, Wilbrands, edited by Siats	417

#### METEOROLOGY.

The larger relations of climate and crops in the United States, Ward	417
Report of the chief of the Weather Bureau, 1918	417
Monthly Weather Review	417
Climatological data for the United States by sections	418
The rainfall of France, Mathias	419

#### COILS-FERTILIZERS.

Soils and soil cultivation, Gardner	419
Soil survey of Caldwell County, N. C., Cobb and Davidson	419
Pleistocene and recent deposits in the vicinity of Ottawa, Johnston	419
Pyrolusite from Virginia, Watson and Wherry	420
Rate of formation of soluble material in cropped and virgin soils, Millar_	420
Changes in soil and water extract following manure, Hibbard	420
Parallel formation of carbon dioxid, ammonia, and nitrate in soil, Gainey_	421
Capillary moisture-holding capacity, Gardner	422
Penetration of periodic temperature waves into the soil, Aichi	422
Effect of certain colloidal substances on wheat seedlings, Jennings	422
Effect of soil and fertilizer on nitrogen and ash of crop, Maschhaupt	422
The abnormality of soils in field-placed cylinder experiments, Mooers	423
Mining and manufacture of fertilizers and relation to soils, Lloyd	423
Farm manure, Nagant	424
The world's supply of nitrogenous fertilizers, Anderson	424
War-time production of nitrogen compounds in Germany, Bueb	424
Comparative experiments with nitrogenous fertilizers, Schneidewind	424
Comparative test of several nitrogenous fertilizers, Bachelier	424
Field experiments with nitrate of ammonia, Hendrick	424
Setting of superphosphate and ammonium sulphate, Fowweather	425
Phosphate demonstration in Stevens County in 1918, McMiller et al	425
The phosphate industry, Hendrick	425
American potash, Roe	426
The Alsatian potash industry, Cameron	426
Value of sodium when potassium is insufficient, Hartwell and Damon	426
Relation of sulphates to plant growth and composition, Miller	427
Available fertilizer from smelter by-products, O'Gara	427
Lime requirements determined by plant and chemist, Hartwell et al	428
An artificial fertilizer, Gautier and Clausmann	428
Fertilizers in Cochin China, Bussy	428

#### AGRICULTURAL BOTANY.

AGRICULTURAL BOTANY.	
	Page.
The biological normal spectrum, Raunkiær	428
Statistical studies on vegetative formations, Raunkiær	429
The theory of limiting factors, Brown	429
The origination of ascidia under quasi-experimental conditions, Lloyd	429
Shrinkage and elongation of Cestrum nocturnum, Brown and Trelease	429
Algological notes.—III. Gemontia lignicola n. sp., Moore	429
A study of stomata. Rehfous	429
The taxonomic position of the genus Actinomyces, Drechsler	430
Morphology of the genus Actinomyces, Drechsler	430
A comparison of Azotobacter with yeasts, Mulvania	430
The use of iron in nutrient solution for plants, Corson and Bakke	430
Relation of varying degrees of heat to viability of seeds, Burgess	430
Additional notes on pollination of red clover, Pammel and Kenoyer	430
Studies on self-terility II. Pollen tube growth, East and Park	430
The behavior of the chromosomes in fertilization, Sax	431
Segregation of Enothera brevistylis from E. lamarchiana, Davis	431
Twin hybrids of <i>Œnothera hookeri</i> , de Vries	431
Merrillia, a new rutaceous genus of the tribe Citreæ, Swingle	432

#### FIELD CROPS.

Determining plat yields by square-yard method, Arny and Steinmetz	432
[Report of field crops work in Nebraska]	433
Soy beans and cowpeas for North Carolina, Herman	434
Rotation of potatoes, rye and squashes, onions, oats, and hay, Damon	434
Varieties of small grains and market classes of wheat, Stewart	434
Carrying capacity of native range grasses in North Dakota, Shepperd	434
Baling hay, McClure	435
Alfalfa on corn-belt farms, Drake, Rundles, and Jennings	435
Alfalfa in Michigan, Cox	435
Barley culture in South Dakota, Champlin, Morrison, and Martin	435
A reason for the contradictory results in corn experiments, Carrier	436
Factor relations in maize with reference to linkage, Jones and Gallastegui	436
Structure of the maize ear as indicated in Zea-Euchlæna hybrids, Collins	436
Inheritance of waxy endosperm in maize, Kempton	437
Factors influencing carrying qualities of American export corn, Boerner	438
Community cotton improvement in North Carolina, Winters	439
Potato seed certification in New Hampshire, Prince	439
Effect of environment on weight and germination of potatoes, Butler	439
Gigantism in Nicotiana tabacum and its alternative inheritance, Allard	440
Behavior of aurea character in a cross of Nicotiana mustica, Allard	440
Tobacco growing in Ireland, Keller	440
Blooming and fertilization of wheat flowers, Leighty and Hutcheson	440
Dry farming for wheat yields: Columbia and Snake River Basins, Hunter_	442
Seed Reporter	442
Seed-testing [in New Zealand], Levy	442
Plants detrimental to agriculture: Characteristics and control, Fron	442

#### HORTICULTURE.

Protecting American crop plants against alien enemies, Galloway	443
Report of inspection service, Headlee, Cook, and Weiss	443
Analyses of insecticides and fungicides, Patten and Berger	443
Judging vegetables, McLennan	443
[Variety tests of vegetables at Wisley in 1918]	443
Standardizing the hamper, Downing	443
Berry boxes and fruit baskets, Downing	443
Refrigeration for conserving, storing, and transporting fruits, Douane	443
Varieties of fruits for various localities, Gardner	444
A report on fruit growing in Denmark, Gram	444
Some observations on the pruning question, Reed	444
Pruning and spraying the home orchard and vineyard, Bentley	444
The commercial apple industry in the United States, Folger	444
"P. J. Bergius," a new apple variety, C. and R. Florin	444
Minimum temperature sustained by apricot in Pecos Valley, Hallenbeck	444

	Page.
Cover crops in the peach orchard, McCue	444
The culture of peach trees in the German climate, Rudolph	445
Relation of weather to fruitfulness in the plum, Dorsey	445
Tests with unfruitful plum trees, Esam	445
Varieties of gooseberries, currants, and black currants. Esbjerg	445
A commercially new blueberry, Murrell	445
Manual of American grape growing, Hedrick	446
The future of the hybrid direct bearers, Pée-Laby	446
Medlar tree flower and origin of the stoneless medlar in Italy, Pierpaoli	446
Olive culture in Argentina, Vallejo	446
Avocados, particularly Guatemalans, Popenoe	446
[Stocks for citrus trees], Davis	446
Fertilization of citrus groves with high-priced fertilizers, Prizer	. 447
Past and new practices in growing coconuts, van der Wolk	447
Contribution to the study of tea in Indo-China, Eberhardt and Aufray	447
Abnormal growth of scion in relation to stock in almonds, Passerini	447
The butternut and the Japan walnut, Bixby	447
Smith's chrysanthemum manual, Smith	448
Progress in breeding freesias, Van Fleet	448
Spring-flowering stocks tried at Wisley, 1916–17	448
Color in my garden, Wilder	448
Report of the botanist, Dunbar	448
Winter injury to ornamental trees and shrubs, Buck	448

#### FORESTRY.

Lumber export and our lorests, Graves T	TO
Firewoods: Their production and fuel values, Webster 4	49
Germination trials with Hevea seed, Maas 4-	49
Wound curing and healing with Hevea trees, Keuchenius 4	49
Report of forest administration in Baluchistan, Muhammed Afzal 4	49
Forest administration in Ajmer-Merwara, Shambhoo Datt Joshi 4	49

#### DISEASES OF PLANTS.

Plant pathology today, Shear and Stevens	450
Progress in control of plant diseases, Vaughan	450
[Plant diseases in South Africa, 1917–18], Evans	450
[Outgrowths on plants], Schoevers	450
[Verticilliose] in cultivated crops, van der Lek	450
Clover stem rot, Wolf and Cromwell	450
"Heart damage" in baled jute, Finlow	451
Heart rot or black pit of pea, van der Lek	451
Potato diseases, VI–VIII, Doidge	451
Leptonecrosis of the potato plant, and allied diseases, Quanjer et al	451
The use of lime in controlling finger-and-toe in turnips, Hendrick	451
"Little leaf" of deciduous fruits, Hodgson	452
A new disinfectant for pear blight, Reimer	452
Citrus canker [in the Transvaal], Evans	452
Bud curl of the lemon tree, Miller	452
On a tree of <i>Æsculus pavia</i> killed by <i>Botrytis cinerea</i> , Brierley	453
Walnut blight [in South Africa], Doidge	453
Polysaccum crassipas: A fungus in eucalyptus plantations, van der Bijl	453
Heart rot of <i>Ptæroxylon utile</i> caused by <i>Fomes rimosus</i> , van der Bijl	453
Decayed wood and the fungi therein as seen with the microscope, Lee	453
The decay of timbers in buildings, Blair	453

#### ECONOMIC ZOOLOGY-ENTOMOLOGY.

A review of the ornithology of Minnesota, Roberts	454
Recent investigations on the food of certain wild birds, Collinge	454
Some further investigations on the food of wild birds, Collinge	454
North American pseudophyllidean cestodes from fishes, Cooper	455
Work connected with insect and fungus pests and their control, Watts	455
[Insects and insect control in British Guiana], Bodkin	455
Common British beetles and spiders and how to identify them, Sedgwick_	455

	100
Notes and observations on agricultural entomology, del Guercio	400
[Report of] division of entomology, Lounsbury	455
Annual report of the government entomologist, Gowdey	455
[Report on] entomology	455
Insect pests of low-country products, Henry	455
Florida truck and garden insects, Watson	455
Cotton pests in Montserrat	455
Insect pests of tea, Andrews	455
The occurrence of forest insects in Sweden in 1917, Trägårdh	455
Damage done to stored grain and flour by insects and mites	456
Necessary proof of insect transmission or causation of disease, Pierce	456
Clean cultivation in relation to the control of insect nests King	456
Taxie action of volatile substances on insects Bertrand and Bosenblatt	456
The Pontetomoidea of Illinois with love to the Nearchie genera Hart	456
The function paragita of the pariodical sized a Spara	456
The head log hand her	450
The best lear hopper: A report on its occurrence in Contonna, severing	450
The fear hoppers of the genus Gypona north of Mexico, Gloson	400
Report on supposed cure for frognoppers, withams	400
Species list of Aphidide and their food plants, wilson and vickery	456
Fighting the walnut aphis, Hodgson	457
The Aphididæ of Lahore, Bashambar Das	457
Host list of fluted or cottony cushion scale, Merrill	457
The Coccidæ of southwestern United States, Ferris	457
Lice and their menace to man, Lloyd	457
An investigation of the louse problem, Moore and Hirschfelder	457
Anatomy, physiology, and biology of body louse, I, Sikora	458
Silk and silkworms in the Far East, Mr. and Mrs. Booth-Tucker	458
The peach twig borer (Anarsia lineatella), Merrill	458
Life history of oriental neach moth, Harukawa and Yagi	459
The rice moth Chittenden	459
The greenhouse leaf-typer ( <i>Phluctania ferrugalis</i> ) Gibson	460
Lasd arsonata · Effectiveness of different brands Terry and Schlupp	460
A microlanidontaren injurious to avocado Busch	460
<i>Calcelia ocallatella</i> a now onewy of the boot in Italy dol Cuoraio	460
Distribution of fortail midge in Donmark and its docting Dostrun	400
On the biology of M Indian in Sumatra, Schüffnar et al.	400
Unter photogy of <i>M</i> . <i>tuatowi</i> in Sumatra, Schuling et al.	400
Note on the hight of mosquitoes through norizontal water pipes, King	401
Synopsis of the economic Syrphidae of Japan, Matsumura and Adachi	461
New species of the economic Syrphide of Japan, Matsumura	461
Biology of Dermatobia hominis in all stages, Neiva and Gomes	461
Anthrax: Transmission of infection by nonbiting files, Morris	461
Compsilura concinnata, parasite of gipsy and brown-tail moths, Culver	461
Cane borer parasite work in 1919, Holloway	462
Sugar cane and hardback grubs in Antigua, Ballou	462
Wireworm control, a method practiced by Japanese growers, Treherne	462
Extermination of cotton boll weevil, Ransdell	463
Shot-hole borer (Xyleborus fornicatus), Speyer	463
Langstroth on the hive and honeybee, Dadant	463
Beginnings in heekeeping, Alexander	463
Report of the Illinois State Beekeepers' Association, Stone	463
Commercial comb honey production. Demuth	463
Isle of Wight disease in hive bees, Rennie and Harvey	463
Foul brood, Kindig	462
Edema of the evelids caused by ants Chambers and Marshall	462
New Chaleidide Malanotti	469
Descriptions of four new parasitie Hymonoptore Debuen	403
The life history of a call mite on Nonhrolania history at a Giaconha and	403
Acarida (mitoa) in stored grain and four Newstood and Dur-	403
The amount of food actor by the grider (Anguer and Duvall	463
Aconthecenhole from the Illinois Dinon Ven Glear	463
Studion on the paparita of the termiter, Van Cleave	464
Studies on the parasites of the termites, 1-1V, Korold and Swezy	464

#### FOODS-HUMAN NUTRITION.

The zinc content of some food products, Birckner	464
Zinc in oysters, Hiltner and Wichmann	464

Page

	Page.
The normal existence of zinc in the human organism, Ghigliotto	465
The nutritive value of yeast protein, Osborne and Mendel	465
Is lactalbumin a complete protein for growth? Emmett and Luros	465

## EXPERIMENT STATION RECORD.

Vol. 41.

**OCTOBER**, 1919.

No. 5.

Looking backward is not necessarily an unprofitable procedure. Especially is this true when progress seems slow and difficulties are disturbing, as sometimes appears to be the case in agricultural investigation. In such a mood, as well as at other times, a review of the toil and travail through which a strong and prosperous research institution has been developed may be well worth while.

Opportunity for such a retrospect has recently been afforded by an article entitled Beginnings of Agricultural Education and Research in California. This article was prepared as a contribution to the recent Semicentennial of the University of California, and is embodied in the latest report of the California Experiment Station. Its author is Prof. E. J. Wickson, emeritus professor of horticulture, who has been connected with the College of Agriculture and Experiment Station for thirty-eight years and who was its dean and director for seven years. Thus it contains a fund of first-hand and authoritative information regarding the early days of the institution, and which, true to the author, is set forth in a graphic and entertaining way.

Although one of the newer States in point of settlement, California was among the first to manifest an interest in agricultural education and research. The promotion of agricultural improvement was specifically included as a legislative function in the constitution of 1849, under which the State was admitted to the Union. Efforts to establish an agricultural college began soon afterwards. A speaker at the State Fair in 1857, after citing what had already been done in Michigan and Wisconsin, declared that "there is tenfold greater necessity for an agricultural school here. Although agriculture has been successfully pursued here for the last four or five years, yet farming has hitherto been a matter of experiment and must continue so for many years to come. We have a different climate, a different soil, and different modes of culture must be adopted from what we have hitherto been accustomed to. The farmer has everything to learn. The books treating of agriculture written in the older States or in England are to him of little account, and notwithstanding all the knowledge and experience acquired by him elsewhere, he finds himself a novice here, ... We want then an agricultural college."

Two years later another writer advocated an institution for the collection and experimental trial of fruits and other plants. This

work, he maintained, "can only be done by legislative endowment, which, by the judicious expenditure of public funds, receives back the evidence of its enlightened stewardship by the prosperity of the people thus promoted."

Efforts to establish an experimental farm under powers granted in 1854 to the State Agricultural Society, and by another society to operate a garden near Sonoma for plant introduction and propagation, had already proved abortive. So also did attempts to provide an agricultural college until 1868. In that year a merger was effected of a proposed "Agricultural, Mining, and Mechanical Arts College," chartered two years previously, with the College of California to constitute the University of California and to receive the Federal land-grant under the Morrill Act of 1862.

Organization of agricultural instruction at the university began with the appointment in 1869 of a "professor of agriculture, chemistry, agricultural and applied chemistry, and horticulture." The first building to be erected by the university was denominated the "college of agriculture," and announcement was made in 1870 of the purpose of the institution "to furnish the facilities for all needful experiments; to be the 'station' where tests can be made of whatever claims attention; to become the exponent and repository of our progressive knowledge."

Despite this auspicious beginning Professor Wickson records many discouragements and setbacks. The "college of agriculture" building was, upon completion, largely preempted by the scientific departments, the library, and certain administrative offices of the university, leaving to the agricultural work for several years only half of the basement. Not until 1889 did the department really have an instruction building of its own, and this a \$16,000 frame structure, supplemented by numerous other small buildings which from time to time had become available through abandonment for other purposes.

Similarly for many years no land was available for the professor of agriculture, who at the outset, we are told, was not "permitted to plant a tree or make a single experiment on the grounds of the university, either in agriculture or horticulture." After the appointment as professor of agriculture of Dr. E. W. Hilgard in 1874 this condition was to some extent remedied, yet the lack of adequate farm facilities up to the purchase and development of the 779-acre university farm at Davis constituted a most serious handicap for over thirty years to both education and research in agriculture.

Notwithstanding these obstacles and others which are feelingly described, an experiment station was established by the board of regents in 1873. Dr. Hilgard was appointed its director in 1874, and in the following year he began the first field experiments, a comparison of deep with shallow plowing for grain growing and long-con-

402

tinued tests of various fertilizers. In the same year a laboratory for work in agricultural chemistry was equipped, funds of \$250 a year for two years being allotted by the board of regents. At the end of this time, the legislature took up the matter and provided for the continuation and some extension of the work by special and varying appropriations from year to year.

Once experimental work was under way, the large area of the State, coupled with its great diversity of agricultural conditions and interests, made quite difficult the concentration of such restricted resources as were available. As Professor Wickson states, "there was such a pressure toward diversified knowledge that the experiment station was actually not allowed to classify, correlate, and discriminate, but was forced to take up a bargain-counter business, by research into foreign records, by local observation, and by current experimentation, which would supply each of a throng of patrons with the particular goods which he conceived to be desirable to him. The California Station, therefore, laid out little work from its own reasonable conception of what it should do to erect a system of agriculture locally desirable, as many other State stations had plenty of chance to do. In California it was from the beginning merely a question of doing as much as possible of what the public demanded, and this has been its main problem to the present day."

One result of the pressure for local experiments, however, elementary, was the splitting up of the Hatch funds when these became available through the establishment and maintenance of four "outlying culture stations" distributed through the State. The history of these substations is recounted in the article under the suggestive heading of "ships that passed in the night." Since these four substations, part of the operations of the central station, and the supervision of all of them were supported by the \$15,000 per year of the Hatch fund, it is easy to accept the statement that the financial stringency of the agricultural department of the university was in no way relieved by the Hatch appropriations.

The closing of the last of the quartet in 1909 after about a decade's operations terminated "the careers of this brood of outlying stations without mourners. Their chief crime was poverty, which restricted their undertakings, reduced their custodians to care-takers, and made it impossible to even aim at results of wide significance. And while they existed they prevented development of the central station from securing additional experts who were needed and from properly equipping such workers as were secured. Their chief contribution to the development of the department was the demonstration which they furnished of interest and activity of the institution in local problems, and this afterwards assisted in securing opportunities for more capable local undertakings." One useful sequence of the demand for local research facilities was the establishment in 1905 by the legislature of the Plant Disease Laboratory at Whittier. An even more important outcome was the Citrus Experiment Station at Riverside, subsequently expanded into the Southern California Graduate School of Semi-Tropical Agriculture and Citrus Experiment Station.

The only line of work which was "formally predestined for the California Station was, it appears, soil investigation and exposition." The fundamental studies of Dr. Hilgard and his associate Dr. Loughridge were summarized in these pages at the time of their retirement from active service in 1909<sup>1</sup>. Starting in 1877 with analyses of a few California soils the work was steadily continued and developed, embracing the first comprehensive soil survey in this country, the first systematic investigation of the alkaline soils of the Pacific slope, the classic researches of soil investigation of the utmost value.

Mention has already been made of the importance attached in the pioneer days to plant introduction and distribution. Despite the shortage of land a garden of economic plants was begun in 1879 and continued with some modifications until 1918, when its site was utilized for military purposes. This garden attracted much attention from visitors, and served as a source of supply for the annual distribution of seeds and plants for many years. Special attention was given to the testing of drought-resistant perennial forage plants, and much service was rendered in demonstrating the suitability of numerous species and the worthlessness of others. Another important phase was with cereals, including tests to demonstrate the possibility of growing in the State wheat rich in gluten. Other work had to do with forest trees, notably eucalyptus, some of these trials being conducted at the forestry substation established and maintained at Santa Monica.

As a specific illustration of the extent to which the policies of the station were shaped by insistent demand from the public rather than its own conception of what was fundamental and most widely useful, Professor Wickson cites the development of viticultural work from the standpoint of wine making. In 1875, soon after the opening of the station, wine analyses were begun. Field studies of the phylloxera were instituted the same year, and the work as a whole was so developed that from 1880 to 1895 the station publications on viticulture were almost equal in volume to those on all other subjects combined. A viticultural laboratory was definitely established in 1880, following State appropriations of \$3,000 per annum, a portion of the one-story university carpenter's shop being utilized for the purpose after a small cellar had been excavated for fermentation studies. In recent years attention has been concentrated more largely
upon the cultural phases of the industry and the protection of vines from insects and fungus diseases, much of this work being directly applicable to the table grape and raisin industry, and making the studies of the grape and its products among the most comprehensive undertaken anywhere.

Another popular demand led to extensive variety testing of olives and to a less degree of numerous other fruits. In 1893 no fewer than 1,158 varieties of tree fruits were under observation at Berkeley and the various substations. The results of these tests, however, were very disappointing as regards the discovery of improved sorts, and Professor Wickson concludes his summary of these tests as follows: "It seems, therefore, wise that the station investigators in more recent years have directed effort toward fundamental problems which are less susceptible of solution by practical experience than are the adaptability and serviceability of varieties. If it could have been foreseen thirty years ago that varietal effort should be directed toward securing the best forms and performances of varieties already demonstrated to be suitable, rather than to find substitutes for them, more profound horticultural philosophy would have been disclosed and greater public service rendered."

In entomology and plant pathology progress was retarded for many years by financial inability to provide specialists. For more than a decade the institution had no trained entomologist, and in 1891 when funds became available the selection of candidates was decided, we are told, by the fact that the successful aspirant had also listened to a lecture course on fungi and bacteria. None-theless, considerable had been accomplished along both these lines. Tests of Millardet's "copper-lime" fungicidal discovery (Bordeaux mixture) were undertaken in 1886. A year later analyses of insecticides were made and warnings given as to adulterations; spraying for codling moth under California conditions was done; and the feasibility of hydrocyanic acid gas for the fumigation of citrus trees was demonstrated. Numerous more technical investigations were begun as State funds became available. In 1907 the plant pathologist who came to California alone four years previously had twelve field and laboratory assistants, with two laboratories in Southern California as well as laboratory headquarters at the college.

Although there was little popular interest in fertilizers for many years, analyses were begun in 1877. Fertilizer control legislation was advocated in 1877, and after long agitation a law requiring labeling to show both the content and source of the material was enacted in 1903. This law not only accomplished its primary purpose, but proved of much assistance to the station as a source of revenue, which was still sorely needed.

Research in animal industry was practically precluded by the lack of a station farm and other facilities until the acquisition of the university farm at Davis in 1905. Analyses of feeding stuffs, however, were begun as early as 1882. The first feeding experiment, a test of beet pulp for dairy cows, was made in 1901. At the solicitation of poultry farmers, a special appropriation for poultry research was granted in 1903 and work begun in poultry diseases, feeding problems, and the like. At about the same date a discarded horse shed was remodelled into a veterinary laboratory, and considerable attention began to be given to hog cholera control and other animal diseases.

Special mention should also be made of the study on human foods, first undertaken in 1895. In 1900 the station became one of the group cooperating with the nutrition investigations of the U. S. Department of Agriculture, studying particularly the nutritive value of fruits and nuts. Many interesting and valuable results were secured from this work, but as Professor Wickson states, "perhaps the difficulties under which these elaborate studies were pursued is the most interesting academic aspect of them. These may be indicated by the fact that the work was done in the only places which could then be found for it, viz: a corner of the main laboratory, a corner of an abandoned boiler shop, and a corner of an attic lighted by a small skylight, but it proved to be work done in a corner proclaimed from a house top, and its influence has been very great and wide-reaching in promotion of wholesome living and the recognition of the food value of California fruit products."

The summary here given of Professor Wickson's article is necessarily much abbreviated, with no attempt to present a complete review of the station's accomplishments. The aim has been rather to bring out some of the difficulties under which the work was conducted in the pioneer days, and especially the fact that these handicaps were not allowed to dishearten or continue insuperable. Inadequate funds, lack of buildings and equipment, popular pressure for immediate results, however localized and ephemeral their value, these have unfortunately been all too common in the history of most of the stations, but the experience of California is a concrete illustration that slowly but none the less surely progress can be made.

In that State, the total income of the station of \$250 in 1874 has grown to over \$200,000 a year. The basement rooms have given place to stately buildings, extensive experimental fields, and a score or more of well-equipped laboratories, representing a permanent investment of more than a million dollars. The staff has increased from a fraction of the director's time to a corps of upwards of a hundred specialists and other trained workers. An extended list of projects is under way, and the fruits of many are being widely applied. The confidence of the State has long since been gained, and the position of the station within its field has become one of unquestioned leadership. These are a few of the inspiring facts to be gleaned from Professor Wickson's interesting narrative.

# **RECENT WORK IN AGRICULTURAL SCIENCE.**

## AGRICULTURAL CHEMISTRY-AGROTECHNY.

An introduction to the study of biological chemistry, S. B. SCHRYVER (London: T. C. & E. C. Jack, Ltd. [1918], pp. 340, figs. 26).—This volume, which is designed particularly for students of medicine and biology, deals primarily with the structure of materials of which the bodies of living objects are composed. The subject matter includes chapters on the general scope of biochemical study; the identification and analysis of organic compounds; the "constitution," or "structure," of some of the simpler organic compounds; stereoisomerism; the chief chemical constituents of the animal body; the methods employed for investigation of chemical changes within the animal organism; and the chemical processes taking place in plants.

The chemical examination of three species of larkspurs, O. A. BEATH (Wyoming Sta. Bul. 120 (1919), pp. 55–88, figs. 16).—This bulletin gives a preliminary and general report of a chemical investigation of three species of larkspurs, Delphinium barbeyi, D. glaucescens, and D. geyeri, with a view to determining the nature of the poisonous principles and their variation in kind and amount in the different species and at different periods of growth. The subject matter is divided into four parts. Part 1 contains a general discussion based upon the literature of the distribution and toxicity of larkspurs, cattle losses from larkspur, and the characteristic symptoms of larkspur poisoning. Part 2 deals with the experimental methods employed in the chemical investigation, part 3, with the chemical analysis of the three varieties studied, and part 4, with the treatment for larkspur poisoning as outlined in U. S. Department of Agriculture Bulletin 365 (E. S. R., 35, p. 779).

In the preliminary examination of the larkspurs, the green plants were macerated with water and the extracts tested for their toxicological value by administration to rabbits through a stomach tube. The toxic substances proved to be alkaloidal and capable of being extracted completely with water, indicating their occurrence in the plant in the form of water-soluble salts. Extracts from the leaves of *D. geycri* and *D. barbeyi* were more active than those from the stems and flowers, and those from immature plants of these species from three to four times more effective than those prepared from a similar quantity of mature plants. No fatalities resulted from the extracts of *D. glaucescens* nor from extracts prepared from plants in the seeding stage of any of the species. Repeated administration of the poison did not produce immunity in rabbits.

For the separation and determination of the alkaloids, the three species, with the exception of *D. geyeri*, were employed at three periods of growth immature, mature, and seeding stages. The material was air-dried and reduced to a uniform powder, percolated with alcohol, the percolate concentrated, extracted with water, acidified, clarified by filtration and by the use of animal charcoal and potassium sulphocyanid, made alkaline with ammonium hydroxid, and the alkaloids finally extracted with chloroform. The customary separation of the alkaloidal constituents by the use of immiscible solvents was employed.

140363°-19-2

The results obtained with *D. barbeyi* indicate that three distinct amorphous alkaloids are present throughout the life of the plant, and that one crystalline alkaloid exists in the free state during the early stages of growth. The principal poison from the standpoint of activity is an amorphous alkaloid precipitated from acidulated solutions by ammonium hydroxid and hydrolyzed by alcoholic potassium hydroxid into simpler derivatives. Plants at the flowering stage were found to contain more of this poison than the undeveloped plants.

Front the leaves and stems of *D. geyeri* three alkaloids were isolated, one amorphous and two crystalline. The amorphous alkaloid corresponded in its physical and chemical properties to the principal alkaloid isolated from *D. barbeyi*, but yielded a different crystalline base on hydrolysis and appeared to be of somewhat milder toxicity. The crystalline alkaloids did not resemble that of *D. barbeyi*.

In *D. glaucescens* the number and form of the alkaloids remained uniform throughout the life of the plant, and differed in quantity only in the different parts of the plant. These consisted of one crystalline and one amorphous fornf. The amorphous alkaloid was insoluble in water, not precipitated by ammonium hydroxid, and was decomposed on hydrolysis into nonalkaloidal substances. This would seem to have some bearing on the fact that *D. glaucescens* is much less poisonous than the other species studied.

"From a chemical point of view, therefore, the three species vary in many respects. Important plant products, not mentioned in this preliminary bulletin, have been isolated and examined which add further evidence to the statement that there is a specific difference involved in the three species."

Composition of the fruit of Cicer arietinum, A. ZLATAROFF (ZLATAROW) (Ztschr. Untersuch. Nahr. u. Genussmtl., 31 (1916), No. 6, pp. 180–183; abs. in Chem. Abs., 11 (1917), No. 17, p. 2512).—This investigation completes the study of C. arietinum (chick-pea) previously noted by Zlatarow and Stoikow (E. S. R., 30, p. 558).

The composition of the chick-pea calculated on a dry basis was as follows: Ash 2.87 per cent, fat 6.3, starch 50.32, crude fiber 3.62, total N 3.34, protein N 2.11, nuclein N 0.10, ammonia N 0.10, amid N 0.01, amino acid N 0.12, peptone N 0.007, N by difference 0.797, total  $P_2O_5$  0.998, lecithin  $P_2O_5$  0.142, protein  $P_2O_5$ 0.486, inorganic  $P_2O_5$  0.118, and soluble organic  $P_2O_5$  0.244 per cent.

Soft corn: Its chemical composition and nitrogen distribution, G. SPITZER, R. H. CARR, and W. F. EPPLE (*Jour. Amer. Chem. Soc.*, 41 (1919), No. 8, pp. 1212– 1221, figs. 2).—This investigation, reported from the Purdue Experiment Station, was undertaken to determine the composition of soft corn and the nature of its proteins and to secure data on which qualitative classification can be made as to the maturity of corn. Three series of samples were used, one series selected because of the extreme softness of the corn and its failure to germinate, another representing more mature corn capable of germinating, and a third an intermediate grade.

The analytical data presented include a table showing the comparative composition of normal corn and of the three series studied. The principal differences in composition as brought out by this table are as follows:

The total nitrogen of soft corn is only slightly lower than that of mature corn, but the amid nitrogen is nfuch higher. Zein is present in smaller amounts in soft than in mature corn, while the other proteins are present in about the same amounts in both. This is thought to indicate that zein is formed last and that amid is formed at the expense of zein. The acid-hydrolyzed proteins do not differ significantly in the different grades of corn. The percentages of 1919]

normal starch and nitrogen-free extract appear to be higher and the fat lower in soft than in mature corn.

As a basis for grading corn for feeding purposes, the authors recommend the determination of antid nitrogen together with the degree of acidity. The calorific determination is considered to be of little value.

**Ilex vomitoria as a native source of caffein**, F. B. POWER and V. K. CHESNUT (*Jour. Amer. Chem. Soc.*, 41 (1919), No. 8, pp. 1307–1312, pl. 1).—The authors have applied the method noted on page 412 to a systematic examination of representative samples of *I. vomitoria* and of other American species of Ilex for the purpose of determining their availability as a commercial source of caffein.

It was found that an abundant source of caffein is available in *I. vomitoria*, but that no other North American species of Ilex appears to contain caffein. It is also not found in the leaves of the European holly (*I. aquifolium*).

Isolation of the iodin compound which occurs in the thyroid, I, E. C. KEN-DALL (Jour. Biol. Chem., 39 (1919), No. 1, pp. 125-147, figs. 2).—The author describes in detail the investigations of the chemical constituents of the thyroid gland leading up to the isolation of thyroxin, the iodin-containing compound to which the activity of the gland is ascribed. A discussion is included of the various conditions which influence the isolation of thyroxin in pure crystalline form.

Previous reports on this subject have been noted from other sources (E. S. R., 39, p. 803).

The catalytic decomposition of hydrogen peroxid, G. PHRAGMÉN (Meddel. K. Vetensk. Akad. Nobelinst., 5 (1919), No. 22, pp. 13, figs. 5).—The decomposition of hydrogen peroxid in alkaline solutions is shown to depend upon some catalyzer present either in the solution or in the glass of the apparatus employed. The extent of decomposition of hydrogen peroxid by living yeast cells was found to depend upon the amount of the yeast and, to a less extent, upon the H-ion concentration.

Catalase action in yeast cells, H. VON EULER and R. BLIX (*Meddel. K. Vetensk. Akad. Nobelinst.*, 5 (1919), No. 23, pp. 26, figs. 2).—The catalase action in yeast cells is shown to be increased about 6 times by the addition of a small amount of protoplasma poison such as toluol or chloroform, from 10 to 15 times by drying the cells in air in such a way that the enzym is not destroyed, and from 20 to 25 times by heating an emulsion of the fresh yeast for from one to two hours at a temperature of from 55 to 63° C.

Studies of the concentration of catalase in urine, chyme, and feces, A. V. S. NORGAARD (*Jour. Biol. Chem.*, 38 (1919), No. 3, pp. 501-514, figs. 3).—This paper describes methods of estimating catalase in urine, chyme, and feces, and discusses the interpretation of results from a chemical standpoint. The pyometer, or apparatus for measurement of oxygen, which is used by the author in catalase determinations is described and illustrated.

Action of enzyms upon starches of different origin, H. C. SHERMAN, F. WALKER, and M. L. CALDWELL (Jour. Amer. Chem. Soc., 41 (1919), No. 7, pp. 1123-1129).—This paper reports the results of a comparative study of the hydrolysis products of various purified starches as brought about by the action of different purified enzyms. The investigation included experiments upon the hydrolysis of wheat, maize, rice, and potato starches by means of saliva, pancreatin, purified pancreatic amylase, malt extract, purified malt amylase, takadiastase, and purified amylase of Aspergillus oryzæ. The general plan was to purify the starches in four different ways: (1) Washing with water only, (2) with very dilute alkali, (3) with ether after washing with water, and (4) with

ns were allowed to act upon a 1 per

[Vol. 41

ether after washing with alkali. The enzyms were allowed to act upon a 1 per cent dispersion of the boiled starch for 30 minutes at  $40^{\circ}$  C., using such an amount of the enzym solution as would result in the formation of about one-third to one-half of the theoretically possible amount of maltose, and finally determining the reducing sugar formed by titration against Fehling's solution. The results, which are expressed in tabular form in percentage of starch digested in 30 minutes, may be summarized as follows:

When similarly purified by washing with a very dilute alkali, wheat, maize, and rice starches were all transformed into reducing sugar at essentially the same rate whatever the digestive agent. When washed with water only, potato starch was almost pure, but the cereal starches appeared to contain sufficient amounts of fatty or waxy matter to interfere appreciably with the action of the enzyms. This was true to a greater extent of the maize than of the wheat starch, a result which emphasizes "the importance of such preparation of maize products as shall insure their very thorough mastication and admixture with saliva." The removal of the fatty matter by ether tended to increase the rapidity of digestion of the cereal starches, but not always to the same extent as purification with dilute alkali.

The rate of enzymic hydrolysis of potato starch was in general equal to or slightly greater than that of the cereal starches. This is in agreement with preliminary results obtained in the same laboratory by K. Hattori in a study of the comparative rate of hydrolysis of rice and potato starches by means of saliva. A slightly higher yield of reducing sugar was obtained from the potato than from the rice starch, the difference increasing gradually with the extent of digestion.

The growth of certain bacteria in media of different hydrogen-ion concentrations, B. COHEN and W. M. CLARK (*Jour. Bact.*, 4 (1919), No. 4, pp. 409-427, figs. 4).—An investigation of the influence of pH upon rates of growth of bacteria during that period in the life history of a bacterial culture commonly known as the period of logarithmic increase is reported from the Bureau of Animal Industry, U. S. Department of Agriculture. The results obtained are summarized as follows:

"There is a broad zone of pH within which the rates of growth are quite uniform for those short periods during which the increase of viable cells approaches the logarithmic rate. On the borders of these zones of pH slight change in the pH produces a marked effect upon reproduction. The acid border shifts with the nature of the acid. A distinct difference between the effect of hydrochloric and that of acetic acid was noted. While no distinct optimum reaction was found when only the logarithmic increase was considered, more distinct optima appear when longer periods of growth are observed. The period of 'lag' is more pronounced in alkaline than in acid media. Evidence is presented which suggests that the effect of pH upon specific fermentative processes, upon reproduction in its several stages, and upon rates of death must be kept distinct."

The use of coal as a substitute for talcum to induce rapid boiling, E. C. KENDALL (Jour. Amer. Chem. Soc., 41 (1919), No. 8, pp. 1189, 1190).—Anthracite coal has been found to be an ideal agent for bringing about the rapid boiling of a solution and for preventing bumping in Kjeldahl flasks and in the distillation of organic liquids. One or two pieces about 1 cc. in size are considered better than many smaller pieces. The coal becomes less active after being kept under water for some time, but can be reactivated by heating in an oven.

The use of turpentine resin in turpentine as a foam breaker, E. C. KENDALL (*Jour. Biol. Chem.*, 38 (1919), No. 3, p. 529).—The author has found that from 1 to 2 cc. of a 20 per cent solution of resin in turpentine is very efficient as a

foam breaker for use in the rapid aeration of blood and other fluids and is much cheaper than caprylic or amyl alcohol. If the resin solution is not neutral to alizarin, either N/10 sodium hydroxid or sulphuric acid should be added to exact neutralization.

The rapid estimation of perchlorates, alone, or in the presence of chlorates and chlorids, J. G. WILLIAMS (*Chem. News*, 119 (1919), No. 3090, p. 8).—The method described is based on the oxidation of titanous chlorid by perchlorates in the presence of sulphuric acid and the estimation of the oxidation by titration of the cooled solution with ferric alum solution, using as an indicator two or three drops of a 10 per cent solution of potassium thiocyanid. The method is said to give a good degree of accuracy and to be much more rapid than the fusion method.

A method for the volumetric estimation of sulphates, A. C. D. RIVETT (*Chem. News, 118 (1919), No. 3085, pp. 253, 254).*—The method depends upon the fact that moist precipitated barium oxalate reacts quantitatively with soluble sulphates of certain metals to give barium sulphate and the soluble oxalates of these metals. The latter may be titrated in the filtrate with potassium permanganate.

Tables are given showing the percentage error under different conditions, from which the following limitations of the method are deduced: "It is inapplicable in acid solutions, and can not be used to determine sulphates of metals forming insoluble oxalates or sulphates in presence of salts containing radicals capable of forming insoluble barium salts. The presence of halids is objectionable in preventing accurate titrations with permangante. There will, however, be many works solutions to which the method may be applied with accuracy and considerable saving of time."

The determination of phosphoric oxid, particularly in fertilizers, soil extracts, and the like, B. DE C. MARCHAND (So. African Jour. Sci., 15 (1919), No. 5, pp. 357-363).—The method described, which is attributed to H. J. Vipond, is a combination of von Lorenz's method of precipitation for ammonium phosphomolybdate (E. S. R., 13, p. 14) and Pemberton's volumetric method for the determination of the precipitate (E. S. R., 5, p. 444).

Analytical data are presented from which the factor for conversion of cubic centimeters of N/10 sodium hydroxid to grams of phosphoric oxid has been found to be 0.000284 instead of 0.0003089 as used by Pemberton.

The volumetric method is recommended for soil extracts and plant ashes, and is thought to be capable of greater accuracy than methods such as that of Neubauer (E. S. R., 17, p. 731), in which the phosphoric oxid is weighed as magnesium pyrophosphate.

A note by B. J. Smit on the recovery of ammonium molybdate from the residues from the above method is appended.

The determination of total nitrogen in soils containing rather large amounts of nitrates, R. S. SNYDER (Soil Sci., 6 (1918), No. 6, pp. 487-490).— Determinations by various methods of the total nitrogen in soils containing large amounts of nitrates, in soils originally containing no nitrates but to which known amounts had been added, and in soils very low in organic carbon, are reported. From the analytical data presented the following conclusions are drawn:

"Many soils have a high nitrate content (up to 10 per cent of the total nitrogen) and the recovery of this nitrate is necessary in total nitrogen determinations. If the organic matter of the soil is within the usual average (0.8 to 3 per cent), it is not necessary to use the modified methods for total nitrogen, the common unmodified methods (Hibbard or mercury) giving quite as accurate results. Methods for total nitrogen, modified to include the nitrogen of nitrates,

1919]

must be employed, however, if the soils are lower than 0.5 to 0.6 per cent of organic carbon."

Aids to the analysis of food and drugs, C. G. MOOR and W. PARTRIDGE (London: Baillière, Tindall & Cox, 1918, 4. ed., pp. XI+268).—This book contains in compact form information dealing with the analysis of foods, the more common drugs, disinfectants, and soaps. In this fourth edition the subject matter has been revised, and several new sections have been added. An appendix enumerates the alterations in the composition of food and drugs in England necessitated by the war.

An improved method for the quantitative determination of caffein in vegetable material, F. B. POWER and V. K. CHESNUT (*Jour. Amer. Chem. Soc.*, 41 (1919), No. 8, pp. 1298–1306).—Inaccuracies in previous methods of determining caffein are pointed out, and an improved method developed at the Bureau of Chemistry, U. S. Department of Agriculture, is described and its accuracy indicated by control experiments. The essential features of the method, the technique for which is described in full, consist in the extraction of the caffein by hot alcohol, treatment of the extract after evaporation of the alcohol with magnesium oxid to liberate the caffein from its combinations and to remove the tannin and other acidic substances from solution, hydrolysis of the hot water extract of the above acidified with 10 per cent sulphuric acid to decompose saponins, and finally extraction of the acid filtrate with six successive portions of chloroform and recovery of the caffein by distillation of the chloroform after the addition of a 1 per cent solution of potassium hydroxid to remove coloring matter.

The method is said to give results in close agreement with those obtained by the U. S. Pharmacopæia method of assay, and to possess some advantages over that officially adopted.

Analytical data are presented on the yields of caffein by the gravimetric method and as calculated from nitrogen determinations in samples of tea, coffee, coffee leaves and pulp, and guarana. The pulp of the coffee berry yielded about 0.89 per cent of caffein, an amount which is thought to render its utilization for the production of caffein worthy of consideration in view of the large amounts of material available.

Process for the estimation of butter fat, coconut fat, palm kernel fat and their mixtures, S. H. BLICHFELDT (Jour. Soc. Chem. Indus., 38 (1919), No. 11, pp. 150T-152T, fig. 1).—Certain alterations in the previously noted process for estimating butter and coconut fats in margarin (E. S. R., 24, p. 213) are described, and analytical results obtained by the method at different laboratories are reported. The development of the process and some of the analytical data supplied are attributed to P. S. Arup.

The iodin value (Wijs) of palm kernel oil, R. H. ELLIS and E. M. HALL (*Jour. Soc. Chem. Indus., 38 (1919), No. 10, p. 128T*).—Tables are given of the maximum, minimum, and mean values for the iodin number (Wijs) of a large number of samples of both crude and refined palm kernel oil, obtained by expression from kernels crushed in the mills under ordinary works conditions.

The mean iodin value of the expressed oil was in every case outside the range of the values usually given in standard texts. The authors conclude that the normal range of iodin value (Wijs) is from 16 to 23, and that any oil giving a value outside this range would be of doubtful purity.

The cuprous chlorid-iodin method for reducing sugars simplified, F. M. SCALES (*Jour. Indus. and Engin. Chem.*, 11 (1919), No. 8, pp. 747-750).—Certain improvements in procedure in Clark's modification (E. S. R., 40, p. 114) of the author's earlier method (E. S. R., 34, p. 611) for determining reducing sugars are described which are said to simplify the method and render it more accurate,

the ratio of reducing sugar to thiosulphate not varying as in the Clark modification.

The principal change is the use of dilute acetic acid to acidify the solution after the precipitation of the cuprous oxid. As this has no effect upon cuprous oxid, a known excess of iodin may be added and the cuprous oxid then dissolved by the addition of a very small quantity of hydrochloric acid. The cuprous chlorid formed is immediately acted upon by the iodin, and consequently no precautions against oxidation by the air are necessary. As soon as the cuprous oxid has been entirely dissolved by the hydrochloric acid the excess of iodin is titrated with thiosulphate, using starch as an indicator.

The method may be used for any reducing sugars.

A note on the determination of the inorganic constituents of blood and other physiological material, I. GREENWALD (Jour. Biol. Chem., 38 (1919), No. 3, pp. 439, 440).—The author calls attention to the method previously described incidentally (E. S. R., 35, p. 714) of separating the organic constituents of the blood from the inorganic by precipitation with picric acid. With blood it is considered advisable to dilute to almost 10 volumes with water, add 1 per cent of acetic, hydrochloric, or sulphuric acid, saturate with picric acid, and then dilute to an exact multiple. After standing a few minutes the mixture can be filtered and measured portions of the protein-free filtrate taken for the analyses.

A table is given of the values obtained by the author with this method for the sodium, potassium, calcium, and "acid-soluble" phosphorus of dog blood and serum.

Determination of ammonia in the blood, S. MORGULIS and H. M. JAHB (Jour. Biol. Chem., 38 (1919), No. 3, pp. 435-438).—The essential features of the method described consist in precipitating the blood proteins with *m*-phosphoric acid as soon as the blood is taken (to prevent the splitting off of ammonia), adding a known amount of standard ammonium sulphate to the blood filtrate to increase the ammonia content sufficiently to make it possible to examine the color produced by the nesslerization without changing the colorimeter, and absorbing the ammonia by permutit, which does away with the necessity of driving off the ammonia by aeration. The control is made with Ringer's solution, to which the same reagents are added in equivalent amounts. The technique of the method is described in detail, and a series of determinations of ammonia in the blood of normal individuals is given.

Note on the Lewis-Benedict method of blood sugar determination, S. MOR-GULIS and H. M. JAHR (*Jour. Biol. Chem.*, 39 (1919), No. 1, pp. 119–123).—Data are presented which show that the presence of creatinin increases the blood sugar value as determined by the Lewis-Benedict method. Concentrations of less than 2 mg. of creatinin per 100 cc. were found to have no effect upon the accuracy of the reaction, but with greater concentration the error in the sugar analysis increased progressively. The method is therefore considered by the authors to be without value in the sugar analysis of blood containing more than 3 mg. of creatinin per cubic centimeter.

A method for determination of minute amounts of lead in urine, feces, and tissues, W. DENIS and A. S. MINOT (*Jour. Biol. Chem.*, 38 (1919), No. 3, pp. 449-452).—The process, which is described in detail, "consists essentially in the removal of most of the organic matter by fusion with sodium nitrate, the precipitation of the lead as sulphid, its electrolytic deposition as lead peroxid, and the titration of the iodin liberated from potassium iodid when the lead peroxid deposit is treated with dilute acid."

The authors have been able to recover by this method lead added to urine, feces, and tissues in amounts varying from 0.5 to 4 mg. to the average extent of 95 per cent of the amount added.

A revised colorimetric method for determination of uric acid in urine, O. FOLIN and H. WU (*Jour. Biol. Chem.*, 38 (1919), No. 3, pp. 459, 460).—The method is essentially the same as that described in a method for determining uric acid in blood (E. S. R., 41, p. 13). The preparation of solutions required and the technique of the method are described in full.

A simplified macro-Kjeldahl method for urine, O. FOLIN and L. E. WRIGHT (*Jour. Biol. Chem.*, 38 (1919), No. 3, pp. 461-464, fig. 1).—A simplified macro-Kjeldahl method for the determination of nitrogen in urine is described, which requires very little equipment and by means of which it is stated that a urinary nitrogen determination can be finished in from 20 to 25 minutes. The technique is as follows:

To 5 cc. of undiluted urine in a 300 cc. Kjeldahl flask are added 5 cc. of the phosphoric-sulphuric acid mixture previously described in connection with the micromethod (E. S. R., 41, p. 13), 2 cc. of 10 per cent ferric chlorid solution, and from 4 to 6 small pebbles. The mixture is boiled vigorously for 3 or 4 minutes over a microburner until dense white fumes appear. The mouth of the flask is covered with a small watch glass, and the heating continued vigorously for 2 minutes and gently for 2 minutes longer. The flame is removed and the flask cooled for not more than 5 minutes, after which 50 cc. of water and then 15 cc. of saturated sodium hydroxid are added, and the flask is connected promptly by means of a rubber stopper and ordinary glass tubing with a receiver containing from 35 to 75 cc. of N/10 acid, a drop or two of alizarin red, and water to make a total volume of 150 cc. The flask is again boiled for 4 or 5 minutes, after which the contents of the receiver are titrated to a faint red without cooling.

It is stated that the simplified distillation process is applicable to other determinations involving the removal of ammonia. The destructive digestion process is not applicable to highly resistant material, such as milk or urines containing much sugar, unless fuming sulphuric acid be used in place of the ordinary acid.

Vinegar making from apples, S. F. ANDERSON (*Jour. Agr.* [*New Zeal.*], 18 (1919), No. 4, pp. 218–220, figs. 2).—Directions are given for making cider vinegar on a small scale. The author recommends for final clarification treatment with isinglass, whites of eggs, or Spanish clay, and filtration through flannel.

A fermentation process for the production of acetone and ethyl alcohol, J. H. NORTHEOP, L. H. ASHE, and R. R. MORGAN (*Jour. Indus. and Engin. Chem.*, 11 (1919), No. 8, pp. 723–727, figs. 2).—The method described, which is protected by U. S. Patent 1,293,172 dedicated to public use, consists of the fermentation of a dilute solution of molasses with the production of ethyl alcohol and acetone by means of a culture of an organism to which the name *Bacillus acetoethylicum* has been given. The general characteristics of the organism, together with the optimum conditions for its growth, are summarized and the details of the process of fermentation described.

The optimum H-ion concentration was found to be from pH 8 to pH 6, which could be maintained by the addition of lime to the fresh mash. The fermentation when conducted on an experimental scale was complete in from 50 to 60 hours, with a yield of from 8 to 8.5 per cent of the sugar as acetone, and from 20 to 21 per cent of alcohol, mostly ethyl, but with traces of propyl and butyl alcohols. The fermentation may be made continuous in a fermenting tank filled with some inert substance, such as coke or beech shavings covered with a culture of the organism, by adding the fresh mash at the bottom and allowing the fermented mash to run off at the top.

Biochemistry of Bacillus acetoethylicum with reference to the formation of acetone, J. H. NORTHROP, L. H. ASHE, and J. K. SENIOR (*Jour. Biol. Chem.*, 39 (1919), No. 1, pp. 1-21, fig. 1).—The biochemical studies leading to the development of the process noted above are described in detail.

The production of acetone and butyl alcohol by a bacteriological process, H. B. SPEAKMAN (Jour. Soc. Chem. Indus., 38 (1919), No. 12, pp. 155T-161T, figs. 7).—This paper deals with the production on a factory scale of acetone and butyl alcohol by the bacterial fermentation of a concentrated corn mash.

Contribution to the bacteriology and technology of the preservation of meat, A. Kossowicz and R. NASSAU (Wiener Tierärztl. Monatsschr., 3 (1916), No. 3, pp. 81-102, figs. 2; abs. in Chem. Abs., 11 (1917), No. 17, pp. 2508, 2509).— This is a discussion of the methods of canning meat commonly employed in Germany and of the causes of spoilage in the canned products.

*Proteus vulgare* and *Bacillus putrificus* are the two organisms considered by the authors to be the most important causes of spoilage. Perfect sterilization of the cans is said to be attained with a temperature of approximately 120° C. for 60 minutes.

Studies on the preparation of vegetable decolorizing carbons for the cane sugar industry, F. W. ZERBAN, E. C. FREELAND, and D. D. SULLIVANT (*Louisiana Stas. Bul. 167* (1919), pp. 44).—The investigation reported in this bulletin comprised three phases: The preparation of decolorizing carbons from organic materials by impregnation with mineral substances and a comparative study of the resulting efficiency; the preparation of decolorizing carbons from materials impregnated by nature or by some manufacturing process; and the preparation of carbons from by-products and similar materials.

For the first study, the raw material generally employed was the sawdust of long-leaf yellow pine (Pinus palustris) and the impregnating material, welldefined chemical compounds—acids, bases, halids, and other salts. A definite amount of the sawdust was mixed with the different impregnating compounds in chemically equivalent quantities and subjected to similar methods of treatment, involving a final heating for two hours in a mufile furnace at about 900° C. After leaching with suitable solvents and washing with dilute hydrochloric acid and finally with water, the resulting carbon was dried at 105°. The decolorizing effect for sugar products of the carbons thus prepared was determined by adding 5 gm. of the carbon to 200 cc. of a standard molasses solution containing 30 gm. per liter of a final molasses. The mixture was brought to the boiling point, filtered through a folded filter, and the color determined by the use of the tint-photometer as described in a previous bulletin (E. S. R., 41, p. 203). The efficiency of each carbon was calculated from the color remaining in the treated solution in terms of Norit used as a standard. From the results of the impregnation tests, which are given in tabular form, the following conclusions may be drawn:

Organic nitrogen added to or present in the raw material increases the decolorizing power of the resulting carbon. Materials which are either gaseous or solid at the temperature of final heating produce effective carbons, while those which are liquid give poor ones. Compounds which attack carbohydrates most vigorously give effective carbons if liquids are not formed at the temperature of final heating. The fineness of division of both raw material and impregnating substance has a favorable effect on the resulting carbon. The decolorizing power of the carbon increases directly with the quantity of impregnating substance used per unit of raw material. The method of preliminary carbonization and the temperature of final heating influence the decolorizing power of the carbon. The first heating should be conducted in such a way that the

1919]

fumes evolved escape freely, and within certain limits the higher the temperature of final heating the greater the decolorizing effect of the resulting carbon.

In the second investigation, various plant materials high in ash were used for the preparation of decolorizing carbons with a view to the discovery of some cheap raw material for the production of effective carbon on a commercial scale. Of the materials examined, two were thought to be promising for commercial use—rice hulls and Pacific const kelp. The most efficient methods for preparing these are described in detail. The former under the process finally adopted yields a carbon of a decolorizing power of 145 in percentage of Norit, and the latter of over 300.

The by-products and similar materials employed in the last part of the investigation included bagasse, filter press cake, impregnated molasses carbon, and a mixture of a black vegetable mold and finely divided calcium carbonate which occur in consecutive strata in some districts in Porto Rico. While not possessing the high efficiency of the carbon noted above, some of these materials would seem to offer cheaper sources of carbons greatly superior to bone black in decolorizing power.

The deterioration of cane sugar by fungi, N. and L. KOPELOFF (*Louisiana Stas. Bul. 166* (1919), pp. 3-72, figs. 3).—This bulletin contains a survey of the fungus flora of the different types of cane sugar and the results of an investigation of the deterioration of cane sugar by fungi in pure culture, and of the presence of these organisms in the different stages of sugar manufacture.

Various media and a wide range of cane sugars were used for the isolation of the fungi. Czapek's agar was found to have the greatest relative efficiency of all the media studied for isolating a variety of fungi. A modification by the authors of this medium resulted in a more rapid colony development. This modification consisted in increasing the sucrose content from 30 to 50 gm. per liter and substituting 5 gm. of peptone and 1 gm. of ammonium nitrate for 2 gm. of sodium nitrate in the original formula.

The fungi isolated belonged chiefly to the Aspergilli and Penicillia. Aspergillus niger and a blue Aspergillus occurred in practically all samples. The latter, which appeared with the greatest frequency in all sugars, also had the greatest deteriorative power. Sterilized sugars inoculated with pure cultures of fungi deteriorated rapidly when the moisture content was appreciable, but only very slightly, if at all, when the moisture content was reduced to a minimum. Slight evidence of deterioration occurred in plantation granulated sugar with a factor of safety of 0.1 and in Cuban raw sugar with a factor of 0.2, which would indicate that the factor of safety for sugars infected with fungi is lower than generally supposed. The fungi spores were found to contain invertase and consequently to be responsible for the inversion of sucrose.

A daily bacteriological and mycological examination of each stage in the process of sugar manufacture showed that fungi and bacteria were found in greatest numbers in the raw juice. The clarification process served to sterilize the juice but reinfection took place in the massecuite in and about the centrifugal.

As practical deductions from this study the authors emphasize the importance (1) of reducing the moisture content of the sugar as much as possible and avoiding the subsequent access of moisture, and (2) of using every precaution to prevent reinfection of the massecuite after it leaves the vacuum pans. Suggestions are given for improvements in factory conditions and for proper methods for the handling and storage of the sugar after it leaves the centrifugal.

A list of 46 references to the literature is included.

An improvement in casein making, J. L. SAMMIS (Jour. Indus. and Engin. Chem., 11 (1919), No. 8, pp. 764–767).—As the result of a study of the causes of lack of uniformity in casein as it comes from the creamery, with resulting irregularity in the finished glue, revised directions for making casein are suggested.

The principal changes in method recommended are heating the skim milk to 95° F. instead of to a higher temperature, adding the dilute sulphuric acid slowly with vigorous stirring until a clear whey is obtained (avoiding excess of acid), and washing the resulting curd with water at 95° equal in volume to one-fourth the volume of the milk used.

Revised directions, suitable for the use of casein makers, are given in full. Agricultural industries, F. WILBRANDS, edited by H. SIATS (Lehre von den Landwirtschaftlichen Gewerben. Hildesheim: August Lax, 1917, 7. ed., pp. VII+79, figs. 32).—The industries treated in the seventh edition of this handbook are starch manufacture, sugar manufacture, and the brewing and distilling industries.

### METEOROLOGY.

The larger relations of climate and crops in the United States, R. DEC. WARD (Quart. Jour. Roy. Met. Soc. [London], 45 (1919), Nos. 189, pp. 1-19, fig. 1; 190, p. 146; abs. in U. S. Mo. Weather Rev., 47 (1919), No. 4, pp. 238-240, fig. 1).—The various factors controlling the geographical distribution of staple crops and certain agricultural operations in the United States are briefly noted, the fundamental importance of climate being especially emphasized. The article is based largely upon information drawn from Geography of the World's Agriculture (E. S. R., 38, p. 895), and on the work of J. Warren Smith, Kincer, Reed, and others. The broad climatic characteristics of the agricultural provinces of the United States, proposed by M. Smith et al. (E. S. R., 35, p. 191), are described, and the specific climatic requirements of corn, wheat, oats, barley, and rye; cotton; hay, forage, and pasture; tobacco; citrus and other fruits; and potatoes and other truck crops, are discussed in some detail, as are the climatic conditions controlling live stock production, dairying, dry farming, irrigation, and forest growth. There is also a brief note on the relation of agricultural prosperity to the general welfare.

**Report** of the chief of the Weather Bureau, 1918 (U. S. Dept. Agr., Weather Bur. Rpt. 1918, pp. 292, pls. 7).—This report contains, as usual, a review of the work of the Weather Bureau during the year with special reference, however, to war conditions and service. It is noted that the activities of the division of agricultural meteorology "have been continued, improved, extended, and given specially direct application as far as possible to all agricultural activities of the Nation." This division "has continued its study of the relation between weather and climate and crops. Data have been collected and tabulated and results obtained which are proving of marked advantage to agriculture."

There are also included in this report a general summary of the weather conditions in the United States during the year 1917, with charts, a list of observing stations and changes therein during 1917, and records of sunshine and details of excessive precipitation during that year.

Monthly Weather Review (U. S. Mo. Weather Rev., 47 (1919), Nos. 3, pp. 143-204, pls. 16, figs. 14; 4, pp. 205-278, pls. 16, figs. 16).—In addition to special forecasts and warnings, river and flood observations, notes on the effect of weather on crops, halo phenomena, and seismological reports for March and April, 1919; lists of additions to the Weather Bureau Library and of recent papers on meteorology and seismology; notes on the weather of the months; solar and sky radiation measurements at Washington, D. C., during March and

April, 1919; condensed climatological summaries, and the usual climatological tables and charts, these numbers contain the following articles:

No. 3.—Convectional Clouds Induced by Forest Fires (illus.), by F. A. Carpenter; Notes on a Cumulus Cloud Formed over a Fire, by C. A. Reichelt; Rain from Cumulus Clouds over Fires (illus.), by J. P. Espy (extracts); Heights of Cumulus Clouds Forming over Fires (illus.), by S. P. Fergusson and C. F. Brooks; Results of Observations of Clouds during the Solar Eclipse, June 8, 1918 (illus.), by S. Loveland; Tornado in Southern Alabama, March 5, 1919 (illus.), by P. H. Smyth; The Larger Relations of Climate and Crops in the United States (illus.), by R. DeC. Ward (Abs.) (see p. 417); Minimum Temperatures Sustained by Apricots during March, 1919, in the Pecos Valley, N. Mex., by C. Hallenbeck (see p. 444); The Meteorological Activities of the Late Prof. Edward C. Pickering, by R. DeC. Ward; Walter Gould Davis, by R. DeC. Ward; and Measurements of the Solar Constant of Radiation at Calama, Chile, by C. G. Abbot.

Climatological data for the United States by sections (U. S. Dept. Agr., Weather Bur. Climat. Data, 6 (1919), Nos. 3, pp. [212], pls. 4, figs. 2; 4, pp. [209], pls. 4, figs. 2).—These volumes contain brief summaries and detailed tabular statements of climatological data for each State for March and April, 1919, respectively.

The rainfall of France, E. MATHIAS (Ann. Chim. et Phys., 9. ser., 12 (1919), Mar.-Apr., pp. 109-244).—The rainfall data for eight different zones of France are summarized and analyzed along the lines indicated in an article previously noted (E. S. R., 41, p. 119), that is, with special reference to the influence of altitude and latitude. The general conclusion reached is that within wide limits (the area of France, for example) the coefficient of altitude is constant along a given parallel of latitude, regardless of variations in the surface of the soil.

#### SOILS-FERTILIZERS.

Soils and soil cultivation, F. D. GARDNER (*Philadelphia: John C. Winston Co., 1918, pp. 223, pls. 3, figs. 101*).—This book is designed "to be a handy reference work on soils, their classification and treatment, and the proper adaptation of crops, with a view to preserving and increasing the fertility of the soil and producing the largest yield in point of quality. . . .

"Not only are directions given for the management of the soil, but the best types of farm buildings and equipment are fully described and illustrated, including farm machinery of the latest type, farm sanitation, drainage, and irrigation."

Soil survey of Caldwell County, N. C., W. B. COBB and S. F. DAVIDSON (U. S. Dept. Agr., Adv. Sheets Field Oper. Bur. Soils, 1917, pp. 29, fig. 1, map 1).—This survey, made in cooperation with the North Carolina Department of Agriculture, deals with the soils of an area of 327,680 acres situated in the northwestern part of the State. The topography of the northern two-thirds of the county is described as mountainous, and that of the southern third undulating to rolling. Natural drainage is well established.

The soils of the area are included in the Piedmont Plateau, the Appalachian Mountains, and the River Flood Plains provinces. The Piedmont soils have been derived largely from granite, gneiss, and schist, and the mountain soils chiefly from Carolina gneiss. The alluvial soils include both first-bottom and terrace material. In addition to rough, stony land, 13 soil types representing 8 series are mapped. Porters loam, Ashe loam, and Cecil clay loam, occupying 34.9, 19.6, and 15.9 per cent of the total area, respectively, predominate.

Pleistocene and recent deposits in the vicinity of Ottawa, with a description of the soils, W. A. JOHNSTON (*Canada Dept. Mines, Geol. Survey Mem.* 101 (1917), pp. II+69, pls. 2, figs. 7).—This report deals with the geology and soils of an area of 419 square miles along the Ottawa River and within the St. Lawrence drainage basin. The soils of the area are as a whole somewhat calcareous and are of glacial and marine origin. They are light to medium dark in color.

"The 'lightest' soils of the district are the æolian, river gravel, and beach soils. They occupy small areas and, on account of the relief of the surface and open porous character of much of the material, tend to be excessively drained and are easily affected by drought in dry seasons. The marine fine sand is also a light soil and has a loose porous structure, but on account of its nearly level or gently sloping surface and finer texture is not so easily affected by drought. The 'heaviest' soils of the area are the marine clay and clay loam soils. The soils intermediate between the light and heavy soils are the marine fine sandy loam soil and the glacial soils, of which the most important is the gravelly fine sandy loam. These soils are also of considerable extent."

The marine soils, including fine sand, fine sandy loam, clay loam, and clay, are the most extensive, covering over 60 per cent of the land of the area.

**Pyrolusite from Virginia**, T. L. WATSON and E. T. WHEREY (*Jour. Wash.* Acad. Sci., 8 (1918), No. 16, pp. 550–560, fig. 1).—This is a report of a study of the geology and mineralogy of manganese oxid crystals and crystalline minerals from the Virginia locality.

The comparative rate of formation of soluble material in cropped and virgin soils as measured by the freezing-point method, C. E. MILLAR (Soil Sci., 7 (1919), No. 4, pp. 253–257, figs. 2).—Tests conducted at the Michigan Experiment Station are reported in which 6 different soils in cropped and virgin condition were washed with distilled water until the concentration of the soil solution was reduced to only a few parts per million, and the effect of such treatment measured on the subsequent rate of formation of soluble material as determined by the freezing-point method. Soils 1 and 2 were silt loams relatively deficient in organic matter, 3 and 4 were lowland soils containing considerable organic matter, 5 was a sand soil, and 6 a very fine sandy loam.

It was found that the tendency for the concentration of the soil solution to reach a maximum and decrease before the end of the 40-day period was practically overcome by the washing. Some tendency for the concentration to decrease was exhibited by the virgin sample of soil 1 and by both the cropped and virgin samples of soil 4. The changes, however, were not sufficient to affect the conclusions. Nos. 1, 2, and 5 showed a decidedly greater rate of formation of soluble material in the virgin than in the cropped samples. In addition, the total concentration of the soil solution was much higher in the case of the virgin samples.

Of the remaining soils, Nos. 3 and 4 showed very little difference in either the rate of formation of soluble material or the total concentration of soil solution attained. These two soils showed very little change in productivity as a result of several years' cultivation. Soil 6 showed only a slightly greater rate of formation of soluble material in the virgin than in the cropped sample, the final concentration of soil solution being virtually the same.

The author feels justified in suggesting that "a marked decrease in the rate of formation of soluble material is one of the changes a soil may undergo as a result of several years of cultivation with the return of little fertilizing material."

Changes in composition of the soil and of the water extract of the soil, following addition of manure, P. L. HIBBARD (Soil Sci., 7 (1919), No. 4, pp. 259-272, figs. 3).—In experiments at the University of California, fresh manure was mixed with silty clay loam and sandy loam soils at rates of 1, 2, and 5 per cent and the mixtures kept in loosely covered glass jars under optimum moisture conditions.

Periodic analyses showed that the carbon dioxid content of the soil atmosphere was increased in proportion to the amounts of manure added, while the total carbon content gradually decreased, such decrease being more rapid for the larger amounts of manure. The total nitrogen content remained constant.

The total water-soluble matter decreased within a few weeks in the 1 per cent mixture to below that of the control soil, after which it gradually increased to considerably more than that in the control soil, but never to an amount equal to the sum of that in the control soil and that in the added manure. The 2 and 5 per cent manure mixtures showed relatively greater decreases and increases.

The changes were not relatively the same for the different ions and complexes. In the soil extract there was less change in calcium and magnesium than in potassium, sulphates, and nitrates. The nitrates at first quickly disappeared and later increased considerably over the amounts in the control. These changes are attributed to biochemical action. It is concluded that "when fresh manure is mixed with soil the resulting reaction decreases the amount of water-soluble plant food, so that crops started at that time might be retarded or at least not immediately benefited by the manure. When the manure becomes well decomposed, it adds materially to available plant food. Consequently, fresh manure should not be added to **a** soil just previous to or during the time a crop is growing.

"If the soil is kept sufficiently open to the air, there should be no loss of nitrogen due to the addition of manure. Liberation of large amounts of  $CO_2$  in the soil by rotting manure does not always greatly influence the composition of the water extract of the soil."

"Increase in water-soluble mineral matter after the addition of manure to soil can be accounted for largely by that derived from the mineral matter of the manure itself."

**Parallel formation of carbon dioxid, ammonia, and nitrate in soil, P. L.** GAINEY (Soil Sci., 7 (1919), No. 4, pp. 293-311, figs. 8).—Studies of the parallel formation of carbon dioxid, ammonia, and nitrate in a silt loam soil, conducted at the Kansas Experiment Station, are reported.

It was found that "there is a remarkable similarity and agreement between the several carbon dioxid and ammonia curves when constructed from data secured under anything like similar conditions. If conditions are favorable for bacterial activity and cottonseed meal is added there is at first a very rapid formation of carbon dioxid and ammonia, the maximum being reached during the second 24 hours. After this the formation of both carbon dioxid and ammonia decreased rapidly, the curves soon tending toward straight lines. When dried blood was added to the soil the curves for both carbon dioxid and ammonia were different. Formation during the first four days was very slow, the maximum being reached between the sixth and eighth.day analyses. The formation of carbon dioxid from dried blood was never so rapid as from cottonseed meal...

"Insufficient moisture retards both carbon dioxid and ammonia formation, the latter much more markedly. The minimum moisture for active carbon-dioxid production is lower than for active ammonia production. For the soil used ...12 cc. of water per 100 gm. soil was near the minimum for vigorous carbon dioxid production, and increasing the moisture beyond this point had little effect upon the formation of carbon dioxid. A moisture content below this results in a lowered carbon dioxid production. The moisture necessary for optimum ammonia formation is higher than that for carbon dioxid.

"Insufficient aeration will also cause a depression or marked delay in carbon dioxid and ammonia production... In no instance where the current of air was not continuous was the production of carbon dioxid and ammonia equally as rapid as where it was. In the case of carbon dioxid it appears to be simply a delayed production, the total quantity soon reaching that produced where aeration was abundant. The total ammonia produced under limited aeration did not, in most instances, reach the production where aeration was abundant. So long as the current of air was continuous, increasing the volume apparently had no effect...

"Nitrate production in all experiments was for some unknown reason exceptionally low for this particular soil. As a rule there was no accumulation during the first few days. In fact, the small quantity of nitrate nitrogen initially present usually disappeared completely before the first analysis. Where aeration was insufficient, the beginning of accumulation was delayed still more. Where the moisture content was varied, nitrate accumulation was directly proportional to moisture content; the maximum not being reached until the maximum moisture that would be retained was reached. Where aeration was varied, insufficient aeration retarded the initial accumulation, but after nitrification became active in all samples the accumulation was inversely proportional to aeration."

Capillary moisture-holding capacity, W. GARDNER (Soil Sci., 7 (1919), No. 4, pp. 319-324, fig. 1).—The author reviews and analyzes the work of others bearing on the subject, and is of the opinion that the dynamic character of typical soil moisture phenomena can not be overlooked in the attempt to define such a constant as moisture capacity. "In order to make postitive progress from a scientific as well as practical point of view, it would seem that fundamental concepts of this character should be carefully considered." A laboratory study of the dynamic phases of soil moisture is in progress at the Utah Experiment Station.

On the penetration of the periodic temperature waves into a substance having no uniform constitution especially into the soil, K. AICHI ( $T\delta ky\delta S \hat{u}g$ . But. Kizi [Proc.  $T\delta ky\delta$  Math. Phys. Soc.], 2. ser., 9 (1918), No. 22, pp. 527-541).— This is an intricate mathematical analysis of the subject, made in conjunction with actual temperature measurements in Japanese soils and in snow. It is shown that elaborate calculations, for example, by the use of the method of least squares, do not give sufficiently accurate information on which to base discussion of underground temperatures as compared with actual observations.

The effect of certain colloidal substances on the growth of wheat seedlings, D. S. JENNINGS (Soil Sci., 7 (1919), No. 3, pp. 201-215).—Experiments at the Utah Experiment Station with a complete nutrient solution, agar, silica, sand, ferric hydroxid, and aluminum hydroxid cultures with wheat are reported. The purpose was to determine whether or not the change in concentration due to solid adsorbing surfaces is sufficient to modify the production of dry matter in a plant.

It was found that "the effect of adding agar to nutrient solutions was to increase the growth of wheat seedlings in low concentrations and to decrease the growth in higher concentrations of nutrient salts. The introduction of colloidal silica into nutrient solutions resulted in increased weight of wheat seedlings. The increase was apparently due to direct absorption of silica by the plant and not to a change in the effective concentration of the nutrient solution. Silica gel is, therefore, considered unsuited for studies of the character described in this paper. The introduction of quartz sand, ferric hydroxid, and aluminum hydroxid into nutrient solutions resulted in decreased growth of wheat seedlings. It appears that these substances by their absorptive properties reduce the effective concentration of the nutrient solution."

The influence of kind of soil and fertilization on nitrogen and ash content of crops, J. G. MASCHHAUPT (Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefstat. [Netherlands], No. 22 (1918), pp. 25-114, fig. 1).—Continuing experiments previously noted (E. S. R., 28, p. 520), plat experiments with heather, moor, swamp, loam, and clay soils to determine the effect of the kind of soil and the fertilizers sodium nitrate, potassium nitrate, and ammonium sulphate on the contents of nitrogen and ash in barley, rye, beets, oats, and potatoes are reported.

A smaller increase in crops was obtained with potassium nitrate than with sodium nitrate on these soils. The influence of the kind of soil was greater with straw and beet and potato leaves than with grain or roots, and was greatest in the silica content of straw. The average silica content of straw from clay soils was five times that of straw from heather soils. There was no comparative effect on the content of bases. The composition of beet and potato leaves was more strongly affected by the kind of soil than was the composition of straw, with special reference to nitrogen, potash, phosphoric acid, and lime. The kind of fertilizer had no marked influence upon the nitrogen and ash content of crops on these soils.

The acid constituents were influenced more than the basic constituents by both agencies.

The abnormality of soils in field-placed cylinder experiments, C. A. MODERS (Soil Sci., 7 (1919), No. 4, pp. 247-251).—In soil nitrogen studies at the Tennessee Experiment Station five different kinds of soil, when placed in cylinders sunk in the ground and exposed otherwise to natural conditions, were found to become unproductive to the extent of complete crop failure in the course of from three to eight years, except where limed.

Annual addition of acid phosphate, potassium chlorid, and sodium nitrate had little or no effect in preventing crop failure. Barnyard manure applied at the outset in moderate and even large amounts delayed crop failure only a year or two in most cases. The only unusual condition apparent was the projection of the cylinder rims for 2 to 3 in. above the soil surface, thereby preventing all run-off of water in times of heavy rainfall. The increased moisture supply and the excessive leaching were assumed to reduce the natural soil supply of calcium bicarbonate until it became the limiting factor in crop production and finally induced crop failure. The evidence also indicated an increased loss of nitrogen and uncertainty with regard to the phosphorus and potassium, the availability of which may have been increased. It is suggested that usual field conditions may be approached by providing each cylinder with an adjustable vertical slot, providing either a constant outlet or permitting run-off only at certain times of the year at the discretion of the operator.

Mining and manufacture of fertilizing materials and their relation to soils, S. L. LLOYD (New York: D. Van Nostrand Co., 1918, pp. VI+153, figs. 9).—This book is intended for fertilizer manufacturers, agricultural chemists, and farmers desiring advanced knowledge in agricultural chemistry, and deals essentially with the manufacture and mixing of commercial fertilizers from the standpoint of their practical use. A discussion of the chemistry of fertilizers and soils and of their relation is followed by a description of phosphate mining and manufacturing practice, nitrogen fixation, the mining and manufacture of nitrogenous and potassic fertilizers, and the mixing of compound fertilizers.

With reference to the fertilizers resulting from the fixation of atmospheric nitrogen the author summarizes experimental work with the statements that "calcium cyanamid neither suits humic acid soils, peaty soils, nor light sandy soils. On the other hand, it may be used in all loamy soils of average fertility. ... The action of cyanamid is weaker than nitrate of soda; it is also slower than the latter. But as the unit nitrogen is supplied cheaper by the new manure, a greater amount can be used to restore the balance.... According to the experiment made, this manure succeeds very well on clay soils, but less so in sandy soils....

"Nitrate of lime acts normally up to the second application in loamy soil and up to the third in sandy soil; but beyond that there is an injurious action, especially in loamy soils. The high percentage of basic nitrate of lime and the still higher percentage of nitrate of lime produce injurious effects.

"Nitrate of soda, Chile saltpeter, and sulphate of ammonia have regularly produced higher yields and better utilization of the nitrogen than cyanamid."

Two final chapters are included on the examination of fertilizers and fertilizing materials and on the examination of soils.

140363°-19-3

Farm manure, H. M. NAGANT (*Min. Agr. Prov. Quebec Bul. 53* (1918), pp. 29, figs. 8).—This bulletin deals with the composition, fertilizing value, and conservation of barnyard manure, with special reference to conditions in the Province of Quebec. The use of manure pits is specially discussed.

The world's supply of nitrogenous fertilizers, G. W. ANDERSON (*Chem. News*, 119 (1919), No. 3090, pp. 6, 7).—This is a review of the nitrogen resources of the world, from which it is concluded that the production of nitrogenous products in Germany has been greatly promoted during the war and that in consequence a strong competition may be expected. Data are reported to show that there is a considerable excess of production over the probable consumption based on prewar estimates.

"Although the cost of production has gone up considerably, German manufacturers were able to write-off their plant during the war, and thus have the great advantage of low capital costs. This, together with the present favorable rate of exchange for exports, places the German trader in an advantageous position."

War-time production of nitrogen compounds in Germany, BUEB (Jour. Gasbeleucht., 62 (1919), pp. 2, 3; abs. in Jour. Soc. Chem. Indus., 38 (1919), No. 7, pp. 219A, 220A).—It is stated that the prewar production of nitrogen compounds in Germany was in excess of the requirements, but production was insufficient after war began and imports of Chilean nitrate ceased. Ammonia from coal distillation furnished about one-third of the amount required. New plants for the production of cyanamid were started but not completed. and effort was concentrated on the development of existing plants. The synthesis of ammonia by the Haber process was found to be the most economical in labor and fuel, and the process was put into successful operation at two places. The catalytic process for producing ammonia was widely used, the end product being sodium nitrate. As a result of the exigencies of war the supply of nitrogen fertilizers was cut down one-half. It is anticipated that under normal peace conditions synthetic products in combination with potash will suffice to make Gemany independent of imported nitrogen compounds.

Comparative fertilizer experiments with new nitrogenous fertilizers, SCHNEIDEWIND (Bl. Zuckerrübenbau, 26 (1919), No. 3-4, pp. 28, 29).—Comparative top-dressing experiments with sugar beets on a loess loam soil rich in organic matter are reported, in which it was found that potash ammonium nitrate gave as good results as sodium nitrate when used in an equal amount, while ammonium nitrate gave better results than ammonium sulphate but not so good results as sodium nitrate. The differences were not large. Ammonium chlorid gave as good results as ammonium sulphate.

Further experiments in which lime nitrogen was added before planting, added one-half as top-dressing and one-half drilled in after planting, and added one-half as top dressing and one-half broadcast after planting, showed that the addition before planting yielded the best results.

Comparative test of several nitrogenous fertilizers, BACHELIER (Compt. Rend. Acad. Agr. France, 5 (1919), No. 5, pp. 164–170; abs. in Chem. Abs., 13 (1919), No. 10, p. 1115).—Ammonium nitrate was compared with ammonium sulphate and sodium nitrate in field experiments with sugar beets. As good results per unit of nitrogen were obtained with the ammonium nitrate as with the other substances used.

Field experiments with nitrate of ammonia, J. HENDRICK (*Jour. Soc. Chem. Indus.*, 37 (1918), No. 8, pp. 146R-148R).—Field experiments with hay and oats on several different soils, conducted by the North of Scotland Agricultural College to compare ammonium nitrate with sodium nitrate, ammonium sul-

phate, calcium nitrate, and commercial calcium cyanamid as a source of nitrogen, are reported.

It was found as a general result of these experiments that "nitrate of ammonia may be expected to give, at least as great increases of crop, weight for weight of nitrogen, as any of the other concentrated nitrogenous manures in use."

Ammonium nitrate showed the best average results with both oats and hay. This result is considered unusual and possibly due to accidental causes. "If it is confirmed that nitrogen in nitrate of ammonia is more effective as a fertilizer than an equal weight of nitrogen in nitrate of soda, nitrate of lime, or sulphate of ammonia, it will be necessary to seek for an explanation of such an unexpected result."

The setting of mixtures of superphosphate and ammonium sulphate, F. S. FOWWEATHER (Jour. Soc. Chem. Indus., 38 (1919), No. 9, pp. 110R-112R).—Experiments to determine the conditions that influence the setting into hard lumps of mixtures of ammonium sulphate with superphosphate are reported, in which mixtures of superphosphate, containing about 30 per cent soluble phosphate and ammonium sulphate, were placed under a heavy weight to bring the particles into intimate contact.

The conclusions drawn are that the rate of setting of such mixtures is increased by the reduction of free acid in the mixture. "The presence of moisture also tends to increase the rate of setting, but this effect is not very marked unless accompanied at the same time by reduction of free acid."

A large scale test confirmed the above conclusions. "Thus a compound fertilizer made from fairly fresh mineral superphosphate and ammonium sulphate to which a small amount of limestone was added set very considerably when stored in a heap for a few days, and after regrinding and putting into bags, no further trouble was experienced as regards setting."

Phosphate demonstration in Stevens County in 1918, P. R. McMILLER, P. E. MILLER, and G. H. NESOM (Univ. Minn. Agr. Ext. Div. Spec. Bul. 34 (1919), pp. 7, figs. 2).—Cooperative field experiments with acid phosphate on 25 farms in the county are reported in which the phosphate was added to fields ranging in size from 1 to 30 acres at the rate of 200 lbs. per acre. The soil in general is a black silt loam with silt loam subsoil. Of the 14 farmers who tried the phosphate on wheat nearly all secured a marked increase, ranging from 2.1 to as high as 10.5 bu. per acre. No increase was obtained with acid phosphate on oats, but there was an increase in six cases out of seven with barley.

"No heavy investments in phosphate are suggested, but the results of the experimental work in Stevens County to date make it appear a wise business measure for those farmers of Stevens and the immediately surrounding counties who have heavy soils on which some fields have received little or no manure, to apply on one of these half a ton or more of acid phosphate at the rate of 200 lbs. per acre, using wheat or barley as the trial crop and preferably seeding with clover."

The phosphate industry, J. HENDRICK (Jour. Soc. Chem. Indus., 38 (1919), No. 9, pp. 155R-157R).—The author discusses the phosphate industry throughout the world, with special reference to the United States and Great Britain, and reports the average results of 66 field experiments with turnips covering four years at the North of Scotland Agricultural College comparing soluble and insoluble phosphates.

"The general result of the experiments is to show (1) that the average effect of superphosphate is only slightly greater than that of insoluble phosphate, such as basic slag or ground mineral phosphate, when equal weights of phosphoric acid are applied, and (2) that if one-third of the phosphoric acid is given as soluble phosphate and the remainder as insoluble phosphate the average result is as good as when the whole of the phosphoric acid is given as soluble phosphate. Experiments with other crops and especially with grass give a similar result. The only conclusion one can come to is that soluble phosphate is overvalued, and insoluble phosphate, such as exists in basic slag and ground mineral phosphate, undervalued. It should be possible in future to use a large part of the rock phosphate in the form of finely ground powder instead of in superphosphate. This will effect a great saving in acid and in expense."

American potash, H. H. ROE (*Mining and Sci. Press*, 119 (1919), No. 6, pp. 195-202, figs. 11).—This is a summary of the various potash resources of the United States, from which it is concluded that this country has potash resources sufficient for future requirements but that the present supply will for some time to come be inadequate for the growing demand.

The Alsatian potash industry, F. K. CAMERON (Amer. Fert., 51 (1919), No. 4, pp. 49-54).—It is stated that the Alsatian potash deposits cover an area of about 77 square miles, and consist of a lower bed with an average thickness of 11.5 ft. and an upper bed with a thickness of about 4 ft. The cubical contents of the two layers are estimated at approximately 1,350,000,000 cu. yds., containing approximately 1,500,000,000 tons of salt, or roughly 275,000,000 tons of potash. The soluble salts of the deposits are potassium and sodium chlorid alone, and the average potash content is said to be at least 18 per cent as compared to 12 per cent for the Stassfurt salts.

While the industry is too young to give accurate cost figures, an approximate estimate indicates that for potassium chlorid averaging 18 and 45 per cent potash, respectively, the cost is \$11.00 and \$28.75 per ton.

Features of the mining and manufacturing processes are described.

The value of sodium when potassium is insufficient, B. L. HARTWELL and S. C. DAMON (*Rhode Island Sta. Bul. 177 (1919)*, pp. 4-32, fig. 1).—This bulletin reports the crop results for the period of 1905–1918, inclusive, of a series of field experiments begun in 1894 to ascertain the value of sodium as an entire or partial substitute for potassium and previously noted from time to time (E. S. R., 18, p. 1113; 21, p. 224; 29, p. 419). Sodium and potassium were applied in various amounts, both as carbonates and chlorids and in connection with different amounts of lime. Nitrogen and phosphorus were applied equally to all plats, usually in such amounts as to render potassium the only deficient element. The crop data are presented in tabular form, and include information on the effect of the different treatments upon flat turnips, radishes, rutabagas, table beets, cucumbers, buckwheat, cabbage, sugar beets, mangels, oats, hay, onions, carrots, rape, and potatoes. The results secured may be summarized as follows:

Where an insufficiency of potassium occurred, sodium was generally useful, confirming earlier work with water cultures of cereal seedlings, which likewise showed that when potassium was deficient sodium became beneficial. It was commonly observed that if in the absence of sodium a depression of 30 per cent in the growth of the seedlings was caused by partially withholding potassium, the growth was not depressed more than half as much in a similar culture to which sodium was added, indicating a direct beneficial action of sodium, for under the conditions of the experiment it could not liberate potassium. In the field, however, more potassium was removed in the larger crops which usually resulted when sodium was increased in connection with an insufficient amount of potassium, in spite of the fact that sodium frequently decreased the percentage of potassium in the crop. A portion of the benefits arising from the use of sodium in the field is, therefore, believed to be due to indirect action, although the culture solutions indicate that direct beneficial effects were also probably obtained in the field. The yield in grains due to sodium are deemed sufficient to merit careful consideration at the present time of the utilization of our liberal supply of sodium salts as economic supplements to a limited amount of potassium.

Relation of sulphates to plant growth and composition, H. G. MILLEE (Jour. Agr. Research [U. 8.], 17 (1919), No. 3, pp. 87-102, pls. 4).—In this contribution from the Oregon Experiment Station it is reported that "pot experiments to show the effect of sulphur fertilizers—namely, sodium sulphate, calcium sulphate, and sulphur on red clover, rape, and oats were carried on with three different soils, including one with a high sulphur content, one that did not respond to elemental sulphur in the field, and one that did.

"To eliminate the sulphur compounds acting upon the insoluble plant food and soil organisms these plants were also grown on sand receiving the sterilized soil extract, and certain pots received the additional sulphur fertilizers as the soil. Sodium sulphate and calcium sulphate were added daily in solution form. The elemental sulphur was mixed with the soil and calcium carbonate at the time of sowing the seed. Sodium nitrate solution was added daily to eliminate available nitrogen as a limiting factor of growth, and also to determine what effect sulphates would have on nitrogen assimilation by the plant. The plants were grown for two and one-half months, and the dry weights of the tops were recorded. The total sulphur and nitrogen was determined in the majority of cases.

"Addition of sulphate and elemental sulphur enhanced the growth of the plants grown in pots in the greenhouse. The corresponding increases obtained on the soil extracts indicated that sulphur acted directly in promoting this growth. The great increase in the nitrogen content of the clover grown on the soil where sulphates had been added is the result in all probability of the sulphates stimulating the action of the legume bacteria. Sulphates caused increased root development and number of nodules on the clover grown in the soil pots."

A list of references to literature on the subjct is given.

Available fertilizer from smelter by-products, P. J. O'GABA (*Proc. Wash. Irrig. Inst., 5* (1917), pp. 102-110).—Experiments on the effects of sulphur dioxid on alkali soil and on crops showed that "(1) the water solubility of the alkali was lowered; (2) there was a reduction in carbonate; (3) there was an increase in sulphate; (4) there was an increase in available potash; (5) crops fumigated daily throughout their period of growth with sulphur dioxid in concentrations just below the toxic limit...showed either a slight gain, or at least no loss in total vegetable matter produced, as compared with check plats grown under identical conditions but not treated with sulphur dioxid; (6) the sulphur content of the plants was increased."

Field experiments with field and truck crops in which elemental sulphur was added at the rate of 400 lbs. and sulphuric acid at the rate of 2,172 lbs. per acre showed that as compared with untreated soils in check plats, the water solubility of the alkali was reduced about 20 per cent, while the availability of potash and phosphorus were increased approximately 20 per cent. The treated soils showed an increase in sulphate content, a decrease in carbonate content, and an increase in all crops grown.

"One of the striking effects of sulphur and sulphuric acid treatment of soils on the soil microorganisms is the decided and consistent increase in total bacteria as determined by the plate method. Under certain conditions in a period of three weeks the sulphur and sulphuric-acid-treated plats showed 50 per cent more microorganisms than did the untreated checks. The sulphur plats in general showed a greater increase in the number of organisms than did the sulphuric-acid-treated soils . . . In general the sulphur-treated plats

[Vol. 41

showed a greater increase in total vegetable matter produced than did the sulphuric-acid-treated plats as compared with the checks."

"The results so far obtained lead to the general conclusion that sulphur and sulphuric acid have a decidedly beneficial effect upon the soil flora."

Lime requirements as determined by the plant and by the chemist, B. L. HARTWELL, F. R. PEMBER, and L. P. HOWARD (Soil Sci., 7 (1919), No. 4, pp. 279– 282).—Experiments conducted at the Rhode Island Experiment Station are reported in which surface soil, described in a previous and related report (E. S. R., 32, p. 622), was limed in amounts varying from 378 to 4,000 lbs. of calcium oxid per acre and planted to beets and lettuce. The basic nutrients were brought to optimum. The lime requirement of the soil was determined by the ammonia and Veitch methods before planting.

It was found that "in general after maximum crops had been attained by liming the soil still showed a lime requirement of about 5,000 lbs. In fact, the lettuce, although a crop which is very sensitive to 'soil acidity,' was depressed in growth when an application equivalent to 4,000 lbs. of calcium oxid was made to the limed nitrate of soda soil, and the subsequent lime requirements thereby reduced to 2,800. A carbon-dioxid determination made in this soil showed that not more than about 10 per cent of the added lime remained in carbonate at the end of the experiment... The limed nitrate-of-soda soil had a lime requirement of 3,700 by the ammonia method, and yet not much advantage was derived from liming. When about this amount was added for lettuce there was less crop than where smaller amounts were used. And yet the Veitch method yielded even higher results than the ammonia method."

It is thought that the "elimination of the effect of the aluminum in acid soils seems likely to prove of more importance than the neutralization of the acidity, and attention should be given to methods of determining active aluminum while developing those for soil acidity."

An artificial fertilizer, A. GAUTIER and P. CLAUSMANN (Sci. Amer. Sup. 88 (1919), No. 2275, p. 95).—Pot experiments with plants grown on (1) a charcoal soil to which no fluorin had been added, (2) an artificially fluorated charcoal soil, and (3) ordinary garden soil showed that "of 12 species cultivated under similar conditions but with the addition or nonaddition of fluorid, the influence of the fluorin was favorable to 7 (cress, cabbage, California poppy, spinach, viper's bugloss, spurrey, and hemp); exerted no effect upon 3 (convolvulus, onion, and rye); while it produced inferior crops in 3 (sweet peas, chick-peas and centaury)."

These results are not considered entirely conclusive owing to the small size of the experiment and to the fact that potassium fluorid was used. Field experiments using other fluorids are to be reported later.

Fertilizers in Cochin China, P. BUSSY (Bul. Agr. Inst. Sci. Saigon [Cochin China], 1 (1919), No. 2, pp. 40-51).—The author discusses the fertilizers of animal, vegetable, and mineral origin which are adapted for use in Cochin China from the standpoint of availability, and gives analyses of some of the more important types, including fish waste, oil cake, bone meal, green manure, stable manure, bat guano, natural phosphate, and the common nitrogenous and potassic mineral fertilizers.

## AGRICULTURAL BOTANY.

The biological normal spectrum, C. RAUNKLÆR (K. Danske Vidensk. Selsk., Biol. Meddel., 1 (1918), No. 4, pp. 17).—This is an attempt to express mathematically the net results of conditions affecting the attainment of stability in the make-up of the biological complex in any given region, and to obtain comparable expressions for the results of climatic and other factors as recorded in the life forms developing in any locality under natural conditions.

Statistical studies on vegetative formations, C. RAUNKLER (K. Danske Vidensk. Selsk., Biol. Meddel., 1 (1918), No. 3, pp. 80).—This contribution employs the term formation (for a fundamental unit to be used as a basis for classification and discussion of vegetations) in a way to correspond somewhat to the term species in classification of individual plants. It defines the term as a growth somewhat homogeneous as regards its composition and general character determined by the conditions of the environment, being a biological expression of such conditions. Several main sections deal with the degree of frequency of species as applied to floristic characterization of plant formations, the law of distribution of frequencies, utilization of the degree of frequency as a biological characteristic of formations, and the degree of covering of the soil by species as applied to physiognomic characterization of formations.

The theory of limiting factors, W. H. BROWN (*Philippine Jour. Sci., Sect. C,* 13 (1918), No. 6, pp. 345-351, fig. 1).—This is a critical review of Blackman's theory of limiting factors (E. S. R., 18, p. 923; 24, p. 533) and of facts and views contributed by other authors.

The origination of ascidia under quasi-experimental conditions, F. E. LLOYD (*Proc. and Trans. Roy. Soc. Canada, 3. ser., 11 (1917), Sect. IV, pp. 71-80, figs.* 4).—The author describes the results of abnormal development in a large number of seedlings of *Gossypium herbaceum*, supposedly due to the mechanical pressure resulting from disharmonious growth. The plants were allowed to grow for over a year in 3-in. pots, during much of which time they were either dormant or growing under higher temperatures or more abundant watering than usual, finally settling down to a balance of activities scarcely sufficient to keep them alive. Such buds and shoots as formed were highly abnormal as regards form, the leaves produced remaining juvenile in character. It appears probable that the tendency to form ascidia is an abnormal expression of an attempt to form separate lobes. The malformations observed are not supposedly identical with tomosis.

Alternate shrinkage and elongation of growing stems of Cestrum nocturnum, W. H. BROWN and S. F. TRELEASE (*Philippine Jour. Sci., Sect. C, 13* (1918), No. 6, pp. 353-360).—From among a number of rapidly growing plants in Manila which wilt during a comparatively dry summer day, the authors chose 2 plants of *C. nocturnum* as material for the study of this phenomenon. It was found that the shoots wilt regularly, frequently decreasing in length owing to excessive transpiration on every comparatively dry day, but regain their original length in the evening or night, after which they elongate rapidly.

Algological notes.—III, A wood-penetrating alga, Gomontia lignicola n. sp., G. T. MOORE (Ann. Missouri Bot. Gard., 5 (1918), No. 3, pp. 211-224, pls. 3).— The author reports a study of an alga occurring partly on and partly within the tissues of a yellow-pine board submerged in fresh water. The organism is described as G. lignicola n. sp. Apparently the penetration of the wood was not a consequence of disintegration.

A study of stomata, L. REHFOUS ([*Trav.*] Inst. Bot. Univ. Genève, 9. ser., No. 6 (1917), pp. 110, figs. 135; abs. in Rev. Gén. Bot., 30 (1918), No. 359, pp. 366, 367).—This is a detailed account of studies on stomata in a large number of plant families, emphasis being placed on such minute details as number, arrangement, or cutinization of cells in relation with stomata. Descriptions are given of new stomatal types in Polypodium, Platycerium, Cycas, and Casuarina. A practical phase of the work is presented in connection with a possibility of detecting adulteration in such articles of commerce as drugs and tea. It is thought also that these data may serve as a point of departure for studies in regard to means and results of adaptation by plants.

The taxonomic position of the genus Actinomyces, C. DRECHSLER (*Proc. Nat. Acad. Sci.*, 4 (1918), No. 8, pp. 221–224).—This is a brief statement of the results of a study made by the author on a large number of saprophytic species of Actinomyces. The view that this genus should be regarded as a transition between Hyphomycetes and the Schizomycetes is regarded as not well supported by the facts at hand. The author prefers to class this genus with the Hyphomycetes as a mucedineous group with tendencies toward an erect isarioid habit.

Morphology of the genus Actinomyces, C. DRECHSLER (*Bot. Gaz.*, 67 (1919), *Nos. 1, pp. 65-83; 2, pp. 147-168, pls. 8*).—The general conclusion drawn from this study is stated in the less detailed article noted above.

A comparison of Azotobacter with yeasts, M. MULVANIA (*Tennessee Sta. Bul. 122* (1919), pp. 3-6).—The morphological resemblance of Azotobacter in many of its cytological forms to yeast cells has led the author to make a comparative study of the morphology and physiology of Azotobacter and certain yeasts. The results of this study are given in tabulated form, and in discussing them the author states that he is compelled to believe that the three members investigated belong in a single narrowly restricted group of organisms. The gas-producing quality was found to be confined to Azotobacter, but was never observed in either pink or white yeast. Other resemblances between Azotobacter and yeasts, as well as contrasts with true bacteria, are pointed out.

The use of iron in nutrient solution for plants, G. E. CORSON and A. L. BAKKE (*Proc. Iowa Acad. Sci.*, 24 (1917), pp. 477-482, figs. 4).—A study of wheat and Canada field peas, germinated in clean quartz sand and grown in Shive's 3-salt solution (E. S. R., 34, p. 333) with a small proportion of iron compound, is said to show that the proportion of iron is more important than is generally supposed. Ferrous phosphate is less efficient than the ferric form, and wheat is more improved than the field pea by the presence of ferric phosphate at a concentration of 0.0044 gm. per liter.

Relation of varying degrees of heat to the viability of seeds, J. L. BURGESS (*Jour. Amer. Soc. Agron., 11 (1919), No. 3, pp. 118-120*).—Corn, wheat, oats, rye, cowpeas, soy beans, and garden beans were subjected to varying degrees of dry heat for different lengths of time in tests conducted at the North Carolina Department of Agriculture seed laboratory in an effort to ascertain the effect of high temperatures employed in the control of insect pests on the viability of the seed.

While the results as a whole are deemed rather unsatisfactory, the minimum temperature used, 140° F., as well as much higher temperatures in certain instances, failed to show any harmful effect on the viability of garden beans, soy beans, oats, and rye. Corn and wheat were seriously injured at temperatures above 150°, while data are lacking as to the effect of lower temperatures. Cowpeas appeared to withstand fairly well heating to 140° for one hour.

Some additional notes on pollination of red clover, L. H. PAMMEL and L. A. KENOYER (*Proc. Iowa Acad. Sci., 24 (1917), pp. 357-366*).—Noting more recent work than that formerly participated in by one of them (E. S. R., 31, p. 134), the authors report that while honeybees do not appear to be active pollinators of red clover they do appear to be able to effect limited pollination during certain seasons.

Studies on self-sterility.—II, Pollen tube growth, E. M. EAST and J. B. PARK (*Genetics*, 3 (1918), No. 4, pp. 353-366).—This report deals with the phenomena outlined in the authors' account of work previously noted (E. S. R., 38, p. 823).

It is stated that pollen grains of the four species of Nicotiana employed herein, as previously, germinated freely on many artificial media as well as on the stigmas of the plants, but that they reached only a fraction of the length attained under normal conditions, the growth moreover being abnormal. The pollen tubes produced after selfing were five to ten times as numerous as required to fecundate the ovules. Pollen tubes after selfing are indistinguishable in size from those following a cross. Variations in length of pollen tubes after self-pollination and cross-pollination seem to be due wholly to differences in the rate of germination of the pollen grains or to environment. Pollen tubes produced after self-pollination grow at a uniform rate, and to all appearances normally, but too slowly to reach the ovary before the flower decays. After a compatible cross the growth of the pollen tube is rapid and accelerated. The corresponding curve when plotted suggests an autocatalytic reaction. Crosssterile combinations resemble selfings as regards rate of pollen tube growth. Near the end of the flowering season the rate of growth of self-pollen tubes becomes more rapid, though little evidence has been obtained of acceleration during their passage down the style.

These results are thought to show that pollen tubes in a selfed pistil are not inhibited in their growth by substances secreted in that pistil, but that substances are secreted in the pistil after a compatible cross which accelerate growth. The direct cause of this secretion is a catalyzer, which the pollen-tube nucleus is able to produce because the zygotic constitution of the plant producing it is different in certain particular hereditary factors from that of the plant on which it is placed.

The behavior of the chromosomes in fertilization, K. SAX (Genetics, 3 (1918), No. 4, pp. 309-327, pls. 2).—The purpose of this study was to consider not only the behavior of the chromosomes of the gametic nuclei, but also in the triple fusion, which is considered as comparable to the union of the gametic nuclei so far as inheritance of endosperm characters is involved. The material was obtained from about 4,000 cases of fertilization in *Fritillaria pudica* and 200 in *Triticum durum hordeiforme*, both of which furnish a complete series of stages in the first division of the fertilized egg. The behavior observed in each of these plants is detailed with discussion.

The segregation of Enothera brevistylis from crosses with  $\mathbb{C}$ . lamarckiana, B. M. DAVIS (Genetics, 3 (1918), No. 6, pp. 501-533, figs. 7).—An account of studies carried on during 1916 and 1917 with species of  $\mathbb{C}$ . brevistylis and  $\mathbb{C}$ . lamarckiana and their crosses, direct and reciprocal, is given with results which are tabulated and discussed.

It is stated that the  $F_1$  generations of reciprocal crosses between these plants are uniform and essentially indistinguishable one from another. The  $F_2$  generations from reciprocal  $F_1$  hybrids present a perfectly sharp segregation of *brevistylis* plants from *lamarckiana* in proportions approximating the monohybrid Mendelian ratio of 1:3, the distinguishing characters of *brevistylis* being inherited in closely associated relations (behaving as a unit). Other observations are detailed with discussion. The breeding data indicate that crosses between *brevistylis* and *lamarckiana* result in a simple monohybrid situation.

Twin hybrids of Cenothera hookeri, H. DE VRIES (Genetics, 3 (1918), No. 5, pp. 397-421).—Having been convinced by recent studies cited that lethal factors and hybrid mutants play a considerable part in the splitting phenomena which accompany the normal mutations of many species of CEnothera, the author outlines the steps leading to this view and studies in connection therewith.

Summarizing the data and conclusions of this work, he states that *Œ*. hookeri produces a splitting *læta* and a uniform *velutina* in its crosses with *Œ*. grandi-

flora, just as in those with *Œ. lamarckiana*. This production of twin hybrids is due to the mass mutation of *Œ. grandiflora* into *Œ. grandiflora* ochracea, the typical gametes producing the velutina, whereas the mutated ones give rise to the *læta*. The fact that there is almost complete analogy between the twins of *Œ. lamarckiana* and those of *Œ. grandiflora* is considered as evidence of a mass mutation into a velutina-producting mutant for *Œ. lamarckiana*.

Splitting *læta* and splitting *rubiennis* have been produced only by three largeflowered races, namely, two Californian species, *Œ. hookeri* and *Œ. franciscana*, and *Œ. lamarckiana velutina*. In a large number of other cases the hybrids of the Œnotheras, whether twins or monotypic, are constant in their progeny, apart from the rare cases of Mendelian splitting. The *læta* and *rubiennis* always split into two types, one of which repeats their marks whereas the second resembles the other grandparent. No constant specimens of *læta* or *rubiennis* have been found among them.

Merrillia, a new rutaceous genus of the tribe Citreæ from the Malay Peninsula, W. T. SwINGLE (*Philippine Jour. Sci., Sect. C, 13 (1918), No. 6, pp.* 335-343, pls. 2).—Six genera (9 species) of citrus plants containing what are supposed to be the surviving representatives of a once larger group, and now ranging widely in eastern tropical regions, are treated as comprising a natural group inside the tribe Citreæ, namely (subtribe) Balsamocitrinæ. The Katinga of Siam and the Malay Peninsula is assigned to this group, being the sole representative of the genus newly erected to receive this form (perhaps the most remarkably aberrant of the citrus fruits), which is described under the name Merrillia caloxylon.

## FIELD CROPS.

Field technique in determining yields of experimental plats by the squareyard method, A. C. ARNY and F. H. STEINMETZ (Jour. Amer. Soc. Agron., 11 (1919), No. 3, pp. 81–106, figs. 3).—This paper, a contribution from the Minnesota Experiment Station, deals with more extensive observations along lines described by Arny and Garber in a previous article (E. S. R., 40, p. 623), together with a discussion of a method equally well adapted to sampling broadcasted and drilled forages and grains on experimental plats. The work was conducted on variously treated tenth-acre fertilizer plats of barley, wheat, oats, and rye on University Farm and on outlying experiment fields located at Waseca, Morris, Grand Rapids, and Duluth. Ten square yard areas of the standing grain were harvested from each plat shortly before harvesting the entire plat. The areas were located not less than 7 ft. within the plat from sides and ends. The yield of grain in grams was ascertained for each square yard, and various combinations of square-yard areas compared with the yield secured by harvesting the entire plat.

A comparison of the probable error for single determinations of the yields from entire plats and from square-yard areas removed from them led to the conclusion that "from relatively uniform standing grain 4 to 5 systematically distributed square-yard areas removed from tenth-acre plats gave approximately the same probable error for yield as harvesting the products of entire plats; and the probable error for the yield from 10 square-yard areas removed from tenth-acre plats was approximately two-thirds that for the tenth-acre plats from which the square yards were removed. Where the stands of grain were relatively nonuniform, 5 to 10 systematically distributed square-yard areas were necessary to reduce the probable errors to approximately equal those for the yields from the tenth-acre plats from which the square-yard areas were removed. These results are strictly applicable for the seasons of 1918 and 1917 to the plats on the series mentioned. It appears, however, that where determinations are sufficiently large in number and are made covering varying conditions of soil and climate, probable errors for areas of given size are very similar."

Tabulated data are presented and discussed comparing the increases in yield following the different fertilizer treatments on the various experiment fields as ascertained by the tenth-acre plat and the square-yard methods, together with data showing the yields secured from the entire tenth-acre plats and from the square-yard areas removed from them. The effect on yields of alleys along the sides of plats and of cultivated roadways at the ends, as indicated by investigations described by Arny and Hayes (E. S. R., 40, p. 226), is pointed out, and the statement made that the yield of entire plats subject to this effect should ordinarily be about 5 to 10 per cent higher than that of square-yard areas not subject to border effect. The cost of removing 10 square-yard areas from a tenth-acre plat, thrashing, and weighing the product is said to be approximately the same as for harvesting the entire area with the binder, thrashing the grain with the ordinary thrashing machine, and weighing the product.

The authors conclude that "the variations in the calculated probable error for the yield determinations at the different locations emphasizes the desirability of deriving probable error for use in the interpretation of the results of each test. The pairing method may be used to advantage in deriving probable error where the yields from a sufficient number of check plats is not available for this purpose. Yields determined from 4 to 5 systematically distributed square-yard areas removed from plats one-tenth acre in size or less of relatively uniform crop may be confidently substituted for those from the entire plats. Under similar circumstances the yields from a greater number of squareyard areas may be considered more accurate than those from the entire plats. From very nonuniform crops the yield from 10 square-yard areas systematically distributed may not be as accurate as the yields from the entire plats. The method of determining yields by the removal of relatively small systematically distributed areas, square yards or rod rows, from plats may be used to advantage: (a) Where facilities for making yield determinations from entire plats are lacking, (b) to check the accuracy of yield determinations on plats, [and] (c) where more accurate determinations of yield are desired than can be secured from the limited number of larger plats that can ordinarily be devoted to a series of tests."

[Report of field crops work in Nebraska] (*Nebraska Sta. Rpt. 1918, pp. 21, 22-24*).—This briefly describes work conducted during 1918 on the North Platte, Scottsbluff, and Valentine substations.

The average yield of spring wheat at North Platte was 8.9 bu. per acre, and of winter wheat 7 bu. per acre, although most of the latter was winterkilled. Spring wheat following summer tillage produced 17.5 bu., as compared with 3.7 bu. under continuous cropping. Winter wheat following corn produced 5.6 bu., and after summer tillage 19 bu. Without irrigation potatoes yielded 84.5 bu. per acre, corn for silage 4.5 tons, and winter wheat 8.3 bu., as compared with 135 bu., 9.1 tons, and 26.2 bu. per acre, respectively, with irrigation.

Observations on irrigated crop rotations at Scottsbluff showed that low yields followed continuous cropping; that poor grade and extremely scabby potatoes were secured from short rotations; that fall seeding of alfalfa in grain stubble gave better results than seeding alone in the spring except during seasons when grasshoppers were bad, when early spring seeding is deemed preferable; that barnyard manure was beneficial; and that there was a marked residual effect from alfalfa. Sugar beets grown on manured plats produced at the rate of 21,3

#### 1919]

tons per acre as compared with 14.3 tons without manure. Commercial fertilizers have not materially increased the yield of sugar beets.

Thinning sugar beets on June 8, 18, and 22 resulted in yields amounting to 19.26, 19.02, and 15.83 tons per acre, respectively. Potatoes grown on alfalfa land produced more than twice as much as when grown on land never planted to alfalfa. Plowing corn land failed to show any advantage over disking for either oats or barley. In a comparison of pasture crops sweet clover is said to be more promising than any of the grasses tested. It is recommended that sweet clover be sown in the spring with a grain crop and irrigated sufficiently to furnish some pasture the first summer.

Corn gave the best results of the forage crops tested at the Valentine substation. Early seedings of sweet clover (about April 7) gave good results, while alfalfa failed with all seedings made before May 10. Potatoes grown on heavy, unmulched soil from seed produced under mulch showed an increase in yield of 20 per cent over those from seed grown by ordinary methods. The Pinto bean appeared to be more drought resistant than any of the other varieties tested.

Soy beans and cowpeas for North Carolina, V. R. HERMAN (North Carolina Sta. Bul. 241 (1919), pp. 7-40, figs. 10).—This bulletin reports results of cultural, fertilizer, and variety tests with soy beans and cowpeas conducted at various points in the State in cooperation with the U. S. Department of Agriculture, together with a discussion of the adaptability and utilization of the two crops in North Carolina.

A five-year rotation of potatoes, rye straw and squashes, onions, oats and rowen, and hay, S. C. DAMON (*Rhode Island Sta. Bul. 178 (1919)*, pp. 4–16).— This bulletin comprises a report on the crop yields, the fertilizer ingredients applied and removed, and the total cost, value, and net returns of the various crops in a 5-year rotation, previously described (E. S. R., 36, p. 528), for the period of 1893 to 1916, inclusive.

It is concluded that "a definite rotation with liberal fertilization and careful cultivation, followed for a long period, results in increased fertility in the soil and in a reasonable profit." The average profit per acre for the different crops was estimated to be as follows: Potatoes, \$31.30; rye straw, \$10.43; squashes, \$13.69; peas (grown for 11 years), \$65.58; turnips (grown for 11 years), \$19.85; onions (grown for 13 years), \$100; oats, \$7.77; and hay and rowen, \$7.52.

The varieties of small grains and the market classes of wheat in Utah, G. STEWART (Jour. Amer. Soc. Agron., 11 (1919), No. 4, pp. 163-169).—This paper, a contribution from the Utah Experiment Station, presents the results of a field survey made in 1918 in an effort to ascertain what varieties of wheat, oats, and barley are grown in the State. Samples of these cereals were collected from all available local sources and grown at Logan for identification. Results secured by the Utah-Idaho Grain Exchange in the market grading of wheat for the year ended July 31, 1918, are also briefly reviewed.

These studies are held to indicate that the varieties of small grains grown in Utah are badly mixed, and that varietal names are frequently misapplied. The commonest varieties of wheat and those deemed best adapted include Dicklow and New Zealand for irrigated farms, and Turkey, Kofod, Bluestem, and Gold Coin for dry-land farms. Oats are practically standardized to Swedish Select. Market grades substantiate the results of the field survey, 44 per cent of the wheat graded falling in the class of mixed wheat, while other reductions in grade, due to different factors, are considerable.

Carrying capacity of native range grasses in North Dakota, J. H. SHEPPERD (Jour. Amer. Soc. Agron., 11 (1919), No. 4, pp. 129–142, pls. 3, fig. 1).—This paper reports the progress of grazing experiments, conducted by the North Dakota Experiment Station in cooperation with the U. S. Department of Agriculture near Mandan, in which an effort is being made to determine the carrying capacity of native range pastures without regard to their maintenance or improvement. Two-year-old grade beef-bred range steers, comprising Shorthorn, Angus, and Hereford grade and crossbred cattle, have been adopted as the grazing unit and studies made of pasturing ratios of 3, 5, 7, and 10 acres of grass area per steer. The work was begun in 1915 when the entire area of 250 acres was grazed as one pasture. In 1916 the area was divided into 30, 50, 70, and 100 acre pastures, each grazed by ten 2-year-old steers or their equivalent. By means of quadrats 20 by 300 ft. fenced off in the 30 and the 100 acre pastures, information has been secured relative to the dominant, primary, and secondary species of grasses and of plants other than grasses occurring in the different pastures. Perquadrats 4 meters square (about 19.14 sq. yds.) are opened for grazing each year and a similar perquadrat taken in from the pasture. Population studies of these areas for ten years are expected to furnish data concerning the flora of areas grazed from one to ten years.

The 1918 results are given in some detail, and summarized statements presented for the whole period of the experiment showing the average gains per head, per day, and per acre for the different pasture ratios, and the gains per day for different grazing periods. It is stated that although the results are not yet regarded as conclusive they indicate that less than 7 acres of native range pasture per 2-year-old steer is insufficient, that the principal gains are made by cattle during the early part of the grazing season, that late season grazing is done without gains, if not at an actual loss in weight, and that "the number of acres supplied per steer in practice will depend upon the farm management questions of the cost of supplementing pastures and the price of land used for grazing, as heavy early season pasturing gives maximum per acre yields."

**Baling hay, H. B.** McClube (U. S. Dept. Agr., Farmers' Bul. 1049 (1919), pp. 34, figs. 8).—Various types of hay presses and their operation are described, and farm practices conducive to maximum efficiency in baling hay indicated.

Alfalfa on corn belt farms, J. A. DRAKE, J. C. RUNDLES, and R. D. JENNINGS (U. S. Dept. Agr., Farmers' Bul. 1021 (1919), pp. 32, figs. 16).—Based on information secured from 235 farms in Ohio, Indiana, Illinois, and Iowa, where alfalfa was found to be grown successfully, this publication discusses the cropping systems and the methods of handling the crop employed by experienced corn belt growers to overcome the labor conflict between alfalfa and corn.

The principal means of attaining this end is said to comprise the speeding up of the haying operations and corn cultivation by the utilization of laborsaving devices and more efficient management. The use of alfalfa for pasture has also aided to some extent.

Alfalfa in Michigan, J. F. Cox (*Michigan Sta. Spec. Bul.* 97 (1919), pp. 3-16, figs. 7).—Field practices and cultural methods employed in growing the crop in the State are described.

Barley culture in South Dakota, M. CHAMPLIN, J. D. MORBISON, and J. MAB-TIN (South Dakota Sta. Bul. 183 (1919), pp. 11-69, figs. 14).—This bulletin describes variety and cultural tests with barley conducted in cooperation with the U. S. Department of Agriculture at Brookings, Cottonwood, Eureka, Highmore, and Newell, over a period of several years. The crop is said to rank fourth among the cereal crops of the State. The results secured may be summarized as follows:

In general, barley has produced more food per acre than other small-grain crops, although there have been some notable exceptions. No advantage was found in growing barley in mixtures with oats or emmer. Odessa (S. D. 182) is said to have given good results in all parts of the State where tried and is recommended as a general purpose variety for the State as a whole, while other varieties are recommended for special conditions. Rust, smut, ergot, stripe disease, and blight are regarded as among the important barley diseases, while control measures include early seeding, seed disinfection and grading, and the rotation of crops.

Barley responded readily to good rotation methods. It is recommended that a firm seed bed be prepared with a shallow mulch. Early seeding is deemed very important. Six pecks per acre was found to be the best rate of seeding in general, and the proper depth of seeding about 2 in. Seeding with a drill is recommended.

It is stated that barley can be grown as a cultivated crop to good advantage in sections where corn is not a highly profitable crop. Careful shocking and stacking is strongly advised in order to secure grain of good market quality.

A reason for the contradictory results in corn experiments, L. CARRIER (Jour. Amer. Soc. Agron., 11 (1919), No. 3, pp. 106-113).—In this paper, a contribution from the Bureau of Plant Industry, U. S. Department of Agriculture, the author discusses briefly the unreliability of the common methods of variety and ear-to-row testing of corn whereby the influence of the pollen on the size and yield of grain is overlooked, although this factor may affect the results as much or more than inherent differences in the corn under examination. It is suggested that the farmer be advised to continue to select seed corn conforming to the well established types of the locality and occasionally to introduce some seed from an outside source, preferably of the same variety, but not closely related to his own strain.

Finally it is stated that "corn still offers great opportunities to the agronomist who will break away from the old methods of conducting experiments and work in the light of all the known facts regarding this crop. A method must be followed which will allow the plants to develop normally and at the same time effectually control the matter of pollination. The equipment for such experiments will be expensive, but relatively no more so than that used in lysimeter and some other work. The importance of the corn crop would seem to justify any such outlay of public funds."

Some factor relations in maize with reference to linkage, D. F. JONES and C. A. GALLASTEGUI (*Amer. Nat., 53 (1919), No. 626, pp. 239–246*).—The authors describe what they consider to be "a fairly good case of linkage between the tunicate factor which determines the production or inhibition of the glumes covering the seeds and the factor for starchy or sweet endosperm," and discuss evidence secured by other investigators relative to linkage in corn.

A half-tunicate ear produced from open-pollinated seed of a perfect flowered segregate was self-pollinated. Upon examination this ear was found to have segregated into 173 starchy and 43 sweet seeds. Assuming linkage, a classification of  $F_2$  progeny into starchy tunicate, starchy nontunicate, sweet tunicate, and sweet nontunicate plants is said to agree rather closely with the nearest theoretical results. Observations on the progeny of a similar ear crossed with a yellow, starchy, nontunicate corn is said to show no indication of linkage between the factors for tunicate ear and yellow endosperm.

It is stated further that "since the number of known factor differences in maize is already some three or four times the number of chromosomes, more definite knowledge of the behavior of all these factors in relation to each other will be awaited with interest, especially since maize is one of the best materials from the plant side to which the chromosome hypothesis, as worked out in Drosophila, can look for contradiction or support."

Structure of the maize ear as indicated in Zea-Euchlæna hybrids, G. N. Collins (Jour. Agr. Research [U. S.], 17 (1919), No. 3, pp. 127-135, pls. 3, fig.

1).—In this paper, a contribution from the Bureau of Plant Industry, U. S. Department of Agriculture, the author describes observations made on hybrids derived largely from a cross between Florida teosinte and Tom Thumb popcorn in an effort to throw some light on the morphology of the maize ear, together with a possible explanation of its evolution. Six  $F_1$  plants were grown, and from the self-fertilized seed of one of these 127  $F_2$  plants were produced. Several hundred  $F_3$  plants from open pollinated seed were also examined.

In order to make a detailed comparison of the pistillate inflorescences of Zea and Euchlæna, it was deemed necessary to recognize as a morphological unit the organs borne by a single metamer of the rachis, this unit being designated as an alicole. The single spikelets, two-ranked alicoles, and separate alicoles of the pistillate inflorescence of Euchlæna were then contrasted with the paired spikelets, many-ranked alicoles, and yoked alicoles of the pistillate inflorescence of Zea. The stages between the Euchlæna spike and the Zea ear as observed in hybrids between the two genera are summarized as follows:

"The suppressed pedicelled spikelet in each alicole reappears. The alicoles become more crowded and their number is increased. The alicoles associate themselves in pairs or yokes. The axis twists, increasing the row of alicoles. The order in which these changes occur is by no means fixed, but taken together they comprise all the changes necessary in deriving the maize ear from the Euchlæna spike.

"In this series of intermediate stages nothing was observed that affords support for either the fasciation or 'reduced branch' theory of ear formation. There is also evidence from the maize ear itself that the association of alicoles into pairs is more fundamental than the linear arrangement.

"In all the hybrids between maize and Euchlæna that have been observed there has appeared no suggestion of either pod corn or *Zea ramosa*. Since it can scarcely be doubted that the peculiar characteristics of both of these mutations represent the reappearance of ancestral characters common to the Andropogoneæ, it would seem that in crossing maize and Euchlæna, and thus calling forth a series of intermediate forms, we are not returning to the point in the ancestry of maize where it became differentiated from the Andropogoneæ. Furthermore, if the stages shown in the hybrid plants were to be taken as indicating the path of evolution of the ear, it would be necessary to assume that the central spike of the staminate inflorescence or tassel had evolved separately and along different lines. The close homology between the ear and the central spike of the tassel makes such an assumption unreasonable.

"In the present article emphasis has been placed on the shortening and twisting of the axis of a single spike as a possible method of deriving a structure like the maize ear from the inflorescence of Euchlæna. This has been done, not because the method is believed to represent the most probable course of evolution, but because the present discussion has been restricted to the evidence afforded by hybrids of maize and Euchlæna, which seems to require such an interpretation. Facts of other kinds are more easily interpreted by the theories of fasciation and reduction of branches, but there are also facts that do not seem to accord with any of the theories yet proposed. Until the apparently contradictory evidence can be reconciled, it seems best to keep the several possibilities in mind and await additional evidence before attempting a complete interpretation."

Inheritance of waxy endosperm in maize, J. H. KEMPTON (U. S. Dept. Agr. Bul. 754 (1919), pp. 99, figs. 14).—This bulletin describes the results of investigations begun in 1910 in a further effort to study the correlation between endosperm texture and the color of the aleurone. A series of crosses were made between the white Chinese variety of corn having waxy endosperm described by Collins (E. S. R., 22, p. 443) and an African popcorn. While the results are said to be similar, on the whole, to those previously reported, such large numbers of individuals were examined as to place the deviations from the expected ratios beyond question and to establish more definitely the existence of a correlation between the characters studied. The evidence is also believed to be of value in testing the general applicability of current theories of the segregation or alternative inheritance of characters, as well as theories that may be advanced in the future. Considerable tabulated data from which the pedigrees may be readily traced are presented and fully discussed. The author summarizes the results secured as follows:

"The number of seeds with the waxy endosperm reappearing in the perjugate generation of waxy×horny crosses is less than the expected for a simple Mendelian character, but this deviation, though significant, is too small to warrant the predication of additional factors. In making this determination, more than 100,000 seeds were classified, and it has been possible therefore to establish the actual percentage within 0.3 per cent. The same material was used to test the inheritance of aleurone color, which also was found to depart from the theoretical ratios. Unlike the waxy endosperm texture, no definite trend above or below the expected ratios was observed, but many abnormal ratios were obtained which necessitated further refinements in the factorial analysis of this character.

"From the results of the Mendelian analysis of aleurone color and endosperm texture it must be concluded that in many cases uniform Mendelian reactions are obtained, which allow certain predictions to be made with respect to the behavior of these characters in subsequent generations. But that these predictions, based upon the gametic analysis will be uniformly fulfilled must not be supposed... Aberrant behavior is far from uncommon, increasing with the progress of investigation and the refinement of analysis. The fact is coming to be appreciated that instead of a few simple unassociated factors most characters are composed of many complex units, which may no longer be considered singly, but that their interrelations or correlations must be taken into account.

"The present investigations show that certain of the more definitely alternative characters of maize are subject to variation or fluctuating behavior that renders these supposed Mendelian factors too irregular to justify a belief that the very definite relationship predicted in theories of gametic coupling could exist between such characters. There can be little doubt, however, that at least with several combinations of characters the gametic ratios are to a certain extent regular, but that these ratios fit any arbitrary series is not so well demonstrated. For the breeder of crop plants where most of the desired characters are almost infinitely complex, seldom alternative, and often intangible, Mendelism seems to have little of practical value to offer, whether the attempt of some investigators to so extend the theory as to embrace such characters be approved or not. While Mendelism may assist in making desired combinations, there is nothing to show that it can serve as a substitute for selection either in finding the best stocks or in preserving them from subsequent deterioration."

Factors influencing the carrying qualities of American export corn, E. G. BOERNER (U. S. Dept. Agr. Bul. 764 (1919), pp. 99, figs. 72).—In a continuation of investigations previously noted (E. S. R., 23, p. 35), this bulletin describes observations made on eight representative cargoes of corn accompanied from the United States to various European ports, and on an additional cargo which was carefully sampled at the time of loading in America and again at the time of discharge in Europe. The purpose was to determine the effect upon the carrying qualities of export corn of the moisture content, quality, and condition of the corn as loaded, the length of the voyage, the season of the year, the weather conditions during shipment, and the position of the cargo in the vessel. Daily observations and tests were made of those cargoes accompanied to Europe from the time the corn was put into the vessels until it was discharged, electrical-resistance thermometers being placed at definite points in the cargo at the time of loading. As the thermometers were put in place, 3-qt. samples of corn were taken from the grain surrounding each thermometer with which to determine changes in the quality and condition of the corn during the voyage. One-half of each sample was retained for analyses, and the remainder was placed in a crossed wire container fastened to the thermometer and recovered as the corn was unloaded. Information concerning the studies made on each cargo is presented in considerable detail supplemented by tabulated data, diagrams, and graphs. The results may be summarized as follows:

Corn which was dry and in a sound condition when shipped arrived in Europe in a like sound condition, regardless of the position in which it was stowed, the time of year in which it was shipped, or the length of the ocean voyage. The higher the percentage of moisture in the corn when shipped, the greater was the danger of spoilage during the voyage. Various contributing factors also worked with the moisture in causing spoilage, a combination of two or more such factors resulting in much greater spoilage than one factor alone.

"It may reasonably be expected in other export shipments, if the quality and condition of the corn and the shipping conditions are similar to those found in the nine cargoes described, that the quality and condition of the corn on arrival at European ports will be the same as in those cargoes. As the quality, condition, and temperature of corn to be exported can be determined before it is delivered on board the vessel, and as the season of the year during which shipment is to be made, the place of stowage, and the probable length of voyage are known or can be ascertained, an estimate of the condition of the corn on arrival can be made in advance."

Community cotton improvement in North Carolina, R. Y. WINTERS (Jour. Amer. Soc. Agron., 11 (1919), No. 3, pp. 121–124).—This paper, a contribution from the North Carolina Extension Service, briefly outlines the methods employed and some of the results secured in community cotton improvement work inaugurated in the State in 1914. It is stated that 16 communities in 11 counties have been organized for this purpose, and that during the past three years good strains of cotton have been introduced which have produced an income of from \$10 to \$60 per acre more than the varieties previously grown in the community.

**Potato** seed certification in New Hampshire, F. S. PRINCE (*New Hampshire Sta. Circ. 19* (1918), pp. 3–10).—The advantages of potato seed certification are discussed and the requirements for certification in the State outlined as approved by the New Hampshire Potato Growers' Association.

The effect of the environment on the loss of weight and germination of seed potatoes during storage, O. BUTLER (Jour. Amer. Soc. Agron., 11 (1919), No. 3, pp. 114–118).—A study of the effect of temperature, oxygen supply, and humidity on the germination and loss of weight of stored seed potatoes conducted at the New Hampshire Experiment Station led to the conclusion that germination can be satisfactorily retarded by lowering the temperature to  $3.74^{\circ}$  C. ( $38.7^{\circ}$  F.), or by reducing the oxygen supply to a point corresponding to storage in "dead air"; that germination can be more effectively retarded by storage in "dead air" at a mean temperature of  $9.31^{\circ}$  than by storage in free air at  $3.74^{\circ}$ ; and that loss of weight is markedly affected by the relative humidity of the air, saturated air and dry air both to be avoided.

140363°-19-4

Gigantism in Nicotiana tabacum and its alternative inheritance, H. A. ALLARD (Amer. Nat., 53 (1919, No. 626, pp. 218-233).—The occurrence of giant or mammoth tobacco plants, having an abnormally high leaf number and possessing a vegetative period of such length as to preclude normal blossoming in the field, is described. This form is said to have appeared in different commercial varieties, including the Maryland, Cuban, Connecticut Havana, and Sumatra types, as well as in certain varietal and species crosses. Observations on the possibilities of combining the mammoth character with other characters of commercial value by crossing mammoth types with common varieties are described in the present paper. The behavior of a number of such crosses and the appearance and behavior of a new mammoth type in a line originating from a species hybrid are discussed in some detail.

In summarizing the results it is stated that "not only giant or mammoth types which breed true, but intermediate or hybrid types occur spontaneously which subsequently give rise to a greater or less proportion of mammoth forms." In crosses with normal varieties gigantism behaved as a recessive unit character, appearing in the  $F_2$  in the expected 3:1 ratio.  $F_1$  plants are said to have blossomed invariably and to have exhibited a somewhat higher average number of leaves than the normal parent entering into the cross.

The Mendelian behavior of aurea character in a cross between two varieties of Nicotiana rustica, H. A. Allard (Amer. Nat., 53 (1919), No. 626, pp. 234-238).—The author records observations on the  $F_1$ ,  $F_2$ , and  $F_3$  progeny of crosses between a distinctive white-stemmed and a green-stemmed type of N. rustica, begun at Arlington, Va., in 1914, together with the behavior of certain back crosses. The term "aurea" is applied to a peculiar varietal form of chlorosis characteristic of a light, yellowish-green type of N. rustica, having white stems and midribs and introduced from Russia, where it is said to be grown commercially as a pipe and cigarette tobacco. "In this variety of N. rustica, the stems of young plants, especially if they have been somewhat etiolated by crowding, are almost snow white. A cross section of the stems of such plants one month old reveals the fact that this whiteness is not merely superficial, but extends entirely through the stems, whereas in green varieties of N. rustica the internal structure of the stems is green throughout. The cotyledons are decidedly chlorotic, and the leaves have a pale yellowishgreen chlorotic appearance which becomes more marked as the plants approach maturity." The results secured may be summarized as follows:

In the  $F_1$  the aurea type behaved as a simple recessive to the green-stemmed type, the  $F_2$  plants segregating into green-stemmed and white-stemmed plants in approximately the expected ratio of 3:1. Some heterozygous individuals were found among the green plants and again segregated into green and aurea types in a 3:1 ratio. Extracted aurea recessives of the  $F_2$  proved to be homozygous for the white character. Back crosses between a heterozygous  $F_1$  and the dominant green type resulted in all green-stemmed plants, while in a similar back cross with the recessive aurea type the progeny consisted of green and aurea plants in about the expected 1:1 ratio.

**Tobacco growing in Ireland**, G. N. KELLER (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 17 (1917), No. 2, pp. 461-466; 18 (1918), No. 3, pp: 296-299; 19 (1919), No. 3, pp. 298-302).—The progress of work previously noted (E. S. R., 36, p. 533) is briefly discussed for the seasons of 1916, 1917, and 1918.

On the blooming and fertilization of wheat flowers, C. E. LEIGHTY and T. B. HUTCHESON (Jour. Amer. Soc. Agron., 11 (1919), No. 4, pp. 143-162, figs. 2).— The authors describe observations made at the Minnesota Experiment Station and the Arlington (Va.) Experiment Farm during the summer of 1914 on the
time of blooming of several varieties of wheat and on the fertilization of emasculated wheat flowers left unprotected from foreign pollination.

Different types of wheat, represented by Velvet Chaff, Haynes Bluestem, Glyndon Fife, Kubanka, Arnautka, Kharkov, and Turkey at St. Paul, and by Dietz, Fultz, Mealy, Giant Squarehead, Turkey, Bluestem, and Fife at Arlington, were examined for time of blooming. Individual heads were marked and a diagram prepared upon which the flowers were recorded as they bloomed. Examinations were made usually at 7 a. m., 12 m., and 5 or 6 p. m. A flower was considered as having bloomed when the glumes had opened appreciably. It is stated that "the process of blooming of a wheat flower is very rapid. From the time that they first begin to open the glumes may be fully open in less than 1 minute; the anthers may be extruded and emptied of pollen within 2 or 3 minutes; the glumes may be half closed within 5 minutes, loosely closed within 10 minutes, and tightly closed at the end of 15 or 20 minutes. The entire process, from the time that the first opening movement of the glumes can be observed until they are again tightly closed, seldom requires more than 20 minutes."

More frequent observations were also made at Arlington on 25 heads of wheat between 4 p. m., May 26, and 10 a. m., May 30, and on 10 heads between 2 p. m., June 1, and 3 p. m., June 5. Data secured at this time are held to indicate that the other records possess a high degree of reliability, and that while blooming occurred at most hours of the day it was most intense at rather definite periods.

Altogether the time of blooming was recorded for 2,977 flowers on 69 heads, 1,492 of these flowers blooming at night (from 5 or 6 p. m. to 7 or 8 a. m.), while 1,485 bloomed during the day. Of the latter, 764 bloomed before noon. At St. Paul 70 more flowers bloomed at night than during the day, while at Arlington 63 more bloomed during the day. The time of blooming appeared to depend to some extent upon the variety, although this is not regarded as the principal factor involved. Two periods of extensive blooming were observed during the day, a morning period from about 7 to 9, and an afternoon period from 2 or 3 to 4. A secondary morning period occurred about 11 o'clock. One or more periods are also said to occur at night or probably in the early morning, the exact time not being determined. The blooming period of the flowers on a wheat head ranged from 2 to 7 days, with an average of about 3 days. "The results of these observations should serve to correct the erroneous impression of many that wheat flowers always bloom very early in the morning (apparently true under some conditions) and that it is necessary to visit such plants at very early hours in order to secure opening anthers."

Flowers on a number of heads of several varieties of wheat were emasculated before the pollen matured and left without covering, while flowers on other heads of the same varieties were similarly treated but covered with soft tissue paper at St. Paul, and with paraffined paper bags at Arlington. The varieties employed in Minnesota for this work included Kharkov, Red Fife, Haynes Bluestem, Velvet Chaff, Glyndon Fife, Kubanka, and Arnautka, and at Arlington Fultz, Lancaster, C. I. Nos. 3614, 1733, and 1933, Tennessee Fultz, China, Early Genesee Giant, Acme, and Kanred. At the Minnesota Station kernels were formed by 507 of 1,240 flowers on 70 heads emasculated and left uncovered, while only 2 kernels were formed by 388 flowers emasculated and the heads covered. Where flowers were emasculated, pollinated, and the heads covered, 41.7 per cent formed seed. Kernels were formed by 1,103 flowers out of a total of 1,324 on 83 heads emasculated and left uncovered at Arlington. Only 6 kernels formed from 642 flowers on 40 heads emasculated and covered, 3 of these kernels being harvested under bags that had been torn. "When wheat flowers are emasculated and not pollinated the glumes, apparently some time after the regular time of blooming, open and remain open for several days. The style also grows to an abnormal length. Opportunity is thus presented for the entrance of pollen. When fertilization has taken place the glumes remain closed... In view of the results obtained in these experiments, there seems no doubt that in studies of inheritance in wheat hybrids and in breeding operations where hybrids of known parentage are desired it is necessary to protect emasculated flowers from undesired pollination."

Dry farming for better wheat yields.—The Columbia and Snake River Basins, B. HUNTER (U. S. Dept. Agr., Farmers' Bul. 1047 (1919), pp. 24, figs. 18).—This publication comprises a general discussion of improved dry-farming methods found to give the best results on grain farms, with special reference to winter and spring wheat production in the Columbia and Snake River Basins, which have an annual rainfall of less than from 18 to 20 in. The recommendations are also deemed applicable to all farms in the region where summer fallowing is practiced.

It is stated that the early plowing and thorough cultivation of the summer fallow is imperative for the best results. The use of the summer fallow on "blow" and "nonblow" soils is described, and methods for preventing and stopping the blowing of soils are outlined.

Seed Reporter (U. S. Dept. Agr., Seed Rptr., 2 (1919), No. 11, pp. 8, figs. 5; 3 (1919), No. 1, pp. 8).—Both these numbers contain the usual statistics relative to forage-plant seeds permitted entry into the United States.

The first number also comprises a discussion of European seed conditions based on information furnished by A. J. Pieters, of the Bureau of Plant Industry, and Director Sorensen, of the Danish Seed Growers' Association; market notes for different sections of the country; reports on the sugar-beet seed. Bermuda-onion seed, and crimson-clover seed outlook; vegetable-seed crop conditions in California and the North Pacific division; data relative to commercial vegetable seed acreage and production, and wholesale and retail field seed selling prices as of April 30, 1919; and information on the total quantity of different varieties of velvet beans normally handled by wholesale and retail seedsmen in various southern States, together with the total quantity of the different sorts normally shipped out from producing sections by local shippers. Tentative seed production and consumption maps are presented, showing the counties normally producing a surplus, a sufficient, and an insufficient quantity of both crimson and white clover seed. Diagrams are also given showing the daily closing cash prices of "prime" seed of red and alsike clover and timothy on the Toledo market from September to April, inclusive, for the seasons of 1916-17, 1917-18, and 1918-19, respectively.

The second number contains articles on Some Factors That May Affect the Red Clover Seed Crop, by A. J. Pieters; Critical Studies in Seed Production, by R. A. Oakley; and Some Aspects of Seed Control, by W. A. Wheeler. Information is also presented relative to the outlook for seed of hairy vetch, orchard grass, redtop, meadow fescue, crimson clover, and Kentucky blue grass, together with notes on vegetable seed crop conditions, the production of onion sets near Chicago, and sources of field seeds for planting in the different States.

Seed-testing [in New Zealand], E. B. LEVY (*Jour. Agr. [New Zeal.*], 18 (1919), No. 3, pp. 129–139, figs. 9).—The methods employed in conducting and reporting germination and purity tests at the seed-testing station of the New Zealand Department of Agriculture are described.

Plants detrimental to agriculture: Botanical characteristics and methods of control, G. FRON (Plantes Nuisibles a l'Agriculture: Caracteres Botaniques et Agricoles Methodes de Destruction. Paris: J. B. Bailliere & Sons, 1917, pp. 346, figs. 151).—The work is divided into two parts, the first dealing in a general manner with weed growth and with the destruction of weeds, and the second part with brief descriptions of a large number of weeds arranged by families.

### HORTICULTURE.

Protecting American crop plants against alien enemies, B. T. GALLOWAY (*Trans. Mass. Hort. Soc., 1919, pt. 1, pp. 75–87*).—A popular review, with discussion following, of the work of the U. S. Department of Agriculture in protecting American crop plants against the attack of foreign insects and diseases, including the main features of recent quarantine measures.

**Report of inspection service**, T. J. HEADLEE, M. T. COOK, and H. B. WEISS (*N. J. Dept. Agr. Bul.* 6 (1917), *pp.* 199–213).—A report for 1916 on the inspection for injurious insects and diseases of nurseries and nursery stock in New Jersey, as well as nursery stock shipped into New Jersey from foreign countries and other States.

Analyses of insecticides and fungicides, A. J. PATTEN and E. F. BERGER (*Michigan Sta. Spec. Bul. 96 (1919), pp. 3–18*).—Analyses of samples of various insecticides and fungicides collected during 1917 and 1918 are reported. Special attention was given in 1917 to proprietary smut remedies and formaldehyde solutions, and in 1918 to commercial Bordeaux and Bordeaux-arsenate preparations.

**Judging vegetables**, A. H. MCLENNAN (*Ontario Dept. Agr. Bul.* 270 (1919), *pp. 30, figs. 60*).—A set of standards is given for judging all the more important vegetables when placed on exhibition, including a table showing the number or quantity of each vegetable to make up an exhibit for judging and illustrations of various vegetables prepared for exhibition.

[Variety tests of vegetables at Wisley in 1918] (Jour. Roy. Hort. Soc., 44 (1919), pp. 95-116).—Results of tests conducted with a large number of stocks of runner beans, climbing French beans, leeks, and vegetable marrows at Wisley in 1918 are reported.

Standardizing the hamper, F. P. DOWNING (Amer. Food Jour., 14 (1919), No. 7, pp. 9–12, figs. 3).—This is the first of a series of articles in which the author is to consider the need of standardizing fruit and vegetable containers by Federal legislation. This article discusses present variations in the hamper basket and suggests proposed standards. Future articles are to deal with various other fruit and vegetable packages.

Berry boxes and fruit baskets, F. P. DOWNING (West. Fruit Jobber, 6 (1919), No. 4, pp. 15-21, figs. 3).—The author discusses some of the effects of Federal legislation providing for standard baskets or other containers for small fruits, berries, and vegetables; illustrates and describes the prevailing types of boxes and baskets; and recommends the elimination of a number of shapes now being manufactured. A table is given containing suggestive specifications for berry baskets and boxes.

Utilization of refrigerating processes for the conservation, storage, and transportation of fruits, DOUANE (Bul. Mens. Off. Renseig. Agr. [Paris], 16 (1917), Apr.-June, pp. 229-251).—A report on this subject to the French Commission for the organization and development of the fruit industry. The principal part of this report comprises the reproduction of an article by M. Pintaud, published in 1912, on the influence of artificial refrigeration on the fruit industry. In this article the selection of fruits for cold storage, as well as storage practices for various kinds of fruits and the history of refrigeration, are considered. With this article as a basis, the author presents certain conclusions relative to refrigerative practices applicable to France.

Varieties of fruits for various localities, V. R. GARDNER (*Oreg. Countryman*, 11 (1918), No. 2, pp. 18-21, fig. 1).—A list of varieties of orchard and small fruits and grapes recommended for different sections of Oregon.

A report on fruit growing in Denmark, M. GRAM (*Tidsskr. Planteavl*, 26 (1919), No. 1, pp. 80–185).—A report on the development and present condition of fruit culture in Denmark, based on investigations made by the Commission on Fruit Culture under the direction of the State Commission for Plant Culture in 1917.

Some observations on the pruning question, H. S. REED (Cal. Citrogr., 4 (1919), No. 10, pp. 258, 282, fig. 1).—A contribution from the California Citrus substation, in which the author briefly discusses natural and artificial difficulties in solving the pruning question. The greatest natural obstacle, he points out, is the lack of fundamental knowledge of processes which take place within the tree. The work of Kraus and Kraybill dealing with the nitrogen and carbohydrate relations within the tomato plant (E. S. R., 40, p. 40) is cited as a step in the right direction. A serious artifical obstacle to successful pruning is the wholesale adoption of certain systems that, although giving success under a limited set of conditions, have not been thoroughly compared with other systems under varying conditions.

**Pruning and spraying the home orchard and vineyard**, G. M. BENTLEY (*Tennessee Sta. Bul. 121 (1918)*, *pp. 19-47*, *figs. 50*).—Practical instructions on pruning and spraying, with special reference to the home orchard and vineyard.

The commercial apple industry in the United States, J. C. FOLGER (*Pure Products*, 15 (1919), No. 8, pp. 380-386).—A discussion of the commercial phases of the industry, including a brief description of the relative importance of different regions and the factors which influence their development.

"P. J. Bergius," a new apple variety, C. and R. FLORIN (Acta Horti Bergiani [Stockholm], 6 (1918), No. 5, pp. 7, pl. 1, fig. 1).—A red apple of dessert quality, which originated in the Bergielund fruit tree garden of the Royal Swedish Scientific Academy, is illustrated in color and described. The P. J. Bergius variety is a fall apple, and is believed to have originated as a bud sport from the Swedish variety Sävstaholm.

Minimum temperatures sustained by apricots during March, 1919, in the Pecos Valley, N. Mex., C. HALLENBECK (U. S. Mo. Weather Rev., 47 (1919), No. 4, p. 240).—The author presents tabular data illustrating a remarkable resistance to temperatures below freezing after a period of low atmospheric humidity.

Apricot buds were showing pink on March 1, 1919, and were opening on March 3, 1919, and during the entire period, March 1 to March 19, inclusive, the blossoms were subjected to daily minimum temperatures below freezing with a temperature of 14° below freezing when in full blossom. On March 25 a thorough examination of the trees at different elevations showed less than 7 per cent of the fruit dead or injured. Inasmuch as the percentage of dead and injured fruit was not above normal it is not certain that this injury was caused by the cold.

On April 8, 1919, apples in the Pecos Valley were, when in full blossom, subjected to a snowstorm lasting 15 hours, during which the temperature was continuously below freezing, and below 30° F. in portions of the orchard district for several hours. Nevertheless, no noticeable damage was sustained to the fruit.

Cover crops in the peach orchard, C. A. McCUE (Delaware Sta. Bul. 120 (1918), pp. 3-31, fig. 1).—Cover crop studies in peach orchards were started in

444

1909 and continued through 1917. The results secured each season are here reported in detail. A summary of the results in general has been previously noted (E. S. R., 41, p. 145).

The culture of peach trees in the German climate, F. RUDOLPH (*Die Freiland*zucht des Pfirsichbaumes im deutschen Klima. Frankfort-on-the-Oder: Trowitsch & Son, 1918, 2. ed., rev. and enl., pp. X+84, figs. 35).—A practical treatise on peach culture in Germaný.

Relation of weather to fruitfulness in the plum, M. J. DORSEY (Jour. Agr. Research [U. S.], 17 (1919), No. 3, pp. 103-126, pls. 3, fig. 1).—A contribution from the Minnesota Experiment Station, giving the results of the author's investigations, together with a review of the literature on related work. The author considers the effect of various weather factors, such as wind, temperature, sunshine, and rain, on the pollination process and fruit setting.

Summarizing the results of the investigations as a whole, it is concluded that unfavorable weather at blooming time may completely prevent the setting of fruit in the plum, even though there be a full bloom. Rain and low temperatures are the most harmful factors, although prolonged strong winds are also important. The greatest damage from wind is due to interference with insect action and, hence, pollination at critical times. Wind pollination is insufficient even under the most favorable conditions. Frosts occur only occasionally during bloom and injure the pistil more than pollen. The greatest damage from low temperatures is in the retarding of pollen-tube growth. Other conditions being favorable, cloudiness does not prevent the setting of fruit. Rain prevents pollen dissemination by closing the anthers or by preventing them from opening. It does not burst pollen nor kill it. On account of the adhesive action between stigma and pollen, rain does not completely wash pollen from stigmas.

The stigma is receptive for 4 to 6 days, and following the active period of secretion the stigmatic cells rapidly disintegrate. The style abscisses in 8 to 12 days after bloom. As a result of the rapid disintegration in the stigma and the abscission of the style, a delay in pollination or slow tube growth when the temperature is low renders fertilization uncertain. Tube growth appears to be relatively slow in the plum even under favorable conditions.

Analysis of the prevailing weather at bloom shows that the weather factor responsible for the status of the setting of fruit may vary from season to season. Both early and late blooming varieties have been affected by unfavorable weather. Practical remedies under orchard conditions do not appear readily available, but since tube growth seems to be the process most directly affected by low temperatures it is suggested that remedial measures should be sought in suitable pollinizers which show the fastest tube growth.

Tests with unfruitful plum trees, G. ESAM (Jour. Agr. [New Zeal.], 18 (1919), No. 3, pp. 162–164, fig. 1).—A series of pruning and girdling experiments was started under the direction of the New Zealand Department of Agriculture to determine the cause for the failure of plum trees to set fruit on some of the heavier land in the Hawke's Bay district. The results to date point to cross-pollination as an important factor in securing a good crop of plums. The experiments are to be continued.

Experiments with varieties of gooseberries, currants, and black currants, N. ESBJERG (*Tidsskr. Planteavl*, 26 (1919), No. 1, pp. 52-79).—The results for the period 1911–1917 are given of a variety experiment started in 1909 at the experiment station at Spangsbjerg, near Esbjerg, Denmark.

A commercially new blueberry, G. E. MURRELL (Jour. Heredity, 10 (1919), No. 6, pp. 271-275, figs. 3).—The author describes a small blueberry plantation in northwestern Florida that was established from wild native plants, possibly *Vaccinium virgatum*, although showing certain differences from that species,

Plantings aggregating 8.5 acres have been made during the past 20 years, and have been commercially successful. There is no apparent difference in productiveness between 20-year-old and 12-year-old bushes, although there is a marked variation in yield between individual plants. From the age of 8 years onward, they average 0.5 bu. of fruit per plant annually, or 3,200 qt. per acre. It has been found that in transplanting suckers from the swamps to the home garden, they should be set somewhat more deeply than they originally grew.

Manual of American grape growing, U. P. HEDRICK (New York: The Macmillan Co., 1919, pp. XIII+458, pls. 32, figs. 54).—A practical manual for both commercial and amateur grape growers, prepared with the view of covering the whole field of grape growing in America. The successive chapters discuss the domestication of the grape, grape regions and their determinants, propagation, stocks and resistant vines, the vineyard and its management, fertilizers for grapes, pruning the grape in eastern America, training the grape in eastern America, grape pruning on the Pacific coast, European grapes in eastern America, grapes under glass, grape pests and their control, marketing grapes, grape products, grape breeding, miscellanies, grape botany, and varieties of grapes.

The future of the hybrid direct bearers, E. PÉE-LABY (*Rev. Vit.*, 50 (1919), *No. 1283, pp. 65-67*).—The author briefly notes some of the more important phases brought out by an investigation, relative to the value of hybrid direct bearers, conducted by the agricultural society of Haute-Garonne. He concludes that, as a result of the knowledge acquired in the demonstration fields established in the various regions of France, the culture of hybrid direct-bearing grapes is believed to offer to viticulture in general actual guaranties of security for the future.

Observations on the medlar tree flower and the origin of the stoneless medlar in Italy, I. PIERPAOLI (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 27 (1918), I, No. 3, pp. 121–125; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 10 (1919), No. 1, pp. 48, 49).—Observations made on specimens of the medlar tree (Mespilus germanica), grown in the garden of the Botanical Institute of the University of Rome, revealed all stages of transition between the normal medlar and the stoneless medlar. The stoneless medlar seems to have originated through the successive reduction of the pistils up to their complete disappearance and through the asexual reproduction of the germs which showed this character for the first time.

The total absence of the pistils is accompanied by the total absence of such secondary characters as the downy areas on the surface of the expansion of the receptacle and the yellow halo of the stamens on the edge of the receptacle.

Olive culture in Argentina, C. VALLEJO (Bol. Min. Agr. [Argentina], 23 (1918), No. 1, pp. 124-147, pl. 1, figs. 17).—This paper discusses methods of growing olives and the preparation of olive oil, with special reference to the development of the industry in Argentina.

Avocados, particularly Guatemalans, W. POPENOE (*Fla. Grower, 19* (1919), *Nos. 23, pp. 6, 18-20, figs. 2; 24, pp. 6, 7, 12, 13, figs. 2).*—A paper on this subject, based on the author's study of the avocado in Guatemala (E. S. R., 41, p. 45), in which the author gives special consideration to factors influencing the successful introduction and culture of Guatemalan varieties in Florida.

[Stocks for citrus trees], R. A. DAVIS (Union So. Africa, Dept. Agr. Rpt., 1917–18, pp. 73, 74).—A summary of results secured in a test of various stocks for citrus trees conducted under the direction of the Department of Agriculture of the Union of South Africa for a number of years.

More success has been obtained with the rough lemon and the sweet orange than with any other kind of stock. The lemon has been proved suitable for practically all of the many varieties of oranges which have been worked on it. A tendency to the production of a slightly elongated shape of orange has been observed as distinct front the rounder form presented by the same variety of fruit when budded on sweet orange. The flavor of the fruit on the older trees budded on lemon stock is equally as good as that grown on sweet orange stock, but with younger trees there is a slight indication of lemon flavor in the oranges. The skin of the Washington Navel fruit from young trees growing on rough lemon stock is rougher than with fruit grown on any other stock. At 10 years old no outward difference can be observed, but the skin is, as a rule, slightly thicker than when sweet or trifoliate roots have been used. The use of rough lemon stock does not appear to influence the color, size, weight, or juice content of the fruit. No instance of root-rot has been met with either on rough lemon or any other stock.

All the different varieties worked on sweet lime root have suffered badly from chlorosis. In addition, this stock has almost as much of a dwarfing effect as trifoliate. Bitter Seville and Florida sour oranges are classed as useless for nursery purposes under soil conditions existing at the experiment stations. No success has been met with in the use of the shaddock and pomelo as budding stock. Trifoliata roots have a marked dwarfing effect upon practically all sweet oranges excepting Valencia Late and De Roi, and are not recommended for general use.

Fertilization of citrus groves during period of high-priced fertilizers, J. A. PRIZER (*Cal. Citrogr.*, 4 (1919), No. 9, pp. 231, 255, fig. 1).—A contribution from the California Citrus substation, in which the author presents a fertilizing program for citrus growers, with special reference to the conservative use of highpriced commercial fertilizers.

Past and new practices in growing coconuts, P. C. VAN DER WOLK (*Cultura*, 31 (1919), No. 369, pp. 153-182).—A paper on this subject read before the Tropical Agricultural Society at Wageningen, in which the author points out the importance of the coconut industry to the Netherlands Indies, discusses native methods of growing coconuts, and suggests new cultural practices based on his investigations of the coconut palm previously noted (E. S. R., 39, p. 244).

Contribution to the study of tea in Indo-China, P. EBERHARDT and AUFRAY (Bul. Écon. Indochine, n. ser., 21 (1918), No. 133, pp. 999–1023, pls. 13).—A review of the present status of tea culture in Indo-China, including analyses of various samples of tea from Laos, Tonkin, and Annanf.

Abnormal growth of scion in relation to stock in some cultivated almonds, N. PASSERINI (Bul. Soc. Bot. Ital., No. 1 (1919), pp. 6, 7, fig. 1).—An illustrated description with circumference data is given of almond trees growing on the grounds of the Agricultural Institute of Scandicci, Florence, Italy. In these the scions have not only greatly overgrown the stocks but have tended to increase the circumference of the stocks in the region of the graft over that at the base of the trees. The normal fruiting of the trees, which are about 25 years of age, has not been interfered with by the abnormal development of the graft.

The butternut and the Japan walnut, W. G. BIXBY (Amer. Nut. Jour., 10 (1919), No. 6, pp. 76-79, 82, 83, figs. 11).—As a result of requests sent out for superior butternuts the author received specimens from various parts of the country, many of which were rough-shelled Japan walnuts so near like butternuts as to be readily mistaken for them, and some of which were sent in as butternuts. An examination of the evidence now at hand leads to the conclu-

sion that all instances of rough-shelled Japan walnuts have been found in butternut territory. He concludes that the only reasonable explanation of this remarkable change of the Japan walnut from smooth to rough-shell in this country is that it hybridizes with the native butternut.

Smith's chrysanthemum manual, E. D. SMITH (Adrian, Mich.: Elmer D. Smith & Co., 1919, 4. ed., pp. 75, pl. 1, figs. 40).—In the present edition of this manual (E. S. R., 28, p. 543), many of the chapters have been revised and enlarged, giving more complete details.

**Progress in breeding freesias**, W. VAN FLEET (*Jour. Internat. Gard. Club*, 3 (1919), No. 2, pp. 232-239, pl. 1).—A popular review of progress made in breeding improved varieties of freesias, both in this country and abroad.

Spring-flowering stocks tried at Wisley, 1916–17 (Jour. Roy. Hort. Soc., 44 (1919), pp. 117–122).—Descriptions and notes are given on different varieties of stocks tested at Wisley in 1916–17.

Color in my garden, L. B. WILDER (Garden City, N. Y.: Doubleday, Page & Co., 1918, pp. XV+410, pls. 24, figs. 3).—In a previous book (E. S. R., 36, p. 142) the author gave her experience in planning and making an ornamental garden. The present book, which is based on color effects developed in this garden, presents suggestions relative to the selection and arrangement of plants with special reference to harmony in color and the development of a series of color pictures throughout the season. The text is accompanied by numerous garden pictures illustrated in color by A. Winegar.

**Report of the botanist**, J. DUNBAR (*Proc. Soc. Amer. Florists*, 32 (1916), pp. 164–173; 33 (1917), pp. 197–204).—The first of these is a report to the Society of American Florists and Ornamental Horticulturists on new trees and shrubs introduced from Western China to North America during the past 18 years. Some 18 genera and 117 species, varieties and hybrids, all of which have come under the author's personal care in the parks at Rochester, N. Y., are considered. The second report deals with important hardy trees and shrubs new or rare in cultivation.

Winter injury to ornamental trees and shrubs, F. S. BUCK (Ann. Rpt. Pomol. and Fruit Growing Soc., Quebec, 1918, pp. 47-53).—An account with discussion following of the nature and extent of winter injury to trees and shrubs in Canada during the severe winter of 1917–18, including lists of trees and shrubs grouped according to the amount of injury which they sustained.

#### FORESTRY.

Lumber export and our forests, H. S. GRAVES (U. S. Dept. Agr., Off. Sec. Circ. 140 (1919), pp. 15).—A discussion of the foreign demand for American timber and other forest products, the available supply in this country, the probable effect of an increased export trade on this supply, measures that are being taken in foreign countries to preserve and increase forest products, and the great necessity of similar measures in this country.

The author considers the situation to be serious to our wood-using industries and to all consumers of forest products. He advocates appropriate legal and administrative measures to insure adequate forest protection and the use of such methods of cutting as will make possible forest replacement by natural reproduction, together with a broad policy of public acquisition of forests, National, State, and municipal.

It is believed that the adoption of such measures will render safe and wise the encouragement in a large way of the export of lumber and other forest products. Firewoods: Their production and fuel values, A. D. WEBSTER (London: T. Fisher Unwin, Ltd., 1919, pp. 95, pls. 8, figs. 3).—This work deals particularly with the firewood problem in Great Britain. The successive chapters discuss sources from which firewood may be obtained; preparing the firewood; comparative value of different firewoods, percentage of water, etc.; heating properties of firewood—scented wood, etc.; firewood value of various home-grown woods; firewood and faggots—storing, capacity, and price; charcoal wood, charcoal burning, comparative value of wood for charcoal, returns from charcoal; charcoal wood for gunpowder; and wood fires and grates. Tabular data on the weight of firewood, cord measurements, and prices, together with the State fuel wood order, issued by the London Board of Trade in 1918, are included.

Germination trials with Hevea seed, J. G. J. A. MAAS (Arch. Rubbercult. Nederland. Indië, 2 (1918), No. 9, pp. 666-725).—Experiments were started to determine the cause of speedy loss of germinative power in consignments of Hevea rubber seed and the best method of preserving and shipping the seed to obviate rapid deterioration.

The results thus far secured indicate that all measures adopted in the preserving and dispatch of seed should be directed toward preventing the seed from drying up, as they dry quickly and thus lose a large proportion of their germinative power. The fermentation of seed packed in closed cases is also a source of injury.

Instructions are given for preparing and handling the seed in transit, in storage, and in the nursery.

Wound curing and healing with Hevea trees, P. E. KEUCHENIUS (Arch. Rubbercult. Nederland. Indië, 2 (1918), No. 9, pp. 639-665, figs. 15).—Wounds in cases where the bark was totally pared off recovered more quickly than where the bark was not wounded down to the cambium (ordinary tapping cuts). Totally pared bark, however, retards retapping operations as compared with partly wounded bark, because in partly wounded bark there always remain a certain number of lactiferous layers intact which may be tapped sooner, even though the renewed bark is thinner than the renewed bark of a totally pared off wound. These results indicate that in cases of canker infection paring should only be sufficiently deep to remove all traces of the infection. See also a previous note (E. S. R., 40, p. 448).

The time after which renewed bark, either on a superficial wound or on a wood wound, becomes tapable again can not be given in general terms, because trees differ in the number of latex rings formed in a given time. Experiments in the chemical treatment of wounds showed that recovery was accelerated by 43.5 days by treating the wounds with a solution of 0.25 gm. of calcium chlorid and 0.25 gm. magnesium chlorid in 100 cc. of water. Treatment with distilled water also gave good results. Directions are given for treating and bandaging wounds.

Progress report of forest administration in Baluchistan for 1917-18, MUHAMMED AFZAL (*Rpt. Forest Admin, Baluchistan, 1917-18, pp.* [6]+20).— The usual report on the administration of the State forests in Baluchistan for the year ended June 30, 1918. Data relative to alterations in forest areas, yields in major and minor forest products, miscellaneous work, revenues, expenditures, etc., are appended in tabular form.

Annual report on the forest administration in Ajmer-Merwara for the year 1917-18, SHAMBHOO DATT JOSHI (Ann. Rpt. Forest Admin. Ajmer-Merwara, 1917-18, pp. 26).—A report similar to the above on the administration of the State forests in Ajmer-Merwara.

### [Vol. 41

# DISEASES OF PLANTS.

**Plant** pathology to-day, C. L. SHEAR and N. E. STEVENS (*Sci. Mo.*, 7 (1918), *No. 3, pp. 235-243*).—This is a brief account, with illustrations, of the progress of plant pathology as regards aims, methods, accomplishments, limitations, restrictions, present tendencies, and opportunities for this work, and more particularly of the broader outlook of pathologists and of the general tendency toward effective cooperation, both within and between States and Nations.

**Progress in control of plant diseases, R. E.** VAUGHAN (Ann. Rpt. Wis. State Hort. Soc., 48 (1918), pp. 179–186).—It is stated that by employment of sanitary measures, coupled with spraying, a number of diseases can be controlled, though chief reliance is placed on the development of resistant plants. The fungus causing cherry leaf spot was found (as is the case also with apple scab) to overwinter on falling leaves. Angular leaf spot and anthracnose of cucumber are controlled by seed treatment. Cucumber mosaic appears to be associated with the presence of the striped cucumber beetle. Strains of kraut cabbage resistant to yellows have been developed. Tobacco strains resistant to root rot have also been obtained. Bordeaux mixture at a strength of 3:3:50 gives control of cherry shot-hole leaf spot with only two applications if these are timely and are combined with sanitary measures.

[Plant diseases in South Africa, 1917–18], I. B. P. EVANS (Union So. Africa Dept. Agr. Rpt., 1917–18, pp. 65–68).—In this portion of the report on the division of botany, the author gives brief notes on investigations carried out on citrus canker, bacterial spot of citrus (Bacillus citrimaculans), walnut blight (Bacterium juglandis), bean blight (B. phaseoli, Pseudomonas sp.), sugar cane root disease (Marasmius sp.), cane leaf spot (Cercospora sacchari or Helminthosporium sp.), papaw leaf spot (Phoma sp.) and fruit spit, and pineapple black rot (Penicillum sp.), together with a list of papers issued during this period on plant diseases.

It is stated that a further outbreak of citrus canker was discovered at Wolhuterskop near Rustenburg in June, 1917. Apparently the disease had been present in one locality for 8 or 9 years, being traceable to nursery-stock, buds, or cuttings.

[Outgrowths on plants], T. A. C. SCHOEVERS (*Tijdschr. Plantenziekten*, 24 (1918), Nos. 3, pp. 123-132; 4, pp. 133-148).—This is mainly a discussion of known data on crown gall, with references to contributions on the subject.

[Verticilliose] in cultivated crops, H. A. A. VAN DER LEK (*Tijdschr. Planten*ziekten, 24 (1918), No. 3, pp. 81, 82).—A brief account is given of a study during 1916–17 of verticilliose in cucumber, said to be identical with the disease caused by *Verticillium alboatrum* in potato and other plants.

**Clover stem rot, F. A.** WOLF and R. O. CROMWELL (North Carolina Sta. Tech. Bul. 16 (1919), pp. 5–18, pls. 3).—The presence in North Carolina of a stem rot disease of crimson clover has led to a study of this disease, which is said to be prevalent in Europe and rather widely distributed in the United States. The disease is due to Sclerotinia trifoliorum and, in addition to the crimson clover, the fungus attacks red clover, white clover, alsike clover, and alfalfa. The disease prevails from October to March and may be recognized by the sudden wilting and death of plants in spots, a rotting off or decay of the stem near the ground, and the presence of black sclerotia on the decaying stems.

A study was made of the development of *S. trifoliorum* in comparison with *S. libertiana*, and infection experiments were made with the different organisms. Comparative morphological studies indicate that they are distinct species. The sclerotia are said to remain dormant in infested soils, and to be carried by contaminated seed as well as on implements, soil, hay, etc. It is recommended that

care be exercised in the transfer of soil in the inoculation of new fields with the nitrogen-fixing organism, and in not returning manure to clover fields when hay from infested fields has been fed. The adoption of a system of crop rotation is said to be the only reliable means of control for infested fields.

"Heart damage" in baled jute, R. S. FINLOW (Mem. Dept. Agr. India, Chem-Ser., 5 (1918), No. 2, pp. 33-68).—Reporting results of studies carried on since 1907, the author states that heart damage of jute occurs only where damp jute is closely packed in mass. In the center a rise of temperature occurs, due to the action of thermophilic bacteria which attack the cellulose constituent of the fiber, which is apparently hydrolyzed and rendered useless for spinning purposes. Isolated bacterial cultures reproduced the heart damage in the laboratory. Aspergillus fumigatus, although almost always present, is supposed simply to live on the degradation products of the cellulose.

Tight packing lowers the water requirement conditioning heart damage, which never occurs in so-called genuine jute, this term being applied to jute which has been perfectly dried and which has not been exposed to night dews or otherwise watered. Ship damage is supposed to be identical with heart damage, although it originates on the outside of the bales.

Heart rot or black pit of pea, H. A. A. VAN DER LEK (*Tijdschr. Plantenziekten*, 24 (1918), No. 3, pp. 102–114, pl. 1).—This trouble, which appears to have been present in Holland for some years, has been associated with bacteria and also with *Ascochyta pisi*, but further studies regarding the causal organism are considered necessary.

Potato diseases, VI-VIII, E. M. DOIDGE (So. African Fruit Grower, 5 (1918), Nos. 1, pp. 6, 7, figs. 2; 3, pp. 47, 48, figs. 6; 5, pp. 94, 95, figs. 2).—Three papers are given.

VI. The Rhizoctonia disease of potatoes (Corticium vagum solani).—C. vagum solani is discussed, as occurring in its sclerotial stage R. solani on potato, in connection with rosette, little potato, aerial potato, stem rot, and russet scab, with conditions favoring the disease (heavy soil, poor drainage, and high temperature) and its control (including the use of corrosive sublimate, 2.5 oz. to 15 gal. water, treatment for seed tubers, clean cultivation, and rotation).

VII. Late blight or Irish potato blight (Phytophthora infestans).—It is stated that although late blight (P. infestans) is ordinarily of secondary importance in South Africa as compared with early blight (Macrosporium solani), it occasionally appears during very wet seasons in epidemic form, being favored by the presence of other hosts, but is controllable by the proper use of Bordeaux mixture in due season.

VIII. Internal brown fleck.—This disease is supposed to occur wherever potatoes are cultivated and to be quite common in South Africa, appearing to be connected with deficiency of lime, sulphates, and perhaps nitrogen.

Leptonecrosis [leaf roll] of the potato plant, and allied diseases, H. M. QUANJER, H. A. A. VAN DER LEK, and J. A. BOTJES (Ann. Sci. Agron., 4. ser., 6 (1917), Nos. 7-9, pp. 301-357, figs. 11; 10-12, pp. 455-494, figs. 2).—This is a translation into French by V. Antoine of a contribution previously noted (E. S. R., 36, p. 847). It includes an extended bibliography.

The use of lime in controlling finger-and-toe in turnips, J. HENDRICK (*Trans. Highland and Agr. Soc. Scot.*, 5. ser., 30 (1918), pp. 137-145).—Having noted in a previous report (E. S. R., 31, p. 424) a reduction of finger-and-toe in turnips associated with the use of lime either in burnt form or as carbonate, the author now gives attention to some criticisms offered regarding the use of lime, presenting illustrations of successful applications of such treatments during the years 1915 to 1917 employing ground lime or waste lime from paper works,

452

The conclusion drawn by the author is that finger-and-toe in turnips can be kept in check or entirely prevented by using lime in sufficient quantity to neutralize all sourness and leave some excess of carbonate of lime in the soil. It is not necessary to lengthen the rotation in order to prevent the disease, since turnips can be grown in short rotation year after year on the same soil provided the soil is kept sufficiently supplied with lime.

"Little leaf" of deciduous fruits, R. W. HODGSON (*Mo. Bul. Cal. Com. Hort.*, 7 (1918), No. 9, pp. 529-532, figs. 3).—In a progress report of studies on little leaf, it is stated that in the exceptionally dry season of 1917 little leaf was unusually prevalent, particularly in dry-farmed sections where the water supply is early exhausted. A decided relation of the occurrence of the trouble to light sandy soils was also observed. Most regions of California have, of the conditions related to winter dormancy elsewhere, only that of soil moisture deficiency. Severity of desiccation may be expressed by the development of little leaf, which is frequently present in only a portion of a tree, possibly a part which is deficient as regards water supply and which is backward as regards maturity.

On the other hand, a different type of injury is associated with overirrigation, apparently due to exhaustion of the food reserve due to the abnormal continuation of growth late in the season.

A tree may suffer from the lack of moisture, it is thought, even when the water table has been raised by irrigation to within a foot of the surface, since only the capillary water above the water table can be utilized. This may account for the presence of little leaf where the water is near the surface. The rise of the water may actually deprive the roots of their capillary water supply under the conditions thought to exist in this region.

A new disinfectant for pear blight, F. C. REIMER (Mo. Bul. Cal. Com. Hort., 7 (1918), No. 10, pp. 562-565).—In experiments which were started in June, 1918, to test the effectiveness of disinfectants for pear blight on wounded trees, it was found that under specially favorable conditions as regards concentrations, etc., the application of Bordeaux paste, corrosive sublimate, cresol, lime-sulphur, blackleaf 40, and chlorazene failed to prevent severe infection by pear blight brushed on wounded surfaces. Cyanid of mercury was completely preventive at 1:500, while at 1:1,000 occasional development of pear blight occurred and at 1:300 severe injury was caused. It is thought, therefore, that a strength of 1:500 is both safe and effective for application to tree wounds. Corrosive sublimate is considered effective for use with the tools employed for cutting out diseased wood, the only curative treatment yet found to be effective against pear blight.

Citrus canker [in the Transvaal], I. B. P. EVANS (So. African Fruit Grower, 5 (1918), No. 3, pp. 44, 49).—A résumé is given with remarks made at the Transvaal Agricultural Union Meeting, September, 1918, on citrus canker in regard to its appearance at different points in the Cape and Transvaal Provinces. The disease is said to have spread to an extraordinary extent in the citrus orchards on account of the exceptionally wet season of 1917. Vigorous action resulted in complete suppression of the disease in several districts, so that it is hoped that it may soon be completely eradicated in these regions.

Bud curl of the lemon tree, C. C. MILLER (Mo. Bul. Cal. Com. Hort., 7 (1918), No. 9, pp. 515-519, figs. 5).—Explanation is given of the author's conception regarding the production of bud curl or pinch at the grafting union in case of lemon trees (especially when grafted on orange stock), and of the means to be employed to remove or rather to avoid such obstruction to the flow of elaborated sap toward the roots. The plan discussed involves slitting the bark in such a way that the wounds will unite by continued inrolling above and below the graft union, and bridging the pinched region with a live layer of bark and cambium, thus eliminating the pinched belt which previously blocked the path of the elaborated sap.

On a tree of Æsculus pavia killed by Botrytis cinerea, W. B. BRIERLEY (Roy. Bot. Gard. Kew, Bul. Misc. Inform., No. 9-10 (1917), pp. 315-331, pl. 1, figs. 2).—An account is given, with discussion, of the killing of a specimen of  $\mathcal{E}$ . pavia supposedly within 15 days after invasion by a fungus, apparently B. cinerea. The tree was killed above the belt of attack, apparently by checking very quickly the upward flow of water in the trunk. The tissues below the limit of fungal extension remained alive, exuberantly healthy, while those above soon became dry and shriveled. To determine the nature of the hypothetical occlusion of the water-conducting tissues, a thorough comparative examination of the diseased tissues was carried out, revealing the presence of approximately ten times as many tyloses in the diseased area as in the corresponding area of healthy wood and suggesting that the stoppage of the upward flow may have been due to their sudden accumulation.

Discussion is given also of the formation of conidiophorous stromata and of true sclerotia and of the constant relation of these to the lenticels.

It is stated that features presented by the morphology of the fungus in the tissues are to be described in a later publication.

Walnut blight [in South Africa], E. M. DOIDGE (So. African Fruit Grower, 5 (1918), No. 4, pp. 68, 69, figs. 2).—Walnut blight appearing recently in portions of South Africa is said to have been shown by investigations to be due to Bacterium juglandis, which is identical with the organism causing a similar disease in America and New Zealand. The blight appears to have been introduced with nursery stock, and to be greatly favored by the prevalence of rain and mist in spring and early summer during the growth of the nuts, many or most of which may drop at an early stage of development. The disease is carried over in leaves and in the lesions on the twigs.

Note on Polysaccum crassipes: A common fungus in eucalyptus plantations around Pretoria, P. A. VAN DER BIJL (*Trans. Roy. Soc. So. Africa*, 6 (1917), *pt. 3, pp. 209–213, pls.* 6).—The author gives a brief note on *P. crassipes*, which is a very common fungus in eucalyptus plantations around Pretoria. It is suggested that the relation between fungus and host is that of symbiosis, as the tissues of the plant do not appear to suffer from the presence of the fungus. Reference is made to the earlier and more general works on symbiosis.

Heart rot of Ptæroxylon utile caused by Fomes rimosus, P. A. VAN DER BIJL (*Trans. Roy. Soc. So. Africa, 6 (1917), pt. 3, pp. 215–225, pls. 6*).—The author gives an account of heart-rot disease in *P. utile*, ascribed to *F. rimosus*, as regards distribution of the fungus and its effect on the wood. This fungus is stated to have been reported in the Union of South Africa on 11 genera belonging to S different natural orders.

Decayed wood and the fungi therein as seen with the microscope, H. N. LEE (*Trans. Nat. Assoc. Cotton Manfrs., No. 102 (1917), pp. 220–226, figs. 6).*—This is a preliminary description of the effect of important wood destroying fungi on structural timbers taken from cotton mills and of the appearance of the fungi in the wood, with an outline of projected study to identify the fungi in the absence of fruiting bodies.

The decay of timbers in buildings, R. J. BLAIR (*Trans. Nat. Assoc. Cotton Manfrs.*, No. 102 (1917), pp. 242-250, figs. 6).—The question of decaying wood being considered as mainly, if not purely, a matter of moisture (relative humidity), an account is given illustrating the operation of this factor; also of

special devices which are described for the projected study of the critical humidities for the growth of fungi. The first test is to be made with *Lenzites sepiaria* on hemlock.

# ECONOMIC ZOOLOGY-ENTOMOLOGY.

A review of the ornithology of Minnesota, T. S. ROBERTS (Univ. Minn. Current Prob. No. 11 (1919), pp. VI+101, figs. 49).—This contains a synopsis of the bird life of Minnesota, a check-list of birds known to occur regularly in Minnesota, lists of birds that are rare or accidental in Minnesota, introduced species, unsettled species, extirpated species, and vanishing birds, a hypothetical list, a synopsis of Minnesota bird laws and of the Federal migratory bird law and the migratory bird treaty act, wild life refugees in Minnesota, a list of Minnesota game and wild life refugees, and outlawed and questionable birds. An abridged bibliography of Minnesota ornithology, together with an index thereto by authors' names and dates and a subject index are also included.

Some recent investigations on the food of certain wild birds, W. E. Col-LINGE (Jour. Bd. Agr. [London], 25 (1918), No. 6, pp. 668-691, figs. 17).-From an examination of the stomach contents and of the crop where present of 3,670 adult birds and 595 nestlings, embracing 9 species of wild birds, the author concludes that the volumetric method or percentage by bulk is the only reliable one for estimating the nature of the food and a bird's true economic position. and that the numerical method is highly misleading and unsatisfactory. Two of the 9 species of wild birds treated, namely, the house sparrow and wood pigeon, are distinctly injurious; 2, the rook and sparrow hawk, are too numerous and consequently injurious; 1. the missel thrush, is locally too numerous; and 4. the skylark, the green woodpecker, the kestrel, and the lapwing, are highly beneficial. In the interest of agriculture it is very desirable that strong repressive measures be taken against the house sparrow and wood pigeon and for the time being that all protection be withheld from the rook, sparrow hawk, and the missel thrush, while every protection should be given to the 4 species that are highly beneficial.

It is further concluded as a result of this investigation that all of the commoner species of wild birds require reinvestigating so far as their food and feeding habits are concerned, and that their various food items should be worked out and estimated by the volumetric method.

A list of 23 references to the literature is appended.

Some further investigations on the food of wild birds, W. E. COLLINGE (Jour. Bd. Agr. [London], 25 (1919), No. 12, pp. 1444-1462, figs. 9).—In this article, which is in continuation of that above noted, the author reports upon examinations made of the stomach contents of 798 adults and 166 nestlings, embracing 8 species of wild birds.

It was found that "the jackdaw, yellow bunting, great tit, blue tit, song thrush, and fieldfare are distinctly beneficial. The great tit, blue tit, and fieldfare are beneficial to such an extent that their protection is advisable. In spite of the injuries it commits, it would be unwise to recommend any repressive measures for the chaffinch. The starling has been allowed unduly to increase. At the present time it is far too numerous, and the injuries it commits are far greater than the benefits it confers. Temporary repressive measures would, no doubt, help to restore a more normal population of this bird, with considerable benefit to both the farmer and the fruit grower."

A list is given of 9 references to the literature.

North American pseudophyllidean cestodes from fishes, A. R. COOPER (*Ill. Biol. Monographs, 4 (1918), No. 4, pp. 243, pls. 13*).—This report of studies includes a bibliography of 10 pages.

Work connected with insect and fungus pests and their control, F. WATTS (*Imp. Dept. Agr. West Indies, Rpt. Agr. Dept. St. Vincent, 1917–18, pp. 12–14*).— This report relates entirely to the cotton stainer (*Dysdercus delauneyi*) and the measures taken in its control.

[Insects and insect control in British Guiana], G. E. BODKIN (*Rpt. Dept. Sci. and Agr. Brit. Guiana*, 1917, pp. 53–66).—A discussion of the occurrence of and work with the more important insects of the year, in which particular attention is given to the locust invasion and their combat.

Common British beetles and spiders and how to identify them, S. N. SEDG-WICK (London: Charles H. Kelly [1919], pp. 62, figs. 285).—A small pocket handbook.

Notes and observations on agricultural entomology, G. DEL GUERCIO (Agr. Colon. [Italy], 12 (1918), Nos. 4, pp. 216–230, figs. 5; 5, pp. 273–323, figs. 41; 13 (1919), No. 1, pp. 31–62, figs. 31).—Papers are presented on a New Enemy of the Beet (Gelechia ocellatella) (pp. 216–230) (see p. 460); A Thysanopterous Enemy of the Vine in Bengasi (Dictyothrips agyptiaca) (pp. 273–286); The Carob Cecidomyid (Eumarchalia gennadiosi) (pp. 287–297); The Pink Bollworm and Its Endophagous Enemies (pp. 298–311); The Dipterous Enemy Rondaniella phorodontis n. sp. of the Hop Aphis (pp. 31, 32); The Dipterous Enemy R. macrosiphonis n. sp. of the Artichoke Macrosiphon (pp. 33–35); etc.

[Report of] division of entomology, C. P. LOUNSBURY (Union So. Africa Dept. Agr. Rpt. 1917-18, pp. 87-107).—A detailed account of the work of the year ended March 31, 1918, in which particuar attention is given to the work with locusts.

Annual report of the government entomologist, C. C. Gowdey (Ann. Rpt. Dept. Agr. Uganda, 1918, pp. 42-51).—Brief notes are given of the insect pests of the year under the headings of pests of coffee, cacao, Para rubber, etc. A large part of the report deals with studies made of the variegated bug (Antestia orbitalis faceta), which attacks both Coffea arabica and C. robusta.

[Report on] entomology (*Rpt. Prog. Agr. India, 1917–18, pp. 85–101*).— The occurrence of and work of the year with the more important insect pests is reported upon.

Insect pests of low-country products, G. M. HENRY (*Ceylon Agr. Soc. Year Book, 1919–20, pp. 107–113*).—Brief accounts are given of the pests of coconut, grain crops, bandakka, legumes, cucurbits, sweet potatoes, and mustard and means for their control. A list of the common pests of food crops is included.

Florida truck and garden insects, J. R. WATSON (Florida Sta. Bul. 151 (1919), pp. 113-211, figs. 57).—A revision of Bulletin 134, previously noted (E. S. R., 37, p. 356).

Cotton pests in Montserrat (Agr. News [Barbados], 18 (1919), No. 447, p. 182).—This discussion relates particularly to the cotton stainer and a slug (Veronicella occidentalis).

Insect pests of tea, E. A. ANDREWS (Indian Tec Assoc., Sci. Dept. Quart. Jour., No. 1 (1919), pp. 22-25).—A brief discussion of the more important species.

The occurrence of forest insects in Sweden in 1917, I. TRÄGÅRDH (Meddel. Stat. Skogsförsökanst., No. 16 (1919), pt. 4, pp. 67-114, figs. 14).—The species of which particular mention is made are Scolytus ratzeburgi, Ips acuminatus, Myelophilus piniperda, M. minor, I. typographus, Bupalus piniarius, and Cephaleia signata.

140363°-19-5

Preliminary memorandum on current views as to the damage done to stored grain and flour by insects and mites, and the best means of prevention (*Roy. Soc.* [London], War Committee Memo. 1 (1918), pp. 2).—A brief reference to the literature.

Some necessary steps in any attempt to prove insect transmission or causation of disease, W. D. PIERCE (Science, n. ser., 50 (1919), No. 1284, pp. 125-130).—An outline of the steps necessary for successful investigation.

Clean cultivation in its relation to the control of insect pests, H. H. KING ([Wellcome Trop. Research Lab.] Ent. Bul. 8 (1918), pp. 4).—A brief discussion.

A comparison of the toxic action of volatile substances on insects, G. BERT-RAND and MRS. M. ROSENBLATT (*Compt. Rend. Acad. Sci.* [*Paris*], 168 (1919), *No.* 18, pp. 911-913).—Of the eight substances tested by the authors on the caterpillar of *Bombyx neustria* chloropicrin was found to be most toxic, being slightly more so than hydrocyanic acid gas.

The Pentatomoidea of Illinois, with keys to the Nearctic genera, C. A. HART (Ill. Dept. Registr. and Ed., Div. Nat. Hist. Survey Bul., 13 (1919), Art. 7, pp. 157-223, pls. 6).—This work, edited by J. R. Malloch, the manuscript having been only partly completed at the time of the author's death, includes descriptions of nine species and a genus (Cydnoides) new to science.

The fungus parasite of the periodical cicada, A. T. SPEARE (Science, n. ser., 50 (1919), No. 1283, pp. 116, 117).—This is a preliminary account of studies of Massospora cicadina, a detailed report of which is soon to be issued.

The beet leaf hopper.-- A report on investigations into its occurrence in California, H. H. P. SEVERIN (Facts About Sugar, 8 (1919), Nos. 7, pp. 139, 131. 134, fig. 1; 8, pp. 150, 151, fig. 1; 9, pp. 170, 171, 173, fig. 1; 10, pp. 190, 191, fig. 1; 11, pp. 210, 211; 12, pp. 230, 231, fig. 1; 13, pp. 250, 255, fig. 1).-This report is accompanied by tables which give the details relating to the occurrence of the beat leaf hopper in California. The data thus presented include the number of beet leaf hoppers captured on plants in the desert and in the cultivated area of the Imperial Valley, on the plains and foothills, and in the cultivated area of the San Joaquin Valley, and under natural conditions and in the cultivated area of Salinas Valley; lists of plants in which the beet leaf hopper deposited eggs in the cultivated area of the San Joaquin, Sacramento, and Salinas Valleys: plants on which the beet leaf hopper was collected and transmitted curly leaf to sugar beets; plants from which the beet leaf hopper was reared and transmitted curly leaf to sugar beets; number of dark male and female beet leaf hoppers captured in cultivated and natural breeding areas: and number of days beet leaf hoppers lived without food during winter.

A review of the leaf hoppers of the genus Gypona north of Mexico, E. H. GIBSON (*Proc. U. S. Mat. Mus., 56 (1919), pp. 87-100*).—Thirty-three species are recognized, of which eight are described as new to science.

Report to the froghopper committee on Mr. Glasgow's supposed cure for froghoppers, C. B. WILLIAMS (*Bul. Dept. Agr. Trinidad and Tobago*, 18 (1919), No. 1, pp. 10-15, figs. 4).—Demonstrations given failed to prove the liquid sufficiently effective in destroying either the eggs or nymphs of the froghopper or the fungi causing root disease.

A species list of the Aphididæ of the world and their recorded food plants, H. F. WILSON and R. A. VICKERY (*Trans. Wis. Acad. Sci., Arts, and Letters, 19* (1918), pt. 1, pp. 22–355).—The first part (pp. 26–180) of this list consists of a species list of the Aphididæ of the world with their recorded food plants, and the second part (pp. 181–355) of a list of aphid food plants and the aphids said to attack them. Fighting the walnut aphis, R. W. HODGSON (*Cal. Cult.*, 53 (1919), No. 3, p. 53, fg. 1).—The author describes a new dusting method for controlling the ravages of the walnut aphis as worked out by R. E. Smith, which consists in the use of a dry dusting mixture of 74 per cent kaolin and 24 per cent hydrated lime upon which 2 per cent of nicotin sulphate has been sprayed. This mixture is blown onto the trees by means of a duster, driven by a 3 h. p.-gasoline engine. The average application per tree of from 2 to 3 lbs. of the material gives a kill of 95 per cent. The mixture is prepared at a cost of 5 cts. per pound and from 20 to 40 acres can be dusted per day, depending upon the size

"The kill is effected largely by the fumes and is very rapid, as within a few minutes after dusting clouds of dead aphis may be seen falling from the trees. The zone of effective killing is comparatively large, as for two or three rows beyond the dusted area the trees will be found to be comparatively free from aphis."

of the trees and the way in which the rig is set up.

The results of the work in 1919 clearly indicate that it is possible in this way to control the pest effectively. The method has reduced the cost more than one-half, and made it possible to get over the orchard from five to six times as fast as formerly.

It is pointed out that as reinfestation from adjoining infested orchards will take place in a few days the control of the walnut aphis is a community problem. "With the new method it seems possible to cover quickly and effectively a large enough acreage to make one application sufficient. This is apparently what has occurred this past season in Santa Barbara County, it being reported that practically every ochard in the county was dusted."

"The new method also gives promise for successful control of the new codling moth worm for which it is now being used in infested areas, dry powdered lead arsenate being added to the aphis dusting compound."

The Aphididæ of Lahore, BASHAMBAR DAS (Mem. Indian Mus., 6 (1918), No. 4, pls. 18).—The plates here published illustrate the work previously noted (E. S. R., 40, p. 650).

Host list of fluted or cottony cushion scale, G. B. MERRILL (Quart. Bul. Plant Bd. Fla., 3 (1919), No. 4, pp. 125-133).—This is a compilation of the hosts of the cottony cushion scale.

A contribution to the knowledge of the Coccidæ of southwestern United States, G. F. FERRIS (*Leland Stanford Jr. Univ. Pubs.*, *Univ. Ser.*, 1919, pp. 68, figs. 38).—This report is based, for the most part, upon material collected by the author in the course of an extended tour through the arid southwestern portion of the United States during an investigation of the abundance and distribution of a lac-producing scale insect, *Tachardia larreæ*.

Of the 59 species representing 33 genera noted, 13 are described as new to science.

Lice and their menace to man, L. LLOYD (London: Henry Frowde and Hodder & Stoughton, 1919, pp. XIII+136, figs. 17).—This book brings together the present status of knowledge of lice for the general reader. Following an introduction the several chapters deal with the subjects as follows: Structure of the body louse, life history and habits, dissemination of the body louse and lousiness, disinfestation, the head louse, the crab louse, increased migration of body lice in fevers, relapsing fever, typhus fever, and trench fever. A subject index is included.

An investigation of the louse problem, W. MOORE and A. D. HIRSCHFELDER (Univ. Minn., Studies Biol. Sci., No. 3 (1919), pp. 86, pl. 1, figs. 7).—The details of the investigation here reported are briefly summarized by the authors as follows:

458

"Lice may be reared under incubator conditions in large numbers if fed with human blood twice daily, but under such conditions the life cycle is slowed down and the daily and total egg production per female is reduced. Fever, rash, and a general lassitude are produced as a result of the louse bites.

"Lice and their eggs are destroyed by the ordinary laundering processes used in the washing of cotton and khaki goods; for woolens slight alterations in the methods of washing are necessary. Chlorpicrin may be used for fumigation of garments, accomplishing the desired results in a short period of time with a small quantity of the chemical, without the use of high temperatures. The sachet method of controlling is ineffective or very expensive. Louse powders may be used with success, but being a wasteful method of applying an insecticide are not recommended. Impregnation of the underwear is the most promising method of louse control between lousings. Active chemicals of very low volatility are necessary to prove effective for the longest period of time. Halogenated phenols such as dibrommetacresol, dichlormonobrommetacresol, and their sodium salts, dibromcarvacrol, and dibromxylenol were found to be the most promising under laboratory conditions."

In an appendix the authors describe the preparation of certain compounds used in the experiments. A bibliography of 44 titles is included.

Contribution to the anatomy, physiology, and biology of the body louse (Pediculus vestimenti), Z. H. SIKORA (Arch. Schiffs u. Tropen Hyg. 20, (1916), Beiheft 1, pp. 76, pls. 3, figs. 24).—This part deals with the anatomy of the alimentary canal.

Silk and silkworms in the Far East, MR. and MRS. BOOTH-TUCKER (Agr. Jour. India, 14 (1919), No. 1, pp. 140-155).—This contains information gathered during a recent visit to China, Japan, Korea, Manchuria, and French Indo-China.

The peach twig borer (Anarsia lineatella), D. E. MERRILL (New Mexico Sta. Bul. 116 (1918), pp. 15, figs. 11).—This is a report of studies of the peach twig moth commenced in the summer of 1912 with a view to determining the life history and habits of the pest and testing control measures under local conditions. Injury is caused in two ways (1) to the tender shoots in spring when starting to grow and (2) by the summer broods to the fruit by eating into the surface or into the pit, resulting in dropping or decay and rendering such fruit worthless for shipping. It is said that from 5 to 15 per cent of the fruits of later varieties is not an unusual amount of injury, and in years of severe infestation the damage may reach 50 per cent. The species now occurs in the Mesilla and Pecos Valley regions, New Mexico, having been first met with by the author in Mesilla Valley in 1912, in which year it was quite numerous. Since then it has been moderately injurious on an increasing scale until 1918, when the damage again was very severe, 50 per cent of the crop in many orchards being more or less injured.

There appear to be three generations each year in New Mexico, the broods overlapping. The small overwintering larvæ emerge and begin work on the leaf buds about the first few days in April, from which time until about May 1 they may be found damaging the growing shoots. Apparently only very young larvæ hibernate, which it is thought represent parts of two broods. The eggs, which are usually laid singly on the twigs near the peaches or directly upon the fruit, hatch in about 5 days. In midsummer the larvæ mature in from 8 to 13 days, pupation taking place about 24 hours after maturity is reached, at which time the average length is from 10 to 12 mm. From 8 to 12 days are passed in the pupal stage.

Control work showed that spraying with powdered arsenate of lead, 3 lbs. to 100 gal, or lime-sulphur (1:10) weaker than the usual dormant spray just

as the buds become pink, is quite effective. It is pointed out that control work should be practiced by the entire community since reinfestation will otherwise take place during the summer. Summer control methods proved to be of no practical value.

A record by Morrill of the occurrence of the species for the first time in Arizona in 1917, when it was very destructive to peaches in three widely separated orchards in the Salt River Valley, has been noted (E. S. R., 40, p. 853).

The life history of the oriental peach moth (Laspeyresia molesta), C. HARUKAWA and N. YAGI (*Ber. Öhara Inst. Landw. Forsch.*, 1 (1917), No. 2, pp. 151–170, pls. 2).—It is pointed out by the authors that there are three closely related enemies of the peach in Japan, namely, the codling moth, *Carpocapsa persicana*, and *L. molesta*. It is believed that *L. molesta* is not a native of Japan, since damage by it was not observed prior to 1899 and it has attracted attention only since 1902. The species is distributed throughout Japan, except in Hokkaido and the northern portions, and also occurs in Korea.

There are five generations on the southern coast of western Japan and four in the Province of Schimane. In field cages the length of the life cycle varied from 26 to 37 days. From 5 to 65 eggs were deposited by each female, the egg stage lasting from 2 to 4 days, the larval from 11 to 15, and the pupal from 6 to 10 days. The caterpillars of the last generation hibernate, the adults emerging about the end of April. The authors have observed its oviposition on *Pyrus sinensis*, pear, *Prunus mume*, Japanese cherry, common cherry, apple, plum, and sand cherry, and reared the pest on all but apple. Much of the data are presented in tabular form.

Studies of this pest in the United States by Quaintance and Wood (E. S. R., 36, p. 358), Wood and Selkregg (E. S. R., 39, p. 259), and by Garman (E. S. R., 39, p. 260) have been noted.

The rice moth, F. H. CHITTENDEN (U. S. Dept. Agr. Bul. 783 (1919), pp. 15, pls. 5, figs. 2).—Complaints of damage by what proved to be Corcyra cephalonica received in October, 1911, from a firm manufacturing chocolate in western Pennsylvania and a year later from another manufacturer in the same State led to the discovery for the first time of the occurrence of this insect in the United States, but it was not identified until 1916. While the origin of the species is unknown, it has been introduced at many points in other continents and has been found commonly in England, where it was introduced in rice, chiefly from India and Burma, and also in dried fruits. While it has only been recognized in this country from western Pennsylvania and Port Rico, it is thought to occur without doubt at other points.

The species is inclined to be omnivorous, breeding in rice, dried fruits, cacao leaves and the various products of cacao, such as cocoa, cacao shells, and sweetened and unsweetened chocolate, shop biscuits, and sesame seeds. No partiality is shown for any of these food substances, however.

While its complete life history has not been ascertained, it reproduces nearly the year around under average indoor conditions. In the United States, infestations appear to die down from time to time, but are stimulated through shipments of cacao beans from South and Central America. It produces copious and dense external webbing to which food materials, such as rice, coccoa, and other matter, strongly adhere. In this respect its work and injury resemble those of the fig moth (*Ephestia cautella*) and related species and the Indian meal moth.

Control measures include the clearing out of infested warehouses, fumigation of sacks which have contained rice or other cereal, cacao beans, etc., and destruction of waste by burning, after which the plant should be fumigated with hydrocyanic acid gas or heat applied (120 to 130° F.) for several hours. The greenhouse leaf-tyer (Phlyctænia ferrugalis), A. H. GIBSON (Agr. Gaz. Canada, 6 (1919), No. 7, pp. 626-629, figs. 2).—This pest, also known as the celery leaf-tyer, is a European insect, long known in the United States, which has increased in recent years to a serious extent in many greenhouses in eastern Canada. It attacks a wide range of greenhouse plants and a number of vegetables.

Eggs kept under observation at Ottawa hatched in 14 days. There are 5 larval instars, all stages having been found developing at the same time and at various seasons, and the generations apparently overlap. The larvæ, which feed almost entirely on the underside of the leaves, eat away the green tissue. In the case of the mature larvæ, conspicuous portions of the leaves are entirely eaten. The length of the pupal stage is from 17 to 20 days. In observations made at Ottawa during the winter months, from 70 to 75 days were required for the completion of its life cycle. It is estimated that under greenhouse conditions there is time from the end of September to the end of May for at least 3 or possibly 4 generations. For control the author recommends the use of soluble sulphur 1 oz., blackleaf 40, 1 fluid ounce, and water 6 gal.

Tests of lead arsenate.—Effectiveness of different brands in controlling codling moth, H. B. TERRY and W. F. SCHLUPP (So. African Fruit Grower, 6 (1919), No. 5, pp. 108, 109, 111, fig. 1).—This is a progress report in which tables are given showing the results obtained in 1917–18 and 1918–19 with a considerable number of preparations.

A microlepidopteran injurious to avocado, A. BUSCK (*Proc. Ent. Soc. Wash.,* 21 (1919), No. 6, pp. 125, 126).—This note relates to a species (*Stenoma catenifer*) which feeds in the fruit and seed of the avocado (*Persea* spp.) and appears to be of considerable economic importance because of its destructiveness. The species has been received from Guatemala and Ecuador, and it is said to be almost impossible to buy a single avocado in the market of Ecuador which has not at least one of the worms in the seed.

Gelechia ocellatella, a new enemy of the beet in Italy, G. DEL GUERCIO (Agr. Colon. [Italy], 12 (1918), No. 4, pp. 216-230, figs. 5; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 9 (1918), No. 1, p. 1384).—This pest was recorded for the first time in Italy during the summer of 1917, when it was observed to be a pest of beets in the lower Valdarno, near Florence.

The young larvæ begin to feed on the tender leaves of the beet in July and soon reach the root by tunneling. As a result the foilage withers and the development of the root is more or less stopped. Of the various control measures experimented with, arsenicals seem to promise good results.

The distribution of the foxtail midge (Oligotrophus alopecuri) in Denmark and experiments in methods for its destruction. S. ROSTRUP (*Tidsskr. Planteavl*, 26 (1919), No. 1, pp. 38-51).—Almost all of the seed of the meadow foxtail received at the State Seed Testing Station is said to be more or less severely attacked by the larvæ of this midge, and only where the plant has not previously been grown for seed and where there is but little grown can the seed crop escape severe infestation. The larvæ hibernate in the seed, where a large percentage survive thrashing, cleansing, and drying. Experimental destruction of the larvæ without dstroying the germinating power of the seed has shown that dry heat can be applied for 35 minutes to a temperature of 59 to 60° C. (138.2° to 140° F.), or the seed treated with carbon disulphid (1 gm. CS<sub>2</sub> per liter of air) for 9 hours.

On the biology of M. ludlowi in Sumatra, W. SCHÜFFNER, N. H. SWELLEN-GREBEL, J. M. H. SWELLENGREBEL DE GRAAF, and ACHMAD MOCHTAR (Meded. Burgerl. Geneesk. Dienst Nederland. Indië, No. 3 (1919), pp. 65-90, pls. 5).—A detailed report of biological studies of Myzomyia ludlowi, an anopheline which the authors' experiments show to be easily infected with parasites of pernicious and tertian malaria and much more so than all other species examined up to the time of writing. Experiments with the quartan type had not been concluded.

A note on the flight of mosquitoes through horizontal water pipes, W. W. KING (*Pub. Health Rpts.* [U. S.], 34 (1919), No. 9, pp. 386-390, fig. 1; Sci. Amer. Sup., 87 (1919), No. 2255, p. 186).—The author's observations, conducted in St. Thomas, Virgin Islands, with a species thought to be *Culex quinquefasciatus* are summarized as follows:

"Mosquitoes entered the left cisterns through unscreened perpendicular waterspouts 2.5 and 3 in. in diameter and 14 and 10 ft. high. Mosquitoes did not enter cisterns through larger unscreened waterspouts when these pipes had a horizontal section from 12 to 32 ft. long. No observations were obtained of a horizontal distance of less than 12 ft.

"Mosquitoes bred in the cisterns and septic tank and having no other means of exit passed through horizontal pipes 4 and 5 in. in diameter for a distance of 191 ft. in the longest instance, aided probably to a certain degree by air currents. No doubt they would pass through greater distances."

Synopsis of the economic Syrphidæ of Japan, S. MATSUMURA and J. ADACHI (Ent. Mag. [Japan], 2 (1916), No. 1, pp. 1-26, pl. 1; 2 (1917), No. 4, pp. 133-156, pl. 1; 3 (1917), No. 1, pp. 14-46).—This synopsis includes descriptions of 8 genera, 59 species, and 1 variety new to science.

New species of the economic Syrphidæ of Japan, S. MATSUMURA (*Jour. Col. Agr. Hokkaido Imp. Univ.*, 8 (1918), No. 1, pp. 31, pl. 1).—Four genera are erected and 54 species are described as new, in addition to those recognized in the paper noted above.

The biology of Dermatobia hominis observed in all its stages, A. NEIVA and J. F. GOMES (Ann. Paulistas Med. e Cirurg., Sao Paulo, 8 (1917), No. 9, pp. 197-209, fig. 1; abs. in Rev. Appl. Ent., Ser. B, 7 (1919), No. 4, pp. 65, 66).—A report of observations on the biology of this parasite at Sao Paulo.

Anthrax: Transmission of infection by nonbiting flies, H. MORRIS (Louisiana Stas. Bul. 168 (1919), pp. 3-12).—This is a report of experiments conducted to determine the possibility of infection being carried to wounds of healthy animals by flies which have fed upon or developed in anthrax-infected material. The results of the work have been summarized by the author as follows:

"The house fly (*Musca domestica*) and the blue bottle or green bottle flies (*Calliphora erythrocephala, Lucilia cæsar*, and *L. sericata*), are capable of carrying anthrax infection to wounds on healthy animals, after having fed upon anthrax-infected flesh. The house fly and the stable fly (*Stomoxys calcitrans*) are capable of carrying anthrax infection to wounds on healthy animals after having fed upon the discharges from an open carbuncular swelling on an animal sick with anthrax. Flies bred out of an unopened anthrax infection. The results would indicate that flies bred in the presence of anthrax spores do carry anthrax infection. The results would indicate that flies bred in the presence of anthrax spores do carry anthrax in the unopened carcass is destroyed by the process of decomposition." It is pointed out that the results prove the necessity for prompt and complete destruction of all anthrax carcasses.

The author's report of an investigation relating to anthrax transmission by bloodsucking insects has been noted (E. S. R., 39, p. 161).

A study of Compsilura concinnata, an imported tachinid parasite of the gipsy moth and the brown-tail moth, J. J. CULVER (U. S. Dept. Agr. Bul. 766 (1919), pp. 27, pls. 2, figs. 10).—This is a report of investigations conducted, with a review of the present status of knowledge of this important larviparous

parasite, first introduced into Massachusetts from Europe in 1906. It occurs in Europe over practically all the territory covered by the brown-tail moth, attacking both nocturnal and diurnal hosts comprising 58 species, a list of which is given, together with a host list of 33 species recorded for this country. It is found in almost any part of New England within the gipsy moth area.

The account includes a discussion of the importation of this parasite into the United States, colonization, spread, recovery, classification, larval stage, life history, action on hosts other than the gipsy and brown-tail moths, seasonal history, secondary parasitism, superparasitism, and supernumerary parasitism. A map showing its distribution in New England, and points outside of such territory where it has been colonized, is attached.

In discussing its economic importance, it is pointed out that the white-marked tussock moth, which a few years ago was a serious pest in many localities in New England, has practically disappeared. The promethea moth (*Callosamia promethea*), which in past years was very common in the area covered by Compsilura, is now quite rare. The cabbage worm has been materially lessened in some sections. The celery worm (*Papilio polyxenes*) is not so common as previous to the importation of Compsilura, and the fall webworm, which was found in large numbers in eastern Massachusetts in 1910, is scarcely noticed now. While this parasite is not the sole cause of the disappearance of these pests, it is significant that the decrease has occurred since its introduction. The gipsy and brown-tail moth infestations have been materially lessened in sections where this parasite has been firmly established, and it appears to have played an important part in causing the decrease. It is the most important of the tachinids introduced for combating the gipsy and brown-tail moths, and attacks both freely.

A bibliography of the literature relating to *C. concinnata* and its specific synonyms is appended.

Cane borer parasite work in 1919, T. E. HOLLOWAY (*La. Planter*, 63 (1919), *No. 8, pp. 122, 123, fig. 1*).—This is a brief report on the status of tachinid parasites introduced from Cuba. Considerable numbers were introduced during the month of July, and colonization is being attempted in several localities in the cane-growing sections of Louisiana.

Sugar cane and hardback grubs in Antigua, H. A. BALLOU (Agr. News [Barbados], 18 (1919), No. 449, pp. 218, 219).—This is a report of the imperial entomologist based on a trip to Antigua in March, 1919.

Wireworm control, with special reference to a method practiced by Japanese growers, R. C. TREHERNE (*Agr. Gaz. Canada, 6 (1919)*, *No. 6, pp. 528-530*).— A method practiced by Japanese growers in the Okanogan Valley, B. C., where the onion crop in particular suffers very seriously from wireworm attack, consists of baits composed of rice shorts or rice bran and water, sunk in the soil. The rice shorts or bran is roasted dry in pans or on sheets of tin over a fire, being turned frequently as it browns. The shorts thus dried gives forth a pronounced odor, which is held by the Japanese to be the cause of attracting wireworms in the soil. The roasted shorts is moistened by a little water and molded by hand into small, compact balls, which are placed in shallow holes (made with a hoe) about 10 ft. apart between rows of onions and covered with soil. In a week or ten days the baits are scratched up, broken open, and the wireworms found therein are removed by hand and placed in small collecting boxes, after which the baits are remolded and reset to be examined in the same way a week or ten days later.

The author considers this method to have its merits, the number of wireworms apparently having been considerably reduced. Individual baits which had only been set one week in the soil yielded from 0 to 67 wireworms.

**Extermination of cotton boll weevil**, J. E. RANSDELL (*Cong. Rec.*, 58 (1919), No. 77, pp. 4399-4404).—This discussion includes correspondence relating to the control of the boll weevil by dusting and a summary of the present status of the work up to August 1, 1919, by B. R. Coad.

Shot-hole borer (Xyleborus fornicatus), E. R. SPEYER (*Dept. Agr. Ceylon Bul.* 44 (1919), pp. 8).—A control pruning scheme and its practical modification.

Langstroth on the hive and honeybee, DADANT (Hamilton, Ill.: Dadant & Sons, 1919, 20. ed., pp. X+575, pls. 28, figs. 229).—A revised edition of the work previously noted (E. S. R., 20, p. 1155), in which the principal changes relate to diseases of bees.

Beginnings in beekeeping, W. P. ALEXANDER (Cornell Reading Course for the Farm, No. 138 (1918), pp. 73-96, figs. 13).—A popular account.

Eighteenth annual report of the Illinois State Beekeepers' Association, J. A. STONE (Ann. Rpt. Ill. State Beekeepers' Assoc., 18 (1919), pp. 218, figs. 13).—The papers presented at the annual meeting are included in this report.

Commercial comb honey production, G. S. DEMUTH (U. S. Dept. Agr., Farmers' Bul. 1039 (1919), pp. 40, figs. 14).—This is a revision of Farmers' Bulletin 503, previously noted (E. S. R., 27, p. 865).

Isle of Wight disease in hive bees, J. RENNIE and E. J. HARVEY (Scot. Jour. Agr., 2 (1919), No. 2, pp. 176-189).—The authors report the results of work carried on in continuation of investigations previously noted (E. S. R., 37, p. 360). They conclude that the causal organism of Isle of Wight disease has not yet been found.

Foul brood, B. F. KINDIG (*Michigan Sta. Circ. 39* (1919), pp. 4).—This is a supplement to Special Bulletins 58 and 64 previously noted (E. S. R., 31, p. 553), and relates to the control of European foul brood.

Edema of the eyelids caused by ants, A. J. CHAMBERS and A. MARSHALL (Jour. Trop. Med. and Hyg. [London], 22 (1919), No. 12, p. 117, pl. 1).—Monomorium bicolor nitidiventre is reported to have caused edema through its attaching to the eyelids of man in Anglo-Egyptian Sudan.

New Chalcididæ, E. MALENOTTI (Redia, 13 (1918), No. 1-2, pp. 77-92, figs. 17; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 9 (1918), No. 9, pp. 1122, 1123).—With the discovery of Aphelinus bovelli eight chalcidids are known to parasitize Chrysomphalus dictyospermi.

Descriptions of four new parasitic Hymenoptera, S. A. ROHWER (Canad. Ent., 51 (1919), No. 6-7, pp. 160-162).—Tetrastichus rugglesi reared as a para site of Agrilus arcuatus at University Farm, St. Paul, Minn., and Trigonura hicoria, Ecphylus hicoria, and Heterospilus blackmanni, all three reared from pignut (Hicoria glabra) at Syracuse, N. Y., are described as new.

The life history of a gall mite on Nephrolepis biserrata, K. GIESENHAGEN (Jahrb. Wiss. Bot. [Pringsheim], 58 (1917), No. 1, pp. 66-104, pls. 2, figs. 3).— A detailed report of studies of Eriophyse nalepaï.

Second memorandum on acarids (mites) occurring in stored grain and flour, R. NEWSTEAD and H. M. DUVALL (Roy. Soc. [London], War Committee Memo. 4 (1918), pp. 11, pls. 2).—The first part of this memorandum deals briefly with the life history and habits of Aleurobius farinæ, Glyciphagus cadaverum, Cheyletus eruditus, and Acarophenax tribolii; the second part, with economic and experimental work with acarids in stored grain and in flour. A more detailed account has been previously noted (E. S. R., 40, p. 855).

The amount of food eaten by the spider (Aranea sericata), C. E. NEBEL (Trans. Wis. Acad. Sci., Arts. and Letters, 19 (1918), pt. 1, pp. 524–530).—This paper deals with the amount of food eaten by seven specimens of A. sericata, and the amount which they gained or lost in weight during a period of four months in which the fruit or pomace fly ([Drosophila] Melanogaster ampe-

*lophila*) raised on overripe bananas was used as food. The data, which are presented in tabular form, show that a spider will consume an average of 2.5 poinace flies per day. The author made counts in representative fields in Wisconsin and found approximately 10,000 Araneas to an acre of land.

Acanthocephala from the Illinois River, with descriptions of species and a synopsis of the family Neoechinirhynchidæ, H. J. VAN CLEAVE (Ill. Dept. Registr. and Ed., Div. Nat. Hist. Survey Bul., 13 (1919), Art. 8, pp. IV+225-257, pls. 7).—This account of Acanthocephala from fresh water hosts includes a bibliography of 34 titles.

Studies on the parasites of the termites, I-IV, C. A. KOFOID and O. SWEZY (Univ. Cal. Pubs. Zool., 20 (1919), Nos. 1, pp. 1-20, pls. 2, fig. 1; 2, pp. 21-40, pls. 2, figs. 2; 3, pp. 41-98, pls. 8, figs. 4; 4, pp. 99-116, pls. 2, fig. 1).—These papers deal, respectively, with Streblomastix strix, a Polymastigote Flagellate with a Linear Plasmodial Phase; Trichomitus termitidis, a Polymastigote Flagellate with a Highly Developed Neuromotor System; Trichonympha campanula n. sp.; and Leidyopsis sphærica n. g. and n. sp.

## FOODS-HUMAN NUTRITION.

The zinc content of some food products, V. BIRCKNER (Jour. Biol. Chem., 38 (1919), No. 2, pp. 191-203).-The zinc determinations reported in this contribution from the Bureau of Chemistry, U. S. Department of Agriculture, were made by slight modifications of the turbidimetric method suggested by Brever in Scott's Standard Methods of Chemical Analysis (E. S. R., 37, p. 310). The zinc was precipitated as sulphid from the chlorid instead of the sulphate. The turbidity test with potassium ferrocyanid was carried out in Nessler jars, the comparison with the standards being made by looking vertically through the jars at a printed paper placed underneath. The method, if carried out according to the technique described in detail, is said to be accurate within  $\pm$  0.05 mg., provided the amount of zinc in the sample is below 0.5 mg. Sources of error to be guarded against are a loss of zinc during ignition and an incomplete precipitation of the zinc sulphid due to an excessive concentration of formic acid.

The zinc content of a number of food materials determined by this method is reported. The zinc in market milk ranged from 3.6 to 5.6 mg, per kilogram of milk, the average of 12 determinations being 4.2 mg. The zinc content of milk of individual cows varied somewhat in different animals and at different stages of lactation, being highest during the early part of the lactation period. The so-called "neutralization precipitate" of cow's milk, described by Osborne and Wakeman (E. S. R., 36, p. 862) contained nearly all of the zinc of the original milk. The zinc content of human milk was considerably higher than that of cow's milk in spite of the higher total ash content of the latter.

In hen's eggs practically all of the zinc was found in the yolk, amounting to about 0.005 per cent of the yolk or a total amount of about 1 mg. per egg. Zinc was also found in varying amounts in tap water, soy beans, peas, carrots, bone ash, baker's yeast, barley malt, various cereals, agar, gelatin, and in large amounts in oysters.

The normal occurrence of zinc in such important animal products as milk and eggs, as well as in many other foods, is thought to be an indication that it exerts some important nutritive function, the nature of which is not at present understood.

Zinc in oysters, R. S. HILTNER and H. J. WICHMANN (*Jour. Biol. Chem.*, 38 (1919), No. 2, pp. 205-221).—This paper reports the results of a series of studies made in the laboratories of the Bureau of Chemistry, U. S. Department

of Agriculture, at New York, Philadelphia, Boston, and Denver of the occurrence of zinc and copper in oysters from various localities on the Atlantic seaboard, the relation of zinc in oysters to the zinc content of the water in which they grew, and the ratio of zinc to copper in oysters.

Copper and zinc were determined in one weighed portion (100 gm.) of a homogenous sample obtained by thoroughly comminuting at least a pint of the oysters. After preliminary destruction of organic matter by the acid digestion process, the copper was separated from the zinc by precipitation from slightly acid solution with hydrogen sulphid, and the zinc determined by titration from its chlorid with a standardized solution of potassium ferrocyanid.

Zinc was found in all the oysters examined and was always associated with copper. There appeared to be no direct relation between the zinc content and the body weight of the oysters, nor uniformity of ratio of zinc to copper, nor correlation between the zinc content of the oysters and the water in which they grew. As the vegetable and organic matter dredged up with oysters in the single locality studied contained considerable zinc and in some instances traces of copper, the possibility is suggested that the zinc content of the oyster is an indication of the character of its food rather than of the character of the sea water in which it grows. "It seems probable that zinc, as well as copper, can be absorbed and retained in the tissues of the oysters in quantities far in excess of functional requirements, especially in oysters grown in waters badly polluted with metallurgical and factory wastes."

The blue or bluish green coloration noticeable in some oysters is said to be a reliable indicator of the presence of large amounts of copper and indirectly of zinc, with which it is always associated.

The normal existence of zinc in the human organism, C. GHIGLIOTTO (Ann. Falsif., 12 (1919), No. 123-124, pp. 12-14).—The author reviews conflicting statements in the literature as regards the presence of zinc in the human body, and reports the results of the examination of the viscera of 22 victims of accidental death. The content of zinc oxid found varied from 0.0015 to 0.0028 per cent of the viscera. Zinc was also found in a human and a bovine fetus. This is thought to be an indication that zinc is a normal constituent not only of the human organism but of the animal organism in general.

The nutritive value of yeast protein, T. B. OSBORNE and L. B. MENDEL (Jour. Biol. Chem., 38 (1919), No. 2, pp. 223-227, fig. 1).—The authors report that they have kept rats successfully for more than a year, covering the period of growth, upon a diet in which brewers' yeast furnished the sole source of nitrogen as well as water-soluble vitamin. The yeast comprised from 30 to 40 per cent of the ration, probably representing an actual protein concentration of less than 18 per cent. The nitrogen utilization as estimated by a comparison of the feces with the intake was from 74 to 83 per cent.

When bred with vigorous females which had grown up on a normal mixed diet, two of the animals proved to be fertile but produced inferior young while two others failed to breed. The testes of the latter showed an absence of germ cells. The authors are, however, of the opinion that this infertility is not caused by the yeast per se, and that there is no toxic factor present in the yeast.

Is lactalbumin a complete protein for growth? A. D. EMMETT and G. O. LUROS (Jour. Biol. Chem., 38 (1919), No. 1, pp. 147-159, figs. 7).—Recent conflicting opinions as to the growth-promoting value of lactalbumin are reviewed and discussed, particularly those of Osborne, Mendel, et al (E. S. R., 37, p. 864) that lactalbumin is a complete protein, and of McCollum, Simmonds, and Parsons (E. S. R., 40, p. 762) that it is incomplete and that the excellent results obtained by Osborne and Mendel were due to the nitrogenous matter in the protein-free milk employed. The present contribution to the question is the re-

port of a study of the growth-promoting property for rats of rations containing lactalbumin as the sole protein and differing only in respect to the kind of synthetic protein-free milk used. From the results obtained the following con-

clusions were drawn: "Lactalbumin is a complete protein in the sense that it does not lack any of the nitrogenous cleavage products essential for growth. It can supplement a deficient growth-promoting protein (corn gluten) and, incorporated as the sole protein in a ration containing lactose, it produces a normal rate of growth when present to the extent of only 10 per cent. Lactalbumin is a protein which either is sensitive to certain toxic substances, and under these conditions growth is retarded unless adequate adjustment is made in the diet; or it is a protein which does not appear to be able to absorb what we tentatively designate

"Lactose seems to be the essential constituent in the protein-free milk that contributes the accessory which makes an otherwise incomplete lactalbumin diet bring about normal growth in rats. Lactose, when added to a lactalbumin diet, either may have the physiological property of overcoming the toxicity that inhibits growth taking place, or else it may carry a water-soluble vitamin (other than water-soluble B) which appears to be essential to growth."

as a vitamin (other than water-soluble B).

The stability of lactalbumin toward heat, A. D. EMMETT and G. O. LUROS (*Jour. Biol. Chem.*, 38 (1919), No. 2, pp. 257–265, figs. 7).—Continuing the investigations on the growth-promoting value of lactalbumin noted above, a study is reported of the effect of heat upon the nutritive value of lactalbumin as determined by feeding experiments with rats on a basal diet of protein-free milk 28 per cent; butter fat 5, 18, or 28 per cent; lard none or 10 per cent; and starch to make up the balance after adding the protein (10 per cent lactalbumin subjected to different temperatures up to 6 hours in the autoclave at 15 lbs. pressure).

The data obtained indicate that "high temperatures do not influence the growth-promoting value of lactalbumin when dried in vacuo at  $55^{\circ}$ , or heated in an air oven at 90 to  $100^{\circ}$  for 16 hours, or in an autoclave at 15 lbs. pressure for 2 to 6 hours, respectively; that the amount of butter fat, whether 5, 18, or 28 per cent, when used with a 2-hour-autoclaved lactalbumin, has no influence on the rate of growth; that heated lactalbumin is not toxic for young growing rats."

The authors correlate these results with the somewhat conflicting results obtained by McCollum and Davis (E. S. R., 34, p. 368), Funk and Macallum (E. S. R., 36, p. 160), and Hogan (E. S. R., 37, p. 467) with heated casein, on the hypothesis noted in their previous communication that there is a vitamin factor involved which is different from water-soluble B at least in being unstable toward heat.

In the diets in which satisfactory results were obtained with heated case in or lactalbumin, this vitamin is thought to be furnished probably by the lactose of the protein-free milk.

Distribution of the antineuritic vitamin in the wheat and corn kernel.—A contribution to the biology of the antineuritic vitamin, C. VOEGTLIN and C. N. MYERS (*Amer. Jour. Physiol.*, 48 (1919), No. 4, pp. 504–511, figs. 4).—The investigation reported was conducted on adult pigeons, series of which were fed on the following mixtures: Degerminated corn (corn kernel from which the germ had been removed); 90 per cent degerminated corn, 5 per cent purified casein, and 5 per cent salt mixture; 85 per cent degerminated corn, 5 per cent purified casein, 5 per cent salt mixture, and 5 per cent butter fat; whole corn; and degerminated wheat.

The results obtained are considered to indicate that removal of the germ or embryo from corn and wheat deprives these cereals of their antineuritic vitamin, that is, that the antineuritic substance is located entirely in the embryo of the grain. This suggests that this accessory food is necessary for the metabolism of the growing plant as well as the animal body. A table compiled from the observations of various authors is given showing the occurrence of this vitamin in cells with an especially active metabolism.

Attention is also called to the bearing of the results of the study on the question of the nutritive value of bread. The advisability is suggested of so altering the milling process as to allow the germ of the cereal without the bran to be incorporated in the finished flour.

Food flours and their derivation products, E. COLLIN (Ann. Falsif., 11 (1918), No. 121–122, pp. 372–384, figs. 7; 12 (1919), No. 123–124, pp. 14–29, figs. 10).— The physical and microscopical characteristics of flour prepared from wheat, barley, maize, rice, buckwheat, potatoes, tapioca, durra, bananas, chestnuts, soy beans, cacao beans, oil cake, and algæ are described and suggestions given for their detection in mixed flours and in bread. The value of several of these flours as wheat substitutes is discussed.

Digestibility of bacon, K. BLUNT and M. G. MALLON (*Jour. Biol. Chem.*, 38 (1919), No. 1, pp. 43-48, fig. 1).—Digestion experiments with normal young women on a diet of bacon, shredded wheat biscuit, orange juice, and sugar were conducted to determine the coefficients of digestibility and utilization of bacon fat, the former coefficient representing the percentage of fat hydrolyzed as calculated from the neutral fat found in the feces, and the latter representing the percentages of fat hydrolyzed and absorbed as calculated from the free fatty acids found in the feces.

The average percentage of digestion of the fat of slightly cooked bacon was 96.3, and of the thoroughly cooked, 97, while the average percentages of utilization were 92.8 and 95, respectively. Later experiments in which moderately cooked bacon was used gave coefficients of utilization of 96.2, 95.7, and 96.5 per cent. While the nitrogen of the diet was not so well utilized (79.8 to 80 per cent), the low figures are thought to be due not to the bacon nitrogen but to the shredded wheat.

The ripening of sausage, E. P. CÉSARI (*Compt. Rend. Acad. Sci.* [*Paris*], 168 (1919), No. 15, pp. 802, 803).—The ripening of sausage is thought to be due to the action of certain yeasts which possess a moderate proteolytic power and the property of producing aromatic products. The possibility is suggested of modifying advantageously the natural ripening by inoculating the paste with pure cultures of the yeasts in question, selected to obtain the most pleasing odor and taste.

Beverages and their adulteration, H. W. WILEY (*Philadelphia: P. Blakiston's* Son & Co., 1919, pp. XV+421, pls. 2, figs. 40).—The subjects treated in this companion volume to Foods and Their Adulteration (E. S. R., 40, p. 459) are waters, soft drinks, fruit juices, coffee, tea, cocoa, chocolate, fermented and distilled beverages, alcoholic remedies, and beverages containing cocaine. The description of each beverage includes its origin, methods of manufacture, composition, the proper conditions attending its transportation and use, and the common adulterations and misbrandings.

The gastric response to foods.—II, A fractional study of the coagulation of milk in the human stomach, O. BERGEIM, J. M. EVVARD, M. E. REHFUSS, and P. B. HAWK (*Amer. Jour. Physiol.*, 48 (1919), No. 4, pp. 411-418, pls. 3, figs. 2).— By the use of a normal man who was able to regurgitate at will, an extensive investigation was made of the coagulation of milk in the human stomach. Studies of two kinds were made, one in which small samples of stomach contents were regurgitated at intervals throughout the curding period of the milk, the other in which the stomach was completely emptied a half hour after a pint of milk had been ingested. The results obtained, which are described and illustrated by photographs, may be summarized as follows:

Milk drunk rapidly left the stomach sooner and produced a smaller curd mass than milk drunk slowly or sipped. Raw whole milk formed firm, white, rubberlike curds, the maximum curd formation taking place about one hour after the milk had entered the stomach. Milk which had been boiled five minutes formed small, soft, flaky, yellow curds which left the stomach sooner and were much more easily digested than the tough curds from the raw milk. A mixture of 80 per cent boiled whole milk and 20 per cent raw whole milk gave curds similar in character to those obtained from the ingestion of raw whole milk. These results would indicate that, dietetically, boiled milk is to be preferred to the raw product except for the fact that its antiscorbutic value may have been lowered.

Skim milk formed large, harder curds than whole milk. The curds of raw milk were larger and harder than those of the boiled milk. The fat content is considered to be an important factor in determining the character of the curd in milk. In general the more fat the less curd, and the smaller and softer the curd. When 40 per cent cream was drunk, no curds were formed during the first half hour. Milk of high fat concentration was also very slow to leave the stomach.

The curds of pasteurized milk were intermediate in character between the curds of raw and boiled milk. The drinking of water before the milk was ingested tended to make the curds somewhat smaller and softer. The temperature of the milk was found to have but little effect on time of curd formation, although lowering the temperature had a slight tendency to delay the formation of curds.

The minimum of sugar and fat, H. BIERRY (Compt. Rend. Soc. Biol. [Paris], 82 (1919), No. 3, pp. 124–127).—Arguments are given to prove the necessity of a minimum of fat as well as a minimum of carbohydrate (E. S. R., 40, p. 563) in the diet. The importance of certain fats in furnishing vitamins is pointed out.

Nutritional studies on the growth of frog larvæ (Rana pipiens), A. D. EM-METT and F. P. ALLEN (Jour. Biol. Chem., 38 (1919), No. 2, pp. 325-344, pls. 4, fig. 1).—This is a preliminary report of a series of nutritional studies in which tadpoles were used in place of larger animals for the purpose of determining facts regarding their nutrition with respect to size and degree of metamorphosis. Immediately after hatching, the tadpoles were placed in enameled trays in groups of 500 each and fed at specified times on synthetic diets so arranged as to show the effect of various modifications. The record of progress of growth was obtained by means of photographs taken each week of a selected group from each colony. Histological studies were also made of representative specimens. The results are summarized of the effect of diet upon the size and upon the development of hind legs of the tadpole, and the following tentative conclusions drawn:

A large amount of fat in the diet was very injurious to both growth (body size) and development of hind legs. Vitamins of both the water-soluble and fatsoluble type appeared to be necessary for normal growth and development. The lack of water-soluble B was slightly more apparent than that of fat-soluble A. The amount of protein, from 10 to 20 per cent of lactalbumin, seemed to have little effect on the development of hind legs whether both vitamins, one, or neither were present, but the high protein-fed tadpoles were largest when both vitamins were present. The quality of the protein was an important factor in the rate of development. No difference was noted between dextrin and starch as to the effect either on growth or development.

The results as a whole are thought to indicate definitely the possibility of so adjusting the diet by means of variations in such nutrients as fat, protein, and vitamins, as to alter the size of the tadpole and the rate of metamorphosis. Attention is, however, called to other factors, such as temperature and food control, which also play an important part.

A biological analysis of pellagra-producing diets.—VI, Observations on the faults of certain diets comparable to those employed by man in pellagrous districts, E. V. McCollum, N. SIMMONDS, and H. T. PARSONS (*Jour. Biol. Chem.*, 38 (1919), No. 1, pp. 113–146, pl. 1, figs. 10).—In continuation of the series of studies on pellagra-producing diets previously noted (E. S. R., 40, p. 69), the authors present the results of feeding experiments with rats on diets comparable to those employed by man in pellagrous districts, together with similar experiments in which such diets were supplemented by food additions containing the factors (proteins, certain salts, and fat-soluble A) which previous study had shown to be deficent in the so-called pellagra-producing diets.

The results of the studies reported show that in no case was a condition analogous to pellagra in man produced in the rats, although all showed a generalized poor condition as evidenced by slight deformities, early aging, and inability to produce and rear young successfully. This condition was remedied in varying degrees by the addition to the diet of salts, leafy vegetables, meat powder, and milk or milk powder.

In connection with the interpretation of these results a detailed discussion is given of previous work by the authors and other investigators on the relation of diet to pellagra. The evidence as a whole is considered by the authors to support the conclusions of Siler, Garrison, and MacNeil (E. S. R., 31, p. 858) "that pellagra is caused by an infectious agent, and that unless it has been introduced into a district there may develop such a condition of lowered vitality from faulty diet or other debilitating influence as would predispose one to an attack, without the appearance of the disease. The debilitating effects on animals of diets derived from cereals, tubers, roots, and any food products formed from the milling of grains, together with legume seeds and meats, are so striking that we believe similar diets would produce in man a susceptibility to infectious diseases such as tuberculosis or pellagra. We have come to hold the view . . . that the predisposing influence for both is in general the same, and the character of the unsanitary conditions surrounding the individual may determine which of these two diseases he will develop."

In discussing the relative values of several foods as correctives in the diet of the pellagrous, the authors recommend the regular and liberal use of leafy vegetables, and above all the inclusion in the diet of a suitable amount of milk because of its cheapness.

Biochemical studies of the saliva in pellagra, M. X. SULLIVAN and K. K. JONES (*Pub. Health Rpts.* [U. S.], 34 (1919), No. 20, pp. 1068–1080).—A study of the mixed saliva of individual pellagrins at the pellagra hospital of the U. S. Public Health Service at Spartanburg, S. C., was undertaken to determine whether the saliva, from a biochemical standpoint, differed from that of normal individuals.

The rate of flow and diastatic power were found to vary within the limits established by normal controls. The specific gravity was slightly higher than that of the controls. Total solids, ash, organic matter, and mucin were also higher, but the differences are thought to bear no relation to the mouth symptoms. The sulphocyanate content was much less marked, indicating that in pellagra patients there is both a lessened protein intake and a detoxicating power feebler than normal. The reaction of the saliva in pellagra was somewhat more alkaline than that of normal saliva.

Medical studies in Roumania during the war, especially the treatment and etiology of pellagra, L. Külz (Arch. Schiffs u. Tropen Hyg., 22 (1918), No. 22-23, pp. 401-430).—Several diseases intensified by war conditions in Roumania are discussed. These include typhus, malaria, dysentery, scurvy, pellagra, and other diseases of minor importance. The author attributes the large number of cases of pellagra to the extensive consumption of corn, three factors being considered responsible for determining the incidence of the disease: (1) The amount of corn consumed, (2) the quality of the corn, and (3) individual susceptibility. It is pointed out that when corn forms only a small fraction of the diet pellagra does not occur, but that increase in the amount of corn consumed is invariably accompanied by an increase in pellagra. All corn, even fresh, is thought to contain the substance which is the primary cause of the disease, but the amount of this toxic substance increases as the corn deteriorates so that a much smaller amount of spoiled than of fresh corn is necessary to produce the disease. Individual variations in susceptibility are illustrated by the fact that not all members of the family on the same diet become pellagrous. In treating the disease, the author recommends the elimination of corn from the diet and the administration of iron, iodin, and arsenic, the latter in the form of neosalvarsan.

Studies of experimental scurvy.—Effect of heat on the antiscorbutic properties of some milk products, E. B. HART, H. STEENBOCK, and D. W. SMITH (Jour. Biol. Chem., 38 (1919), No. 2, pp. 305–324, figs. 20).—The authors report studies of experimental scurvy in guinea pigs, the results of which confirm the conclusions of Chick, Hume, and Skelton (E. S. R., 40, p. 272) on the quantitative relation of raw milk consumption to the development of a scorbutic condition in the guinea pig, and refute the hypothesis of McCollum and Pitz (E. S. R., 38, p. 568) that scurvy is related to intestinal putrefaction and retention of the feces. In addition, data are given indicating that commercial condensed milks, commercial milk powders, and milk sterilized for 10 minutes at 120° C. do not possess antiscorbutic properties when used in quantities equivalent to an amount of raw milk which would prevent scurvy in guinea pigs on a diet of rolled oats and dried hay.

The antiscorbutic properties of concentrated fruit juices (*Jour. Roy. Army Med. Corps, 32* (1919), *No. 1, pp. 48–56*).—In the first part of this paper, by A. Harden and R. Robison, feeding experiments with guinea pigs are reported which show that the antiscorbutic principle in orange juice is not volatilized when the juice is distilled at 40° C. under reduced pressure. The solid residue obtained by this process was found to have strong antiscorbutic properties which were not appreciably diminished on keeping the substance in a dry atmosphere at room temperature for six months.

In the second part, by R. Robison, an extension of the investigation to other fruit juices is reported. Lime juice concentrated in the Kestner evaporator under reduced pressure was found to retain nearly all of its antiscorbutic value, although the acidity of the concentrated juice rendered it rather unsatisfactory in the guinea pig experiments. Apple juice concentrated in the same manner to about one-sixth of its original volume formed a soft palatable jelly of valuable antiscorbutic properties, although not in the same degree as the dried orange juice.

The general use of fruit jellies prepared by this or similar processes is recommended as a substitute for ordinary jams or jellies wherever there is reason to suspect that the diet is deficient in the antiscorbutic principle. The time of appearance of the antiscorbutic substance in germinating barley and the harmful effect on guinea pigs of barley in different stages of germination, E. WEILL and G. MOURIQUAND (Compt. Rend. Soc. Biol. [Paris], 82 (1919), No. 5, pp. 184–186).—The authors by feeding guinea pigs with barley in different stages of germination have confirmed the conclusions previously noted (E. S. R., 40, p. 565) that barley, after three days' sprouting, does not possess antiscorbutic properties, but on the contrary causes a more acute form of scurvy, although appearing later.

The first appearance of the antiscorbutic property was after five days' germination. Guinea pigs fed on barley which had germinated for five days or longer did not develop scorbutic symptoms, but frequently succumbed after varying intervals of time to what appeared to be an acute intoxication. When the feed consisted of a mixture of 40 gm. of barley germinated for three days and 20 gm. of the green or white growth of 10 days' germination no symptoms of scurvy or acute poisoning appeared, each substance apparently neutralizing the harmful effect of the other.

Changes in the teeth of the guinea pig produced by a scorbutic diet, S. S. ZILVA and F. M. WELLS (*Proc. Roy. Soc.* [London], Ser. B, 90 (1919), No. B 633 pp. 505-512, pl. 1).—To study the effect of a scorbutic diet on the teeth, microscopical examination was made of sections of decalcified teeth of guinea pigs in normal condition and in various stages of scurvy.

Two important features disclosed by these experiments are that the tooth is one of the first, if not the first, part of the system to be affected by a deficiency of antiscorbutic material, and that changes of a profound nature occur in the teeth even when scorbutic symptoms during life are so slight as to be almost unrecognizable. The degeneration appears to be complete pulpar fibrosis, the fine cellular connective tissue of the normal tooth being replaced by a fibrous structure devoid of cells, nuclei, etc. Similar radical changes in the teeth have also been noted in monkeys on a scorbutic diet.

In discussing the application of these results to human nutrition, the authors suggest the possibility that dietary deficiency is an important factor in the great prevalence of tooth decay in civilized communities. They point out that cases of scurvy so mild as to escape detection may occur more often than is usually suspected and may reasonably be expected to influence dentition.

The effect of diet on the healing of wounds, A. H. CLARK (*Bul. Johns Hop*kins Hosp., 30 (1919), No. 339, pp. 117-120, figs. 5).—The effect of diet on wound healing was studied by producing artificial wounds in dogs on specific diets and observing the rate of healing of the wound.

The length of the initial quiescent period of wound healing was found to be affected by the diet, varying from zero in dogs fed on protein, 3 days on carbohydrate and 4 days on mixed diet to 6 days on fat. This variation was more marked in smaller wounds. The subsequent periods of contraction, epidermization, and cicatrization were apparently not affected by the diet.

In conclusion the author points out that the results obtained confirm the suggestion of Benedict and Carpenter (E. S. R., 40, p. 270) that proteins have a specific influence in stimulating the whole cellular system to greater activity.

## ANIMAL PRODUCTION.

Cattle feeding on pasture, W. A. COCHEL (Breeder's Gaz., 76 (1919), No. 8, pp. 307, 308, fig. 1).—This is an outline of the methods of beef production on pasture lands, with a brief note on the distribution of common grasses in the grazing areas of the United States.

140363°-19---6

The cattle of eastern France, E. N. WENTWORTH (*Breeder's Gaz.*, 76 (1919), No. 8, p. 311).—This is a note on the triple-purpose cattle of the eastern Departments of France. There are four breeds of economic importance in this section, the Friburg, the Simmental, the Brown Swiss, and the Jurassic. The first named is the most popular, and the better cows are said to give over 40 lbs. of milk daily. The last is a native breed, taking its name from the Department of Jura. A movement for its rehabilitation has been inaugurated. It is claimed to be very resistant to tuberculosis, has a strong constitution, and is apparently capable of higher milk yields than the Friburg.

Present state of sheep breeding in Canada, J. R. ARKELL (Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 8 (1917), No. 10, pp. 1333– 1338).—The progress of the sheep industry in Canada since the founding of cooperative associations of wool producers under government supervision in 1912 is briefly outlined.

The decennial census reports from 1871 to 1911 and annual reports from 1912 to 1916 as to the number of sheep in the several Provinces are tabulated.

Genetic studies in poultry.—I, Inheritance of leg-feathering, R. C. PUNNETT and P. G. BALLEY (*Jour. Genetics*, 7 (1918), No. 3, pp. 203-213).—Experimental crosses are reported between feather-legged (Langshan) and clean-legged (Brown Leghorn and Golden Pencilled Hamburg) fowls. The  $F_1$ s in general were moderately feathered, but there was considerable variation and one of the hens of the Hamburg cross was clean legged, although she produced feather-legged offspring by a clean-legged cock. The Leghorn  $F_2$ s consisted of 323 feathered and 106 clean-legged chicks, and the Hamburg  $F_2$ s of 117 and 31, respectively. These are considered good approximations to 3:1 ratios.

Individual  $F_{2S}$  that seemed to be homozygous for feathering were identified. Some  $F_{2S}$  were more heavily feathered than typical Langshans. Moderatelyfeathered birds mated to clean-legged ones frequently produced stronglyfeathered offspring; in such matings more males than females were heavily feathered. Modifying factors are postulated to explain these facts.

On the basis of Davenport's data (E. S. R., 23, p. 75), it is suggested that two factors are responsible for the leg-feathering in Cochin and Dark Brahma bantams.

On the sterility of hybrids between the pheasant and the Gold Campine fowl, D. W. CUTLER (*Jour. Genetics*, 7 (1918), No. 3, pp. 155–165, pl. 1).—The author has examined histologically the testes of about a dozen male hybrids resulting from crosses between male pheasants (no species designated) and domestic hens of the Golden Campine breed, and has also studied spermatogenesis in pheasants and in Golden Campine cocks. The breeder who made the crosses secured no female hybrids with one doubtful exception. The hybrids, it is stated, were all sterile.

Technical difficulties made chromosome counts uncertain. The hybrids showed 19 to 21 in the spermatogonia, the pheasants 20 to 22, and the domestic fowl 18 to 20. The following quotation, from which references to figures have been omitted, summarizes the other conditions found in the hybrids:

"The early development of the primary spermatocytes is normal; a granular spireme is formed which retracts to one side of the nucleus, producing a closely packed mass of threads. . . The synaptic threads, instead of breaking into bivalent chromosomes, form a varying number of irregularly shaped clumps of chromatin. There is no uniformity as regards the number produced, and a series can easily be formed in which the number varies from two to three large masses up to the condition where the chromosomes are almost all bivalent, or where many have separated as univalents. This failure of the synaptic threads to form bivalent chromosomes is evidently the cause of the sterility in the hybrids. This is the final stage in spermatogenesis, for divisions of the primary spermatocytes do not occur nor is there any trace of abnormal mitoses."

Partial self-fertilization contrasted with brother and sister mating, R. B. ROBBINS (Jour. Genetics, 7 (1918), No. 3, pp. 199–202).—If a fixed proportion of the individuals of each generation of an ideal population reproduce by selffertilization and the remainder by random pairing, and if only a single typical Mendelian character is considered with respect to its distribution in successive generations, the author finds by the use of algebraic methods that heterozygotes can never entirely disappear and that the proportion present steadily approaches a definite limit different from zero. The claim of Bruce (E. S. R., 37, p. 769) that this mixed type of reproduction would give results essentially similar to brother and sister mating is thus disproved, for in a previous communication (E. S. R., 38, p. 367) the author shows that in continued brother and sister mating the heterozygotes do tend to disappear.

On the nature of size factors, S. WRIGHT (*Genetics*, 3 (1918), No. 4, pp. 367-374).—The author announces a theorem in the calculus of correlation whereby the observed correlation between two structures or organs of the body can be expressed as a function of those fractions of the variation in each of the characters which result from the same "causes." By making certain simplifying assumptions, it is thus possible to estimate the relative influence of those hereditary size factors which affect the animal body as a whole and those which affect only a particular part.

The method is applied to data published by MacDowell (E. S. R., 32, p. 573) on the length and width of skull and the lengths of humerus, femur, and tibia in rabbits. It was found that general body factors could be assigned from 62 to 75.5 per cent of the influences which determine the magnitude of the individual dimensions, that 6.6 to 31.5 per cent resulted from factors operating on a particular dimension and not on any of the others, while the remainder could be attributed to causes acting on more or less independent groups of bones. The skull bones form one such group and the leg bones another. The femur and tibia also form a subgroup subject to certain influences not affecting the humerus, while the femur and humerus, which are homologous bones, are influenced by another set of factors independently of the tibia.

### DAIRY FARMING-DATRYING.

Dairying with purchased feeds only, F. W. WOLL (Hoard's Dairyman, 58 (1919), No. 1, pp. 5–7, figs. 9).—This is an account of a profitable dairy herd where 330 Holstein cows receive only purchased feeds. It is operated by a creamery company near Los Angeles, Cal., on land worth over \$500 per acre. Low producers are speedily discarded and the cows in the herd average about 1 lb. of butter fat daily per head. Four per cent, grade A, milk is sold for \$4 per hundredweight. The concentrates fed to all animals are coconut meal, wheat bran, and dried beet pulp, while cows that are milked three times daily receive in addition rolled oats and bran. A relatively high proportion of concentrates is fed, a profitable practice with high producers when alfalfa hay is \$22 a ton. Corn for silage is contracted for at \$3.50 a ton, but charges for hauling and labor add \$1.50 or more to the cost. Considerable income is derived from the sale of manure and young stock.

Factory butter, cheese, and condensed milk production during the war, T. R. PIRTLE (*Hoard's Dairyman*, 57 (1919), No. 20, p. 1000, fig. 1).—Data from the census of 1909, the manufacturing census of 1914, and the reports issued by the Bureau of Markets of the United States Department of Agriculture on the production of factories in 1916, 1917, and 1918, are briefly summarized to show the amounts of milk used in the United States in the manufacture of creamery butter, cheese, and condensed and evaporated milk. In 1918 more milk was used by condensories than by cheese factories.

### VETERINARY MEDICINE.

Proceedings of the Wisconsin Veterinary Medical Association fourth annual meeting, held at Madison, Wis., January 14, 15, and 16, 1919, edited by F. B. HADLEY (*Proc. Wis. Vet. Med. Assoc.*, 4 (1919), pp. 128, figs. 15).— Among the papers here presented are the following: Hairless Pigs, by E. B. Hart (pp. 32–36); Swine Plague, by L. G. Hart, jr. (pp. 36–39); Barley for Fattening Pigs, by F. B. Morrison and G. Bohstedt (pp. 39–47); The Hog Cholera Situation in Wisconsin, by J. T. Purcell (pp. 47–49); The Outlook for the Veterinarian in the Philippines, by G. San Agustin (pp. 50–54); Hemorrhagic Septicemia, by W. L. Richards (pp. 54–57); A New Vaccine Against Contagious Abortion, by F. B. Hadley (pp. 57–61); Report of the State Detention Farm for Tuberculous Cattle, by O. H. Eliason and J. P. West (pp. 61–68); Bots in Horses, by S. B. Fracker (pp. 69–72); Necrobacillosis in Pigs, by J. B. Collins (pp. 72–74); Report of Board of Veterinary Examiners, by T. H. Ferguson (pp. 74, 75); and A Few Cases of Traumatic Pericarditis in Cows, by H. Lothe (pp. 75–81).

[Report of] veterinary research, A. THEILER (Union So. Africa Dept. Agr. Rpt., 1917-18, pp. 55-58).—A brief account of investigations conducted during the year.

**Reports of the National Serum Institute, Holland, 1916–17, J.** POELS (Verslag Rijksseruminricht. [Netherlands], 1916–17, pp. 79).—These are the reports of the institution for 1916 and 1917, containing the usual data (E. S. R., 38, p. 180).

Notes on the hydrocyanic acid content of jowar (Andropogon sorghum), MANMATHANATH GHOSH (Agr. Jour. India, 14 (1919), No. 1, pp. 106-115).— The author concludes that the weather, particularly the rainfall, is mainly responsible for the development of the poisonous elements in the jowar, and that the soil is only of minor importance and accountable only so far as it can hold up nitrogenous food materials to the plant.

Comparative toxicity of triphenylmethane and flavin dyes for tissue and bacteria, J. H. MUELLER (Jour. Path. and Bact., 22 (1919), No. 3-4, pp. 308-318, figs. 2).—The technique employed to determine the relative toxicity of various triphenylmethane and flavin dyes for tissue and bacteria was as follows:

Small fragments of chick embryos were suspended in a Petri dish in sterile Ringer's solution which had been first inoculated with several drops of a 24-hour broth culture of the organism desired. The medium used for the culture was chicken plasma, which was kept in paraffined tubes on ice and diluted at the moment of making the culture with an equal volume of a solution of the antiseptic in Ringer's solution of twice the concentration desired in the culture. After thorough mixing, a small drop of the plasma containing the dye was placed on a cover-glass and, after adding a fragment of the inoculated tissue, the cover-glass was sealed with vaselin on a hollow-ground slide. Growth was observed in 24 and 48 hours. The bacteria used for testing were streptococci, staphylococci, *Bacillus coli*, and *B. pyocyaneus*. In addition to the tissue experiments, the inhibitive action of the various dyes upon the bacteria in broth culture was also tested.

In the broth experiments the streptococcus was always the first of the bacteria to show inhibition and the pyocyaneus the last, but a great variation was observed in the interval between the two with different dyes. The flavins apparently showed no specific action, while the triphenylmethane dyes showed a definite specificity for one or another type of organism. Malachite and brilliant green affected the streptococcus and the colon bacillus, methyl and crystal violet affected the colon and pyocyaneus bacilli, and Victoria and night blue were specific for Gram-positive organisms. The formation of addition products of the dye with a halid as in methyl green and iodin green greatly reduced the toxicity for all bacteria, and sulphonation destroyed it.

In the tissue experiments it was found that tissue cells were always inhibited before streptococci by the triphenylmethane dyes, while with the flavins, the dilution producing inhibition was the same for tissue and streptococci, although other bacteria required greater concentrations. With brilliant green and night blue there was evidence of specific toxicity for tissue cells, thus indicating that better clinical results might be expected from the use of flavin than brilliant green in wound dressings.

Attention is called to the fact that in every case a greater concentration of the dye was necessary to inhibit bacterial growth in the presence of serum and tissue than in plain broth, a result in variance with the claim of Browning at al. (E. S. R., 41, p. 188) that flavin is more bactericidal in the presence of serum than in plain broth. It is pointed out, however, that in the experiments here reported the tissue cells were growing under highly artificial conditions, and that in the body a greater resistance to the antiseptic is probably shown by the cells and a smaller resistance by the bacteria.

"Bipp " treatment.—Bismuth iodoform paste, E. S. W. PEATT (Vet. Jour., 75 (1919), No. 527, pp. 163–173).—The author presents the results of 16 cases treated with bismuth iodoform paraffin paste and compares it with the Carrel treatment. He finds that both methods give excellent results but differ in certain points.

"In respect to the type of wound for which each is suitable, Bipp can be used in any wound, whereas Carrel treatment can not, on account of the difficulty of keeping the tubes fixed in the wound, e. g., in a punctured foot; unless there is a communicating wound above the coronet, it is impossible to keep a Carrel tube in position. The same applies to wounds of very mobile parts of the body and parts difficult to bandage, e. g., the ear; it is also difficult to keep a tube in a vertical wound opening downwards, e. g., a dental fistula of the lower jaw. In all these cases Bipp is the better treatment.

"Bipp is the more suitable dressing in punctured wounds from which there is not an excess of purulent discharge, and which can be plugged, e. g., picked up nail. It is also preferable in operation wounds which it is desired to keep aseptic and in which healing by first intention is expected, especially if the wound is sutured.

"Carrel treatment, on the other hand, is more effective than Bipp in the more septic and larger types of wound with profuse purulent discharge, and in conditions which must be treated as open wounds. Here the continuous instillation of eusol rapidly cleanses the wound both by its mechanical and chemical actions. Whereas, if Bipp were used in this latter case, too frequent dressings and a large quantity of the paste would be required, and the treatment would not be economical because the area so to be dressed is extensive and the paste would rapidly be carried out of the wound in the discharge.
